The Arctic

The Arctic is the area of the far north that is characterized by distinctively polar conditions of climate, plant and animal life, and other physical features. The term is derived from the Greek *arktos* ("bear"), referring to the northern constellation of the Bear. It has sometimes been used to designate the area within the Arctic Circle—a mathematical line that is drawn at latitude 66°30′ N, marking the southern limit of the zone in which there is at least one annual period of 24 hours during which the Sun does not set and one during which it does not rise. This line, however, is without value as a geographical boundary, since it is not keyed to the nature of the terrain.

While no dividing line is completely definitive, a generally useful guide is the irregular line marking the northernmost limit of the stands of trees. The regions north of the tree line include Greenland, Spitsbergen (Svalbard), and other polar islands; the northern parts of the mainlands of Siberia, Alaska, and Canada; the coasts of Labrador; the north of Iceland; also, a strip of the Arctic coast of Europe. The last-named area, however, is classified as subarctic because of other factors.

Conditions typical of Arctic lands are extreme fluctuations between summer and winter temperatures; permanent snow and ice in the high country, and grasses, sedges, and low shrubs in the lowlands; and permanently frozen ground (permafrost), the surface layer of which is subject to summer thawing. Three-fifths of the Arctic terrain is outside the zones of permanent ice. The brevity of the Arctic summer is partly compensated by the long daily duration of summer sunshine.

International interest in the Arctic and subarctic regions has steadily increased during the 20th century, particularly since World War II. Three major factors are involved: the advantages of the North Pole route as a shortcut between important centres of population; the growing realization of economic potentialities such as mineral (especially petroleum) and forest resources and grazing areas; and the importance of the regions in the study of global meteorology.

The article is divided into the following sections:

Physical and human geography

THE LAND

Relief and geology. The Arctic lands have developed geologically around four nuclei of ancient crystalline rocks. The largest of these, the Canadian Shield, underlies all the Canadian Arctic except for part of the Queen Elizabeth Islands. It extends eastward beneath Baffin Bay to include most of Greenland. The Baltic Shield, centred on Finland, includes all northern Scandinavia (except the Norwegian coast) and the northwestern Soviet Union. The two other blocks are smaller. The Angara (or Anabar) Shield is exposed between the Khatanga and Lena rivers in north central Siberia and the Aldan block is exposed in eastern Siberia.

Between the shields, particularly around their margins, there have been long periods of sedimentation, and consequently the shields are partly buried. In some areas thick sediments were subsequently folded, thus producing mountains, many of which have since been destroyed by erosion. Two main mountain-building periods have been recognized in the Arctic. In Paleozoic times there developed a complex mountain system that includes both Caledonian and Hercynian elements. It extends from the Queen Elizabeth Islands through Peary Land and down the east coast of Greenland. Mountain building occurred during the same period in Svalbard, Novaya Zemlya, the northern Urals, the Taymyr Peninsula, and Severnaya Zemlya. There is considerable speculation as to how these mountains are linked beneath the sea. The second period of folding was in Mesozoic and Cenozoic times. These mountains survive in northeastern Siberia and Alaska. Horizontal or lightly warped sedimentary rocks cover part of the shield in northern Canada, where they are preserved in basins and troughs. Sedimentary rocks are even more extensive in northern Russia and in western and central Siberia; they range in age from Early Paleozoic to Quaternary.

In the Tertiary Period (65,000,000 to 2,500,000 years ago) two Arctic areas experienced igneous activity. One

was associated with mountain building around the North Pacific, and active volcanoes are still found in Kamchatka, the Aleutian Islands, and Alaska. The other area of igneous activity extended across the North Atlantic and included the whole of Iceland, Jan Mayen Island, and east Greenland south of Scoresby Sound; it was probably connected to west Greenland and Disko Bay and to east Baffin Island. Volcanism continues in Iceland and on Jan Mayen, and hot springs are found in Greenland.

Little is known about the climate of the northern lands during Late Tertiary time; it is possible that the tree line was at least 1,000 miles (1,600 kilometres) farther north than at present, although even at this time Greenland may have been covered by ice.

Roughly 1,000,000 years ago the climate of polar regions began to deteriorate, and the Pleistocene ice sheets began to form. They are known to have expanded several times, but detailed information for the Arctic is available only for the last glaciation. In North America the main ice sheet of the final glaciation developed on Baffin Island and swept south and west across Canada, amalgamating with smaller glaciers to form the Laurentide ice sheet, covering much of North America between the Atlantic Ocean and the Rocky Mountains and between the Arctic Ocean and the Ohio and Missouri river valleys. A smaller ice cap formed in the western cordillera. The northern margin of the ice lay along the Brooks Range (excluding the Yukon Basin) and across the southern islands of the Canadian Archipelago. To the north the Queen Elizabeth Islands supported small, probably thin, ice caps.

Formation of Pleistocene ice sheets

The Atlantic Arctic islands were covered with ice except, as in Iceland, where isolated mountain peaks projected through the ice. In Europe the Scandinavian Ice Sheet covered most of northern Europe between Severnaya Zemlya in the Soviet Union and the British Isles. Northeastern Siberia escaped heavy glaciation, although, as in northern Canada, the ice sheet was more extensive in an earlier glaciation.

When the ice melted special landforms were left which, although not restricted to the Arctic, are often best developed there and in the absence of vegetation are clearly visible. In the areas of crystalline rocks, including large parts of the northern Canadian Shield and Finland, the ice left disarranged drainage and innumerable lakes. In the lowlands on weaker rocks, deep glacial deposits produced a smoother landscape, often broken by low ridges and hills of glacial material (drumlins). In the uplands the characteristic glacial landforms are the U-shaped valleys. Near the coasts these have been submerged partly to produce fjords, which are well developed in southern Alaska, along the east coast of Canada, around Greenland, in east and west Iceland, along the coast of Norway, and on many of the Arctic islands.

When the Pleistocene ice sheets melted the land remained depressed, and the sea flooded the Arctic lowlands. Subsequent emergence of the land has elevated beaches and marine deposits to considerable heights. The highest of these features are now found 500 to 900 feet (150 to 270 metres) above sea level in many parts of the western and central Canadian Arctic and somewhat lower in the east. Comparable elevations are found in the Eurasian Arctic. Comparable emergence is indicated on Svalbard, Greenland, the northern Urals, and on the Franz Josef Archipelago, where it may be more than 1,500 feet. In many of the emerged lowlands, such as those south and west of Hudson Bay, the raised beaches are the most conspicuous features in the landscape, forming hundreds of low, dry, gravel ridges in the otherwise ill-drained plains. Emergence is still continuing, and in northern Canada and northern Sweden uplift of two to three feet a century is found. Occasionally submergence is indicated, particularly at the mouths of such large rivers as the Mackenzie.

Although the detail of the terrain in many parts of the Arctic is directly attributable to the Pleistocene glaciations, the major physiographic divisions reveal close correlation with geological structure. The two largest shield areas, the Canadian and the Baltic, have developed similar landscapes. The landscapes west of Hudson Bay, on southern Baffin Island, and in Karelia are low and rocky with countless lakes and disjointed drainage. Uplands, generally 1,000 to 2,000 feet above sea level and partially covered with glacial deposits, are more widely distributed. They form the interior of Quebec–Labrador and parts of the Northwest Territories in Canada, and the Lapland Plateau in northern Scandinavia. The eastern rim of the Canadian Shield in Canada from Labrador to Ellesmere Island has been deeply dissected by ice to produce fjords and leave mountain peaks more than 6,000 feet high. The shield in Greenland is also a dissected upland, reaching similar elevations for long distances around the east and west coast. Where sedimentary rocks mantle the shields, as in north central Siberia and north of Hudson Bay, plains, plateaus, and hills result, the plateaus often being deeply dissected by narrow valleys. In Canada there are mainly plains and plateaus, while around the Angara Shield, hills and even mountain ranges are dominant.

Far beyond the margins of the shields, extensive plains have developed on soft sedimentary rocks. In North America these form the Mackenzie lowlands, Banks and Prince Patrick Islands, and the Arctic plains section of northern Alaska; in northern Europe they form the Severnaya Dvina and Pechora Plains. In Siberia the Ob Delta, its northeastern extension to the Laptev Sea, the north Siberian plains, the west Siberian lowlands, and farther east the Lena-Kolyma plains (including the New Siberian Islands) have developed on sedimentary rocks. Although there are differences in degree, these terrains are essentially flat, occasionally broken by low rock scarps, and covered with numerous shallow lakes. The plains are crossed by large rivers that have laid down deep alluvial deposits.

The strongly folded rocks associated with the two periods of mountain building in the Arctic form separate physiographic regions. The original mountains of the older, Paleozoic folding were long ago destroyed by erosion, but the rocks have been recently elevated and renewed erosion, often by ice, has produced a landscape of plateaus, hills, and mountains very similar to the higher parts of the shields. In Ellesmere Island the mountains are nearly 10,000 feet high. In Peary Land and Vestspitsbergen maximum heights are about 6,000 feet, while in east Svalbard and on Novaya Zemlya and Severnaya Zemlya the plateaus rarely exceed 2,000 feet.

The younger groups of fold mountains of northeast Siberia and Alaska are generally higher. Peaks of 10,000 feet are found in the Cherski Range, 15,000 feet in Kamchatka, and even higher in southern Alaska. Characteristic of this physiographic division are the wide intermontane basins often drained by large rivers such as the Yukon and Kolyma.

Throughout the Arctic, excluding a few maritime areas, the winter cold is so intense that the ground remains permanently frozen except for a shallow upper zone, called the active layer, which thaws during the summer. This permanently frozen ground (permafrost) covers nearly one-quarter of the Earth's surface. In northern Alaska and Canada scattered observations suggest that permafrost is 800 to 1,500 feet deep; it is generally deeper in northern Siberia. The deepest known permafrost is in northern Siberia, where it exceeds 2,000 feet. The depth of the permafrost depends on the site, climate, vegetation, and recent history of the area, particularly whether it was covered by sea or glacier ice. The very deep permafrost was probably formed in unglaciated areas during the Ice Ages. To the south in the subarctic, the permafrost thins and eventually becomes discontinuous, although it may locally still be 200 to 400 feet thick; along its southern boundary permafrost survives under peat and bogs. In areas of continuous permafrost the active layer may be many feet thick in sandy well-drained soils with little vegetation; it is usually less than six inches thick beneath peat.

Permafrost

Permafrost occurs in both bedrock and surface deposits. It has little effect on rock but in fine-grained, unconsolidated sediments, particularly silts, lenses of ice, called ground ice, grow by migration of water, and in extreme cases half the volume of arctic silts may be ice. Ground ice is often exposed in river banks and sea cliffs, where it may be 20 to 30 feet thick. In northern Siberia fossil ice has been reported up to 200 feet thick, although in these

cases it may be glacier or lake ice that has subsequently been buried under river deposits. If ground ice melts, due to a change in climate, pits are formed in the ground and quickly fill with water to form lakes and ponds. In their frozen state the silts have considerable strength, but if they thaw they change in volume, lose their strength, and may turn to mud. Variations in volume and bearing capacity of the ground due to changes in the permafrost constitute one of the major problems in Arctic construction.

Drainage and soils. Continuous permafrost totally inhibits underground drainage. Consequently shallow lakes are numerous over large areas of the Arctic, and everywhere in early summer there is a wet period before the saturated upper layers of the ground dry out. During the summer waterlogged active layers on slopes may flow downhill over the frozen ground, a phenomenon known as solifluction. It is ubiquitous in the Arctic but is particularly intense where the soils are fine-grained, as in the coastal plain of north Alaska, or where the precipitation is heavy, as on Bear Island (Bjørnøya) in the Norwegian Sea. The effect of solifluction is to grade slopes so that long, smooth profiles are common; slopes are normally covered with vegetation, but if the soil movement is too fast plants may not be able to survive. Under these conditions the surface material is often graded, with narrow strips of pebbles and boulders separated by broader strips of finer particles.

Formation of soil patterns

Many soils in northern areas show distinctive patterns produced by complex processes of freezing and thawing, which cause frost heaving and sorting of debris; although permafrost is not essential to these formations, it is usually present. There are many different types of pattern ground. In some, coarser material, pebbles, and boulders form polygonal nets with the finer materials concentrated in the centre. When sorting is widely spaced stone circles develop. Another kind of pattern, formed in sands and muds, is outlined by frost-crack fissures or strips of vegetation. Individual polygons vary from about one foot to more than 300 feet in diameter. Mounds due to frost heaving in the soil are also widespread. They grow rapidly, disrupting leveled fields in a few years.

Arctic soils are closely related to vegetation. Unlike soils farther south they rarely develop strong zonal characteristics. By far the commonest are the tundra soils, which are circumpolar in distribution. They are badly drained and strongly acid and have a variable, undecomposed organic layer over mineral horizons. Some of the drier heath and grassland tundras overlie Arctic brown soils, which have a dark-brown upper horizon with gray and yellowish-brown lower horizons. The active layer in the permafrost is normally deep in them.

Many exposed rock surfaces in the Arctic have been quickly broken up by frost action so that much rock is buried under a cover of angular shattered boulders. These mantles are known as *felsenmeer* (sea of rock) and are found principally on Actic uplands. Their continuity and depth varies with climate, vegetation, and rock type, but they may be as much as 12 feet deep. *Felsenmeer* are especially well developed on basalts and are consequently numerous on the Icelandic plateaus. They also develop quickly on sedimentary rocks and are widespread in the Canadian Arctic, all the way down to sea level.

Glaciation. Although the Arctic is commonly thought to be largely ice-covered, less than two-fifths of its land surface in fact supports permanent ice. The remainder is ice-free because of either relatively warm temperatures or scant snowfall. Glaciers are formed when the annual accumulation of snow, rime, and other forms of solid precipitation exceeds that removed by summer melting. The excess snow is converted slowly into glacier ice, the rate depending on the temperature and annual accumulation. In the Arctic, where most glaciers have temperatures far below freezing point, the snow changes into ice slowly. In northwest Greenland a hole 1,400 feet deep was made into the ice sheet without reaching glacier ice. The hole showed more than 800 annual snow layers, from which it was possible to determine precipitation changes for the last eight centuries.

The altitude at which ice accumulates over a period

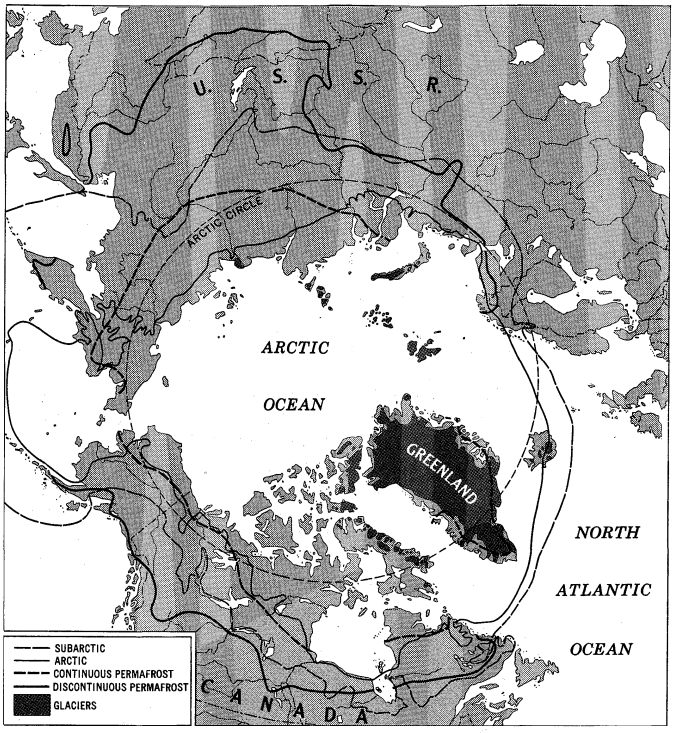

Figure 1: Division of subarctic and Arctic regions showing distribution of permafrost and glaciers.

of years is known as the glaciation limit and is roughly equivalent to the snow line. It is often very variable within short distances. On Baffin Island the glaciation limit is a little more than 2,000 feet above sea level in the extreme southeast, rising to more than 4,500 feet in the Penny Ice Cap 300 miles to the north and descending to about 2,000 feet in the north of the island. In Greenland the limit is at about 6,000 feet in the south and decreases irregularly to about 3,000 feet in the north. Nowhere in the Arctic regions is the glaciation limit at sea level; glaciers found close to the sea have all flowed down from higher levels. The domes of some arctic ice caps are below the glaciation limit but they continue to survive because of their low internal temperatures; the winter snowfall melts completely but refreezes in contact with the cold ice. This phenomenon, first observed on the Barnes Ice Cap of Baffin Island, is now known to be widespread in the high Arctic.

The glaciers of the north polar regions can be divided into two groups depending on the source of their snow; the larger group is around the Atlantic and the smaller around the Pacific Ocean. The largest ice mass, the Greenland inland ice, is part of the first group and is the largest glacier in the Northern Hemisphere. It extends about 1,570 miles from north to south, has a maximum width of some 600 miles, an average thickness of about 5,000 feet, and covers an area of more than 700,000 square miles (1,800,000 square kilometres), nearly 85 percent of Greenland. It is contained within an elongated saucer-shaped depression, the sides of which are mountains (called nunataks) that rise through the margins of the ice. In the centre the base of the ice is more than 1,000 feet below sea level. This discovery has led to the suggestion that Greenland is an archipelago rather than one large island. Although this might be so for a short time if the ice melted, the land would soon rise when the ice mass disappeared, forming a plateau at about 3,000 feet. The crest of the inland ice, which exceeds 10,000 feet above sea level midway between the east and west coasts in the northern part of the island, is displaced to the east in the south. In the centre the surface of the ice is undulating and is frequently covered with wind-drifted formations of snow called *sastrugi*. The ice cap slopes off to the sides, reaching the sea in a 240-mile front along Melville Bay in the west and along two smaller stretches in the northeast. Elsewhere huge outlet glaciers flow down to the sea. All combine to produce the vast numbers of icebergs that bar the coast of Greenland and

are carried south in the Labrador Current to the Atlantic shipping lanes. In summer the margins of the inland ice are covered with soft, sticky, granular snow. Three main ice-free areas are found in Greenland: in the southwest, where the inland ice is separated by 100 miles from Davis Strait; north of Scoresby Sound in the east; and in Peary Land in the north.

Location of ice caps

In Arctic Canada the permanent ice is restricted, with few exceptions, to the northeast, which is a result of the greater relief and precipitation around Baffin Bay and Davis Strait. The most southerly ice is found in the Torngat Mountains of northern Labrador, where there are small cirque glaciers. Immediately north of Hudson Strait on the plateau south of Frobisher Bay, there are two small ice caps. Larger ice caps and highland ice (through which mountains project) are present farther north along the east of Baffin Island and on Bylot Island; only the Barnes Ice Cap lies west of the coastal group. North of Lancaster Sound the ice is more extensive and large parts of Devon, Ellesmere, and Axel Heiberg islands are glacierized. In many ways these ice caps are small versions of the Greenland inland ice, with a central dome-shaped section and outlet glaciers pouring down through the mountains toward the sea. The ice cap on Meighen Island, the most westerly of the group, is an exception, as it is circular in shape and lies on low ground. Except for three small, unexplored glaciers on Melville Island, there are no glaciers in the Canadian western Arctic. Only a few of the Canadian glaciers reach the sea and form icebergs. In the Arctic Ocean off northern Ellesmere Island there is an area of floating shelf ice that may at one time have been joined by glaciers, but the glaciers no longer reach the sea. This shelf ice has been the principal source of the ice islands of the Arctic Ocean.

Other glaciers are found north and east of the Atlantic Ocean and its continuation in the Norwegian and Barents seas. Iceland has five major ice caps, the largest of which, Vatnajökull, covers more than 3,200 square miles. All have small outlet glaciers, although none reaches the sea. The ice caps owe their survival to extremely heavy precipitation. The western part of Vatnajökull buries a volcano, Grímsvötn, which erupts every six to 10 years; the heat of the eruption forms a vast subglacial lake which bursts in great floods over the margins of the glaciers.

North of Iceland, Jan Mayen Island supports a glacier on the volcano Mt. Beerenberg. The glaciers of Svalbard cover about 90 percent of the land. On the largest island, Vestspitsbergen, the plateaus are covered with highland ice from which outlet glaciers reach the sea; there are also numerous independent valley and cirque glaciers. North East Land, the second largest island, supports two ice caps on its plateaus. On the east side of the Atlantic Ocean precipitation is heavy over the Scandinavian highlands, but temperatures are also high, and the total area of ice is only about 2,000 square miles, a small part of which is in north Sweden and the remainder in Norway. To the northeast beyond the Barents Sea, precipitation is far less, but the summer is shorter and permanent ice is widespread.

Farthest north in this group are the islands of the Franz Josef Archipelago. Although at no point are they higher than 2,500 feet, probably more than 90 percent of their area is covered with ice; some of the smaller islands are completely buried by glaciers. The southern island of Novaya Zemlya supports a few small glaciers; on the northern island they become more numerous and the northern four-fifths of the island is ice-covered, with large outlet glaciers reaching the sea.

Weather disturbances penetrate into the Kara Sea beyond Novaya Zemlya and produce sufficient snow for ice to form on Severnaya Zemlya (North Land). There are four major and many minor islands in the group. Although they are low-lying, consisting primarily of plateaus less than 2,000 feet high, all the larger islands have ice caps that cover rather less than half the total area. Outlet glaciers reach the sea and are an occasional source of icebergs. Elsewhere the Russian northern areas are remarkably free of ice. Small cirque glaciers are found in the Ural Mountains and the mountains of northeastern Siberia. Not until the Pacific is approached do the mountains again have alpine glaciers, another indication of the importance of moisture for the development of glaciers.

The glaciers around the North Pacific are concentrated in Alaska. The glaciers of southern Alaska are alpine rather than Arctic and include some of the finest mountain glaciers in the world. All types of ice are present, from small valley glaciers to highland ice almost burying mountain ranges, with piedmont glaciers spreading out in the lowlands. The largest ice centres are around the Fairweather Range, the St. Elias Mountains, and the Chugach Mountains. Glaciers in these areas include the Hubbard, 90 miles long, intermontane glaciers such as the Seward, and piedmont glaciers such as the Malaspina. Smaller glaciers also occur inland on the Alaska Range and in the Brooks Range of northern Alaska; there is more ice farther east in the Romanzof Mountains, where one glacier, the Okailak, is 10 miles long. There are a few small glaciers in the Aleutian Range, and ice is found infrequently on the Aleutian Islands.

The overwhelming majority of Arctic glaciers, except for the Greenland inland ice, are in retreat, and many areas are more ice-free than ever before in the historical period. In Iceland, where glacier movements are well recorded, the ice appears to have been restricted from the 10th until about the 14th century. The ice then advanced, reaching a maximum about 1750. A second advance followed a minor retreat, culminating about 1850, and a major retreat set in about 1890. The recession was slow at first but by the 1930s it was generally rapid and has continued since.

Climate. The climates of northern lands are highly varied. It has been customary to divide them into two large groups corresponding to the climate of ice caps, in which no mean monthly temperature exceeds 32° F (0° C), and the tundra climates, with at least one month above 32° F but no month above 50° F (10° C). A more satisfactory division is to classify them as polar maritime climates, located principally around the Atlantic and Pacific oceans, in which winter temperatures are rarely extremely low and snowfall is high; and the polar continental climates, as in north Alaska, Canada, and Siberia, where winters are very cold and snowfall is generally light. Included in the polar continental climate type are the Arctic Islands (also called the Canadian Arctic Archipelago), which are influenced only slightly by the sea in winter because of thick ice. In addition to these two climates, there are smaller transitional zones, limited areas of "ice" climates and, adjacent to the Arctic, the subarctic climates.

Record low temperatures

Although the polar continental climates have low winter temperatures, they are not as cold as the subarctic. The lowest temperatures ever recorded in the Northern Hemisphere were measured in the subarctic of northeast Siberia, the coldest area being around Oymyakon. In North America a temperature of −81° F (−63° C) was observed at Snag, Yukon Territory. Temperatures below −80° F (−62° C) have been recorded on the Greenland Ice Cap. Colder temperatures have not been found in the tundra regions because generally windier conditions prevail.

Winter sets in toward the end of August in the far north and about a month later near the tree line. The temperature continues to drop rapidly until about December. January, February, and early March have uniform conditions with mean temperatures about −35° F (−37° C) in the central Siberian Arctic and −20° to −30° F (−29° to −34° C) in North America. The lowest extreme temperatures in the winter are between −50° and −65° F (−46 and −54° C). A better indication of low temperatures as they affect man is given by the windchill, a measurement of the cooling power of the atmosphere on human skin. It reaches a maximum north of Hudson Bay, where strong and persistent northwest winds, typical of the Canadian eastern Arctic, are combined with low air temperatures. This area is stormy in winter with moderately high snowfall (50 to 100 inches [1,300 to 2,500 millimetres]), rapidly changing temperatures, and even occasional rain. Elsewhere the winter continental climate is quiet, with long periods of clear sky and low snowfall. Visibility may be poor locally if there are open channels of water in the sea ice and is universally reduced when the wind blows drifting snow. The lowest snowfall is in the northern Canadian

islands and in north Greenland, where the total annual precipitation is frequently less than four inches of water.

Winter in the maritime Arctic (the Aleutians, coastal southwest Greenland, Iceland, and the European Arctic) is a period of storminess, high winds, heavy precipitation in the form of either snow or rain (the latter at sea level), and moderate temperatures. The coldest month is rarely below 20° F (−7° C) and extremely low temperatures are unknown.

Summer temperatures are more uniform across the whole of the Arctic. On the southern margin the monthly mean temperature reaches 50° F (10° C), and in continental positions short spells of hot weather with temperatures in the 80s, continuous sunshine, and calm weather are not uncommon; such weather often ends with thunderstorms. In the maritime climates, along the coasts, and on the northern islands when there is open water in the sea ice, the summer is relatively cool. In the south the temperatures are about 45° F (7° C), decreasing north to 40° F (4° C) or less; a maximum of 60° F (16° C) is hardly ever reached. Fog and low clouds are widespread, and at this time of the year these areas are the cloudiest in the world. In areas that experience continental winters, precipitation is heaviest during the summer months; light rain and snow showers are frequent, but the average fall is rarely high. The summer is everywhere a time of sudden changes. Calm, clear weather with sunshine and temperatures of about 50° F will be followed by sudden winds, often causing a temperature drop of 20° to 30° F and accompanied by cloud and fog. These changes are often local, and fine weather may continue in the next valley or at the head of a fjord.

The frost-free and growing periods are relatively short throughout the Arctic. For the most part there is no true frost-free period; frost and some snow have been recorded in every month of the year. At a few places near the tree lines, notably in the Canadian western Arctic, the frost-free period may be the same as the less favourable parts of the prairies.

The polar basin has a winter similar to that of northern Alaska and Siberia with long, clear, cold periods and occasional storms, accompanied by a brief rise in temperature. The summers are cloudy and foggy, winter snow melts off the pack ice, and the mean temperature rises to about 35° F (2° C). The climate of Svalbard and Novaya Zemlya is transitional between maritime and continental conditions with a cool rather than cold winter (mean temperature 0° F [−18° C]).

The only extensive ice climate in the Northern Hemisphere is in Greenland. In the south the ice cap has maritime characteristics with heavy precipitation, mainly snow from passing cyclone disturbances. In the north conditions are less severe and the snowfall consequently less. Although the air temperature may sometimes rise to 32° F, the mean temperature is much lower.

Changes in polar climates

The polar climates have changed noticeably during the 20th century, the climatic amelioration that produced the retreat of the glaciers having been widely felt. Sea ice around Iceland, Svalbard, and southwest Greenland has decreased in extent. The pack ice in the Arctic Ocean is thinner. Birds, animals, and especially fish have appeared farther north than before; in Greenland this led to a complete change in the economy, as its traditional dependence on seals has yielded to dependence on fishing, particularly cod, which are caught north of the 70th parallel. The cod, unlike the seal, does not provide fuel and clothing in addition to food; consequently the economy, once extraordinarily self-sufficient, is now based on cash and international trade. With the warming of the climate, sheep farming also has been introduced successfully in the southern part of Greenland.

The main changes in the climate result from increases in air and sea temperatures. The increases in air temperatures have been greatest during the North Atlantic Ocean winters around Svalbard but are found at all seasons and in all areas. The warming began at the beginning of the 20th century, reached a maximum in the 1930s, and declined briefly in many localities in the early 1940s, only to increase again temporarily. The primary cause is not known, although it results directly from increased penetration of southerly winds into the polar regions.

Plant life. Two main vegetation zones are found in the polar lands. In the south is the subarctic, formed by the northern subzones of the circumpolar boreal forest. To the north is the Arctic proper, where the vegetation is generally referred to as tundra, from the Finnish word for an open rolling plain; in North America the descriptive term Barren Grounds is frequently applied. The two zones are separated by the tree line. This is by definition the absolute northern limit of treelike species, although even beyond it the same species may be found in low shrubs and dwarfed forms. The tree line is composed of different species. In Alaska and northwestern Canada white spruce is dominant, while in Labrador–Quebec it is black spruce and occasionally larch. By contrast, in northern Europe and Siberia the tree line is formed by larch, pine, and fir. The tree line is related to summer warmth, which may be correlated closely with tree growth. Alexander Supan found good coincidence between the tree line and the 50° F July isotherm, a figure later modified by Otto Nordenskjöld to allow for spring temperatures.

In North America the tree line extends from the shores of Bering Strait along the Brooks Range of Alaska to the Mackenzie Delta and then curves southeastward across the Northwest Territories to Churchill and James Bay. East of Hudson Bay it crosses northern Quebec to Ungava Bay and then continues into Labrador. In western Scandinavia, the tree line is within a few miles of the sea; it curves east and crosses northern Siberia 50–150 miles south of the Arctic Ocean.

Arctic plants have to contend with a harsh environment including low temperatures, continuous daylight in summer, poor soil and permanently frozen ground, and in many areas strong, dry winds and blowing snow. The species that survive are few and are frequently dwarfed. Many plants grow in compact cushions for maximum protection from the climate. The growing season is so short that annuals are rare and perennials reproduce asexually by shoots or runners. Even so, Arctic plants have a rapid seasonal life cycle. Spring growth often begins when snow is on the ground and there are still heavy frosts; the flower and seed stages follow in a period as short as six weeks. The sudden blooming of flowers is spectacular, particularly along the southern edges of the tundra, and for a short time in July the Barren Grounds are covered with a mass of flowers. The species vary but typical are those in the western American Arctic, which include the blue-spiked lupine, wild crocus, mountain avens, arctic poppy, and saxifrage. By late August the cycle is complete, and the plants are awaiting winter.

At first sight many parts of the Arctic are rocky wastes without soil or vegetation. Closer inspection shows that some plant life is always present, and even on permanent ice there are often algae. The bare rock surfaces support thin brown, black, or gray crustaceous lichens that swell and become soft when wet; some of the larger black lichens are edible and are generally known as "rock tripe." In the past these lichens have been used for food by starving explorers. Higher plants grow in rock crevices and succeed in forming tussocks on patches of soil. Close to the southern edge of the Arctic, dwarf shrubs are found in protected sites on these rock deserts.

Tundra vegetation

Tundra areas have a continuous cover of vegetation, and many different tundra associations (plant communities) may be recognized. In the drier and better drained parts, heath tundra, made up of a carpet of lichens and mosses with isolated flowering plants, is dominant. In some areas, notably west of Hudson Bay, a similar environment results in tundra grassland. When there is more moisture, sedges and grasses become important and form tussock or hillock tundra; willow and dwarf birch may be found between the individual mounds. This type of tundra reaches its greatest development on the north Alaskan coastal plain.

In the warmer parts of the Arctic, woody dwarf shrubs, willow, birch, juniper, and, locally, alder are profuse. In the southern Arctic several of these shrubs modify the heath tundra, and low scrub woods may be quite extensive. On sheltered, south-facing slopes, tall thickets of willow, birch,

and alder develop, and under optimum conditions these bushlike "trees" may be more than 10 feet high. This type of vegetation is common in all circumpolar lands close to the tree line and is conspicuous in the inner fjords of southwest Greenland and in northern Iceland. The bushes may be used in the western Canadian Arctic for fuel or for mats, and in former times were used by Eskimos for arrow shafts. The wood is unsuitable for bows, spears, or boat building; for these purposes the Eskimos either had to travel to the tree line or search for driftwood, which was widely distributed along the Arctic coasts.

The tundra vegetation is the source of food for the northern grazing mammals but contains few foods of direct value to man. Berries are found throughout the southern Arctic. Most widely used by the native population has been the black crowberry (*Empetrum nigrum*), eaten either raw or mixed with animal oil. Europeans have found the cloudberry (*Rubus chamaemorus*), bilberry (*Vaccinium uliginosum*), and mountain cranberry (*V. vitisidaea minus*) more palatable. Mushrooms are widely distributed and can be used for a welcome change of diet.

South of the tree line is the subarctic forest-tundra. Its bare windswept ridges are covered with tundra associations, while in the sheltered valleys there are woodlands, which may become continuous near large rivers and, if the rivers flow north, may project many miles into the Barren Grounds. These areas, known as *galeria* forests, are found along the Coppermine River of Canada and frequently along the north Siberian rivers. The woods contain the same coniferous species as forms the tree line, together with several broad-leaved species, notably birch.

(J.B.Bd.)

Animal life. Animal life in the Arctic, compared with that of warmer parts, is poor in species but often rich in individual numbers. This is generally considered to be the result of at least two factors—the comparative novelty of polar glacial climates, allowing only a limited time for adaptation since their onset; and the much lesser variety of habitats available for colonization in the north as compared with the lower latitudes.

Fauna of the true Arctic Zone

The fauna considered in this section is from the true Arctic Zone only. On the land, this is the zone north of the tree line; in the sea, the area in which the upper water is of North Polar Sea origin, without admixture of Atlantic or Pacific water. This excludes most of the west Greenland waters and the waters of west and southern Iceland, the Faeroe Islands, and Norway; it also excludes the Labrador Sea and the waters of the Labrador coast south of Hudson Strait.

Animals of the land and fresh water. The typical and best known Arctic land mammals and birds are those highly successful forms, most of them circumpolar in distribution, that survived the Pleistocene glaciations probably both south and north of the ice sheets: south along the ice perimeter and north in ice-free refuges such as northern Alaska, the Bering Strait (then dry land) and northeastern Siberia, certain of the Arctic Islands, and probably northernmost Greenland. These include the polar bear (as much a marine as a terrestrial animal), caribou, Arctic wolf, Arctic fox, Arctic weasel, Arctic hare, the brown and collared lemmings, ptarmigan, gyrfalcon, and snowy owl. This fauna, together with the vegetation that feeds the lemming, ptarmigan, and caribou, forms a tight ecological system that is virtually self-sufficient. During the winter, and during periods of low lemming population, which occur every three to five years, the carnivores make some use of seashore life and (through the agency of the polar bear) of seal and fish. In extreme starvation conditions, there is a tendency for the snowy owls and gyrfalcons to go south in winter and for the foxes and wolves to become scavengers.

The caribou is a migrant, but only between the Arctic tundra and the conifer (subarctic) zone to the south, and there are far northern groups of caribou whose migrations are more restricted. The musk-ox is a special case. Now restricted to the North American Arctic (including north Greenland), it was formerly more widespread and is probably a "refugee" species, chased into the far north and on the defensive in the evolutionary sense.

Hibernation is not a phenomenon of animal behaviour in the Arctic because frost-free refuges are not available; all the nonmigrant, warm-blooded animals therefore must remain active all winter. Any incipient hibernation, shown for instance by the Arctic ground squirrel, proves abortive, as the animals will shiver themselves awake after only a few days.

Most of the birds of the Arctic Zone are migrants, coming from wintering grounds as far away as the southern United States, Central America, Brazil, or even the subantarctic zone. By migration the birds obtain the advantage of the long northern summer days and of the high productive capacity of plant foods in the short but intense growing season. There is increasing evidence that food is not a limiting factor on summer bird populations in the Arctic, except in the case of strictly predaceous species during years of scarcity of prey. Typical land and freshwater birds of the Arctic Zone are the redpoll, Lapland longspur, snowbird, wheatear, pipit, certain plovers and sandpipers, loons, rock ptarmigans, ducks, and geese.

There are no reptiles in the Arctic Zone, owing to the absence of frost-free winter refuges, but one amphibian, the wood frog, does penetrate just north of the tree line in Arctic Canada. It breeds in July and early August in ponds and small lakes and spends the rest of the year buried in the mud at the bottom. The mud does not freeze, and the frogs are able to breathe through the skin, which the reptiles cannot do.

Freshwater fishes in the Arctic are represented by a few species only: whitefish, lake trout and speckled trout, Arctic grayling, two species of stickleback, the Alaskan blackfish, and the Arctic char. In some regions the burbot, northern pike, and Atlantic salmon penetrate north of the tree line.

The invertebrate fauna of the Arctic land and fresh water consists largely of insects, including the chief scourges of the north, mosquitoes and black flies. Among the most northern navigators are certain species of spiders that winter even in northern Ellesmere Island. Crustacea are represented by the branchiopods, which form an important part of Arctic pond life, and by the copepods. There is, in addition, a very considerable number of smaller species belonging to many phyla. (For animals of the sea, see below *The Arctic Ocean.* For further details on physical and human geography, see below *The Arctic Islands; Greenland; Novaya Zemlya;* and *Svalbard.*)

(M.J.Du.)

THE ARCTIC OCEAN

The Arctic Ocean is by far the smallest of the Earth's five oceans, having only a little over one-sixth the area of the next largest, the Indian Ocean. Its area of 4,732,000 square miles (12,257,000 square kilometres), however, is five times larger than that of the largest sea, the Mediterranean. The deepest sounding obtained in Arctic waters is 18,050 feet (5,502 metres), but the average depth is only 3,240 feet.

Distinguished by several unique features, including a cover of perennial ice and almost complete encirclement by the landmasses of North America, Eurasia, and Greenland, the north polar region has been a subject of speculation since the earliest concepts of a spherical Earth. From astronomical observations the Greeks theorized that north of the Arctic Circle there must be a midnight sun at midsummer and continual darkness at midwinter. The enlightened view was that both the northern and southern polar regions were uninhabitable frozen wastes, whereas the more popular belief was that there was a halcyon land beyond the north wind where the Sun always shone and people called Hyperboreans led a peaceful life. Such speculations provided incentives for adventurous men to risk the hazards of severe climate and fear of the unknown to further geographic knowledge and national and personal prosperity.

The ocean floor. From the late 19th century, when the Norwegian explorer Fridtjof Nansen first discovered an ocean in the central Arctic, until the middle of the 20th century, it was believed that the Arctic Ocean was a single large basin. Explorations after 1950 revealed the true com-

A U.S. Coast Guard icebreaker and an oceangoing tugboat travelling through the Arctic Ocean on a mission during the brief Arctic summer.

plex nature of the ocean floor. Rather than being a single basin, the Arctic Ocean consists of two principal deep basins that are subdivided into four smaller basins by three transoceanic submarine ridges. The central of these ridges extends from the continental shelf off Ellesmere Island to the New Siberian Islands, a distance of 1,100 miles. This enormous submarine mountain range was discovered by Soviet scientists in 1948–49 and reported in 1954. It is named the Lomonosov Ridge after the scientist, poet, and grammarian Mikhail Vasilyevich Lomonosov.

The Lomonosov Ridge has an average relief of about 10,000 feet and divides the Arctic Ocean into two physiographically complex basins. These are referred to as the Eurasia Basin on the European side of the ridge and the Amerasia Basin on the American side. The Lomonosov Ridge varies in width from 40 to 120 miles, and its crest ranges in depth below sea level between 3,100 and 5,400 feet.

Eurasia Basin and Amerasia Basin

The Eurasia Basin is divided into two smaller basins by a trans-Arctic Ocean extension of the Mid-Atlantic Ridge. This Arctic segment of the global ridge system is called the Nansen Cordillera. Although it is a locus of active ocean floor spreading, its topography is less well developed than other oceanic ridges. The Fram Basin lies between the Nansen Cordillera and the Lomonosov Ridge at a depth of 14,070 feet. The geographic north pole is located over the floor of the Fram Basin near its juncture with the Lomonosov Ridge.

The smallest of the Arctic Ocean sub-basins, called the Nansen Basin, lies between the Nansen Cordillera and the Eurasian continental margin, and has a floor depth of 13,800 feet.

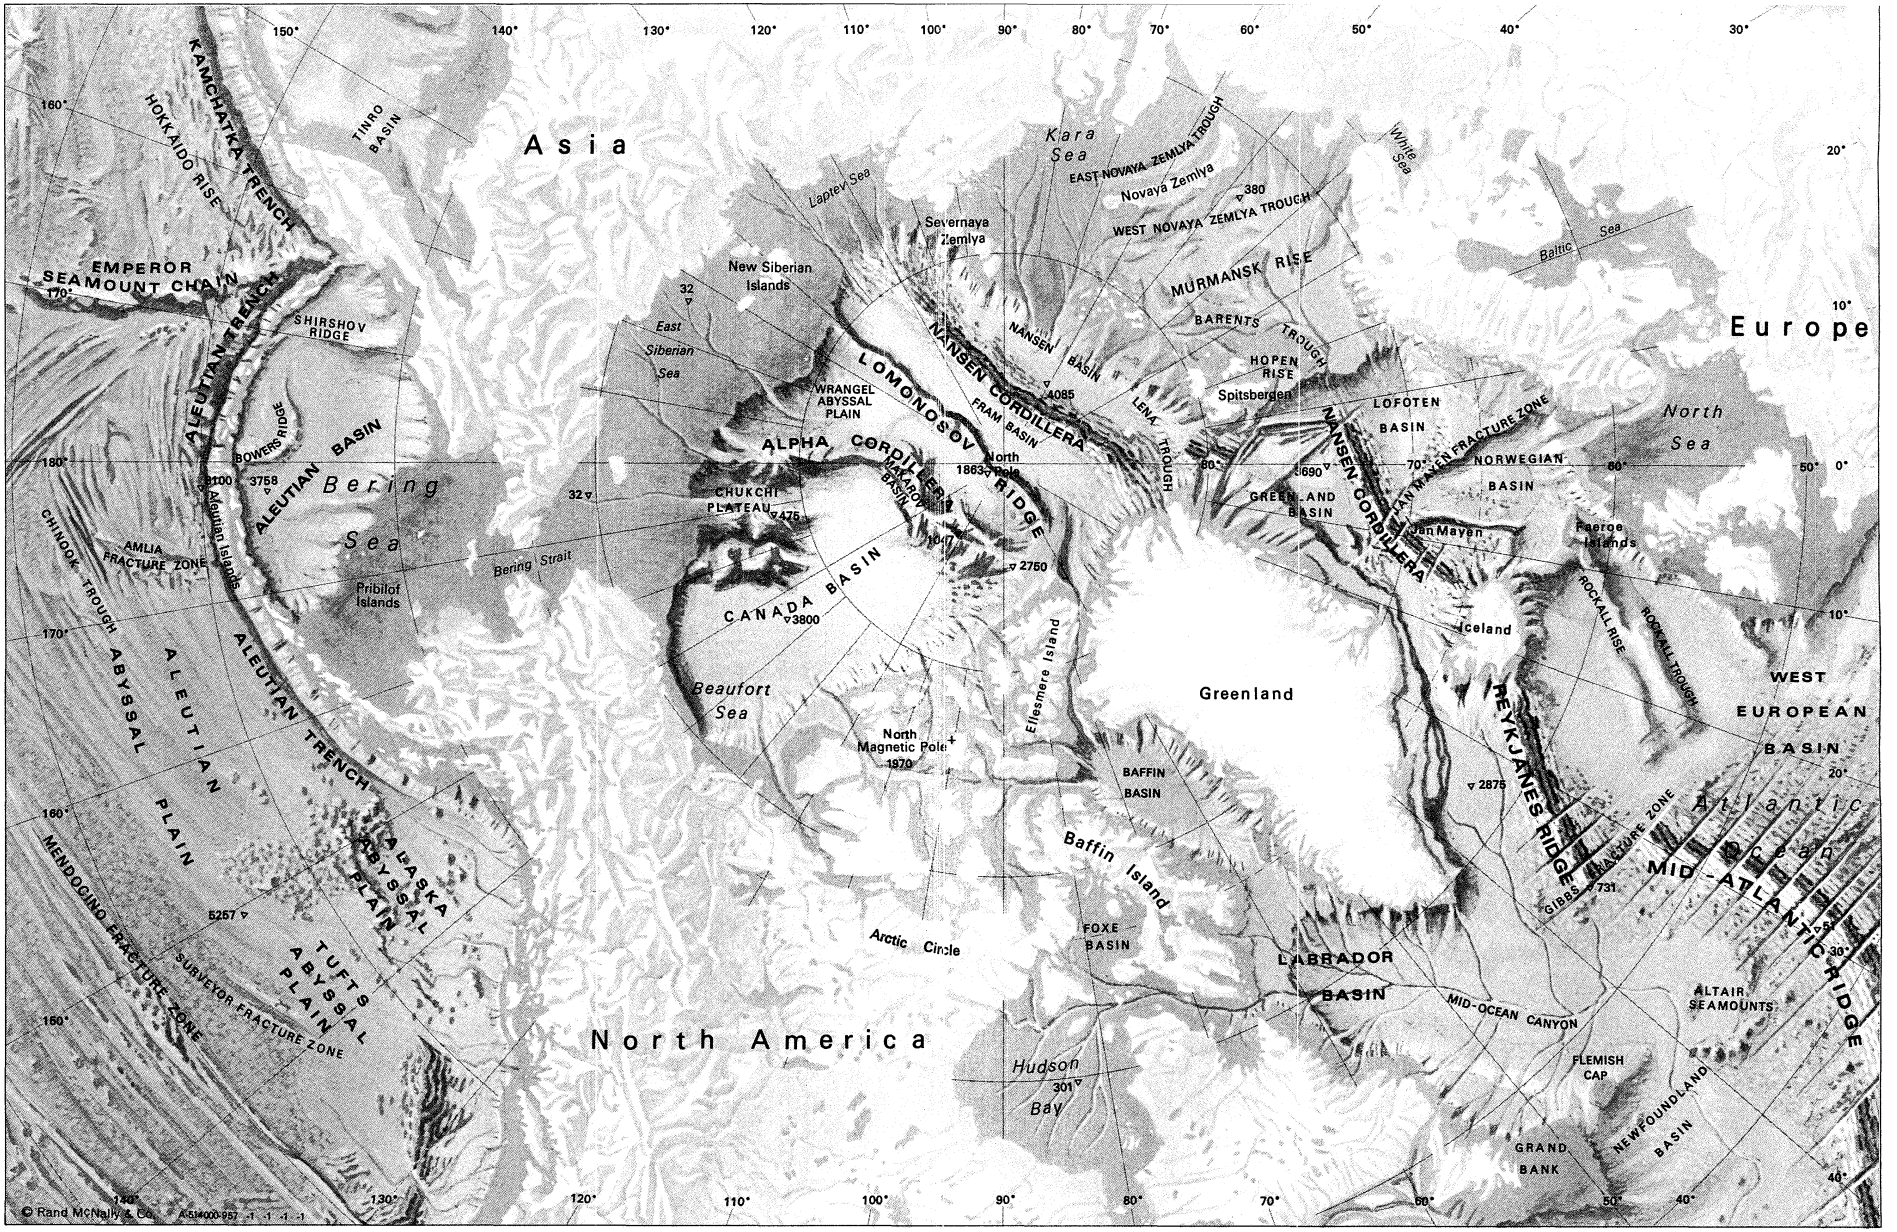
The Amerasia Basin is divided into two unequal basins by the Alpha Cordillera, a broad rugged submarine mountain chain that extends to within 4,600 feet of the ocean surface. The cordillera is believed to be a no longer tectonically active segment of the global rift system. The Makarov Basin lies between the Alpha Cordillera and the Lomonosov Ridge, and its floor is at a depth of 13,200 feet. The largest sub-basin of the Arctic Ocean is the Canada Basin, which extends approximately 700 miles from the Beaufort Sea Shelf to the Alpha Cordillera. The smooth basin floor slopes gently from east to west where it is interrupted by regions of sea knolls. The average depth of the Canada Basin is 12,500 feet.

The Arctic Ocean is unique in that nearly one-third of its total area is underlain by continental shelf, which is asymmetrically distributed around its circumference. North of Alaska and Greenland the shelf is 60 to 120 miles wide, which is the normal width of continental shelves. In contrast, the Siberian and Chukchi shelves off Eurasia range from 300 to 1,100 miles in width. The edge of the continental margin is dissected by numerous submarine valleys. The largest of these, the St. Anna Trough, is 110 miles wide and 300 miles long.

Oceanography. As an approximation, the Arctic Ocean may be regarded as an estuary of the Atlantic Ocean. The major circulation into and from the Arctic Basin is through its single, deep channel connection to the World Ocean: the passage that lies between the islands of Spitsbergen and Greenland. The connection of the Arctic Ocean with the Pacific Ocean is of minor importance. There are, however, factors in the Arctic Ocean that make its processes significantly different from those of the Atlantic. Most notable is the covering ice pack, which reduces the exchange of energy between ocean and atmosphere by about 100 times. In addition, sea ice greatly reduces the penetration of sunlight needed for the photosynthetic processes of marine life and impedes the mixing effect of the winds. A further significant distinguishing feature is the high ratio of freely connected shallow seas to deep basins. Whereas the continental shelf on the North American side of the Arctic Ocean is of a normal width (approximately 40 miles), the Eurasian sector is hundreds of kilometres broad, with peninsulas and islands dividing it into five main marginal seas: the Chukchi, East Siberian, Laptev, Kara, and Barents. These marginal seas occupy 36 percent of the area of the Arctic Ocean, yet they contain but 2 percent of its water volume. With the exception of the Mackenzie River of Canada and the Colville River of Alaska, all major rivers discharge into these marginal shallow seas. The combination of large marginal seas, with a high ratio of exposed surface to total volume, plus large summer inputs of fresh water, greatly influences surface-water conditions in the Arctic Ocean.

Main directions of flow

The balance of the Arctic Ocean's water budget (input and output) is still very poorly known. Although the largest volume of water transport is between Greenland and Spitsbergen, this mechanism is the least understood of all. The inflow of dense bottom water from the Atlantic occurs mainly on the eastern side of the passage and is estimated to be 78 percent of the total volume brought



ARCTIC OCEAN Depths in metres

Colours used are thought to be those of the various rocks and sediments on the sea floors. Differences in relief are shown by relief shading.

0 400 800 1200 km
0 400 800 1200 mi

into the Arctic Ocean. This is balanced by the surface outflow of colder but less saline waters in the form of the East Greenland Current. Very few data are available on the transport volume of this current, but, from indirect evidence, it is estimated to account for 83 percent of the total discharge from the Arctic Basin. Of this figure, 2 percent is in the form of icebergs. Although the volume of water transported as ice is a small fraction of the total, it is of considerable importance to oceanic heat balance and poses a major problem to North Atlantic shipping.

The flow of water out of the Arctic Ocean through the Canadian Arctic Archipelago is about 17 percent of the total discharge, and, compared to loss through the Greenland Sea, the transport of ice is negligible. There is essentially no northward flow of water through the shallow channels separating the islands of the Archipelago.

The volume of water entering the Arctic Ocean through the Bering Strait is better known than that from the Atlantic and is approximately 20 percent of the total. The amount of fresh water entering the Arctic Ocean is about 2 percent of the total input. Precipitation is believed to be about 10 times greater than loss by evaporation, although both figures can be only roughly estimated.

Through all of these various routes and mechanisms, the exchange rate of the Arctic Ocean is estimated to be approximately 210,000,000 cubic feet (5,900,000 cubic metres) per second.

All waters of the Arctic Ocean are cold. Variations in density are thus mainly determined by changes in salinity. On the basis of density, Arctic waters have a two-layer system: a thin and less dense surface layer is separated by a strong density gradient, referred to as a pycnocline, from the main body of water, which is of quite uniform density. This pycnocline restricts convective motion and the vertical transfer of heat and salt, and hence the surface layer acts as a cap over the larger masses of warmer water below.

Major water masses

Despite this overall similarity in gross oceanographic structure, the waters of the Arctic Ocean can be classified into three major masses and one lesser mass.

(1) The water extending from the surface to a depth of about 650 feet is the most variable and heterogeneous of all that in the Arctic. This is because of the latent heat of freezing and thawing; salt-brine addition from the process of ice freezing; freshwater addition by rivers, ice melting, and precipitation; and great variations in insolation (rate of delivery of solar energy) and energy flux as a result of sea ice cover. Water temperature may vary over a range of 7° F (4° C) and salinity from 28 to 34 grams of salt per kilogram of seawater (28 to 34‰).

(2) Warmer Atlantic water everywhere underlies Arctic surface water from a depth of about 650 to 3,000 feet. As it cools it becomes so dense that it slips below the surface layer on entering the Arctic Basin. The temperature of this water is about 34° to 37° F (1° to 3° C) as it enters the basin but is gradually cooled so that by the time it spreads to the Beaufort Sea, it has a maximum temperature of 32.9° to 33.1° F (0.5° to 0.6° C). The salinity of the Atlantic layer varies between 34.5 and 35‰.

(3) Bottom water extends beneath the Atlantic layer to the ocean floor. This is colder than the Atlantic water (below 32° F or 0° C) but has the same salinity.

(4) An inflow of Pacific water can be observed in the Amerasia Basin but not in the Eurasia Basin. This warmer and fresher water mixes with colder and more saline water in the Chukchi Sea, where its density enables it to flow as a wedge between the Arctic and Atlantic waters. The Pacific water, by the time it reaches the Canada Basin, has a temperature range of 31.1° to 30.8° F (−0.5° to −0.7° C) and salinities between 31.5 and 33‰.

Surface-water movement

Arctic waters are driven by the wind and by density differences. The net effect of tides is unknown but could have some modifying effect on gross circulation. The motion of surface waters is best known from observations of ice drift. The most striking feature of the surface circulation pattern is the large clockwise gyre (circular motion) that covers almost the entire Amerasia Basin. Fletcher's Ice Island (T–3) made two orbits in this gyre over a 20-year period, which is some indication of the current speed. The northern extremity of the gyre bifurcates and jets out of the Greenland–Spitsbergen passage as the East Greenland Current, attaining speeds of six to 16 inches per second. Circulation of the shallow Eurasian Shelf seas seems to be a complex series of anticlockwise gyres, complicated by islands and other topographic relief.

Circulation of the deeper Atlantic water is less well known. On entering the Eurasia Basin, the plunging Greenland Sea water appears to flow eastward along the edge of the continental margin until it fans out and enters the Amerasia Basin along a broad front over the crest of the Lomonosov Ridge. There seems to be a general anticlockwise circulation in the Eurasia Basin and a smaller clockwise gyre in the Beaufort Sea. Speeds are slow—probably less than two inches per second.

The circulation of the bottom water is unknown but can be inferred to be similar to the Atlantic layer. Measured values of dissolved oxygen show that the bottom water is well ventilated, dissolved oxygen everywhere exceeding 70 percent of saturation.

Sea ice. The Arctic Ocean's cover of sea ice suppresses wind stress and wind mixing, reflects a large proportion of incoming solar radiation, imposes an upper limit on the surface temperature, and impedes evaporation. Wind and water stresses keep the ice pack in almost continuous motion, causing the formation of cracks (leads), open ponds (polynya), and pressure ridges. Along pressure ridges the pack ice may be locally stacked high and project downward into the ocean several tens of metres.

Besides its deterrence to the exchange of energy between the ocean and the atmosphere, the formation of sea ice generates vast quantities of cold waters that help drive the circulation of the world ocean system.

Sea ice rarely forms in the open ocean below a latitude of 60° N but does occur in more southerly enclosed bays, rivers, and seas. Between about 60° N and 75° N the occurrence of sea ice is seasonal, and there is usually a period of the year when the water is ice-free. Above a latitude of 75° N there is a more or less permanent ice cover. Even there, however, as much as 10 percent of the area consists of open water due to the continual opening of leads and polynyas.

In the process of freezing, the salt in seawater is expelled as brine. The degree to which this rejection takes place increases as the rate of freezing decreases. Typically, newly formed sea ice has a salinity of 4 to 6‰. Even after freezing the process of purification continues but at a much slower rate. By the time ice is one year old it is sufficiently salt-free to be melted for drinking. This year-old, or older, salt-free sea ice is referred to as polar pack. It can be distinguished by its smoother, rounded surface and pale blue colour. Younger ice is more jagged and grayer in colour. Because the hardness and strength of ice increases as the salts are expelled, polar pack is a special threat to shipping.

Longevity of the ice pack

Important evidence concerning the long-term stability of the Arctic ice pack has been found by studying the sedimentary record of the ocean floor. This research has recently shown that there is strong evidence of an uninterrupted existence of sea ice on the Arctic Ocean during at least the past 3,000,000 years. Such evidence strongly refutes those theories of the cause of ice ages that postulate rapid variability of the Arctic ice cover.

Plant and animal life. *Plankton.* The chain of marine food supply is founded on floating microscopic plants, the phytoplankton. The annual productivity of these plants in the Arctic Basin is less than 10 percent of that of other ocean areas. The factor limiting this primary production is the ice pack itself, which reduces the penetration of solar energy needed for photosynthesis. Recent studies have shown, however, that Pacific water entering the Amerasia Basin is rich in detritus and nutrients. This is presumably true of Atlantic water coming through the Greenland Sea.

The next link in the food chain are zooplankton, small animals that feed on phytoplankton. Available information on the zooplankton under the permanent ice pack is even more fragmentary than for phytoplankton. But many of the Arctic zooplankton (and fishes) grow larger than their near relatives in warmer seas. This is believed

to be due to their delayed sexual maturity in cold water rather than to their speed of growth.

Fish. Free swimmers, or nekton, depend upon zooplankton as their food base. In truly Arctic waters fish play a minor role in human economy compared to marine mammals. The reverse is true in the bordering seas, in which there is an admixture of warmer Atlantic or Pacific waters and in which fisheries abound. The most important fish is the Arctic char (*Salvelinus alpinus*), a member of the salmon family. It spends most of its life in fresh water and comes into the sea for a few weeks in the summer. Only the polar cod (*Boreogadus*) has been taken from the central Arctic Basin, although bottom photographs have shown at least one other species of fish and shallow sonic scattering, apparently from fish schools, has been noted during summer months.

Mammals. The large sea mammals are the most conspicuous polar wild life. All are important to the hunting natives, and some of them are of commercial interest. These include the suborder Pinnipedia, including the eared or fur seals, the hair seals, and the walrus. Fur seals do not occur as close to the pole as the other groups, reaching only the southern edge of the Arctic. The Pribilof Islands in the Bering Sea are one of the main breeding areas. Hair seals include the harbour seal, the jar or ring seal, the bearded seal, the harp seal, and the hooded seal. The first three of these are widely distributed in the Arctic throughout the year and are of importance to the Eskimo. The latter two are migratory, and have been exploited commercially. The walrus is divided into two species, Atlantic and Pacific, and inhabits shallow waters, feeding on clams and other bottom fauna, which it can root up with its ivory tusks.

A wide variety of whales frequents Arctic waters, either for the entire year or during the summer months. They include sperm, killer, white, bottlenose, finback, humpback, blue, and narwhals.

Polar bears range throughout the Arctic, including the central ocean basin, throughout the year. They are frequently followed by the scavenging Arctic fox.

(N.A.O.)

The seabirds in the true Arctic Zone are represented by the auk family (murres, guillemots, auklets, and little auk), the sea duck (eider, scoter, old squaw), the gulls and terns (especially the glaucous and glaucous-winged gulls, many of the herring gull group of species, Sabine's gull, and the common and Arctic terns), the jaegers (parasitic, pomarine, and long-tailed), and the waders (sandpipers, etc.). One of the petrel group, the fulmar, breeds on certain Arctic cliffs. These are all migrant species that fly south in the fall. The Arctic tern makes a remarkable migration to subantarctic waters. (M.J.Du.)

THE PEOPLE

Ethnic groups. *Western Arctic.* There are no tribes of Eskimos, the word tribe being used in the sense of social groupings with internal political organization; nor may the term be used in the sense of populations conscious of their own tribal identities as opposed to other tribal groups. The Eskimos call themselves Inuit or Innuit ("the people") and are careful to distinguish themselves from non-Eskimos, and particularly from American Indians, who are their nearest neighbours; but this is a general identification and involves no elements of social structure or organization. The only Eskimo social units with validity from the Eskimo point of view are the immediate family, the household (often made up of two families), and the local residence group, which is identified only by a designation for the location, or place, with the suffix "miut," meaning the people of that place. Thus, the Birnirkmiut are those people who dwell at Birnirk (a location in the bend of a lagoon). The designators for larger groupings that have become standard in Eskimo studies are conventions introduced by field workers and scholars (see Figure 2 for the location of these conventionally named groups). Some names, such as Iglulik, Netsilingmiut, and Caribou Eskimos, refer to a particular subsistence characteristic (*iglu,* or "igloo"; *net,* or "seal"; caribou). Others have territorial referents, such as the North Alaskan Eskimo, Bering Strait Eskimo, and South Alaskan Eskimo. Whether in the first or the second category these conventionalized groupings have become established because they reflect various ecological adaptations within the general Eskimo way of life. The major groupings are as follows:

Social organization among Eskimos

Major Eskimo groupings

Siberian Eskimo (Yuit), including St. Lawrence Island Eskimo, hunters of walrus, whales, and seals, using the whaleboat (umiak) for whaling and voyages.

Aleut, fishers and hunters of seals, sea otters (for furs), and other sea mammals, using kayaks with two cockpits.

South Alaskan Eskimo, fishers (chiefly of salmon) and coastal dwellers in a forested area, using kayaks.

West Alaskan Eskimo (Nunivak Island and adjacent coast, Norton Sound), hunters of seals, walrus, and seabirds and fishers of salmon and other fish.

Bering Strait Eskimo (including Diomede Island and Cape Prince of Wales), hunters of walrus, whales, and seals, using whaleboats (umiak).

North Alaskan Eskimo (Point Hope, Point Barrow, and the North Alaskan Interior Eskimo), primarily whalers but also hunters of walrus, seals, waterfowl, and caribou.

Mackenzie Eskimo, hunters of whales and seals and fishers of salmon.

Copper Eskimo (including Victoria Island) and Netsilingmiut Eskimo (including Boothia Peninsula), hunters of seals (in winter, at breathing holes, and, in summer, from kayaks in open water) and of caribou.

Iglulik Eskimo, hunters of seals, walrus, and caribou.

Baffin Land Eskimo, hunters of seals and sea fowl.

Caribou Eskimo (Barren Grounds, Chesterfield Inlet, Back River), primarily hunters of caribou, but also of musk ox and, rarely, sea mammals, using no boats.

Southhampton Island Eskimo (extinct since 1904), hunters of caribou and seals, using no boats.

Labrador Eskimo, hunters of seals (from the ice edge and in open water from the kayak) and of caribou, and dwellers in or near subarctic forests.

West Greenland Eskimo, hunters of seals, using kayaks.

East Greenland Eskimo (Angmagsalingmiut), hunters of seals, using kayaks.

Polar Eskimo (northwest Greenland), hunters of seals, walrus, and seabirds, using no boats.

There is general agreement among specialists in studies of the indigenous peoples of North America that all of the Eskimo area, including the Aleutians, makes up one culture area in contrast to the various American Indian culture areas south of the Arctic. There also is considerable agreement among specialists that the Eskimo, or Western Arctic, culture area is divided into two major subcategories: a central and eastern subculture area, which extends across the northern Canadian archipelago and includes Greenland and the coast of Labrador, and a western subculture area, which coincides closely with the Alaskan regions, including the Aleuts and also the Siberian Eskimo (Yuit) on the northeast tip of Siberia. Various traits have different forms in the two subregions. Dog teams, for instance, are hitched differently. In the western subregion the dogs are attached in tandem along a central trace (a mode of hitching also used in the Eurasian Arctic). In the central and eastern subregion, dogs in a team are attached to separate traces of varying lengths and run in a fan formation. Kayaks, harpoon heads, house design, and other things show similar contrasts. There are a series of traits, not geared to mere survival but to more sophisticated living, that are found in the western area but not in the central and eastern region. Among these are labrets (ornaments worn in the perforated lip), dance masks, coiled basketry, pottery, grave monuments, mourning feasts, property distributions, war parties, and kin groups larger than the family. Collectively, these make the western cultures more elaborate or complex than those of the central and eastern region. One interpretation is that the western elaboration represents traits inherited from ancestral Asian cultures and that many such traits were sloughed off as the Eskimos migrated eastward and had to cope with a harsher environment that left them little opportunity for traits and practices that could have been considered superfluous.

Major Eskimo subculture areas

Some studies further divide the central and eastern areas

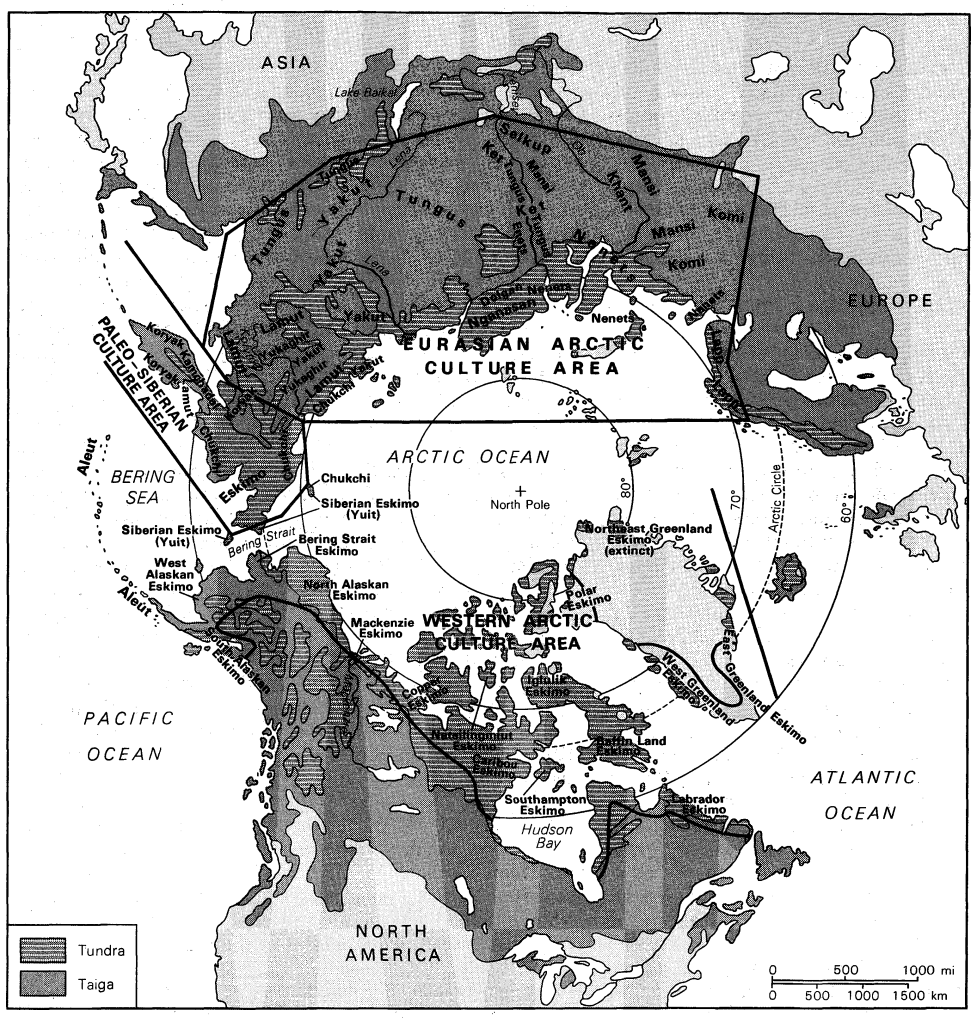


Figure 2: Distribution of Arctic peoples.

into separate categories. The people in the central area are largely nomads who dwell in snowhouses; the people in the east, particularly in Greenland, live in semisubterranean houses in fixed villages of considerable size. It is the nomad of the central groups (especially Iglulik, Netsilingmiut, Copper, and Caribou Eskimo) who provides the popular stereotype of Eskimo life; but actually most Eskimos, in both the east and west, are not nomads living in snow winter houses, but instead they are sedentary village dwellers living in subterranean sod-walled houses. Village living is made possible for the Eskimos by their efficient modes of transportation—dog teams in winter and boats made of skin (kayak and umiak) in summer. Only hunters with good transportation can range far enough to gain sufficient food for sedentary village living. (W.K.C.)

Eastern, or Eurasian, Arctic. Although many hunters and fishers are found in Arctic Eurasia, it is the keeping of domestic reindeer that defines the culture area and gives it unity. The herds and correlated traits, in harmony with the required mobility, set the Eurasian Arctic apart from the Western Arctic, despite many common circumpolar traits. The reindeer complex also differentiates Arctic from non-Arctic cultures in Asia; but some boundaries are blurred, particularly in southern Siberia, by transitions between the herding of reindeer and the herding of other domestic animals, such as cattle, or by transitions to agriculture within single ethnic groups.

The peoples of the Eurasian Arctic more genuinely divide into different ethnic groups (in contrast to the Eskimo groupings); each group has its own language (though many are linguistically related), and each considers itself as having its own name and tradition. The major Eurasian Arctic groups number 19 and go by various names (the alternative names appear below in parentheses):

Major Eurasian Arctic ethnic groups

Lapp (Saamian, Lopari), reindeer herders and fishers, speaking a West Finnic language (of the Finno-Ugric family, a subdivision of Ural-Altaic).

Komi (Zyryan), various groups of reindeer herders, cattle herders, hunters, and agriculturalists, speaking a Permian language (of the Finno-Ugric family).

Mansi (Vogul), reindeer herders, hunters, and fishers, speaking an Ugrian language (of the Finno-Ugric family).

Khant (Ostyak), reindeer herders, hunters, and fishers, speaking an Ugrian language (of the Finno-Ugric family).

Selkup (Ostyak-Samoyed), reindeer herders, hunters, and fishers, speaking Selkup (of the Samoyed family, a subdivision of Ural-Altaic).

Enets (Yenisey-Samoyed), reindeer herders, hunters, and fishers, speaking Entsy (of the Samoyed family).

Nganasan (Tavgi Samoyed), reindeer herders, hunters, and fishers, speaking Nganasan (of the Samoyed family).

Nenets (Samoyed, Yurak), reindeer herders, hunters, and fishers, speaking Nentsy (of the Samoyed family).

Yakut (northern Yakut: Sakha, Jeko), chiefly cattle and horse herders but also some reindeer herders, hunters, and agriculturalists, all speaking a Turkic language (of the Altaic family, a subdivision of Ural-Altaic).

Dolgan, reindeer herders, hunters, and fishers, ethnically a Tungus group but speaking the language of the Yakut.

Lamut (Even, Oven), reindeer herders, hunters, and fishers, speaking a Manchu-Tungus language (a subdivision of Ural-Altaic).

Tungus (Evenk), reindeer herders, hunters, and fishers, speaking a Manchu-Tungus language (a subdivision of Ural-Altaic).

Yukaghir (Odul), a Paleo-siberian group, formerly primitive hunters but now largely reindeer herders, speaking Yukaghir (an unaffiliated language).

Koryak (Nymylan), a Paleo-siberian group of reindeer herders and hunters and of sea hunters and fishers, speaking Koryak (of the Chukchi-Koryak-Kamchadal family).

Chukchi (Chukchee, Luorawetlan), a Paleo-siberian group of reindeer herders and hunters and of sea hunters and fishers, speaking Chukchi (of the Chukchi-Koryak-Kamchadal family).

Kamchadal (Itelmen), a Paleo-siberian group of sea hunters and fishers, speaking Kamchadal (of the Chukchi-Koryak-Kamchadal family).

Eskimo (Yuit), Asiatic Eskimo sea hunters and fishers, speaking Eskimoan.

Aleut (Unangan), Asiatic Aleut sea hunters and fishers, speaking Aleut.

Ket (Yeniseian, Yenisey-Ostyak), western Paleo-siberian hunters, speaking Ket (an unaffiliated language).

Lapp, Komi, and Samoyed

Of northern Finno-Ugrian-speaking peoples west of the Urals, the Lapp and the Komi are the only recognizable entities remaining in the late 20th century. The Lapp comprise small minorities in northern Norway, Sweden, Finland, and on the Kola Peninsula in the Soviet Union; their principal livelihoods are fishing and reindeer breeding. The Komi, by contrast, are concentrated in the northern Soviet Union between the Pechora and Vychegda rivers (southeast of the White Sea); most are agriculturalists, but in the northern part of their area, some are hunters and reindeer breeders. The Komi Autonomous Soviet Socialist Republic has been in existence since 1936.

East of the Komi and on both sides of the Urals lies the traditional area of the Samoyed peoples. Their languages and the languages of the Finno-Ugrians make up the Uralian language stock. The majority of the Samoyed are located along the coast and lower reaches of rivers between the White Sea and the Taymyr peninsula, where they have adapted to a tundra ecology based principally on reindeer breeding, hunting, and fishing. These groups are now known in the Soviet Union as the Nenets, Nganasan, and Enets. A fourth group of Samoyed, the Selkup, is settled well to the south of the others and along the upper reaches of the Ob River. Their nearest non-Russian neighbours are two Finno-Ugrian-speaking peoples who moved to the east of the Urals: the Ostyak, now called the Khant, and the Vogul, now called the Mansi. Earlier, the Selkup, Khant, and Mansi were hunters and fishers only; later, they adopted reindeer breeding (Nenets influence), fur trapping (tsarist influence), and fur farming (Soviet influence).

The Siberian home of most of the Tungus people, who speak what is called a Manchu-Tungus language, is in the vast area between the Yenisey River and Lena River, to the east and south of the Samoyed peoples. These Tungus are now known in the Soviet Union as Evenk. Like the Nenets, they are traditionally reindeer breeders, hunters, and fishers principally; the culture of the Evenk, however, is adapted to the taiga and not to the tundra. There are also the Dolgan, a small Tungus group of 5,100 persons, living north of the Evenk and in the southern part of Taymyr in ecologic conditions approaching those of the Samoyed groups. The Dolgan are now Yakut-speakers. One group of Siberian Tungus lives well to the east of the Yenisey–Lena area; they are the Lamut, now called Even, whose culture and language are held to be closely similar to the Evenk. The dispersed Tungus, or Evenk, population continues to the east and south beyond the Lena River to the Sea of Okhotsk and the Amur River; it is particularly in these areas that Evenk culture becomes blended with Yakut.

The Yakut are distributed on both sides of the middle basin of the Lena and on to the Kolyma River in Northeastern Siberia. The Yakut speak a Turkic language that combines with the Manchu-Tungus language of the Tungus to form the so-called Altaic linguistic family. Only a minority of the Yakut are reindeer breeders, most of them having kept cattle and horses; agriculture and hunting also are traditional practices. The Yakut may have moved northward into their present locations not long before the Russians arrived in that part of Siberia in the 17th century; local groups of other ethnic populations (besides Dolgan and Evenk, also Yukaghir and even Russian settlers) were assimilated by the Yakut, who have always had an important role as traders. Since 1922 there has been a Yakut Autonomous Soviet Socialist Republic.

Paleo-siberians

Far Eastern Siberia is the ancestral home of some of the different peoples known collectively as Paleo-siberians. They do not form a linguistic group of their own, and, unlike all other Arctic peoples of the Eastern Hemisphere, they do not have linguistic affinities with peoples to the south. They appear to have been in Siberia much longer than the other peoples, who are sometimes therefore designated collectively as Neosiberians. The Yukaghir, who inhabit the area immediately to the northeast of the Yakut, are Paleo-siberians who used to practice a primitive hunting economy over wide areas of tundra. Privation, disease, and assimilation (particularly to the Even, Yakut, and Russians) have taken a severe toll on their populations, however, and there are only about 800 persons who call themselves Yukaghir. Many of them are reindeer breeders, and about a third of them regard Russian as their native tongue. East of the Yukaghir are the Koryak and the Chukchi, both of whom are traditionally adapted to the tundra (reindeer breeding and hunting) as well as to the sea (hunting and fishing). Both offered relatively severe opposition to the Russians, the Chukchi not becoming Russian subjects until as late as 1789. Only the Chukchi expanded their territory and numbers in historical times, however, and this was at the expense of the Koryak as well as of the Yukaghir.

Along the Bering Sea are Asiatic Eskimo interspersed with Chukchi settlements. There are also Kamchadal, now called Itelmen, who live along the western coast of the Kamchatka Peninsula; the economies of both these peoples are marine. The languages of the Koryak, Chukchi, and Itelmen are related. Finally, there are Aleut on Commander Island off the Kamchatka coast, and far to the west there are the Ket, who are hunters, trappers, and fur farmers living along the middle reaches of the Yenisey. Both of these peoples are included among the Paleo-siberians; the language of the Ket is the sole survivor of a linguistic group earlier present in the area.

(W.K.C./R.P.B.P.)

Physical types. Two of the major varieties of mankind are represented among the Arctic peoples—Mongoloid (Asian) and Caucasoid (European). The idea that mankind varies in continuous distributions of physical characteristics, which should be plotted in terms of frequency occurrences (clines) of these traits rather than broken into discrete categories (races and subraces), is demonstrated in a general way among the Arctic populations. There is more or less a cline from Mongoloid to Caucasoid extending from Arctic America and eastern Siberia across northern Asia and into northern Europe, with the more generally Mongoloid nearer to the American and Siberian end and the more generally Caucasoid nearer to the European end. Comparative studies of the ethnic populations reveal, however, that the distribution of traits is not strictly continuous; some groups not fitting the pattern intrude here and there, and the cline extremes are not truly at the geographical ends of the distribution.

Biology of major groups. In regard to physical type, the Eskimos are much more closely related to northern Asians than they are to American Indians, as shown by blood types as well as by morphological features (principally facial features and body proportions). Sources variously refer to an "Eskimo" subrace of Mongoloids or to an "Arctic" subrace. When "Arctic Mongoloid" is used as a category, the Chukchi and some other groups of northeastern Siberia are included; however, field workers report that the Chukchi and their neighbours, the Siberian Eskimos, differ enough so that most individuals can be identified without reference to language or other cultural traits; and early sources reported that skulls unearthed from ancient tundra burials showed considerable differences, with Eskimo crania being higher and Eskimo facial breadths greater than those for the Chukchi.

The Tungus and Yakuts

West of the Arctic Mongoloids, the Tungus and Yakuts show some of the highest frequencies of extreme Mongoloid traits found anywhere. They are among the most Mongoloid of all peoples, with low-bridged noses and

forward-projecting cheekbones (malars) that are covered with pads of fatty tissue, resulting in extreme facial flattening. Eye forms show a high frequency of epicanthic (or "Mongoloid") eye folds. Hair is straight, black, and large in cross section; it is abundant and long on the head but sparse in beards and body hair. Skin colour is yellow or yellow brown, and eye colour is consistently brown. In stature the Tungus and Yakuts are short, with the shortness accentuated in lower limbs. Legs below the knee (tibia and fibula) are short relative to the legs above the knee (femur); and elbow to hand lengths (radius and ulna) are short relative to upper arms (humerus). Resulting total limb lengths are short relative to trunk lengths. The type is labelled "classic" Mongoloid or the "extreme" Mongoloid. Broad heads, relative to head lengths (brachycephalic), are also stated to be characteristic of extreme Mongoloids in most discussions of racial types; but this ratio depends on a combination of factors, and changes through time occur within ethnic populations. Many Tungus are longheaded (dolichocephalic), and in recent times there has been a trend in all northeastern Asian Mongoloids toward an intermediate head form (mesocephalic).

The Tungus and Yakuts have been frequently cited as extreme Mongoloids who are placed geographically between the Caucasoids of the Urals and the Caucasoid-like Ainu of the northern Japanese islands; moreover, the Tungus and Yakuts are equally intrusive between the less Mongoloid Arctic peoples who are their immediate neighbours, particularly the Yukaghirs and the Kets. The physical characteristics of these various groups and their distributions are consistent with the hypothesis that the extreme Mongoloids derived from a people who originally had more generalized Mongoloid characteristics (and were more like Caucasoids) and who, isolated in Siberia during a period of extreme cold in the Ice Age, developed the distinctive facial and body characteristics of the extreme Mongoloid as adaptations to the glacial environment. Prior to the development of the extreme Mongoloid, some people of the generalized Mongoloid type had migrated across the Bering Strait area to become ancestors of the American Indians, while other generalized Mongoloids remained in scattered populations elsewhere in Asia. After the ice receded, the physical characteristics of the extreme Mongoloids, though adaptive to very cold conditions, were no handicap in warmer environments and were continued and spread by migrations; but the centre of highest frequency for extreme Mongoloid traits remained near the point of origin. Seen relative to this hypothesis, the Tungus and Yakuts are representative of the extreme Mongoloid type, and the Yukaghirs and Kets are near the generalized Mongoloid in physical type. In appearance the Kets are suggestive of some American Indians. Old photographs of the Yukaghirs show Caucasoid-like facial features, but this is not inconsistent with the idea of a generalized Mongoloid type.

West of the Yenisey River, the Khants and Mansi (Voguls) are basically Caucasoids (as are the Komi and Lapps farther to the west), although the frequency of blood type B is somewhat higher (a Mongoloid trait), and individuals with epicanthic eye folds are more common than in European populations. The Khants, Mansi, and Komi are usually classified as belonging to a "Ural" subrace of Caucasoids. (Soviet sources refer to a "Europoid" type.) The Ural type is characterized by straight, brown or light-brown hair, fine in cross section; light skin colour; mostly light or mixed eyes; moderately thick beards; comparatively short and moderately wide faces; concave or upturned noses; thin lips; medium ratio of head breadth to head length (mesocephaly); and short stature (with a mean of about five feet, three inches [160 centimetres] for adult males).

Compared to their neighbours, the Khants and Mansi, the Samoyedic speakers—Nenets, Nganasans, Enets, and Selkups—have a higher frequency of Mongoloid features, including particularly the epicanthic eye fold, and they are often identified as Mongoloid outliers in Europe and western Siberia. Compared with the extreme Mongoloids, however, they are clearly closer to Caucasoids in many features. They lack pronounced malars and have higher nasal profiles, and their facial proportions are more comparable to Europeans than to Asian types. Clearly, they are intermediate in the continuum found among Arctic peoples.

Caucasoid features of Lapps

The Lapps of the Scandinavian countries and northwestern Russia are now recognized as Caucasoids. Formerly, they were not always so classified, probably mainly due to the marked contrast with their Indo-European-speaking Scandinavian neighbours, who show a high proportion of tall Nordic types. Whereas the Scandinavians, particularly the people of Sweden, are the tallest of Caucasoids and among the tallest groups of mankind, the Lapps are among the shortest, with a mean stature of only five feet, three inches for males and four feet, 10 inches for adult females. Some sources formerly classified the Lapps as Mongoloids, but they lack most sorting criteria for Mongoloids, having only a moderate incidence of B-type blood (an Asian trait), shovel-shaped incisors (also Asian), and other dental characteristics to suggest this affiliation. Some authorities have even assigned the Lapps to their own individual major racial category, thinking of them as a remnant of some archaic Caucasoid-like people. In most traits, however, they are close to the Ural type, and systematic assessment places them among the Caucasoids. Their Mongoloid traits are terminal effects of the Arctic Mongoloid-Caucasoid cline.

In most physical characteristics, the Eskimos are close to the extreme Mongoloid type. They also share the general characteristics of short stature, thick torso, and small extremities found among all the Arctic peoples. Uniquely Eskimoid features include very broad faces, thin noses, and high cranial vaults with sloping sides ("gabled" parietals). Eastern Eskimos and the crania from old Eskimo archaeological sites are longheaded (dolichocephalic), and for this reason many summaries characterize the Eskimos as the longheaded subtype among Mongoloids. Not all Eskimos, however, are dolichocephalic. Group means vary from dolichocephaly through mesocephaly to the lower range of brachycephaly. Anthropometric studies also report variations in stature from group to group (from about five feet, two inches, to five feet, six inches, for adult males).

General adaptive features. Considered as a whole, the Arctic peoples share certain physical features regardless of the predominance of Mongoloid or Caucasoid traits. The most evident of their shared traits is their small size—or, more correctly, short stature, since such people as the Chukchi are described as being massive in build, though only two or three inches above five feet in mean stature for adult males. Other shared characteristics include large girths relative to body lengths, short limbs relative to torso lengths, short lower legs and lower arms relative to upper limb segments, and small hands and feet. All of these characteristics are in harmony with general biological principles regarding adaptation to cold environments.

Cold-adaptive body mechanisms

Experimental studies, particularly since World War II, have identified at least two specific cold-adaptive body mechanisms (largely vascular) that have become hereditary among the Arctic populations. One of these results in increased blood flow in exposed body parts, such as the hands, and heightened basal metabolism to keep blood temperatures within tolerable limits (found among Eskimos and other Mongoloids in the Arctic). The second form of cold-adaptation involves shunting of blood from one artery to a paired artery and warming of venous blood leaving the body extremities before it returns to the heart. Thus, the extremities can be reduced in temperature without affecting more critical body parts such as the brain. (This second cold-adaptive characteristic has been found among the Lapps.) Even before these cold-adaptive features were identified by experimental physiology, they were acknowledged by ethnographers in statements asserting that the Chukchi men could work for considerable periods with bare hands when temperatures were −30° F (−35° C), or that the Chukchi would strip to the waist and complain of the heat if the temperature rose much above 40° F (4° C).

ARCTIC CULTURES

Two major manners of earning a living are found among the cultures of the Arctic—that of the hunter and that of the reindeer herder. In the Western, or New World,

Arctic, only hunters are found and all are Eskimos (including the closely related Aleuts of the Aleutian Islands). Hunting cultures also occur in the Eastern, or Eurasian, Arctic; but more typical are reindeer herders distributed in a great arc across northern Eurasia, from the Chukchi of Northeastern Siberia to the Lapps of northern Europe.

When defined as a culture area, the Arctic includes some regions that are subarctic in climate. Physical geographers often place the southern boundary of the Arctic either at the Arctic Circle or at a line marking the regions where the warmest month has a mean temperature that is not above 50° F (18° C); in Eurasia this coincides closely with the northern limit of trees and represents a real division in vegetation, climate, and habitat. But this geographical boundary is not a cultural boundary, since most of the Eastern Arctic cultures are found in both the treeless desert-like tundra of the Arctic and the northern reaches of the swampy, coniferous forests, or taiga, of the subarctic. Some groups live in the taiga and some on the tundra, and others are seasonal nomads (transhumants), wintering their reindeer in the taiga and moving them in the spring and summer to graze on the tundra along the Arctic Ocean. Considered as a culture area, the Arctic is determined by relative uniformity of practice and custom, not solely by geography.

In many ways the Eskimos are the people most adapted to the Arctic, the people most specialized for Arctic living. Most Eskimos are coastal dwellers, specialized in hunting sea mammals, particularly the several species of seals, and in some places walrus and whales. Fish and birds also are important. Although there are some inland Eskimos in northern Alaska and Canada who depend especially on hunting the caribou, a wild relative of the domesticated reindeer of Eurasia, an orientation toward the sea characterizes the patterning of most Eskimo cultures. And although some Eskimos live in the forested areas of the subarctic (in Labrador and southern Alaska), the characteristic Eskimo settlement is along a coast of the Arctic Ocean or along some northern strait with tundra at the back of the village. Most Eskimo villages are between latitudes 60° and 72° N. The most northerly of the Eskimos—and most northerly of all the world's peoples—are the so-called Polar Eskimos of northwestern Greenland, who are found as far north as 79°.

Ecology and cultural adaptations. The most demanding environmental conditions for Arctic peoples are the cold and high winds, the seasonal variations in the hours of daylight, the limited numbers of natural species, both flora and fauna, and the restricted range of raw materials for making houses and tools. Contrary to widely held impres-

Character of the Arctic environment

sions, the people who live on the tundra are not buried in the snow. Precipitation is very light in much of the Arctic (often less than four inches of water a year). The Arctic would be recognized as a desert except that the long, cold winters and short summers reduce evaporation and prevent runoff of groundwater or ice; much of the land is permanently frozen soil, or permafrost. Expressed in temperatures, the cold is more intense in the boreal forests of the interior taiga; but on the tundra high winds persist throughout the year, and in winter the resulting windchill makes exposure critical and the needs for protective housing, clothing, and equipment more demanding. (See above *Climate.*)

Arctic habitations, clothing, and equipment. For those peoples who still follow their traditional way of life, survival in such conditions requires highly functional housing and clothing. The provisions to meet these requirements are particularly revealing. The construction materials have to be those readily available in the immediate vicinity.

Types of housing

Some Eskimos use snow blocks to build the domed house widely identified as an igloo; but most Eskimos (before the introduction of prefabricated structures in the Arctic) lived in earth- or sod-walled structures built on a frame of driftwood, sometimes with large whale bones as structural members. Many of the design features to offset cold and wind are common to both the snowhouse and the semi-subterranean sod house: both include an entrance shelter or storm shed, frequently long and narrow, to block cold winds, and a raised bench ("sleeping bench") to keep the occupants up out of the colder levels of the house. The sleeping bench is the centre for many activities other than sleeping during the long winter nights, activities such as eating, making tools, and mending equipment. In summer, the Eskimos move out onto the tundra, living in skin tents.

For the nomadic or seminomadic reindeer herder of the Eurasian Arctic, the winter habitation is more apt to be a tent, in many cases a double-skin tent (subterranean houses are possible only among some taiga pastoralists who can winter their herds in a sheltered area and keep them in one place for several weeks or more). The Eurasian tent, which is used both summer and winter, is conical (somewhat resembling the tepee of the North American Plains Indians) and is covered with reindeer skins on the tundra and with bark in the subarctic forests. The winter tent is sometimes banked with sod and often, if not always, with snow. Some are fitted with raised benches and with storm sheds. The main tent surface may be doubled with insulating materials between the layers; in other cases, as among the Chukchi and Koryaks, there may be separate boxlike sleeping shelters within the main canopy, each for several occupants. Toward the western end of the Eurasian area, approaching northern Europe, the winter house is more akin to European prototypes, such as the Scandinavian log house, usually with a flat roof that is earth-covered; some Lapp herders of Scandinavia, however, spend winters in conical tents banked with sod and snow. The Arctic Eurasians who do not depend on reindeer but are seamammal hunters and fisher folk, and thus largely sedentary, live in semi-subterranean winter houses.

Arctic clothing

Clothing is no less critical (and perhaps more critical) than housing for survival in the Arctic. Eskimo clothing, similar in general to clothing in the Eurasian Arctic cultures as well, is so suited to the environmental conditions that until recently none made elsewhere could equal it, and explorers and others from the outside world adopted it after a short period in an Arctic winter. The general aspects of Eskimo clothing are well known—garments fashioned of the skins of fur-bearing animals with emphasis on a pullover jacket with an attached hood (parka) and bootlike footgear with watertight seams. The parka and trousers (worn by both sexes) are double-skin garments—two layers of skins placed back to back with the fur surface of the outer layer on the outside and the fur or hair of the inner layer inside, against the wearer's skin. Caribou skins with the hairs at just the right stage of development are selected. Not only does the hair of the inner layer provide warmth, but air trapped between the short, fine hairs of the inner caribou skins provides additional insulation. Other functional aspects of clothing design provide for ventilation and perspiration control. Even at temperatures well below zero, a man exerting considerable effort, as in running after a dog sledge, often perspires. If he is wearing conventional undergarments, these inner garments become damp with perspiration; and when the activity rate is decreased and the body cools, the perspiration-dampened clothing freezes. In the fully developed Eskimo garments, drawstrings are provided at the end of each sleeve and at the opening for the face. A belt closes the lower edge of the parka. If the wearer perspires, he loosens these bindings, permitting the outside air to percolate through the hairs of the inner fur layer. The cold, dry, ambient air, which is warmed by passage over the person's body, becomes extremely dry and quickly absorbs the moisture. With the perspiration stopped, the wearer pulls the bindings tight again to prevent overcooling. Other items of Arctic clothing include various types of footgear for differing weather, outer rain garments to keep the exterior fur layer dry, and mittens, each item with design features providing similar functional fit and solving particular environmental problems.

Technology and equipment

It has become customary to state that Arctic dwellers were able to occupy their difficult environment only through application of much ingenuity. Other references credit the Eskimos, for instance, with the invention of the toggle-headed harpoon (one whose spurred head detaches from the shaft after piercing a struggling animal); the semi-subterranean house; the composite bow (one of wood, bone, and sinew glued and lashed together); the throwing stick, or atlatl (a rodlike device for hurling darts or spears); and other items of material culture. In terms of skill in manufacturing and eagerness to adopt new items, Arctic peoples were indeed ingenious; but this does not mean that they invented all of the items that they used. With the exception of the domed snowhouse, a trait exclusive to the Eskimos, even the most typical items in the material culture of Arctic peoples were widely shared with other peoples in more southerly areas.

A list of material items used in both the Eurasian and Western Arctic would include the semi-subterranean house with entranceway and sleeping bench; tailored clothing, including the parka; the toggling head and other harpoon parts; blunt arrowheads for birds and small game; the atlatl; barbed darts for taking birds; the semicircular slate knife (ulu); snow goggles with slits as eye openings; sledge forms; dog teams for traction; skin boats both large and small (kayak); the bow drill; the composite bow; ice picks for harpoon shafts; the tambourine-type drum used in healing rites; and so on. The semi-subterranean house is shared with American Indians south of the Eskimo area and distributed across the Eurasian Arctic. The hooded parka was used as far west as northern Europe and can be identified in art objects far back in time (as in the Siberian Neolithic Period). The toggling harpoon head was used in hunting sea mammals by some prehistoric and later cultures of northern Europe. (W.K.C.)

Traditional culture patterns. *Western Arctic.* The cultural and social life of the peoples of the North American Arctic can in large measure be interpreted in terms of an adaptation to Arctic hunting. Theirs was a highly successful material adaptation, marked by an ability to exploit an essentially hostile environment. A price had to be paid, however, for the stress on technology and hunting. Because the Eskimo lacked agriculture and, for reasons unknown, were uninclined to exploit whatever wild vegetation was available, their populations and settlement patterns were limited by the available game. In general, they stressed cooperation among close kindred in the pursuit and use of game—this necessarily at the expense of any tribal definition or solidarity. They had to be pragmatic, relying on the physical strength, technical ability, and survival skills developed in their own small groups.

Importance of hunting

It is not wholly accurate to describe the Eskimo culture as nomadic; although a group might range widely through a given territory in seasonal search for food, a group knew its own territorial range and generally kept to it. Every cliff, rock, bay, and discernible hummock of tundra land was named, and it was to this familiar terrain that

the individual and family were generally bound. On the other hand, this attachment to a traditional area was not immutable. People could on occasion move and establish relations or affirm kinship ties with other groups.

The family group

The primary unit of affiliation lay in the family, not only in the nuclear family of spouses and children but in the extended family in which both the maternal and the paternal lines figured. The system made no provision for an elaborate genealogical accounting; indeed, one's relatives were those who stood close to one in both reckoning and residence—brothers and sisters, parents and their siblings, the children of such, one's own children and grandchildren. One might try to keep alive a sense of relationship with a person who had moved to a different group for marital or other reasons, but usually such ties eroded over time. In line with the eminently practical sense of the Eskimo, one's relatives were those with whom one could interact directly, from whom one could freely ask support and have it demanded in turn. This feature in turn gave rise to the sense of collective responsibility, the sense of loyalty and obligation to one's resident relatives, which so vitally underlay Eskimo societal and legal organization.

Alliances among kin were nevertheless sought beyond domain of the immediate family. Local groups of Eskimo and Aleut developed mechanisms for the formation of cooperative alliances, those designed to effect success in collective hunting, as well as in the exchange of goods and services. The individual could thus make demands on affinal kindred, persons who were related to him through marriage.

Marital patterns

The basis of marriage lay in a fairly sharp division of labour between the sexes; the men hunted, made tools and household goods, and built the homes; the women cooked the food, dressed the skins, and made the clothing. Each partner owned his own personal goods, such as clothing and tools; shelters and food might be held in common, though men had personal rights to the kayak and the umiak (an open boat) and to sleds, sledges, and dog teams. Indeed, the whole rationale for marriage among the Eskimo lay in the recognition of such sexual division of labour and property.

In general, Eskimo marriage was not arranged but open to freedom of individual choice. A young man could settle down with an unmarried woman, either within his own family grouping or hers; children might be born to the couple; but, until there was public recognition of the marital status, legal marriage did not in fact exist. It was not unusual for women to cohabit with several men in succession or even, as in the central regions, with several at the same time, giving rise to a kind of polyandry. Actually, the birth of a child, increasing as it did the cooperative circle of kindred, tended to give some permanence to the marital union. At that, however, a woman whose fertility had been demonstrated was much in demand as a wife, especially if she exhibited the cardinal virtue of industriousness. Divorce under such circumstances was relatively simple, meaning no more than that one or both partners broke the residential unit to find a new spouse. In cases in which there were children, however, even divorce did not entirely break the relationship, the child having relations with both his paternal and maternal kindred and they to each other through him.

Although polyandry could occur, it was almost never of the fraternal type; that is, the husbands could not be brothers. Similarly, two or more wives could reside with a skilled hunter in polygynous unions, but the wives were rarely sisters—the point being that sisters should marry divergently so as to extend the cooperative bonds of kinship. A man, it is true, might be responsible for his wife's unmarried sister and engage in sexual relations with her, but she was not his wife and could leave almost at will. An interesting feature among the Eskimo was the stress on competition for women; a man might easily lose a wife to an abductor, particularly if the union lacked strong support from his kindred.

An important mechanism for ensuring alliances was wife exchange—that is, the arrangement whereby a husband allowed another, unrelated man to have temporary sexual relations with his wife, with the understanding that the favour would be reciprocated. Partly this was an expression of hospitality, but the sharing of wives between two men could initiate and foster a lasting partnership and friendship. Lacking either a tribal or national sense, the various Eskimo groups were obliged to devise means whereby kinship right and privilege could in some measure be extended to persons unrelated by blood or marriage. The problem, as viewed by the Eskimo, was that anyone not related by blood or marriage was a potential enemy.

Legal mechanisms

Involved in these issues of kinship and alliance was the concept of blood feud. Because there were no chiefs or headmen, no formal arbiters of disputes, and clearly no sense of broad territorial community as such, there had to be means whereby any group could be held responsible for wrongdoing by one of its members. The means was the blood feud, whereby not only the malefactor in a group but also his kin could be pursued by an outside group that had been wronged. One result of this practice was to deter wrongdoing in the first place; group opinion tended to restrain any individual from putting the whole group into jeopardy. Another more fearful result was that a vengeful killing might touch off a series of counterkillings—bloody retaliations back and forth between the groups, a true blood feud. Fear of the blood feud, it may be said, probably played an important role in keeping populations territorially apart. Finally, the blood feud, with its implicit element of collective responsibility, also served to enforce family solidarity.

There were of course other means of social control. Public opinion and public ridicule and shaming were effective in maintaining order. There was also, among the central and eastern Eskimo, a kind of surrogate blood feud called the song duel, in which, at a public gathering, two rivals would voice their quarrel by insulting each other in extemporaneous song. The loser, bested in the singing, was often forced to leave the community. Similarly, men might wrestle to settle disputes.

Among the Eskimo there was a large measure of freedom of individual choice in economic pursuits; that is, men were free to seek whatever way they could find to eke out a living in the harsh environment. This freedom, however, tended to be socially divisive; it could mean the breakaway of certain individualistic members of a group. It was not unknown, for example, for a man to leave his wife and children to settle in another place in order to take advantage of economic opportunities there. While away, he might marry again, produce a new family, and ultimately lose contact with his original group. A wife had no recourse in such a case but to fall back on the resources of her own kindred; she too might marry again. Nor did the authority of a parent extend to the demand that a child follow a particular activity. Everyone had the primary goal of seeking food, but each person was free to realize the goal in whatever way suited him best. A result was the beginning of some economic and labour specialization. One person might specialize in a certain kind of hunting or trapping; another might excel in organizing a collective hunt; still others might make weapons, boats, or other items that could be traded for food. The sole demand was that each individual produce.

Trade

Trade and barter figured prominently in the native cultures. Crafted items could always be exchanged informally within a community, but beyond this there were the very important trading patterns that developed between groups—as, for example, in northern Alaska, where the inland caribou hunters traded skins and furs to the maritime residents for pokes of seal oil, ivory, whalebone, and other products of the sea. In the west, these trading arrangements took on the form of elaborate ritualistic feasts called "asking feasts" or "messenger feasts," which, while not basically religious, involved a strong element of ceremony. In these ceremonies, one man of demonstrated skill and leadership publicly feasted his counterpart from another community, and in the process there would be a large exchange of surplus goods, all attended by humour and banter.

Food resources varied across the vast expanse of the Arctic regions. Maritime Eskimo hunted seals of various species and populations. The Aleut sought principally the

sea otter but also hunted seals and whales. All along the north Alaskan coasts, west and south of Point Barrow to the Bering Strait, the natives specialized in the tracking of whales. Other groups hunted the walrus (both Pacific and Atlantic subspecies), polar bears, and various Arctic birds. Many Eskimo groups, in northern interior Alaska and Canada, hunted the caribou, which were especially prized not only for food but also for their skin and fur. Sea fishing was not very important, except perhaps among the western Eskimo; freshwater-stream fishing was important almost everywhere.

Against land animals the Eskimo used the bow and arrow, along with a great variety of traps, and against sea mammals they used the retrieving harpoon. Some groups of Eskimo also used rawhide nets for capturing seals, as well as hooks and tridents, weirs, and traps for gathering fish. From the skin-covered, one-man kayak they harpooned the seals in the sea and speared the swimming caribou in the lakes and rivers. This vessel was not practical, however, for whaling; for this, Eskimo employed, in summer, the umiak, a larger boat, also skin-covered, which resembled the European whaleboat and which served otherwise to transport the family and its possessions. Winter transport was provided by dogsled.

Group hunting

The hunting of such large and often elusive game as whales, walrus, and caribou usually required the efforts of a large expedition, often larger than the labour resources a single kinship group could supply. In such cases the mechanisms of alliance between different groups would come into play. The means could be informal; a man of proven skill and ability as a leader of hunts could randomly attract a following of both relatives and nonrelatives for a specific enterprise. Or the means could be more formal (as it was most characteristically among western Eskimo); a would-be leader might bribe men to join his hunting crew, and the relation between leader and crew member might be further cemented by temporary wife exchange. Whether formal or informal, however, the leadership lasted for only the length of the hunting season or the particular enterprise.

Individual hunting alternated with group hunting. An individual hunter, for instance, might snare seals under the ice during the dark winter days, join a crew for caribou or sea hunting in the spring, move with his family in summer to a fishing site, engage in trade with others, and then return to a permanent encampment in the winter months to begin the cycle again.

It seems true of the Eskimo, as of many other nonliterate peoples, that there was little interest in either the problem of origins or a life hereafter. There was a vague concept of reincarnation but not a well-defined eschatology. Indeed, the Eskimo were less concerned with the dead or less afraid of the dead than many of the world's peoples; a corpse was frequently left for the wolves. It was rather the animal domain that excited interest and about which myth evolved. If there was any ultimate philosophical notion, it lay in a concept of the continuity of life flowing from animal to man and back again into the animal domain. All animals were endowed with human characteristics and, indeed, were considered morally and intellectually superior to men. The beasts and birds allowed themselves to be taken by the hunter either because they felt pity for helpless man or because man, through ritual and magic, could attain some degree of temporary control over them. In any event, they had to be placated, respectfully treated, and accorded the proper ritual handling. To offend animals was to invite sickness, accident, and death. It was hardly sufficient to hunt without making adequate preparation in the way of ritual. Each hunter owned magical songs that were sung over weapons, boats, amulets, any devices relating to hunting. These songs were viewed as property and could be traded or sold.

Endowing animals with spiritual force

There were countless regulations and taboos, those relating directly to food being the most numerous and complicated. They differed from region to region, but everywhere had the same purpose, to avoid antagonizing the spirits of animals and nature and thus preserve harmony between man and the environment. Sometimes the taboos were collective; all members of a group might be forbidden the flesh of wolves or killer whales, for example. Or the taboos might be personal; an individual's song, talisman, or name might be operative, for instance, only if he avoided the flesh from the front flippers of the ribbon seal or from the back fat of the female caribou. Personal prohibitions were particularly intense in the western regions.

Faced with the hard practical realities of living, the Eskimo were not much given to speculating on the nature of the cosmos or devising explanatory myths. In the eastern regions, there was a supernatural woman of the sea, Sedna, who was looked upon as a kind of deity because she was presumed to control the supply of seals, but she was not worshipped; the Eskimo sought to control or curb her by use of magic or incantation. In the West, there was an anthropomorphic raven who was presumed to have created the world; but it was more the subject of trickster tales than a true divine figure. In general, the purpose of Eskimo myths and folktales was to define or illustrate relations between man and environment, not to provide a corpus of actual belief.

Communal festivals generally centred on the hunt. The whaling cult in northern Alaska, for example, brought men together well in advance of the hunt itself to clean and refurbish the gear, to clean out the meat cellars, and to sing the ritual songs associated with whaling. Later, in the hunt, the boat owner and crew leader greeted the whale, giving it fresh water to drink, a common treatment of sea mammals, and generally acting in a priestly role. Such ceremonial festivals (others were conducted for the seal and the caribou) not only brought groups of people together in meaningful social ways but also affirmed the continuity of life and its source, the continual renewal of the world.

Shamanism and illness

Illness resulted from the violation of taboo or ritual prohibition or because of the malevolence of an enemy; death, in any case, was not considered natural. The Aleut performed autopsies to determine the ritualistic cause of death and so to locate the nature of the infraction or the person of a magician. In this context arose the shaman. The term is drawn from the Tungusic languages of Central Asia and refers to a person who enters into various ecstatic or spiritually possessed states and, in such states, is capable of many feats of magic and can cure or send diseases, control weather, and find lost persons and articles. Not a priest, the shaman was the principal focus of day-to-day religious activity among the Eskimo. In this sense he differed from a hunt leader who, in a priestly role, might make an offering of thanks to game for allowing itself to be taken.

Illness resulted when the soul, a kind of spiritual double of the individual's personality, departed from the body and went wandering; it would ordinarily leave because it was offended by the actions of the body (which may have violated a taboo or a regulation regarding animals). The shaman's task was thus to find the soul and entice it back into the patient's body. Alternatively, illness could be caused by the actions of a hostile shaman, who would steal the soul. This ability not only to cure but also to cause disease did not make shamans wholly popular. Feared by the general population, shamans ran a risk of being killed by an offended patient or the patient's kinsmen. Finally, another cause of disease was the penetration of the body by some foreign object, either real or imagined; the shaman, in a trancelike state, located the object and operated to remove it, singing as he did so. (A broken bone, a toothache, or a headache, it should be noted, might not qualify as illness and could be treated by anyone with the necessary practical skills.)

In spite of their severe environment and their severe belief about it, the Eskimo remain a generally cheerful people, given to much joking and entertainment. Their cheerful temperament undoubtedly contributed to their ability to endure the great natural perils without complaint or fear and to find happiness in a land that others have thought uninhabitable. (R.F.S.)

Eastern, or Eurasian, Arctic. From earliest times to the present day, the way of life of many of the Eastern Arctic peoples has centred upon the reindeer; indeed, they have had to adjust their lives to the pecularities of the species.

Important in this regard are the seasonal migrations of reindeer between tundra and taiga; their movement in herds; their seasonal preferences for certain grasses, mosses, and fungi; their dependence upon salt; and their relative helplessness—and panic—when attacked by mosquitoes and other flying insects in the summer and such predators as the wolf and wolverine in the winter. The situation has always given rise to a number of similarities in all types of reindeer economy, among the more important of which are the seasonal movements of camps and the seasonal differences in their size and composition.

Reindeer hunting, breeding, and herding

There are, however, distinctive ecological and economic differences among the Arctic peoples of the Old World, relating to each of the three principal ways in which they utilize reindeer. The traditional Paleo-siberian Yukaghir, for example, were simply reindeer hunters. Although they "monitored" the seasonal movements of the reindeer, they made no effort to herd the animals or to use them for transportation (the Yukaghir adopted both these practices later, however, after contact with neighbouring peoples, particularly the Even). They used decoy reindeer in the hunt and travelled on foot or ski, by dogsled (though this was never general), and by canoe or raft. Reindeer were by far their most important source of food and of skins for clothing and tent covering, so that their lack of control over the condition and movement of the herds left the Yukaghir susceptible to unpredictable periods of privation. Fishing, the hunting of other species, and berry gathering were also essential to the economy.

Another basic way of using reindeer is represented by the many Tungus groups that partly controlled reindeer breeding as an adjunct to a basic economy of hunting and fishing in the taiga. Geldings were ridden, used as pack animals, and sometimes harnessed to sleds; females were milked, making possible various dairy products; dead reindeer were an important source of skins, bone, antler, and sinew for clothing, shelter, and simple utensils. These Tungus secured their meat, however, not from their domesticated reindeer but from wild reindeer, Asiatic red deer, and elk that they hunted. The domesticated herd was always small (herds of up to 25 reindeer per household were usual); the animals usually pastured in the vicinity of the camp, securing protection from wolves there in the winter and finding relief from the summer mosquitoes in the smudge fires provided by the camp for that purpose. These hunting and herding Tungus, it may be noted, also used dogs—as camp sentinels to warn against predators or strangers and as "pointers" in hunting small game such as sable or squirrel.

The third basic method of using reindeer was controlled breeding and herding. This was the principal or sole livelihood of several other Tungus groups (many Nenets and Enets and some Nganasan), of the tundra Chukchi and Koryak in Northeastern Siberia, of the northern Samoyed in Western Siberia, and of many Lapp. All these groups depended upon the herded reindeer for food, and many used dogs to shepherd the herds, which sometimes were large in number. Prestige and social status, indeed, were measured by the size of a household's herd; and competition for prestige sometimes had damaging ecological consequences: pastures would be overgrazed or aggressively expanded, or epidemics would decimate large, closely packed herds. As a result, impoverished reindeer owners would be driven to find alternative livelihoods in villages or elsewhere; some would revert to reindeer nomadism. (State-imposed regulations in both the Soviet Union and Scandinavia are ameliorating such problems.) As a supplement to herding, most of these peoples pursued fishing in the summer, and they bartered extensively with urban, village, and agricultural populations.

The peoples of the Eastern Arctic have been studied and written about far less than the Eskimo of the Western Arctic. In tsarist Russia and the Soviet Union, in particular, there has always been some tendency to play down any attention to national differences. Most investigations have thus depended on inferential sources. They have tried, that is, to reconstruct the social relations of certain Eastern Arctic peoples by piecing together information derived from myths, legends, and other folklore that have been published. They have also tried to infer the social systems of Arctic peoples by reference to the social structures of their Turkic and Mongol neighbours and kinsmen farther south, who have been more thoroughly studied—the assumption being that the systems are probably similar.

Tribes and clans

Among all the Eastern Arctic peoples, there appear to have been large territorial groups that may be called tribes—*i.e.*, clusters of communities that could act together for such common purposes as warfare and trade. One tribe could make alliances and establish systems of exchange with other tribes. Below the level of the tribe, at least among the Neo-siberians, there were probably clans, groups of people having a stricter sense of kinship. Normally, clans would be exogamous; that is, marriage within the clan would be forbidden. Further, a person's lineage within the clan would be important in determining his residence, role, and inheritance.

From the 17th century onward, however, clans—and even tribes—had to leave their traditional territories and disperse in smaller units and "mixed" kin units to search for new territories. This happened to the Tungus when they were faced with the exhaustion of reserves of fur that had to be supplied to the Russians and when they were faced with the continual encroachment of Russian settlement. The movement of Tungus groups created pressures on the territories of other neighbouring peoples; the northern movement of the Yakut had similar effects in Northeastern Siberia. The competitive expansion of grazing lands could also disrupt traditional social relations, as it apparently did among the northern Samoyed. Various demographic and economic changes, in short, could have serious social consequences. Finally, there was the political influence. The tsarist Russian government tried to consolidate the tribe–clan system and use it to administer all northern peoples, but the administrative use of tribe and clan, being a foreign idea, tended paradoxically to sever the already weakening association between kinship and territorial organization. Among most groups, therefore, the village or camp emerged as the relevant territorial and social unit in the 19th and early 20th century.

Dominance of village and camp

Village or camp enterprises of a seasonal nature generally involved each of the three principal livelihoods: reindeer breeding, hunting, and fishing. When hunting and fishing was pursued collectively, the game or catch was distributed collectively. When production was not collective, responsibilities for distribution were limited, and they were minimal or absent when furbearing animals were caught for trade with foreigners. Villages and camps (and subdivisions made within these units) claimed rights to the produce from hunting and fishing grounds usually on an annual or lifetime basis. Among reindeer breeders, herding was undertaken collectively, and rights to pasture were claimed collectively, also. The animals, however, were owned individually. The size and composition of herding camps could be adjusted at each season of the year.

In all ethnic groups, close interpersonal bonds of friendship arose between non-kinsmen within the village or camp. Kinship nevertheless remained in many ways the most important principle of interpersonal and group relations. Many privileges and obligations of kinship practiced by the Eskimo were also recognized by Eastern Arctic peoples. Among the more onerous was the prosecution of the blood feud, a retaliatory killing and counterkilling between different kin groups that might continue for generations. Blood feuds seem to have been widespread even at the end of the 19th century, indicating that clanship was still a recognizable principle but without any territorial meaning, for villages and camps were then composed of persons from different clans.

The incidence of cross-cousin marriage, in which certain categories of first cousins were obliged to marry, remained notable among many of the eastern Arctic peoples. Practiced in conjunction with the general rule of patrilocal residence, this marriage preference had earlier supported the territorial groupings of persons in clans; the preference remained even after the development of villages and camps in which cousins remained anyway, without the compulsion of marriage. The matching of several siblings of one family with those of another and a close bond

between husbands of sisters—sometimes denoted as closer than that between brothers—were prevalent among the northern Eurasians. So, too, was the injunction that a bridegroom provide several years' service to his father-in-law before being allowed to set up his own marital household. Common among the reindeer breeders only was the establishment of marriages through contributions of wealth (including reindeer) from both the parties (bride price from the groom, dowry from the bride). Having two or more wives was a privilege of personal rank and occurred most frequently among preeminent hunters or warriors, shamans and smiths, and well-to-do reindeer owners. These marriage practices (except those prohibited by law) persist among some contemporary Lapp groups in Scandinavia. Among the Lapp, building up a reindeer herd was probably the most influential factor governing marital patterns.

In all these societies there have been strains of social and economic inequality. At the very least, the need for authority in organizing work teams promoted village or camp elders, local headmen, lead hunters, and so on; among some peoples—the Chukchi are notable—an ethic of success and of male reputation licensed the presence of "strong men" and aggressive behaviour. Intertribal warfare, fairly general though sporadic throughout northern Eurasia, led to the use of captives as slaves. Among the reindeer breeders, differential accumulation of herd capital placed some herdsmen in employer–employee relationships.

Animism and shamanism

Traditionally, there were broad similarities among the spiritual cultures of Eastern and Western Arctic peoples. Like the Eskimo culture, Eurasian Arctic culture emphasized the practice of animism—*i.e.*, a belief that everything in nature, every beast and bird, stone and earth, wind and snow, is alive with soul or spirit—and all believed in shamanism. Siberian shamans were frequently women; male and female transvestism in shamans was common.

The shaman's power was often associated with the properties of iron, and there was a corresponding association of the profession of shaman with that of smith. The role of the smith had particular prestige among the Tungus and Yakut.

Christianity reached these peoples at different historical periods; some Lapp were converted as early as the 16th century, whereas some Chukchi probably were never converted, even before the Russian Revolution discouraged religious faith. Christianity, when it was adopted, usually came in the wake of trade with the Western world and with the West's imposition of taxes. In any event, animism and shamanism rarely died completely but became blended with Christian beliefs, rituals, and liturgy. Christian motifs, for instance, appeared in the drawings on Lapp shamans' drums; Christian crosses and crucifixes were worn together with amulets and other talismans of animistic belief. (R.P.B.P.)

Contemporary trends. *Western Arctic.* The establishment of trading centres and, more recently, industrialization and mining have influenced Arctic living. In the period 1900–50 such developments tended to diminish the diffuse residential pattern of the Eskimo, concentrating the Eskimo more and more in towns and other more concentrated population centres. Generally Eskimo and Aleut are moving into the competitive situation of modern life and have demonstrated their ability to adapt well to it.

Eskimo involvement in the money economy

Since early in the 20th century, paternalistic administrations have attempted to devise ways by which the native peoples could develop their Arctic resources to secure much-needed cash. Such attempts go back to the promotion of fur trapping in the 1910s. Some native groups in Canada still depend on furs as a means of trade and a primary source of cash. Clearly, money, in the Western sense, is a present necessity. The purchase of guns, ammunition, whaling bombs, outboard motors, yard goods for clothing, and innumerable other industrial items are now viewed as a necessity. The snowmobile, with the costly gasoline that it requires, has begun to replace the dog team. Adoption of the snowmobile accelerates the change to a moneyed economy and may cause profound changes in Arctic ecology as well. The utilization of the oil resources in Alaska and Canada, along with the natural-gas potential, provides new sources of employment (it has already happened in Alaska) and draws the Eskimo more directly into modern Western culture.

Eastern, or Eurasian, Arctic. The abolition of serfdom in 1861 brought millions of Russian peasants to Siberia in a comparatively short time; Soviet settlement, development, and industrialization during the 20th century has affected the demographic structure of Northern Siberia even more. Although it must be recognized that no non-Soviet observer has been permitted to study any of the northern peoples since the 1930s or even earlier, some historical trends and events are clearly evident. First, it can be noted that attempts to deal administratively with northern peoples began as early as 1922. Then, between 1924 and 1935, a Committee for Assistance to the Peoples of the Northern Regions (the Committee of the North) sought determinedly to bring the native peoples into the Soviet administrative structure and to establish among them "integral cooperatives," collective farms, and educational, medical, technical, and social programs. In 1925 Leningrad State University accepted the first students from among the northern peoples, and in 1930 the Institute of Northern Peoples was established at the university with 195 pupils in attendance from 19 ethnic groups. The institute closed in 1941, but its work was continued after World War II at several regional institutions. Among its principal objectives has been the training of native persons as teachers and administrators.

Collectivization and russification

The editors of the monumental Soviet work *The Peoples of Siberia* (1964; originally published in Russian, 1956) stated that, "By the present time, the village soviet has become the principal local unit of Soviet administration among the peoples of the North, while the collective farm now is universally the fundamental economic unit." The progress toward this state of affairs, however, was beset by difficulties and controversies. The Committee for Assistance to the Peoples of the Northern Regions, for instance, ruled, in 1926, in favour of "clan-based native soviets," but this arrangement proved unworkable because the clan elders were not too willing to support, explain, and enforce Soviet policies. Accordingly, the native soviets were redesigned between 1929 and 1932 as territorial units at the bottom rung of the standard Soviet administrative structure; above the soviet was established the region (*rayon*) and then the district (*okrug*). The northern *okruga* were named after the dominant minority people of the region; by the end of 1932 there were nine such *okruga* of northern peoples, 82 *rayony,* and 462 soviets. Native membership in the executive committees of these *okruga* and *rayony* has varied from 33 to 97 percent.

The progress of collectivization among the northern peoples was recorded as 12 percent of households in 1931, 36 percent in 1934, 75 percent in 1940, and 97 percent in 1948. The program met its chief resistance from reindeer breeders. The problem at heart is a conflict between ideology and ecology or economics. Official Soviet ideology holds that nomadism is an unworthy way of life in a Socialist society, but this is not easily reconciled with the ecological fact that reindeer pastoralism can be conducted successfully only on a nomadic basis, for reindeer must move seasonally. These difficulties have adversely affected not only production in the Soviet reindeer industry but also recruitment to it. Lately, however, ethnographers have tried to persuade administrators and other officials that "production nomadism" is necessary and is compatible with an otherwise stable or sedentary way of life. Probably of greater significance for the future is the issue of whether northern peoples should be encouraged to join the Siberian industrial force or, on the contrary (as Soviet ethnographers seem to urge), be encouraged to remain in their traditional pursuits and to retain their traditional skills.

In education, a number of native grammars were published and used in schools in the early 1930s. The change from a Roman-based to a Cyrillic-based alphabet in 1937, however, presaged greater Russian influence. This seems to have continued, and Russian is now the lingua franca of much of the north, although the Komi and Yakut languages still appear to retain a respected status.

One of the most notable aspects of ethnic relations in

the Soviet north is its complexity. Even at the level of the village soviet, there can be polyethnic membership, and this mixture of representatives from various ethnic groups increases at the levels of the *rayon* and the *okrug;* there are polyethnic collectives such as the Nenets–Enets–Nganasan–Dolgan collective in the Taymyr and the Yukaghir–Lamut–Chukchi one in the northeast; Russians also sometimes belong to northern peoples' soviets and collectives. Some ethnic groups—the Yakut and the Komi—are deemed to have reached the level of "Socialist nation"; others, having national *okruga* and written languages, are perhaps progressing in that direction. But the majority are unlikely ever to achieve nationhood. It seems clear that they will either remain as minorities or disappear. Russification is the dominant trend.

The Lapp of Norway, Sweden, and Finland today form small minorities even in the northern regions of these countries, but they are receiving greater recognition than ever before. The explanation may lie more in the changing attitudes of Scandinavians, who are becoming more tolerant of diversity, than it does in any activism on the part of the Lapp themselves. In any event, the Lapp of Sweden, for instance, have their own ombudsman, whose work is particularly concerned with the legal position of Lapp groups faced by public or private encroachments on their reindeer pastures. There are Lapp language primers, and school readers are now available in each of the three countries (though by no means are all schools with Lappish-speaking children using them); and there are Lappish high schools, Lapp-language newspapers and radio programs, and Lapp-language courses in several Scandinavian universities.

Combined ethnic and national trends among the Lapp

The reindeer-breeding industry is, in general, in good condition. In Norway it is predominantly a Lappish livelihood, and in Sweden it is exclusively so (in Finland, however, the Finns predominate in most reindeer breeding localities). The nomadic way of life associated with reindeer pastoralism is becoming seriously modified, but most of the modifications either are initiated by individual households or camps (and hence vary locally) or emanate from the regional and national associations that have been formed by the reindeer owners themselves. Direct legislation by the state is less important in this process, though the indirect influence of the state—as the principal source of capital loans, subsidized housing, and infrastructure amenities—should not be minimized. Cooperatives for the purchase and marketing of reindeer products are established in many areas.

Lappish individuals and communities in the latter half of the 20th century, without exception, have a heightened sense of national citizenship, and all persons except the very old and perhaps the very young are conversant in the language of the country of their citizenship. Indeed, individuals who leave reindeer breeding are likely to assume a non-Lappish identity: in Sweden such persons usually join the northern industrial labour force or move to Stockholm. In Norway, where the majority of Lapp reside, most families of Lappish descent have never been involved in reindeer herding; most of them have been and are fishermen. Among these people, Lappish culture, in all its respects, is fast being replaced by Norwegian culture.

(R.F.S./R.P.B.P.)

History

ARCTIC PEOPLES

Eurasian prehistory. The polar regions were not populated during much of the Pleistocene Epoch (from 2,500,000 to 10,000 years ago), when most of man's prehistory was unfolding. Man began as a tropical animal, and the Arctic was the last area (except for the Antarctic, only now being explored) to become a habitation area. Areas just south of the Arctic, which, in Pleistocene times, had climates similar to the Arctic, do show significant early developments. At archaeological sites on the Upper Yenisey River and at Lake Baikal and at other locations across the steppes into European Russia, for instance, there have been found the world's oldest known houses—semi-subterranean dwellings with central fire pits, probably ancestral to the earth dwellings of the Eskimos and other Arctic peoples. (For such a functional trait, the possibility of independent invention in different times and places must be considered.) Associated with these finds were flint points and scrapers, fine blade tools, and bone, antler, and ivory tools.

Lateness of Arctic settlement

The Lake Baikal region also supplies evidence for later developments (this time supplemented by some discoveries within the Arctic itself). Around Lake Baikal are to be found a number of stages of development. The earliest of these stages, beginning between 5000 and 4000 BC, is marked by a hunting culture using the bow and arrow. In the second stage, after 4000 BC, pottery and ground-stone tools are present, and in the third, beginning in the 3rd millennium BC, reinforced bows (wooden with bone plates), finely worked implements of bone and ground stone, and effigies of animals (especially fish) are suggestive of artifacts found in later periods all across the Arctic. These materials and additions from later periods in Siberia are reflected in old cultures around the Bering Strait and in the American Arctic.

The Arctic sites contain no evidences of cultivated plants and no evidence of domestic animals other than the dog, so the use of "Neolithic," or New Stone Age, to describe the sites is based on the presence of other Neolithic traits such as ground stone implements and pottery. Even reindeer seem to have been hunted in the wild only, until later times when they were substituted for other domestic animals by groups moving northward, who had kept horses and cattle in warmer regions.

The origin and movements of the Eurasian Arctic peoples are not clear and are subject to scholarly conjecture and controversy. In general, however, rather recent movements from south to north are probable. The Chukchi, Koryaks, and Kamchadals are believed to have entered Northeastern Siberia about 2,000 years ago, finding the ancestors of the Eskimos already living along the coasts. Because the Yakuts and Tungus were still expanding into the northlands after the Russians arrived, it was formerly held that they had migrated there only recently; but the archaeological evidence renders this questionable. Some sources refer to movements of the Yakuts from south to north and of the Tungus from north to south; however, the most tenable hypothesis at present suggests that both the Yakuts and the Tungus developed from groups associated with the Baikal region (or from groups further to the south and east), with the Yakuts expanding north and west over a long period, arriving in the middle Lena by the 17th century and assimilating earlier Arctic residents along the way, while the Tungus expanded both north and south.

Prehistorical migrations in the Eurasian Arctic

Among those assimilated and replaced were many Yukaghirs, who are thought by Soviet prehistorians to have been in the area from about 4000 to 3000 BC and formerly to have extended westward to the Yenisey. The Kets also are held by some scholars to be remnants of a cluster of groups who were early Arctic dwellers, although some Ket traits suggest recent south-to-north movements along the Yenisey. For the Samoyedic speakers (Nenets, Nganasans, Enets, and Selkups), different categories of data provide conflicting conclusions. Linguistic distributions and other language studies suggest that they once lived west of the Urals in the Pechora Basin (now occupied by the Komi and Russians). Their physical type, however, suggests Asian origins. A tenable hypothesis held by some scholars is that a Caucasoid people speaking a Samoyedic language migrated eastward through the Urals about the beginning of the Christian era and intermixed with Mongoloids who had moved westward into Northwestern Siberia. Beginning about AD 1000, the Khants and Mansi, under pressure from the Komi, followed the same migration route, completing their movement across the Urals about 1400. The Komi, themselves under pressure from the Slavs, had moved northward and arrived in their present area about 800 years ago.

More study by linguists, physical anthropologists, ethnologists, and archaeologists has been devoted to the origins of the Lapps than to any other Arctic people (with the possible exception of the Eskimos)—but with no certain results. Some scholars conclude that the Lapps originated

in central Europe, where they were adapted to an Alpine habitat. Others consider them to be an ancient Arctic people who adapted to polar conditions during the Pleistocene. So far, archaeological studies of their shifting camps have shed little light on the question. The most developed hypothesis maintains that the modern Lapps are descendants of a people of Caucasoid physical type who were Stone Age hunters living south and east of their present area and outside the present Arctic but in an area of similar environmental conditions. When the Pleistocene ice retreated, they moved north and west and were the earliest Finnic-speaking people in northern Europe. They adopted reindeer herding according to patterns of animal domestication used for cattle by Europeans further south, augmented with ideas of reindeer herding diffused across the Urals from Asia.

Western prehistory. Two general problems are dominant in archaeological studies in the American Arctic. These are, first, the origin of the Eskimo and, second, the migrations of the ancestral American Indians as they crossed the Bering Strait region from Asia and moved through Arctic America to spread out in other parts of the continent.

Origins of the Eskimo

Two major theories have dominated discussions of Eskimo origins: (1) that the Eskimos evolved from a northern group of American Indians who began to emphasize their winter living patterns and became specialized to tundra dwelling and sea-mammal hunting, or (2) that the Eskimos adopted their way of life in Asia, later migrating to fill a northern void in the New World at a time much later than when most of the ancestors of the American Indians left Asia. In the latter hypothesis, the Asian Eskimos (Yuit) are seen as a remnant along the migration route. In the former hypothesis, the Siberian Eskimos are regarded as a late backwash in counterdirection to the major migrations. Archaeological discoveries, almost from the beginning, have seemed to support the Asian origin, for the earliest sites clearly in the Eskimo tradition have been found around the Bering Strait (Okvik-Old Bering Sea) and in Siberia (Uellen).

There is little evidence of man in the American Arctic in the period between 25,000 and 10,000 years ago, and there are only a few scattered artifacts for the period between about 8000 and 5000 BC, even though the ancestors of the American Indians passed through the Alaskan area in the earliest years of these periods. For the period from 5000 to 3000 BC, however, in the Seward Peninsula and in the Brooks Range of Alaska, there are indications of a land-hunting and, to some degree, sea-mammal-hunting group that may have been related to some of the forest cultures to the south. Then, between 3000 and 2000 BC,

Arctic Small Tool Tradition

the so-called Arctic Small Tool Tradition developed in northwestern Alaska. It was based on the hunting of caribou and other tundra animals, along with some hunting of sea mammals. This culture included elements from the northern movement of the American Plains hunters to northwestern Canada but was primarily derived from northeastern Siberia. It gradually spread eastward in the Canadian tundra to the northwest and northeast side of Hudson Bay, into extreme northeastern Canada, and to western and northern Greenland. This eastern spread was accomplished by 1000 BC.

The Arctic Small Tool Tradition is considered by most prehistorians to be too distinctive to be called Eskimo. The oldest known Eskimo culture is that in the so-called Aleutian and Southern Tradition, dating from as early as 2000 BC (though the earliest archaeological discovery, stone implements found at Anangula Island in the Aleutians, dates back about 8,000 years). Prehistoric south Alaskan and Aleutian culture was basically Eskimo in character but specifically different in many respects from that of western and northern Alaska. It was somewhat simpler technologically; its most important achievements were the production of things made of stone (lamps, chipped knives, and points), bone (harpoon heads, fishhooks, and wedges for splitting driftwood), and ivory (lip ornaments, figurines, and needles). Although the Aleutian and south Alaskan region had the greatest population density of any part of the Eskimo territory, its culture was remarkably stable, in contrast to the Bering Strait region, where culture changes were frequent and pronounced.

In western and northern Alaska is to be found what is probably the next most ancient Eskimo cultural sequence—that of the Old Whaling, Choris, Norton, and other cultures, each known from only one or a few sites north of Kotzebue Sound near the Bering Strait, the earliest dating from about 1800 BC. Included in this sequence is the Ipiutak culture, which, discovered in 1939, is a major enigma in Eskimo prehistory. Ipiutak, known from the type site at Point Hope and a few other western locations, contains many traits of the Eskimo tradition, including toggle-headed harpoons and other items for sea hunting (although harpoon heads are outnumbered by arrowheads for hunting caribou); but the culture lacks many typical Eskimo items and stands by itself in the large size of the village and the regular arrangement of houses along streets. The Ipiutak site contains more than 600 shallow semi-subterranean dwellings with central fireplaces. The slight accumulations of debris argue for a short period of occupation (estimated to be about 100 years). Dating also is somewhat uncertain. Some radiocarbon dates for Ipiutak are as late as AD 1000, whereas some artifacts suggest overlap with the earlier phases of the Northern Maritime Tradition. Most summaries conclude that Ipiutak dates from about AD 300 to 400 and drew upon both the Northern Maritime Tradition (for seal-hunting techniques) and the northeastern Asian cultures (for certain implements and ceremonies).

Dorset culture

In the eastern parts of the American Arctic—including the Hudson Bay region, Labrador, Newfoundland, and Greenland—there is another very early culture, known as Dorset, dating from about 1000 BC and lasting to about AD 1000 or 1200 (when Eskimos in the Northern Maritime Tradition overran the area). The relationship between Dorset and other Eskimo traditions is somewhat enigmatic. Dorset sites contain semi-subterranean houses and some Eskimo traits such as the toggle-headed harpoons, lamps, and ivory carvings; but many of the artifacts were somewhat different in form, smaller in size, and more delicate; moreover, these sites lack dogsleds, bone arrowheads, lip ornaments, and other typical Eskimo traits. Many prehistorians think that the Dorset culture developed from the Small Tool Tradition and marks the migration of people who began moving from the western end of the American Arctic about 3000 BC, bringing with them implements in the Arctic Small Tool Tradition, and who by 1000 BC had reached the eastern extent of the Eskimo area and developed a largely independent culture. Some materials in later Dorset sites, however, resemble similar items in the Northern Maritime Tradition. Most summaries of Eskimo prehistory conclude that the Dorset Eskimos were overrun by the eastward migration of the Thule Eskimos, who were carriers of the Northern Maritime Tradition. Some scholars believe that the Eskimos of Southampton Island, extinct in 1904, and somewhat different from neighbouring Eskimos, represent a late survival of the Dorset peoples.

Northern Maritime Tradition

The best known early Eskimo cultural sequence is that of the Northern Maritime Tradition, which began in the area from the Bering Sea to Point Barrow about 500 BC. In this tradition, the most typical traits of Eskimo culture, including the semi-subterranean house and the toggle-headed harpoon (with all other parts of the seal-hunting complex), are present from the start. Although some less typical traits were added as the tradition developed and the emphasis in some areas changed (as from chipped-stone to ground-stone implements), the phases in the Northern Maritime Tradition are mainly demarcated only by stylistic changes, as in the design of harpoon parts, arrowheads, needle cases, and art objects.

In art the general trend is from more elaborate to less elaborate. Tools and other implements also become plainer and more utilitarian in later periods, although more efficient. The Birnirk and Thule cultures are the most widely distributed examples of the Northern Maritime Tradition, with Birnirk sites reported from the mouth of the Kolyma River in Siberia to the Mackenzie Delta in Canada, and Thule even more widely distributed, reach-

ing from the Bering Strait to Greenland. The spread of Thule, after it developed out of Birnirk some time before AD 1000, has been traced eastward from Alaska, arriving in Greenland about 1200, where it was influenced by the medieval Norse settlements in the subsequent century. Later there was a resurge of Thule back toward the west, reaching all the way to Bering Strait and accounting for the relative uniformity in language and other aspects of Eskimo culture in early contact times.

At many locations throughout the area of the Northern Maritime Tradition, archaeological materials have been studied that trace the development of Thule into historically identified groups of Eskimos. Although there are many specific problems yet to be resolved, in general the Northern Maritime Tradition has the feeling of history.

Modern populations. Although many nations participated in the exploration of the Arctic, only a few have contributed settlers, and all are Indo-European speakers. Russians predominate in Eurasia (and numerically throughout the Arctic), although they were preceded in Arctic Europe by Scandinavians. Currently, Norway, Sweden, and Finland all have settlements north of the Arctic Circle. In Arctic Alaska and Canada, English-speaking peoples are found in small numbers; and in Greenland, Danish settlers have intermixed with the Eskimos, though Eskimo speech has been retained.

Russian settlement of Siberia

Russians began crossing the Urals in the 16th century and continued in flood tide after the abolition of serfdom in the Russian Empire in 1861. Settlement of the northlands was further accelerated by the building of the Trans-Siberian Railroad in the late 19th and early 20th centuries and was continued as state policy by the Soviet government after the Revolution. In the late 20th century there were more than 5,000,000 people in the parts of the Soviet Union north of latitude 60° N. A condition of note for the modern populations of the Arctic Soviet Union is that around three-quarters live in urban concentrations, whereas only around half of the people of the Soviet Union as a whole are urban. Concentrated living in the north shows that the modern populations are mainly involved in extractive industries, such as mining, petroleum, and lumbering (in the subarctic). The Russian settlers, who outnumber the indigenous peoples, are the inhabitants of the Arctic cities; but some of the native peoples are also becoming urban dwellers, particularly the Komi.

American Arctic settlements

In the American Arctic there are no comparable populations. Canada has more than 1,000,000 people in the Arctic and subarctic, almost all of them in the subarctic. In Alaska the population is mostly concentrated in the subarctic, although one major city, Fairbanks, is close to the Arctic Circle. (In this comparison, however, it should also be noted that the "Soviet North" includes much of the subarctic, and most of the Russian settlers live outside the Arctic proper.) A process of population concentration has, in fact, occurred in the American Arctic, even though it has not resulted in cities. In Alaska and Canada, the Eskimos of the north have abandoned many small settlements and concentrated in fewer towns—a response to opportunities for employment and other appeals of living in larger communities. Only in Greenland, with its rapidly growing population, has there been an increase in the number of communities. (W.K.C.)

EXPLORATION

The earliest references to Arctic exploration are shrouded in superstitious beliefs concerning the uninhabitable "frigid zone," and also in an obscurity resulting both from inaccurate ideas of the shape of the Earth and from primitive navigation techniques, which make it very difficult to interpret early maps and accounts of voyages. Probably the first to approach the Arctic regions was a Greek, Pytheas, who in the 4th century BC made an astonishing voyage from the Mediterranean, around Britain, to a place he called Thule, variously identified as the Shetlands, Iceland, and Norway. The accounts of this remarkable explorer were for centuries discredited, but the idea of his Thule, shrouded in fog and believed to be the end of the Earth, caught the imagination of many.

Iceland is known to have been visited by Irish monks in the 8th and 9th centuries, but it was the Vikings from Norway who settled the island, late in the 9th century. In the course of the next four centuries, these hardy seamen established trade routes to the White Sea; visited Greenland (*c.* 982) and founded two settlements on the southwest coast (which disappeared, for unknown reasons, before the 16th century); reached the coast of North America; and probably also reached Spitsbergen and Novaya Zemlya. Unfortunately, however, they left scant records of their voyages, and many of the places they visited had to be rediscovered by others.

Viking settlement

The Northeast Passage. After a long period of inactivity following the decline of the Norsemen, leadership in Arctic exploration was assumed in the early 16th century by the Dutch and the English. The motive was trade with the Far East. The known sea routes around the southern tips of Africa and South America had been claimed as a monopoly by Portugal and Spain respectively and besides were long and arduous; the overland routes were even worse. There remained, however, the northern latitudes, and the attempts of English and Dutch merchants to find a Northeast and Northwest Passage gave a strong stimulus to exploration of the Arctic.

In 1553 the English sent three ships to the northeast under the command of Sir Hugh Willoughby, with Richard Chancellor as chief pilot. Willoughby, with two ships, wintered in a harbour on the Kola Peninsula, where he and all his men perished. Chancellor, who in the "Edward Bonaventure" had become separated from the others in a gale, reached what is now Archangel and made an overland journey to Moscow (1,500 miles in all) before returning home to England. It is interesting to note that these waters were already well known to Russian seamen, who used the route around North Cape to western Europe as early as 1496, but this was not generally known at the time.

After Chancellor's voyage the Muscovy Company was formed, and there grew up a very lucrative trade with Russia, the success of which rather distracted the minds of the English from the Northeast Passage. Nevertheless, in 1556 Stephen Borough sailed in the "Searchthrift" to try to discover the Ob River. He was stopped by ice and fog at the entrance to the Kara Sea, which he described in such discouraging terms that it was not until 1580 that another English expedition, under Arthur Pet and Charles Jackman, attempted its passage. They too failed to penetrate it, and England lost interest in searching for the Northeast Passage.

In the meantime, however, the Dutch had taken up the search, largely because of the efforts of Olivier Brunel, who in 1565 established a trading post at Archangel, to the consternation of the English traders. In the course of an eventful career, Brunel made an overland journey to the Ob and in 1584 tried to reach it by sea, but like Pet and Jackman he got no farther than Yugorski Strait. He was followed by Willem Barents, an outstanding seaman and navigator, who in 1594 discovered Novaya Zemlya and sailed to its northern tip; his two companions, Cornelis Nai and Brant Tetgales, penetrated a little way through Yugorski Strait into the Kara Sea. In 1596, with Jan Cornelisz Rijp and Jacob van Heemskerck, he was more successful. Heading due north from Norway instead of following the coast around, Barents discovered Bear Island (Bjørnøya) and Spitsbergen, which he mistook for Greenland. Rijp then went home with one ship, but Barents and Heemskerck in the other headed east and rounded the north of Novaya Zemlya. They were forced to winter in Ice Haven on the northeast coast and thus became the first Europeans to winter successfully in the Arctic. They built a house of driftwood and passed the season with remarkable fortitude and success, although they were in almost every way unprepared for it. In the spring, the ship being hopelessly damaged, they escaped across the open Barents Sea in two small boats. Barents died on the journey. In 1609 Henry Hudson, the Englishman, sailed in the "Half Moon" to the Barents Sea in the service of the Dutch East India Company, but his crew, afraid of having to winter like Barents, mutinied and forced him to sail west, where he explored the coast of North America north of Virginia and ascended the Hudson River.

Dutch voyages

While the English and the Dutch were thus engaged, Siberia was gradually being annexed to Russia by bands of Cossacks spreading slowly eastward from the Urals. Conquering and trading as they moved, the Cossacks reached the Pacific Ocean by the middle of the 17th century and traversed the northern coastline in small, flat-bottomed boats. One of these hardy wanderers, Semen Dezhnev, is believed to have sailed through the Bering Strait in 1648. Like the Norsemen, however, the Cossack settlers made few records of their activities, and only rumours of the existence of a strait separating Asia from America reached the ears of Peter I the Great.

In order to find and above all to map the sea route to the east, Peter conceived a series of expeditions that culminated in the Great Northern Expedition (1733–42) and, under his successors, mapped the Arctic coastline of Siberia as far east as the Kolyma River. The work of the expeditions was planned by Vitus Bering, a Dane with long service in the Russian Navy, and directed by the admiralty college. In 1728 Bering, who himself took charge of activities in the Pacific, sailed through Bering Strait from the south, but because of bad weather failed to recognize its significance. In 1741 he crossed the North Pacific and landed on the coast of Alaska. Other important figures among the many who made up the Great Northern Expedition are Lieut. Semyon I. Chelyuskin, who in 1741 reached the cape named after him, the most northern point of the Siberian mainland; and the brothers Laptev, Dmitry and Khariton, who charted the coast from the Taymyr Peninsula to the Kolyma River.

The question of the existence of a strait separating the continents remained uncertain until 1778 when Capt. James Cook, the great British explorer, sailed through Bering Strait and reached North Cape (now Cape Schmidt) on the Siberian coast. Unlike Bering, he was able to see both sides of the strait and so establish fairly conclusively that the continents were separate.

Attempts to complete the mapping of the northern coast were made by a Russian merchant named Nikita P. Shalaurov in 1760–62 and by Joseph Billings, an Englishman in the service of the Russians, in 1787; it was eventually finished by Baron Ferdinand von Wrangel, a Russian of Swedish parentage, in a series of sledge journeys from 1820 to 1824.

Wrangel's companion, P.F. Anjou, worked in the New Siberian Islands. These strange islands of silt and ice were discovered in 1770 by a merchant named Ivan Lyakhov, who saw caribou coming south to the mainland and followed their tracks north. The islands produced a fortune in mammoth ivory and were further explored and mapped in the years that followed, notably by an official survey party under an exile, Matvey M. Hedenström.

The main features of the Northeast Passage were now investigated and mapped; it remained to be successfully navigated. One attempt to do so, by an Austrian expedition under Julius Payer and Karl Weyprecht in 1872–74,

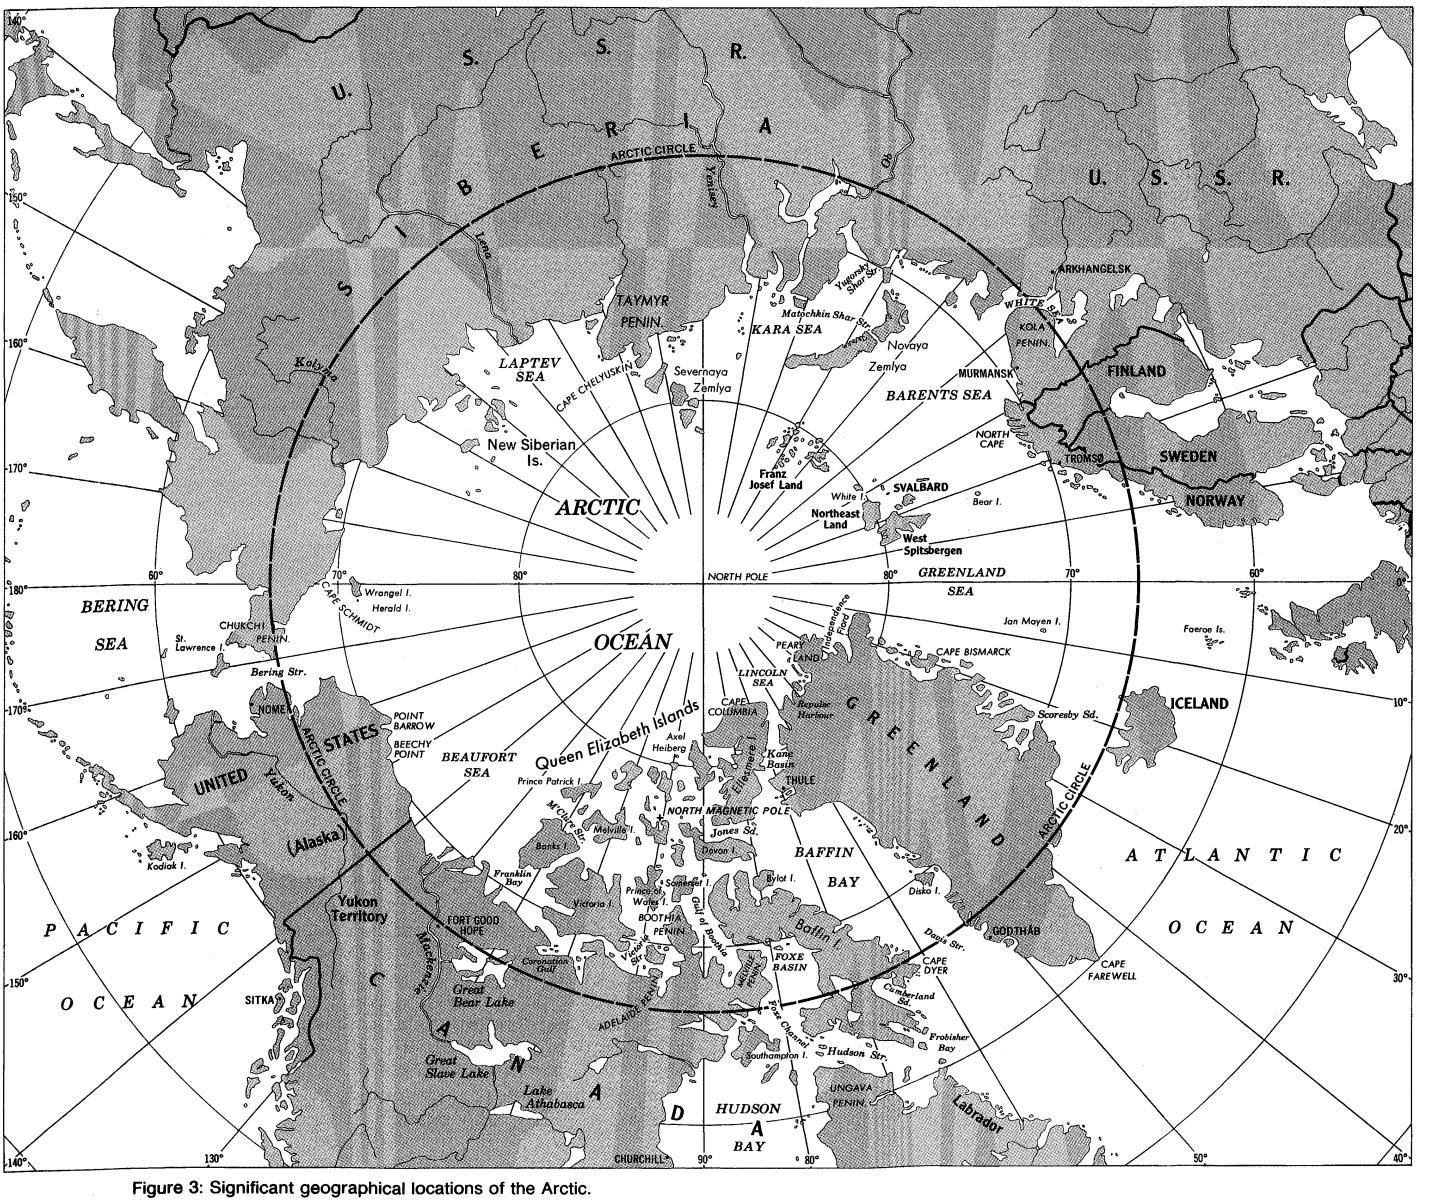

Figure 3: Significant geographical locations of the Arctic.

led to the accidental discovery of Franz Josef Land. While trying to sail around the north end of Novaya Zemlya, their ship, the "Tegetthoff," became caught in the ice and drifted helplessly north and west for more than a year, to be deposited by the ice on the shore of a new land. In the spring of 1874 Payer made a long sledge journey, reaching the northernmost point of the archipelago. The ship had to be abandoned, and the party sailed in small boats to Novaya Zemlya, where they were picked up by a Russian fishing vessel.

A.E.Nordenskiöld

The first successful navigation of the passage was accomplished in 1878–79 by one of the greatest of Arctic explorers, the Swedish baron A.E. Nordenskiöld, who saw in it not so much a route to the Far East as an avenue of trade between Siberia and the rest of the world. After two reconnaissance trips to the Yenisey in 1875 and 1876, Nordenskiöld set out in 1878 in the "Vega" accompanied by three cargo ships, two bound for the Yenisey and one for the Lena. Aided by a good ship and a year of rather light ice conditions, he managed to reach the Chukchi Peninsula before being forced to winter only 120 miles from the Bering Sea. The passage was next navigated from east to west by Comdr. B.A. Vilkitski of the Russian Navy, who was engaged in hydrographic work. In 1913, while trying to pass Cape Chelyuskin, he was forced north and discovered Severnaya Zemlya, first called Nicholas II Land. He had to turn back and winter on the Pacific coast but succeeded in completing the passage in 1914–15. Two west–east attempts in 1912 by G.L. Brusilov and V.A. Rusanov ended disastrously with the almost complete loss of both expeditions. In 1932 the icebreaker "Sibiryakov" was the first to make the passage in one season, sailing from west to east. During the late 20th century the passage has been kept open by Soviet icebreakers, such as the nuclear-powered "Sibir," which opened a southern route across the northern Siberian coast in 1978.

The Northwest Passage. The search for the Northwest Passage may be said to have begun with the European discovery of America, for the voyages of Cartier and his successors to the St. Lawrence and the Cabots and Côrte-Reals to Newfoundland and Labrador were all undertaken with the aim of finding the passage. The first such voyage to enter the Arctic, however, was that of Sir Martin Frobisher in 1576. At this time the map was a blank between southern Labrador and Greenland. To complicate matters further, there existed a spurious map, published in 1558 from the voyage of Niccolò Zeno in 1380, that showed an entirely imaginary country called Friesland lying between Iceland and Greenland. Because of the supposed existence of this land, confusion in mapping and identifying newly discovered lands persisted for 200 years.

Frobisher set out with the "Gabriel" and "Michael" and a tiny pinnace of 10 tons. He made his North American landfall on the southeast coast of Baffin Island, after weathering terrible storms in which the pinnace was lost with all four of its crew and the "Michael" deserted and went home. In the "Gabriel" Frobisher sailed about 60 miles up the long inlet named after him, which he took to be a strait, and brought home among his trophies a rock sample that was identified wrongly as containing gold. The Northwest Passage was forgotten, and in the next two years Frobisher made two further voyages for the sole purpose of establishing a gold mine. The last voyage was an astonishing enterprise involving 15 ships and had the aim of founding a settlement of 100 men. Included in the cargo was a prefabricated house. The ships, however, were scattered by storms, at least one was sunk, and Frobisher, unable to set up his colony, loaded the remaining ships with ore and returned home only to find that his cargo was worthless.

Next to seek the passage was John Davis, one of the finest of the early seamen and something of a scientist as well. In three voyages, 1585–87, Davis rediscovered Greenland (lost to Europeans since the decline of the Norse settlements); he visited the southeast coast and sailed up the west coast to beyond Disko Island (72° N). He also traced the coasts of Baffin Island and Labrador from Cape Dyer south. Davis showed great imagination in his dealing with the Greenland Eskimos. He took musicians with him and had his sailors dance to the music, thus immediately establishing cordial relations with these sociable people.

In 1602 George Weymouth sailed a short way into Hudson Strait, and in 1610 Henry Hudson made his last voyage, sailing the "Discovery" into Hudson Bay and down to James Bay, where he was forced to winter. In the spring there was a mutiny aboard; Hudson and about eight of his crew, including his young son, were set adrift in a small boat to die, while the mutineers sailed the ship home. Retribution, however, overtook the ringleaders in Hudson Strait, where they were killed by Eskimos in one of the rather rare instances when these peaceful and good-natured people have attacked explorers. The remnant that reached England in September was imprisoned; nothing was ever heard from the deserted men.

Discovery of Hudson Bay

The early exploration of Hudson Bay led to a long series of voyages seeking a western outlet to this large inland sea, and at the end of 20 years its shores were fairly well known. Sir Thomas Button in 1612–13 (with Robert Bylot, a Hudson survivor, as pilot) was the first to reach the west coast of the bay, wintering near the site of York Factory and discovering Roes Welcome Sound; William Baffin, again with Bylot, sailed halfway up the northeast coast of Southampton Island in 1615; Jens Munk, a Dane, wintered at the mouth of the Churchill River in 1619–20, where nearly all his men died of scurvy, only Munk and two others surviving to sail one of the two ships home; and in 1631 Luke Foxe sailed into Foxe Channel.

In the meantime Baffin, the outstanding navigator of his day, had explored Baffin Bay (1616), but the significance of this exploration was not recognized for 200 years. With Bylot as master of his ship (Hudson's old "Discovery"), Baffin sailed up the west coast of Greenland to the head of Baffin Bay (78° N) and down the west side of the bay, discovering the three sounds that lead out of it, Smith, Jones, and Lancaster. Unfortunately, he reported that all three were merely bays and that there was no passage out of Baffin Bay. Even more unfortunately, his map was never published, and in time the very existence of "Baffin's Bay" came to be doubted. Search was continued in the Hudson Bay area up to the end of the 18th century, but at a greatly reduced pace. By that time traders were opening up the interior and hope of a passage by this route was fading.

The 19th century brought an entirely new era. Up until that time the search had been undertaken mainly by merchants; now it was the turn of governments. The end of the Napoleonic Wars had left the British Navy relatively unemployed, and the British government, spurred by the enthusiasm of Sir John Barrow, secretary to the admiralty, was persuaded to equip a whole series of large naval expeditions for the discovery of the Northwest Passage. The first of them, under Capt. John Ross in 1818, retraced almost exactly Baffin's journey of two centuries earlier, and repeated his error of mistaking the sounds for bays. Second in command to Ross was Lieut. W.E. (later Sir William Edward) Parry. He was not convinced that no sound existed, and in 1819–20, in HMS "Hecla" and "Griper," he made a voyage through Lancaster Sound to Melville Island in the western part of the archipelago, where he wintered. Blocked by ice in M'Clure Strait, he next (1821–23) tried the route through Foxe Channel, spending two winters in Foxe Basin. Again he was stopped by ice in the narrow Fury and Hecla Strait (named after the two ships he used on this expedition). A number of rather unsuccessful ventures followed. Parry on a third voyage (1824–25) explored Prince Regent Inlet; Capt. G.F. Lyon and Capt. George Back made unsuccessful attempts to reach Repulse Bay; and Capt. John Ross, on a privately financed venture in 1829–33, sailed down Prince Regent Inlet into the Gulf of Boothia, passing by one of the keys to the Northwest Passage, the narrow Bellot Strait, which washes the northernmost tip of the North American continent. The latter expedition added greatly to the extent of mapped territory, mostly through the work of Ross's nephew, J.C. Ross, who established the position of the North Magnetic Pole in southwest Boothia Peninsula. After three winters trapped in the ice, Ross had to abandon his ship, the "Victory," and retreat by sledge and boat,

spending a fourth winter on the way before being picked up by a whaler in Lancaster Sound.

In the meantime the British were also attacking the problem from the west by both sea and land. In 1819–22 and 1825–27 two expeditions under Capt. John Franklin, working overland and by boat from wintering bases in the Mackenzie Basin, surveyed the coastline from Turnagain Point, about 200 miles east of the Coppermine River, to Cape Beechey, Alaska. There Franklin almost made contact with the survey of Lieut. F.W. Beechey, who in 1825–26 reached Point Barrow from the west. In 1833–35 Capt. George Back discovered the Back River and mapped it to its mouth in Chantrey Inlet, and in 1837–39 P.W. Dease and Thomas Simpson, Hudson's Bay Company employees, made three coastal journeys by boat, filling in the gap in the Alaska coastline left by Franklin and joining Franklin's survey to Back's at Chantrey Inlet. In 1847 another Hudson's Bay Company employee, John Rae, joined Parry's Fury and Hecla Strait to Ross's survey in the Gulf of Boothia. Rae was a most remarkable traveller, far ahead of his time in adopting Eskimo methods and living off the land.

Capt. John Franklin

Most of the continental coastline and a considerable amount of the Canadian Arctic Archipelago had now been charted, and still the Northwest Passage remained elusive. The British government was getting tired of the project but prepared to send out one last expedition. This was the famous and tragic last voyage of Sir John Franklin, who sailed into Lancaster Sound in 1845 in HMS "Erebus" and "Terror" and was never seen again. The loss of this expedition produced a reaction of profound shock and resulted in a 12-year search that contributed tremendously to geographical knowledge. At its peak in 1850, as many as 14 ships were in the area at the same time, and a further expedition was at work from the mainland. The story eventually pieced together was that Franklin had wintered at Beechey Island at the west end of Lancaster Sound, after sailing up Wellington Channel to 77° N, and in the spring of 1846 turned south down Peel Sound, hitherto unnavigated, to Victoria Strait, off the north tip of King William Island, where his ships eventually had to be abandoned. There were no survivors.

The first to become anxious was Sir John Richardson, a veteran of Franklin's earlier expeditions, who in 1847–49 conducted a search along the northwest mainland coast, accompanied by Rae. The first official search parties were sent out in 1848; Sir James C. Ross, with "Enterprise" and "Investigator," was to enter from the east, and Capt. Henry Kellett, with the "Herald" and "Plover," had orders to stand by in Bering Strait to meet Franklin on his way out. Ross wintered in Somerset Island and traced most of its coastline before returning in 1849 without news. In an atmosphere of mounting alarm, a more thorough search was made in 1850. Capt. Horatio Austin wintered with four ships, the "Resolute," "Assistance," "Intrepid," and "Pioneer," off the south coast of Cornwallis Island, from which base extensive sledge trips traced many miles of coastline. Two more ships, under Capt. William Penny, a whaler, were in the same area, as was also Sir John Ross, then 73 but still active. The first U.S. expedition to the Arctic, financed by Henry Grinnell and led by Lieut. E.J. de Haven, sailed in the "Advance" and "Rescue" to Wellington Channel. Franklin's winter quarters at Beechey Island were found by Austin's and Penny's expeditions, but no record had been left to point the way from there.

Search for Franklin party

At the same time, in 1850, Capt. Richard Collinson was to enter from the west and meet Austin in a pincer movement. His two ships became separated in the Pacific, however, and operated independently. Comdr. Robert McClure in the "Investigator" discovered Prince of Wales Strait, rounded Banks Island by the west, and entered Mercy Bay on the north coast, where the ship remained frozen in for two years and was finally abandoned. McClure and his men were rescued by another expedition and returned home in 1854 by the eastern route. He was thus the first to make the Northwest Passage, though in more than one ship and partly on foot. Collinson in the "Enterprise" spent three years in Victoria Island, reaching Victoria Strait. There he was within a short distance of the place where Franklin's ships had been abandoned, as was also Rae, travelling by boat two years earlier. Neither found any clues. In 1852 a private expedition financed by Lady Franklin and led by a whaling captain, William Kennedy, discoverd Bellot Strait, named after a French volunteer in the search.

Voyage through Northwest Passage

After this the search moved north, which was generally thought to be the most likely direction; only Lady Franklin held firmly, and correctly, to the view that her husband had gone south as directed by his orders. In 1852 Capt E. Inglefield in the "Isabel" sailed north up Smith Sound to 78°35′ N, and another large expedition, under Sir Edward Belcher and Henry Kellett, sailed into Lancaster Sound with Austin's four ships plus a supply vessel, the "North Star." Splitting into an eastern and a western party and spending two winters in the Arctic, this expedition mapped many miles of new coastline north of Lancaster Sound, rescued the survivors of McClure's expedition, and then without apparent justification abandoned all four ships in the ice and sailed home in the "North Star." One ship, the "Resolute," was later found drifting in good condition in Davis Strait by a whaler, sailed to New England, refitted, and returned to the British government by the United States.

In 1853 an American, E.K. Kane, sailed in the "Advance" to Kane Basin, wintering twice and searching northward to Kennedy Channel. In the same year Rae was sent by the Hudson's Bay Company to complete the charting of the mainland coast between Chantrey Inlet and Boothia. The company had given up the search as hopeless, but ironically it was this expedition that brought back the first real news, obtained by Rae from Eskimos in Pelly Bay and backed by identifiable relics. The British government considered the search closed, but Lady Franklin was not satisfied; she financed a final expedition in the "Fox" under Capt. F.L. McClintock, who had been on three previous expeditions and was largely responsible for developing the sledging techniques used during the search. He travelled around the coasts of King William Island, finding many bodies and relics of the expedition, and also the only record left by it, at Victory Point.

So the Northwest Passage was at last found to be a reality, and official recognition went to McClure as its discover, though Franklin too had proved its existence and should share the honour. An unsuccessful attempt to navigate it was made by Allen Young in the "Pandora" in 1875. In 1903 Roald Amundsen, the great Norwegian explorer, sailed down Peel Sound in his tiny yacht "Gjöa" and passed around the east side of King William Island, where he spent two winters taking magnetic and other scientific observations. After a third winter spent west of the Mackenzie, he passed through Bering Strait in 1906, the first to navigate the Northwest Passage. It was navigated again in 1940–42 and 1944 by Henry A. Larsen of the Royal Canadian Mounted Police in the "St. Roch," west–east by way of Bellot Strait and east–west in one season by Prince of Wales Strait. In 1954 the first passage by a deep-draught vessel was made by HMCS "Labrador," a Canadian naval icebreaker. In 1969 the "Manhattan," the largest and most powerful commercial ship ever built in the United States to that time, smashed through 650 miles of ice between Baffin Bay and Point Barrow, Alaska, to assess the commercial feasibility of the passage. The future of the Northwest Passage as a regular commercial route remained uncertain, however, in the late 20th century.

Navigation of Northwest Passage

Whale fisheries and the fur trade. Many advances in geographical knowledge were due, directly or indirectly, to the whale fisheries that flourished in the Arctic for three centuries. On his first voyage in 1607, in the service of the Muscovy Company, Henry Hudson sailed up the east coast of Greenland in search of a direct polar route to Cathay. Reaching 73°30′ N, he turned east along the edge of the pack ice to Spitsbergen and on his way home discovered Jan Mayen Island. He was impressed by the number of whales he saw, and, as a result of his recommendation, a thriving whaling industry prospered under English, Dutch, Danish, French, and other companies, which continued until the whales were gone. In the 18th century the whaling spread to East Greenland waters, and

in the 19th century to Baffin Bay, Hudson Bay, and, after 1850, the Beaufort Sea, where U.S. whalers played a prominent part. By 1920 the industry was dead.

Much of the geographical knowledge accumulated by the whalers was never recorded and died with them; some, especially in the early days, was deliberately suppressed so as to keep it from competitors, but a great deal did find its way onto the maps. The coasts of Spitsbergen were first mapped by Dutch and English whalers, and the Dutchman Cornelis Giles discovered an island east of Spitsbergen that was long known as Giles (Gillis) Land, now White Island. Later details were added by Norwegian sealers. The considerable part played by whaling captains in the Franklin search has already been noted; in addition, the names of many whalers are perpetuated on the maps of Baffin Island and Hudson Bay. A whaler, William Adams, established the insularity of Bylot Island, and another, George Comer, made the first complete map of Southampton Island. Going farther west, Wrangel Island was discovered by Thomas Long, a U.S. whaler.

By far the most famous of the whalers were the William Scoresbys, father and son. Scoresby Sr., a farmer's son, was a first-rate navigator, inventor of the crow's nest and other aids to ice navigation, and the first to suggest the use of sledges to reach the pole. His son, who inherited his father's talents and added to them a scientific education, wrote two important books on the Arctic. In 1806 the Scoresbys reached 81°12′ N, north of Spitsbergen, a record northing at the time, and in 1822 the younger Scoresby made a detailed map of the east coast of Greenland from 75° to 69° N.

Just as whaling led to improved knowledge of the coastlines, the fur trade helped to open the interiors of Arctic lands. The Cossacks who settled Siberia were mainly engaged in this profitable trade, and the interior of Spitsbergen was first frequented by Russian hunters, who in the 18th century hunted the furbearers almost to extinction. In North America the influence of the fur traders was also great.

The formation of the Hudson's Bay Company was a direct result of the 17th-century voyages into Hudson Bay in search of the Northwest Passage. Following an exploratory voyage by Capt. Z. Gillam in 1668, the company was incorporated in 1670 and a trading post established at the foot of James Bay. Soon posts were set up on the west side of the bay at York Factory and Churchill, and these served as bases for further exploration. It was a hundred years, however, before the Hudson's Bay Company made any real attempt to explore the hinterland; Samuel Hearne was sent to look for a source of copper reported by Indians who traded at the coast. Hearne set out from Churchill with a band of Indians in 1770–71 and with them made a remarkable journey to the mouth of the Coppermine River, returning by way of Great Slave Lake. In 1789 Alexander Mackenzie of the rival North-West Company of Montreal travelled by canoe from Lake Athabasca down the Mackenzie River to the sea, establishing a second known point on the Arctic coast. By the time the two companies merged in 1821, there were trading posts on Great Slave Lake and down the Mackenzie to Ft. Good Hope; it was the existence of these posts that made possible the overland expeditions of Franklin and his successors, among whom were many Hudson's Bay Company men.

The Hudson's Bay Company

Pushing westward from the Mackenzie through the mountains and into Alaska, the Hudson's Bay Company met Russian traders working from the west coast. The Russians had established a colony in Alaska toward the end of the 18th century and carried on a vigorous trade at Kodiak, Sitka, and other settlements. In 1831 Baron von Wrangel, governor of the colony from 1829 to 1834, established a post on St. Michael's Island and had the lower Yukon explored. Competition and strife between the Russian and British traders ended with the purchase of Alaska by the United States in 1867 and the joint survey of the Alaska–Yukon boundary.

The North Pole. The North Pole did not become in itself a goal of exploration until fairly late; the few early expeditions that tried to reach the pole were looking for a polar route to the East rather than for the pole itself. After Hudson's first attempt in 1607, nearly 200 years elapsed before the British government sent another expedition, under Capt. C.J. Phipps in 1773, to try to sail across the North Pole. He got only as far as the north of Spitsbergen, and Capt. David Buchan in 1818 did no better. In 1827 Parry was the first to try the sledging technique suggested by Scoresby, breaking the latter's record by reaching 82°45′ N.

All these attempts had been in the area between Greenland and Spitsbergen, which actually is not the accessible route to the Arctic Ocean that it appeared to be, owing to the strong southerly drift of the ice. The Franklin search opened a new route, up the west coast of Greenland. In 1860 I.I. Hayes attempted to reach the pole by this route in the schooner "United States." Hayes was a firm believer in a theory, then prevalent, that the polar sea was ice-free and that it could be reached by breaking through the fringing belt of pack ice. Ironically, he met with unusually heavy ice conditions and got only as far as Etah on the coast of Smith Sound. In 1871 Charles Francis Hall, another American, with more luck and a better ship, reached 82°11′ N and charted both sides of the channel to its northern end at the entrance to the Lincoln Sea. Hall himself died during the winter and his ship, the "Polaris," was caught in the ice on the voyage south and drifted to Smith Sound, where it was almost wrecked. A party of 19, including an Eskimo mother with a two-month-old baby, became separated from the ship and drifted all winter on an ice floe, being picked up by a whaler in April 1873 off the coast of Labrador. In 1875–76 a British expedition under Capt. G.S. Nares in the "Alert" and "Discovery" reached the Lincoln Sea by ship, the "Alert" wintering near Cape Sheridan on the north coast of Ellesmere Island, the "Discovery" farther south at Lady Franklin Bay. Sledge parties in the spring traced the coasts of Ellesmere Island and Greenland to Yelverton Bay and Sherard Osborn Fjord respectively, and one, under Comdr. A.H. Markham, reached 83°20′ N over the pack ice, a new record northing.

In the meantime the Spitsbergen route was not neglected. In 1869–70 a German expedition under Karl Koldewey in the "Germania" sailed up the east coast of Greenland to 72°30′ N and traced it by sledge to Cape Bismarck. A second ship, the "Hansa," became separated and was crushed in the ice, and the crew drifted south on a floe around Cape Farewell, reaching the settlement of Frederiksdal in safety. A.E. Nordenskiöld made two journeys toward the pole from Spitsbergen, in 1868 by ship and in 1873 by reindeer sledge.

An entirely new approach was tried in 1879 by a U.S. expedition in the "Jeannette," led by Lieut. Comdr. G.W. De Long. At that time it was believed by many that Wrangel Island was a large land mass stretching far to the north, and De Long hoped to sail north as far as possible along its coast and then sledge to the pole. Accordingly, he sailed through Bering Strait, but his ship was caught in the ice near Herald Island and drifted west for 22 months, passing north of Wrangel Island and revealing its limited extent. The "Jeannette" sank near the New Siberian Islands and the crew reached the Lena Delta on foot, where many of them died, including De Long himself. A search expedition under Lieut. R.M. Berry surveyed Wrangel Island.

Wreckage from the "Jeannette" was found a year or two later on the southwest coast of Greenland, having apparently drifted right across the Arctic Ocean. Fridtjof Nansen conceived the daring idea that a ship might be made to do the same, thus providing a base for scientific investigation of the Arctic Ocean and incidentally a means of reaching the pole. In a new vessel, the "Fram," specially designed to rise under lateral pressure and so avoid being crushed, Nansen left Norway in 1893 with Otto Sverdrup and sailed into the Kara Sea. Near the place where the "Jeannette" sank they drove the "Fram" into the pack and began a drift that lasted almost three years and ended with the safe release of the vessel north of Spitsbergen in 1896; a formidable amount of scientific data was collected. Nansen himself left the "Fram" in 1895 with one companion, Hjalmar Johansen, in an attempt to reach the pole by

First voyage of the "Fram"

sledge, starting from 84° N in the longtitude of Franz Josef Land and setting a new record of 86°13′ N before having to turn back and winter in Franz Josef Land. In the spring, by a strange and lucky coincidence, he met Frederick Jackson, a British explorer, and returned home in his ship. Jackson was investigating Franz Josef Land as a possible steppingstone to the pole, but on hearing Nansen's account gave up the polar attempt. In his three-year stay (1894–97), however, he revolutionized the map of this complicated collection of islands and did a great deal of valuable work.

Up to that time the desire to reach the pole had been coupled with that of mapping unexplored territory and collecting scientific data; after the "Fram" expedition there was no longer any doubt that the central part of the polar basin was an ice-covered sea, and that any land still to be discovered would be peripheral. The race for the pole then degenerated into an international sporting event. Several expeditions, following in Jackson's footsteps, tried to reach the pole from Franz Josef Land. Three were American: Walter Wellman in 1898–99, the Baldwin–Ziegler expedition in 1901–02, and the Fiala–Ziegler expedition in 1903–06. An Italian expedition led by the Duke of the Abruzzi set a new record in 1900, when Capt. U. Cagni reached 86°34′ N.

Robert E. Peary started working toward his polar journeys in 1891–92 and 1893–95, when he made two long journeys across northwest Greenland, discovering the largely ice-free Peary Land. He intended to use north Greenland as his jumping-off place but later changed this to north Ellesmere Island, farther from the pole but more accessible. In 1898–1902 he laid a large supply cache in Lady Franklin Bay from bases in Smith Sound, sledged around the north coast of Greenland, and reached 84°17′ N from Cape Hecla, Ellesmere Island. In 1905, aided by the expert ice navigation of Capt. Bob Bartlett, he sailed in the "Roosevelt" to Cape Sheridan, near the "Alert's" old winter quarters, and from Cape Hecla set a new record of 87°6′ N. He also sledged around the north coast of Ellesmere Island, mapping the coast from where Nares left off. In 1908–09 he returned and from Cape Columbia in 1909 made a sledge journey to the pole. His technique was to start with a large party and set up depots at regular intervals, the support sledges turning back one by one as the depots were laid. With Peary on the final dash were his black dog-driver Matthew Henson and three Eskimos.

Just before Peary's return to the United States in September 1909, Frederick A. Cook, an American who had been with Peary in Greenland in 1891–92 and who had spent 1907–09 in the Arctic, announced that he had reached the pole the year before with two Eskimos, from the north point of Axel Heiberg Island. The matter aroused considerable controversy, and, to substantiate his claim, Cook submitted his journal to the University of Copenhagen, which considered it inadequate proof; he did not appear to challenge the decision. The question of whether Peary or Cook actually reached this theoretical point on the moving ice pack is hard to prove or disprove; but until there is fresh documentary evidence or improved knowledge that supports a different interpretation of the existing documents, Peary's claim seems the more valid one. In any event, it was accepted by the U.S. Congress and geographical institutions in many countries.

Early flights to the pole

The first attempt to fly to the pole was made as early as 1897 when a Swedish scientist, S.A. Andrée, left Spitsbergen in a balloon. It was not until 1930 that the fate of Andrée and his two companions was known, when their bodies and diaries were found on White Island. In 1909 Walter Wellman made an unsuccessful attempt by dirigible, and in 1925 Roald Amundsen, with two Dornier-Wal flying boats, reached 87°44′ N. The first to reach the pole was Richard E. Byrd, who with Floyd Bennett as pilot flew from Spitsbergen to the pole and back on May 9, 1926. Two days later Amundsen, with Lincoln Ellsworth and Umberto Nobile, set off from the same base in a semirigid airship and flew across the pole to Alaska.

Scientific exploration. An important secondary motive in much of the exploration so far discussed was pure scientific curiosity, the desire to add to the general store of knowledge of the world. With the passage of time and the disappearance of the old dreams of gain and glory, this became more and more the primary motive of exploration, though it was sometimes combined with a hope of developing such mineral or other resources as might be found.

In 1875 an important proposal for international cooperation in collecting scientific data was made by Karl Weyprecht, and the suggestion led to the establishment of the first International Polar Year, 1882–83, during which stations throughout the Arctic took observations and pooled the results. The countries participating were Norway, Sweden, Denmark, Finland, Russia, The Netherlands, Germany, Austria, the United States, and Great Britain. The 11 stations, reading eastward from Spitsbergen, were Isfjord (Ice Fjord), Spitsbergen; Bossekop, north Norway; Sodankylä, Finland; west coast of Novaya Zemlya; Sagastyr Island, Lena Delta; Point Barrow, Alaska; Great Slave Lake; Lady Franklin Bay, Ellesmere Island; Cumberland Sound, Baffin Island; Godthåb, Greenland; and Jan Mayen Island. In 1932–33 a similar pattern was followed by the second International Polar Year, but with more stations, and the technique was extended to cover the whole world in the International Geophysical Year of 1957–58.

Spitsbergen. Starting in 1827 a series of expeditions, most of them Swedish, surveyed Spitsbergen and studied its geology and natural history. Among those who carried out this work were B.M. Keilhau, Otto Torell, and A.E. Nordenskiöld. Sir Martin Conway crossed the interior of Vestspitsbergen in 1896–97, and in 1898 A.G. Nathorst explored the east coast and adjacent islands. Oceanographic and other work was done by the Dutch in the "Willem Barents" after 1878, by the Prince of Monaco and W.S. Bruce (1898–1914), and by the Russian admiral S.O. Makarov in the icebreaker "Yermak" (1899). At the turn of the century coal mining was begun in Isfjord, and this led to further survey activity by Norwegian government expeditions and others. A British expedition from Oxford University under George Binney in 1924 was the first scientific expedition to make extensive use of an aircraft.

The Russian Arctic. Between 1821 and 1824 F.P. Litke of the Russian Navy made four voyages to Novaya Zemlya, surveying the west coast and improving the mapping of Matochkin Strait and the White Sea coast, and in 1832–35 P.K. Pakhtusov surveyed much of the east coast of Novaya Zemlya. In 1880 Leigh Smith made the first of two voyages to Franz Josef Land and was the first to sail a ship there under its own power. On his second voyage his ship, the "Eira," was nipped by ice and sank. Smith built a hut on the shore and wintered, surveying the south coast and collecting scientific data. In the spring the party sailed to Novaya Zemlya in small boats. In 1886 and again in 1893 and 1900–02 Baron E. von Toll, a Russian explorer, worked in the New Siberian Islands. He perished in an attempt to find Sannikov Land, an island reported north of the New Siberian Islands, which, like many similar "lands" in the Arctic, probably does not exist. Some coordinated hydrographic work was done by the Russians in the Barents Sea from 1898 to 1908, in the Kara Sea from 1894 to 1904, and east of Cape Chelyuskin from 1910 to 1915.

In 1918 Amundsen set out in the "Maud" to emulate Nansen's drift in the "Fram" but with the hope of getting into a more northerly latitude by starting the drift nearer to Bering Strait. He took three seasons to sail east through the Northeast Passage, and it was not until 1922 that the "Maud" began its drift, under the scientific leadership of H.U. Sverdrup. In two years it was carried back to the New Siberian Islands, duplicating the path of the "Jeannette" rather than the "Fram," but useful scientific work was done throughout both phases of the expedition.

Increase in Russian exploration

After the Russian Revolution in 1917, the scale and scope of exploration increased greatly as part of the work of developing the northern sea route. Polar stations, of which five already existed in 1917, increased in number, providing meteorological, ice reconnaissance, and radio facilities. By 1932 there were 24 stations, by 1948 about 80, and by the 1970s more than 100. The use of icebreakers, and, later, aircraft, as platforms for scientific work

was developed. In 1929 and 1930 the icebreaker "Sedov" carried groups of scientists to Franz Josef Land and also to Severnaya Zemlya, the last major piece of unsurveyed territory in the Soviet Arctic; it was completely mapped under G.A. Ushakov between 1930 and 1932.

The one-season voyage of the "Sibiryakov" through the passage in 1932 accomplished much scientific work and was the first to use the route north of Severnaya Zemlya. It gave a further stimulus to development of the sea route, and icebreaker operations to study sea and ice became annual. Particularly worth noting are three cruises of the "Sadko," which went farther north than most; in 1935 and 1936 the last unexplored areas in the northern Kara Sea were examined and the little Ushakova Island discovered, and in 1937 the ship was caught in the ice with two others and forced to winter in the Laptev Sea, adding valuable winter observations to the usual summer ones.

Greenland. The history of modern Greenland may be said to begin with the voyage in 1721 of Hans Egede, a Danish-Norwegian missionary whose aim was to find and reestablish the Norse colonies. Travelling up and down the west coast, he found no survivors of the old colonists, but he stayed to found his own settlement at Godthåb and to begin the enlightened development of the country and its Eskimo people that has made Danish Greenland a model of colonial administration.

Greenland has received a great deal of study. The west and north coasts became fairly well known during the 19th century. The east coast was less easily explored because of severe ice conditions that make it hard to approach by ship. In 1806–13 Karl Ludwig Giesecke, a German mineralogist, used the native umiak to study the southeast coast, and so did Lieut. W.A. Graah in 1829–30. In 1823 captains D. Clavering and E. Sabine, following in the steps of William Scoresby the year before, carried the survey north to 76° N and took pendulum observations. In 1876 the Danish Committee for the Geographical and Geological Investigation of Greenland was formed, and since then a consistent program of research has been carried out. The gaps in the southeast coast were filled in by naval expeditions under L.A. Mourier (1879), G. Holm (1883 and 1885), and C.H. Ryder (1891–92), and the rest by Lieut. G.C. Amdrup in the "Antarctica" (1898–1900), the Duke of Orléans in the "Belgica" (1905), and Ludvig Mylius-Erichsen in the "Danmark" (1906–08). On the latter expedition long sledge journeys by J.P. Koch and Mylius-Erichsen traced the whole northeast corner of the island, but Mylius-Erichsen and two companions were lost. The last details were recorded in 1901–12 by Ejnar Mikkelsen, who traced the route followed by the dead men and found their records. A series of expeditions, known as the Thule Expeditions because they were based on the little trading settlement of Thule in northwest Greenland, did considerable work in north Greenland between 1912 and 1921 under Knud Rasmussen and Lauge Koch.

Expeditions to the Greenland ice cap

The Greenland ice cap presented a formidable barrier to travellers and at the same time a challenge to both adventurer and scientist. Early attempts to penetrate it from the west coast settlements were made by Edward Whymper in 1867, by Nordenskiöld in 1870 and 1883, by J.A.D. Jensen in 1878, and by Peary in 1886. Peary, the most successful, penetrated 100 miles from the coast. In 1888 the young Fridtjof Nansen adopted the bold plan of starting from the uninhabited east coast, thus leaving himself no retreat but at the same time avoiding the necessity of retracing his steps. With five companions, using snowshoes and skis, he crossed the ice cap from 64°23′ N on the east coast to Godthaab on the west. Since then the ice cap has been crossed many times, even in its widest parts. Peary was the first to cross the northern part, from Inglefield Gulf to Independence Fjord in 1892. Other crossings have been made by Knud Rasmussen and by A. de Quervain in 1912, by J.P. Koch in 1913, by Lauge Koch in 1921, and by others.

In 1930–31 three expeditions, simultaneous but independent, maintained stations on the ice cap throughout the winter, securing meteorological data vital to the study of world air circulation. They were the British Arctic Air Route Expedition led by H.G. Watkins, the German Greenland Expedition under Alfred Wegener, and the University of Michigan Expedition under W.H. Hobbs. After World War II this work was continued on a larger scale by the French explorer Paul Emile Victor (1947–53) and the British North Greenland Expedition under Comdr. C.J.W. Simpson (1952–54).

The North American Arctic. By the beginning of the first Polar Year in 1882, most of the coastlines of the North American Arctic were known except for the islands west of Ellesmere Island and the south and west coasts of Ellesmere. The U.S. Polar Year station at Lady Franklin Bay, in addition to its scientific program, explored a considerable amount of new terrain in Ellesmere Island and reached 83°24′ N on the north coast of Greenland, a record northing at the time. Led by Lieut. A.W. Greely, the expedition set up its station, Ft. Conger, in 1881. In 1883, as no supply vessel had arrived, Greely started south in five small boats, according to instruction, and reached Cape Sabine in Smith Sound. There a quite inadequate depot awaited him, together with a record to the effect that the supply ship "Proteus" had sunk in Kane Basin. After a terrible winter the survivors—seven from an expedition of 25—were rescued by Capt. W.S. Schley in the "Thetis."

Three earlier expeditions by Americans in search of Franklin's records are worth noting. C.F. Hall, having failed in a plan to reach King William Island by boat from Baffin Island, spent the years 1860–62 in Frobisher Bay, which only then, three centuries after its discovery, was proven not to be a strait; he found interesting relics of Frobisher's visits. From 1864 to 1869 he lived among the Eskimos at Repulse Bay and made an overland trip to the south coast of King William Island. In 1878 Lieut. F. Schwatka travelled overland from Hudson Bay and made the first summer search in the area, returning by a remarkable winter journey to Hudson Bay. Franklin's scientific records were never found, either then or since.

Exploration by the Geological Survey of Canada

Further exploration of the interior was carried out by the Geological Survey of Canada, notably by the journeys of J.B. Tyrrell, A.P. Low, and Robert Bell. Between 1884 and 1897 four Canadian government expeditions studied conditions in Hudson Strait and Hudson Bay with a view to establishing a sea route, and after 1903 a series of voyages into the archipelago by Low and Capt. J.E. Bernier visited many of the islands and did some survey and geological work. Two Germans, Franz Boas, the well-known anthropologist (1883–84), and Bernhardt Hantzsch (1909–11), contributed to the geography of Baffin Island.

In 1898–1902 a Norwegian scientific expedition in the "Fram" under Otto Sverdrup did a tremendous amount of work in south and west Ellesmere Island and north Devon Island and discovered three islands to the west—Axel Heiberg Island and the Ringnes Islands. Sverdrup's original intention had been to try to circumnavigate Greenland, but heavy ice in Kane Basin forced him to change his plans. The last gaps in the outline of Ellesmere Island were filled in by W.E. Ekblaw, geologist and botanist with the Crocker Land Expedition (1913–17) under D.B. MacMillan. Crocker Land, which Peary in 1906 conjectured to be north of Axel Heiberg Island, proved to be nonexistent; MacMillan failed to find it in a 200-mile journey over the ice.

The last large-scale expedition in the old tradition in the North American Arctic was the Canadian Arctic Expedition, 1913–18, led by Vilhjalmur Stefansson. It was divided into two parties, of which the southern one, under R.M. Anderson, did survey and scientific work on the north mainland coast from Alaska to Coronation Gulf, while the northern travelled extensively in the northwest, discovering the last remaining islands in that area. Stefansson, a magnificent hunter, successfully adopted Eskimo methods and was able to travel long distances by living off the land, avoiding the necessity of carrying large quantities of supplies. In 1921–24 the fifth Danish Thule Expedition under Rasmussen worked in Melville Peninsula and Baffin Island, and Rasmussen journeyed overland to King William Island and on to Alaska, studying the Eskimos. In the 1930s a number of British expeditions under Noel Humphreys, J.M. Wordie, and T.H. Manning worked in the Canadian Arctic; Manning completed the mapping of

the west coast of Baffin Island, the last major gap on the map of Canada. The last new land, however, was not added until 1948, when a Royal Canadian Air Force photo-survey aircraft found three islands in Foxe Basin, one of them, Prince Charles Island, about 3,500 square miles in area.

The exploration of Alaska after its purchase by the United States in 1867 proceeded slowly at first but later at a rapid speed. Coastal surveys by the Coast and Geodetic Survey were started immediately; among others, inland journeys were made by I. Petrof (1880); by Lieut. F. Schwatka (1883) and Lieut. H.T. Allen (1885), both of the U.S. cavalry; and by Lieut. G.M. Stoney, U.S. Navy (1883–85), one of whose party made the first overland journey to Point Barrow. After the Yukon gold strike of 1897, the Geological Survey began a large-scale systematic study of all Alaska that has continued along with work in other fields of natural science. Outstanding in the early days of the project were A.H. Brooks, chief geologist of the Geological Survey in Alaska, 1903–17, and E. de K. Leffingwell, who worked on the North Coastal Plain between 1906 and 1914.

The Arctic Ocean. It is a comment on the unimportance of the North Pole as an incentive to exploration that hardly any of the real exploration of the Arctic Ocean can be credited to the pole seekers. The great exception is Nansen, whose work in the "Fram" stood alone until the 1930s; but, although Nansen made a bid to reach the pole, his primary aim was rather to study the waters and bottom contours of the Arctic Ocean and the drift of the ice and to find out whether there were new lands still to be discovered in the centre of the polar basin. In accord with popular opinion, Nansen expected to find only shallow water in the North Polar Basin. Consequently the "Fram" was equipped to make soundings to only 6,000 feet. Soon after the drift began, depths in excess of this were encountered. Unravelling one of the ship's steelwire cables and joining the individual strands end-to-end permitted 11 successful soundings to be completed under most difficult conditions. These soundings gave depths ranging from 11,000 to 13,000 feet, showing that there was a deep basin under at least part of the North Polar Sea. These deep soundings mark the true discovery of the Arctic Ocean.

Exploration by aircraft

The advent of the airplane revolutionized exploration techniques and made possible investigation of the Arctic Ocean on a scale never before dreamed of. Following the polar flights of Byrd and Amundsen, G.H. (later Sir Hubert) Wilkins and C.B. Eielson made the first flight by airplane across the Arctic Ocean in 1928, from Point Barrow to Spitsbergen, and in 1937 two long-distance transpolar flights were made by Soviet flyers, V.P. Chkalov and M.M. Gromov. These flights were mainly intended to prove the capabilities of aircraft, but a third Soviet flight in the same year made a large but tragic contribution to exploration. A four-engined aircraft piloted by S.A. Levanevski disappeared in the Arctic Ocean and set in motion a large-scale, though unsuccessful, search which covered vast areas hitherto unexplored and added tremendously to flying experience.

It was also in 1937 that the U.S.S.R. set up the first floating scientific station, using four-engined aircraft based on Franz Josef Land to land a four-man party under I.D. Papanin at the North Pole in late May. The station, now known as North Pole 1, drifted south for nine months and was taken off its melting ice floe in the Greenland Sea. In the same year the icebreaker "Sedov" was caught in the ice in the Laptev Sea and began a 27-month drift that almost duplicated that of the "Fram" and yielded interesting comparative data. In 1941 an aircraft carrying a team of scientists made three landings on the ice at about 80° N, 175° E.

After World War II scientific work in the Arctic Ocean increased greatly, and today there remain no unexplored areas. After 1947 the United States carried out routine weather-reporting flights over the Arctic Ocean from Alaska and used icebreakers and aircraft to do oceanographic work in the Beaufort Sea. In 1952 a weather station was established on the ice island T3 and maintained for two years, being reoccupied briefly in 1955, and on a more permanent basis as an International Geophysical Year station in 1957. From that time there was continuous occupation of stations, usually two at any given time.

The Russians explored the Arctic Ocean on a large scale by means of floating stations and large-scale airborne expeditions which made many landings on the ice to take observations. Station North Pole 2 was established in 1950 north of Wrangel Island and was maintained for a year. After 1954 there was a continuous succession of stations, usually two at once and each occupied for one or two years or more, until they drifted into a region where they ceased to be of interest or joined the drift to the Greenland Sea. North Pole 15 was set up in April 1966.

Technological advances in power (nuclear engines), marine technology (especially designed icebreakers, scientific vessels, and commercial ships), and navigation (inertial and satellite guidance systems) have permitted expeditions such as the 1958 voyages of the USS "Nautilus"

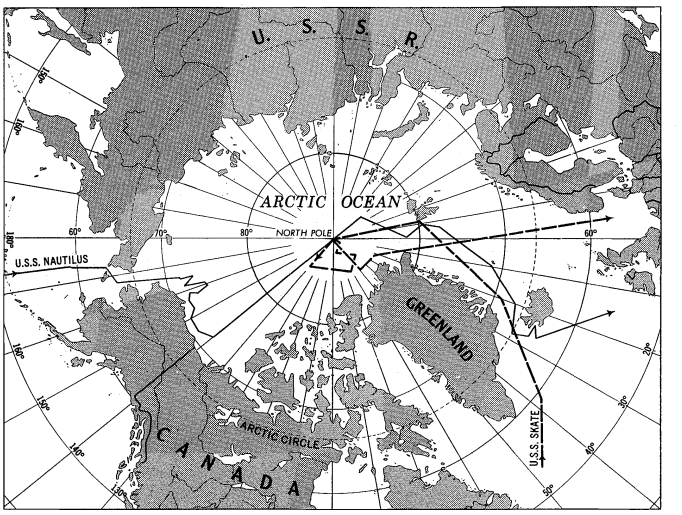

Figure 4: Arctic routes of the transpolar voyages of the U.S. submarines "Skate" and "Nautilus," August 1958.

and "Skate," which made successful polar cruises, in both winter and summer, and proved to be excellent platforms for oceanographic work; the 1969 and 1970 voyages of the "Manhattan," an ice-breaking oil tanker; and the 1978 voyage of the Soviet nuclear icebreaker "Sibir," opening a southern passage across the coast of northern Siberia. The discovery of oil in near- and offshore polar areas of North America provided the economic impetus for much geological exploration of the Beaufort Sea, the Canadian Arctic Islands, and other areas in the 1970s and 1980s.

(N.A.O.)

The discovery phase of Arctic exploration is over; there is no longer any possibility of finding new lands. Photo surveys have provided reasonably accurate maps, and improved aircraft and base facilities are making the once formidable "frigid zone" increasingly accessible; commercial airlines fly across the North Pole. Nevertheless, much detailed exploration of lands and seas remains to be done.

(M.Dr.)

The Arctic Islands

Location and general characteristics

The islands lying north of the Canadian mainland, forming one of the world's great archipelagos, extend about 1,500 miles east to west and 1,200 miles from the mainland to Cape Aldrich, the northernmost point of Ellesmere Island. Two large peninsulas, Boothia and Melville, extend northward from the mainland and will be discussed here as parts of the archipelago. The land area of this region exceeds 500,000 square miles, about one-seventh of the area of Canada.

The Arctic Islands, also called the Canadian Arctic Archipelago, lie far north of the temperature line, or isotherm, along which 50° F (10° C) is the mean July temperature; this line coincides closely with the northern limit of trees

Figure 5: The Arctic Archipelago of North America.

on the mainland and commonly is used to define the southern limit of the world's Arctic region. Like much of the adjoining mainland, the Arctic Islands are characterized by permanently frozen ground, or permafrost, except for a thaw to the depth of about one foot during the summer months.

Ice restricts sea access to most of the islands to the late summer and early winter. The few and widely scattered permanent settlements lie mainly on the southern islands. Although remote, the region has become accessible the year round through a network of airfields and air routes connecting centres of population to the south. For thousands of years the archipelago was peopled only by Eskimo, who evidently migrated to this land from Asia. Norsemen may have reached the easternmost islands in the 10th and 11th centuries, and from the 16th century numerous European expeditions carried out a prolonged search for a northwest passage through the islands to the Orient.

A few minerals and rocks have long been used by the aboriginal Eskimo—native copper and flint for knives and weapons and soapstone for lamps and cooking pots—but economically valuable minerals have played only a small part in the history of the Arctic Islands. Exploitation began with mining and shipping of "gold ore" (probably amphibolite with minor, bronze-coloured biotite) from Baffin Island in the 16th century by the English explorer Sir Martin Frobisher. Graphite, mica, and coal have been mined on the same island. In the late 20th century, increased mineral exploration has resulted in promising discoveries of iron and lead–zinc. Most spectacular, however, was the modern oil and gas exploration program that followed discovery of a major oilfield in northern Alaska in 1968. An oil-producing zone also has been found by drill, and several wells have been capped as gas wells.

The Canadian Arctic Islands and Boothia and Melville peninsulas form the District of Franklin, one of three administrative divisions of Canada's Northwest Territories. Government is by both elected and appointed councillors seated at the territorial capital, Yellowknife, on the mainland.

PHYSICAL GEOGRAPHY

Relief and geology. The surface of the archipelago includes plains, lowlands, uplands, plateaus, highlands, and mountains. Most elevated surfaces are rolling and dissected by valleys and deep channels. Physiography generally expresses the type and structure of the bedrock: extremely resistant granitic and gneissic rocks form mountains, highlands, and uplands; folded sedimentary rocks form ridged mountains and uplands; slightly folded or flat-lying limestones and related rocks form extensive plateaus and lowlands; and weakly consolidated sandstones and shales underlie lowlands and plains.

Geology and geomorphology of the archipelago

Mountains and highlands lie along the eastern coasts of Baffin, Devon, and Ellesmere islands to form a high eastern edge of the archipelago. The surface slopes generally westward through plateaus and lowlands interrupted by upland and some mountain areas, then drops away to the low Arctic Coastal Plain that lies along the northwestern margin of the region. The eastern mountain belt, in which the highest land attains an elevation of about 7,000 feet,

is deeply dissected by fjords to form a region of high relief and rugged scenery. Another belt of rugged mountains forms Axel Heiberg Island and the northern edge of Ellesmere Island. The highest point of the Canadian Arctic Islands lies in northern Ellesmere Island: Barbeau Peak has an elevation of 8,544 feet (2,604 metres). Plateaus in the central part of the archipelago reach average elevations of 800 to 2,000 feet, with hills and mountains of about 2,500 feet.

Structural regions. The Canadian Arctic comprises two geological provinces: the Central Stable region in the south and the Innuitian orogenic region (a once mobile belt) in the north. The Central Stable region includes the vast crystalline complex of the Canadian Shield, formed during the Precambrian (with radiogenic dates between 2,800,000,000 and 600,000,000 years ago), and large areas of overlying, little-deformed sedimentary rocks of Late Precambrian and Paleozoic (more than 225,000,000 years ago) eras. The Innuitian region is a sinuous belt of slightly to severely folded rocks ranging in age from the Late Precambrian Era to the Tertiary Period (*i.e.,* up to as little as 2,500,000 years ago).

The Innuitian region was the site of two major sedimentary basins: the Franklinian Geosyncline and the Sverdrup Basin. The Franklinian Geosyncline, the earlier of these tectonic depressions, or regional downwarps, received sediments nearly continuously from Late Precambrian to Late Devonian times (about 345,000,000 years ago). An episode of folding and faulting of the geosyncline in latest Devonian time is named the Ellesmerian orogeny, or mountain-building episode. Following this orogeny, much of the area was again depressed to form the Sverdrup Basin, which received sediments between Late Mississippian and Early Tertiary times. The rocks of the Sverdrup Basin were deformed during the Early Tertiary, some 65,000,000 years ago, by compressive forces of the Eurekan orogeny.

Ages and thicknesses of geological formations. The Canadian Shield of Precambrian metamorphic rocks forms a "basement" complex along the southern and eastern edges of the archipelago. Rocks of the Shield are mainly granite, gneiss, and schist. Late Precambrian to Tertiary sedimentary rocks overlie the shield to form northeast-trending belts to the north and northwest; these younger rocks include limestone, dolomite, shale, sandstone, gypsum, and volcanic rocks such as andesite and basalt. Bedded rocks of Late Precambrian Era attain thicknesses of 12,000 to 19,000 feet on Victoria and Baffin islands but are absent over large areas due to later erosion. More widely exposed on the southern islands are Early Paleozoic sedimentary formations with a maximum total thickness of 10,000 feet. The Early Paleozoic formations pass northward into a 40,000-foot-thick, mainly marine sedimentary sequence that occupies the Franklinian Geosyncline. The geosynclinal sequence passes from marine to nonmarine in the uppermost (Devonian) part, in which thin coal seams, as well as plant and fish remains, occur in sandstones. On northern Axel Heiberg and Ellesmere islands, volcanic rocks and related sediments occur along with a metamorphic complex that in part predates the geosyncline but may in part derive from it. The Sverdrup Basin, overlying the folded and partially eroded geosyncline, contains some 50,000 feet of mainly marine sedimentary rocks. Nonmarine strata in the upper part of the sequence include coal and basaltic flows. Late Paleozoic anhydrite deep in the basin was forcibly intruded into overlying beds by orogenic pressures or by the weight of the superimposed rocks and now appears at the surface as conspicuous gypsum–anhydrite diapirs, or "domes."

The Arctic Coastal Plain is a narrow belt of very low relief underlain by Late Tertiary and Early Quaternary sand and gravel and is presumably continuous with the continental shelf, which extends about 100 miles into the Arctic Ocean.

Final shaping and drainage. The form and drainage pattern of the archipelago probably dates from Late Tertiary and Pleistocene times, or since about 25,000,000 years ago. The bedrock was deeply eroded after the Early Tertiary orogeny, and remnants of the erosion surface now stand at various elevations. Faults evidently border many islands, and many channels and major valleys probably are related to Tertiary faults. The subsequent drainage system was modified by Pleistocene glaciation and now is largely submerged in marine waters.

Glacial geology. Successive glacial advances and interglacial intervals of the Pleistocene Epoch followed worldwide climatic changes some 2,000,000 to 3,000,000 years ago. The Arctic Islands were largely ice covered during this epoch, as was most of the rest of Canada. The effects of the latest, or classical Wisconsin, glacial invasion (climaxing about 20,000 years ago) are most abundant and fresh, but earlier advances and interglacial events are recorded at many places. Some areas of the westernmost islands lack obvious evidence of glacial activity and may have escaped glaciation entirely.

Two main ice sheets occupied the islands: the Laurentide Ice Sheet flowing northward from the mainland to override the southern islands, and the Innuitian Ice Sheet, a coalescing series of glacier complexes that were especially well developed in the highlands and mountains of the eastern part of the archipelago. Markedly linear glacial features, such as drumlins (hills of glacier-deposited drift) and eskers (glacial stream deposits), are abundant on the lowlands of the southern islands, while glacial valleys, rounded rock surfaces, and other alpine glacial features are evident in the higher eastern islands.

Effects of the ice sheets

Layered sediments containing plant and woody material occur at several localities beneath glacial till, between till layers, and overlying older till beyond the recognized limit of the late Wisconsin Ice Sheet. Radiocarbon ages greater than 30,000 years have been obtained from the organic matter, which includes pollen of grasses and sedges, other herbaceous plants, and alder, willow, and spruce trees. Willow and spruce wood, some beaver gnawed, is found. Evidently the interglacial climate was somewhat more favourable than at present.

Marine shells yielding radiocarbon ages from 20,000 to more than 40,000 years occur in stratified deposits up to a few hundred feet above sea level and as scattered debris at higher elevations, as on upland surfaces. The dates are minimums, and the "old" shells indicate marine events prior to the last glaciation. Some of the older shells are broken and abraded and must have been transported and dispersed by glacial ice.

Deglaciation in the Arctic Islands was well advanced by about 9,000 years ago, as dated by shells from the highest beaches. Deglaciation of the islands, as elsewhere, appears to have been marked by fluctuations of the ice front. Scattered proglacial lakes formed as the ice abated, and the sea invaded the land, which was then still depressed because of the former ice load. Remarkable flights of raised beaches, now standing from a few feet to about 500 feet or more above sea level, attest to postglacial uplift following removal of the ice load. The greatest uplift occurs in a linear, nearly central zone trending northeasterly through the islands from Boothia Peninsula. The emerged marine features, however, present a complex pattern because of the rise in sea level during deglaciation, the variation in time of ice retreat—and hence of marine incursion—from area to area, and possible deformation or possible fault movement along some coasts.

Climate. The southern boundary of the Arctic climate region is usually placed at the tree line, which lies on the Canadian mainland. North of this distinct natural boundary, the growing season is too short and cold to allow tree growth.

The climate of the Arctic Islands is unique in many respects because of the high latitude, the barren nature of the land surface, and the maritime influence of the Arctic Ocean, Baffin Bay, and the interisland waterways. The winters are longer and the summers cooler than more southerly parts of Canada, but conditions in the Arctic are usually not so fierce or extreme as some popular accounts would suggest.

The Arctic region is snow and ice covered for more than half the year, subjected to a cold, dry climate. The daily average temperatures of the three coldest months range from −20° F (−29° C) in southern sections to −30° F (−34° C) in the north. The average temperatures generally

Temperature ranges

remain below 0° F (−18° C) during six cold months and rise above the melting point only during June, July, and August. The record low temperatures of −55° to −60° F (−48° to −51° C) at Arctic stations are not as low as the −70° F (−57° C) and colder temperatures reported for parts of the mainland. The summer temperatures are cool, generally below 45° F (7° C), with occasional brief sunny intervals of 65° to 70° F (18° to 21° C). Winter sets in about the end of August in the highest latitude and in early or mid-September in the southern islands. The lowest temperatures occur between December and April, with January the most severe month in southern parts and February in the high latitudes. Thawing begins in late May to early June, and the snow has disappeared from much of the land by early July. The breaking up of sea ice, which attains thicknesses of about five to seven feet, occurs considerably later than the beginning of the thaw, but by late July it is well advanced in the southern and eastern periphery of the archipelago. Open water suited to ship navigation advances slowly into the archipelago during August and September, but the channels between the northwestern islands are ice choked the whole season (June to September).

The prolonged Arctic cold season is a result of the far northern latitude: incoming solar radiation is minimal during daylight because of the low angle of the sun's rays and is absent during the long Arctic night. In addition, although the amount of solar energy available during the periods of long days and continuous daylight is even greater than in southern latitudes, only a small percentage reaches the ground because of the high reflectivity of the snow and ice surfaces and cloud layers. The sustained cooling results in a continuous winter ice cover on the seas and channels, generally stable, cloud-free air, and consequent light snowfall. During the thaw season the open water and wet, thawing land result in high humidity and notorious, low-lying stratus clouds and coastal fogs.

Annual precipitation is low—about three to seven inches—throughout the archipelago except along the mountainous eastern coastal sections, where the height of the land and the proximity to the open waters of Baffin Bay, Davis Strait, and the North Atlantic result in anomalously high precipitation and persistent ice caps.

The worst climate in the Arctic Islands is that of the Hudson Strait region. Dominated by open water and frequent cyclonic activity, this region has the highest average temperature, the heaviest snowfall, the highest average wind speeds, and the greatest number of days of summer fog in the Canadian Arctic. (R.L.Ch.)

Plant and animal life. Plants and animals of the Canadian Arctic Islands are relatively few for so large an area but are of great interest through their adaptations to extremely severe conditions. Spitsbergen, lying far north of the Scandinavian Peninsula but bathed by the Gulf Stream, supports many temperate plants that cannot grow in more southerly Canadian islands, which are surrounded by cold water flowing from the Arctic Ocean. The continuous ice and smooth wind-packed snow cause seeds and other reproductive structures to be blown great distances in winter gales. Many plants are circumpolar without local variation, indicating dispersal between Old and New World lands. There is evidence that some insects may be carried similarly.

Environmental hazards and adaptive mechanisms. Flowering plants must flower and fruit rapidly in a short, cold summer, freeze with impunity at any time, resume full growth as soon as they thaw, and withstand abrasion by gritty snow crystals in winter gales. All other Arctic plants—ferns, horsetails, mosses and liverworts, lichens, algae, and fungi—as well as insects—the primitive arthropods known as springtails, spiders, and mites—share the ability to freeze at any time and resume full metabolism as soon as the temperature permits it. This is the most important characteristic of all Arctic organisms except birds and mammals. A few crucifers, members of the mustard family, may mature their seed in a second year if snow cover is complete, while many fungi and insects mature gradually in two to several years, stopping growth at any stage and continuing the next spring.

Suspension and reactivation of metabolic functions

Although small animals may take shelter from gales, plants must either grow in sheltered sites or tolerate snow abrasion. A common protection is assumption of a compact cushion, in which the winter buds lie below the level of the old stems and leaf tips. The projecting parts cause eddies that slow down snow particles.

Mammals of or above the size of Arctic hares can carry fur heavy enough to give them excellent insulation, and they need little shelter. Such coats are unmanageable for such small species as ermine and lemmings, which must spend most of the winter below ground or below the snow. Snowfall is often very light, and large areas may be swept bare by wind. Soil temperature may then be so depressed that lemmings fail to reach breeding condition.

Native species. The most widespread mammals are Arctic fox, wolf, ermine, polar bear, Arctic hare, collared lemming, caribou, and musk-ox. The brown lemming (*Lemmus sibiricus*) occurs on the southern islands, while the red fox and wolverine occur on Baffin Island.

Most birds leave the Arctic Islands before winter begins, but a few willow ptarmigan, snowy owls, and ravens (*Corvus corax*) remain. Common birds in the high-latitude Queen Elizabeth Islands include the red-throated loon, snow goose, old-squaw and king eider ducks, rock ptarmigan, a few sandpipers, long-billed jaeger, glaucous gull, Arctic tern, and a few buntings. About 35 other species, notably plovers and gulls, breed regularly in the southern islands.

The most important fish in the archipelago region is the Arctic char, a staple food item of the Eskimo and increasingly popular for shipment south. No reptiles or amphibians reach the islands.

The insect life is of major consequence. A few moths and bumblebees reach northern Ellesmere Island, but the true flies, or Diptera, are by far the most abundant order. They include many midges, a few mosquitoes, and some muscoid flies. By their great numbers, they are important in pollination, and they are the main food for various birds. Beetles are few, except in the southern islands. Other orders are scarce or absent.

About 325 species of flowering plants grow in the region. Grasses, sedges, and rushes are common, but most other monocotyledons are absent. Dwarf birch and several willows reach the southern islands, but only one prostrate willow reaches northern Ellesmere. Other conspicuous species or groups include mountain sorrel, bistort, various Caryophyllaceae, buttercups, various Cruciferae, poppies, saxifrages, cinquefoils, mountain avens, crowberry, fireweed, louseworts, fleabanes, and dandelions.

Several ferns, horsetails, and clubmosses are recorded, all southern species that survive on sterile sites where competition is lacking. Mosses, liverworts, and some groups of algae are plentiful; but few species are endemic to the Arctic, and some are nearly cosmopolitan. Lichens are numerous and often conspicuous. They are important in delaying water loss from gravel, thus helping to establish mosses and flowering plants. Large lichens are major items in the diet of caribou.

Fungi are of great ecological importance, for they largely replace bacteria in breaking down plant remains. Various mushrooms and a few puffballs and large cup fungi grow in soil; and nearly 300 species of microfungi are parasitic or saprophytic on leaves and stems.

Plant cover is governed by summer climate and by soil and rock type. The numbers of vascular plants correlate closely with the July mean temperature; the flora diminishes precipitously as the freezing point in summer is approached. In many of the western islands, low relief and rapidly weathering sandstone or limestone give extremely barren substrates with much less than 1 percent ground cover.

Total productivity is not known for any site, but breeding-bird censuses give rough comparisons. Isachsen yielded 9.61 birds per square mile; Hazen Camp, 24.99; and grassy tundra in southwestern Baffin, 391 and 544. (In contrast, temperate forests and swamps range from 1,000 to 11,785.) Such figures emphasize the low productivity and the precarious balance of Arctic ecosystems.

(D.B.O.S.)

HISTORY

In the 19th century British interest in the Northwest Passage brought Sir John Ross (1818) and Sir William Edward Parry (1820) to the Arctic archipelago and led to the discovery of the magnetic pole on the Boothia Peninsula by Ross's nephew, Sir James Ross (1831). Sir John Franklin's ill-starred expedition by sea (1845–48), his disappearance with all his men, and the loss of his ships occasioned the famous search (1848–59) that incidentally added much to the knowledge of the Arctic coast.

Until the mid-20th century the total white population consisted of about 50 on Baffin Island and perhaps 20 more people scattered through adjacent islands. With the advent of air services and the extension of meteorological and radio research, this number increased considerably. A notable event was the Canadian military expedition ("Exercise Musk-ox") early in 1946, in which a group of army men travelled by tractors from Churchill to Cambridge Bay on Victoria Island, returning via Coppermine and Norman Wells. Of great interest also were the voyages of "St. Roch," which twice traversed the Northwest Passage. In 1941 and 1942 it made the journey from Cambridge Bay to Pond Inlet in Baffin island, wintering near the magnetic pole. In 1944 Sgt. Henry Larsen made the return journey and traversed the difficult portion of the journey—from Pond Inlet to the Beaufort Sea—in 18 days. He found the narrow Prince of Wales Strait (north of Victoria Island) practically free of ice and so was able to accomplish this feat of navigation in record time. The "St. Roch" was the only vessel to traverse the historic passage both ways. An expedition in 1947 investigated the site of the north magnetic pole. Survey by the aeroplane "Aries" seemed to show that it had moved north from Boothia Peninsula by perhaps as much as 300 miles. About that time the United States cooperated with Canada in establishing weather and loran (long range radar aid to air navigation) stations on various islands of the archipelago, including such locations as Eureka Sound, Winter Harbour, and Cambridge Bay, and on Resolution and Nottingham islands.

(Ed.)

Greenland

Greenland (Danish Grønland; Greenlandic Kalaallit Nunaat), the largest island in the world and an integral part of the Kingdom of Denmark, lies in the Northern Hemisphere, on a northeastern extension of the structural shelf fringing the continent of North America. Its icy, inhospitable environment is mostly within the Arctic Circle and extends to within less than 500 miles (800 kilometres) of the North Pole.

Physical dimensions

Greenland forms a wedge-shaped mass of about 840,000 square miles (2,175,600 square kilometres), of which more than 700,000 square miles are ice covered. Its maximum north–south extension is about 1,660 miles, and it is some 650 miles across at its widest point, at about 70° N. The length of its indented coastline has been estimated at 24,430 miles—almost exactly equal to that of the circumference of the Earth at its Equator. Its southernmost tip is Kap Farvel (Uummannarsuaq), at 59°46′ N, while Kap Morris Jesup, at 83°39′ N, was, until a recalculation in 1969 of the position of Kaffeklubben Island, some 20 nautical miles to the east, considered as the nearest land to the North Pole. The westernmost point, Kap Alexander, at 73°08′ W, is farther west than the U.S. city of Boston, while its easternmost point, Nordostrundingen, at 12° W, is almost as far east as Ireland. At its narrowest point, Greenland is only 16 miles from Ellesmere Island in the Canadian north.

A submarine ridge, no deeper than 600 feet, connects the island physically with North America, from which Greenland is separated at sea level, from north to south, by the Nares Strait, the Robeson Channel, the Kennedy Channel, the Kane Basin, Smith Sound, Baffin Bay, Davis Strait, and the Labrador Sea. To the north lies the Lincoln Sea and the ice masses of the Arctic Ocean, while on the east and south lie the Greenland Sea, Denmark Strait, and the Atlantic Ocean. At a depth of about 2,000 feet, the Yermak Plateau, another submarine ridge, connects Greenland with Spitsbergen, while at the same depth the Faeroe-Iceland Ridge snakes across the ocean floor to Scotland and the European continent.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and geology.* Structurally, Greenland is an extension of the Canadian Shield, the rough plateau of the Canadian north, made up of hard Precambrian gneiss and granite rocks. In addition, the northern shoulders of Greenland (the mountains of Peary Land and their westward extension to Ellesmere Island) are structurally linked, via Spitsbergen, to the Caledonian orogeny of Europe.

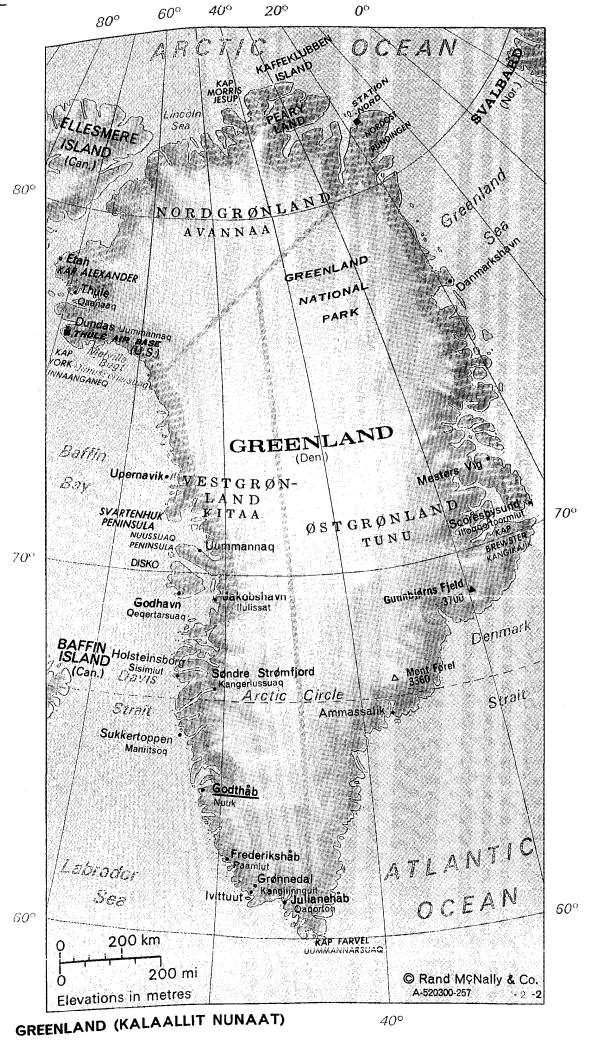
From the dawn of geological time, the vast mass of Greenland, now largely obscured by ice, has been molded by a series of volcanic and orogenic processes. At the earliest period, volcanic activity took place along the eastern edge. Later, sand and clay were washed out from ancient mountains into a long structural trough along the east coast. This became filled with layers of sandstone, limestone, and shale many thousands of feet thick, which were then uplifted to form the fold mountains of East Greenland. In more recent times, sandstones were laid down on both the east and west coasts, and coal of the Cretaceous Period, about 100,000,000 years ago, is found in the coastal areas of Disko Island (Qeqertarssuaq) and the Nuussuaq Peninsula. Later, about 50,000,000 years ago, further volcanic activity formed horizontal layers of hardened lava streams, which can be seen as black bands interlacing exposed rock faces. Basaltic survivals of this period are at the Scoresbysund (Scoresby Sound) hot springs area in the east, at Julianehåb (Qaqortoq) in the south, and on Disko Island and Nuussuaq and Svartenhuk peninsulas in the west. The fossils in the sandstones and coal deposits testify that a temperate climate existed in the Cretaceous Period.

The onset of the Ice Age, 1,000,000 or so years ago, totally changed the Greenland environment. Vast accumulations of ice slid from the interior to the coasts, scouring away the rock masses beneath through debris frozen to the base of the slowly moving ice. Lakes formed on the coastal periphery, and sand and clay plains also developed from sediments washed out from under the advancing ice. In the 20th century the indented, island-strewn coast forms, in part, a narrow, ice-free fringing strip. Long, deep fjords reach far into both the east and west coasts in complex systems, offering magnificent, if desolate, scenery. The Scoresbysund network on the east coast is the largest, with a length of about 185 miles and a breadth of 125 miles. A range of mountains 7,000 feet high also runs along the east coast, with Mt. Gunnbjorn, 12,139 feet, marking the highest point in Greenland. Along many parts of the coast, the ice sheet fronts directly on the sea, with large chunks breaking off the tongueing glaciers and sliding into the waters as icebergs.

The ice sheet

The ice sheet itself, the major feature of the Greenland landscape, is the largest ice mass found outside of Antarctica. It is contained by coastal mountains on the east and, to a lesser extent, on the west, although the rock floor far beneath its surface is at, or slightly beneath, current sea level. The average depth of the ice is 5,000 feet, with a maximum depth of 10,000 feet. Layers of snow falling on its barren, windswept surface become compressed into ice layers, which constantly move outward to the peripheral glaciers—the Jakobshavn Glacier, often moving 100 feet a day, is among the world's fastest glaciers. Nunataks—lofty, isolated peaks—emerge occasionally around the rim of the ice sheet, whose total area is 708,100 square miles.

Climate. The climate of Greenland is bleak and Arctic, modified only by the slight influence of the Gulf Stream in the southwest. Rapid changes, from dazzling sunshine to impenetrable blizzards, are common and result from the eastward progression of low-pressure air masses over a permanent layer of cold air above the ice. January average temperatures at Prins Christianssund, the southernmost station, are 21° F (−6° C) with July readings of 45° F (7° C), while at Station Nord, the northernmost station, the corresponding figures are −31° F (−35° C) and 39° F (4° C). Average monthly precipitation decreases from 9.3 inches (238 millimetres) in the south to 0.6 inch (15



GREENLAND (KALAALLIT NUNAAT)

millimetres) in the north, with summer rainfall concentrated in the southwest; snow can, and does, fall in any month. Although summers can be quite pleasant on the southwest coast, the inland ice is uniformly cold, with a July average of 10° F (−12° C) and a February mean of −53 F (−47° C).

In 1966 U.S. Army engineers drilled a 4,600-foot (1,400-metre) ice core near Dundas (Uummannaq), and in 1974 another 1,325-foot core was drilled in central Greenland. The cores have been studied to determine and date climatic fluctuations up to 100,000 years ago and to establish correlations with the fossil "raised beaches" of the coasts, which indicate relative changes in sea and land levels. The climate became noticeably warmer during the early part of the 20th century, with a 1930 maximum, associated with northward seal movements and an increase in the cod population. By the late 20th century, sea temperature was dropping again, causing a serious decrease in cod fishing.

Recent climate changes

Plant life. The vegetation of Greenland is represented mainly by tundra types, with heather, birch, willow, and alder scrub together with sedge, cotton grass, and lichen. The Greenland summer is rich in plant life. Of the 400 or more species, 300 are of North American origin, 50 or so were imported by the earliest Norse inhabitants, and the rest, on the isolated nunataks, have survived the ice ages. In southernmost Greenland, winter hay is grown for sheep, and along the western coast such vegetables as radishes, cabbage, and lettuce are raised, with potatoes in the extreme south.

Animal life. The rich animal life of the surrounding seas is the basis of existence for Greenlanders. The sea mammals—seals and whales—were formerly the main sources of nourishment, with ring- and black-sided seals predominating. Land mammals are represented by seven species—polar bears, musk-oxen, reindeer, arctic foxes, snow hares, ermines, and lemmings. Half of the breeding birds are native, and most of the remainder are from North America. The most important sea birds are eiders, guillemots, auks, wild geese, ducks, and gulls, while land birds include ptarmigans, ravens, white-tailed eagles, gyrfalcons, peregrine falcons, snowy owls, snow buntings, and longspurs. Among insects, mosquitoes appear in summer. Salmon and trout are found in the rivers, while cod, salmon, flounder, halibut, and *angmagssat* (capelin) are important saltwater fish.

The people. Ancient and modern influences had created by the late 20th century a uniquely blended society in Greenland. The strongest element stems from Eskimo culture, whose representatives, many with admixtures of European blood, are known as Greenlanders. By the late 20th century they accounted for more than three-quarters of the total population. The pure Eskimo are now found only in the far north, near Thule, and in East Greenland. In terms of origin, the Eskimo are believed to have crossed from North America to northwest Greenland, using the islands of the Canadian Arctic as stepping stones in a series of migrations that stretched from 4000 BC to AD 1000. Each wave of migration was represented by different cultures, beginning with Independence cultures (named after a nearby fjord), which followed the musk-ox and reindeer north to Peary Land. About the same time, the Sarqaq culture spread along the west coast and even reached east Greenland, although the lack of hunting grounds impeded movement around the northern rim of the island. Later migrations brought the Dorset, Dundas (Thule), and Inugsuk cultures.

The Eskimo contribution

Greenlanders today retain a clear linguistic and cultural identity (the Eskimo refer to themselves collectively as Inuit, or Innuit, meaning "the people"). The Eskimo dialects, taken together, form a language group differing from all others. A Greenlander grammar (1851) and a dictionary (1871) built up an Eskimo literary language, and Eskimo is the predominant spoken language of Greenland. The material culture, especially in the north, includes such beautifully constructed practical hunting equipment as the kayak, often considered the most elegant boat in the world.

The second element in Greenland society is represented by European, specifically Danish, influence. Apart from the early Norse settlers—whose colonies became extinct

MAP INDEX

by the early 15th century as a result of climatic deterioration and who left only an archaeological legacy—the Eskimo remained the sole inhabitants of the island until 1721, when a Danish missionary initiated new settlement. Greenland was a closed society until 1951, and Danish immigration was small, consisting largely of administrators. Faeroese and Danish settlement increased during the 1950s and 1960s. The modernization of Greenland society was given great impetus by developments in air communications and global strategy during and following World War II. Lying between the great superpowers of the Northern Hemisphere, Greenland became of prime importance in radar and air communications and in weather observations. One result was the construction of the giant United States base at Thule in 1951, although American personnel had little direct contact with, or influence on, the indigenous population.

Permanent settlement is extremely dispersed and entirely confined to the coastal fringe. About three-fifths of the population is urban, a proportion that is growing as a continuation of trends visible after World War II: concentration and industrialization of the fishery industry in the towns, the growth of job opportunities in these towns, and the concomitant decline of village-based fishing and hunting. The capital, Godthåb (Nûk), contains about a fifth of the urban population. Demographically, since mid-century the population has experienced a decline of about two-thirds in its death rate, a consequence of improved health care and nutrition, and a decline of more than half in its birth rate, due to increasing sale and use of contraceptives.

The economy. Seal hunting, once the mainstay of the Greenland economy, declined drastically in the early part of the 20th century, partly as a result of overintensive hunting and partly due to climatic amelioration. By the late 20th century sealing was still the occupation of a small portion of the population, based mainly along the western coast near Ûmának, Upernavik, and Thule, but also along the east coast of Greenland. Fishing, which flourished in the warmer waters, replaced seal hunting as the most important economic activity, and cod fishing, canning, and freezing have played major roles in modernizing Greenland's economy and sustaining population growth. The state owns most fishing plants and several fishing trawlers. There are also a small number of private plants and a large number of private trawlers and smaller fishing boats. The combination of lowered water temperatures and overfishing, however, had reduced landings of cod and other species by the mid-1980s to the point that employment, export earnings, and control of inflation were at risk. These risks, however, were probably short-term, pending determination by marine biologists of sustainable yields for fish stocks that would permit control by quota.

Hunting and fishing

Animal husbandry is marginally possible in the milder southwestern portion of Greenland, where reindeer, first introduced from Norway in 1953, and sheep are raised.

Mining

Mining operations have been erratic: deposits may be rich, but extraction and transportation costs have often been high. The Ivigtut cryolite mine, opened in 1864, closed down its production in 1963, when it proved no longer economically feasible to operate what had been the world's largest natural deposit of this mineral. The coal deposits on Disko Island and the zinc and lead mines at Mesters Vig have been exhausted or are uneconomical to mine. On the other hand, extensive explorations by international companies have discovered considerable potential in terms of uranium, molybdenum, zinc, lead, and other important deposits, and copper deposits were discovered on the east coast of central Greenland. Lead and zinc mining began along the western coast in the late 20th century.

Greenland's trade has continued to fall largely into government hands, in spite of the ending of the official state trading monopoly in 1951. The Royal Greenland Trade Department (Den Kongelige Grønlandske Handel; KGH) continues to supply the country with necessary goods by controlling the import-export business. There is a great excess of imports over exports. The state employs the largest number of Greenlanders—more than one-third of the labour force—and a large contingent of Danes are economically active in the public and private sectors. Greenland's industrial enterprises, like its trade, are either private or government concerns. The latter are run by the KGH or the the Greenland Technical Organization (Grønlands Tekniske Organisation; GTO), which transfers its small factories, workshops, and other enterprises to local, private ownership after setting them up. A good proportion are now in Greenlander, as opposed to Danish, ownership.

Transportation. By the late 20th century the transportation system of Greenland, both internal and external, had undergone a complete transformation linked with the development of a market economy and with technological improvements, notably in air communications. Freight continues to be largely shipped by sea, although access to the ports is seasonally interrupted, while mail and passenger traffic are usually airborne. The airport at Søndre Strømfjord (Kangerlussuaq), in addition to its function as a stopover on transpolar flights to North America and Asia, handles passengers and mail travelling between Greenland and North America and Denmark. Flights to and from Denmark—most often via Iceland—also use airports in East Greenland and in Narssaq in southernmost West Greenland. Helicopters provide internal service between the western towns and the airports at Søndre Strømfjord and Godthåb; a passenger plane has also operated out of Godthåb since 1979.

Traditional dog-drawn sledges remain indispensable to travel in East, North, and northernmost West Greenland. Almost three-fourths of Greenland's motor vehicles and all of its motorcycles are privately owned. There is a high number of vehicles in relation to the island's small road network.

Greenland has a sophisticated telephone, telegram, telex, and radiotelephone network, as well as a military communications network associated with NATO and the North American radar defense system.

Administrative and social conditions. *Government.* On November 29, 1978, the Danish parliament approved legislation granting home rule to Greenland. The legislation was approved by Greenland in a referendum held in January 1979, and it became effective on May 1, 1979. In accordance with home rule, Greenland remains under the Danish crown, which retains jurisdiction over foreign affairs. Each Greenlander is a Danish citizen, enjoying equal rights with all other Danes.

Links with Denmark

Greenland's parliament, called the Landsting, is composed of 21 members elected to four-year terms by all adults 18 years of age or older. The leader of the majority party in the Landsting becomes the chairman; he forms an administration, the Landsstyre, that is composed of himself (as chairman) and four other members of his party from the Landsting. Meetings of the Landsting are scheduled twice each year, each session of about one month's duration; committees are constituted to act as intermediaries between the Landsting and the Landsstyre.

Some matters of government were immediately transferred to the Landsting from Denmark's Ministry for Greenland, while others were to be transferred on a gradual, scheduled basis. The Ministry for Greenland continues to act as a link between the Greenland government and that of Denmark. The two governments are also linked by the two members of the Danish Parliament elected from Greenland by all Danish subjects (Greenlanders and Danes) 18 years of age or older who are resident in Greenland. The local representative of the Danish government in Greenland is the Rigsombudsmand (High Commissioner), whose duties are similar to those of a county prefect.

Greenland is divided into three administrative districts—Nordgrønland (North Greenland), Østgrønland (East Greenland), and Vestgrønland (West Greenland). There are, in addition, a number of municipalities, each with a council elected by adult suffrage every four years and chaired by its locally elected burgomaster.

Justice. The High Court (Landsret) consists of a judge, a graduate of the faculty of law of the University of Copenhagen, and two lay judges. The district courts are headed by lay judges, from whom appeal can be made to the High Court, and, ultimately, to the Supreme Court

in Copenhagen. The police districts are headed by a chief constable.

Education. The educational system is administered by the Director of Education for Greenland, with inspectors for every school district. Preschool and kindergarten facilities are either public or attached to factories. Since 1979, education has been compulsory for the nine years of elementary school, but attendance is voluntary for the next four years—two years in "continuation" school and two in "course" school. There is a teacher-training school in Godthåb, and occupational and vocational training is available at several schools. Special vocational training is available in Denmark, where Greenland's students may also prepare for, and study at, universities and other higher educational institutions. An educational board was established by the Landsstyre in Copenhagen to supervise the education of Greenlanders in Denmark.

Health and welfare. The health service is state supported and without charge, utilizing Danish-trained staff, a doctor, and a small hospital in each district. The central hospital is located in Godthåb. An intensive campaign has nearly eliminated tuberculosis, which was a leading cause of death in the mid-20th century.

The social welfare service is under the jurisdiction of the Landsstyre, which acts in cooperation with the municipal councils. Welfare services are paid for by the Danish government in an annual grant to the Landsstyre. Despite a general improvement in the standard of living in Greenland, the range of social welfare services is wide. A major problem is that of unemployment, which varies from one municipality to another and with the seasons. The Social Welfare Department operates a branch in Copenhagen to care for Greenlanders living in Denmark.

Cultural life. The cultural heritage of the Greenlanders finds most prominent expression in the Eskimo material culture: kayaks, umiaks, sledges, harpoons, and soapstone lamps, all of which have a close relationship to the environment. Cultural values, in the wider sense, arose from the design concepts developed during the construction of these artifacts and found expression in sculptures (some made for the commercial market) in the mediums of ivory, wood, and soapstone. Eskimo legends maintain a relationship to the past and to other Eskimo groups around the Arctic (see above *Arctic cultures*). Modern poetry attempts to revive old traditions but points to a break between Greenlandic and Danish culture, with the Greenlander feeling the danger of losing his cultural identity in the developing market economy and modern European values. A folk high school attempts to support Greenlandic traditions.

Crisis in cultural identity

The press of Greenland dates back to the 1860s, when the newspaper *Atuagagdliutit* (literally "Something to Read") made an appearance in Godthåb. It is still published, in Greenlandic and Danish. There is also an embryonic local press, a product of the movement in the late 20th century to the towns. Broadcasting, which started in World War II, has expanded considerably and provides a wide range of programming.

HISTORY

The history of Greenland is bound up with the history of Arctic exploration. Since the 10th century people have not only settled on the coast but have visited and explored the island in the course of their journeys into the polar regions.

Discovery and exploration. *Exploration of the coasts.* In the beginning of the 10th century the Norwegian Gunnbjorn Ulfsson (son of Ulf Kraka) is reported to have found islands to the west of Iceland. In about 982 Erik the Red sailed from Iceland to find Gunnbjorn's land and spent three years on Greenland's southwestern coasts. On his return in 985 he called the land Greenland in order to make people more willing to go there; and in 986 he started again with 25 ships, of which 14 reached Greenland, where a colony was founded on the southwest coast (see below *Colonization and political developments*). Communication between the Norse settlements and Norway, however, was broken off in the 15th century. In the following century Danish and Norwegian expeditions tried in vain to reestablish the communication, and the rediscovery of Greenland was made by the English navigator Sir Martin Frobisher, who landed on the west coast of Greenland in 1578.

Other explorers, including Gaspar Côrte-Real, had meanwhile seen it, and the work of John Davis (1586–88), Henry Hudson (1610), and William Baffin (1616) afforded further knowledge of the west coast. The east coast was sighted by Hudson at about 73°30′ N in 1607 and in 1617 by the Dutchman Joris Carolus at about 66° N. During the 17th century the coasts were probably visited by many whalers who finished the rediscovery of the country's outline.

The first Danish settlement

Exploration was impossible without bases on the coast and was not started until 1721, when the Danish-Norwegian missionary Hans Egede founded a settlement near Godthåb on the west coast. Egede studied the nature and the people, travelling northward and southward from Godthåb, and in 1752 Peder Olsen Walloe reached a point at 61° N on the east coast.

In the 19th century scientific exploration was accelerated. The southern west coast was mainly explored by Danes from the Danish settlements there, but in the northern region of the west coast English and American explorers were leading. John Ross (1818) found the polar Eskimos at Cape York; E.A. Inglefield (1852) sailed into Smith sound; E.K. Kane (1853–55) worked northward through Smith sound into Kane basin; and C.F. Hall (1871) explored Kennedy strait and Robeson channels to the north of Kane basin. The first to give more accurate information of the east coast was William Scoresby (1822), who made the first fairly trustworthy map of the coast between 69° and 75° N. Captains E. Sabine and D. Clavering visited this coast in 1823 and met the only Eskimo ever seen in this part of Greenland. The German K. Koldewey expedition reached 77° N (Cape Bismarck) in 1870, and the Duke of Orléans penetrated to about 78°16′ N in 1905. The rest of the northern east coast was explored by the Danish L. Mylius-Erichsen–J.P. Koch expedition (1906–08), which discovered Northeast Foreland, the easternmost point. E. Mikkelsen (1909–12) mapped those regions. The southern part of the east coast was first explored by the Dane W.A. Graah (1929–30), and other Danes, G. Holm and T.V. Garde (1883–85) and C. Ryder (1891–92), mapped, respectively, the coast from Cape Farewell to 65°16′ N and the Scoresby Sound. The Dane G. Amdrup (1899–1900) explored the still unknown coast between Angmagssalik and 69°10′ N and the Swede A.G. Nathorst (1899) discovered the large King Oscar Fjord.

Toward the close of the 19th century several explorers visited north Greenland, including L.A. Beaumont of the Nares Expedition (1876), J.B. Lockwood of the Greely Expedition (1882), and R.E. Peary on several journeys (1892, 1895, and 1901). The Danish exploration of north Greenland began in 1910 with the foundation of the station of Thule in North Star bay (at 76°32′ N) by K. Rasmussen. It was the base of five Danish expeditons under Rasmussen and L. Koch.

In 1924–34 expeditions under Rasmussen, Koch, and Mikkelsen continued researches on the east coast, which was also explored by the English–Danish expedition under A. Courtauld and E. Munck (1935–36) and by E. Knuth's expedition in 1938–39. After World War II Koch and Knuth continued their work on the east coast. Great areas were mapped from airplanes.

Exploration of the ice cap. Exploration of the great ice cap, or inland ice, which covers the whole of the interior of Greenland, was attempted in the 18th century but failed and so did E. Whymper's and R. Brown's attempt in 1867. Jens Jensen reached, in 1878, the Jensen nunataks (5,512 feet above the sea) about 45 miles from the western margin at 62°50′ N. A.E. Nordenskiöld penetrated, in 1883, about 80 miles inland at 68°20′ N and two Lapps of his expedition went still farther on skis to about 43° W, at an elevation of 6,600 feet. Peary and C. Maigaard reached, in 1886, about 100 miles inland, a height of 7,500 feet at 69°30′ N. The Norwegian Fridtjof Nansen, with five companions, in 1888 made the first complete crossing of the inland ice, working from east to west,

about 64°23′ N, and reached a height of 8,922 feet. Peary and E. Astrup, in 1892, crossed the northern part of the inland ice between 78° and 82° N and determined the northern termination of the ice covering. Mylius-Erichsen crossed the northeastern corner of the inland ice in 1907, as did Mikkelsen in 1910. In 1912 K. Rasmussen and P. Freuchen crossed from Inglefield Gulf to Danmarkfjord and back and verified that Peary Land is an integral part of Greenland and not, as previously supposed, separated by a strait. In 1912 the Swiss A. de Quervain crossed the inland ice from Disko Bay to Angmagssalik and J.P. Koch and A. Wegener crossed from Louise Land on the northeast coast to Upernavik on the west coast in 1913. The first crossings of the inland ice by airplane were made in 1931 by the German W. von Gronau from Scoresby Sound to Godthåb and by the American Parker Cramer from Holsteinborg to Angmagssalik.

The development of modern air traffic and the fact that Greenland weather is of fundamental importance for predicting conditions on the North Atlantic and in western Europe have meant that since about 1930 weather observations were an important reason for Greenland explorations. In 1930–31 a British expedition under H.G. Watkins made weather observations high on the inland ice 40 miles north of the Arctic Circle; at the same time a German expedition under A. Wegener wintered 300 miles farther north. In 1933 a University of Michigan expedition went up still farther. During World War II Allied military weather stations were at work, and after the war there were weather stations from the south to the far north.

F. Johnstrup first advocated the foundation of a permanent geological survey of Greenland in 1944. Seven years later, in 1951, Grønlands Geologiske Undersogelse became a permanent institution, and since then exploration has been centred on geology, structure, movement of the inland ice, and hydrography. Both Danish and foreign expeditions have undertaken this work. (H.Ln.)

Colonization and political development. *Early settlement.* After discovering Greenland in about 982, Erik the Red settled just north of the present Julianehåb. Soon two colonies had been formed, Eystribygd, in the present district of Julianehåb, and Vestribygd, farther north, in the present district of Godthåb. At the height of their prosperity the colonists numbered about 3,000 on 280 farms. Numerous ruins indicate the location of these colonies. Somewhat later the colonists met the Eskimos farther north in the neighbourhood of Disko Bay, where the Norsemen went to catch seals and walrus. The Eskimos were probably migrating south at that time. Christianity was introduced by Leif (Leifr) Eriksson about 1000, and in 1126 Greenland was assigned its own bishop, who lived at Gardar on Igalikofjord.

Greenland allegiance to Norway

Greenland was a republic until 1261, when the colonists swore allegiance to the king of Norway, who in return charged himself with supplying them with commodities. In the 14th century deterioration in Greenland's climate made it difficult to breed cattle, the colonists' main livelihood. Moreover, the monopolistic trading policy, forced on the kings by the Hanseatic merchants, caused grave trouble to the Greenlanders' trade, and in consequence the colonists diminished in number, and in the 15th century the settlement became extinct. The last vessel from Greenland returned to Norway in 1410, but vessels in the Icelandic fish trade may have visited Greenland until about 1500. Excavations in the Norse burial grounds show 15th-century European influence in the style and texture of the clothes; there is no indication of absorption into the Eskimo groups or of destruction by Eskimo onslaught. Skeletons that show malformation suggest extermination by excessive intermarriage and adverse conditions of life. (B.S.B.)

Recolonization. Norway had been united with Denmark in 1380–81, and in the 16th and 17th centuries the Danish kings several times planned to resume communication with Greenland. The recolonization of Greenland began in 1721 with the voyage of the missionary Hans Egede to Godthåb. He thought that he would find descendants of the Norsemen, but he found only Eskimos. He was deeply disappointed but stayed and started medical and missionary work among them. It was his idea that the economic activities of the colony were to be entirely subordinated to his missionary work. This, however, proved impossible, and a few years later the Danish state had to come to his assistance. Later the Greenland trade was assigned to private interests, but in 1774 it was again taken over by the state and was carried on as a government monopoly until 1951, when Greenland was opened to private Danish enterprise, though the government-owned Royal Greenland Trading company continued its activities. During the period of the government monopoly, Denmark aimed to aid the Greenlanders in cultural respects so as to enable them gradually to establish contact with the outside world without becoming subject to exploitation. Consequently Greenland was shut off from free contact with the outside world, and all resources were reserved for the Greenlanders, who were to sell their surplus production in return for goods required for maintaining and further developing their standard of life.

Establishment of Danish sovereignty. At the dissolution of the union between Norway and Denmark in 1814, Greenland was retained by Denmark. Until 1916 Denmark's sovereignty extended only over the west coast between Cape Farewell and 74°30′ N and the one trading station of Angmagssalik on the east coast, founded in 1894. In 1916, however, the United States declared that it had no objection to the extension of Denmark's political and economical interests to the whole of Greenland. Similar declarations were made by other countries, including Great Britain, and in 1921 Danish sovereignty was extended to embrace the whole island, which led to a dispute with Norway regarding hunting and sealing rights in the uncolonized areas of the east coast. In 1931 some Norwegian hunters, on their own initiative, occupied the east coast between 71° N and 75° N in the name of the Norwegian king, and after some hesitation the Norwegian government recognized the occupation. Denmark at once summoned Norway into the International Court of Justice at The Hague, and in 1933 the occupation was found invalid, the premises stating that Danish sovereignty extended over both the colonized and the uncolonized areas of Greenland. In 1924 a colony had been founded on Scoresby Sound on the east coast, and the privately founded colony of Thule in the far north was taken over by the government in 1937.

Temporary U.S. protectorate

On April 9, 1941, a year after the German occupation of Denmark, Henrik Kauffmann, Danish minister to the United States, signed an agreement that made Greenland a temporary protectorate of the United States. Danish sovereignty was recognized, and the arrangement was to last only for the war emergency; the United States obtained the right to build bases for aircraft and radio and weather stations and to "do any and all things necessary" to hold these positions. New York City displaced Copenhagen as the key point for export and import arrangements, but local Danish officials and the existing Danish government system continued almost unaltered. After World War II the communication between Greenland and Denmark was fully resumed, but U.S. forces remained in some bases. On April 27, 1951, however, an agreement was signed in Copenhagen between Denmark and the United States for the joint defense of Greenland, concluded within the framework of the North Atlantic Treaty Organization (NATO) and replacing the provisional agreement of April 9, 1941. In the areas under U.S. command the United States would enjoy certain rights of use without impairing Danish sovereignty; all defense areas could be used by the ships, aircraft, or armed forces of other NATO countries; U.S. forces in Greenland would respect Danish laws and administration concerning the indigenous population. In accordance with this agreement the United States, in 1951, started the establishment of the great air and radar base at Thule. In 1947 a special committee of Greenlanders and Danes was set up to examine measures to modernize Greenland's political, social, and economic life in accordance with the Greenlanders' desires and the necessity of bringing their way of life to conformity with the new epoch that had come to Greenland as a consequence of modern air strategy and air communications. The examinations

resulted in the abolition of the monopoly of the Royal Greenland Trading Company in 1951 and of the colonial status of Greenland in 1953, when Greenland became an integral part of the kingdom of Denmark. In the following years housing and health services were improved, and harbour and canning facilities increased the possibilities of the fishing trade. (H.Ln.)

Novaya Zemlya

Novaya Zemlya is an Arctic archipelago off the coast of the Russian Soviet Federated Socialist Republic, U.S.S.R. Administered as part of Archangel *oblast*, it consists of two large islands separated by a narrow winding channel 56 miles long, the Matochkin Shar (strait), and many small islands. It lies between latitudes 70°26′ and 77° N and between longitudes 51°26′ and 69°12′ E and forms an elongated crescent, being more than 600 miles long, with a width of 25 to 68 miles and an area of about 31,382 square miles. It separates the Barents Sea on the west from Kara Sea on the east. Along with Vaygach Island, 30 miles to the south, Novaya Zemlya (New Land) forms a continuation from the mainland of the Khrebet Pai-Khao, a branch of the Ural folds.

PHYSICAL GEOGRAPHY

The greatest heights occur near Matochkin Shar (about 3,500 feet). Ice covers about a quarter of the total area, lying mostly in the north island.

A central zone of upper Cambrian and Devonian rocks extends along the islands. These quartzites, conglomerates, and dolomites are flanked by carboniferous shales and limestones. Copper and other metallic ores are known. The coast is severely indented and has raised beaches that give good landing places.

Novaya Zemlya is colder than Spitsbergen (which lies more to the north), as in some degree it shares in the continental conditions of northern Russia and Siberia. The middle and northern parts of the west coast are not so cold as the east. Temperatures at Karmakuly on the west coast (the warmest part) are 2° F (−17° C) in February and 43° F (6° C) in July. Snow is universal from October to May.

Climate

Vegetation is solely tundra and decreases from south to north. It is most luxuriant in the southwest. There are few trees or bushes. The flowering plants number about 200.

In the ice-free areas there are foxes, lemmings, bears, and reindeer. Insects are numerous near the coast. Countless birds come from the south for the breeding season, and at certain parts of the seacoast the rocks are covered with millions of guillemots, while great flocks of ducks, geese, and swans swarm every summer on the valleys and lakes of the south. Whales, walruses, and various seals are frequently seen. The Arctic char and some salmonate species appear in the rivers, and cod frequent offshore waters.

The abundance of sea mammals and birds attracted Russian hunters, and even in the 16th century they had extended their huts to the extreme north of the island. Many of them wintered for years on Novaya Zemlya. Because of the ice in the White Sea, Russian hunters found Novaya Zemlya less accessible than did the Norwegians. But about 1877 systematic attempts at settlement were begun by the Russian government, several families of Nenets (Samoyeds) being established at stations on the west coast of the south island, including Pomorka Bay and Belushya Bay, and Malye Karmakuly on Moller Bay.

HISTORY

Novaya Zemlya was probably known to Novgorod hunters in the 13th century and to Norse hunters earlier still. In 1556 Stephen Borough reached the southern extremity of Novaya Zemlya, being the first western European to do so. Willem Barents touched the island (1594) at Sukhoy Nos (latitude 73°46′) and followed the coast north to the Orange Islands (Ostrova Oranskiye) and south to the Kostin Shar. In 1596, after his discovery of Spitsbergen, Barents wintered at Ice Haven, 76°12′ N. In 1760 Savva Loshkin cruised along the east coast; he spent two winters there and in the next year returned along the west coast, thus accomplishing the first circumnavigation; but the records of his voyage have been lost. In 1768 Lieut. F.F. Rozmyslov explored Matochkin Shar, where he spent the winter. The first scientific information about the island is attributable to the expeditions (1821–24) of F.P. Litke (Lütke; 1797–1882). Nearly all the west coast as far as Cape Nassau, as well as Matochkin Shar, was mapped and valuable scientific information obtained. In 1832 and 1835 Lieut. P.K. Pakhtusov mapped the east coast as far as 74°24′. Karl Ernst von Baer made further investigations in 1837, and A.K. Tsivolka in 1838–39. Expeditions have become less dramatic and more numerous since the middle of the 19th century, particularly since 1920. A weather station has functioned at Karmakuly since 1896; to this was added an observatory at Matochkin Shar (1923), and further weather stations at Cape Zhelaniya (1931), Russkaya Gavan (1932), Capes Stolbovoy and Vykhodnoi (1934), and Cape Menshikova (1953). The settlements in the south island continued to exist, maintained by trapping, raising reindeer, and collecting eiderdown. (T.E.Ar.)

Svalbard

Svalbard is part of the kingdom of Norway and comprises all islands in the Arctic Ocean between longitudes 10° and 35° E and latitudes 74° and 81° N. The main group of islands, known as Spitsbergen, consists of Vestspitsbergen, Nordaustlandet (North East Land), Edgeøya (Edge Island), Barentsøya (Barents Island), Prins Karls Forland (Prince Charles Foreland), and numerous smaller islands. Surrounding the Spitsbergen group from north to south on the east are Kvitøya (White Island, or Gilles Land), Kong Karls Land (King Charles Land, or Wiche Islands), and Hopen (Hope Island). Farther to the south is Bjørnøya (Bear Island). The total area of Svalbard is 23,958 square miles, that of the Spitsbergen group is 23,641 square miles, with Vestspitsbergen 15,075 square miles. Other areas are: Nordaustlandet 5,610 square miles; Edgeøya 1,942 square miles; Barentsøya 514 square miles; Prins Karls Forland 247 square miles; Kong Karls Land 128 square miles; Kvitøya 102 square miles; Bjørnøya 69 square miles; and Hopen 18 square miles. There are no indigenous inhabitants. The population, consisting of miners and administrative staff living at the Norwegian and Soviet mining towns (see below), and some trappers and radio operators, changes seasonally. The administrative centre is Longyearbyen in Vestspitsbergen.

PHYSICAL GEOGRAPHY

The land. *Relief and geology.* More than half of Svalbard is covered by ice. The mountains along the west coast of Vestspitsbergen are rather wild with sharp ridges and peaks formed by folded and metamorphic pre-Devonian sediments. The eastern part of the island and Edgeøya and Barentsøya have plateau-formed mountains built up of nearly horizontal, younger sediments. In the northern part of Vestspitsbergen and Nordaustlandet there are more rounded mountains built up partly of granites and gneisses. The highest peaks are in Ny Friesland, where Newtontoppen reaches 5,633 feet. In the southern part of Vestspitsbergen, Hornsundtind (4,695 feet) is the highest mountain. Many large fjords penetrate the west and north coasts of Vestspitsbergen. The most important are Hornsund, Bellsund with Van Mijenfjorden and Van Keulenfjorden, Isfjorden with several branches, Kongsfjorden and Krossfjorden on the west coast, and Woodfjorden and Wijdefjorden on the north coast. The west and north coasts of Nordaustlandet are also indented by fjords, but the east coast of this island is formed by the front of the inland ice. Many of the glaciers reach the sea, but in Vestspitsbergen there are also large ice-free valleys, such as Sassendalen, Adventdalen, Colesdalen, and Reindalen. In many parts of the coast there are extensive coastal plains, formed by the sea when its level was higher. Bjørnøya consists of an ice-free plain with many lakes, rising to Miseryfjellet (1,759 feet) in the southeast.

Svalbard's mountains

The principal features of the geology are known. Most formations from early Paleozoic, and perhaps Archean, to Recent, occur. The oldest rocks appear chiefly on the west and north, including Prins Karls Forland and

Nordaustlandet. They are the Heclahuken (Hecla Hoek) series of Precambrian, Cambrian, and the Ordovician dolomites, limestones, shales, and quartzites that form the Caledonian folds and overthrusts of the west. The folds can be traced as far east as the west of Nordaustlandet. Granite and gneiss were probably involved in the Caledonian foldings. The metamorphosed Hecla Hoek series and eruptives are in the northwest, uncomformably overlain by Devonian sandstones and shales. These are unconformably followed by Lower Carboniferous sandstones and shales with some coal, Middle Carboniferous or Upper Carboniferous limestones, Permocarboniferous cherts, and Permian sandstones and shales. Next come Triassic, Jurassic, and Cretaceous sandstones, and shales with some small coal seams. Unconformably, Tertiary sandstones and shales with several coal seams follow. Tertiary folding is obvious in the west against the Hecla Hoek beds. In the central part of southern Vestspitsbergen the Tertiary beds form a large syncline. Heavy faulting also occurred in Tertiary times. Intrusions of dolerites and basalt were probably of Cretaceous (Neocomian) date. An extinct volcano and several hot springs (28° C [82° F]) in Bock Bay are Quaternary. The *strandflat* is well developed up to 180 feet; and postglacial raised beaches are marked. Glacial and postglacial debris on low ground generally mask the solid rock, and loose screes form fans on the lower slopes. Many Devonian and later deposits in Svalbard are extremely rich in fossils.

Climate. The sea around Spitsbergen is shallow, and ice readily accumulates around the shores. Pack ice prevents access to most shores except for a few months in the year. The warm North Atlantic drift, however, sends a branch to the western shores of Spitsbergen, moderating its climate and leaving an open passage that permits vessels to approach the western coast during most months of the year. The fjords are frozen from October or November to May or June.

February and March temperature means are about 5° F (−15° C), and July means are about 43° F (6° C). Extreme temperatures may rise to more than 70° F (21° C) in summer and fall below −40° F (−40° C) in winter. In September, autumn sets in. The Arctic night begins in October and lasts until the end of February. The annual precipitation at Grønfjorden (Green Harbour) is 11.6 inches; precipitation is often less in the interior. Winds are generally light except on the west coast. There is mist in the west.

Plant and animal life. The only trees are the polar willow, which does not exceed two inches in height, and the rare dwarf birch (*Betula nana*). The vegetation consists mostly of lichens and mosses, variegated with the golden-yellow flowers of the ranunculus, the large-leaved scurvy grass, the cuckoo flower, many saxifrages, foxtail grass, etc.; while on the driest spots yellow poppies, whitlow grasses, and mountain avens are found—poppies sometimes even on the higher slopes, 2,500 feet or more above the sea. Most species of flowering plants are also found in Europe and many are circumpolar. In the ice-free valleys of Vestspitsbergen there is a comparatively rich vegetation of *Salix polaris,* grasses, moors with cotton grass, and Arctic flowers.

According to the explorer William Scoresby, no fewer than 57,590 whales were killed between 1669 and 1775. Reckless extermination of seals also took place. Walruses are now rarely seen in the water west of Spitsbergen. There is a rich bird life. The fulmars, the glaucous gull or burgomaster, little auks, black guillemots, ivory gulls, and kittiwake gulls breed on the cliffs, while Arctic (Brünnich's) guillemots, puffins, pink-footed brant and barnacle geese, purple sandpipers, red-necked phalarope and other waders, and Arctic terns frequent the tundra and its pools. The commonest passerine bird is the snow bunting. The eider duck breeds on the islands, but its numbers have become noticeably reduced. These birds, however, are only summer visitors, the ptarmigan being the only species that stays permanently. Red char are the only fish found in the rivers and lakes. Land mammals are the polar bear, reindeer, and Arctic fox (both blue and white). There was heavy slaughter of reindeer before they became protected in 1925. The musk-ox, introduced from Greenland in 1929, is also protected and has thrived, unlike the Arctic hare, another import from Greenland.

The economy. Except for coal deposits, ore and mineral deposits are rather poor and scanty. Deposits of anhydrite with gypsum, marble, iron ore, asbestos, galena, zinc blende, and pyrites have been found. Coal deposits were discovered in 1610, but it was not until the beginning of the 20th century that the deposits were thoroughly surveyed. From 1898 to 1920 many areas, most of them containing coal seams, were claimed by companies and persons from various countries. When Norway took over the sovereignty, a Danish commissioner was nominated to decide upon the ownership of these claims. He recognized a total area of 1,631 square miles as private property, of which by the late 20th century the majority belonged to Norway and the remainder to the Soviet Union. All other land is the property of the Norwegian government and may not be transferred into private possession, but the subjects of all signatory powers to the treaty of 1920 have equal rights to exploit mineral deposits. Coal mining on a commercial scale was started by John M. Longyear's Arctic Coal Company (Boston) in Longyeardalen, south of Adventfjorden, in 1906 and by an English company on the north side of this fjord. The U.S. company exported 147,000 tons of coal between 1907 and 1915. In 1916 the property was sold to a Norwegian group that established Store Norske Spitsbergen Kulkompani A/S. A Swedish mine that was worked during 1917–25 at Sveagruva on the north side of Braganzavagen was sold to Store Norske in 1933. A Dutch company worked the mines at Barentsburg on the east side of Grønfjorden until 1926, but sold the property to the Soviet company Arktikugol in 1932. This company also took over the properties at Grumantbyen and Pyramiden. In the late 20th century the Store Norske's in Adventdalen and Arktikugol's at Barentsburg and Pyramiden were still being mined.

Mineral claims

Apart from mining, the only economic activity is trapping and hunting of fox, polar bear, and seal, and increasing activity by U.S., Soviet, and Norwegian oil prospectors.

Besides the coal steamers, a mail and passenger steamer makes trips during the summer from Tromsø to the Vestspitsbergen harbours. In summer Svalbard is also visited by large tourist steamers and many sealers. There are navigation lights and radio beacons in Bellsund-Van Mijenfjorden, Isfjorden, and Kongsfjorden, and Isfjord Radio at Kapp Linné provides a radar service. Svalbard Radio, situated in Longyearbyen, receives transmissions from Norway; the other mining towns have local stations.

Administration. Svalbard is administered by a governor (*sysselmann*), who is also district judge, chief of police, notary public, and revenue officer, and has his residence in Longyearbyen. An inspector of mines (*bergmester*) supervises mining activities. An income tax is payable by Russians as well as by Norwegians. There are primary schools for children.

HISTORY

Exploration. It is probable that the Svalbard (Cold Coast) discovered in 1194, according to Icelandic annals, and mentioned in the *Landnámabók* was Spitsbergen; modern knowledge of Svalbard, however, dates from its discovery by Willem Barents and Jacob van Heemskerck in June 1596. They first discovered Bjørnøya and later saw the northwest coast of Vestspitsbergen. After visits by Stephen Bennett in 1603, Henry Hudson in 1607, and Thomas Marmaduke in 1609, the Muscovy company sent an expedition in 1610, which resulted in the establishment of the whaling industry in 1611, in which English and Dutch whalers took part. Later, French, Hanseatic, Danish, and Norwegian whalers also participated, and the king of Norway-Denmark laid claim to "this part of Greenland," as it was then considered. Quarrels among the whalers resulted in the division of the coast. The English had whaling rights south of latitude 79° N, whereas the Dutch erected their cookeries at Smeerenburg on Amsterdamøya, where more than 1,000 persons might be assembled in summer. The French were driven away from the coast in 1632 and had to boil their blubber on

The whaling industry

board their ships. After about 1640 the whales began to withdraw from the fjords and had to be caught off the coast. English whaling at Spitsbergen ceased in 1660, and Dutch whaling in about 1800, by which time the Greenland whale had been exterminated. English whalers were the first to winter in Spitsbergen, in 1630–31. Probably it was not until about 1715 that the Russians first visited Spitsbergen, wintering there to hunt walrus, seal, bear, fox, and reindeer. Many of them were sent out by the Solovetskiy monastery. Russian activity ceased in about 1850, but already at the end of the 18th century Norwegian sealers from Tromsø, Hammerfest, and other towns had been hunting in the Spitsbergen waters, and from 1822 they also wintered there to trap fur-bearing animals. This wintering was, however, not regular until the last years of the 19th century.

Many expeditions have made Spitsbergen their base for polar exploration, as C.J. Phipps in 1773, D. Buchan and John Franklin in 1818, D.C. Clavering and Edward Sabine in 1823, and William Edward Parry, who in 1827 reached 82°45′ N. In the same year the Norwegian geologist B.M. Keilhau visited the islands, and in 1837 Swedish exploration began with Sven Lovén's expedition. This was followed by many Swedish expeditions, including those of Otto Torell in 1858, A.E. Nordenskiöld in 1864, 1868, and 1872–73, A.G. Nathorst, Gerard De Geer, and others, which were the foundation for later exploration. Other 19th-century exploration included the German expedition under K. Koldewey to the eastern part in 1868, that of Sir Martin Conway, who crossed Vestspitsbergen in 1896–97, and the Swedish–Russian expeditions of 1898–1902. In 1896 the Norwegians built a hotel on Hotellneset at Adventfjorden and started weekly trips by tourist steamers. In the first half of the 20th century Spitsbergen was visited by numerous scientific and exploring expeditions. In 1906 and 1907 the Prince of Monaco sent a party, led by W.S. Bruce, which worked on Prins Karls Forland, and another party, led by Gunnar Isachsen, began mapping the northwestern part of Vestspitsbergen. This led to Isachsen's expeditions of 1909–10, and later to Norwegian expeditions under the leadership of Adolf Hoel, A. Staxrud, and others. After 1948 this work was continued by the Norsk Polarinstitutt, Oslo. From the early 1920s many British expeditions, associated particularly with the Oxford University Exploration Club, visited Spitsbergen, and some wintered there.

Spitsbergen has also been used as a base for polar flight. The first (fatal) attempt was in 1897, when the Swedish scientist S.A. Andrée and two companions set off by balloon from Danskøya; their remains were found on Kvitøya 33 years later. Roald Amundsen started from Ny-Ålesund on his unsuccessful flight to the pole in 1925 and on his flight with Lincoln Ellsworth and Umberto Nobile in the dirigible "Norge" across the pole in 1926. Richard E. Byrd also started from Ny-Ålesund on his transpolar flight in 1926. Sir George Hubert Wilkins landed at the entrance of Isfjorden in April 1928 after his flight from Alaska, and in May Nobile started there in the dirigible "Italia," which met disaster north of Nordaustlandet.

Political development. Despite diverse interest in, and claims to, the islands by British, Dutch, Norwegians, Swedes, Danes, Russians, and Americans, the question of sovereignty was long unsolved, and Spitsbergen was a *terra nullius.* Norway initiated a conference on the matter in Christiania (Oslo) in 1910, which was followed by others in 1912 and 1914, all without result. In 1919 F.H.H. Wedel Jarlsberg persuaded the Allied Supreme Council to grant Norway sovereignty over Spitsbergen, Bear Island, and all the lands lying between 74° and 81° N and between 10° and 35° E. This was put into effect by a treaty of February 9, 1920, signed by Great Britain and the British dominions, the United States, France, Italy, Japan, The Netherlands, Denmark, Norway, and Sweden; the Soviet Union adhered later. Norway took formal possession on August 14, 1925, and declared the region a part of the kingdom of Norway, under the old name Svalbard.

The 1920 treaty forbade the erection of any naval base or fortress within Svalbard. During World War II Spitsbergen was, nevertheless, the scene of serious operations. In August–September 1941 an Allied force destroyed the radio stations, power stations, stocks of coal and oil, etc., and evacuated all Russians to the Soviet Union, and Norwegians to Scotland. In the autumn the Germans erected a meteorological station in Longyearbyen. In May 1942 two vessels, "Isbjørn" and "Selis," were sent from England to prevent the mines from falling into German hands, but on reaching Grønfjorden they were destroyed by German aircraft. A small Norwegian force from England landed in July 1942 and occupied Barentsberg, Longyearbyen, and Sveagruva. After a German meteorological station had been destroyed in Krossfjorden in 1943, a large German force consisting of the "Tirpitz," the "Scharnhorst," and about 10 destroyers entered Isfjorden on September 8, 1943, and totally demolished the mining towns of Barentsburg, Grumantbyen, and Longyearbyen. In 1944 a German submarine set fire to Sveagruva. The Norwegian garrison was, however, maintained throughout the war. After the war all towns were rebuilt. (A.K.O.)

World War II Norwegian garrison

Arctic cultures: H.B. COLLINS, *Arctic Area* (1954), contains a general archaeological summary and an ethnographic sketch of the American Arctic. For general introductions to the entire Arctic area and to the culture area orientation, see M.G. LEVIN and L.P. POTAPOV (eds.), *The Peoples of Siberia* (1964; originally published in Russian, 1956); M.A. CZAPLICKA, *Aboriginal Siberia* (1914); WALDEMAR JOCHELSON, *Peoples of Asiatic Russia* (1928); WALDEMAR BOGORAS, "Elements of the Culture of the Circumpolar Zone," *A. Rep. Smithson. Instn. 1930,* pp. 465–482 (1931), and "New Data on Types and Distribution of Reindeer Breeding in Northern Eurasia," in *Proc. 23rd Int. Congr. Americanists,* pp. 403–410 (1930); A.L. KROEBER, *Cultural and Natural Areas of Native North America* (1939); and VILHJALMUR STEFANSSON, *The Northward Course of Empire* (1922). RONALD ST.J. MACDONALD (ed.), *The Arctic Frontier* (1966), contains an authoritative symposium. CARLETON S. COON, *The Origin of Races* (1962), and, with EDWARD E. HUNT, *The Living Races of Man* (1965); and E.A. HOOTON, *Up From the Ape,* rev. ed. (1946), are good for information on physical

types in the Arctic in context of all the world's peoples. R.F. SPENCER *et al., The Native Americans: Prehistory and Ethnology of the North American Indians* (1965), includes a summary of Eskimo archaeology on pp. 88–91 and a summary of Eskimo ethnography on pp. 120–154. WALDEMAR BOGORAS, *The Chukchee,* 3 pt. (1904–09, reprinted 1966), and *The Eskimo of Siberia* (1913), are among the many monumental, basic ethnographic monographs on Arctic peoples. ELMAN R. SERVICE, "The Copper Eskimo" and "The Reindeer Tungus of Siberia," in his *Profiles in Ethnology,* rev. ed. (1971), contain some very readable secondary ethnographies of individual Arctic cultures. For aspects of the contemporary Arctic, see TERENCE ARMSTRONG, "The Administration of Northern Peoples: The USSR," and MARGARET LANTIS, "The Administration of Northern Peoples: Canada and Alaska," in RONALD ST.J. MACDONALD (*op.cit.*), pp. 57–119; TERENCE ARMSTRONG, *Russian Settlement in the North* (1965); and DIAMOND JENNESS, *Eskimo Administration,* pt. 1–3, *Tech. Pap. Arct. Inst. N. Am.* (1962–65). Of the ethnological monographs, the following are primary: И. ВЕНЯМИНОВ, *Записки об островах уналашихинскаго отдела,* 3 vol. (1840), still the classic source on the Aleut; KAJ BIRKET-SMITH, *The Chugach Eskimo* (1953); MARGARET LANTIS, *The Social Culture of Nunivak Eskimo* (1946); E.W. NELSON, *The Eskimo About Bering Strait* (1899, reprinted 1971); JOHN MURDOUCH, *Ethnological Results of the Point Barrow Expedition* (1892); R.F. SPENCER, *The North Alaskan Eskimo: A Study in Ecology and Society* (1959, reprinted 1969); NICHOLAS J. GUBSER, *The Nunamiut Eskimos: Hunters of Caribou* (1965); H.B.S. OSTERMANN (ed.), *The Mackenzie Eskimos After Knud Rasmussen's Posthumous Notes* (1942); DIAMOND JENNESS, *The Life of the Copper Eskimos* (1922, reprinted 1970), and *The People of the Twilight* (1928, reprinted 1959); VILHJALMUR STEFANSSON, *The Stefánsson-Anderson Arctic Expedition* (1914); KNUD RASMUSSEN, *Intellectual Culture of the Copper Eskimos: Report of the Fifth Thule Expedition, 1921–24* vol. 9 (Eng. trans. 1932). KAJ BIRKET-SMITH, *The Caribou Eskimos: Report of the Fifth Thule Expedition, 1921–24* (Eng. trans. 1929); KNUD RASMUSSEN, *Observations on the Intellectual Culture of the Caribou Eskimos: Report of the Fifth Thule Expedition, 1921–24,* vol. 7, no. 2 (Eng. trans. 1930), *The Netsilik Eskimos: Social Life and Spiritual Culture: Report of the Fifth Thule Expedition, 1921–24,* vol. 8 (Eng. trans. 1931), and *Intellectual Culture of the Iglulik Eskimos: Report of the Fifth Thule Expedition, 1921–24,* vol. 7 (Eng. trans. 1929); DAVID DAMAS, *Igluligniut Kinship and Local Groupings: A Structural Approach* (1963); FRANZ BOAS, *The Central Eskimo* (1888). WILLIAM THALBITZER (ed.), *The Amassilik Eskimo,* in *Meddelelser om Grøland,* vol. 39–40 (1914–23); KAJ BIRKET-SMITH, *Ethnography of the Egedsminde District with Aspects of the General Culture of West Greenland,* in *Meddelelser om Grønland,* vol. 66 (1924), and *Eskimoerne* (1927; Eng. trans., *The Eskimos,* 2nd ed., 1959, reprinted 1971); E.W. WEYER, *The Eskimos: Their Environment and Folkways* (1932, reprinted 1971). (*Religion*): MARGARET LANTIS, "The Alaskan Whale Cult and Its Affinities," *Am. Anthrop.,* 40:438–464 (1938); "The Religion of the Eskimos," in V.T. FERM (ed.), *Forgotten Religions,* pp. 309–340 (1950). (*Contemporary problems*): C.C. HUGHES, "Under Four Flags: Recent Culture Change Among the Eskimos," *Curr. Anthrop.,* 6:3–54, 64–69 (1965). For a discussion of art, see HENRY B. COLLINS *et al., The Far North: 2000 Years of American Eskimo and Indian Art* (1977). Other cultural studies include ROBERT COLES, *The Last and First Eskimos* (1978); D.E. DUMOND, *The Eskimos and Aleuts* (1977); JEAN MALAURIE, *The Last Kings of Thule: With the Eskimos as They Face Their Destiny* (1982).

Siberian ethnographies include BOGORAS, *op.cit.,* and JOCHELSON, *The Koryak* (1905–08), *The Yukaghir and the Yukaghirized Tungus* (1910–26), and *The Yakut* (1933). An early report from the Samoyeds is KAI DONNER, *Bei den Samojeden in Sibirien* (1926; Eng. trans., *Among the Samoyed in Siberia,* 1954). A work on the Tungus is S.M. SHIROKOGOROFF, *Social Organization of the Northern Tungus* (1933, reprinted 1966); the author, however, is concerned with Tungus of the Manchurian–Chinese–Russian border area. Important reviews of the contemporary situation are TERENCE ARMSTRONG, "The Administration of Northern Peoples: The USSR," in R.ST.J. MACDONALD, *op.cit.;* STEPHEN and ETHEL DUNN, "The Transformation of Economy and Culture in the Soviet North," *Arctic Anthrop.,* 1:1–28 (1963); and ETHEL DUNN, "Educating the Small Peoples of the Soviet North: The Limits of Cultural Change," *ibid.,* 5:1–31 (1968). A great deal of ethnography has been written about the Lapp of Scandinavia. Two general works are BJORN COLLINDER, *The Lapps* (1949), particularly strong on the culture of the Lapps of Sweden; and ORNULV VORREN and ERNST MANKER, *Samekulturen,* 2nd ed. (1958; Eng. trans., *Lapp Life and Customs: A Survey,* 1962), an overview of all the Lapp groups of Scandinavia with particular attention to the various ecologic divisions. The contemporary situation of the Lapp in Finland is outlined in KARL NICKUL, *Report on Lapp Affairs* (1952). HARALD EIDHEIM, *Aspects of the Lappish Situation* (1971), provides a social anthropological analysis of the Lapp minority situation in Norway.

History: For archaeological summaries, see JESSE D. JENNINGS, *Prehistory of North America,* pp. 287–320 (1968); and GORDON R. WILLEY, *An Introduction to American Archaeology,* vol. 1, pp. 69–72 and 410–453 (1966). H.B. COLLINS, *Archaeology of St. Lawrence Island, Alaska* (1937); HELGE LARSEN and FROELICH RAINEY, *Ipiutak and the Arctic Whale Hunting Culture* (1948); and S.I. RUDENKO, *The Ancient Culture of the Bering Sea and the Eskimo Problem* (1961; originally published in Russian, 1947), are basic archaeological monographs.

On exploration, see T.E. ARMSTRONG, *op.cit.;* ANDREW CROFT, *Polar Exploration* (1939); RICHARD CYRIAX, *Sir John Franklin's Last Arctic Expedition* (1939); MOIRA DUNBAR and KEITH R. GREENAWAY, *Arctic Canada from the Air* (1956); A.W. GREELY, *The Polar Regions in the Twentieth Century* (1928); F. MOWAT (ed.), *Ordeal by Ice* (1960); P. FREUCHEN, *Men of the Frozen North* (1962); JEANNETTE MIRSKY, *To the Arctic!: The Story of Northern Exploration from Earliest Times to the Present* (1948); FRIDTJOF NANSEN, *In Northern Mists* (1911); LESLIE H. NEATBY, *In Quest of the North West Passage* (1958); LOUIS SEGAL, *Conquest of the Arctic* (1939); VILHJALMUR STEFANSSON, *The Northward Course of Empire* (1922), and *Unsolved Mysteries of the Arctic* (1939).

The Arctic Islands: CANADIAN HYDROGRAPHIC SERVICE, *Sailing Directions: Arctic Canada,* 3rd ed., 3 vol. (1978–82), a general account of geography, history of exploration, ice characteristics, and climate for navigators; ANDREW TAYLOR, *Geographical Discovery and Exploration in the Queen Elizabeth Islands* (1955), a résumé of geographical discovery and exploration in the northern islands to about 1940; R. THORSTEINSSON and E.T. TOZER, "Geology of the Arctic Archipelago," in the *Geological Survey of Canada, Geology and Economic Minerals of Canada* (1970), a summary account; H.S. BOSTOCK, "Physiographic Subdivisions of Canada," *ibid.;* H.A. THOMPSON, *Climate of the Canadian Arctic,* an augmented reprint from the *Canada Yearbook* (1967). KEITH J. CROWE, *A History of the Original Peoples of Northern Canada* (1974); T. FENGE *et al., Land Use Programs in Canada: Northwest Territories* (1979), provides a historical and contemporary discussion; MORRIS ZASLOW, *A Century of Canada's Arctic 1880–1980* (1981). J.A. DOWNES, "Arctic Insects and Their Environment," *Can. Ent.,* 96:279–307 (1964), a review of several studies; W.E. GODFREY, *The Birds of Canada* (1966); J.D. MCPHAIL and C.C. LINDSEY, *Freshwater Fishes of Northwestern Canada and Alaska* (1970); A.H. MACPHERSON, "The Origin of Diversity in Mammals of the Canadian Arctic Tundra," *Syst. Zool.,* 14:153–173 (1965), with range maps; A.E. PORSILD, *Illustrated Flora of the Canadian Arctic Archipelago,* 2nd ed. (1964), keys, descriptions, illustrations, and range maps; D.B.O. SAVILE, "The Botany of the Northwestern Queen Elizabeth Islands," *Can. J. Bot.,* 39:909–942 (1961), on glacial and postglacial plant geography, and *Arctic Adaptations in Plants* (Canada Department of Agriculture, 1972).

Greenland: DANISH COMMISSION FOR THE DIRECTION OF THE GEOLOGICAL AND GEOGRAPHICAL INVESTIGATIONS IN GREENLAND, *Meddelelser om Grønland,* 189 vol., containing papers in English, German, Danish, French, and Greenland Eskimo (1879–), is the largest existing work about Greenland, written by prominent specialists, and mostly covering geological, geographical, and ethnographic subjects. *Greenland,* 3 vol. (1928), a useful source of information, notably in matters concerning the physical environment and ethnography; KAJ BIRKET-SMITH, *The Eskimos,* 2nd ed. (Eng. trans. 1959, reprinted 1971), the most authoritative work on the Eskimos and their culture; PETER FREUCHEN, *Book of Eskimos* (Eng. trans. 1961), an entertaining account by a famous Danish explorer; VILHJALMUR STEFANSSON, *Greenland* (1942), a readable work on Eskimo culture by a famous American explorer, now mainly of historic interest; SVEND KLITGAARD, *Greenland* (Eng. trans. 1970), an extensive volume covering all aspects of Greenland life. For history, see POUL NORLUND, *De gamle Nordbobygder ved Verdens Ende,* 2nd ed. (1936; trans. by W.E. CALVERT, *Viking Settlers in Greenland and Their Descendants During Five Hundred Years,* 1936); FINN GADD, *The History of Greenland,* 3 vol. Argentina

Argentina (República Argentina) occupies most of the southern portion of South America. It is the eighth largest country in the world, with an area of 1,073,399 square miles (2,780,092 square kilometres). Shaped like an inverted triangle with its base at the top, it is only about 884 miles (1,423 kilometres) across at its widest from east to west, but it stretches 2,360 miles from the subtropical north to the subantarctic south. This great length embraces regions of striking diversity, including the Andes Mountains; the thorny scrubland and seasonal swamps of the Gran Chaco; the broad, fertile plains of the Pampa; the stark tableland of Patagonia; and an undulating Atlantic coastline of 2,936 miles. Argentina also claims a 49° wedge of Antarctica and several islands in the South Atlantic, including the British-ruled Falklands (Islas Malvinas). It is bounded by Chile on the south and west, Bolivia and Paraguay on the north, and Brazil, Uruguay, and the Atlantic Ocean on the east.

For many foreigners, especially Europeans, Argentina has presented the traditional New World image of a land of romance and opportunity. It received its name, roughly translated as "land of silver" or "silvery one," from Spanish explorers of the 16th century who were lured there by rumours that portrayed the presence of vast mineral wealth. In the 19th century the former colony of Spain was the land of gauchos, the lone horsemen of the pampas, and of estancieros, ranchers who lived like kings on estancias the size of small countries. In the last part of the 19th century and the first quarter of the 20th, Argentina became for the poor of Europe a place where they could earn a decent living on the expansive farmland of the interior or in the growing cities of the coast. During this period millions of immigrants came to Argentina, bringing skills that helped transform it into a modern country whose agriculture and industry remain among the most productive of Latin America.

Historically, Argentina has often been ruled by a caudillo figure, a strong leader, often of the military, who dominated the nation, usually until he was deposed or died. During its periods of democratic rule Argentina has been administered as a federation of autonomous states with a republican system of government. In the late 20th century Argentina has been set back by failed policies that have at times brought hyperinflation and led the country into misadventures such as the Falkland Islands war of the early 1980s, a venture that cost dearly in terms of both morale and finances. Its recovery from such disappointments and its future development are based on the potential manifested in its excellent resources and its well-educated populace.

This article is divided into the following parts:

Physical and human geography

THE LAND

Major landform regions

Argentina encompasses a variety of major landforms that are often grouped together into four major regions: the Andes, the North, the Pampa, and Patagonia. The Andean region extends some 2,300 miles along the western edge of the country, from Bolivia to southern Patagonia, forming most of the natural boundary with Chile. It is commonly subdivided into two parts: the Northwest and the Patagonian Andes, the latter of which is discussed here under Patagonia. The North is commonly described in terms of its two main divisions: the Gran Chaco, or Chaco, comprising the dry lowlands between the Andes and the Paraná River, and Mesopotamia, an area between the Paraná and Uruguay rivers. The centrally located plains, or Pampa, are grasslands subdivided into arid western and more humid eastern parts called, respectively, the Dry Pampa and the Humid Pampa. Patagonia is the cold, parched, windy region that extends some 1,200 miles south of the Pampa, from the Colorado River to Tierra del Fuego.

Relief. *The Northwest.* This part of the Andes region includes the northern half of the main mountain mass in Argentina and the transitional terrain, or piedmont, merging with the eastern lowlands. The Andean system of north–south-trending mountain ranges, 16,000 to 22,000 feet (4,900 to 6,700 metres) high and separated by flat-floored structural valleys ranging from 10,000 to 13,400 feet, gradually decreases in size and elevation southward from Bolivia to the upper Colorado River, which forms

the southern border of the region. South America's highest mountain, Aconcagua (22,831 feet [6,959 metres]), lies in the Northwest, together with a number of other peaks that reach over 21,000 feet. Some of these mountains are volcanic. In the northern part of the Argentine Andes are the high undissected structural valleys referred to as puna.

To the south and east, where the parallel to subparallel ranges become lower and form isolated, compact north–south-trending units, the flat valleys between are called *bolsones* (basins). This southeastern section of the Northwest is often referred to as the Pampean Sierras, a complex that has been compared to the Basin and Range region of the Southwestern United States. They are characterized by west-facing escarpments and gentler east-facing backslopes such as are found in the spectacular Sierra de Córdoba at the eastern edge of the Pampean Sierras. The Pampean Sierras have variable elevations; ranges begin at 2,300 feet in the Sierra de Mogotes in the east and rise to 20,500 feet in the Sierra de Famatina in the west.

The Pampean Sierras

The Gran Chaco. The western sector of the North region, the Gran Chaco, extends beyond the international border at the Pilcomayo River into Paraguay, where it is called the Chaco Boreal (North Chaco) by Argentines. The Argentine sector between the Pilcomayo River and the Bermejo River is known as the Chaco Central. Southward to the 30th parallel, where the Pampa begins, Argentines have named the area the Chaco Austral (South Chaco). The Gran Chaco in Argentina, though descending in flat steps from west to east, is poorly drained and has such a difficult combination of physical conditions that it remains one of the least inhabited parts of the nation. Its subtropical climate is characterized by some of Latin America's hottest weather; it is largely covered by a thorny vegetation; and it is subject to summer flooding.

Mesopotamia. East of the Chaco lies a narrow depression, 60 to 180 miles wide, called Mesopotamia, which is bordered on the north by the Brazilian Shield. The narrow lowland stretches for 1,000 miles southward, finally merging with the Pampa south of the Río de la Plata. Its designation as Mesopotamia (between the rivers) reflects the fact that its western and eastern borders are large rivers, namely the Paraná and Uruguay. In the south there are small hills, around which the rivers flow. The northeastern part of this region, Misiones Province, between the Upper Paraná and the Uruguay rivers, is higher in elevation.

The Pampa. Pampa is a Quechua Indian term meaning "flat surface." As such it has a broad applicability in southeastern South America beginning in Uruguay where grass-covered plains commence south of the Brazilian massif. In Argentina the plains broaden out west of the Río de la Plata to meet the Andean forelands, blending imperceptibly on the north with the Chaco Austral and southern Mesopotamia and extending southward to the Colorado River. The eastern boundary is the Atlantic coastline.

The flat plains

The main landmass of the Pampa is flat. Thick deposits of silt interrupted only by occasional caps of alluvium and volcanic ash rest on its surface. In the area of the southern Pampa, the landscape rises gradually. There the morphology is changed by the emergence of sierras formed from old sediments and crystalline rocks.

Patagonia. This region consists of an Andean zone (also called Western Patagonia) and the main Patagonian plateau south of the Pampa, which extends to the tip of South America. The surface of Patagonia descends east of the Andes in a series of broad, flat steps extending to the Atlantic coast. Evidently, tectonic activity related to the formation of the Andes created the gigantic platforms and coastal terraces. The coastline is cliffed along its entire length as a result. The northern cliffs are rather low but tend to rise in the south, where they reach heights over 150 feet. The landscape is cut by eastward-flowing rivers—some of them of glacial origin in the Andes—that have created broad valleys and steep-walled canyons.

Other features of Patagonia include a series of basins, some of which contain lakes, nestled between the Patagonian Andes and the plateau, and volcanic hills in the central plateau west of the city of Río Gallegos. These hills and accompanying lava fields are characterized by dark colours spotted with lighter-coloured bunchgrass, which creates a leopard-skin effect that intensifies the desolate, windswept appearance of the Patagonian landscape. A peculiar type of rounded gravel called *grava patagónica* lies on level landforms, including isolated mesas. Glacial ice in the past extended beyond the Andes only in the extreme south, where there are large moraines.

Leopard-skin coloration

Drainage. The largest river basin in Argentina is that of the Río de la Plata (often called the River Plate in English). It drains an area of 1,600,000 square miles, which includes, in addition to northern Argentina, the whole of Paraguay, eastern Bolivia, most of Uruguay, and a large part of Brazil. The river is actually an estuary formed by the confluence of the Paraná and Uruguay rivers; its name, meaning "River of Silver," was given it in colonial times before explorers found that there was neither a single river nor silver upstream from its mouth. Other tributaries of this system are the Iguazú (or Iguaçu), Paraguay, Pilcomayo, Bermejo, Salado, and Carcarañá. Before the Iguazú River joins the Paraná at the point where the borders of Argentina, Brazil, and Paraguay meet, it plunges over the escarpment of the Brazilian massif, creating the Iguazú Falls—one of the world's most spectacular natural attractions.

The "River of Silver"

Because most of Argentina is flat or only gently sloping from the Andes to the Atlantic, the country's river drainage is poor. Grand rivers flow across the Gran Chaco flatlands, but their shallow nature rarely permits navigation, and never with regularity. Moreover, long-lasting summer floods cover vast areas and leave behind ephemeral swamplands that gradually dry out in winter. During winter, most rivers of the Gran Chaco dry up, the air chills, and the land seems visibly to shrink. Only three of the region's numerous rivers (the Pilcomayo, Bermejo, and Salado) manage to flow from the Andes to the Paraguay–Paraná system in the east without dying somewhere en route and forming salt pans (salinas) due to evaporation. The region's largest rivers follow a veritable maze of courses during flood season, however.

In the Northwest the Desaguadero River, the upper course of the Salado, and its tributaries in the Andes Mountains water the sandy deserts of Mendoza Province. The principal tributaries are the Jáchal, Zanjón, San Juan, Mendoza, Tunuyán, Diamante, and Atuel. In the northern Pampa, Lake Mar Chiquita, the largest lake in Argentina, receives the waters of the Dulce, Primero, and Segundo rivers but has no outlet. Its name, meaning "Little Sea" Lake, refers to the high salt content of its waters. Rivers that cross Patagonia from west to east diminish in volume as they travel through the arid land. The Colorado and Negro rivers produce major floods after seasonal snow and ice melt in the Andes. In the south, the Santa Cruz River is a notable stream that flows eastward out of the glacial Lake Argentino in the Andean foothills to the Atlantic.

Soils. Soil types in Argentina range from the light-coloured saline formations of the high puna to the dark, nutritive, and friable type found in the Pampa. Golden-brown loess soils of the Gran Chaco, sometimes lighter where salinity is excessive, turn darker toward the east in the Mesopotamian border zone where poor drainage occurs. These give way to soils ranging from rust to deep red colorations in Misiones. South of the Pampa, grass-covered dark soils begin to turn brown as the drier parts of northern Patagonia are reached. Light-tan arid soils of varying texture cover the rest of this region. Grayish podzolic types and dark-brown forest soils characterize the Andean slopes.

Climate. Argentina lies almost entirely within the temperate zone of the Southern Hemisphere, unlike the rest of the continent to the north, which lies within the tropical zone. Only occasional tropical conditions invade the provinces of Formosa and Misiones in the extreme north. On the other hand, a landmass extending to 55° south latitude might be expected to possess a continental climate with at least one month having an average temperature below freezing, similar to comparable latitudes in North America. The continent narrows so rapidly toward its southern tip, however, that the moderating effect of both the Pacific and Atlantic oceans influences a predominantly temperate climate despite the high latitudes. The

The temperate climate

MAP INDEX

temperate climate is interrupted by a long, narrow north–south band of semiarid to arid conditions, which makes Argentina the only place in the Southern Hemisphere with an extensive portion of arid eastern coastline. Zones of tundra climate and polar climate predominate in the high Andes and in southern portions of Tierra del Fuego. The temperate regions of the nation have an average cold month temperature from 50° to 65° F (10° to 18° C).

Precipitation is moderate to light throughout most of the country, with the driest areas in the far northwest and

Chip and Rosa Maria Peterson

in the southern part of Patagonia. Most rainfall occurs in the northeast, in the Humid Pampa, Mesopotamia, and the eastern Chaco. Thunderstorms, called *pamperos,* with lightning and hail are common. Weak fronts create another mechanism that produces rain, often bringing long periods of winter moisture. Dull, gray days and damp weather characterize this season, especially in the Pampa. Between winter storms, tropical air masses make incursions southward and bring mild relief from the damp cold.

The *pamperos*

In the Andean Northwest region, there is in some places an annual temperature range of more than 36° F (20° C), and occasional continental climatic conditions occur. Winter temperatures sometimes fall below freezing on cloudless days and nights.

Tundra climate

The high-elevation, cold climatic phenomenon in Argentina is sometimes referred to as tundra climate and, in even colder mountaintop areas, as polar. Generally, the tundra climate occupies the mountain zones where average annual temperatures are below 50° F (10° C); in the north this occurs above 11,500 feet. Moving southward, tundra climate occurs at gradually decreasing elevations until it reaches sea level in southern Tierra del Fuego. The highest Andean peaks may have permanent snow or ice cover.

A longitudinal rain-shadow zone (created when winds lose their moisture in passing over high mountains) on the east side of the Andes causes an arid to semiarid climate in the interior of Argentina. The zone begins in the Andean Northwest and extends along the eastern slopes of the Andes southward to, but not including, Tierra del Fuego. The rain-shadow area has a central core of arid or desert climate rimmed by semiarid, or steppe, conditions. The steppe areas have about twice the annual precipitation found in the arid zones, but evaporation exceeds precipitation in both zones, which therefore remain treeless. Most of the arid region is subjected to strong winds that carry abrasive sand and dust. This is particularly true in Patagonia, where the windblown dust creates a continuous haze that considerably reduces visibility.

The Pampa is a transitional area between high summer temperatures to the north and cooler summers to the south. Buenos Aires, located on the north edge of the Pampa, has a climate similar to cities in the southeastern United States, with hot, humid summers and cool, mild winters. Mean temperatures for summer months (December to February) range from about 72° to 75° F (22° to 24° C) and for winter months (June to August) about 46° to 55° F (8° to 13° C). In the Humid Pampa the rainfall varies from 39 inches (990 millimetres) in the east to 20 inches in areas near the Andes—about the minimum for nonirrigated crops. Cold fronts that move northward from Patagonia, chiefly in July, bring occasional frosts and snow to the Pampa and Mesopotamia. On rare occasions a dusting of snow covers Buenos Aires itself.

Plant and animal life. Argentina's fauna and flora vary widely from the country's mountainous zones to its dry and humid plains and its subpolar regions. In heavily settled regions, the natural animal and plant life have been profoundly modified by man.

Northwest. Vegetation in the Northwest region includes the high puna desert, with mostly exposed soil and bunchgrass, the forested slopes of the Andes, and the subtropical scrub forests of the Pampean Sierras, which merge with the deciduous scrub woodland in the Gran Chaco. The vegetation of the puna consists of dwarf shrubs and tough grasses; these and other plants in the region are almost the brown colour of the ground itself. The region is the land of the guanaco and its near relatives, the llama, alpaca, and vicuña.

Forests continue along the eastern border of the puna region southward to the colder Andean zones so that they cover many slopes in this part of the mountains. Above 1,650 feet, the so-called mistol forest thrives. There is a subtropical rain forest at elevations of about 4,000 feet, composed of laurels, cedars, and other species. Above 3,300 feet, the giant cedars and some other tree species disappear. The tree heights are less impressive, and the growth becomes more of a cloud forest type; myrtles and poorly developed laurels predominate, and pine trees reach above 7,000 feet. Above this forest grow the *queñoa,* small crooked trees that in places extend to the tree line at 11,500 feet.

Southeast of the Andean region described above, xerophytic scrub forests, called *monte,* and intervening grasslands spread across the Pampean Sierras. Vegetation includes mimosas and acacias, and there is a smattering of cactus. Hares, skunks, and small deer abound in this part of the Northwest.

The thorny Gran Chaco

Gran Chaco. The western Gran Chaco has growths of thorn forest dominated by algarroba in the drier and often saline zones. Quebracho is present, but not to the extent that it is farther east. In areas with finer salt at the surface, even halophytic plants, which normally grow in salty soils, do not survive. Coarse bunchgrasses are common in the dry steppe. Overall, dense scrub forests intermixed with prickly pear, barrel, and many other types of cactus and trees blend with the steppe areas.

The vegetation of the Chaco becomes increasingly lush as it spreads to the east. The thorn forest gradually becomes dominated by dense forest with another, less valuable quebracho species; there are some pure stands of algarroba. Some 90 miles west of the Paraná River, some of the giant trees that are also found in the much more humid Misiones Province begin to appear. The rich wildlife of the Chaco includes deer, peccaries, monkeys, tapir, jaguars, pumas, ocelots, armadillos, capybaras, and agoutis. The vast birdlife includes a refuge for the rhea; streams harbour numerous fish species, including the piranha; and snakes and reptiles abound.

Mesopotamia. In Mesopotamia, thin stands of tall wax palms occupy the flood zones. Groups of trees and grassy areas form a park landscape of noted beauty. The quebra-

cho from which tannin has been extracted since colonial times, *urunday,* and *guayacán,* used for tannin and lumber, are common. Gallery forests growing along rivers become denser and taller in Misiones Province. At higher elevations, the Paraná pine appears. Mesopotamia is the habitat for jaguars, monkeys, deer, tapir, peccaries, many snake varieties, and numerous birds, such as the toucan and hummingbird, as well as stingless honeybees.

Pampa. The principal Pampa vegetation is *monte* in the Dry Pampa and grassland in the Humid Pampa. The north–south boundary between the Dry and Humid pampas lies approximately along the 64th meridian. In the most humid areas, knee-high grasses appear. To the north, west, and south, where precipitation decreases, tougher grasses give way to the *monte* of the Dry Pampa. Planted grasses and trees have replaced much of the original flora. Pampa wildlife includes the rhea and the guanaco. Both animals are fleet-footed, which is probably the reason for development of the bola, a device used by the Indians to trip the animals. Small deer, introduced hares, and viscacha, a burrowing rodent, are common.

Monte vegetation of the Dry Pampa

Patagonia. Patagonian vegetation consists of deciduous Andean forests and the steppe and desert zones east of the Andes. The largest area—the steppe region—lies in northern Patagonia between the Colorado River and the port city of Comodoro Rivadavia. This zone represents an extension southward of the *monte,* which gives way gradually to a xerophytic shrub region without trees except along river banks. In the extreme west on the Andean border, small stands of araucaria survive, and clumps of wiry grasses are also present. South of Comodoro Rivadavia to the tip of the continent, low scrub vegetation and green grass steppe alternate. Wildlife in the region includes the now rare guanaco and rhea, as well as eagles and herons, burrowing rodents and the Patagonian hare, mountain cats and pumas, and various poisonous reptiles.

In Tierra del Fuego, it appears that grasses first covered glaciated zones, but after volcanic ash settled there, forests advanced. Antarctic beech colonized rapidly in valleys and grows along with cypress on steep slopes. A phenomenon in the southern tip of the continent is the existence of species of parrots and canaries, both of which are more associated with the tropics than with Patagonia.

The Patagonian Andes have coniferous and broad-leaved forests that spread into Chile. Antarctic beech and needle-leaf trees mixed with araucaria are common. The Patagonian Andes do not have a flourishing animal life. The smallest known deer, the pudu, dwells there, and wild pigs, introduced by Europeans, have multiplied.

Settlement patterns. The varied topography, climate, and natural resources of Argentina shaped the pattern of settlement in its major regions from the beginning of colonization. Although modern transportation and industry have partly effaced regional differences, the organization of life in both city and country still follows patterns that were set in the years of the first European settlement.

The Northwest. Numerous archaeological sites in the region indicate the presence—before the Spanish invasion—of permanently settled Indians with irrigated and terraced farming in the oasis-like valleys. The Spanish, coming from Peru, first established Santiago del Estero in 1553, eastward on the lowland plain in the Chaco away from belligerent natives. Not long afterward, forts arose in the Northwest at Tucumán, Salta, Jujuy, and San Luis; Córdoba, to the south, was founded in 1573. Meanwhile, the Northwest received colonists still farther south from Chile. Chileans founded the cities of Mendoza and San Juan in the early 1560s.

Early settlement

The cities in the Northwest were founded originally as centres for agriculture and livestock raising and to serve as support for the silver mines of the Viceroyalty of Peru, particularly at Potosí (now in Bolivia). Later, as Buenos Aires developed and the mines became less profitable, the country's orientation switched to the southeast. The Spanish established a trade route between Chile and Buenos Aires that went through Córdoba and Mendoza, both of which thrived. This northward path was chosen because of the need to avoid the Pampa Indians, and it remains an important transportation route. In the 600-mile-long rain-shadow zone east of the Andes, beginning just south of San Miguel de Tucumán, settlement took place in river oases stretching to San Rafael, south of Mendoza.

Rail transportation, which tied Mendoza to the Pampa in 1885, brought about an emphasis on viticulture in the Mendoza region. With access to Buenos Aires came new capital, more settlers, better grape stock, and larger markets. Once the problem of a labour shortage was solved with European immigrants, Mendoza and oases such as San Rafael expanded. Tucumán, lying amid more humid Andean foothills outside the rain shadow, responded to the new markets across the Pampa by increasing sugar production, which had had a modest beginning during early colonial times. Major change followed the first direct rail link between Tucumán and the Pampa in 1875, which provided access to expanding sugar markets and more modern machinery. Most of the tens of thousands of workers needed to harvest the crop came to live year-round on the large plantations, making Tucumán Province the most densely settled in Argentina.

Growth of Tucumán

The Gran Chaco. Although the Gran Chaco is still considered to be a frontier region, its settlement has often followed efforts supported by the government to exploit its economic potential. Agricultural colonies and cities grew first along the Paraná–Paraguay water route and then along railroads built to serve the quebracho industry. Resistencia was founded in 1878 and Formosa in 1879.

The harsh physical conditions of the Gran Chaco explain why its native peoples did not engage in sophisticated agriculture and why their sporadic attempts at farming were unsuccessful. Early Spanish expeditions aiming to conquer the Chaco came from Santiago del Estero to the west, Santa Fé to the southeast, and Asunción, across the Paraguay River to the northeast. None of these succeeded in subduing the warlike Indians, however.

Chaco Indian resistance

Settlement in the Chaco ultimately took place from Santiago del Estero, where irrigated cotton was successfully produced as early as the mid-16th century, and from Santa Fe, where cattle ranchers had purchased enormous acreages on which to raise tough criollo (or Creole) cattle, which had survived from earlier expeditions. Ranchers reached the northern frontier of the Argentine Chaco around the Bermejo River after subduing the Indians in 1885. Logging operations followed the ranchers and helped open parts of the Chaco—particularly in the east, where tannin from the quebracho tree met the demand of the Argentine leather industry. At the start of the 20th century, European settlers in the eastern Chaco began raising cotton, a crop that could withstand the long drought period. Small cotton areas spread westward nearly to Tucumán, north to the Paraguayan border at the Pilcomayo River, and east into Mesopotamia.

Mesopotamia. The northern part of the Mesopotamian region was first settled by Spaniards from Asunción (now the capital of Paraguay), who in 1588 founded the city of Corrientes near the confluence of the Paraná and Paraguay rivers. In the south, settlers from Santa Fe crossed the Paraná and established what became the city of Paraná. Having founded towns along navigable rivers, the Spanish secured the water route to the Río de la Plata estuary.

When the Spanish first entered the Mesopotamian region, supply distances between settlements were so great that the settlers found it necessary to produce their own subsistence crops. This they accomplished mainly by subjugating the remaining Indians under the encomienda system, which granted settlers the use of Indian labour on lands awarded by the crown. Indian rebellions became so serious, however, that the Spanish had to resort to military force to keep peace, and the conflicts forced many Indians to flee. Finally, in the early 17th century, the crown turned to the Jesuits to restore peace and protect the natives. Within a century the Jesuits had built numerous *reducciones,* or mission settlements, in Mesopotamia, which later acquired the name Misiones. Under Jesuit rule northern Mesopotamia became the most important centre of colonization in eastern South America.

The Jesuit *reducciones*

The Territory of Misiones was created in the early 1880s, and Europeans, particularly Germans, began to settle the forested zone in the north. Yerba maté, citrus, and veg-

etables, as well as tung trees, tea, and sugarcane, were grown on small farms. Outside the agricultural zones of Mesopotamia, cattle ranching came to dominate.

The Pampa. The Pampa was originally inhabited by Indians such as the Querandí, who reportedly had no agriculture but were hunters who developed the bola, for entangling the fleet-footed guanaco and rhea. Fierce attacks by the Querandí forced Spanish settlers in Buenos Aires to flee upriver to Asunción in 1541. After Buenos Aires reemerged in 1580, the Spanish showed less interest in opening up the southern Pampa than in keeping open the northern trade route to Santa Fe, Asunción, and Alto Perú; as a result the estancias, huge cattle ranches, were first established northwest of Buenos Aires.

The estancias

The estancias became one of the most important institutions in the economy, politics, and culture of Argentina. They began as gigantic tracts of land, often measuring in the hundreds of square miles, that were sold or granted to the Creole descendants of Spanish settlers during the 17th century. Herds of criollo cattle and horses ran half-wild on these tracts. To manage the herds, the estancia owners hired gauchos. These ranch hands worked the estancias until the open ranges disappeared late in the 19th century.

On the estancias widely dispersed *ranchos,* or simple adobe houses with dooryard gardens, marked the headquarters of the estancieros. More primitive huts, or leantos, housed the gauchos. In addition, there were small pulperias, centrally located inns where marketing, banking, eating and drinking, and other functions took place. Some pulperias grew into villages. Gradually the estancia region of the Pampa spread west and south of Buenos Aires.

Buenos Aires and Santa Fe survived as small, sparsely populated towns until the mid-19th century. After that time rapid growth in agriculture changed the face of the Pampa. The world market for food products was increasing, and estancieros modernized their operations to meet the demand. Sheep and more productive breeds of English cattle replaced the criollo. The new cattle, unable to live on the Pampa grass, had to be fed with alfalfa. Gauchos were not numerous or willing enough to cultivate this crop, obliging their employers to contract European immigrants as tenant farmers. The southern frontier of the Pampa was pushed back so that by 1880 no Indian interference to settlement remained north of the Negro River in Patagonia. By 1914 several million European workers had arrived to work ranches and farms. Gradually, small farming and tenant farming operations spread west and south from Santa Fe and Entre Ríos provinces.

The growth of agriculture spurred the growth of cities in the Pampa. Railroads radiating from Buenos Aires penetrated the interior of the Pampa, forming the densest network in the country. After the late 1800s foreign-owned frigorificos, meat-packing plants for the export of beef and mutton, were established on the Río de la Plata estuary. Efforts by the government in the 20th century to encourage the growth of manufacturing favoured the port cities, attracting most immigrants as well as many workers from the countryside. Buenos Aires subsequently became one of the most populous and cosmopolitan cities of the world, and the Humid Pampa became the most prosperous industrial and agricultural region of Argentina.

Patagonia. Most approaches to Patagonia from the sea were hampered by inhospitable coastal cliffs and by high tides. With the Pampa Indians acting as a buffer against Europeans to the north, the Patagonian Indians thus remained unmolested until the mid-19th century. The Conquest of the Desert, as the Patagonian Indian wars were called, ended in 1879, smashing the Indian resistance to settlement. Argentines began to colonize Patagonia, with soldiers and financial contributors to the Desert War receiving large land grants. Settlement proceeded south from the Pampean port city of Bahía Blanca and from Neuquén in the Andean foothills. Pioneers came from other countries as well. Chileans from Punta Arenas settled in Tierra del Fuego. Welsh, Scottish, and English immigrants spread along the coast and inland, with the result that English is still spoken in parts of Patagonia.

Subjugation of the Patagonian Indians

The southernmost city in the world, Ushuaia, on Tierra del Fuego, began as a missionary settlement and is still reached only by ship or airplane. About the end of the 19th century sheep ranching began along the rail line connecting the port of Río Gallegos with coal deposits at Río Turbio. Comodoro Rivadavia became an important oil and natural gas centre, and the Negro River fruit region began to develop in 1886 when the area east of Neuquén was settled by soldiers of the Desert War and by others.

THE PEOPLE

Heavy immigration, particularly from Spain and Italy, has produced in Argentina a people who are almost all white and of European ancestry. In the colonial period, though, the Spanish explorers and settlers encountered a number of native peoples. Among these were the Diaguita tribes of the Andean Northwest, a town-dwelling, agricultural people who were forced into labour after they had been conquered. They were divided by the Spanish into small groups and were sent to work in Peru and the Río de la Plata area. In the Mesopotamian region the agricultural Guaraní were also forced into labour.

Most other Argentine Indians belonged to hunting tribes who fought the Spanish tenaciously but were eventually exterminated or driven away. In the Gran Chaco were the Guaycuruan tribes among others. The Araucanian Indians came over the mountains from Chile and raided Spanish settlements in the southern Pampa until the Conquest of the Desert in the 1870s. Another Pampa Indian tribe was the Querandí, who inhabited the region of Buenos Aires. In Patagonia the largest group was the Tehuelche, and on Tierra del Fuego the Ona.

Ethnic mix in 1810

Population estimates of the colonial period suggest that by 1810 Argentina had more than 400,000 people. Of these perhaps 30 percent were Indian. Ten percent were black and mulatto, either slaves or descendants of slaves who had been smuggled into the country through Buenos Aires, and there was a large element of mestizos (white and Indian mixture). The whites were in the minority.

It was the great wave of European immigration after the mid-1800s that molded the present-day ethnic and racial character of Argentina. The Indians and mestizos were pushed aside or absorbed, and the blacks and mulattos disappeared, apparently also absorbed into the dominant population. Mestizos from Chile, Bolivia, and Paraguay have grown numerous in bordering regions, but the urban areas remain largely white.

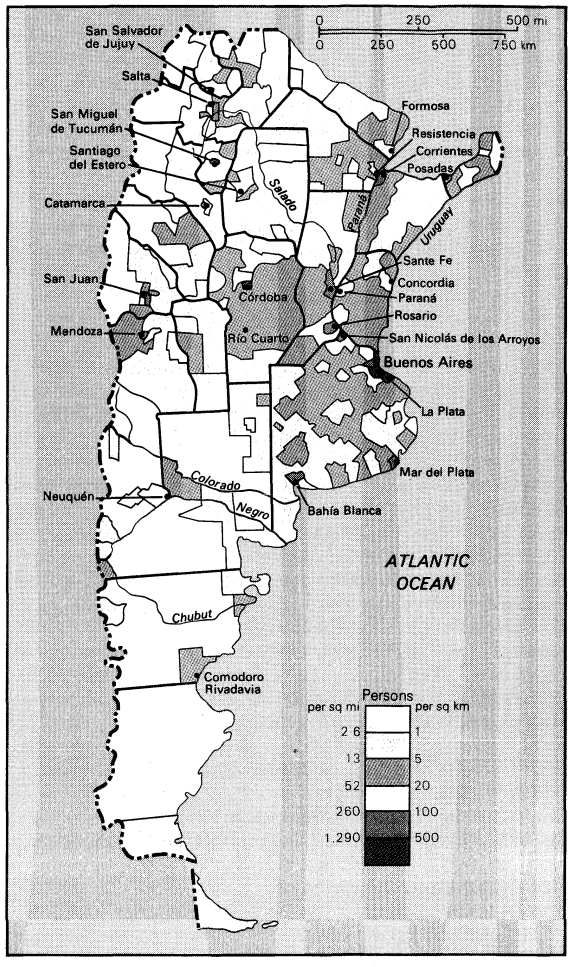
Almost half of the European immigrants in the late 19th and early 20th centuries were Italian and about one-third were Spanish. Substantial numbers also came from France, Poland, Russia, and Germany. In 1869 the foreign-born made up 12 percent of the population; this had grown to about one-third by 1914, and in large cities foreigners outnumbered natives by as much as two to one. As immigration slowed later in the 20th century, the proportion of foreign-born Argentines dropped.

Influence of European cultures

The Italian influence on Argentine culture became the most important of any immigrant group. Other major foreign influences have come from the Spanish and Polish groups. Smaller groups have also made notable contributions, however. English capital and management, for example, built railroads and created the meat-processing industry; Germans established farm settlements and cooperatives; the French contributed their viticultural expertise; and Japanese invested in business.

The children of immigrants were quick to identify themselves as Argentines, so that the people were not divided into antagonistic ethnic groups. But Argentine society developed a serious division between the rural interior and the urban coast. Many rural people grew to resent the wealth, political power, and cultural affectations of the *porteños,* the "people of the port," in the Buenos Aires region, while many *porteños* looked upon residents of the interior as ignorant peasants. These divisions became deeply rooted in the politics of the country.

Spanish is the national language, although in Argentina it is spoken in many accents and has absorbed many words from other languages, especially Italian. Numerous foreign languages and dialects can be heard, from Basque and Sicilian to Welsh and Gaelic. Toward the end of the 19th century an underworld language called *lunfardo* de-



Population density of Argentina.

veloped in Buenos Aires. It was composed of words from many languages—among them Italian, Portuguese, Spanish, French, German, and African. Most of the Argentine people are adherents of Roman Catholicism, the official state religion. Of the remainder about equally small percentages are Protestants and Jews. Roman Catholic influence is strongly reflected in government and society, and the religion is officially recognized in the constitution, although freedom of worship is professed.

Religion

The population of Argentina has increased by more than 17 times since 1,800,000 people were recorded there by the first census in 1869. This rapid growth began to decline after the early part of the 20th century as both the birthrate and immigration began to drop off. By the late 20th century Argentina's birthrate and growth rate were among South America's lowest; the percentage of young people has declined proportionally. The nation's population density is also among the continent's lowest, although certain areas are quite heavily populated, including the Humid Pampa, Mesopotamia, and parts of the eastern Northwest. The population is growing faster in urban areas—especially Buenos Aires—than in the rest of the country. More than four-fifths of the people live in urban areas, about a third in greater Buenos Aires alone.

THE ECONOMY

In the 60 years after the founding of the farming colony at Esperanza in 1856 the base of Argentine agriculture shifted from livestock to crops. The spread of wheat, corn (maize), and flax roughly conformed to the estancia region of the Pampa. Although agriculture there did not become as intensive as in North America, soils were good and land was abundant. Argentine industry became important when manufacturers (mostly foreign-dominated) developed food products for export. The growth trend continued well into the 20th century as Argentina became one of the most prosperous countries in Latin America. Meat and grain were exported to the expanding markets of Europe in exchange for fuel and manufactured products.

In the early decades of the 20th century Argentina became the world's leading exporter of corn, flax, and meat. Prosperity was curtailed, however, by World War I and the Great Depression of the 1930s, which considerably damaged the Argentine economy by reducing foreign trade. In response, successive governments over the next 40 years followed an import-substitution strategy designed to transform Argentina into a country self-sufficient in industry as well as agriculture. This was accomplished mainly by imposing high tariffs on imports, thereby sheltering Argentine textile, leather, and home-appliance manufacturers from foreign competition. The government's encouragement of industrial growth, however, diverted investment from agriculture, causing agricultural production to fall dramatically. Fruits, vegetables, oilseeds such as soybeans and sunflowers, and industrial crops such as sugarcane and cotton increased their share of total agricultural production at the expense of the dominant grain crops.

By 1960 manufacturing contributed more to the country's wealth than did agriculture. Argentina had become largely self-sufficient in consumer goods, but it also was more dependent than ever on imported fuel and heavy machinery. In response, the government invested heavily in such basic industries as petroleum, natural gas, steel, petrochemicals, and transport; it also invited investment by foreign companies. By the mid-1970s Argentina was producing most of its own oil, steel, and automobiles and also was exporting a number of manufactured products. Manufacturing became the largest single component of the gross domestic product (GDP). The country also had become self-sufficient in fuel while remaining one of the world's major agricultural producers.

At the same time, growing government spending, large wage raises, and inefficient production created a chronic inflation that rose until, in the 1980s, it briefly exceeded an annual rate of 1,000 percent. Successive regimes tried to control inflation through various combinations of wage and price controls, cuts in public spending, and restriction of the money supply. With the peso quickly losing value to inflation, a new currency, the peso argentino, was introduced in 1983, only to be replaced by the austral in 1985.

The era of import substitution ended in 1976, when an economic adjustment program lowered import barriers, liberalized restrictions on foreign borrowing, and gave the peso support against foreign currencies. These measures were intended to control inflation and increase efficiency by forcing competition upon the sheltered Argentine economy. Instead, they made imported products so cheap that many Argentine manufacturers could not compete with them. Between 1975 and 1981 manufacturing's share of the GDP declined from about 32 to 25 percent.

The economic adjustment program brought about another difficult economic problem: a huge foreign debt. Within a decade, borrowing from foreign creditors for many state and private-sector industrial schemes had quintupled Argentina's foreign debt. The overvalued peso made exports expensive, so that export earnings could not keep pace with the growing debt. Even as the government dismantled parts of the economic adjustment program, it had to address fundamental defects in Argentina's economy. The country had agricultural and industrial sectors similar to those of developed countries, but they were considerably less efficient. And despite a high standard of living by South American standards, it had a foreign debt comparable to that of Third World countries.

Resources. Argentine industry is well served by the country's abundance of energy resources. By the late 20th century the country was self-sufficient in power, even to the degree that it could become a power exporter. The two main sources of power are petroleum and hydroelectricity. Petroleum deposits are scattered throughout the country. The basin around the Patagonian port of Comodoro Rivadavia is estimated to hold some two-thirds of the country's onshore reserves. Other deposits are located in Jujuy and Salta provinces, in Mendoza and Neuquén provinces, and at the tip of Patagonia and Tierra del Fuego.

While most of the country's power has traditionally been

derived from petroleum, there has also been emphasis on the need to develop other energy resources. It has been estimated that half of the country's energy reserves lie in the potential of its rivers. Power from hydroelectric projects was increased by 10 times in the 1970s, and plans for the completion of more projects have been made. Such plans also involve the greater realization of abundant natural gas supplies and the production of nuclear energy, the latter being an area in which Argentina, with several nuclear plants, is a Latin-American leader. The main natural gas fields are in the Northwest, near Campo Durán (Salta Province) and Mendoza, and in Patagonia, near Neuquén and Comodoro Rivadavia. Argentina mines some coal, but most of its needs are met by imports. The chief coal deposits are in southern Patagonia.

Nuclear energy

With the exception of oil and natural gas, exploitable mineral reserves are generally small and widely scattered. Reserves of iron ore, uranium, lead, zinc, silver, copper, manganese, and tungsten are worked. A wide range of nonmetallic minerals is found throughout the country. Salt deposits are located on the western and southwestern edges of the Pampa. Materials such as clay, limestone, granite, and marble supply the construction industries.

Agriculture, forestry, and fishing. Argentina is one of the world's major exporters of soybeans and wheat, as well as meat. It is also one of the largest producers of wool and wine, most of the wine being consumed domestically.

Wheat is Argentina's largest crop in harvested land area, and it is the dominant crop in the cattle-raising southern Pampa of Buenos Aires and La Pampa provinces. Wheat and corn dominate in the north. Planting of corn began simultaneously with wheat in the northern Pampa. By the end of World War II, however, corn production had been cut in half due to worldwide competition, and production has only gradually increased since then. About half of the corn produced is used for livestock feed. The total area of the Pampa planted in sorghum and soybeans has grown since 1960 to rank just behind that of wheat and corn. These crops serve primarily as livestock feed and are valuable for export. Another crop of the northern Pampa is flax.

More than 90 percent of the country's grape vines are planted in the Northwest provinces of Mendoza and San Juan; most of the crop is for wine making. Table grapes are a specialty in La Rioja. The warmer northern provinces of Tucumán, Salta, and Jujuy make up the sugarcane-growing region of Argentina. The sugarcane provinces have also introduced citrus crops, because of the unreliable sugar market, and Salta and Jujuy grow tobacco. The best area for cotton growing lies mainly west of the Paraná River, between the Bermejo and Dulce rivers. Most of the crop goes to the Argentine textile industry.

Sugarcane growing in the Northwest

In Mesopotamia yerba maté is the most important product of Misiones Province, although since 1940 inroads have been made by tea farming and by the cultivation of tung trees, from which tung oil is derived. Citrus has also become important. Farther south in Mesopotamia, in the truck-farming area that supports Buenos Aires, oranges, grapefruit, mandarins, and numerous vegetables are grown. The Negro River irrigation district in Patagonia has become one of Argentina's major fruit-producing regions, particularly of apples and pears.

As the source of the country's most valuable export commodity, beef cattle dominate the Pampa. Estancieros have proved quick to adapt to changing markets, switching breeds and supplementing alfalfa feed with grain sorghum in order to produce leaner meat. Most of Argentina's hogs are raised in the Pampa, principally for domestic consumption. The cool, moist area of the southeastern Pampa, between Buenos Aires and the city of Mar del Plata, is an important dairy and sheep-raising district. Corrientes and Entre Ríos remain important cattle-raising provinces, ranking just behind those of the Pampa. Chaco Province began as grazing ground for criollo cattle, but modern breeds seem inevitably to succumb to disease, so that the cattle economy there remains backward. Patagonia has at least half of the country's sheep, most of which are sheared for their wool.

The forestry industry does not supply all of Argentina's needs. Most of the harvest goes to lumber, with smaller amounts to firewood and charcoal. In Mesopotamia the Paraná pine is harvested for lumber; there are also plantations of poplar and willow. The Northwest highlands produce pine and cedar, used for pulp and industry. The red quebracho of the Chaco region is valuable for its tannin, and the white quebracho is used for lumber and charcoal. Scattered stands of algarraba provide local firewood and cabinet wood in the Pampa.

The fishing industry is comparatively small, owing in part to the overwhelming preference among Argentines for beef in their diet. Most coastal and deep-sea fishing is done in the Buenos Aires sector, from the Río de la Plata to the Gulf of San Matías; the major ports are Mar del Plata and Bahía Blanca. Hake, squid, and shrimp make up a large part of the catch, about three-quarters of which is frozen or processed into oil and fish meal for export.

Industry. The product that initiated industrialization in Argentina was beef. This success was due in no small part to refrigeration techniques that, after 1876, made it possible to store and ship fresh meat. By the late 1920s frigoríficos (meat-packing plants) were located in various parts of the country, several of them in the Buenos Aires area. Later, shipments proceeded from La Plata, Rosario, and Bahía Blanca. Frigoríficos at the ports of Patagonia also came to serve the sheep ranches of that region.

Proliferation of frigoríficos

The growth of beef production in Argentina gave rise to a host of associated industries, including those producing tinned beef, meat extracts, tallow, hides, and leather. The Chaco region supplies the necessary tannin, of which it is a major world producer. Argentina has been a consistent world leader in the export of hides. Leather processing occurs locally, and fine leather clothing can be obtained at retail outlets in the cities.

The Argentine grain milling industry has grown in cities that built huge storage silos. As production has increased, grain has become a significant export. Wheat flour produced in the mills that emerged in the silo areas is consumed locally. Certain kinds of food industries based on wheat flour and various pastas have been attracted to the same sites along the Río de la Plata littoral. Smaller but similar activities are emerging in the interior of Argentina, wherever grain production takes place. Textile production in Argentina also developed on the basis of agricultural products, namely wool and cotton. It is concentrated in the cities of the Pampa, where the labour needs can be met and where the largest markets are located.

Textile production

Argentina's refining industry has grown along the coast in Buenos Aires and nearby cities. Tankers and pipelines from Comodoro Rivadavia and Venezuela bring crude oil to this area. The refining industry has also found a base in the petroleum fields north and south of Mendoza, where petrochemical industries have emerged.

The steel industry in Argentina began in the 1940s and grew slowly during the following decades. The Zapla works in Jujuy, the integrated San Nicolás de los Arroyos mill between Rosario and Buenos Aires, and the mill in Rosario produce most of the nation's steel but fall short of supplying domestic demand. A developing automobile industry provides a market for Argentine steel producers.

The Argentine sugar industry of the Northwest is centred mainly in Tucumán, but a few mills also operate in Salta and Jujuy. The sugar mills fulfill domestic demand. Mendoza in the same region is the nation's centre for olive and olive oil production, as well as for wine bottling. Argentine wine shipments to other South American countries and to North America have become common, based on a steadily improving reputation among consumers. The Northwest is also a major area for cement production, and there is a developing aircraft industry at Córdoba.

Finance. Argentina's financial system includes banks owned by the national government, by provincial and municipal authorities, and by private companies. The Banco Central de la República Argentina is the nation's central bank; it issues currency, sets interest and exchange rates, and regulates the money supply by deciding the amount of reserve cash banks must hold.

The central bank

Economic troubles beginning in the 1970s caused the near collapse of the country's financial system. Inflation

made savings deposits almost worthless; liberalized foreign-investment laws and an overvalued peso encouraged excessive borrowing abroad; and defaulted loans caused many bankruptcies. To prevent complete collapse, the government took greater control of the private sector.

Trade. Argentine trade has always been oriented toward Europe and the United States. Following the colonial period, the United Kingdom began acquiring its wheat and meat from the Pampa region. After World War II, Argentina attempted to raise beef and grain prices in order to rebuild lost sterling reserves, but the attempt failed. In addition, Britain's trade was inclined toward those countries seeking consumer goods while, at the same time, Argentina was attempting to become self-sufficient in such needs. Trade with Britain diminished, falling especially after the Falkland Islands war in 1982. Since that war continental European countries (particularly The Netherlands and West Germany) and the Soviet Union have become important trading partners of Argentina, although the United States remains the single most important market for the country's exports. Brazil also ranks high in trade volume with Argentina. Agricultural products are Argentina's major exports, and its imports include nonelectrical and electrical machinery, chemicals, and petroleum and petroleum products.

Major trading partners

Transportation. During the Spanish colonial period, there were three principal overland transportation routes. The most important led from Buenos Aires to the wealthy mining centre in Peru via the northwestern route through Córdoba, Santiago del Estero, Tucumán, and Jujuy. A second route linked Buenos Aires with Chile westward to Villa María, San Luís, and Mendoza. The third route extended north from Buenos Aires to Santa Fe and Corrientes. These and less important side roads were used by mule drivers, horsemen, huge-wheeled oxcarts called carretas, and stagecoaches drawn by six to eight horses.

The transformation of this system did not occur by means of the modernization of roads but rather by the rapid introduction of rail lines during the period just after 1857. British and other foreign capital funded rail networks that led from Buenos Aires in several directions. Road and rail construction continued from that time into the 20th century, extending throughout the nation. By the late 20th century, Argentina had the most extensive transportation system in Latin America. The largest share of surface freight is carried by road, with lesser amounts carried by river, pipeline, and railroad.

Extension of the rail and road network

Small ships that carry passengers and freight have served the coastal cities from Buenos Aires to Río Gallegos since the end of the 19th century. The ocean shipping fleet, however, is not well developed, considering Argentina's extensive export trade. Air transportation provides rapid travel to all regions of the nation. Every major city has a jet airport, and even small, remote centres like Ushuaia in southern Patagonia have good service. The country's most important air transport company, Aerolíneas Argentinas, was founded by the government in 1950 to handle domestic and international traffic. International airports are located in most of the major cities, the most important being Ezeiza outside of Buenos Aires.

GOVERNMENT AND SOCIAL CONDITIONS

Government. Argentina is a federal union of 22 provinces, one territory, and a federal capital, the city of Buenos Aires. Federalism came to Argentina only after a long struggle between proponents of a central government and supporters of provincial interests. The constitution of 1853 was modeled after that of the United States, and, although altered a number of times, the document has sustained Argentina with at least a nominal form of republican, representative, and federal government.

The executive and the legislature

Executive power resides in the office of the president, who is elected with a vice president to a six-year term. The president may not be reelected for consecutive terms. The president is commander in chief of the armed forces and appoints all civil, military, and federal judicial officers. Both the president and the vice president must profess Roman Catholicism. The Argentine legislature, or National Congress, consists of two houses: a Senate, composed of two representatives from each province and the federal capital elected for nine-year terms; and the Chamber of Deputies, whose members are elected for four-year terms, with apportionment based on population. Each province has its own government, with executive, legislative, and judicial branches similar to those of the federal government.

The Argentine judicial system is divided into federal and provincial courts. Supreme Court judges are appointed by the president with approval of the Senate. Federal judges are appointed constitutionally for life, but it has not been unusual for them to serve only as long as the administration that appointed them.

Political parties

The Argentine system of political parties has been volatile, particularly in the 20th century, with numerous parties being formed, taking part in elections, and being disbanded as new factions evolved. Among the major parties operating in Argentina are the Radical Civic Union, a centrist party with moderate leftist leanings; the National Justicialist Movement, the Peronist party (made up of followers of former president Juan Perón), divided into factions and made up largely of nationalists and labourers; and the Union of the Democratic Centre, a coalition of right-wing parties.

Education. Argentina has one of the better educated populations in Latin America, which is reflected in its large number of schools and high literacy rate. Primary education is compulsory and free; secondary and higher education is offered in free public schools and in private schools subsidized by the state. Higher education in Argentina was seriously hampered by the censorship and other strictures of the military government of 1976–83, but efforts to restore the system began after a civilian government was returned to power. The National University of Córdoba, founded in 1613, is the nation's oldest, and the University of Buenos Aires, founded in 1821, is its largest. Other major national universities are at Mendoza, La Plata, Rosario, and Tucumán. The National Technical University is located at Buenos Aires.

Major universities

Health and welfare. An extensive system of hospitals and clinics in Argentina is run by national, provincial, and local authorities as well as by private organizations. Public health and sanitation standards are particularly high in developed areas but can drop off considerably in some of the undeveloped areas. Diseases such as smallpox, cholera, yellow fever, and tuberculosis have been brought under control or eliminated.

Argentina's social welfare services were developed on a large scale during the first presidency of Juan Perón (1946–55). A social security system was set up to provide extensive benefits for all workers. Housing, however, has become a problem in cities because of the movement of workers from rural areas, especially during difficult economic periods. This has produced new living quarters on the outskirts of urban zones that have been built hastily from corrugated iron and scraps of wood, cardboard, and other scavenged materials. These communities are called *villas miserias,* and, despite pressures from various directions, little has been done to improve their condition.

CULTURAL LIFE

Heritage and daily life. Because almost all Argentines are descendants of relatively recent immigrants from Europe, their culture has a more distinctly European orientation than that of their fellow Latin Americans. The people of Buenos Aires, the *porteños,* often call their city the Paris of South America, and, with its culture and glamour, it probably earns that name. But there is another Argentina away from the capital: this is the Argentina of the Pampa and the interior. The interior gave to all Argentines their symbol of national identity, the gaucho, who occupies a position in South American lore similar to that of the cowboy in the United States. Scorned in his heyday of the 18th and 19th centuries as a drinker and vagabond, this mestizo ranch hand rode the open rangeland of the huge estancias in pursuit of wild horses and criollo cattle. Eventually Argentines came to see him as a character whose solitary life in the open taught him self-reliance, courage, indifference to hardship, and love of the land, traits that represented the ideal of their national character.

The gaucho

The tango

Another hybrid of the Old and New Worlds is the tango, which emerged from the poor immigrant quarters of Buenos Aires toward the end of the 19th century and quickly became famous around the world as the Argentine national dance. Influenced by the Spanish tango and, possibly, the Argentine *milonga,* it was originally a high-spirited local dance, but, popularized by such singers as Carlos Gardel, it became an elegant ballroom form danced to melancholy tunes.

The combination of Old and New World cultures is also seen in the Argentine diet. Southern European influences appear especially in the cities, where breakfast is often a light serving of rolls and coffee, and supper is taken, in the Spanish tradition, after nine o'clock at night. The Italian influence is seen in the popularity of pasta dishes. But the New World asserts itself in the Argentine passion for beef, which is overwhelmingly preferred to other meats and fish. Maté, the native tealike beverage brewed from yerba maté leaves, is popular in the countryside.

The arts. The fine arts of Argentina have always found their inspiration in Europe, particularly in France and Spain. In literature the Modernismo movement of the late 19th century and the Ultraísmo of the early 20th were both influenced by the French Symbolist and Parnassian poets. By composing verses of unconventional metre and by using unusual imagery and symbolism, such poets as Leopoldo Lugones and Jorge Luis Borges hoped to draw attention to the beauty of the Spanish language. Borges went on to become one of the most innovative novelists of Latin America. He prepared the way for experimental novelists of the later 20th century.

Music, painting, and sculpture

Composers of the early 20th century, such as Alberto Williams and Carlos López Buchardo, contributed to a nationalist revival in music by adapting folk and gaucho themes to classical forms. A generation later Alberto Ginastera and Juan Carlos Paz experimented with musical forms that were current throughout Europe and the Americas. Painters and sculptors studied in Italy and France and brought the academic, Impressionist, and Cubist styles to Argentina. Later artists were inspired by Mexican murals and by abstract and Pop art in the United States.

Recreation. The most popular sport is football (soccer), introduced by the British in the 19th century; Argentine teams are generally among the best internationally and have won the World Cup. The British also brought polo, at which the equestrian-loving Argentines quickly excelled. There are excellent hiking and fishing areas in the Lake District of the Patagonian Andes, and skiers travel to Andean resorts. In the summer months bathers pack the beaches at resorts, such as Mar del Plata.

Important civic holidays are the Anniversary of the Revolution (May 25) and Independence Day (July 9). Christmas is a national holiday. Regional festivals include the Fiesta del Milagro in Salta, commemorating the salvation of the city from an earthquake in September 1692, the celebration on July 6 of the founding of Córdoba, and the wine festival in Mendoza in March.

Press and broadcasting. The mass media in Argentina are well advanced among Latin American nations. All of the largest newspapers are published in Buenos Aires. The largest daily circulation is claimed by *Clarín;* two other large-circulation dailies, *La Nación* and *La Prensa,* founded in 1870 and 1869, respectively, have high reputations in the Spanish-speaking world as well as among the international press. In the capital various foreign-language papers serve the ethnic groups. The majority of the radio and television stations are privately operated. Throughout the country's postwar history the broadcast media have periodically become agents of state propaganda, only to be returned to some independence by succeeding administrations. This process has also afflicted the press.

For statistical data on the land and people of Argentina, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (R.C.Ei./Ed.)

History

It has been estimated that the population living in the land area of what is now called Argentina before the arrival of the Europeans totaled some 300,000. As in the rest of the New World, it was composed of Indians believed to have been descendants of Asians who, in prehistoric times, are thought to have migrated across the Bering Strait to the North American continent and who gradually spread across North, South, and Central America. The state of civilization of the Argentine Indian did not match those of the Aztec and the Maya and the empire-building Incas. Some of the tribes, such as those in the Chaco and Patagonia, were nomadic hunters and fishers; but others, such as the Diaguitas of the Northwest and the Araucanians of the Pampa, developed a primitive agriculture, handicrafts, trade, and relatively sophisticated weaponry.

EARLY PERIOD

Discovery and settlement. It is well established that Amerigo Vespucci stimulated the Spanish search for a southern strait, which led to the discovery both of the Río de la Plata by Juan Díaz de Solís in 1516 and of the Strait of Magellan by Ferdinand Magellan in 1520. These two voyagers revealed the main outlines of the Atlantic coast of what is now Argentina. Sailing up the Plata, which he called the Mar Dulce, or Freshwater Sea, Solís, with a small party, landed and was ambushed by Indians. Solís and most of his followers were killed; several disappeared. The survivors of the expedition returned to Spain.

Exploration by Sebastian Cabot

The Río de la Plata was not explored again until Magellan arrived in 1520 and Sebastian Cabot in 1526. The latter picked up two survivors of the Solís expedition, who told glowing tales of the wealth of the region. Cabot discovered the Paraná and Paraguay rivers and established the fort of Sancti Spíritus (the first Spanish settlement in the Plata basin). He also sent home reports of the presence of silver.

In 1528 Cabot met another expedition from Spain under Diego García, commander of a ship from the Solís expedition. Both Cabot and García had been supposed to sail for the Moluccas but altered their courses, influenced by excited tales about an "enchanted City of the Caesars," a variant of the Eldorado legend, which later incited many explorations and conquests in Argentina. While Cabot himself was preparing to search for the fabled city, a surprise attack by the Indians in September 1529 wiped out his Sancti Spíritus base.

Inspired by the conquest of Peru and the threat from Portugal's growing power in Brazil, Spain in 1535 sent an expedition under Pedro de Mendoza (equipped at his own expense) to settle the country. Mendoza was initially successful in founding Santa María del Buen Aire, or Buenos Aires (1536), but lack of food proved fatal. Discouraged by Indian attacks and mortally ill, Mendoza sailed for Spain in 1537, dying on the way.

In the same year a party from Buenos Aires under Juan de Ayolas and Domingo Martínez de Irala, lieutenants of Mendoza, pushed a thousand miles up the Plata and Paraguay rivers. Ayolas was lost on an exploring expedition, but Irala founded Asunción among the Guaraní, a sedentary, agricultural people. In 1541 the few remaining inhabitants of Buenos Aires abandoned it and moved to Asunción, which was the first permanent settlement in this area. In the next half-century Asunción played a major part in the conquest and settlement of northern Argentina. The main population of Argentina was concentrated here until the late 18th century. Buenos Aires, reestablished in 1580 by Juan de Garay with settlers from Asunción, was largely isolated from this northern area. Northern Argentina as well as Buenos Aires was settled mainly by the overflow from neighbouring Spanish colonies—Chile, Peru, and Paraguay (Asunción). There was little direct migration from Spain, probably because the area lacked the attractions of Mexico, Peru, and other Spanish colonies—rich mines, a large supply of tractable Indian labour, accessibility, and the privilege of direct trade with Spain. Nevertheless, in the early communities a simple but vigorous society developed on the basis of Indian labour and the horses, cattle, and sheep imported by the Spaniards, as well as native products such as corn and potatoes; some of the Indians worked as virtual serfs. Missions established by the Roman Catholic Church played a notable role in the colonizing process. Because few Spanish women were

Role of Indian labour

among the settlers, there was much intermarriage with the Indians.

Colonial period. Politically, Argentina was a divided and subordinate part of the Viceroyalty of Peru until 1776, but three of its cities—Tucumán, Córdoba, and Buenos Aires—successively achieved a kind of leadership in the area and thereby sowed the seed of community feeling that much later grew into the idea of Argentine national union.

Tucumán's leadership lasted from the latter part of the 16th through the 17th century. Its political and ecclesiastical jurisdiction extended over most of northern Argentina, including Córdoba. Tucumán also dominated the chief economic activity of supplying the rich silver-mining area of Upper Peru (Bolivia) with foodstuffs and livestock in return for European manufactures and other goods brought from Spain. Under the same economic system Córdoba rose to leadership in the 17th and 18th centuries because the expansion of settlement gave the city a central location and because the University of Córdoba, founded in 1613, put the city in the intellectual forefront in Argentina and in Spanish America in general.

Preeminence of Buenos Aires

On the other hand, Buenos Aires, which rose to leadership in the late 18th century, symbolized three important reorientations of Argentine life from west to east. The first, economic, was the shift from trade with the now declining silver mines of Peru to direct transatlantic trade with Europe. Another reorientation, intellectual, resulted from the rise of interest in the new ideas of the European Enlightenment, which found fertile soil in cosmopolitan Buenos Aires. The third reorientation, political, was brought about by Spain's detaching its possessions in the Plata basin (modern Argentina, Uruguay, Paraguay, and southern Bolivia) from the Viceroyalty of Peru and erecting them into the new Viceroyalty of the Río de la Plata, with Buenos Aires as its capital (1776). Spain's main purpose was to put its Plata dominions in a better defensive position. The chief threat came from Brazil, which was growing rapidly in population, wealth, and military potential. For the first time the port of Buenos Aires was opened to transatlantic trade with Spain and, through Spain, with other countries. This resulted in a great increase in both legal trade and the already flourishing smuggling.

Effect of Napoleon's intervention in Spain

Independence. In Argentina, as in most of Spanish America, the independence movement was precipitated mainly by Napoleon's intervention in Spain, beginning in 1808. The break began when Napoleon's intervention plunged Spain into a civil war between two rival governments. One was set up by Napoleon, who placed his own brother Joseph Bonaparte on the throne. The other was created by patriotic juntas in Spain in the name of the exiled Ferdinand VII and aided by the British. In most of Spanish America, however, while there was general sympathy with the regency, both claims were rejected, mainly on the ground that an interregnum existed and that under ancient principles of Spanish law the king's dominions in America had the right to govern themselves pending the restoration of a lawful king.

This view was sustained in Argentina by the Creoles rather than by the "peninsular" Spaniards, and it was given effect by the Buenos Aires cabildo, or municipal council. This ancient Spanish institution had existed in all the colonies since the 16th century. Its powers were very limited, but it was the only organ that had given the colonists experience in self-government. In emergencies it was converted into an "open" cabildo, a kind of town meeting, which included substantial members of the community. On May 25, 1810, such an "open" cabildo in Buenos Aires set up an autonomous government to administer the Viceroyalty of La Plata in the name of Ferdinand VII, pending his restoration. When Ferdinand was restored in 1814, however, he promptly proved himself one of the worst kings Spain had ever had. Thereupon, an assembly representing most of the country met at San Miguel de Tucumán and, on July 9, 1816, declared the country independent under the name of the United Provinces of the Río de la Plata.

Several years of hard fighting followed before the Spanish royalists were defeated in northern Argentina. But they remained a threat from their base in Peru until it was liberated by Simón Bolívar in 1824. The Buenos Aires government tried to maintain the integrity of the old viceroyalty of the Río de la Plata, but the outlying portions, never effectively controlled, soon were lost: Paraguay in 1814, Bolivia in 1825, and Uruguay in 1828. The remaining territory, modern Argentina, was frequently disunited until 1860. The root cause of the trouble, the question of the relation of Buenos Aires to the rest of the country, was not settled until 1880, and, even after that, it continued to cause dissatisfaction.

Conflict between Buenos Aires and the hinterland

EFFORTS TOWARD RECONSTRUCTION, 1820–29

In 1820 there were only two political organizations that could claim more than strictly local and provincial followings: the revolutionary government in Buenos Aires and the League of Free Peoples (Liga de los Pueblos Libres) that had grown up along the Río de la Plata and its tributaries under the leadership of José Gervasio Artigas. But both organizations collapsed simultaneously in that year, and Buenos Aires seemed on the verge of losing its position as the seat of national government. However, as the city regained its function as an intermediary between the nation and foreign governments, it also regained its national prominence.

Dominance of Buenos Aires. In practically all of the provinces, military leaders had assumed power. Each provincial political regime soon acquired its own character, according to the relative power held by military strongmen and by local political interests. This differentiation was not, however, cause for friction among the provinces; their cleavages were more directly attributable to economic and geographical differences. Buenos Aires was able to make significant advances toward national leadership by prudently taking advantage of the interprovincial rivalries.

Reforms of the Party of Order

Within the Province of Buenos Aires itself, the regime of the so-called Party of Order (Partido del Orden) put into effect reform measures that were viewed with favour. Principal among them was the dismantling of the military apparatus that had remained from the war and the dedication of what remained to the defense of the frontier areas and plains against the Indian threat. This prudence on the part of the government in power won the support of the rural landowners as well as the urban businessmen, whose backing assured victory at the polls.

The political order that seemed to be taking hold in Buenos Aires, however, and in the country as a whole was achieved by setting aside, rather than resolving, certain fundamental difficulties. In particular, the institutional organization of the country was not carried out, and nothing was done about the Banda Oriental (the east bank of the Uruguay River), which was occupied first by Portuguese and then by Brazilian troops. By 1824, both problems were becoming urgent. England was willing to recognize Argentine independence if a government was established that could act for the whole country. In the Banda Oriental, a group of eastern patriots had taken over large sectors of the rural areas and agitated for their reincorporation into the United Provinces of the Río de la Plata, forcing the Buenos Aires government to face the possibility of war with the Brazilian empire.

Presidency of Rivadavia. In the meantime an attempt was made to establish a national government through a constituent assembly that met in December 1824. Overstepping its legal authority, the constituent assembly, in February 1826, created the office of president of the republic and installed the *norteño* ("northerner") Bernardino Rivadavia as its first occupant. Civil war flared up in the interior provinces, soon dominated by Juan Facundo Quiroga—the caudillo from La Rioja who opposed centralization. When the assembly finally drafted a national constitution, the major portion of the country rejected it.

War against Brazil had begun in 1825. While the Argentine forces were able to defeat the Brazilians on the pampas of Uruguay, the Brazilian navy blockaded the Río de la Plata and succeeded in crippling Argentine commerce. Unable to end the war on favourable terms, Rivadavia resigned in July 1827, and the national government dissolved. Leadership of the Province of Buenos Aires was given to a federalist, Col. Manuel Dorrego. Behind Dorrego there were local interest groups whose political spokesman

was the great landowner Juan Manuel de Rosas, who had been named commander of the rural militia. Dorrego was prevailed upon to make peace with Brazil. In 1828 the disputed eastern province was constituted as the independent state of Uruguay; the territory that Rivadavia had considered indispensable to the "national integrity" of Argentina was never to be recovered. In December 1828, troops returning from the war overthrew Dorrego and installed Gen. Juan Lavalle in his place; Dorrego was executed.

While there was little resistance to the new governor in the city of Buenos Aires, uprisings began quite promptly in the outlying areas of the province. In Santa Fe a convention of representatives from the provinces dominated by the federalists, under the leadership of Rosas, called upon the Governor of Santa Fe to take steps against the Lavalle regime. Lavalle finally came to terms with Rosas, and they agreed to hold elections in Buenos Aires for a new provincial legislature. Under the compromise agreement, Rosas and Lavalle appointed a moderate federalist as governor of Buenos Aires, but political tensions were too great for this attempt at reconciliation. Rosas reconvened the old legislature that Lavalle had disbanded when he came to power—a triumph for the most intransigent forces of federalism. The legislature unanimously elected Rosas governor on Dec. 5, 1829.

CONFEDERATION UNDER ROSAS, 1829–52

The regime of Rosas in Buenos Aires enjoyed far broader support than any of its predecessors. Special interest groups, landholders, and export-import merchants (along with the British diplomatic contingent that was identified with these interests) all fell behind the new governor. Practically all the influential sectors in the province identified Rosas' triumph with their own best interests.

Hegemony of Buenos Aires under Rosas

Domestic politics, 1829–35. The new governor, however, saw clearly the ambiguities and dangers of such widespread support. He sought a political formula that would enable him to harness the energies of the various sectors to his own purposes. He found this formula in factionalism. By imposing an orthodox federalism, the exact nature of which he alone would determine according to his own political objectives, Rosas would be assured of control over the masses and would be able to use this influence as a restraint on the economic and social elites, with whose interests Rosas fundamentally identified. This blueprint assigned to Rosas the role of permanent arbiter of a delicate and constantly threatened balance.

By 1832 the opposition to federalism had disappeared throughout the country, and Rosas turned over the reins of the government of Buenos Aires to his legal successor, Gen. Juan Ramón Balcarce. Balcarce's assumption of the office fanned sparks of dissidence among those who had pledged to uphold the principles of federalism. Balcarce was overthrown, and his successor took office with a Cabinet composed of Rosas' friends. They adopted policies that were designed to lead to normality. But it was normality that Rosas feared, since it would have entailed the demobilization of his mass political following. The legislature in Buenos Aires was induced to designate Rosas as governor of the province, but under conditions that Rosas himself successfully imposed: he was granted extraordinary resources, absolute public authority, and an extension of the governor's term of office from three to five years.

Foreign policies. In the field of international relations, Rosas' policies also left no room for anything other than total success or total failure. International difficulties arose as extensions of domestic turmoil. At that time it was not clear to everyone that the neighbouring countries of Bolivia, Paraguay, and Uruguay were destined to be independent states and not part of the federal grouping controlled by Buenos Aires. Gen. Andrés Santa Cruz, who had established a confederation of Peru and Bolivia, supported opponents of Rosas in Argentina. Rosas in turn supported the influential governor of the northern Province of Tucumán, when that governor decided to go to war against the forces of General Santa Cruz. In 1839 the war ended in victory for the northern Argentine forces, in part thanks to an alliance with Chile.

Rosas' involvement in civil struggles in Uruguay proved to be costly. It led to the first open friction with France, which sent warships to blockade Buenos Aires in 1838. This created dissension in the coastal region, which had always depended heavily on export trade. Argentine political exiles in Montevideo received French backing in their efforts to overthrow Rosas, and in the north a league of dissident provinces was formed.

This formidable coalition of adversaries soon fell apart. Faced with other problems, France abandoned its adventure in the Río de la Plata area and left its local allies to fend for themselves against Rosas. At the same time, an army organized by Buenos Aires and commanded by the Uruguayan leader Manuel Oribe gained control of most of the Argentine interior. For the first time since 1820, troops from Buenos Aires had advanced as far as the Bolivian and Chilean frontiers. The hegemony of Buenos Aires under Rosas' system of federalism was not to be challenged again. Oribe went on to conquer most of Uruguay, and his predominantly Argentine army began the siege of Montevideo in February 1843. The city was saved only through the intervention of British warships, and in 1845 an Anglo-French fleet blockaded Buenos Aires and a British fleet sailed up the Paraná River. Eventually the British and French withdrew their aid to Montevideo and made peace with Rosas.

The fact that Rosas was able to conduct a vigorous foreign policy for so many years was partly because of the weakness of Brazil, Argentina's natural rival in the Río de la Plata area, which had been involved in a civil war (1835–45) in Río Grande do Sul. Once the rebellion had been put down, it was only a question of time until Brazil's influence was again a factor in the Río de la Plata region. This influence opposed Rosas. It worked in support of a rebellion by Gen. Justo José de Urquiza, governor of the Province of Entre Ríos. In 1851 Urquiza formed an alliance with Brazil and Uruguay. The allies first forced Rosas' troops to abandon the siege of Montevideo and then defeated his main army in the Battle of Caseros (Feb. 3, 1852), just outside Buenos Aires. Rosas, abandoned by most of his troops as well as his political supporters, was taken to England, where he died in 1877.

Economic development, 1820–50. In the 30 years after 1820, Argentina's society and economy underwent considerable changes. Buenos Aires was the province best adapted to the new era of free trade based upon the export of cattle products in return for consumer goods from overseas. The interior provinces adjusted slowly, replacing their traditional markets in highland Peru with new ones in Chile, where a great expansion of the mining industry was taking place. The coastal provinces fared better, although their livestock industry suffered from the effects of the civil war. For Santa Fe, the decade of the 1830s brought a return to moderate prosperity, and a similar trend began in Entre Ríos and Corrientes provinces in the 1840s.

Growth of a cattle economy

NATIONAL CONSOLIDATION, 1852–80

General Urquiza called a constitutional convention that met in Santa Fe in 1852. Buenos Aires refused to participate, but the convention adopted a constitution for the whole country that went into effect on May 25, 1853. Buenos Aires refused to join the new confederation, the first elected president of which was Urquiza and the first capital of which was Paraná. The dissidence was a serious financial handicap to the state, since Buenos Aires kept for itself all the revenues from customs duties on imports. In 1859 Urquiza incorporated Buenos Aires by armed force, but he had to agree to a constitutional revision that underscored the federal character of the government.

Constitutional convention of 1852

Before the unification took effect, however, Urquiza was succeeded in the presidency by Santiago Derqui. Another civil war broke out, but this time Buenos Aires defeated the forces led by Urquiza. The latter came to an understanding with Gen. Bartolomé Mitre, governor of Buenos Aires. They agreed that Mitre would lead the country but that Urquiza would exercise authority over the provinces of Entre Ríos and Corrientes. Derqui resigned, and Mitre was elected president in 1862 with Buenos Aires as the seat of government.

The authority of the new president (1862–68) was pro-

gressively weakened by opposition within his own province of Buenos Aires. The pressures of this opposition forced Mitre definitely toward intervention in the political struggles of Uruguay and thence into a war with Paraguay. From 1865 to 1870, a triple alliance of Argentina, Brazil, and Uruguay carried on a war to the death against Paraguay, employing modern weapons and tens of thousands of troops.

The war with Paraguay did not disrupt Argentina's commerce, as other wars had. In the 1860s and 1870s foreign capital and waves of European immigrants poured into the country. Railroads were built; alfalfa, barbed wire, better breeds of cattle and sheep, and finally the refrigeration of meat were introduced. The national armed force became one of the cornerstones of the new centralized state.

But if the national state seemed to be taking shape with surprising vigour, the process never resulted in consolidation of the hegemony of the so-called liberal faction that had backed Mitre in 1861–62. Moreover, the army refused to uphold the policies of the President. One of Rosas' nephews rallied the support of the military behind the presidential candidacy of Domingo Faustino Sarmiento, a native of San Juan. His victory was guaranteed by the influence of the military combined with the support of the liberal faction in Buenos Aires that opposed Mitre. The new president (1868–74) held office without a political party of his own. Credit from abroad brought a continuing prosperity that allowed Sarmiento to engage in a costly civil war to put down an uprising in Entre Ríos.

Sarmiento was succeeded by his minister of justice, public education, and worship, Nicolás Avellaneda (1874–80), a native of Tucumán, whose victory was a reaction against the hegemony of Buenos Aires. The new president faced serious financial difficulties engendered by the European economic crisis of 1873. When the external sources of capital dried up, the country once again felt the consequences of Buenos Aires' financial superiority. Avellaneda adopted a policy of austerity, and he undertook to reach an agreement with the declining forces of liberal nationalism.

The Roca presidency

Gen. Julio Argentino Roca, who was also from Tucumán and who had influence in Córdoba, became the next president (1880–86). Roca had led a brilliant military career, during which he had brought the long cycle of Indian wars to a victorious close in 1879. This achievement, opening up the pampas to settlement, made Roca a political hero. His campaign for the presidency provoked a new rebellion in Buenos Aires, but the uprising was quickly put down. The perennial question of the city's status was then settled by making it a federal territory and converting it into the national capital; a new capital for the Province of Buenos Aires was established at La Plata.

THE CONSERVATIVE REGIME, 1880–1916

The entire country was now dominated by the National Autonomist Party, which was composed of an alliance of the various groups supporting Roca. These included many of the big ranchers, as well as commercial and business interests who were more than happy with Roca's formula of "peace and efficient administration." Argentina's economic expansion in this period owed much to British capital, which made possible the building of an extensive rail network linking the upriver provinces to Buenos Aires and the sea. Along with the growth of agriculture and ranching, there was also some expansion in other industries, but the impetus came from large-scale foreign investment. This was also an era of rapid growth in population, largely from immigration. Argentina's population grew from less than 2,000,000 in 1869 to nearly 8,000,000 in 1914.

Economic expansion

The crisis of 1890. The economic expansion led ultimately to inflation, accompanied by the issuance of too much paper currency and a crisis of confidence in the London capital market. The financial crisis was followed by a political one. The government of Roca's successor, Miguel Juárez Celman (1886–90), had been wary to launch a necessarily unpopular anti-inflationary program. Discontent was growing, both within and outside the official party ranks. In July a revolt erupted that had strong support from within the army, but it was defeated by loyal elements. Even so, Juárez Celman was forced to step down in favour of the vice president, Carlos Pellegrini, a solid ally of Roca.

The rise of radicalism. The difficulties of the 1890s brought the rise of a new party, the Radical Civic Union, strongly opposed to the ruling regime and the compromise candidate, Luis Sáenz Peña, accepted by Mitre and the more moderate opponents of the Roca–Juárez Celman regime. In 1898 Roca returned to the presidency for a second term (1898–1904) and began an attempt to bring the more moderate radicals effectively back into the loose alliance of local political groups, which after 1890 controlled the national government. The most intransigent radical factions, headed by Hipólito Irigoyen, who later became president twice, remained in opposition.

Broadening of political life

While political opposition was on the decrease, social unrest was becoming more widespread. Within the government itself there was growing disarray. When Roca broke with Pellegrini, it was a final blow for the National Autonomist Party, and Roca was barely able to avoid being succeeded in office by Pellegrini in 1904. The candidate he finally put into the presidency, Manuel Quintana (1904–06), was far from being one of Roca's stauchest supporters. Quintana was forced to quell a radical revolution in 1905, and his death opened the way to the presidency for the Cordoban José Figueroa Alcorta (1906–10), who turned immediately to the task of destroying Roca's political machine. In 1910, Alcorta installed as his successor Roque Sáenz Peña (1910–14), a brilliant politician who was fully prepared to construct a governing coalition on new foundations.

The course of Argentine politics in the final stages of Roca's career had convinced many of his most influential and militant followers that the country needed electoral reform, which was not seen as excessively dangerous since the Radical opposition seemed to have limited support. In 1912, Sáenz Peña had the Congress pass an electoral-reform law that called for a compulsory, secret ballot for all male citizens. His death in 1914 deprived the national leadership of its guiding force, and the electoral law he had authored opened the gates of power to the Radicals. The interim presidency of Victorino de la Plaza (1914–16) was followed by that of the Radical leader Hipólito Irigoyen (1916–22). He was the first Argentine president who owed his victory to the popular vote rather than to selection by the incumbent president among the members of a ruling oligarchy.

THE RADICAL REGIME, 1916–30

The Radical front was a coalition of heterogeneous social groups, which made it difficult to put through economic and social reforms without upsetting the front's equilibrium. Not surprisingly, Irigoyen preferred to concentrate on curing the political ills he had inherited from the conservative regime. The most urgent measure had to do with political patronage, which had been used by the conservatives to keep their candidates in office. Patronage had to be put to the service of the new party in power, and, thus, the Radical machine made itself virtually unbeatable at the polls in almost every province.

Political patronage and university reform

In other fields the Radical administration also showed concern for expanding its political base. Irigoyen achieved substantial rapport with the more moderate labour unions—a rapport expressed in a generally pro-labour policy. That policy had to be tempered after violent clashes occurred in the capital city during the general strike of January 1919, after which the military aligned itself with conservative interest groups. His administration supported organizations and movements among tenant farmers and also put through a university-reform plan.

Irigoyen's influence was a deciding factor in the election of his successor, Marcelo T. de Alvear (1922–28), who represented a safe choice. He, however, was not content with the restrictions that Irigoyen imposed upon him and became the reluctant leader of a conservative wing hostile to Irigoyen. In the elections of 1928, Irigoyen ran for a second term and was elected by a popular vote margin of two to one, establishing him as head of his party.

If Irigoyen was scarcely a revolutionist, his victory over the economic, social, and political elites of the country

had nonetheless earned him their strong enmity. His political machine, while an excellent mechanism for securing power, proved to be incapable of governing; its inadequacies were starkly revealed in the crisis of 1929, precipitated by the army, which expelled Irigoyen from office on Sept. 6, 1930. This marked the end of the constitutional continuity that had lasted for 68 years and also the end of the long period of economic expansion based on the export of raw materials, which had doubled between 1913 and 1928.

Behind the continuing upward trend lay a shift in economic power to foreign merchants and processors at the expense of the Argentine landowning class. Before 1914, these foreign interests had been concentrated mainly in the grain-growing sector; after 1920 they moved into the cattle-raising industry. Private investment still came mainly from Great Britain, which was also the main market for Argentine exports. The United States provided industrial and transportation equipment and was the government's main source of credit, but it had erected tariff and other barriers to the importation of Argentine goods, prompting Irigoyen to adopt an anti-U.S. and pro-British line.

Economic relations with the United States and Britain

THE CONSERVATIVE RESTORATION, 1930–43

The military coup that expelled Irigoyen installed Gen. José Félix Uriburu in the presidency (1930–32). A descendent of an old northern family, the conservative Uriburu leaned toward the Fascist ideas of the 1930s. His influence with the army, however, was not as great as that of Gen. Augustín Pedro Justo, a former minister of war under Alvear, who favoured a conservative reorientation of the country within constitutional limitations. The Radicals had been reorganized under the leadership of Alvear and had won an unexpected victory in trial elections held in the Province of Buenos Aires in April 1931. But the Radicals, under stringent restrictions, boycotted the national election of 1931. General Justo, with the backing of a coalition of conservatives, anti-Alvear Radicals, and independent Socialists and with only the limited use of electoral fraud, was elected by a large majority.

The new president (1932–38) faced a difficult economic situation. The Roca-Runciman Agreement with Great Britain (1933) guaranteed Argentina a fixed share in the British market for meat and ruled out tariffs on British cereal imports. In return, Argentina agreed to certain stipulations with regard to trade, currency exchange, and the preservation of Britain's commercial interests in the country. The treaty sharpened doubts of Argentines concerning the economic relationship between Argentina and Britain. Other unpopular reforms included a restructuring of the monetary system and the establishment of agencies to control exports. After 1935 the economic climate improved.

The election of 1937, in which the government retained its power, was marked by fraud and violence. The next president, Roberto M. Ortiz (1938–40), returned to more proper electoral procedures, calling for federal intervention in the province of Buenos Aires, where a corrupt conservative machine had been in control. Ortiz' poor health obliged him to resign, and his successor, Ramón S. Castillo (1940–43), restored the conservative coalition to power, gaining the support of General Justo.

At the outbreak of World War II, Argentina declared its neutrality and remained neutral even after the United States entered the conflict in 1941. This issue united all the opposition groups, and Castillo imposed a state of siege. In January 1943 a stabilizing influence disappeared with the death of General Justo. President Castillo fell from power in June 1943 in a coup led by his own minister of war, Gen. Pedro P. Ramírez.

THE PERÓN ERA, 1943–55

Transition period. The military government faced several urgent and difficult problems. Neutrality was advocated by some, and a choice between the restoration of a representative system and the installation of a long-term military dictatorship was also required. Gen. Arturo Rawson was made president but resigned after two days when his anti-conservative stance and his advocacy of the United Nations won no military support.

General Ramírez replaced Rawson as president (1943–44); neutrality was maintained, and opposition from all political groups (except the nationalist right wing and the Fascist sympathizers) increased. Press censorship and the dissolution of political parties reflected emergent authoritarianism. Under pressure from the United States, the regime broke off diplomatic relations with Germany. This deed was not favoured by the military officers, and Ramírez turned the presidency over to Gen. Edelmiro J. Farrell (1944–46). But international pressures grew, and to avert ruin Argentina had to face the return to representative democracy.

The search for a solution ended in the rise of Col. Juan Perón to the office of president. Since October 1943, when he had secured the minor job of running the labour department, Perón had been building a political empire based in the labour unions. He helped the unions win favourable settlements from employers; he pushed through a welfare program that provided vacations, retirement benefits, and severance pay. By 1945 he was also vice president and minister of war. His changes included giving autonomy to universities, reconstructing political parties (including the Communist Party, prohibited since 1936), and declaring war on Germany, thereby making it possible for Argentina to enter the United Nations. But with the return of political freedom came renewed opposition, culminating in a mass demonstration in Buenos Aires in September 1945. Emergency measures were enacted, Perón's military support gave way, and on October 9 he was removed from office and arrested. Neither the political nor the military opposition, however, could agree on what to do. Perón's adherents in the unions organized a strike that found enthusiastic support among the people. He was released on October 17, and his foes were forced to resign.

Rise of Perón

Perón in power. Perón campaigned for the presidency in the elections of 1946. He organized a Labour Party that was resisted by all of the old parties and by the major vested-interest groups. His victory, though narrow, gave him control of both houses of Congress and all the provincial governorships. Perón's political strategy and tactics were authoritarian and personalistic. Education and the courts were politically purified; a state of internal war was declared, to allow an expansion of executive authority; revenues were redistributed in favour of the workers; public services were nationalized; and urban and industrial areas were given preferential treatment over their rural counterparts.

Until 1949 Perón's economic policies were successful, largely because of the prosperity of exporters during and just after the war. As inflation increased and terms of trade worsened, however, it became difficult to finance imports of vital raw materials. The constitutional reform of 1949 allowed Perón to be reelected in 1951; his government took on a more conservative hue, hastened by the death of the President's wife, Eva Perón, in July 1952. She had been a powerful political figure in her own right, burnishing the regime's image of popular democracy. After 1952 Perón incurred the increasing hostility of the church and the students. His efforts to eliminate the influence of the church provoked disaffection in the officer corps, and in September 1955 he was overthrown by Gen. Eduardo Lonardi with support from the Córdoba garrison.

Influence of Eva Perón

ATTEMPTS TO RESTORE CONSTITUTIONALISM, 1955–66

General Lonardi was acting president, but he soon gave way to Gen. Pedro Eugenio Aramburu, who became president in November 1955. The new administration (1955–58) was a military dictatorship seeking to restore constitutional government. Taking a fiercely anti-Peronista stance, it dissolved Perón's old party and placed the labour unions under state administration. The Peronistas wielded considerable influence on the factions that were competing for power and in 1958 supported Arturo Frondizi, a radical leader who promised to readmit them to political life in return for their support. Frondizi won the presidency and majorities in both houses of Congress.

The new president (1958–62) showed a keen interest in reviving the flow of foreign investment. A currency devaluation that favoured exporters and foreign investors, however, had adverse effects on the middle and lower classes.

The campaign against inflation brought restrictions on credit, increasing the difficulties of industry, and Frondizi had to use the military to uphold his unpopular policies.

In March 1962 the reorganized Peronistas gained control of important districts, among them the province of Buenos Aires. The armed forces withdrew support from Frondizi, dissolved Congress, and set up a government in the name of José María Guido, president pro tempore of the Senate. Guido's 18-month administration was one of confusion as two military factions fought for control. The Colorados (Reds) sought a dictatorship that would deal strongly with the Peronistas and extreme leftists. The Azules (Blues), who prevailed, favoured a constitutional government by a coalition including the Peronistas, though the latter were to be confined to a weaker role than that indicated by their voting strength.

The elections of July 1963 resulted in victory for Arturo Illia, the candidate of the People's Radical Civic Union. President Illia (1963–66) inherited Frondizi's economic problems, although the drastic reorientation of the economy had begun to show signs of success. Illia tried without success to split the resurgent Peronistas, who now controlled the labour unions, from their exiled leader. Antagonized, the Peronistas supported a coup in June 1966 that brought to power Gen. Juan Carlos Onganía, a former Azules leader and commander in chief of the army.

Onganía takes power

GOVERNMENT BY THE ARMED FORCES

Adalbert Krieger Vasena, minister of economy and labour, strove for economic stability through yet another currency devaluation and also undertook programs in electric power, steel, roads, and housing. In May 1969, disturbances and riots in the cities of Corrientes, Rosario, and particularly Córdoba rose out of student and labour conflicts; these incidents, later known as the Cordobazo, were identified as resentment toward Krieger Vasena's economic policies. Krieger Vasena was removed, but the Onganía administration was unable to agree on an alternative economic policy, and the Cordobazo decisively affected the political climate. Underground activities were organized by a Trotskyite group, the People's Revolutionary Army (Ejército Revolucionario del Pueblo; ERP), and by Peronista groups. In 1970 one of these Peronista organizations, the Montoneros, besides decimating the moderate Peronista union leadership, captured and killed former president Aramburu, who had been organizing a movement for a return to constitutional rule. The armed forces overthrew the Onganía government in June 1970. Gen. Roberto Marcelo Levingston replaced Onganía; but the return of inflation and his political ambitions caused his overthrow, and he was replaced in March 1971 by Gen. Alejandro Agustín Lanusse.

Perón supported the Peronista underground but also used other means in a new bid for power. He maintained a formal alliance with the Frondizi followers, but the cornerstone of his strategy was an understanding with the largest non-Peronista party, the Radicals. Mindful of the vested interests, he purged his economic proposals of any motives that could alarm the propertied classes. The military government prevented Perón's own candidacy but could not stop the electoral victory of the Peronista coalition, the Justicialist Liberation Front (Frente Justicialista de Liberación), in March 1973.

THE RETURN OF PERONISM

The newly elected president, Héctor J. Cámpora, took office in May 1973. Under his administration the Peronista left wing acquired considerable influence. The final return of Perón in June was the occasion of a battle between right and left. The union leadership and Perón's private secretary, José López Rega (appointed minister of social welfare by Cámpora), launched a violent antileftist campaign that had the discreet support of Perón himself. In July Cámpora resigned, and new elections were called. An interim president, Raúl Lastiri, began a purge of leftist influences in the government.

Perón's second presidency. Perón was elected president on a ticket that included his wife, María Estela (called Isabel) Martínez de Perón, as vice president and took office in October 1973. He continued the campaign against the left, and in May 1974 the victims of the purge acknowledged the break with their leader and passed into (still legal) opposition. Underground activities again became evident, and a right-wing organization, the Argentine Anti-Communist Alliance (Alianza Anticomunista Argentina; AAA), suspected by many to be close to the police and intelligence branches of the administration, began to take a heavy toll of political, student, and union leaders.

Split in the Peronista ranks

Perón's economic policies after May 1973 combined monetary stabilization and rigid control of prices and wages with a gradual redistribution of income in favour of wage earners and a limitation on profits of the agrarian exporters. By 1974, however, the world petroleum crisis caused Europe to reduce its substantial imports of Argentine meat, and the balance of payments suffered.

Perón's legacy. When Perón died on July 1, 1974, he left to his widow, who succeeded him, a deeply compromised inheritance. The transition of power was smooth, however, and President Martínez de Perón, in close alliance with López Rega, became even more inflexibly oriented toward the right. Violence reached new heights. López Rega, who used the rightist crusade to consolidate his power base, favoured labour and army leaders who were committed to support him. This course created hostility among union, political, and military leaders. In the autumn of 1975 a drastic devaluation and a steep drop in real wages were proposed. Martínez de Perón was persuaded to dismiss López Rega, but the unrest deepened. In December there was an uprising by the air force, and on March 24, 1976, military officers deposed the President and took over the government. (T.H.D./Ed.)

THE RETURN OF MILITARY GOVERNMENT

The Videla regime. A three-man military junta filled the presidency five days after the coup with Lieut. Gen. Jorge Rafaél Videla, who served two consecutive terms in office (1976–81). During Videla's regime the economy showed some improvement. Inflation dropped from about 600 percent in 1976 to 138 percent in 1982—still the highest in the world for that year. The balance of foreign trade also improved. This economic relief, however, was accompanied by continued political violence. Thousands of citizens were killed or imprisoned or disappeared. The Argentine government, which maintained that it was fighting a civil war, was subject to much criticism at home and abroad for civil rights violations.

Viola and Galtieri. Videla was succeeded on March 29, 1981, by Gen. Roberto Eduardo Viola, who pursued a policy of moderation. On Dec. 21, 1981, the government announced that Viola was stepping down for reasons of health; he was succeeded the next day by Lieut. Gen. Leopoldo Galtieri. Galtieri was occupied by an economy again on the downswing, by increased civil opposition to military rule, and by Argentina's claims to islands in the Atlantic. The government had refused to accept a decision of the International Court of Justice in 1977 awarding the three Beagle Channel islands to Chile. The matter again went into negotiation, under Vatican auspices from 1979, and was resolved in 1984 when Chile was awarded sovereignty of the islands. In February 1982 Argentina increased pressure on the United Kingdom to relinquish the Falkland Islands. With popular support at home, Argentine troops landed on the Falklands and South Georgia island on April 2 and overcame the U.K. Royal Marines stationed at Port Stanley. For the next three weeks, while a British naval force sailed to the Falklands, negotiations between the two belligerents failed to reach a solution. British forces retook South Georgia on April 30, and the Argentine military governor surrendered the Falklands to them on June 14.

Falkland Islands war

Galtieri resigned as commander in chief of the army and president on June 17, 1982. Maj. Gen. Reynaldo Bignone was installed as president on July 1. The members of the junta representing the air force and the navy resigned in protest over Bignone's appointment, but the junta was reconstituted on September 10. Under Bignone, political parties were allowed to resume activities, and general elections were announced. The Peronista party delayed

choosing a presidential candidate and thus lost ground to the Radical Civic Union, led by Raúl Alfonsín, a civilian lawyer; Alfonsín won the election on Oct. 30, 1983, and the Radicals gained the majority in the National Congress, followed by the Peronistas.

Alfonsín's democracy. Soon after his inauguration on Dec. 10, 1983, Alfonsín, in a reversal of legislation passed under Bignone, announced plans to prosecute several members of the former military government, including the former presidents Videla, Viola, and Galtieri. He also repealed a law granting amnesty to those accused of crimes and human rights violations during what came to be called the "dirty war." Hundreds of military personnel were ordered to stand trial. In the trial of nine former junta members in 1985, five were convicted, including Videla and Viola. Although Galtieri was acquitted in that trial, he was convicted in 1986, along with two other officers, of incompetency in the Falkland Islands war. Rebellions broke out within the armed forces in protest over the prosecutions but most of the armed forces stayed loyal. Massive rallies voiced approval of Alfonsín's democracy, and support poured in from the international community.

Alfonsín launched an austerity program, the Austral Plan, which adopted a new currency (the austral) and invoked wage and price controls and currency devaluations. The measures initially brought a generally downward trend to inflation and restored the confidence of international bankers, who allowed Argentina to refinance and reschedule its foreign debts, the growth of which had reached crisis proportions. The inflation rate began to rise again, however, reaching almost 388 percent at the end of 1988, and the austral began a steady decline against the U.S. dollar. The worsening state of the economy and the Alfonsín government's inability to handle it contributed to the defeat of the Radical presidential candidate, Eduardo Angeloz, in May 1989. (Alfonsín was constitutionally ineligible to succeed himself.) Carlos Saúl Menem, a Peronista, led his party to victory in the presidential and congressional elections. Throughout his campaign Menem had openly cultivated an image recalling his party's founder, and it was his appeal to the poor and working classes, the traditional supporters of Peronism, that clinched his victory.

Election of Menem

With the economy crumbling around him, Alfonsín resigned five months early, and Menem officially took over on July 8. Menem's plan was a free-market economy, with lower tariffs based on a wage–price pact between labour, business, and government and the privatization of inefficient government-owned companies. To help carry it out, he enlisted the aid of former top-level executives from Bunge y Born, one of Argentina's leading corporations.

The continuing discontent of the military over wages, equipment, and the trials of those of their number accused of human rights violations during the dirty war had manifested itself in more rebellions in the last months of Alfonsín's tenure. After a bloody attack at La Tablada barracks outside Buenos Aires, Alfonsín initiated a huge military investment program. Menem in turn sought to quell the military's discontent and to win their support in a time of economic emergency by pardoning those accused of human rights violations, a move that was strongly criticized. Former president Galtieri was also pardoned. In October, Argentina and Great Britain formally agreed to end the hostilities that began with the Falklands war, and they reestablished consular ties. Aristotle and Aristotelianism

Aristotle, more than any other thinker, determined the orientation and the content of Western intellectual history. He was the author of a philosophical and scientific system that through the centuries became the support and vehicle for both medieval Christian and Islāmic scholastic thought: until the end of the 17th century Western culture was Aristotelian. And even after the intellectual revolutions of centuries to follow Aristotelian concepts and ideas remained embedded in Western thinking.

Aristotle's intellectual range was vast, covering most of the sciences and many of the arts. He worked in physics, chemistry, biology, zoology, and botany; in psychology, political theory, and ethics; in logic and metaphysics; in history, literary theory, and rhetoric. His greatest achievements were in two unrelated areas: he invented the study of formal logic, devising for it a finished system, known as Aristotelian syllogistic, that for centuries was regarded as the sum of logic; and he pioneered the study of zoology, both observational and theoretical, in which his work was not surpassed until the 19th century.

Even though Aristotle's zoology is now out-of-date and his thought in the other natural sciences has long been left behind, his importance as a scientist is unparalleled. But it is now of purely historical importance: he, like other scientists of the past, is not read by his successors. As a philosopher Aristotle is equally outstanding. And here he remains more than a museum piece. Although his syllogistic is now recognized to be only a small part of formal logic, his writings in ethical and political theory as well as in metaphysics and in the philosophy of science are read and argued over by modern philosophers. Aristotle's historical importance is second to none, and his work remains a powerful component in current philosophical debate.

This article deals with the man, his achievements, and the Aristotelian tradition. For treatment of Aristotelianism in the full context of Western philosophy, see PHILOSOPHY, THE HISTORY OF WESTERN, and PHILOSOPHICAL SCHOOLS AND DOCTRINES.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* Part Ten, Division V, especially Section 51.

The article is divided into the following sections:

THE LIFE OF ARISTOTLE

Early years and background

Aristotle was born in the summer of 384 BC in the small Greek township of Stagira (or Stagirus, or Stageirus), on the Chalcidic peninsula of Macedonia, in northern Greece. (For this reason Aristotle is also known as the "Stagirite.") His father, Nicomachus, was court physician to Amyntas III, king of Macedonia, father of Philip II, and grandfather of Alexander the Great. As a doctor's son, Aristotle was heir to a scientific tradition some 200 years old. The case histories contained in the *Epidemics* of Hippocrates, the father of Greek medicine, may have introduced him at an early age to the concepts and practices of Greek medicine and biology. As a physician, Nicomachus was a member of the guild of the Asclepiads, the so-called sons of Asclepius, the legendary founder and god of medicine.

Because medicine was a traditional occupation in certain families, being handed down from father to son, Aristotle in all likelihood learned at home the fundamentals of that practical skill he was afterward to display in his biological researches. Had he been a medical student he would have undergone a rigorous and varied training: he would have studied the role in therapy of diet, drugs, and exercise; he would have learned how to check the flow of blood, apply bandages, fit splints to broken limbs, reset dislocations, and make poultices of flour, oil, and wine. Such, at least, were the skills of the trained physician of his time. It is not known for certain that Aristotle actually acquired these skills; it is known that medicine and its history were later studied in the Lyceum, Aristotle's own institute in Athens, and that later, in a snobbish vein, he considered a man sufficiently educated if he knew the theory of medicine without having gained experience practicing it.

This early connection with medicine and with the rough-living Macedonian court largely explains both the predominantly biological cast of Aristotle's philosophical thought and the intense dislike of princes and courts to which he more than once gave expression.

First period: in the Academy at Athens. While Aristotle was still a youth, his father died, and the young man became a ward of Proxenus, probably a relative of his father. He was sent to the Academy of Plato at Athens in 367 and remained there for 20 years. These years formed the first of three main periods in Aristotle's intellectual development, years dominated by the formative influence of Plato and his colleagues in the Academy. Aristotle doubtless interested himself in the whole range of the Academy's activities. It is known that he devoted some time to the study of rhetoric, and he wrote and spoke for the Academy in its battles against the rival school of Isocrates.

Death of Plato: Aristotle's departure from Athens

After Plato's death in 348/347 his nephew Speusippus was named as head of the Academy. Aristotle shortly thereafter left Athens—in disgust, it is sometimes claimed, at not being appointed Plato's successor. This interpretation of his motive, however, lacks foundation, for evidence suggests that he was ineligible to be the school's head because of his status as a resident alien who could not hold property legally. It is more likely that his departure from Athens may have been linked with an anti-Macedonian feeling that arose in Athens after Philip had sacked the Greek city-

state of Olynthus in 348. Aristotle's 12-year absence from Athens nevertheless indicates that he valued more the circle of friends who accompanied him on his travels—chief among them Theophrastus of Eresus, his pupil, colleague, and eventual successor as head of the Lyceum—than he did his membership in the Platonic Academy.

Second period: his travels. With him went another Academy member of note, Xenocrates of Chalcedon, whose lethargy became the target of Plato's ridicule. Plato reportedly contrasted it with Aristotle's more energetic manner: "The one needs a spur, the other a bridle .... See what an ass I am training to compete with what a horse." The distinctive characters of the two men, however, seem to have integrated well in establishing a new academy on the Asian side of the Aegean at the newly built town of Assus.

Assus

At Assus, Hermeias of Atarneus, a Greek soldier of fortune, had first acquired fiscal and then political control of northwestern Asia Minor, as a vassal of Persian overlords. After a visit to the Athenian Academy he invited two of Plato's graduates to set up a small branch to help spread Greek rule as well as Greek philosophy to Asian soil. Aristotle came to this new intellectual centre. To this period may belong the first 12 chapters of Book 7 of Aristotle's *Politics.* There he sketches the connection between philosophy and politics, namely, that the highest purpose of a city-state (*polis*) is to secure the conditions in which those who are capable of it can live the philosophical life. Such a life, however, lies only within the capacity of the Greeks, whose superiority qualifies them to employ the non-Greek tribal peoples as serfs or slaves for the performance of all menial labour. Thus, citizenship and service in the armed forces are considered to be the exclusive rights and duties of the Greeks. Aristotle's espousal of an enlightened oligarchy, nonetheless, actually constituted an advance over the political concepts flourishing at the time and it should be viewed in its context as a positive development in the establishment of the noble civilization created by the Greeks.

At about the same time, Aristotle composed the work, now lost, *On Kingship,* in which he clearly distinguishes the function of the philosopher from that of the king. He alters Plato's dictum—for the better, it is said—by teaching that it is

> ... not merely unnecessary for a king to be a philosopher, but even a disadvantage. Rather a king should take the advice of true philosophers. Then he would fill his reign with good deeds, not with good words.

Aristotle thus strove to assure the independent role of the philosopher.

Aristotle was on good terms with his patron, Hermeias, and married his niece, Pythias. She bore Aristotle a daughter, whom he called by her mother's name. In the *Politics,* Aristotle prescribed the ideal ages for marriage—37 for the husband and 18 for the wife. Because Aristotle was himself 37 at this time, it is tempting to guess that Pythias was 18. It is also possible that their own marital relations are reflected in his further, somewhat cryptic, observation: "As for adultery, let it be held disgraceful for any man or woman to be found in any way unfaithful once they are married and call each other husband and wife." In his will Aristotle ordered that "Wherever they bury me, there the bones of Pythias shall be laid, in accordance with her own instructions." Pythias did not live long, however; and after her death Aristotle chose another companion, Herpyllis (whether concubine or wife is uncertain), by whom he then had a son, Nicomachus. She outlived Aristotle, and he made ample and considerate provision for her in his will "in recognition of the steady affection she has shown me."

Mytilene

After three years at the young Assus Academy, Aristotle moved to the nearby island of Lesbos and settled in Mytilene, the capital city. With his friend Theophrastus, a native of that island, he established a philosophical circle patterned after the Athenian Academy. There his centre of interest shifted to biology, in which he undertook pioneering investigations. (The landlocked lagoon of Pyrrha in the centre of Lesbos has been identified as one of his favourite haunts.) He appears to have felt it necessary to justify this new attention to biology by rejecting the arguments that had classed it as an inferior, unattractive study. In his biological researches he focused on a new type of causation, namely teleological. Teleological causation has to do with the aim, or end, of nature, a type that is distinct from mechanical causation but one that is, nonetheless, operative in the inorganic sphere. According to Aristotle, natural organisms—plants and animals—have natural ends or goals, and their structure and development can only be fully explained when these goals are understood. To admit the existence of such ends, or aims, in nature is to argue teleologically (Greek *telos,* "an end") or to admit the idea of a final cause (Latin *finis,* "end"). Teleology, and theory in general, is important in Aristotle's biology; but it is always, in principle at least, subordinate to observation. Thus, confessing his ignorance of the mode of generation of bees, Aristotle wrote in his treatise *On the Generation of Animals:*

> The facts have not yet been sufficiently established. If ever they are, then credit must be given to observation rather than to theories, and to theories only insofar as they are confirmed by the observed facts.

Associated with his researches into plant and animal life were his reflections on the relation of the soul to the body. As revealed by his tract *On the Soul,* Aristotle distanced himself from the Platonic conception of the soul as an independently existing substance that is only temporarily resident in the body. With greater emphasis on the positive value of material existence, he suggested instead that the soul is the vital principle essentially united with the body to form the individual person. With some acknowledgment to Plato, he then proceeded to define the soul as the form of the body and the body as the matter of the soul.

Alexander the Great

In late 343 or early 342 Aristotle, at about the age of 42, was invited by Philip II of Macedon to his capital at Pella to tutor his 13-year-old son, Alexander. As the leading intellectual figure in Greece, Aristotle was commissioned to prepare Alexander for his future role as a military leader. As it turned out, Alexander was to dominate the Greek world and defend it against the Persian Empire. Using the model of the epic Greek hero, as in Homer's *Iliad,* Aristotle attempted to form Alexander as an embodiment of the classical valour of an Ajax or Achilles enlightened by the latest achievement of Greek civilization, philosophy. With his firm conviction of the superiority of Greeks over foreigners, he instructed Alexander to dominate the barbarians—*i.e.,* non-Greeks—and to hold them in servility by refraining from any physical intermixture with them. Despite this advice, however, Alexander later became committed to intermarriage; he chose a wife from the Persian nobility and forced his high-ranking officers (and encouraged his troops) to do likewise.

In other ways too the influence that Aristotle had on Alexander was negligible. Although later, on his return to Athens, Aristotle enjoyed considerable political and economic support from the Macedonians and perhaps received assistance in the organization of his biological researches, it is not likely—as some have held—that Alexander collected and dispatched to Aristotle specimens of rare animals from Persia and India; in fact, Alexander's first penetration of the valley of the Indus did not occur until 328/327, less than six years before Aristotle's death. Indeed, the relation between the two was embittered by the execution of Aristotle's nephew, the historian Callisthenes of Olynthus, who was charged with treason while accompanying Alexander to Persia early in 328 in order to write a chronicle of the campaign. It has even been reported that Alexander meditated revenge on Aristotle himself because he was a blood relative of the victim. But Alexander was diverted by his preoccupation with the invasion of India. Clearly, in matters of political ideology, a gulf separated Aristotle and Alexander. Aristotle showed no awareness of the fundamental changes that Alexander's conquests were bringing to the Greek world; indeed, he was opposed in principle to Alexander's imperial policy because it diminished the importance of the city-state. On the other hand, Alexander gratified his tutor by rebuilding the town of Stagira, Aristotle's birthplace, which Philip II had destroyed earlier.

After three years at the Macedonian court, Aristotle withdrew and returned to his paternal property at Stagira (*c.* 339). There he continued the associations of his philosophical circle, which still included Theophrastus and other pupils of Plato.

Third period: founding and directing of the Lyceum. Aristotle remained in Stagira until 335, when, nearing 50 years of age, he once again returned to Athens. At this time the presidency of the Academy became vacant by the death of Speusippus, and Xenocrates of Chalcedon, his old associate in biological research, was elected to the post. Although Aristotle appears never to have wholly severed his links with the Academy, he nonetheless opened, in 335, a rival institution in the Lyceum, a gymnasium attached to the temple of Apollo Lyceus, situated in a grove just outside Athens. The place had for some time been frequented by other teachers—Plato even mentions it as having been one of Socrates' haunts—and the name of the temple came to be applied to Aristotle's school in particular. But it was probably only after Aristotle's death that the school, under Theophrastus, acquired extensive property. From the fact that his instruction was given in the *peripatos,* or covered walkway, of the gymnasium, the school has derived its name of Peripatetic. Informal as the school may have been under Aristotle, it was very important to him because, by coordinating the work of a number of scholars, he was able for the next 12 years to organize it as a centre for speculation and research in every field of inquiry and to give lectures on a wide range of scientific and philosophical questions. The chief difference between the new school and the Academy was that the scientific interests of the Platonists centred on mathematics whereas the main contributions of the Lyceum lay in biology and history.

Athens: the Lyceum

On the death of Alexander the Great in 323 a brief but vigorous anti-Macedonian agitation broke out in Athens. Aristotle, who had long-standing Macedonian connections and was a friend of Antipater, the Macedonian regent of Athens, felt himself in danger. He therefore left Athens and withdrew to his mother's estates in Chalcis on the island of Euboea. There he died in the following year from a stomach illness at the age of 62 or 63. It was reported that he abandoned Athens in order to save the Athenians from sinning twice against philosophy (referring to Socrates as the earlier victim).

Death

PERSONALITY, CHARACTER, AND PHILOSOPHICAL STANCE

The features of Aristotle, familiar from busts and engravings, appear handsome and refined. An ancient tradition, possibly from an unfriendly source, says, however, that Aristotle had spindleshanks and small eyes and that he spoke with a lisp. In compensation for these physical defects, he was notably well dressed. His cloak and sandals were of the best quality and he sported rings. Presumably he was rich, with large family holdings at Stagira. One use that he made of his money was to collect books. Plato, with a touch of contempt for Aristotle's devotion to reading and perhaps not without some envy of his affluence, called him "the reader." Aristotle was an intellectual but not devoid of passion. A story is told of Plato giving a reading of his *Phaedo,* a purported record of Socrates' last day. The dialogue is moving and solemn. As Plato was reading, however, his audience gradually melted away. In the end, Aristotle alone was left. Probably fictitious, the anecdote was invented to express a truth: Aristotle was, in fact, spellbound by the Socratic doctrine of immortality as expounded by Plato. It not only interested him intellectually but also absorbed him emotionally. His earliest works, dialogues written when he was still a member of the Academy (now lost except for some fragments), were in part concerned with thoughts of the next world and the worthlessness of this one.

The anecdotes related of him reveal him as a kindly, affectionate character, and they show barely any trace of the self-importance that some scholars think they can detect in his works. His will, which has been preserved, exhibits the same kindly traits; he makes references to his happy family life and takes solicitous care of his children, as well as his servants.

This personal happiness is reflected in *On Philosophy,* perhaps the last of his strictly literary works. After writing this work, which he completed in around 348, he devoted his energies to research, teaching, and the writing of more technical treatises. The greatness of *On Philosophy,* which survives only in fragments, is evident in its influence on the thought of later antiquity; perhaps more than any other single work it established philosophy as a profession. In the extant part, Aristotle defines the specific role of the philosopher. Dividing the historical development of civilization into five main stages, Aristotle sees the emergence of philosophy as its culmination. First, men are compelled to devote themselves to the creation of the necessities because without them they could not survive. Next come the arts that refine life and then the discovery of the art of politics, the prerequisite of the good life as Aristotle conceived it. To these necessities and refinements of life is added the knowledge of their proper use in the fourth stage. Only with the emergence of the well-regulated state comes the leisure for intellectual adventure, used at first for the study of the material causes of existing things. Finally comes the shift from natural to divine philosophy, when the mind lifts itself above the material world and grasps the formal and final causes of things, realizing the intelligible aspect of reality and the purpose that informs all change.

Concept of philosophy

This divine philosophy gave its attention to the astral gods. Aristotle had experienced in Athens the long intellectual struggle to discover perfect order in the heavens. He had learned that perfection was not to be confined to the mathematical abstractions, to which Plato had at first directed the attention of his pupils, but had come to recognize that the visible heavens themselves could be accepted as the embodiment of the divine. With the declaration of this intimacy between the deities and the work of their hands in the material universe, Aristotle issued his manifesto, which is an optimistic affirmation of the values of this world; simultaneously he rejected the Platonic doctrine that the soul is imprisoned in the body and in need of struggling free from the bonds of matter. It was by this stroke that Aristotle established his own identity in the history of thought.

WRITINGS

Aristotle's writings fall into two groups: the first consists of works published by Aristotle but now lost; the second of works not published by Aristotle and, in fact, not intended for publication but collected and preserved by others. In the first group are included (1) the writings that Aristotle himself termed "exoteric," or popular—that is, those written in dialogue or other current literary forms

and meant for the general reading public—and (2) those that he termed "hypomnematic," or notes to aid the memory, and collections of materials for further work. Of these, only fragments are extant. Finally, the writings that generally have survived, termed "acroamatic," or treatises (*logoi, methodoi, pragmateiai*), were meant for use in Aristotle's school and were written in a concise and individualistic style. In later antiquity Aristotle's writings filled several hundred rolls; today the surviving 30 works fill some 2,000 printed pages. Three ancient catalogs list a total of more than 170 separate works by Aristotle, a figure corroborated by references and lists of titles in the extant treatises as well as by a number of citations and paraphrases in early commentators. Cicero must have been alluding to Aristotle's popular dialogues when he described in the *Academica* "the suave style of Aristotle . . . . A river of gold." The extant works contain several passages of polished prose, but for the most part their style is clipped.

Lost works published by Aristotle. The lost popular works include poetry and letters as well as essays and dialogues in the Platonic manner. Several problems have confronted scholars in their attempts to reconstitute these lost popular works. The lost dialogues, for example, appear to diverge widely from the doctrines of the surviving treatises. Indeed, they appear to outdo Plato in his own teaching. Thus, what is known of Aristotle's dialogue *Eudemus,* or *On the Soul,* compares the relation of the soul to the body with an unnatural union, like that of the torture that the Tyrrhenian pirates inflicted on their prisoners by binding each of them to a corpse. Inasmuch as Aristotle in his extant treatises criticized his Platonist friends for making soul and body enemies, Alexander of Aphrodisias, an authoritative Aristotelian commentator of the late 2nd century AD, raised the question whether he expressed "two truths," one "exoteric" for public consumption, the other "esoteric" and reserved for his students in the Lyceum. The present consensus of scholars is that Aristotle's popular writings generally derived from the early stage of his intellectual development during his time in Plato's Academy: they represent not his "public" but his juvenile thoughts.

Popular dialogues

Chief among the lost works are: *Eudemus,* in the tradition of Plato's *Phaedo; On Philosophy,* a type of philosophical program containing themes to be developed later in his *Metaphysics;* the *Protrepticus,* or exhortation to the life of philosophy; *Gryllus,* or *On Rhetoric; On Justice,* expressing nascent themes of his *Politics;* and *On Ideas,* which criticizes Plato's theory of Forms.

Extant works. The works that have been preserved derive from manuscripts left by Aristotle on his death; many of them were probably used by him as lecture notes. These are the "esoteric" writings of a concentrated, academic nature intended for the ears of the initiates. From classical antiquity romanticized accounts circulated of the way these manuscripts were preserved; *e.g.,* in Plutarch's *Sulla,* chapter 26; and in Strabo's *Geography* 13:54. According to these versions, Aristotle's and Theophrastus' notes had been bequeathed to an old colleague, Neleus of Scepsis, whose heirs apparently were not interested in the contents but, in order to prevent them from being confiscated for the library of the kings of Pergamum, hid them in a cellar in Scepsis. Long afterward, in the 1st century BC, the descendants sold them to Apellicon of Teos, a philosopher, who brought them back to Athens. When Athens was conquered by Sulla in 86 BC, he appropriated the books and sent them to Rome, where they were purchased by Tyrannion the grammarian. The manuscripts suffered further maltreatment, first at the hands of copyists, then through subjective restoration of worm-eaten passages and systematic ordering irrespective of actual chronology, until Andronicus of Rhodes, the last head of the Lyceum, acquired the copies and edited and published them about 60 BC.

The story is improbable. It is difficult to imagine that the Lyceum would have allowed the manuscripts of its founder to have been so carelessly looked after. And it is now known that the "esoteric" writings were not wholly ignored in the two centuries after Theophrastus' death. It is true, nevertheless, that the Andronicus edition is the first publication of Aristotle's works, even if the story of the edition's appearance was spread by Andronicus to emphasize its novelty. The form, titles, and order of Aristotle's texts that are studied today were given to them by Andronicus almost three centuries after the philosopher's death, and the long history of commentary upon them began at this stage.

These facts have affected the interpretation of Aristotle. The books of Aristotle that are known today were, in effect, never edited by him. Thus, for example, Aristotle is not the author of the work called *Metaphysics;* rather, he wrote a dozen little treatises: on the theory of causes in the history of philosophy, on the chief philosophical problems, on the multiplicity of meanings of certain key philosophical terms, on act and potency, on being and essence, on the philosophy of mathematics, and on God. Those that the editors thought worth collecting were given the title *Metaphysics; i.e.,* the tract that is to be read after the *Physics.* It is not surprising, then, that the *Metaphysics* and the other works of Aristotle sometimes seem to lack unity or any clear progression of thought, that they are sometimes repetitious and at times even contradictory. The texts furthermore suggest that students or subsequent members of the Lyceum even revised Aristotle's expressions. It is probable that Aristotle would never have released the work. Andronicus, assisted by previous editors, imposed a logical and didactic order upon all the writings, undoubtedly influenced by Aristotle's own emphasis on logic as the propaedeutic (preparatory study) of all understanding. By ignoring the chronological order of the treatises and by grouping dissertations from different periods under the same title, the editors fashioned the Aristotelian corpus into a systematic whole. It is quite likely that Aristotle himself had never thought of his writings in this way.

Formation of existing works

Aristotle's treatises reveal the philosopher at work. He defines the problem he is to deal with, assesses the views of his predecessors, formulates his own preliminary opinion, considers whether there is a need to modify it in the light of difficulties and objections, rehearses the arguments for different points of view—always searching, in short, for the most adequate solution or resolution of his problem. The reader, therefore, sees Aristotle at work, not dogmatically propounding a doctrine but often laboriously developing a perspective or an insight that emerges from difficulties, contradictions, and paradoxes. Not surprisingly, few syllogisms appear in Aristotle's treatises; the reader, however, should perceive in them a structure that Aristotle himself terms "dialectical"; *i.e.,* in the manner of a dialogue by an exchange of arguments for and against.

"Dialectical" nature of Aristotle's thought

THEORIES OF THE EVOLUTION OF ARISTOTLE'S THOUGHT

From the conclusions of Alexander of Aphrodisias in the latter part of the 2nd century, a distinction was established between the doctrine expressed in Aristotle's treatises (the technical writings that have come down to the present) and the popular Platonizing dialogues (the "exoteric" works surviving only in fragments). The orthodox view for 17 centuries was that the treatises were the sources for Aristotle's genuine thought; Valentin Rose, a 19th-century German scholar, proposed that all of the lost dialogues are spurious because their doctrine was inconsistent with that of the treatises. The underlying assumption was that a man of such strict and systematic mind as Aristotle would maintain strict constancy and never abandon opinions once formed.

Jaeger's developmental theory and rejoinders. In the first half of the 20th century a developmental theory of Aristotle's thought was submitted by Thomas Case, an English scholar, and elaborated in detail by Werner Jaeger, a German historian of Greek philosophy, in his *Studien zur Entstehungsgeschichte der Metaphysik des Aristoteles* (1912; "Studies in the History of the Origin of Aristotle's Metaphysics") and later in his *Aristoteles: Grundlegung einer Geschichte seiner Entwicklung* (1923; *Aristotle: Fundamentals of the History of His Development*). Employing a historicogenetic methodology, Jaeger announced that the greater part of Aristotle's lost works represented his

thought while he was still at the Academy and under the immediate influence of Plato: the preponderance of such themes as the immortality of the soul, disdain for the material world, the doctrine of the "recollection" of Ideas, the supremacy of wisdom, asceticism, and the existence of God were recognizably Platonic. These dialogues addressed a wide audience and were presented in an elegant literary style that fascinated classical authors. According to Jaeger, Aristotle gradually distanced himself from Plato's position, even during his time at the Academy—rejecting certain Platonic arguments, adopting contrary positions, continually evolving from Platonic Idealism to a marked empiricism.

Theory of Aristotle's early Platonism

In response to this evolutionary theory, critics have noted that the analysis of Aristotle's works generates complex problems, as observed above in the account of the formation of the text of his existing writings. The works edited by Andronicus of Rhodes are compilations of texts from different periods. Thus, the *Metaphysics* covers almost the entire career of Aristotle, as does the *Politics.* Often within the same chapter, even in a single paragraph, one discerns elements from different stages of Aristotle's thought: his early phase at the Academy, his maturity, his period of travel away from Athens, and his Lyceum experience, which purportedly was divided between morning sessions with his best students and afternoon meetings with a wider audience from Athens. Given all this, there are serious obstacles in the way of discussing the chronology of the treatises: it becomes extremely difficult to put a date on a work that was revised and modified in various ways during a considerable portion of Aristotle's intellectual career.

One of Jaeger's main assumptions, moreover, is questionable. He supposes that Aristotle only agreed with Plato during his early years at the Academy or, at the latest, until the close of the first Athenian period (347 BC). This assumption, however, is arbitrary and cannot be corroborated by the evidence.

One could conceivably defend the converse: that Aristotle, in a self-assured youth, could have strongly challenged Plato but, having subsequently become conscious of the more profound significance of his master's philosophical postulates, did not hesitate to integrate with his own thought one or more Platonic theses. Indeed, in one of the logical treatises, *Topics,* considered one of Aristotle's early works because it reflects discussions at the Academy, and in the *Eudemian Ethics,* the first version of Aristotle's course on ethics, there are strongly anti-Platonic views expressed.

Evolution of thought on the soul

Jaeger's theory is most plausible with regard to Aristotle's psychology, as demonstrated by François Nuyens, a Dutch historian of philosophy, in 1939. He held that in his early period, represented by the *Eudemus* and the *Protrepticus,* Aristotle began as a Platonist, describing the soul as a separate substance in an unnatural relationship with the body; next, in an intermediate stage, he described the body as the instrument of the soul, whose function is analogous to that of a pilot steering a ship; finally, in the tract *On the Soul,* he advanced more clearly the concept of a substantial unity of body and soul by making the soul the form, or actuality, of a natural body.

Other authorities on Aristotle have observed that such a linear transition in his thought occurs rarely among his writings. Even in the works on psychology, moreover, Aristotle's concern for metaphysical thought does not end with his intermediate biological phase but continues and extends even into his empirical stage at the Lyceum. Such a simultaneous preoccupation with both scientific and philosophical thought is further manifested in the sequence of books in the *Metaphysics.*

At the other extreme is the hypothesis of the German scholar Josef Zürcher, in *Aristoteles Werke und Geist* (1952; "The Works and Spirit of Aristotle"), who asserted that Aristotle's own thought always remained Platonic and that all of the characteristically Peripatetic philosophy came from his disciple and successor, Theophrastus, who is the true author of about three-quarters of the existing Aristotelian treatises. According to this theory, there never existed a young Aristotle and an elder Aristotle in terms of any development of his thought: there was simply a Platonic Aristotle and an anti-Platonic Theophrastus, an empiricist. This eccentric theory has found no followers. In reaction to it, the Swedish scholar Ingemar Düring suggested in 1966 that Aristotle never really subscribed to the Platonic theory of transcendent Forms, or Ideas, but maintained lifelong and coexistent interests in empirical investigation and metaphysical speculation; for Düring, as for Zürcher, there is no need to postulate any fundamental change or development in Aristotle's thought.

Recent analyses of Aristotle's development and systematizing. Aristotelian scholars have generally concluded that a basis exists for a theory of evolution in his thought but that the determination of the chronology and the degree of change presents a difficult set of problems. It is quite possible to agree with Jaeger that during Aristotle's first years at the Academy he acknowledged Plato's teaching on Ideas, and that he later rejected the theory. It is another matter, however, to suggest that in his later years he renounced such Platonically influenced doctrines as the immortality of the soul or the conception of a religious philosophy concluding in an ultimate being termed God. Increased attention to data of the senses in subsequent phases of his life, moreover, is not a sufficient argument for the emergence of an empiricist Aristotle, who could not but oppose a spiritualist and idealist Plato. It is true that Aristotle later criticized the doctrine of Ideas as inadequate and contradictory. But he continued, nevertheless, to recognize the effectiveness of metaphysical thought in arriving at the concept of a transcendent, nonmaterial, and subsistent intellect as the necessary explanation for the fact that anything exists. The consensus of modern commentators thus suggests that not every aspect of Platonic idealism was rejected by Aristotle as his appreciation of empirical knowledge and of the dynamic aspects of matter grew. Rather, alongside his experimental work in biology and physics was his continued insistence on the crucial differences between perception and thought, between accidental characteristics and the essential natures of things.

The inconsistencies, contrasts, and varying degrees of emphasis on different modes of thought throughout the Aristotelian corpus are not adequately explained either by positing intervening editors and copyists or simply by different stages in Aristotle's thought. He clearly attempted in all of the treatises to relate his own views to the whole history of thought before his time. On many occasions he was concerned, at the same point in the development of his thinking, to state different views seen as alternative possibilities. Often his method was deliberately aporetic; that is to say, he raised difficulties that he knew had to be faced but for which he supplied no immediate or definitive solutions. Left by Plato with a vast body of problems, Aristotle conscientiously pursued the ideal of correcting and complementing the intellectual tradition bequeathed to him. To this end he often followed parallel but distinct paths of investigation. His method was exploratory, and he used it on whatever fertile soil he was free to work. Only relatively late in life was he able to unify his results with any degree of success. The philosophy of Aristotle does not unfold simply by deducing consequences from assumed principles. Rather, it starts from *aporiai,* from puzzles or problems, and it proceeds by piecemeal, tentative, and multiform attempts at solutions. The end result that Aristotle in his optimistic moments hoped to achieve was indeed a fixed body of knowledge, systematically ordered and deductively demonstrated. But his method of inquiry was not deductive, and the finished system remained an aspiration rather than an accomplishment.

Aporetic nature of Aristotle's thought

SYNOPSES OF THE ARISTOTELIAN CORPUS

Works on logic. The term logic was not invented by Aristotle but goes back to Xenocrates of the Academy. Aristotle, however, attributed extensive significance to language (*logos*) and to the rules of discourse; thus he emphasized that language is distinctive of the human species, and he defined man as a rational animal, which in the Greek also means an animal possessing a language or speech or word.

In Aristotle's view, the purpose of language is to express the feelings and experiences of the soul, and consequently

words are signs, or symbols, of thoughts and other mental phenomena.

The logical treatises of Aristotle make up the collection known as the *Organon* ("tool"). This title was adopted by later commentators, who, in accordance with the well-established Peripatetic tradition, regarded logic as an instrument for doing philosophy. In Aristotle's preferred view logic was not included in the classification of the sciences at all, but it was treated as a preliminary to the study of each and every branch of knowledge. Aristotle's own name for logic was "analytics." The term logic, however, is employed in a somewhat restricted sense in Aristotle's own writings; *e.g.,* in the *Topics* I, 14. And there is some evidence that it was beginning to be used as the equivalent of dialectic or analytics almost immediately after Aristotle's death.

Contents of the *Organon*

The *Organon* contains the following treatises: the *Categories, On Interpretation, Prior Analytics, Posterior Analytics, Topics,* and the *Sophistical Refutations.* The arrangement within the collection is meant to be systematic rather than chronological. Indeed, the original chronological order can hardly be determined now with any certainty because Aristotle, or other editors, apparently used later insertions to supplement the original treatises. In a possible sequence of their composition, the *Categories, Topics,* and the *Sophistical Refutations* are listed earlier than *On Interpretation,* and this work, in turn, is earlier than the *Prior Analytics* and the *Posterior Analytics.* The chapters on modal logic in the *Prior Analytics* are probably the last that Aristotle added to the body of the *Organon.* Apart from the *Organon,* the fourth book of the *Metaphysics* could be described as a logical work inasmuch as it is centrally concerned with certain general principles of thought (the principle of noncontradiction, the law of the excluded middle).

In the *Categories,* Aristotle distinguished expressions that exhibit propositional unity from expressions that do not; that is, he distinguished between a simple term and a composite statement that relates a subject to a predicate. This notion of propositional unity can be traced back to Plato, but the treatment of simple expressions was Aristotle's innovation. He considered simple expressions neither true nor false and held that they may signify things in one or another of the following categories: substance, quantity, quality, relation, place, time, position, state, action, and affection. It is by no means clear whether this classification is to be regarded as primarily ontological (concerning the nature of reality) or as primarily verbal—*i.e.,* whether it is about actual things or about words and expressions; the same ambiguity has been characteristic of practically every other scheme of categories suggested since Aristotle's time.

Anti-Platonic evolution of logic

As a part of a theory of reality Aristotle later used the categories to criticize Plato's theory of Forms. For Aristotle, Plato was involved in a confusion between the category of substance and the other categories when, for example, he attributed substantiality, or concrete existence, to qualities such as beauty or wisdom. In chapter 5 of the *Categories,* Aristotle distinguishes within the category of substance between "primary substance" and "secondary substance." Primary substances are particular men, particular horses, particular stones, etc., and secondary substances are the species and genera to which the individuals belong. There Aristotle treated genus and species as substances of a derived kind. In the *Metaphysics,* however, species and forms appear to be substances of a primary kind. Aristotle's view, it must be said, is far from clear—some scholars see the *Metaphysics* as a return to a more Platonic conception of ontology.

On Interpretation begins with a brief but influential discussion of the simple parts of sentences, such as "names" and "verbs"; it then considers complete sentences of various kinds and examines the logical relationships (contrariety, contradiction, implication) holding among them. The work also contains a pioneering account of "modal" sentences ("It is possible that . . ."; "It is necessary that . . .") and a celebrated discussion of "future contingents." (If it is already true that there will be a sea battle tomorrow, then how can the battle be considered a contingent event? For if the truth is already determined, surely the battle is fixed and necessary? Aristotle's answer to this is that certain types of sentences about the future are neither true nor false.)

The *Topics* appears to have been intended as a manual for participants in contests that involved argumentation. For the most part this treatise consists of suggestions about how to look for an argument that will either establish or refute a given thesis; thus it elucidates general logical laws or rules.

The *Sophistical Refutations* exposes forms of reasoning that appear valid on the surface but are in fact fallacious. Examples of fallacious arguments are "begging the question," or circular argument (*e.g.,* a "proof" that the soul continues to exist after death because it is immortal); the "fallacy of the consequent," or arguing from a consequent to its condition (*e.g.,* if a man is a drunkard he becomes destitute; Peter is destitute: therefore Peter is a drunkard); and the "fallacy of the irrelevant conclusion," wherein, instead of proving the fact in dispute, the arguer seeks to gain his point by diverting attention to some extraneous fact.

The main achievement of the *Prior Analytics* is the development of the logical system now known as Aristotelian syllogistic. A syllogism is a form of argument consisting of three propositions (two premises and a conclusion). The stock example of a valid syllogism is the following:

Every Greek is a man.
Every man is mortal.

Every Greek is mortal.

Both premises are either affirmative or negative and contain two terms (the subject and the predicate) together with a sign of "quantity" ("every," "some," "no"). In addition, the propositions are either "assertoric" or "apodeictic" or "problematic"—they express the idea that something is or must or can be the case. "Every man must be rational" is apodeictic and affirmative; it is universal in quantity ("every"); its subject term is "man" and its predicate is "being rational." The *Prior Analytics* examines, with astonishing rigour and sophistication, the various possible forms of syllogistic argument.

In the *Posterior Analytics* Aristotle seeks to apply his logical theory to scientific and epistemological ends. He discusses the proper structure of scientific knowledge, urging that each science must depend on a set of first principles, or axioms, that are necessarily true and directly knowable. The truths, or theorems, that together constitute a science are to be deduced from its axioms, which both necessitate and explain them. Aristotle came to hope that all these scientific deductions could be formulated by way of apodeictic syllogisms. For this reason much of the second book of the *Posterior Analytics* is devoted to the theory of "definition," for Aristotle thought that the most important axioms of any science would be definitions of its proper subject matter. Among the various axioms of geometry, for example, there would be a definition of the triangle—an account of what a triangle really is or of the essence of a triangle.

Works on the philosophy of nature. In his treatise *Physics* Aristotle deals with natural bodies in general, or with all that is corporeal; special kinds of material bodies are discussed in his other physical works, such as *On the Heavens* or the *Meteorology.* The first book of the *Physics* is concerned with the intrinsic, constitutive elements of a natural body, those that he called "matter" and "form"; *i.e.,* the substratum that persists through change and the feature whose acquisition determines the nature of change. The second book treats mainly the different types of cause studied by the physicist, the material and the formal causes just mentioned, and the final and efficient causes, or the goal for the sake of which and the agent by means of which anything comes into being. Books 3 through 7 deal with movement, or motion, and the notions implied in it—such as space, position, and time, their magnitudes and continuity. The subject of Book 8 is the first mover, which, though not itself a natural body, is the cause of all movement in natural bodies; its necessary attributes—such as immovability and eternalness—are also examined.

Whatever the virtues or defects, clarity or obscurity,

of Aristotle's physical treatises, they assume that the distinction between physics and metaphysics (the "first philosophy," or the science of being as being) is valid. Although the conception of a continuous scale of nature from inorganic substances to biological and psychological phenomena is basic in all of his science, explanation does not consist in running uniformly up the hierarchy of beings to God nor in reducing all functioning to some material organ. The sciences of Aristotle are based on a multiple system of classification, not on a simple scheme of mutually exclusive and independently existent genera and species. The very distinction of causes in existing and mutable things permits the differentiation of the subject matters of the natural sciences.

The general principles discussed in the *Physics* are applied to the universe as a whole in *On the Heavens* (where Aristotle argues that the world is spatially finite but temporally eternal) and to the inanimate parts of the universe in *On Generation and Corruption* and the *Meteorology.* The former treatise discusses, in general terms, the four "elements" of the Aristotelian system (earth, air, fire, water) and their interrelations; Aristotle pays particular attention to the question of elemental change, whereby one element can alter and become another. The *Meteorology* deals with what, from a modern point of view, is a miscellany of topics—astronomy (*e.g.,* comets), geography (*e.g.,* rivers), chemistry (*e.g.,* burning), as well as meteorology (*e.g.,* rainbows). In addition to the general principles of physics and the theory of the elements, Aristotle relies on a further postulate: he supposes that "exhalations," some moist and some dry (steam and smoke), are constantly given off by the earth, and he attempts to explain the various phenomena he investigates in terms of the operation of these exhalations.

The principles of the *Physics* are also evident in Aristotle's biological and zoological writings. The largest of these, the *History of Animals* (a better translation of the Greek title would be *Inquiry into Animals*) consists in the main of descriptions of different animal species. Some of these descriptions—notably those of the crustaceans—are remarkable for their detail and accuracy. Some scholars regard the *History* as no more than a repository of raw data, collected for scientific scrutiny but not yet ordered or systematized. Others, however, think that Aristotle is concerned with constructing a biological taxonomy that divides the animal world into genera and species. The truth probably lies somewhere between these two views. There is neither a fully fledged Aristotelian taxonomy nor a fixed system of genera and species, but the material in the *History* is not simply an unorganized heap—the subject matter of the work is intelligently and significantly arranged.

However that may be, the *Parts of Animals* and the *Generation of Animals,* although they too present a quantity of empirical data, are primarily scientific and explanatory in intention. Aristotle is concerned with the nature and the function of the various animal organs and other "parts"; he wants not merely to describe and list them, but to "explain" them, both by reference to similarities across different animal species and also—and more strikingly—by reference to their functions within the animal's bodily system and behaviour. It is here that Aristotle's insistence on teleological explanation is most apparent: "nature," he says, "does nothing in vain," and although he does not, strictly speaking, hold that all features of animate beings have a functional explanation (the colour of eyes, for example, is accidental), such explanations are pervasive and are the mark of good science. The *Generation of Animals* considers specifically the problems of reproduction and growth. What contributions do male and female parents make to the embryo? What characteristics are inherited, and from whom, and how? How do embryos grow and develop, and how in particular do they acquire the different faculties that together constitute their souls? In this, Aristotle's most mature scientific work, the virtues and the vices of his method are most plainly to be seen: he is usually modest, careful, exact; he advances theoretical explanations, but he does not let theory prejudice observation; he attempts to produce a genuinely scientific work. On the other hand, the limitations of his knowledge—and of his means of acquiring new knowledge—are evident; and at least some of his theoretical concepts are crude and inadequate.

The biological works also include two short essays discussing animal locomotion entitled the *Movement of Animals* and the *Progression of Animals.* Here Aristotle attempts—not wholly successfully—to combine a rigorously mechanical account of animal motion, considered in terms of the physiology of the body and the nature of the medium, with a psychological discussion of the mental antecedents (perception, thought, desire) that explain animal behaviour.

Works on psychology. The relation between the active principle and the passive continuum (or between form and matter) that is operational in sentient and intellectual life is examined in *On the Soul.* After exploring the concept and the conditions of life, Aristotle relates the function of matter and form (body and soul) in human life to all of life's biological and psychological phenomena while rejecting Platonic transcendentalist and pre-Socratic materialist theories on the nature of the soul. The soul, as the form of the organic body, consists of an ordered set of faculties; these are, in hierarchical order, the nutritive, the perceptual, and the intellectual faculties. The nutritive faculty is common to all living things and is responsible for growth and nutrition; the perceptual faculty is common to all animals and is responsible for, among other things, sight, hearing, smell, and locomotion; and the intellectual faculty is peculiar to humans. Aristotle gives detailed accounts of the modes of perception (in addition to the five senses and their objects he postulates the existence of a "common sense" that unites their deliverances) and a notoriously difficult account of thought (which distinguishes an "active" from a "passive" intellect). The work also contains a discussion of animal movement and of its preconditions—of imagination and of desire.

In the *Parva Naturalia,* the medieval designation for a collection of short treatises on natural functions, the argument of *On the Soul* is supplemented by a sequence of treatises on sense and the sensible, memory and reminiscence, sleeping and waking, prophecy in sleep, the length and brevity of life, youth and old age, life and death, and respiration.

Works on metaphysics. The study of metaphysics, the function and content of which have generated neither conviction nor consensus of opinion on the scope of its subject matter, is—together with the syllogism and the differentiation of kinds of premises—an innovation of Aristotle. In his *Metaphysics* the doctrines that Aristotle sometimes refers to as "wisdom" and sometimes as "first philosophy" or even as "theology" are developed. Its task is that of describing the most general or abstract features of reality and the principles that have universal validity. In a famous (and misleading) phrase, he describes metaphysics as the study of "being *qua* being." By that he means that metaphysics studies whatever must be true of all existent things just insofar as they exist, that it studies the general conditions which any existing thing must satisfy.

Book 1 of the *Metaphysics* discusses in a preparatory way the problem of causal explanation. Aristotle gives a survey of the forms of explanation used or discussed by his predecessors, and discovers that his own theory of "four causes" represents the truth toward which they were struggling. This survey is one of the most important sources for information about the pre-Socratics and also about certain aspects of Plato's philosophy. Book 2 is a short essay on the principles of science, and Book 3 sets out a long series of metaphysical puzzles, or *aporiai.* The puzzles receive a preliminary discussion: most, but not all, of them are dealt with at greater length in later parts of the *Metaphysics.*

Book 4 explains Aristotle's conception of "first philosophy" as the general study of the conditions of existence, and it contains a defense of the principle of noncontradiction ("not both *P* and not-*P*") and the law of the excluded middle ("either *P* or not-*P*"). Book 5, sometimes called Aristotle's philosophical lexicon, is devoted to ambiguous philosophical terms: Aristotle analyzes and distinguishes

the different usages of some 40 key words. Book 6 returns to the issues of Book 4.

Books 7–9 form a unit. These central books are among the most difficult that Aristotle ever wrote, and they defy summary. The question to which they address themselves is this: What is substance? What are the fundamental constituents of the world, the things that enjoy an independent existence and can be known and defined? Aristotle's discussion is tortuous. It turns on the ideas of matter and form, of substance and essence, of change and generation, of actuality and potentiality. Aristotle's conclusion, it seems, is that substances are, in some sense, forms. They are not abstract Platonic Forms, but concrete, particular forms. They are the things designated by such phrases as "this man," "that horse," or "this oak tree."

Book 10 is a self-contained essay on "oneness"—on unity, continuity, identity, and related concepts. Book 11, which simply summarizes parts of the *Physics* and earlier parts of the *Metaphysics,* is generally regarded as spurious. Book 12 gives Aristotle's "theology": he asks how many causes must be posited to explain the world and arrives eventually at the conception of God, or of the first, or unmoved, mover. Aristotle's God, however, is not a personal God interested in the affairs of this world. Instead he is pure intelligence and as such completely indifferent to the vicissitudes of the world (as is implied in the concept of unmoved mover). In addition, the concept of first mover is not to be understood in a temporal sense. The first mover is not the creator of the world—indeed, Aristotle thought that the world was not created at all but had been in existence for all eternity—but the fountainhead of all motion. In that sense he is the ultimate cause of everything that happens in the world. Finally, Books 13 and 14 contain a long discussion—mostly critical and directed against Plato—of the nature of mathematical objects.

Works on ethics and politics. In emphasizing the crucial differences in the purposes of the theoretical and practical sciences, Aristotle indicates that the practical disciplines, unlike the theoretical, are for the sake of doing or making something and not for the sake of contemplating, defining, or knowing it. Thus, at the start of his *Nicomachean Ethics* he explains how the practical sciences are incapable of the exactness of the theoretical sciences, for their subject matters are not limited to things that are amenable to precise definition, but involve habits and skills, which can be acquired and lost, and associations and institutions, which in their changes affect the accomplishment of political actions and the practicability of moral ends. And however precise biological or psychological definitions may be, man varies as moral agent and as citizen according to environmental determination, educational background, and the influences of family, economic position, social class, means of livelihood, and even the associations of his leisure.

Nature of ethics as a practical science

Relating ethics to politics, Aristotle set out to demonstrate that problems of morality as they affect the individual cannot be separated from each other or from problems of political association. The *Ethics* and *Politics* therefore do not develop separate sciences or independent subject matters but rather supplement each other by treating a common field according to different aspects.

Although he treated moral problems in terms of the potentialities of individual men, the ability to practice and actualize these potentialities is dependent upon political circumstances. Therefore, in the first chapters of Book 1 of the *Ethics,* Aristotle begins by introducing moral considerations into the broad context of political philosophy, and he ends by returning, in the concluding Book 10, from the examination of happiness and the contemplative life to a shrewd statement of the contribution of law to moral questions, which forms the transition from ethics to politics.

Aristotle's approach to ethics is teleological; that is, he discusses ethics not in terms of moral absolutes but in terms of what is conducive to man's good. This approach leads him to examine various kinds of good and to arrive at the identification of the highest good with the attainment of happiness. After careful discussion of the problematic concept of happiness, Aristotle arrives at a definition of happiness as activity of the soul in accordance with virtue.

Aristotle distinguishes moral virtues and intellectual virtues, which are determined, respectively, by the irrational and the rational powers of the soul. Man, however, does not possess these virtues at birth but comes endowed with the capacity, or disposition, for developing them in the course of time. For example, a child begins by following his parents' injunction to tell the truth without initially realizing the moral excellence of his action; yet eventually the habit of veracity becomes an ingrained part of his moral character. Aristotle then differentiates virtue from vice, arriving at the definition of virtue as a "mean," or middle disposition, between the vicious extremes of excess and deficiency; courage, a virtue, for example, is the mean between cowardice and rashness.

Aristotle concludes his discussion by defining the highest happiness open to man. Because happiness is an activity in accordance with virtue, it follows that the highest happiness should be in accordance with man's highest virtue. And that, according to Aristotle, is the activity which distinguishes man from the other animals, namely the activity of reason or activity in accordance with reason. Thus in its ideal form happiness turns out to consist in a life of intellectual contemplation. Aristotle, on the other hand, also concedes that the political life (activity in accordance with moral virtue) can bring happiness, albeit "in a secondary degree."

Happiness as virtuous activity

The *Politics* takes up the problems of human action and association as they bear on the ends of communal life encompassed in living well. But the choice of political ends requires a complex examination of possible criteria capable of application to the vast diversity of men and human conditions. Grounding his argument on the premise that man is "naturally" a political animal, Aristotle develops the theory of the state, distinguishes various kinds of constitution, and considers the best state for the particular circumstances, character, and conditions of the citizens. Aristotle also discusses the nature and causes of political instability and revolution. The last two books of the *Politics*—part of an unfinished description of the ideal state—are largely concerned with education.

Works on art and rhetoric. Aristotle analyzes rhetoric in terms of its end, or final, cause, which is persuasion. Like dialectic it is not a science, and therefore it has no specific subject matter, no single method, and no proper set of principles. It is simply the faculty, or power, of observing in any given case the available means of persuasion. According to Aristotle, there are three modes of persuasion that a speaker may exercise: the persuasive power of his own character, the excitation of desired emotions in the audience, and proof or apparent proof.

In the *Poetics* Aristotle's analysis of poetry provides for careful isolation of the specific character of poetry. In comparing poetry to history, he states that poetry is more philosophic than history and thus of greater intrinsic worth. The difference is attributable not to form—history written in metre is still history—but to the fact that the historian deals with singulars (*i.e.,* with specific events and specific personages). The poet, on the other hand, creates types and situations that, while imitating nature, are, nonetheless, akin to universals; that is, the poet describes what is possible as though it were both likely and necessary. Yet Aristotle also permits the analogy of poetry to oratory as well as the consideration of the moral, political, and educational effects of both. Tragedy, however, which is the only kind of poetry analyzed in the extant portions of Aristotle's work, is defined in terms of its form, not in terms of its purpose, as a kind of imitation rather than as a mode of persuasion or excitation. Thus, in the famous definition of the sixth chapter, it imitates a serious action of great magnitude in a dramatic form and accomplishes the purification (*katharsis*) of the emotions of pity and fear.

Nature of tragic poetry

Using this definition as the basis for the discussion of poetry, Aristotle considered poetic art in terms of the characteristics and interrelations of the six parts, or components, of tragedy: plot, character, and thought (the objects of imitation); diction and melody (the means of imitation); and spectacle (the manner of imitation).

The last four chapters of the *Poetics* return to more general questions of value and to final causes by means of detailed comparisons of tragedy with comparable poetic works and specifically with epic.

ON READING ARISTOTLE

Goethe compared Aristotle's philosophy to a pyramid rising on high in regular form from a broad base on the Earth. Because each part of Aristotle's philosophy contributes to the understanding of other parts, it is generally true of his works—even more than those of most philosophers—that they cannot be read initially with a sure and well-grounded understanding but they must be reread for the sake of perceiving the primary conceptual and methodological relationships. Faced with the mass of materials that constitute the imposing body of his works, the reader might best start with the treatment of those problems that are relevant, interesting, or important to him. Aristotle himself often reiterated the suggestion that the inquirer concentrate first on sense experience as something that is better known to him and attend only afterward to the essential concepts of things in the effort to organize knowledge and constitute the principles of the particular sciences. Indeed, he frequently distinguished the process of inquiry and discovery from that of demonstration and proof.

Interrelationship of all Aristotle's writings

Aristotle's thought can be said to be known in two ways: (1) as remnants of his doctrines constituting the speech of Western culture, in the tradition of Western thought, and in the history of its sciences; and (2) as it is known from the attentive study of his writings. What Aristotle discovered in his intellectual inquiries and what he said can be most readily intelligible to someone of Western culture in the modified form in which it still constitutes part of that thought and conviction. It may be suggested, therefore, that Aristotle be read for the first time in an order the reverse of that in which his works have traditionally been arranged and that his conclusions and analyses be examined before inquiring about his principles. It is true, for example, that what Aristotle said concerning the poetic and rhetorical arts is more complex in manner of analysis and more difficult in systematic construction than what modern writers might say on such subjects; but it, nonetheless, still approximates more nearly to contemporary thought in this area than do his works on physics and metaphysics. And, for the same reason, his moral and political theory led him, in the course of its development, to many distinctions and statements that a modern reader would be disposed to accept or to reject without too lengthy critical discussion.

Once the manner of Aristotle's analysis is more firmly grasped and better appreciated, the reader can proceed to take up his logical works in the *Organon* and his investigations of space, time, and motion in the *Physics.* Through later consultation with the more complex thought in the *Metaphysics* and in *On the Soul,* he can review the earlier tentative conclusions made in the study of ethics and literary theory in the light of the deeper insights, acute distinctions, and strength of argument thus acquired.

When a student approaches Aristotle's conclusions in the light of his principles, allowing the text to illuminate his own experiences, Aristotle can then be appreciated not only for his expression of a philosophy but also as a help in the cultivation of the mind. And this is a task to which Aristotle himself thought all men should devote themselves and to which his philosophy remains a unique contribution. (A.H.Ao./Ed.)

ASSESSMENT AND NATURE OF ARISTOTELIANISM

The extent to which Aristotelian thought has become a component of civilization can hardly be overestimated. To begin, there are certain words that have become indispensable for the articulate communication of thoughts, experiences, and problems. Some words still carry their Greek form, whereas others have become established in their more important meanings as Latin equivalents of Aristotle's own words. The centuries-long impact of Aristotelian schooling lies at the root of the establishment of the following vocabulary: "subject" and "predicate" in grammar and logic; "form" (information, transform) and "matter" as expressing the two correlative aspects of something that has acquired or acquires something else that is possibly essential to it; "energy" as the active power inherent in a thing; "potential" for what is latent but can be released; "substance" and "essence," "quantity" and "quality," "accidental," "relation," "cause" (and the many meanings of "because" corresponding to the four causes), "genus" and "species" (general, special), "individual," "indivisible" (atomic)—these constitute only a small sample of terms that still carry the mark of Aristotle's philosophy.

Characteristic features

Beyond language, features that cumulatively or severally characterize Aristotelianism include, in philosophical methodology, a critical approach to previous, contemporary, or hypothetical doctrines; the raising and discussing of doctrinal difficulties; the use of deductive reasoning proceeding from self-evident principles or discovered general truths; and syllogistic forms of demonstrative or persuasive arguments.

In epistemology, or the theory of knowledge, Aristotelianism includes a concentration on knowledge either accessible by natural means or accountable for by reason; an inductive, analytical empiricism, or stress on experience, in the study of nature—including the study of men, their behaviour and organizations—leading from the perception of contingent individual occurrences to the discovery of permanent, universal patterns; and the primacy of the universal, that which is expressed by common or general terms.

In metaphysics, or the theory of Being, Aristotelianism involves belief in the primacy of the individual in the realm of existence; in the applicability to reality of a certain set of explanatory concepts (*e.g.,* 10 categories; genus–species–individual, matter–form, potentiality–actuality, essential–accidental; the four material elements and their basic qualities; and the four causes—formal, material, efficient, and final); in the soul as the inseparable form of each living body in the vegetable and animal kingdoms; in activity as the essence of things; and in the primacy of speculative over practical activity.

In the philosophy of nature, Aristotelianism denotes an optimistic position concerning nature's aims and its economy; believing in the perfection and in the eternity of the heavenly, geocentric spheres, perceiving them as driven by intelligent movers, as carrying in their circular movements the stars, the Sun, the planets, and the Moon, and as also influencing the sublunary world; and holding that light bodies rise naturally away from the centre of the Earth, while heavy bodies move naturally toward it with a speed related to their weight.

In aesthetics, ethics, and politics, Aristotelian thought holds that poetry is an imitation of what is possible in real life; that tragedy, by imitation of a serious action cast in dramatic form, achieves purification (*katharsis*) through fear and pity; that virtue is a middle between extremes; that man's happiness consists primarily in intellectual activity and secondarily in the exercise of the virtues; and that the state is a self-sufficient society, necessary for men to achieve happiness.

HISTORY OF ARISTOTELIANISM

Continuity of the Aristotelian tradition. Since Aristotle's death there have been, without interruption until the present, schools and individuals who have cultivated the study of his works and fully or partly adopted and expounded his doctrines and methods. They have interpreted or misinterpreted, approved or condemned, and reshaped or utterly transformed them. The languages in which this interest was most forcibly expressed have changed in turn and over time from Greek to Latin; to Syriac, Arabic, and Hebrew; to Italian, French, English, and German. The main centres in which it appeared have been as far apart as Greece, North Africa, and Rome in the ancient world; Persia and Spain, Sicily and the British Isles in the Middle Ages; and Germany and North America in more recent times.

Main centres and traditions

The main strand of the Aristotelian tradition has been the Greek line, which lasted 2,000 years, mainly in the area along the eastern Mediterranean Sea, and branched

off at various stages between the 4th and 15th centuries, giving rise to (or strengthening) other traditions. The Latin branch originated in Rome in the 4th century and acquired a new impulse, probably from Athens, in the early 6th century. From these beginnings it was revived in the 9th century and again in the 12th, at which time a second and even stronger Aristotelian wave emerged from Constantinople, to be followed by a third, via the western Arabic schools, from Spain; and both branches spread to Italy, France, and the British Isles. The final direct contribution from the Greek to the Latin tradition came to Italy, once more from or through Constantinople, in the 15th century.

Shortly after the beginning of Latin Aristotelianism certain Armenian and Syrian members of the Greek schools of Athens and Alexandria in Egypt introduced Aristotelian teachings into their schools. The Armenian tradition was still alive in the 19th century in such places as Madras and Venice; and the Syrian tradition, which never completely disappeared, was still powerful in the 14th century, after having given birth, in the 9th and 10th centuries, to an Arabic tradition. Arabic Aristotelianism was the product of Syrians, Persians, Turks, Jews, and Arabs who wrote and taught in their own countries as well as in Africa and Spain until the 12th century. Much of it and of what the Jews produced in Hebrew in the following two centuries passed into the Latin tradition between 1130 and 1550. Thus, all of the varied heritage that had derived ultimately from the Greek line and had been vastly enriched by other cultures came to be collected, through the Latin branch, by modern Western philosophical movements.

The Greek tradition. *Early development.* For some decades after his death Aristotle's own school, the Peripatos or Lyceum, remained, in a truly Aristotelian spirit, a centre for critical research—not for the dogmatic acceptance of a closed system. Aristotle's immediate successor, Theophrastus, independently elaborated his master's metaphysics and psychology and added to his study of nature (botany and mineralogy) and logic (theory of propositions and hypothetical syllogisms). Various members of the Lyceum coordinated Aristotelian thought with other current schools of philosophy. Thus Aristoxenus joined Aristotelian and Pythagorean doctrines; Critolaus united Aristotle's theory of the influence of the heavens on the world with the Stoic theory of providence; and Clearchus of Soli combined Plato's views on the human soul with Aristotle's.

The Stoics, Skeptics, and Epicureans

Outside the Lyceum, the Stoic school was partly following Aristotle in its interest in formal logic, the theory of meaning, and use of the categories (*e.g.*, substance, quality, relation). It was Aristotelian also in its empiricism, as well as in its concentration on nature, in several aspects of natural science, and in its belief that man is intrinsically a social being. The Skeptics sometimes relied on Aristotelian forms of argument to prove their systematic doubts. Even Epicurus, who may have fought against Aristotle's early theology and psychology and ignored his mature philosophy, was, nonetheless, near him in his doctrine of the will and in his conception of friendship and the pursuit of knowledge as the high aims that give satisfaction and pleasure to man.

Although relatively little was known of Aristotle's "esoteric" works until the 1st century BC, his more popular, literary, and Platonizing writings influenced eclectics such as Panaetius and his pupil Poseidonius; and this influence continued, helped by the Roman philosopher and lawyer Cicero, well into the 4th and 5th centuries AD. Upon it was based the tendency to establish a harmony between the thought of Plato and Aristotle—a feature that recurred through the whole history of Aristotelianism—and perhaps the ascription to Aristotle of the *De mundo* ("On the Universe"), a cosmological treatise of the 1st century BC, which found favour with all of the different traditions until the 16th century.

In the 1st century BC Aristotle's "esoteric" writings were organized into a corpus and critically edited by Andronicus of Rhodes and other scholars. The edition was used by Nicholas of Damascus, a historian and philosopher, in an attempt to expound Aristotle's system. This may be viewed as the beginning of a new era of a scholarly and scholastic Aristotelianism in which Aristotle had to be taken as the basis for the acquisition of true knowledge in a number of fields. Individual works began to be commented and lectured upon; organized philosophical studies began to have as their introduction Aristotle's works on logic, especially the *Categories.* Thus the pattern was set for the next 17 centuries. Almost pure Aristotelianism, based on the "esoteric" works, lived on until the 4th century. Many scholars—the most eminent of them being Alexander of Aphrodisias, who from AD 195 held the Athenian chair of Aristotelian studies created by the Roman emperor Marcus Aurelius—provided the works on logic, ethics, metaphysics, natural philosophy, and psychology with detailed and penetrating commentaries meant for the specialist. The interpretation of Aristotle was for many generations molded by these scholars. Others—the greatest being Themistius, a professor in Constantinople in about AD 350—practically rewrote many of Aristotle's treatises in a more modern language and more readable style.

This new, scholarly Aristotelianism had established itself sufficiently as the philosophical and methodological frame of learning for it to be adopted, at least in part, by most men of culture—including Ptolemy, the greatest astronomer of antiquity, and Galen, the most eminent medical scientist.

The Neoplatonists

Relationship to Neoplatonism. Aristotle's works were adopted by the systematic builders of Neoplatonism in the 3rd century AD. Plotinus, the school's chief representative, followed Aristotle wherever he found a possibility of agreement or development, as he did in Aristotle's theory of the intellect. And Plotinus' pupil Porphyry, the first great harmonizer of Plato and Aristotle, provided the field of logic with a short introduction (*Isagoge*). The *Isagoge,* in fact, is only concerned with a simple and rather mechanical treatment of five concepts that had been much used by Aristotle. These were the concepts of genus, or kind (as animal is the genus, or kind, under which Socrates falls); species, or sort (Socrates is a man); differentia, or distinguishing characteristic (rationality distinguishes men from other members of the genus animal); property (being capable of laughter was said to be a "property" of men inasmuch as all and only men are capable of laughter); and accident, or characteristic in general (as it might be an accident of Socrates to be pale). This introduction soon became an integral part of the *Organon* (the logical works of Aristotle) and thus acquired undeserved Aristotelian authority in all schools for more than 1,500 years. From that time on, Aristotelianism became indissolubly tied up with Neoplatonism.

Neoplatonism dominated the school of Athens, where, apart from logic, Aristotle's writings were destined to be studied mainly as a basis for philosophical disputations—disputations in which the Platonic view was usually victorious. Scholars like Ammonius—a pupil of Proclus, the most accomplished systematizer of Neoplatonism, head of the Athenian school in the mid-5th century, and himself extremely well-versed in Aristotle—found Alexandria a considerably more attractive place for Aristotelian studies, in that it was tolerant of many views. There pagans and Christians coexisted and cooperated, and from there they carried Aristotelian learning to a number of other schools: Simplicius, a pupil of Ammonius who was inclined to Platonism, took it back to Athens and—when Justinian closed that pagan school in 529—to Persia; Sergius, a physician and Nestorian priest, carried it to the Christian schools of Syria; and Stephanus of Alexandria took it to Constantinople. The schools of Alexandria and Athens produced from about AD 475 to 545 the most intensive collection of Aristotelian commentaries, by scholars like Ammonius, philosophers of science like Simplicius, and philosopher-theologians like Philoponus (see also PLATONISM).

Relationship with early Christian theology

Before the 5th century, Christian theology had been affected only marginally and indirectly by Aristotle. The elementary study of Aristotelian logic had proved indispensable for a disciplined training of theologians, and some of the concepts from Aristotle's *Physics* and *Metaphysics* that entered into the elaboration of this logic became equally essential for the rational formulation of points of

dogma. The aforementioned five terms of Porphyry and the 10 categories of Aristotle were used or implied in the mystical theology of Pseudo-Dionysius (an unidentified 5th-century Christian Neoplatonist), which was to become one of the principal components of Christian speculation in the Greek, Oriental, and Latin schools. Descriptions of God and distinctions between the three Persons of the Trinity came to include, in an increasingly technical sense, the Aristotelian terms substance, essence, accident, form and matter, species and nature, quality, quantity, and property; these terms were not always used in a purely Aristotelian sense, however. In this way, as well as through the purely philosophical schools, Aristotelianism entered the first Greek Scholasticism of St. John of Damascus, an 8th-century doctor of the church.

From the Byzantine renaissance to the 15th century. The Byzantine scholarly renaissance in the 9th century included a revival of interest in Aristotle: the old books were rediscovered and reedited (the oldest manuscripts still existing today belong to this time). Photius, patriarch of Constantinople and a leading figure in that renaissance, included in his encyclopaedic works summaries of the elements of Aristotelian logic. More extensive scholarly activity resulted from the reestablishment of the Academy in Constantinople in the 11th and 12th centuries under the successive leadership of such men as Michael Psellus, an encyclopaedic philosopher; his student John Italus; Michael, the archbishop of Ephesus; and Eustratius, the metropolitan of Nicaea. At the Academy teaching and exegetical work went hand in hand; debates on the superiority of Plato or Aristotle and attacks on philosophy by the religious schools did not seriously weaken these activities. There was perhaps not much that was new in the understanding or the development of Aristotle's doctrine; but logic was no longer the only focal point of Aristotelian studies. Indeed, they covered, more widely than had been done in Alexandria, practically the whole corpus, including some work on Aristotle's political theory, on his ethics, and on his biology. In addition, there were philosophical debates similar to those taking place in the Latin schools; they were based on texts of Aristotle and treated such issues as the theory of universals and the logical structure of language.

In the 13th and 14th centuries popularization and systematization—in an encyclopaedic or philosophical form—took the upper hand in the work of Nicephorus Blemmydes, George Pachymeres, and Theodore Metochites. At a time when Greek thought was being strongly influenced by the Latin tradition, especially by the work of Thomas Aquinas, the traditional debate on Plato and Aristotle took new forms. Aristotelianism appeared in the teaching of Barlaam the Calabrian, who sought to champion rationalism in faith; this was combated from a Platonic point of view by Nicephorus Gregoras. In the 15th century, when Greeks were becoming part of the Italian philosophical scene, Aristotelian rationalism was strongly defended by the upholders of Christian theology against such men as George Gemistus Plethon, who proposed a new universal religiosity tinged with an admiration for Plato and paganism. The victory in this intellectual battle went to the moderates like John Bessarion, Plethon's influential pupil, who, though he preferred Plato, admired Aristotle, translated his *Metaphysics,* and collected manuscripts of his works; he converted from the Greek (*i.e.,* the Greek Orthodox) church to the Latin (*i.e.,* what is now called the Roman Catholic) church, in which latter communion he became a cardinal.

The early Latin tradition. The echoes of Aristotle's early writings in Cicero, a few signs of his indirect influence on other writers, and a more considerable contribution to post-Aristotelian logic in Apuleius, a Platonic philosopher who flourished in the 2nd century AD, are indications of the general cultural intercourse in this area between Latins and Greeks. The presence of Plotinus and Porphyry in Rome in the 3rd and early 4th centuries probably started the more serious interest in Aristotle there, of which the first results were, perhaps, Victorinus' adaptations in Latin of Porphyry's *Isagoge* and Aristotle's *Categories.* Logic was still the only part of Aristotle that had entered Latin culture when Themistius' teaching attracted the attention of Roman pagan circles in the 4th century.

Influence on Boethius

Again, only the logical works of Aristotle, together with some extracts from Greek commentaries on them, seem to have reached the hands of Boethius, a Roman scholar and statesman of the early 6th century, when he was attempting to transmit to the Latins as much as he could of Greek learning. He translated these works and elaborated on the commentaries and on some other later texts of logic that are partly based on Aristotle. He acted primarily as a conduit, and some scholars are not prepared to ascribe to him interpretations and plans contained in the Latin works that bear his name. Even the plan of commenting on "as much of Aristotle as would come into his hands" and showing that Aristotle and Plato agreed was the traditional approach going back at least to Porphyry. Nothing remains to show where Boethius himself stood in judging Aristotle and the several parts of his philosophy. The same observations probably hold true with regard to Boethius' various theological treatises, in which the Aristotelian concepts that helped to organize the theology of the Trinity were unmistakably taken over from similar Greek treatises. A disproportionate value, however, was later attached to Boethius' own original contribution in both logic and theology; simply the fact that his name was connected with these texts made people in the Middle Ages ascribe to him the primary responsibility for their contents.

The Syriac, Arabic, and Jewish traditions. The increased sense of linguistic and national identity and the religious movements of the 5th and 6th centuries such as Nestorianism (a heterodox doctrine that so stressed the distinction between the divine and human natures of Jesus Christ as to suggest that they belonged to two persons) and Monophysitism (a heterodox doctrine asserting that there is only one nature in Jesus Christ) led to the foundation of Syriac centres of studies in the Persian and Byzantine empires, especially at Edessa (now Urfa, Tur.) and Antioch. Proba and Sergius of Resaina were among those who contributed, through translations of the basic logical texts and commentaries on them, to the establishment of Aristotelian studies in these centres. At the time of the Arabic invasion of the Byzantine and Sāsānian empires around 640, and for several generations afterward, these centres continued to grow in importance. Most notable was the great school of Kinnesrin, which was represented by such men as Severus Sebokht, who wrote on Aristotle's syllogisms; Jacob, bishop of Edessa, a theologian, grammarian, and translator; and Georgius, bishop of the Arabs, author of a commentary on the *Organon.* Interest remained, however, mainly confined to logic and its application to theology.

The Syrian Christians formed the philosophical and scientific intelligentsia when in the 9th century al-Ma'mūn, the seventh ʿAbbāsid caliph, organized the Arabic centre of learning of the new Islāmic empire in Baghdad. By then the Syrian scholars had acquired and translated most of Aristotle's works. They also then translated them into Arabic, both from the Syriac and directly from the Greek, and added many texts of commentators on Aristotle. In this way Ḥunayn ibn Isḥāq, his son Isḥāq, Abū Bishr Mattā ibn Yūnus, Yaḥyā ibn ʿAdī, and many other Syrians provided the basis for a brilliant philosophical activity in Arabic. The Syrians retained their own independent culture; as late as the 13th century their language was used by the converted Jew Bar Hebraeus, "Son of the Hebrew" (also known as Gregorius or Abū al-Faraj), an encyclopaedist, philosopher, and theologian, who expounded all the works of Aristotle in his *Kĕthabhā dhē-ḥēwath ḥekhmĕthā* (*Book of the Cream of Wisdom*), elaborating many sections on the basis of the Greek and Arabic Aristotelians.

In the 9th century the Arab al-Kindī was the first notable scholar to use the Arabic language in a general introduction of mainly Aristotelian philosophy. In the following century the Turkish Muslim al-Fārābī produced a more specialized study in which he commented upon and expounded the books of logic and attempted to establish the relationship between philosophy and Islām. It was through the writings of Avicenna and Averroës, however,

Contributions of Avicenna and Averroës

that Aristotle's thought became an integral part of lay Arabic culture.

Early in the 11th century, the Arab Avicenna (Ibn Sīnā) made Aristotle's philosophy the foundation of an original system of his own. For this he also found inspiration in a group of Plotinian texts that had been translated into Arabic under the title "Theology of Aristotle." Aristotle became, in Avicenna's hands, a much more systematic and coherent thinker than he really had intended to be; problems and solutions that were, at best, hinted at by Aristotle (*e.g.*, the distinction between essence and existence or the relation between possible and necessary existence) were among the distinctive marks of Avicenna's own work.

For the Spanish Arab Averroës (Ibn Rushd) in the 12th century, Aristotle was "the measure and model offered by nature to show the ultimate perfection of man." He held that philosophy, specifically Aristotelian philosophy, was and taught truth; revelation or revealed religion was a debased philosophy for the simple. Averroës dissected Aristotle's works, analyzing and reconstructing them with a fine scholarly and philosophical sense and an incredible wealth of information derived from previous Greek and Arabic philosophers. He elicited doctrines that are not easily apparent and made them in some cases more compelling than the texts themselves might allow, but he rarely forced his own views onto Aristotle without at least finding some support in the texts themselves. The doctrines concerning the mortality of the individual soul, the eternity of the world, and the existence of a single Mind for the whole human race to the exclusion of individual minds were key doctrines for Averroës; they had some basis—but not much—in the thought of Aristotle.

Relation between philosophy and Judaism

Until the 13th century, Jewish Aristotelianism developed within the Arabic culture of North Africa, Mesopotamia, and Spain. This work was carried out in the Arabic language and distinguished itself for its almost constant concern with the relation between philosophy and Judaism. Many Aristotelian concepts were considered and discussed by Isaac ben Solomon Israeli, a 10th-century Neoplatonist, in his *Kitāb al-ḥudūd* ("Book of Definitions") and *Kitāb al-usṭuqusāt* ("Book of the Elements"). Form and matter were the basis of the metaphysical structure of the Neoplatonic system of Solomon ibn Gabirol, an 11th-century poet and philosopher known as Avicebron. A fully conscious plan of inserting Aristotle—or at least the Aristotle of al-Fārābī and Avicenna—into the intellectual and spiritual life of Judaism was carried out by Abraham ibn Daud of Toledo in the mid-12th century. Moses Maimonides of Córdoba found a way of reconciling the claims of empirical knowledge with those of revelation, which places him into clear contrast with his contemporary Spaniard Averroës, and in so doing he provided a Jewish anticipation of Thomas Aquinas' Christian compromise. His proofs for the existence of God and his acceptance of a theory of creation from eternity were typical of his approach. From the 13th century onward philosophical works, particularly those of Averroës on Aristotle, were being translated into Hebrew; a vast Hebrew literature of "super-commentaries" (those on the works of Aristotle as commented on by Averroës) appeared, and independent works were also produced, notably by Levi ben Gershom (Gersonides), who was faithful to both Maimonides and Averroës. Soon after, however, the more orthodox tradition based upon the Bible and the Talmud prevailed. Aristotelian works by Jews and Hebrew versions of Averroës, translated into Latin, contributed their share to the Italian philosophical movement of the 16th century (see also JUDAISM: *Jewish philosophy*).

The later Latin tradition. *The discovery of Aristotle's works in the Latin West.* Before 1115 only the very short *Categories* and *On Interpretation* were known in Latin, and these two works circulated, from about 800, in a version by Boethius. By 1278 practically the whole of the Aristotelian corpus existed in translations from the Greek, and much of it had a wide circulation. Apart from three other works of logic in translations done by Boethius, which reappeared in about 1115, this wholesale discovery was the result of cultural contacts with Constantinople and a few other Greek centres and the personal initiative of a few scholars. Most notable and first of these was James of Venice, who was in Constantinople and translated the *Posterior Analytics, Physics, On the Soul, Metaphysics,* and several minor texts before or around 1150; other scholars translated anew or for the first time works on ethics, natural philosophy, and logic before 1200. With higher standards of linguistic scholarship, Robert Grosseteste, about 1240, revised and completed the translation of the *Nicomachean Ethics* and translated *On the Heavens* for the first time from the Greek.

Latin translations

The Flemish translator William of Moerbeke, active between about 1255 and 1278, completed the Latin Aristotelian corpus; he was the first to translate the *Politics* and *Poetics* and to give a full and reliable translation of the books on animals; he also translated anew some books of natural philosophy, and he revised several of the older translations. About half of the works were also translated from the Arabic, mainly in Toledo by Gerard of Cremona and Michael Scot, between 1165 and 1230. With two or three exceptions, these translations came after those from the Greek; all had a much more limited circulation and influence. A considerable contribution to the knowledge of Aristotle came from the translations of the ancient commentaries; nearly all of these were made from the Greek.

The view that Aristotle came to be known in Latin by way of the Arabic scholars must be understood as true only in the sense that a number of Aristotelian doctrines—partly transformed in the process—spread in Latin circles from the works of such men as al-Fārābī, Avicenna, and Albumazar before the texts of Aristotle were accessible or had been properly interpreted. Further, there is little truth in a view that in the Latin world in the Middle Ages Aristotle was seen in a Neoplatonic light because Plotinian and Proclan texts translated from the Arabic—namely the *Theologia Aristotelis* ("Theology of Aristotle") and the *Liber de causis* ("Book of Causes")—were ascribed to him.

From the 9th through the mid-13th century. The study of Porphyry's *Isagoge,* of Aristotle's *Categories* and *On Interpretation,* and of theological texts containing Aristotelian elements formed the basis, from the 9th century onward, of logical methodology (dialectic) in a wide number of fields. When applied to problems concerning the Trinity or the Eucharist, or in general to problems concerning individuality and universality of concepts and things, dialectic was perceived as a powerful instrument for clarifying faith or—on the opposite side—for endangering it. For Abelard, the first great Aristotelian of the Middle Ages, dialectic was an essential method for analysis and the discovery of truth. As part of his study, he produced an illuminating account of the linguistic, mental, and objective aspects of universals on the basis of Aristotelian doctrines. Soon thereafter, new developments of Aristotle's theory of language and logic took place, partly as a result of the recently acquired knowledge of his *Sophistical Refutations.*

At the same time, in the later 12th century and during the beginning of the 13th century, Aristotle's physics, cosmology, and metaphysics began to attract attention through the Latin texts both of Arabic works on science and philosophy and of Aristotle's own works, and did so mainly among scientists of the famous medical school at Salerno and among the English philosophers. Around 1190 Alfred of Sareshel used the new texts in his treatise *De motu cordis* ("On the Movement of the Heart"). Between 1210 and 1235 Robert Grosseteste commented on Aristotle's *Physics* and drew on various aspects of Aristotle's natural philosophy for his own scientific and philosophical treatises, and around 1245 Roger Bacon commented on the *Physics* and part of the *Metaphysics.* It would be wrong, however, to try to find in this scholarship the origin of modern experimental science, which is rather to be found in the study of ancient and more recent mechanics, medicine, and technology or in original inventiveness.

Reactions to Aristotelianism at the University of Paris

The introduction of the new Aristotle met with difficulties in Paris. The impact of non-Christian Aristotelian and Arabic philosophy engendered fears, doubts, and suspicions. Although the masters at Paris were free to teach Aristotle's logic, which was value free, and although no obstacle was put in the way of lecturing on any of Aristotle's

works at the universities of Oxford and Toulouse, in the first part of the 13th century the ecclesiastical authorities at Paris imposed a ban on lectures relating to the physics, the metaphysics, and the psychology of Aristotle and his commentators. While this ban succeeded in slowing down some activities it also quickened reactions and aroused strong curiosity; the very demand for some kind of censorship of the works led to more intimate study of them. Certainly by the 1240s the prohibition against teaching Aristotle had become a dead letter at Paris, as can be seen from the fact that Roger Bacon was then commenting on the "dangerous" *Physics* and *Metaphysics.* Shortly thereafter, before 1255, all of Aristotle's philosophical treatises then known had become a required part of the Parisian Master of Arts curriculum, and, around the same time, Albertus Magnus—committed though he was, as a Dominican friar, to safeguarding the purity of faith and dogma—made Aristotle's works an indissoluble part of philosophical and scientific literature in the Latin world. Albertus Magnus announced it as his intention to make all of Aristotle's natural philosophy "intelligible to the Latins." His vast encyclopaedia of secular knowledge and wisdom consisted of an analytical exposition of Aristotle's thought combined with all the information and interpretations that Albertus had gathered from other, mainly Arabic, sources or that he had gained as the product of his own extensive research and speculation. Faced with the danger of being accused of following Aristotle against church dogma, he asserted: "I expound, I do not endorse, Aristotle."

The approach of Albertus' pupil, Thomas Aquinas, to Aristotle was that of a scholar. He wrote numerous detailed commentaries on a variety of Aristotle's works, including the *Physics, Metaphysics, Ethics,* and *Politics;* he analyzed the structure of every section of most works; he tried to discover their organization and to follow the arguments; and he was careful to obtain the best texts and to get from them the genuine meaning. Above all, Thomas Aquinas drew heavily on Aristotle's thought in composing his own masterwork, the *Summa theologiae.* He respected Aristotle's authoritativeness and credited him with reasonableness, even when that was not explicitly justified. Sometimes he drew inferences that went beyond Aristotle's own conclusions, and he allowed himself considerable freedom whenever Aristotle had left loose ends in his attempts to solve difficulties. At these points he often went his own way, without ascribing the new steps to Aristotle but without feeling that he was going against him. Compromises followed; for example, he stepped beyond Aristotle when he argued that the individual soul, although remaining essentially and indissolubly the form of the individual body, is separable from it and immortal. Aristotle's account was stretched almost to the breaking point but it was not transformed. Beyond that point Thomas Aquinas was not a Christian Aristotle but a man of faith and dogma; he divorced himself from Aristotle when necessary and approached closer to St. Augustine, to the Neoplatonists, or to Avicenna.

From the late 13th century through the 15th century. The suspicion that reading Aristotle might lead to heresy became stronger when the closer study of his texts and of Averroës' interpretations enhanced the admiration for The Philosopher and increased the following of The Commentator, as these two thinkers were known respectively. Siger de Brabant was the most redoubtable of many Averroistic Aristotelians. What came to be called Averroism was in fact a tendency to accept genuine or consistent Aristotelian tenets, particularly those concerning the eternity of the world, the unity of the intellect, and the ability of humans to achieve happiness on earth. Ecclesiastical condemnations of propositions considered false or dangerous and threats against the holders of doctrines implied by these propositions gave a more definite status to the Averroists, although many propositions condemned at Paris and Oxford in 1270 and 1277 had nothing to do with Aristotle and little with Averroës. The effect of the condemnations soon became visible: it took the form of a separation between the teaching of "philosophy" in the faculty of arts and the teaching of "truth" in the faculty of theology. This separation became rigid, with the ambiguous result that two "truths"—truth of coherence in philosophical contexts and revealed truth—were thought to coexist.

At the turn of the century, however, Dante's powerful poetical vision could still merge the Averroists' Aristotle, who claimed that natural truths were self-sufficient, and Thomas Aquinas' Aristotle, who endorsed many of the truths of faith. For Dante, as for Averroës, Aristotle was the embodiment of total human knowledge—"the master of them that know." A remarkable index of Dante's commitment to Aristotelianism is the fact that he placed Siger de Brabant, by that time condemned for his Aristotelian heresy, in Paradise. In Aristotle's *Nicomachean Ethics* Dante found moral guidance (he even said that this work "showed man his true happiness"), and in Aristotle's scientific books he found the key to understanding the workings of nature. In some aspects of Averroës' theory of a universal human Intellect combined with the Stoic-Aristotelian principle that all men are by nature citizens of one city, he found the basis of the Empire, seeing it as the one polity (*civilitas*) for the whole human race.

Views of Scotus and Ockham; Averroism

The 14th century was no less Aristotelian than the 13th. Some scholars have indeed claimed that Aristotelianism collapsed, but such an assertion does not take into account the non-Aristotelian components of previous philosophies and the permanent acceptance of Aristotelian doctrines in the new ones. Form, matter, causality, and the idea of a universe in which events occurred with regularity but were not necessitated provided the Aristotelian frame of the system of Duns Scotus. The nominalism (or "terminism") of William of Ockham, an English Franciscan, his rejection of "useless entities," his metaphysics of a world of individual self-contained things, and his conceptualism gave neat, though extreme, expression to Aristotle's theory of language, the economy of nature, and the primacy of individuals in existence and of universals in intellectual knowledge. He followed Aristotle closely in his views on the scientific coordination of notions. He was more faithful to Aristotle than either Thomas Aquinas or Averroës when he said that Aristotle did not give a clear lead on the question of the immortality of the soul. The various schools of Scholastic philosophy—Thomism, Scotism, Ockhamism—that asserted themselves in the 14th century and that lived on had a common Aristotelian basis, but they had different ways of interpreting it (see also PHILOSOPHICAL SCHOOLS AND DOCTRINES, MAJOR WESTERN: *Scholasticism;* CHRISTIANITY: *Christian philosophy*).

Averroistic Aristotelianism flourished in this century in connection with, or independently of, the other trends. The Italian medical faculties at Bologna and Padua were lively centres of logical and philosophical studies; for example, Peter of Abano, a professor of medicine at Padua who had been trained at Paris, pushed Aristotle's cosmology to the brink of determinism in human affairs and used his logic to suggest that Christ's death was only apparent. Political science, which had been a field for lofty speculations or restrained exercises in the analysis and exposition of texts, became important for those who practiced politics and those who wanted to satisfy, under the aegis of Aristotle's doctrine, the potentialities of human beings for happiness. John of Paris wanted France to be self-sufficient, self-controlling, and without interference from the pope; John of Jandun, a successor of Siger de Brabant, upheld Aristotle's *Politics* in all its worldliness; and Marsilius of Padua, John of Jandun's friend in Paris, followed Aristotle in his insistence that government had no supernatural origins but arose naturally from the needs of the governed and that priests should be considered in the same way as members of a guild in a city, without special privileges.

Perhaps with less attachment to the details of Aristotle's doctrines and with a keen critical sense, the Mertonians, a group of logician-philosophers based in Merton College, Oxford (*e.g.,* Thomas Bradwardine, William of Heytesbury), and encyclopaedists, scientists, and philosophers in France (*e.g.,* Jean Buridan and Nicholas Oresme) made laborious efforts to express science wholly in terms of mathematics, to quantify changes in quality, and to determine the nature of continuity in movement and the acceleration and speed of falling bodies. Their starting points were the

Physics and the other texts of Aristotle. In a similar (almost mathematical) spirit, many of the same men carried logic even further than Ockham had done into the fields of logical calculus, paradoxes, and sophisms. Thus one may say that Aristotle was not abandoned but expanded.

Modern developments. *From the Renaissance to the 18th century.* In the 15th century Italy became the focal point at which various forms of Aristotelianism converged. Certain links between Italian universities and religious schools and the University of Paris had already flourished for a long time. In the late 14th century Paolo Nicoletti (Paulus Venetus) returned from Oxford to Padua after having absorbed the new logic and physics of the Mertonians and the radical nominalism of Ockham and after having increased his acquaintance with the French Averroistic trend; works by the Englishmen and by Paolo were textbooks in Italian universities for many generations. At the end of the century a number of Spanish and Italian Jews were passing on, in Latin, still more texts of Averroës on Aristotle, as well as the Jews' own recent contributions to Aristotelian learning.

A more spectacular contribution of books, linguistic and didactic competence, and stimulating debates came with an influx of Greek scholars into the Western sphere. They were attracted by the humanists' craving for classical learning, the theological discussions between Orthodox and Roman Catholic leaders, and the relative freedom offered by the Republic of Venice and by Florence to those who were taking refuge from Turkish domination. Many manuscripts were taken to Italy, and many were transcribed in Italy by the Greeks, who also taught the Greek language to the Italian scholars. An editorial masterpiece by Aldus Manutius, an early printer, publisher, and editor, at the end of the 15th century made accessible to many almost the complete Greek corpus of Aristotle's works. A great number of Greek and Latin scholars—such as Bessarion, John Argyropoulos, Leonardo Bruni, and Lorenzo Valla—produced new translations of those texts; others translated many works on Aristotle previously unknown in Latin.

As soon as printing had been established (that is to say, by the late 15th century), editorial activity was directed to the production of many complete as well as partial editions of the Latin versions of Aristotle and Averroës in both their older and newer versions from the Greek, the Arabic, and the Hebrew. At the universities of Padua and Bologna and at Ferrara and Venice, Averroists such as Agostino Nifo and Nicoletto Vernia and independent interpreters such as Pietro Pomponazzi were dominating the philosophical scene. For Pomponazzi, Aristotle, whether right or wrong, had to be studied directly by way of his own works and not by way of his interpreters; yet he did not think that Aristotle had a monopoly on knowledge, and for this reason his mistakes concerning facts needed to be exposed.

There were others who followed Aristotle in his vast scientific achievements or searched his works for a clearer formulation of scientific methods. It was this scientific spirit that kept alive the interest in Aristotle's methodology and in his philosophy of nature down to the time, in the 17th century, when William Harvey, the English physician who discovered the circulation of the blood, was lecturing on Aristotle's books on animals and Galileo was writing on science and logic.

In a less apparent form, Aristotelianism, still strongly entrenched in most European schools, continued to have its effect on the most modern philosophers. The methodology of Francis Bacon, English philosopher, scientist, and statesman, grew out of it, and his basic metaphysical concepts were borrowed from Aristotle, although he was critical of the distorted version of Aristotelianism in the academic circles of his day. The Polish astronomer Copernicus was still attached to the perfection of circular movements. Gottfried Wilhelm Leibniz, the German Rationalist and mathematician, not only admired Aristotle's logic but also built his own metaphysics of individuals ("monads") around the theory of matter and form. Like Aristotle, political theorists such as Jean Bodin in France carried on their inquiries into the nature of the state by studying existing organizations and their natural backgrounds.

In the literary field, Aristotle's *Poetics,* practically unknown until 1500, was now read and analyzed in both the Greek and Latin versions; its doctrines were compared and partly made to harmonize with the then-prevailing views of the ancient Roman poet Horace, and Aristotle's view that art imitates nature prevailed for many over the conflicting theory that stressed the creativity of the poet. The doctrine of the unities of action, place, and time—though actually a later development resulting from forced interpretations of Aristotle—ruled over the work of many writers of tragedies (*e.g.,* Gian Giorgio Trissino in Italy, Jean Racine and Pierre Corneille in France, and, to a certain extent, Goethe in Germany). Many critics (including the English critics from Sir Philip Sidney to Matthew Arnold) accepted those rules, although few English poets—the great exception was John Milton—welcomed them. A lesser influence was exercised by Aristotle's *Rhetoric* outside the field of systematic theory.

Scholasticism and Aristotle's detractors

Scholasticism in these centuries belonged to the history of Aristotelianism. All over western and central Europe and also in Spanish America the continuance of Scholasticism ensured that higher education remained generally within an Aristotelian framework. Remarkable work was produced by Scholastics in the fields of commentaries and of detailed interpretation; Pedro de Fonseca, the "Portuguese Aristotle," in the 16th century and Sylvester Maurus, author of short but pithy commentaries on all of Aristotle's works, in Rome in the 17th are noteworthy examples. Insofar as the different Scholasticisms were living and interesting philosophical movements, however, they had more to do with newer philosophies than with Aristotle.

Martin Luther's rebellion against Rome, on the other hand, involved a rebellion against Scholastic philosophy and its distorted Aristotelian structure, although not against Aristotle. In fact, when Luther's follower Philipp Melanchthon undertook to reorganize the curriculum for higher education, a more genuine, humanistic Aristotle emerged as the great master of philosophy, independent of theology. Once again, as in the early 13th century in Paris, Aristotle took pride of place, particularly in the realms of logic and ethics, and to a lesser extent in metaphysics and natural philosophy.

The anti-Aristotelianism of the 16th to 18th century touched only a small part of the real Aristotle. Partly it was a reaction against Scholasticism, as though this had faithfully represented Aristotle's own philosophy. Thus, Aristotle was wrongly accused of extreme formalism, irresponsible use of syllogisms consisting of empty or irrelevant concepts, a multiplication of pseudo-real entities, and the application of "scientific" methods to facts that could be vouched for only by faith. For other critics the whole of Aristotle's canon stood condemned because of his unsatisfactory account of local movement and the consequences it had in the areas of mechanics, dynamics, cosmology, and astronomy. His downfall in the 17th century was the result, above all, of his failure to create, in the 4th century BC, a language that allowed him to describe the forms of things and events (*i.e.,* their knowable aspects) in mathematical formulas and of his failure to lay sufficient stress, in his philosophy of experience, on the need for experiments.

Modern critical editions, translations, and studies

The 19th and 20th centuries. The anti-Aristotelian movement was countered mainly by historical and philological scholarship. As Friedrich Adolf Trendelenburg, a German philosopher, saw it, Aristotle's personality and works must be known as exactly as possible because he provides the indispensable historical basis of any serious philosophy. Such a type of study had declined after the great achievements of the 16th century. After the work done between the first new learned edition of the collected Greek texts of Aristotle by J.G. Buhle (1791–93) and a vast collection of all documentary material in the Aristoteles-Archiv at Berlin (which began in 1965), there is little, if anything, that remains to be discovered concerning the original and deteriorated forms of Aristotle's traditional corpus. A monumental edition sponsored by the Prussian Academy from 1831 to 1870 became the ba-

sis for almost innumerable critical editions of individual works. A rich crop of fragments, which were identified and edited in the last centuries, brought to light previously almost unknown aspects of Aristotle's early activity. And in 1890 a papyrus was discovered in Egypt that contained most of the otherwise lost *Constitution of Athens.* European and American academies have sponsored the editing of ancient and medieval commentaries and translations in Greek, Latin, Arabic, and Hebrew. Historical, philological, and philosophical exegesis has explored in great detail the contents and background of most of Aristotle's writings. Translations of all the works into English, German, and French and of many of them into most of the other European languages as well as into Hebrew, Arabic, and Japanese have made Aristotle widely accessible. Historians of ideas have investigated Aristotle's relationship to Plato and to the Greece of his day, his influence in following ages, and his own philosophical development.

Philosophical Aristotelianism has been mainly confined to the German schools established by Trendelenburg and Franz Brentano. Trendelenburg was concerned to effect a revaluation of Aristotle's metaphysics in the face of German idealism; he had a measure of influence in the United States on such thinkers as Felix Adler, George Sylvester Morris, and John Dewey. Aristotle's theories of being and knowledge formed the point of departure for Brentano's "descriptive psychology" and his doctrine of human experience, and they also contributed to Edmund Husserl's phenomenology. Outside Germany, J.-G.-F.-L. Ravaisson-Mollien, a spiritualist philosopher, and Sir David Ross, editor and translator of Aristotle's works, acknowledged a debt to Aristotle, respectively, for their metaphysics and ethics; and the reestablishment of Thomas Aquinas, by Pope Leo XIII in 1879, as the great doctor of the church increased the interest in Aristotle and in his influence on the history of Christian thought. Contemporary philosophy in the Anglo-Saxon world is often associated with a keen interest in Aristotle (nor is he entirely neglected in other philosophical traditions), and the name of the Aristotelian Society (London) reflects the view that good philosophy must be practiced in the spirit of Aristotle.

(L.M.-P./Ed.)

MAJOR WORKS

LOGIC: These six works are known collectively as the *Organon: Katēgoriai* (*Categories*); *Peri hermēneias* (Latin trans., *De Interpretatione;* Eng. trans., *On Interpretation*); *Analytika protera* (*Prior Analytics*); *Analytika hystera* (*Posterior Analytics*); *Topika* (*Topics*); and *Peri sophistikōn elegchōn* (*Sophistical Refutations*).

NATURAL PHILOSOPHY AND NATURAL SCIENCE: *Physikē* (*Physics*); *Peri ouranou* (*On the Heavens*); *Peri geneseōs kai phthoras* (*On Generation and Corruption; On Coming to Be and Passing Away*); *Meteōrologika* (*Meteorology*); *Peri kosmou* (spurious; Latin trans., *De mundo;* Eng. trans., *On the Universe*); *Peri ta zōa historiai* (*History of Animals*); *Peri zōōn moriōn* (*Parts of Animals*); *Peri zōōn kinēseōs* (*Movement of Animals*); *Peri poreias zōōn* (*Progression of Animals*); *Peri zōōn geneseōs* (*Generation of Animals*); and the works collectively known as the *Parva Naturalia: Peri aisthēseōs* (*On the Senses and Their Objects; On Sense and Sensible Objects*); *Peri mnēmēs kai anamnēseōs* (*On Memory and Recollection*); *Peri hypnou kai egrēgorseōs* (*On Sleep and Waking*); *Peri enypniōn* (*On Dreams*); *Peri tēs kath hypnon mantikēs* (*On Divination in Sleep; On Prophecy in Sleep*); *Peri makrobiotētos kai brachybiotētos* (*On Length and Shortness of Life*); *Peri neotētos kai gērōs* (*On Youth and Old Age*); *Peri zōēs kai thanatou* (*On Life and Death*); *Peri anapnoēs* (*On Respiration*); and *Peri pneumatos* (spurious; *On Breath*).

PSYCHOLOGY: *Peri psychēs* (Latin trans., *De anima;* Eng. trans., *On the Soul*).

METAPHYSICS: *Ta meta ta physika* (*Metaphysics*).

ETHICS AND POLITICS: *Ēthika Nikomacheia* (*Nichomachean Ethics*); *Ēthika Eudēmeia* (*Eudemian Ethics*); *Ēthika megala* (spurious; Latin and Eng. trans., *Magna moralia*); *Peri aretōn kai kakiōn* (spurious; *On Virtues and Vices*); *Politika* (*Politics*); *Oikonomika* (spurious; *Economics*); and *Athēnaiōn politeia* (incomplete; *Constitution of Athens*).

AESTHETICS AND LITERATURE: *Technē rhētorikē* (*Rhetoric*); *Rhētorikē pros Alexandron* (spurious; *Rhetoric to Alexander*); and *Peri poiētikēs* (incomplete; *Poetics*).

OTHER WORKS: These remain in the corpus but are believed by scholars to be falsely attributed to Aristotle: *Peri chrōmatōn* (*On Colours*); *Peri akoustōn* (*On Things Heard*); *Physiognōmonika* (*Physiognomonics*); *Peri phytōn* (*On Plants*); *Peri thaumasiōn akousmatōn* (*On Marvellous Things Heard*); *Mēchanika* (*Mechanics*); *Problēmata* (*Problems*); *Peri atomōn grammōn* (*On Indivisible Lines*); *Anemōn theseis kai prosēgoriai* (*The Situations and Names of Winds*); and *Peri Melissou, peri Xenophanous, peri Gorgiou* (*On Melissus, Xenophanes, Gorgias*).

TEXTS: The standard edition of the Greek text is the Berlin Academy edition, *Aristotelis Opera,* ed. by Immanuel Bekker, 5 vol. (1831–70, reissued 5 vol. in 4, 1960–61); and the standard edition of the fragments is *Aristotelis qui Ferebantur Librorum Fragmenta,* ed. by Valentin Rose (1870, reissued 1967). For most works these texts have been superseded by more recent editions, notably by the volumes of the Teubner series, the Oxford Classical Text series, the Loeb Classical Library series (with English translations), and the Budé series (with French translations). The medieval Latin translations of Aristotle are being printed in *Aristoteles Latinus,* ed. by L. Minio-Paluello (1939–); see also *Aristotelis opera cum Averrois commentariis,* 9 vol. in 11 (1562–74, reissued 1962). In addition there is much useful information of a textual nature in the early Greek commentaries, the most important of which have been published in *Commentaris in Aristotelem Graeca,* 23 vol. in 46 (1882–1909). An invaluable aid to the study of Aristotle is Hermann Bonitz, *Index Aristotelicus* (1870, reprinted 1955).

RECOMMENDED EDITIONS: Numerous English translations of the major treatises are available. The standard complete edition is Jonathan Barnes (ed.), *The Complete Works of Aristotle: The Revised Oxford Translation,* 2 vol. (1984). Of the many editions of and commentaries on individual works, the following may be mentioned: J.L. Ackrill (trans.), *Categories, and De Interpretatione* (1963, reprinted 1978); W.D. Ross (ed.), *Prior and Posterior Analytics* (1949, reprinted 1957); Jonathan Barnes (trans.), *Aristotle's Posterior Analytics* (1976); W.D. Ross (ed.), *Physics* (1950, reprinted 1977); W. Charlton (trans.), *Aristotle's Physics: Books 1 & 2* (1970); Edward Hussey (trans.), *Aristotle's Physics, Books III and IV* (1983); Harold H. Joachim (ed.), *Aristotle on Coming-to-Be and Passing-Away* (*De Generatione et Corruptione*) (1922, reprinted 1982); C.J.F. Williams (trans.), *Aristotle's De Generatione et Corruptione* (1982); R.D. Hicks (trans.), *De Anima* (1907, reprinted 1976); W.D. Ross (ed.), *Parva Naturalia* (1955, reprinted 1970); G.R.T. Ross (trans.), *De Sensu and De Memoria* (1906, reprinted 1973); Richard Sorabji, *Aristotle on Memory* (1972); D.M. Balme (trans.), *Aristotle's De Partibus Animalium I; and, De Generatione Animalium I* (1972); Martha Craven Nussbaum (ed. and trans.), *Aristotle's De Motu Animalium* (1978); W.D. Ross (ed.), *Metaphysics,* 2nd ed. (1928); Christopher Kirwan (trans.), *Aristotle's Metaphysics* (1971), Books 4–6; Myles Burnyeat (ed.), *Notes on Book Zeta of Aristotle's Metaphysics* (1979), and *Notes on Books Eta and Theta of Aristotle's Metaphysics* (1984); Julia Annas (trans.), *Aristotle's Metaphysics* (1976), Books 13–14; J.A. Stewart, *Notes on the Nichomachean Ethics of Aristotle* (1892, reprinted 1973); Michael Woods (trans.), *Aristotle's Eudemian Ethics: Books I, II, and VIII* (1982); W.L. Newman (ed.), *The Politics of Aristotle,* 4 vol. (1887–1902, reprinted 1973); Richard Robinson (trans.), *Politics, Books III and IV* (1962); Edward Meredith Cope (ed.), *The Rhetoric of Aristotle,* 3 vol. (1877, reprinted 1973); D.W. Lucas (ed.), *Poetics* (1968, reprinted 1980); P.J. Rhodes (trans.), *The Athenian Constitution* (1984); and Ingemar Düring (ed.), *Protrepticus: An Attempt at Reconstruction* (1961).

BIBLIOGRAPHY

Aristotle. *General works:* There are several good introductions to Aristotle's thought: JONATHAN BARNES, *Aristotle* (1982); J.L. ACKRILL, *Aristotle the Philosopher* (1981); D.J. ALLAN, *The Philosophy of Aristotle,* 2nd ed. (1970, reissued 1978); G.E.R. LLOYD, *Aristotle: The Growth and Structure of His Thought* (1968); W.D. ROSS, *Aristotle,* 5th ed. (1949, reprinted 1977); and FRANZ BRENTANO, *Aristotle and His World View* (1978; originally published in German, 1911). For a comprehensive survey see INGEMAR DÜRING, *Aristoteles: Darstellung und Interpretation seiner Denkens* (1966). Two of the most influential books on Aristotle written in the 20th century are WERNER W. JAEGER, *Aristotle: Fundamentals of the History of His Development,* 2nd ed. (1948, reissued 1962; originally published in German, 1923), which advances a theory of the development of Aristotle's thought; and HAROLD CHERNISS, *Aristotle's Criticism of Plato and the Academy* (1944, reissued 1962), which discusses, in a uniformly critical spirit, Aristotle's knowledge and assessment of Plato's work.

Most of the scholarly work done on Aristotle appears in articles rather than in books. There is a useful anthology: JONATHAN BARNES, MALCOLM SCHOFIELD, and RICHARD SORABJI (eds.), *Articles on Aristotle,* 4 vol. (1975–79). The proceedings of the triennial *Symposium Aristotelicum* contain some of the most up-to-date work.

Life: For all aspects of Aristotle's life, see INGEMAR DÜRING,

Aristotle in the Ancient Biographical Tradition (1957); for his writings, see PAUL MORAUX, *Les Listes anciennes des ouvrages d'Aristote* (1951); for the history of the Lyceum, see JOHN PATRICK LYNCH, *Aristotle's School: A Study of a Greek Educational Institution* (1972); and PAUL MORAUX, *Der Aristotelismus bei den Griechen: Von Andronikos bis Alexander von Aphrodisias,* 2 vol. (1973–84).

Thought: (*Logic*): On Aristotle's formal syllogistic the classic study is JAN ŁUKASIEWICZ, *Aristotle's Syllogistic from the Standpoint of Modern Formal Logic,* 2nd ed. enlarged (1957, reprinted 1967); and the standard work is GÜNTHER PATZIG, *Aristotle's Theory of the Syllogism: A Logico-Philological Study of Book "A" of the "Prior Analytics"* (1969; originally published in German, 2nd ed. 1963). A less formal account can be found in ERNEST KAPP, *Greek Foundations of Traditional Logic* (1942, reissued 1967). See also JONATHAN LEAR, *Aristotle and Logical Theory* (1980); and, for the *Topics,* the introduction to JACQUES BRUNSCHWIG (trans.), *Topiques* (1967). On the development of Aristotle's ideas in logic, see FRIEDRICH SOLMSEN, *Die Entwicklung der aristotelischen Logik und Rhetorik* (1929, reprinted 1975). For Aristotle's modal logic, see STORRS MCCALL, *Aristotle's Modal Syllogisms* (1963); and for less formal treatments of his ideas about modality, see JAAKKO HINTIKKA, *Time & Necessity: Studies in Aristotle's Theory of Modality* (1973); and SARAH WATERLOW, *Passage and Possibility: A Study of Aristotle's Modal Concepts* (1982). On the connection between Aristotle's logic and his scientific methodology, see J.M. LE BLOND, *Logique et méthode chez Aristote: étude sur la recherche des principes dans la physique aristotélicinne,* 2nd ed. (1970).

(*Theory of science*): The standard introduction to the *Physics* is AUGUSTE MANSION, *Introduction à la physique aristotélicienne,* 2nd rev. ed. (1946); see also FRIEDRICH SOLMSEN, *Aristotle's System of the Physical World: A Comparison with His Predecessors* (1960, reprinted 1970). Among the most stimulating recent studies are WOLFGANG WIELAND, *Die aristotelische Physik;* 2nd rev. ed. (1970); RICHARD SORABJI, *Necessity, Cause, and Blame: Perspectives on Aristotle's Theory* (1980), and *Time, Creation, and the Continuum: Theories in Antiquity and the Early Middle Ages* (1983); and SARAH WATERLOW, *Nature, Change, and Agency in Aristotle's "Physics"* (1982).

(*Biology*): It is still worth consulting D'ARCY WENTWORTH THOMPSON, *On Aristotle as a Biologist* (1913); the best recent study is PIERRE PELLEGRIN, *La Classification des animaux chez Aristote: statut de la biologie et unité de l'aristotélisme* (1982).

(*Psychology*): FRANZ BRENTANO, *The Psychology of Aristotle: In Particular His Doctrine of the Active Intellect* (1977; originally published in German, 1867), remains one of the most valuable works in this area. The standard study of the development of Aristotle's views on the soul is FRANÇOIS NUYENS, *L'Évolution de la psychologie d'Aristote* (1948, reissued 1973). Among more recent works are EDWIN HARTMAN, *Substance, Body, and Soul: Aristotelian Investigations* (1977); and DAVID CHARLES, *Aristotle's Philosophy of Action* (1984).

(*Metaphysics*): There are two large and comprehensive volumes: JOSEPH OWENS, *The Doctrine of Being in the Aristotelian Metaphysics: A Study in the Greek Background of Medieval Thought,* 3rd ed. rev. (1978); and PIERRE AUBENQUE, *Le Problème de l'être chez Aristote: essai sur la problèmatique aristotélicienne,* 4th ed. (1977). There is a helpful brief introduction in G.E.M. ANSCOMBE and P.T. GEACH, *Three Philosophers* (1961, reprinted 1963). On special aspects of the metaphysics, see FRANZ BRENTANO, *On the Several Senses of Being in Aristotle* (1975, reprinted 1981; originally published in German, 1862); R.M. DANCY, *Sense and Contradiction: A Study in Aristotle* (1975); SUZANNE MANSION, *Le Jugement d'existence chez Aristote,* 2nd ed. rev. (1976); and A.C. LLOYD, *Form and Universal in Aristotle* (1981).

(*Ethics*): W.F.R. HARDIE, *Aristotle's Ethical Theory,* 2nd ed. (1980), provides a helpful companion. Some of the best recent work is collected in AMÉLIE OKSENBERG RORTY (ed.), *Essays on Aristotle's "Ethics"* (1980). See also STEPHEN R.L. CLARK, *Aristotle's Man: Speculations upon Aristotelian Anthropology* (1975), reprinted 1983); JAMES J. WALSH, *Aristotle's Conception of Moral Weakness* (1963); JOHN M. COOPER, *Reason and Human Good in Aristotle* (1975); ANTHONY KENNY, *The Aristotelian Ethics: A Study of the Relationship Between the Eudemian and Nicomachean Ethics of Aristotle* (1978), and *Aristotle's Theory of the Will* (1979); and TROELS ENGBERG-PEDERSEN, *Aristotle's Theory of Moral Insight* (1983, reprinted 1985).

(*Politics*): The standard discussion is ERNEST BARKER, *The Political Thought of Plato and Aristotle* (1906, reissued 1959); see also R.G. MULGAN, *Aristotle's Political Theory: An Introduction for Students of Political Theory* (1977). On Aristotle's historical interests, see GEORGE HUXLEY, *On Aristotle and Greek Society: An Essay* (1979).

(*Rhetoric*): WILLIAM M.A. GRIMALDI, *Studies in the Philosophy of Aristotle's Rhetoric* (1972). On the psychological aspects of rhetoric, see W.W. FORTENBAUGH, *Aristotle on Emotion: A Contribution to Philosophical Psychology, Rhetoric, Poetics, Politics, and Ethics* (1975).

(*Poetics*): JOHN JONES, *On Aristotle and Greek Tragedy* (1962, reissued 1980); and RICHARD JANKO, *Aristotle on Comedy: Towards a Reconstruction of "Poetics" II* (1984).

Aristotelianism. *Aristotelianism as covered in general histories:* Extensive treatment of Aristotelianism is included in the fundamental history of philosophy by FRIEDRICH UEBERWEG, *A History of Philosophy, from Thales to the Present Time,* 2 vol. (1872–74, reprinted 1972; originally published in German, 4th ed., 3 vol., 1871–73), with a vast bibliography. Useful histories of philosophy, general or partial, are FREDERICK C. COPLESTON, *A History of Philosophy,* 9 vol. (1946–74); MEYRICK H. CARRÉ, *Phases of Thought in England* (1949, reprinted 1972), which is particularly good on Aristotelianism; JOHN HERMAN RANDALL, *The Career of Philosophy,* 2 vol. (1962–65, reissued 1970), imaginative and stimulating; and ÉTIENNE GILSON, *History of Christian Philosophy in the Middle Ages* (1955, reissued 1980), a personal interpretation, with documentation and bibliography.

Aristotelianism in various periods or cultures: INGEMAR DÜRING, "Von Aristoteles bis Leibniz: Einige Hauptlinien in der Geschichte des Aristotelismus," *Antike und Abendland,* 4:118–154 (1954), mostly on Greek and medieval Aristotelianism; LORENZO MINIO-PALUELLO, *Opuscula: The Latin Aristotle* (1972), a collection of articles and essays concerning the Latin transmission of Aristotle's works; and RICHARD MCKEON, "Aristotelianism in Western Christianity," in JOHN THOMAS MCNEILL, MATTHEW SPINKA, and HAROLD R. WILLOUGHBY (eds.), *Environmental Factors in Christian History,* pp. 206–231 (1939, reissued 1970). On Boethius, see HENRY CHADWICK, *Boethius: The Consolation of Music, Logic, Theology, and Philosophy* (1981); and MARGARET GIBSON (ed.), *Boethius: His Life, Thought, and Influence* (1981). (*On Greek Aristotelianism*): EDUARD ZELLER, *Die Philosophie der Griechen,* vol. 2, *Sokrates, Plato, Aristoteles* (1846), and vol. 3, parts 1–2, *Die nacharistotelische Philosophie* (1852), parts of which have been translated from various editions: *Aristotle and the Earlier Peripatetics,* trans. by B.F.C. COSTELLOE and J.H. MUIRHEAD (1897); and *A History of Eclecticism in Greek Philosophy,* trans. by S.F. ALLEYNE (1883), fundamental for the first eight centuries; PAUL MORAUX, *D'Aristote à Bessarion: trois exposés sur l'histoire et la transmission de l'aristotélisme grec* (1970); "Rückblick: Der Peripatos in vorchristlicher Zeit," in FRITZ R. WEHRLI (ed.), *Die Schule des Aristoteles,* vol. 10, pp. 93–128 (1959); KLAUS OEHLER, "Aristotle in Byzantium," *Greek, Roman, and Byzantine Studies,* 5(2):133–146 (Summer 1964); and BASILE TATAKIS, *La Philosophie byzantine,* 2nd ed. (1959), an extensive survey, with a rich bibliography. (*On Latin Aristotelianism*): FERNAND VAN STEENBERGHEN, *Aristotle in the West: The Origins of Latin Aristotelianism,* 2nd ed. (1970; originally published in French, 1946), a scholarly survey of contemporary studies; RICHARD J. LEMAY, *Abu Ma'shar and Latin Aristotelianism in the Twelfth Century: The Recovery of Aristotle's "Natural Philosophy" Through Arabic Astrology* (1962), important contributions; D.A. CALLUS, "Introduction of Aristotelian Learning to Oxford," *Proceedings of the British Academy,* 29:229–281 (1943), original, fundamental research; PAUL MORAUX *et al., Aristote et Saint Thomas d'Aquin* (1957), which includes some of the most reliable studies on the subject; M.-D. CHENU, *La Théologie comme science au XIII^e siècle,* 3rd ed. rev. (1957, reissued 1969), on the interplay of Aristotelian methodology and dogma; and HASTINGS RASHDALL, *The Universities of Europe in the Middle Ages,* new ed., 3 vol. (1936, reissued 1969), basic for Aristotelianism in the schools. (*On Syriac, Arabic, and Jewish Aristotelianism*): ANTON BAUMSTARK, *Geschichte der syrischen Literatur mit Ausschluss der christlich-palästinensischen Texte* (1922, reprinted 1968), with exhaustive factual information and a bibliography; ANTON BAUMSTARK (ed.), *Aristoteles bei den Syrern vom 5. bis 8. Jahrhundert: Syrische Texte* (1900, reprinted 1975), specialized research and texts; T.J. DE BOER, *The History of Philosophy in Islam* (1903, reprinted 1983; originally published in German, 1901); CARL BROCKELMANN, *Geschichte der arabischen Litteratur,* 2 vol. (1898–1902), exhaustive factual information and bibliography; F.E. PETERS, *Aristoteles Arabus: The Oriental Translations and Commentaries of the Aristotelian Corpus* (1968), from Syriac and Arabic; R. WALZER, "Arisṭūṭālīs," in *The Encyclopaedia of Islam,* new ed., vol. 1, pp. 630–633, and related articles; ISAAC HUSIK, *A History of Mediaeval Jewish Philosophy* (1916, reissued 1974); GEORGES VAJDA, *Introduction à la pensée juive du Moyen Age* (1947), limited in scope, with a good bibliography; HARRY A. WOLFSON, "Revised Plan for the Publication of a *Corpus Commentariorum Averrois in Aristotelem,*" *Speculum,* 38(1):88–104 (January 1963), complete lists of Arabic, Latin, and Hebrew texts of Averroës' commentaries, and *Crescas' Critique of Aristotle: Problems of Aristotle's "Physics" in Jewish and Arabic Philosophy* (1929, reprinted 1971); and "Aristot-

le," in *Encyclopaedia Judaica,* vol. 3, col. 445–449 (1971), and related articles. (*On Renaissance and later Aristotelianism*): PAUL OSKAR KRISTELLER, *Renaissance Philosophy and the Mediaeval Tradition* (1966), a brilliant survey, with bibliography, and *Studies in Renaissance Thought and Letters* (1956, reprinted 1969), many relevant essays; BRUNO NARDI, *Saggi sull'Aristotelismo padovano dal secolo XIV al XVI* (1958), one of several fundamental works by this author; PETER PETERSEN, *Geschichte der aristotelischen Philosophie in protestantischen Deutschland* (1921, reprinted 1964), and *Die Philosophie Friedrich Adolf Trendelenburgs: ein Beitrag zur Geschichte des Aristoteles im 19. Jahrhundert* (1913); and CHARLES B. SCHMITT, *Aristotle and the Renaissance* (1983).

Aristotelianism in various areas or disciplines: (*On logic*): WILLIAM KNEALE and MARTHA KNEALE, *The Development of Logic* (1962, reprinted 1984), an objective assessment of the Aristotelian and non-Aristotelian elements in the history of logic; and I.M. BOCHEŃSKI, *A History of Formal Logic,* 2nd ed. (1970; originally published in German, 1956), technical, with much bibliography. (*On science*): GEORGE SARTON, *Introduction to the History of Science,* 3 vol. in 5 (1927–48, reprinted 1975), fundamental, with extensive information and bibliography; RENÉ TATON (ed.), *A General History of the Sciences,* 4 vol. (1963–66; originally published in French, 1957–64); ALASTAIR C. CROMBIE, *Robert Grosseteste and the Origins of Experimental Science, 1100–1700* (1953, reissued 1971), which upholds the view of Aristotelian impact on experimental method; ANNELIESE MAIER, *Studien zur Naturphilosophie der Spätscholastik,* 5 vol. (1949–58), fundamental research; and ALEXANDRE KOYRÉ, *Galileo Studies* (1978; originally published in French, 1939), indispensable for a proper evaluation of anti-Aristotelianism. (*On politics*): GEORGE H. SABINE, *A History of Political Theory,* 4th ed. rev. by THOMAS LANDON THORSON (1973); ALEXANDER PASSERIN D'ENTRÈVES, *The Medieval Contribution to Political Thought: Thomas Aquinas, Marsilius of Padua, Richard Hooker* (1939, reprinted 1959); GEORGES DE LAGARDE, *La Naissance de l'esprit laïque au déclin du Moyen Age,* 3rd ed., 5 vol. (1956–70), fundamental for the 14th century; and HORST DREITZEL, *Protestantischer Aristotelismus und absoluter Staat: Die "Politica" des Henning Arnisaeus (ca. 1575–1636)* (1970), excellent, with an extensive bibliography on German Aristotelianism. (*Poetics and rhetoric*): BERNARD WEINBERG, *A History of Literary Criticism in the Italian Renaissance,* 2 vol. (1961, reprinted 1974), containing good surveys concerning Aristotle; LANE COOPER, *The Poetics of Aristotle: Its Meaning and Influence* (1923, reissued 1972); MARVIN T. HERRICK, *The Fusion of Horatian and Aristotelian Literary Criticism, 1531–1555* (1946), and *The Poetics of Aristotle in England* (1930, reprinted 1976), indispensable complements to Cooper's book; and CHARLES S. BALDWIN, *Renaissance Literary Theory and Practice: Classicism in the Rhetoric and Poetic of Italy, France, and England, 1400–1600* (1939, reissued 1959), useful for both poetics and rhetoric.

(A.H.Ao./L.M.-P./Ed.)

Arithmetic

Arithmetic (a term derived from the Greek word *arithmos,* "number") refers generally to the elementary aspects of the theory of numbers, arts of mensuration (measurement), and numerical computation (that is, the processes of addition, subtraction, multiplication, division, raising to powers, and extraction of roots). As is often the case, however, such meaning, has not been uniform in mathematical usage. An eminent German mathematician, Carl Friedrich Gauss, in *Disquisitiones Arithmeticae* (1801), and certain contemporary mathematicians have used the term to include some aspects of number theory that are considerably more advanced. The reader interested in the latter is referred to NUMBER THEORY.

This article is divided into the following sections:

FUNDAMENTAL DEFINITIONS AND LAWS

In a collection (or set) of 1, 2, 3, or, generally, n objects (or elements), the act of determining the number of objects present is called counting. For an empty set, no object is present, and the count yields the number 0. The numbers n thus obtained are called natural numbers; there are some mathematicians who include 0 among the natural numbers, whereas there are others who do not include it.

If n_1 and n_2 are the numbers of objects in the two sets S_1 and S_2 respectively, then those objects in S_1 and S_2 may possibly be paired in such a way that each pair contains one object from S_1 and one from S_2 and no object from either set remains unpaired. The two numbers n_1, n_2 would then be said to be equal; that is, $n_1 = n_2$. The two sets, in such a case, are said to be equivalent. The concept of equivalent sets is basic to the foundations of modern mathematics and has been introduced into primary education, notably as part of the "new math" that has been alternately acclaimed and decried since it appeared in the 1960s. The theory of sets is discussed in the article SET THEORY.

Equivalent sets

Taking the two sets S_1 and S_2 together to form a new set S_3, it is clear that S_3 contains $n_1 + n_2 = n_3$ objects. The number n_3 is called the sum of n_1, n_2; and each of the latter is called a summand. The operation of forming the sum is called addition, the symbol + being read as "plus."

From the definition of counting it is evident that two fundamental laws hold for the operation of addition (see Box, laws 1 and 2), in which the order of the summands can be changed and the order of the operation of addition can be changed, when applied to three summands, without affecting the sum. These are called the laws of

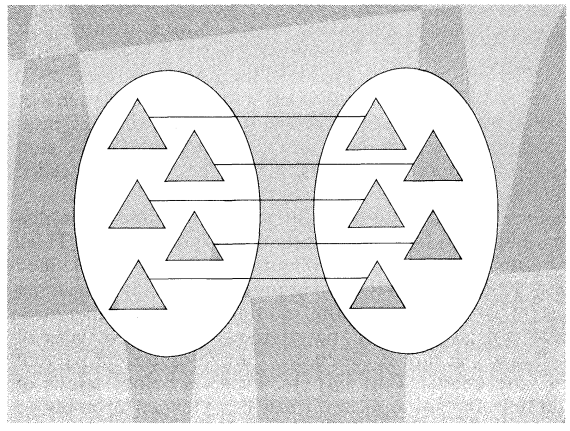

Figure 1: Page from a first grade workbook typical of "new math" might state: "Draw connecting lines from triangles in the first set to triangles in the second set. Are the two sets equivalent in number?"

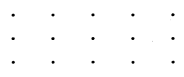
commutativity and associativity for addition. To dispel any notion that these laws are trivially self-evident, it is notable that the first of these, for example, does not hold for the addition of ordinary (finite) rotations. If a closed book that is thin in comparison with its page size is lying flat on a table in an orientation ready to be read, and if a denotes a rotation of the book through 90° about a horizontal axis fixed at the upper edge of the book, and b denotes a similar subsequent rotation about a vertical axis, then adding the rotations $a + b$, in this order, will readily be found to lead to a final position of the book in which the latter is vertical, upside-down, and with the "thin" dimension facing the reader. Performing the sum $b + a$, on the other hand, will cause the book's thin dimension to rest on the table, the front cover facing toward (or away from) the reader. Hence, in this case, $a + b$ is clearly not equal to $b + a$.

ymbols > nd <

If there exists a natural number k such that $a = b + k$, it is said that a is greater than b (written $a > b$), and that b is less than a (written $b < a$). If a and b are any two natural numbers, then it is the case that either $a = b$ or $a > b$ or $a < b$.

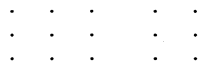
From the above laws it is evident that a repeated sum such as $5 + 5 + 5$ is independent of the way in which the summands are grouped and is written 3×5. Thus, a second binary operation called multiplication is defined. The number 5 is called the multiplicand, the number 3, which denotes the number of summands, is called the multiplier, and the result 3×5 is called the product. The symbol $\times$ of this operation is read "times." If such letters as a and b are used to denote the numbers, the product $a \times b$ is often written $a \cdot b$ or simply ab.

If three rows of five dots each are written, as illustrated below,



It is clear that the total number of dots in the array is 3×5, or 15. This same number of dots can evidently be written in five rows of three dots each, whence $5 \times 3 = 15$. The argument is general, leading to the law (see 3) that the order of the multiplicands does not affect the product, called the commutative law of multiplication. Here again, it is notable that this law does not apply to all mathematical entities. Indeed, much of the mathematical formulation of modern physics, for example, depends crucially on the fact that some entities do not commute.

By the use of a three-dimensional array of dots, it becomes evident that the order of multiplication when applied to three numbers does not affect the product (see 4). Such a law is called the associative law of multiplication. If the 15 dots written above have separated into two sets, namely,



then the first set consists of three columns of three dots each, or 3×3 dots; the second set consists of two columns of three dots each, or 2×3 dots; the sum $(3 \times 3) + (2 \times 3)$ consists of $3 + 2 = 5$ columns of three dots each, or $(3 + 2) \times 3$ dots. In general, one may prove that the multiplication of a sum by a number is the same as the sum of two appropriate products. Such a law (see 5) is called the distributive law.

Subtraction has not been introduced for the simple reason that it can be defined as the inverse of addition. Thus, the difference $a - b$ of two numbers a and b is defined as a solution x of the equation $b + x = a$. If a number system is restricted to the natural numbers, differences need not always exist, but if they do, the five laws of arithmetic, as already discussed, can be used to prove that they are unique. Furthermore, the laws of operations of addition and multiplication can be extended to apply to differences. The natural numbers (including zero) can be extended to include the solution of $1 + x = 0$, that is, the number -1, as well as all products of the form $-1 \times n$, in which n is a natural number. The extended collection of numbers is called the integers, of which the positive integers are the same as the natural numbers (excluding zero). The numbers that are newly introduced in this way are called negative integers.

(1) The commutative law of addition: $a + b = b + a$

(2) The associative law of addition: $a + (b + c) = (a + b) + c$

(3) The commutative law of multiplication: $ab = ba$

(4) The associative law of multiplication: $a(bc) = (ab)c$

(5) The distributive law: $(a + b)c = ac + bc$

(6) $a^m a^n = a^{m+n}$

(7) $(a^m)^n = a^{mn}$

(8) $a^m b^m = (ab)^m$

(9) $a^m \div a^n = a^{m-n} \quad m > n$

Just as a repeated sum $a + a + \cdots + a$ of k summands is written ka, so a repeated product $a \times a \times \cdots \times a$ of k factors is written a^k. The number k is called the exponent, and a the base of the power a^k.

The fundamental laws (see 6–8) of exponents follow easily from the definitions, and other laws (see 9) are immediate consequences of the fundamental ones. The first five laws are often called the five fundamental laws of arithmetic.

THEORY OF DIVISORS

At this point an interesting development occurs, for, so long as only additions and/or multiplications are performed with integers, the resulting numbers are invariably themselves integers; that is, numbers of the same kind as their antecedents. This characteristic changes drastically, however, as soon as division is introduced. Performing division leads to results, called quotients or fractions, which surprisingly include numbers of a new kind, namely, rationals that are not integers. These, though arising from the combination of integers, patently constitute a distinct extension of the natural-number and integer concepts as defined above. By means of the application of the division operation, the domain of the natural numbers becomes extended and enriched immeasurably beyond the integers (see below *Rational numbers*).

Extension of classes of numbers

The preceding illustrates, simply but clearly, one of the proclivities that are often associated with mathematical thought: relatively simple concepts (such as integers), initially based on very concrete operations (for example, counting), are found to be capable of assuming novel meanings, and potential uses, extending far beyond the limits of the concept as originally defined. A similar extension of basic concepts, with even more powerful results, will be found with the introduction of irrationals (see below *Irrational numbers*).

A second example of this is presented by the following: Under the primitive definition, with k equal to either zero or a fraction, a^k would, at first sight, appear to be utterly devoid of meaning. Clarification is needed before writing a repeated product of either zero factors or a fractional number of factors. Yet, limiting attention to the case $k = 0$ here (k = fraction will be considered below), a little reflection shows that a^0 can, in fact, assume a perfectly precise meaning, coupled with an additional and quite extraordinary property. Since the result of dividing any (nonzero) number by itself is unity, it follows that $a^m \div a^m = a^{m-m} = a^0 = 1$. Not only can the definition of a^k be extended to include the case $k = 0$, but the ensuing result also possesses the noteworthy property that it is independent of the particular (nonzero) value of the base a. A similar argument may be given to show that a^k is a meaningful expression even when k is negative,

namely, $a^{-k} = 1/a^k$. The original concept of exponent is thus broadened to a great extent.

Fundamental theory. If three positive integers a, b, and c are in the relation $ab = c$, it is said that a and b are divisors or factors of c, or that a divides c (written $a \mid c$), and b divides c. The number c is said to be a multiple of a and a multiple of b.

The number 1 is called the unit, and it is clear that 1 is a divisor of every positive integer. If c can be expressed as a product ab in which a and b are positive integers each greater than 1, then c is called composite. A positive integer neither 1 nor composite is called a prime. Thus, 2, 3, 5, 7, 11, 13, 17, 19, $\cdots$ are prime numbers. Euclid proved that the number of prime numbers is infinite (*Elements,* book IX, proposition 20).

The fundamental theorem of arithmetic was proved by Gauss in his *Disquisitiones Arithmeticae.* It states that every composite number can be expressed as a product of prime numbers and that, save for the order in which the factors are written, this representation is unique. This theorem follows rather directly from a theorem of Euclid (*Elements,* book VII, proposition 30) to the effect that if a prime divides a product, it divides one of its factors, and the fundamental theorem is therefore sometimes credited to Euclid.

Gauss's contribution

For every finite set $a_1, a_2, \cdots, a^k$ of positive integers, there exists a largest integer d that divides each of these numbers, called their greatest common divisor (GCD). If $d = 1$, the numbers are said to be relatively prime. There also exists a smallest positive integer m that is a multiple of each of the numbers. This is called their least common multiple (LCM).

If $p_1, p_2, \cdots, p_h$ are the distinct primes that divide all of the numbers $a_1, a_2, \cdots, a_k$, and if e_i is the smallest exponent to which p_i occurs in any of them, then (see 10) the product of the powers formed with typical number p_i as base and e_i as exponent is the GCD of $a_1, a_2, \cdots, a_k$. If $p_1, p_2, \cdots, p_i$ are the distinct primes that divide any one or more of the numbers $a_1, a_2, \cdots, a_k$, and if n_i is the largest exponent to which p_i occurs in any of them, then (see 11) the product of the powers formed with typical number p_i as base and n_i as exponent is the LCM of $a_1, a_2, \cdots, a_k$. An example (see 12) is easily constructed. When only two numbers are involved, the GCD and the LCM combine to give the same product as the product of the original numbers.

If a and b are two positive integers, $a > b$, by means of the division algorithm two integers q and r can be determined such that (see 13) a is the sum of q numbers of magnitude b plus a number r that is less than b.

The number q is called the partial quotient (the quotient if $r = 0$), and r is called the remainder. The GCD of a and b is equal to the GCD of b and r. If the division algorithm is applied successively, a remainder 0 must ultimately appear. The last positive remainder is the GCD of a and b. Thus, if $a = 544$, $b = 119$, a simple calculation (see 14) shows that the GCD of 544 and 119 is 17. This process is known as the Euclidean algorithm. By means of it, the GCD can be obtained without first factoring the numbers a and b into prime factors.

(10) $$d = p_1^{e_1} p_2^{e_2} \cdots p_h^{e_h}$$

(11) $$m = p_1^{n_1} p_2^{n_2} \cdots p_t^{n_t}$$

(12) $$a_1 = 2^3 3^1 5^3 7^4 \qquad a_2 = 2^1 3^3 7^3 (11)^2$$
$$d = 2^1 3^1 7^3 \qquad m = 2^3 3^3 5^3 7^4 (11)^2$$

(13) $$a = bq + r \qquad 0 \leq r < b$$

(14) $$544 = 4(119) + 68 \qquad 119 = 1(68) + 51$$
$$68 = 1(51) + 17 \qquad 51 = 3(17)$$

(15) $$\frac{a}{d} = \frac{ka}{kd}$$

(16) $$\frac{a}{d} = \frac{ka}{kd} = \frac{ka}{m}, \qquad \frac{b}{e} = \frac{lb}{le} = \frac{lb}{m}$$

(17) $$\frac{a}{d} \pm \frac{b}{e} = \frac{ka}{m} \pm \frac{lb}{m} = \frac{ka \pm lb}{m}$$

Rational numbers. From a less abstract point of view, the notion of division, or fraction, may also be considered to arise as follows: if the time duration of a given process is required to be known to an accuracy of better than 1 hour, the number of minutes may be specified; or, if the hour is to be retained as the fundamental unit, each minute may be represented by $\frac{1}{60}$, or by $^1/_{60}$.

In general, the fractional unit $1/d$ is defined by the property $d \times (1/d) = 1$. The number $a \times (1/d)$ is written a/d and is called a common fraction. It may be considered as the quotient of a divided by d. The number d is called the denominator (it determines the fractional unit or denomination), and a is called the numerator (it enumerates the number of fractional units that are taken). The numerator and denominator together are called the terms of the fraction. A positive fraction a/d is said to be proper if $a < d$; otherwise it is improper.

Common fraction

The numerator and denominator of a fraction are not unique, since for every positive integer k, the numerator and denominator of a fraction can each simultaneously be multiplied by the integer k without altering the fractional value (see 15). Thus, every fraction can be written as the quotient of two relatively prime integers. In this form it is said to be in lowest terms.

The integers and fractions constitute what are called the rational numbers. The five fundamental laws stated earlier with regard to the positive integers can be generalized to apply to all rational numbers.

Adding and subtracting fractions. From the definition of fraction it follows that the sum (or difference) of two fractions having the same denominator is another fraction with this denominator, the numerator of which is the sum (or difference) of the numerators of the given fractions. Two fractions having different denominators may be added or subtracted by first reducing them to fractions with the same denominator. Thus, to add a/d and b/e the LCM m of d and e, often called the least common denominator of the fractions, is determined. It follows that there exist numbers k and l such that $m = kd = le$, and both fractions can be written (see 16) with common denominator m, so that their sum or difference (see 17) is obtained by the simple operation of adding or subtracting the numerators only.

Multiplying and dividing fractions. The product of two fractions (see 18) is a fraction the numerator of which is the product of the numerators of the factors, and the denominator of which is the product of the denominators of the factors. The quotient of two fractions (see 19) is equal to the product of the dividend by the divisor inverted; that is, the divisor with its terms interchanged.

Theory of rationals. A method of introducing the positive rational numbers that is free from intuition (that is, with all logical steps included) was given by a German mathematician, Ernst Steinitz, in 1910. In considering the set of all number pairs $(a, d), (b, e), \cdots$ in which $a, b, d, e, \cdots$ are positive integers, the equals relation $(a, d) = (b, e)$ is defined to mean that $ae = bd$, and the two operations + and × are defined so that the sum of a pair (see 20) is a pair and the product of a pair (see 21) is a pair. It can be proved that, if these sums and products are properly specified, the fundamental laws (see 1–5) hold for these pairs, and that the pairs of the type $(a, 1)$ are abstractly identical with the positive integers a. Moreover, $d \times (a, d) = a$, so that the pair (a, d) is abstractly identical with the fraction a/d.

Irrational numbers. It was known to the Pythagoreans that, given a straight line segment a and a unit segment u, it is not always possible to find a fractional unit such that both a and u are multiples of it. Thus, the hypotenuse of an isosceles right triangle the sides of which are taken as the unit u must by the Pythagorean theorem have a

(18) $\frac{a}{d}\times\frac{b}{e}=\frac{ab}{de}$

(19) $\frac{a}{d}\div\frac{b}{e}=\frac{a}{d}\times\frac{e}{b}=\frac{ae}{db}$

(20) $(a, d)+(b, e)=(ae+bd, de)$

(21) $(a, d)\times(b, e)=(ab, de)$

(22) $a<\alpha<b \qquad a-b<\epsilon$

(23) $\sqrt[3]{(\sqrt{2}+\sqrt[5]{3})/\sqrt{5}}$

(24) $\sqrt[3]{\frac{125}{18}}=\sqrt[3]{\frac{125(12)}{18(12)}}=\sqrt[3]{\frac{5^3(12)}{6^3}}=\frac{5}{6}\sqrt[3]{12}$

(25) $\sqrt[n]{a}(\sqrt[n]{b})=\sqrt[n]{ab}$

(26) $\sqrt[n]{\sqrt[m]{a}}=\sqrt[mn]{a}$

(27) $(\sqrt[m]{a})^k=\sqrt[m]{a^k}$

(28) $\sqrt[mn]{a^{kn}}=\sqrt[m]{a^k}$

(29) $\sqrt[n]{\frac{a}{b}}=\frac{\sqrt[n]{a}}{\sqrt[n]{b}}$

(30) $a^0=1 \qquad a^{-n}=\frac{1}{a^n} \qquad a^{p/q}=\sqrt[q]{a^p} \qquad a\neq 0$

(31) $\sqrt[n]{a}(\sqrt[n]{b})=a^{1/n}b^{1/n}=(ab)^{1/n}=\sqrt[n]{ab}$

(32) $\sqrt[m]{a^k}=a^{k/m}=a^{kn/mn}=\sqrt[mn]{a^{kn}}$

length the square of which is 2. But there exists no rational number the square of which is 2.

Eudoxus' contribution

Eudoxus of Cnidus, a contemporary of Plato, established the technique necessary to extend numbers beyond the rationals. His contribution, one of the most important in the history of mathematics, was included in Euclid's *Elements,* Book V and elsewhere, and then lay dormant until the modern period of growth in mathematical analysis in Germany in the 19th century.

It is customary to assume on an intuitive basis that, corresponding to every line segment and every unit length, there exists a number (called a positive real number) that represents the length of the line segment. Not all such numbers are rational, but every one can be approximated arbitrarily closely by a rational number. That is, if α is real and ϵ is any positive rational number no matter how small, it is possible to find two positive rational numbers a and b within ϵ distance from each other such that (see 22) α is between them. In problems in mensuration, irrational numbers are usually replaced by suitable rational approximations.

A rigorous development of the irrational numbers is beyond the scope of arithmetic. They are most satisfactorily introduced by means of Dedekind cuts, as introduced by the German mathematician Richard Dedekind, or sequences of rationals, as introduced by Eudoxus and developed by the German mathematician Georg Cantor. These methods are discussed in the theory of functions of a real variable (see ANALYSIS: *Real analysis*).

The employment of irrational numbers greatly increases the scope and usefulness of arithmetic. For instance, if n is any whole number and a is any positive real number, there exists a unique positive real number $\sqrt[n]{a}$ called the nth root of a, whose nth power is a. The root symbol $\sqrt{\ }$ is a conventionalized r for radix, or root. The term evolution is sometimes applied to the process of finding a rational approximation to an nth root.

The symbol $\sqrt{\ }$

Surds. A number (see 23) that is obtainable from rational numbers by a finite number of additions, multiplications, divisions, and root extractions is called a surd. An irrational number of the form $\sqrt[n]{a}$ in which a is rational is called a pure surd of index n. For $n=2$, it is called a quadratic surd or square root and is written simply $\sqrt{a}$. A surd that is not pure is called mixed.

A pure surd of index n may be reduced to a rational multiple of the nth root of a positive integer no prime factor of which occurs to an exponent as high as n. Such a surd is in lowest terms. Thus consider $\sqrt[3]{125/18}$. Since $18=2(3^2)$, it becomes a perfect cube upon multiplication by $2^2(3)=12$. Then (see 24) the cube root of 125/18 can be expressed as a rational multiple of the cube root of 12.

Two surds that can be written as rational multiples of the same surd are called similar. Their sum is similar to each of them, its rational coefficient being the sum of the rational coefficients of the summands.

Properties of surds. The elementary properties of surds are readily provable (see 25–29) and guide one in calculating products of roots (see 25), roots of roots (see 26), powers of roots (see 27), roots of powers (see 28), and roots of fractions (see 29).

The theory of surds can be much simplified by the introduction of negative and fractional exponents, in which (see 30) the zeroth power of a number is unity, the negative power of a number is the reciprocal of the number, and a fractional power is expressed as a surd.

It can readily be shown that the fundamental laws of exponents, together with the properties of the rational fractions, are equivalent to the elementary properties (see 25–28) of surds. Exemplary verification (see 31, 32) is not difficult.

Complex numbers. Early mathematicians were led to consider purely formal situations involving square roots of negative numbers.

Thus, Heron of Alexandria (*c.* AD 100) obtained the quantity $\sqrt{-63}$, and Girolamo Cardan (1545) wrote $40=(5+\sqrt{-15})(5-\sqrt{-15})$. These numbers were considered to be quite meaningless, and the term imaginary was applied to them. They have since become indispensable in several branches of modern mathematics and have applications in mechanics and electricity.

In 1832 Gauss proposed the term complex for numbers of the form $a+bi$ where a and b are real and i is defined as $\sqrt{-1}$. The modern development of complex numbers began with the discovery of a geometric interpretation for them. This was indistinctly set forth by John Wallis (1685) and in completely satisfactory form by Caspar Wessel (1799).

Wessel's work received no attention, and the geometric interpretation was rediscovered by Jean Robert Argand (1806) and again by Gauss (1831). It is frequently called the Argand diagram (Figure 2).

Argand diagram

Just as the real numbers represent points on a line, the complex numbers can be put into correspondence with the points on a plane. The multiples of i are called purely imaginary numbers and are plotted as points on the imaginary axis perpendicular to the axis of reals at the O-point. Then the number $a+bi$ corresponds to the point P where

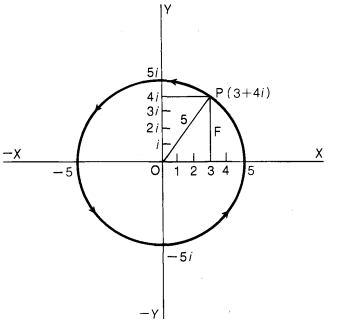


Figure 2: The complex number.

OP is the diagonal of the rectangle whose sides are a and bi. If $a + bi$ is multiplied by -1, its corresponding line or vector *OP* is rotated through 180°. Similarly, if $a + bi$ is multiplied by i, its vector is rotated through 90°. Thus, two successive multiplications by i produce the same effect as one multiplication by -1, so that in this sense $i^2 = -1$.

The first satisfactory introduction of the complex numbers was given by Sir William Rowan Hamilton in 1835, although Gauss afterward stated that the same idea had occurred to him in 1831. (C.C.MacD.)

NUMBER SYSTEMS AND NOTATION

Just as in language, where infinitely many words can be composed of but a small variety of different characters, so also in arithmetic are numbers, infinitely many of them, composed of but a small variety of numerals. The devising of a scheme whereby an infinitude of things can be represented by means of but a small number of symbols must be ranked among the most important achievements of the human intellect, for without it an advanced development of either language or arithmetic is unimaginable. The key ideas are two: the positional principle (to be described below) and the symbol zero. "The idea is so simple," wrote the 18th–19th-century mathematician Pierre-Simon, marquis de Laplace, speaking of the positional principle, "that this very simplicity is the reason for our not being sufficiently aware how much admiration it deserves." Similarly, the invention, probably by the Hindus, of the digit zero has been described as one of the greatest importance in the history of mathematics. Hindu literature gives evidence that the zero may have been known before the birth of Christ, but no inscription has been found with such a symbol before the 9th century.

Argand diagram

Applied to the construction of numbers, the positional principle operates thus: the sequence of digits $\cdots srqp$ is defined to signify a number the magnitude of which is a sum of products involving powers of a number a (see 33), in which a is called the base or radix; that is, the position of each of the coefficients $p, q, r, s, \cdots$ is associated, in reverse order to the representation $srqp$, with the zeroth, first, second, third, $\cdots$ powers of the base a. The number of distinct numerals required in this notation is readily seen to be a.

$$(33) \qquad p \times a^0 + q \times a^1 + r \times a^2 + s \times a^3 + \cdots$$

$$(34) \qquad p \times 1 + q \times 10 + r \times 100 + s \times 1000 + \cdots$$

Each numeral, when part of a number, can therefore be said to have two values: an intrinsic value, which is simply that signified by the isolated symbol itself; and a local value, which is that possessed by virtue of its position, or location, within the sequence of digits used to express the given number.

Systems are called binary, ternary, quaternary, quinary, senary, septenary, octenary (or octal), nonary, denary (or decimal), undenary, duodenary, hexadecimal, vigesimal, and sexagesimal, corresponding to values of $a = 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 16, 20$, and 60, respectively. The pair system, in which the counting goes "one, two, two and one, two twos, two and two and one," etc., is found among the ethnologically oldest tribes of Australia, in many Papuan languages of Torres Strait and the adjacent coast of New Guinea, among some African Pygmies, and in various South American tribes. Other tribes of Tierra del Fuego and the South American continent use number systems with bases three and four. The quinary scale, or number system with base five, is very old but in pure form seems to be used at present only by speakers of Saraveca, a South American Arawakan language; elsewhere it is combined with the decimal or the vigesimal system, where the base is 20. Similarly, the pure base six scale seems to occur only sparsely in Northwest Africa and is otherwise combined with the duodecimal, or base 12, system.

In the course of history the decimal system finally overshadowed all others, and it is now found in all nations of high culture on the entire globe, except those of Mexico and Central America, where the number 20 was used in astronomy and thus became firmly entrenched. Nevertheless, there are still many vestiges of other systems in nations of high culture, chiefly in commercial and domestic units, where change always meets the resistance of tradition. Thus, 12 occurs as the number of inches in a foot, pence in a shilling, months in a year, ounces in a pound (troy or apothecaries'), and twice 12 hours in a day; and both dozen and gross measure by 12s. In English the base 20 occurs chiefly in the score ("Four score and seven years ago . . . "); in French it survives in the word *quatre-vingts* ("four twenties") for 80; other traces are found in pre-English Celtic, Gaelic, Danish, and Welsh.

The number zero

The Babylonians developed (2000–3000 BC) a positional system with base 60—a sexagesimal system. With such a large base it would be awkward to have unrelated names for the digits 0, 1, $\cdots$, 59, so a simple grouping system to base 10 was used for these numbers. For example, the number 258,458 is written in Figure 3 as it would have appeared in Babylon. The base 60 still occurs in measurement of time and angles.

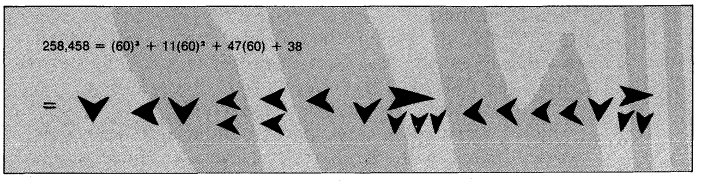

Figure 3: The number 258,458 expressed in the sexagesimal system of the Babylonians and in cuneiform.

In addition to being somewhat cumbersome because of the large base chosen, the Babylonian system suffered until very late from the lack of a zero symbol; the resulting ambiguities may well have bothered the Babylonians as much as later translators.

In the course of early Spanish expeditions into Yucatán it was discovered that the Mayans, at an early but still undated time, had a well-developed positional system, complete with zero. It seems to have been used primarily for the calendar rather than for commercial or other computation; this is reflected in the fact that although the base is 20, the third digit from the end does not signify multiples of 20^2 but of 18×20, thus giving their year a simple number of days. The digits 0, 1, $\cdots$, 19 are, as in the Babylonian, formed by a simple grouping system, in this case to base 5; the groups were written vertically, as in Figure 4.

The earliest numerals of which there is definite record were simple straight marks for the small numbers, with some special form for 10. These symbols appear in Egypt

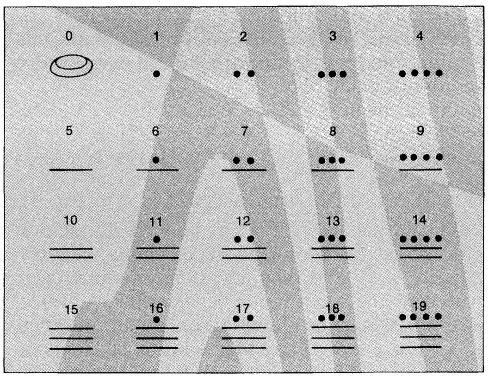

Figure 4: The Mayan vigesimal number system (see text).

as early as *c.* 3400 BC and in Mesopotamia as early as *c.* 3000 BC. These dates long precede the first known inscriptions containing numerals in India (*c.* 300 BC), in China (3rd century BC), and in Crete (*c.* 1200 BC). Some ancient symbols for 1 and 10 are given in Figure 5. This special

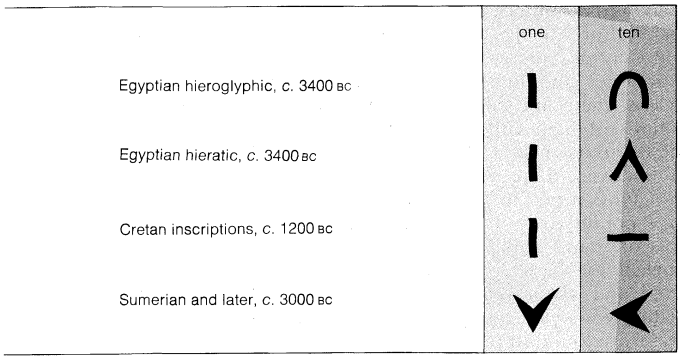

Figure 5: Some ancient symbols for 1 and 10.

position occupied by 10 stems from the number of human fingers, of course, and is still evident in modern usage not only in the logical structure of the decimal system but in the English names for the numbers. Thus, eleven comes from Old English *endleofan*, literally meaning "[ten and] one left [over]," and twelve from *twelf*, meaning "two left"; the endings -teen and -ty both refer to 10, of course, and hundred comes originally from a pre-Greek term meaning "ten times [ten]."

In the decimal system the above number $\cdots srqp$ has a value expressed as a sum of products involving powers of 10 (see 34). The ten numerals 1, 2, $\cdots$ 8, 9, 0 are the only distinct symbols needed here. (These symbols, which originated in large part in India and were widely disseminated by the Arabs, are in several instances stylized forms of the initial characters of the words employed to denote the appropriate numbers. They are called Hindu-Arabic numerals.) This notation is capable of being expanded to include the representation of fractional parts of numbers by means of placing a point (decimal point when $a = 10$) immediately to the right of the coefficient associated with a^0. Thus, $0.uvw \cdots$ represents the sum of products, each term of which includes a negative power of a (see 35).

With the advent of electronic high-speed computers, the choice $a = 2$ and, hence, binary arithmetic have become of great practical importance, though, as has been mentioned above, the binary (or pair) system has been used in tribal, nontechnical cultures. The fundamental reason for the new importance is the basic mode of operation of computing machines, in which an electric current pulse, or the direction of magnetization of an element, has one of two values. The numerals used in the binary system are 1 and 0. As an example, the magnitude of the number $N_2 = 100111$ to the base 2 (indicated by the subscript on N) is $1\times2^0+1\times2^1+1\times2^2+0\times2^3+0\times2^4+1\times2^5$, which in decimal notation becomes $N_{10}=1+2+4+0+0+32=39$. It is apparent that the binary system's use of only two distinct symbols is partly offset by the requirement of many more digits (6 in N_2, as compared with only 2 in N_{10} in the above example). Octal and hexadecimal modes also find frequent application in electronic computing devices.

Binary numbers

In octal notation the above $N_{10} = 39$ is readily seen to become $N_8 = 47$ because $7\times8^0+4\times8^1=7\times1+32=39$ (in decimal notation). (D.E.S./W.J.LeV.)

ARITHMETIC CALCULATION WITH DECIMALS

Addition and subtraction. Numbers in decimal notation can easily be added by adding the coefficients of corresponding powers of 10 and then adjusting, by the process known as carrying, the coefficients that exceed 9. A typical example (see 36) would be the addition of the numbers 47.65, 5.473, and 649.8. One first adds coefficients of equal powers of 10; *e.g.*, one adds 5 and 7 to obtain 12 as a coefficient of 10^{-2}. After adjustment of the coefficients (see 37), this sum becomes 702.923.

The process of addition is commonly carried out as follows (see 38): Beginning at the right, the sum of the coefficients of 10^{-3}, which is 3, is written below the answer line; the sum of the coefficients of 10^{-2} is 12, the digit 2 being placed to the left of the 3 in the sum; however, the 10 becomes a 1 in the preceding position and may be placed at the top of the column of coefficients of 10^{-1}, etc. In practice the carrying is usually performed mentally.

Subtraction is performed by reversing the above procedure. Thus, to subtract 170.8 from 563.142 (see 39), for example, the smaller number is placed under the larger, with the respective decimal points aligned vertically. Again, starting from the right, since $0.8 = 0.800$, 0 subtracted from 2 leaves 2 (which is written below the line), and 0 from 4 leaves 4; but since 8 exceeds 1, a unit is borrowed from the unit's place (which changes the 3 to 2), and thus the 1 in the tenth's place becomes 11; then 8 subtracted from 11 leaves 3, 0 from 2 leaves 2, and so forth.

Another way of performing subtractions consists in finding the number, digit by digit, that, when added to the second, yields the first as sum.

Multiplication. Multiplication of decimal numbers is based upon the distributive law. Thus, the multiplication (see 40) of 25.78 by 7 is accomplished as a sum of four products, each involving 7 as a factor.

By a process known as short multiplication, this may be carried out as follows (see 41): Since $7\times8=56$, the 6 is written below the answer line, starting at the right, and the 5 is placed above the 7 in the multiplicand; then $7\times7=49$, to which is added the 5 that was carried,

(35) $N=0+u\times a^{-1}+v\times a^{-2}+w\times a^{-3}+\cdots$

(36)
$$\begin{array}{r} 47.65 \\ 5.473 \\ \underline{649.8} \\ \end{array}$$

Sum calculated as follows:

$$\begin{array}{r} 4(10)+\ 7+\ 6(10^{-1})+\ 5(10^{-2}) \\ 5+\ 4(10^{-1})+\ 7(10^{-2})+3(10^{-3}) \\ 6(10^2)+4(10)+\ 9+\ 8(10^{-1}) \\ \hline 6(10^2)+8(10)+21+18(10^{-1})+12(10^{-2})+3(10^{-3}) \end{array}$$

(37) $7(10^2)+0(10)+2+9(10^{-1})+$
$+2(10^{-2})+3(10^{-3})=702.923$

(38)
$$\begin{array}{r} \underline{121\ 1} \\ 47.65 \\ 5.473 \\ \underline{649.8} \\ 702.923 \end{array}$$

(39)
$$\begin{array}{r} 563.142 \\ \underline{-\ 170.8} \\ 392.342 \end{array}$$

(40) $25.78\times7=20\times7+5\times7+.7\times7+.08\times7$
$=140+35+4.9+.56=180.46$

(41)
$$\begin{array}{r} \underline{45\ 5} \\ 25.78 \\ \underline{\quad\ 7} \\ 180.46 \end{array}$$

(42)
$$\begin{array}{r} 25.78 \\ \underline{\quad 45.7} \\ 18\ 046 \\ 128\ 90 \\ \underline{1\ 031\ 2} \\ 1\ 178.146 \end{array}$$

making 54; the 4 is written in the answer, the 5 being carried as before. The numbers written above the top line are usually carried mentally.

If the multiplier has more than one digit, long multiplication is used (see 42). This process also is based upon the distributive law. The first partial product is 18.046, which was obtained by multiplying 25.78 by .7 by short multiplication. The second partial product is $25.78 \times 5 = 128.90$; the third is $25.78 \times 40 = 1{,}031.2$. The product is the sum of these partial products. It is customary to ignore the decimal point in these partial products but to indent each partial product one more place than the partial product above it. In the product as many digits are pointed off from the right as the sum of the number of digits to the right of the decimal point in the multiplicand and the number of digits to the right of the decimal point in the multiplier.

(43)
$$\begin{array}{r} 4\,615 \\ 7\overline{)53\,149} \\ 7\,592 \end{array}$$

Division. If a and b are two whole numbers, $a > b$, there exist two whole numbers q and r such that (see 13) a is written as a sum of two terms, one involving q and one involving r. The process of finding these numbers can be carried out by the processes called long and short division.

If $b < 10$, say $b = 7$, short division may be used (see 43). Then, if $a = 53{,}149$, starting at the left, since $5 < 7$ and considering the first two digits, 53, the largest multiple of 7 that is less than or equal to 53 is $49 = 7 \times 7$. The 7 is written below the 3, and the remainder, $53 - 49 = 4$, above the 3. This remainder with the next digit in the dividend is 41; the largest multiple of $7 \leq 41$ is $35 = 7 \times 5$. The 5 is written below the 1, and the remainder, $41 - 35 = 6$, above the 1. The last remainder is 5. Usually the remainders are carried mentally.

It is notable that this process involves guessing the largest multiple of the divisor that is less than a certain number, but only a few guesses are ever required and no practical difficulty is encountered.

Because $53{,}149 = 7{,}592 \times 7 + 5$, one may write (see 44) the ratio of 53,149 and 7 so that 7,592 is the partial quotient and 5 is the remainder.

If the divisor exceeds 10, long division is preferable (see 45). To divide 83,742 by 621, the 1 is written as the first digit of the quotient and 621×1 is subtracted from 837 since the largest multiple of $621 \leq 837$ is 621×1. Actually what is done is to subtract 621×100 from 83,742, leaving a remainder of 21,642. Since only the 2,164 will be used in the next step, the final 2 of the dividend need not be brought down yet. The largest multiple of $621 \leq 2{,}164$ is $621 \times 3 = 1{,}863$, and the remainder is 301. Now the final 2 must be brought down to make 3,012. The largest multiple of $621 \leq 3{,}012$ is $621 \times 4 = 2{,}484$, and the remainder is 528. Binary numbers

Thus, the dividend (see 46) is the sum of a product and a remainder.

The preceding method may be considerably abbreviated by mentally subtracting the partial product as it is formed (see 47). Again, the resultant quotient may be expressed as the sum of an integer and a proper fraction (see 48). If it is desired to express the result as a decimal fraction, carried to a given number of decimal places, the above process is merely continued (see 49). Any two decimal numbers may be divided in this manner. The number of digits to the right of the decimal point in the quotient is equal to the number of such digits in the dividend, diminished by the number of such digits in the divisor, with care being taken to add to the dividend all the 0's that are brought down. Thus, in the present example (49) the proper fraction (see 50) is replaced by a decimal fraction. An alternative and exceptionally clear and simple method for determining the position of the decimal point in the quotient is (see 51) to divide both numerator and denominator by an appropriate power of 10; *i.e.*, expressing the divisor as a number lying between 0 and 10, which renders it obvious that the quotient lies between 100 and 1,000.

Divisibility rules. In both theoretical and practical arithmetic, it is often important to factor a natural number; *i.e.*, to decompose it into numbers that, when multiplied together, will yield the given number as product.

The following tests for divisibility are therefore given. A composite number is divisible

- by 2 if it is even (*i.e.*, if it ends in 0, 2, 4, 6, or 8);
- by 3 if the sum of its digits is divisible by 3;
- by 4 if the number formed by its last two digits is divisible by 4;
- by 5 if it ends in 0 or 5;
- by 6 if it is even and the sum of its digits is divisible by 3;
- by 8 if the number formed by its last 3 digits is divisible by 8
- by 9 if the sum of its digits is divisible by 9;
- by 10 if it ends with 0;
- by 11 if the difference between the sum of its digits in the odd places and that of the digits in the even places is either 0 or divisible by 11.

Similar rules are easily devised with respect to other divisors by means of appropriate combinations of the rules given above. For example, if a number is to be divisible by 132, say, then it must satisfy the test for divisibility by factors of 132—that is, by 3, by 4, and by 11, respectively; *i.e.*, $3 \times 4 \times 11 = 132$.

(53) $(a+b)^3 - a^3 = (3a^2 + 3ab + b^2)b$

Evolution. An algorithm for the determination of the square root of a decimal number, such as 1,578.42, is carried out as follows (see 52): Starting at the decimal point, the number is separated into periods of two digits each. The leftmost period is 15, and the largest square ≤ 15 is $9 = 3^2$. The 3 is written at the right and the remainder $15 - 9 = 6$ is brought down. The next period 78 is brought down beside the 6, giving 678. The 3 is doubled and the result, 6, written at the left. By trial it is found that 9 is the largest digit, such that $69 \times 9 = 621 \leq 678$. The 9 is written after the 3 in the answer, and the difference, 57, is brought down, followed by the next period, 42. The partial answer 39 is doubled and the result, 78, written at the left under the 69. By trial it is found that $787 \times 7 = 5{,}509 \leq 5{,}742$ while $788 \times 8 > 5{,}742$. The next digit in the answer is therefore 7. The process is continued until the desired degree of accuracy is attained. In the present example (see 52) the last remainder, 7,416, exceeds half of the last trial divisor, 7,942, so that 3 is a better approximation than 2 for the last digit. In fact, $39.73^2 = 1{,}578.4729$, but $39.72^2 = 1{,}577.6784$.

The above process is based upon the relation $(a+b)^2 = a^2 + (2a+b)b$. In each step the part of the square root already obtained is a; the part remaining to be found is b. In the example (see 52), $(a+b)^2 = 1{,}578.42$, $a = 30$. Then $2ab + b^2 = 678.42$. In order to determine the largest integer n in b, one must find the largest integer n (namely 9), such that $(2a+n)n \leq 678.42$. The trial divisor is $2a + n = 69$. In the next step $a = 39$, $2ab + b^2 = 57.42$, etc.

Cube and higher roots. The cube root of a number may be calculated by a similar algorithm based upon the relation (see 53) that expresses the difference of two cubes as a product involving a quadratic as a factor. Thus, it is possible to find the approximate cube root of 279,463 by proceeding as in the example (see 54). This last remainder is too large but much closer than the remainder resulting from using 7 as the last digit.

A fourth root is obtained as the square root of the square root. Fifth and higher roots can be obtained by an algorithm similar to those just given, based upon the expansion of $(a+b)^n$ by the binomial theorem. The method is cumbersome and seldom used, for the method of logarithms is easy and rapid. The fifth root of a can also be quickly found by solving the equation $x^5 - a = 0$ by Newton's or Horner's method. (C.C.MacD.)

LOGARITHMS

Basic principles. Logarithms were invented in the early 17th century to speed up calculations, and they were basic in numerical work for more than 300 years. The perfection of the desk calculating machine in the late 19th century and the electronic computer in the 20th has made them obsolete for large-scale computation.

The operation and nature of logarithms can be seen from a table characteristic of logarithms (see 55) that identifies with the number $\frac{1}{2}$ the logarithm -1, with the number 1 the logarithm 0, with the number 2 the logarithm 1, with the number 4 the logarithm 2, and so forth. Here, the constant 2 raised to any logarithmic power gives the corresponding number. A table of this type can be used for multiplication (and division)—the logarithms of the numbers to be multiplied are selected from the table and added, and the number corresponding to the answer is the result of the multiplication. For example, two numbers are taken from the first row and multiplied together; say, $2 \times 8 = 16$. The corresponding values in the second row are 1, 3, and 4; hence, when 2 is taken to the 4th power, 16 is yielded.

The reason for this is that numbers in the first row are the number 2 to the power of the corresponding number in the second. Thus $\frac{1}{8} = 2^{-3}$, $1 = 2^0$, $8 = 2^3$. In the identity $32 = 2^5$ the number 2 is called the base. The exponent 5 is the logarithm of 32 to the base 2 and is written $5 = \log_2 32$. More generally, the two equations have the same meaning; the first serves to define the second. By this definition y is the logarithm of x to the base b if and only

(22)

$\frac{1}{8}$	$\frac{1}{4}$	$\frac{1}{2}$	1	2	4	8	16	32	64
−3	−2	−1	0	1	2	3	4	5	6

if $x = b^y$. The number x is also called the antilogarithm of y to the base b.

It is evidently easy to find logarithms of numbers that are simple powers of the base, and there are quite efficient methods for calculating logarithms of all numbers to as many decimal places as desired.

Multiplication of any numbers m and n can be accomplished by adding their logarithms; *i.e.*, the logarithm of the product is the sum of the logarithms (see 56). Division of numbers can also be accomplished by subtracting the logarithms: the logarithm of the quotient is the difference of the logarithms (see 57). This is not all; powers and roots can also be found with logarithms. For example, the cube of 4 is 64 (*i.e.*, $4^3 = 64$), and from the table the logarithms

(23) $\log_b mn = \log_b m + \log_b n$

(24) $\log_b (m/n) = \log_b m - \log_b n$

(25) $\log_b (n^p) = p \log_b n$

(26) $\log_b \sqrt[q]{n} = \frac{1}{q} \log_b n$

(27) $\log_b \sqrt{n} = \frac{1}{2} \log_b n$

(28) $\begin{cases} b^x \cdot b^y = b^{x+y} \\ b^x / b^y = b^{x-y} \\ (b^x)^p = b^{px} \end{cases}$

(29) $\begin{cases} m = b^x, & \log_b m = x \\ n = b^y, & \log_b n = y \end{cases}$

(30) $mn = b^x b^y = b^{x+y}$

(31) $\sqrt[q]{b^x} = b^{x/q}$

$$(65)\quad \begin{cases} 2 \cdot 41 \times 10 \\ \log_{10} 24 \cdot 1 = \log_{10}(2 \cdot 41 \times 10) \\ \qquad\qquad = \log_{10} 2 \cdot 41 + \log_{10} 10 \end{cases}$$

$$(66)\quad y = \log_b x$$

$$(67)\quad e = 1 + \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \cdots + \frac{1}{n!} + \cdots$$

$$(68)\quad \frac{d}{dx} \log_b x = \frac{1}{x} \log_b e$$

$$(69)\quad \frac{d}{dx} \log_e x = \frac{1}{x}$$

$$(70)\quad \log_e(1 + x) = x - \frac{x^2}{2} + \frac{x^3}{3} + \cdots$$

$$(71)\quad \log_b x = \log_a x \log_b a$$

$$(72)\quad \log_{10} x = \log_e x \log_{10} e$$

of 4 and 64 are 2 and 6. Because $6 = 3 \cdot 2$, the logarithm of 4^3 can be found by multiplying the logarithm of 4 by 3. Study of the table will verify that the logarithm of a power can be found by multiplying the logarithm of the number by the index p of the power (see 58). Because logarithms transform multiplication into addition, division into subtraction, and the taking of powers into multiplication, it might be guessed that they would transform the taking of square roots into division. This is the case, for example, in computing the square root of 16, its logarithm (which is 4) is divided by 2. The result is 2, which is the logarithm of 4, as expected. In general, the logarithm of a root is the logarithm of the number divided by the index q of the root (see 59). Because $n^{1/2} = \sqrt[2]{n}$, square roots are given in the logarithmic form as one-half the logarithm of the number for which the square root is taken to be calculated (see 60). Logarithms work this way because they are exponents; and exponents are added for multiplying, subtracted for dividing, multiplied to take a power, and divided to take a root. These ideas may be expressed as laws of exponents (see 61).

The exponents in these equations can be thought of as logarithms. For example, a variable may be expressed as a power of a base (see 62), and another variable may be expressed as a power of the same base. Their product (see 63) is similarly expressible in terms of a sum. Therefore, $\log_b mn = \log_b m + \log_b n$, the relationship for the addition of logarithms (see 64).

Use of logarithms for multiplication

Common logarithms. The most convenient tables for numerical calculations are those in which the logarithms are to the base 10. These are called common logarithms. They have the advantage that a table of logarithms of numbers between one and 10 can be used to find the logarithms of all other numbers. For example, from tables, $\log_{10} 2.41$ is 0.38202 (this means that $10^{0.38202}$ is 2.41; fractional powers of 10 can be found and tabulated; see below). The logarithm of 24.1 can then be found because 24.1 is expressible as a number between two and three times 10 (see 65). Because $\log_{10} 10 = 1$, the logarithm of 24.1 is 1.38202. Thus each common logarithm has two parts, an integer and a decimal less than one. The integral part is called the characteristic and is determined by the position of the decimal point in the number. Thus the log of 241.0 is 2.38202 and its characteristic is 2; for 2.41 the characteristic is 0, for 0.241 it is -1, and for 0.00241 it is -3. The decimal part of a common logarithm is called the mantissa and is found from a table of logarithms by disregarding the position of the decimal point in the number.

When the characteristic is negative it cannot be written with the minus sign in front of the mantissa without causing confusion. For example, the log of 0.00241 has a mantissa of 0.38202 and characteristic of -3. It cannot be written -3.38202 because it is, in fact, $-3 + 0.38202$ (not $-[3 + 0.38202]$). It is customary to write it in the form $\bar{3}.8202$.

Natural logarithms. The logarithmic function, in algebra, is defined by the relationship that identifies y with the logarithm of x (see 66). The problem of finding its derivative involves the problem of finding the limit of an expression of the form $(1 + t)^{1/t}$, as t approaches infinity. This limit is an irrational number e given by the infinite series that sums the reciprocals of factorials (see 67), in which a factorial is a product of consecutive integers beginning with 1 and ending with the integer whose factorial is being taken. The number e has a value approximated by 2.71828, given here to five decimal places. This result leads to the equation that expresses the derivative of the logarithm to an arbitrary base (see 68). If logarithms to the base e are used, the equation simplifies to the form basic to calculus, expressing the derivative of the logarithm of x as the reciprocal of x (see 69).

Logarithms to the base e are sometimes called natural logarithms. They are less useful for computation than common logarithms but are used in calculation, frequently by means of the series for the logarithm of $1 + x$ (see 70): natural logarithms can be computed to any required degree of accuracy by evaluating a sufficient number of terms of the series. Common logarithms can then be obtained by a change of base using the formula that converts from one logarithmic base to another through the operation of multiplication of logarithms (see 71); this follows from the law of exponents. Thus a common logarithm of x is found by the equation that identifies it with the natural logarithm times a constant (see 72). (Ed.)

History of logarithms. The invention of logarithms was foreshadowed by the comparison of arithmetic and geometric series. In the simple table used above, the top line is a geometric series and the bottom line is an arithmetic series. The first table based on this concept was published in 1620 in Prague by Joost Bürgi. The comparison between the two series was not based on any explicit use of the exponential notation; this was a later development.

John Napier, the Scottish mathematician, published his discovery of logarithms in 1614. His purpose was to assist in the multiplication of quantities that were then called sines. The whole sine was the value of the side of a right angled triangle with a large hypotenuse, say 10^7 units long. His definition was given in terms of relative rates.

> The logarithme, therefore, of any sine is a number very neerely expressing the line which increased equally in the meene time whiles the line of the whole sine decreased proportionally into that sine, both motions being equal timed and the beginning equally shift.

In modern terminology, L is the logarithm and X the

$$(73)\quad \frac{dh}{dt} = a, \qquad \frac{dX}{dt} = -bX$$

$$(74)\quad \begin{cases} L = 0 \quad t = 0 \\ i.e.,\ L(r) = 0 \quad \dfrac{dX}{dt} = \dfrac{-aX}{r} \end{cases}$$

$$(75)\quad \begin{cases} L(x) = r(\log_e r - \log_e x) \\ L(x) = r \log_e \dfrac{r}{x} \end{cases}$$

$$(76)\quad L\left[\frac{XY}{Z}\right] = L(X) + L(Y) - L(Z)$$

$$(77)\quad \begin{cases} \log\left[\dfrac{\sin x}{x}\right] \\ \log\left[\dfrac{\tan x}{x}\right] = \log\left[\dfrac{\sin x}{x}\right] - \log \cos x \end{cases}$$

sine. (In modern notation X would be $r \sin \varphi$.) Thus, with modern techniques derivatives can be used (see 73). At $t = 0$, $X = r$ ($\varphi = 90°$), and, since the motion is "equally swift" at the beginning, $a = br$. Furthermore, the function L is known to have certain values at specific points (see 74). Thus in terms of present logarithms to the base e the function L can be expressed in terms of natural logarithms (see 75). Napier's value of r was 10^7. This expression does not have the expected property for $L(XY)$, but the relationship involving products and division (see 76) does apply.

he
ıodern
laperian
ɔgarithm

In cooperation with the English mathematician Henry Briggs, Napier did adjust his logarithms into the form in which it is usually found. For the modern Naperian logarithm (*i.e.*, the logarithm to the base e) the comparison would be between points moving on two straight lines, marked in units of length, the L point moving uniformly from minus infinity to plus infinity, the X point moving on a half line from zero to infinity at a speed proportional to the distance from zero. Furthermore, L is zero when X is one and their speed is equal at this point. The essence of Napier's discovery is that this constitutes a generalization of the relation between the arithmetic and geometric series; *i.e.*, multiplication and raising to a power of the values of the X point correspond to addition and multiplication of the values of the L point. In modern terminology, $\frac{dL}{dt} = k_0$, $\frac{dX}{dt} = k_0 X$ correspond to $\frac{dX}{dL} = X$, $X = e^L$, $L = \log_e(X)$.

From the point of view of the user it is better to limit the L and X motion by the requirement that $L = 1$ at $X = 10$ in addition to the condition that $X = 1$ at $L = 0$. This produces the common logarithms to the base 10.

These are sometimes known as Briggsian logarithms: the natural logarithms are known as Naperian logarithms.

The calculation of logarithms. The treatment above differs from that of Napier in that the word "exactly" is applicable rather than "very neerely." This obscures the ingenious procedure used for calculating the early logarithms, in which powers of numbers such as 1.00001 were used so that multiplication was minimized and replaced by addition. Thus, $X = (1.00001)^n$, $L = n/10^5$ corresponds approximately to $L = \log_e X$, or the natural logarithm. To obtain the Briggs or base 10 table, the calculation would be continued until X exceeded 10 and then the L scale adjusted so that at $X = 10$, $L = 1$.

In addition to the discrete series procedure, Napier and Briggs suggested the calculation of logarithms by extracting roots of 10; *i.e.*, $\log \sqrt{10} = 0.5$, $\log 10^{1/4} = 0.25$. This permits the n computation of the previous paragraph to be shortened, for the Briggs logarithm can be adjusted for by taking $L = 0.25$ for $X = 10^{1/4}$. Power series were not used in the initial construction of the tables. The power series for $\log(1 + x)$ and e^x were only available in the 18th century and rigorously established in the early 19th century.

Use of
ɔower
ɜeries

Logarithm tables. Napier died in 1617. Briggs published a table of logarithms to 14 places of numbers from 1 to 20,000 and from 90,000 to 100,000 in 1624. Adriaan Vlacq published a 10-place table for values from 1 to 100,000 in 1628, adding the 70,000 values. Both Briggs and Vlacq engaged in setting up log trigonometric tables. Such early tables were either to $^1/_{100}$ of a degree or to a minute of arc. In the 18th century tables were published for 10-second intervals, which were convenient for seven-place tables. In general, finer intervals are required for logarithmic functions in which the logarithm is taken of smaller numbers; for example, in the calculation of the functions $\log \sin x$ and $\log \tan x$. The related functions modified by division by x in the argument of the logarithm (see 77) are easily calculated by series for small values of x.

The availability of logarithms greatly influenced the form of plane and spherical trigonometry. Convenient formulas are ones in which the operations that depend on logarithms are done all at once. The recourse to the tables then consists of only two steps. One is obtaining logarithms, the other obtaining antilogs. The procedures of trigonometry were recast to produce such formulas. (F.J.M.)

Art Conservation and Restoration

Conservation, including maintenance and preservation (protection from damage or deterioration), and restoration have become an increasingly important aspect of the work not only of museums but also of civic authorities and all those concerned with works of art, whether artists, collectors, or gallerygoers. Technical advances of the 20th century have made possible safer methods of cleaning and repairing objects. Art restoration has become an important tool of research, and it enables the viewer to appreciate the original intention of the artist.

This article is divided into the following sections:

ARCHITECTURE

The conservation and restoration of older architecture is an increasing modern preoccupation. The earliest buildings that have survived generally tend to be those that received religious veneration. When these structures were no longer venerated, they disappeared like other buildings. Even the famed ancient Egyptian Sphinx at Giza lay for centuries under the sand, and it was not until the early 19th century that the Forum of ancient Rome was uncovered and explored.

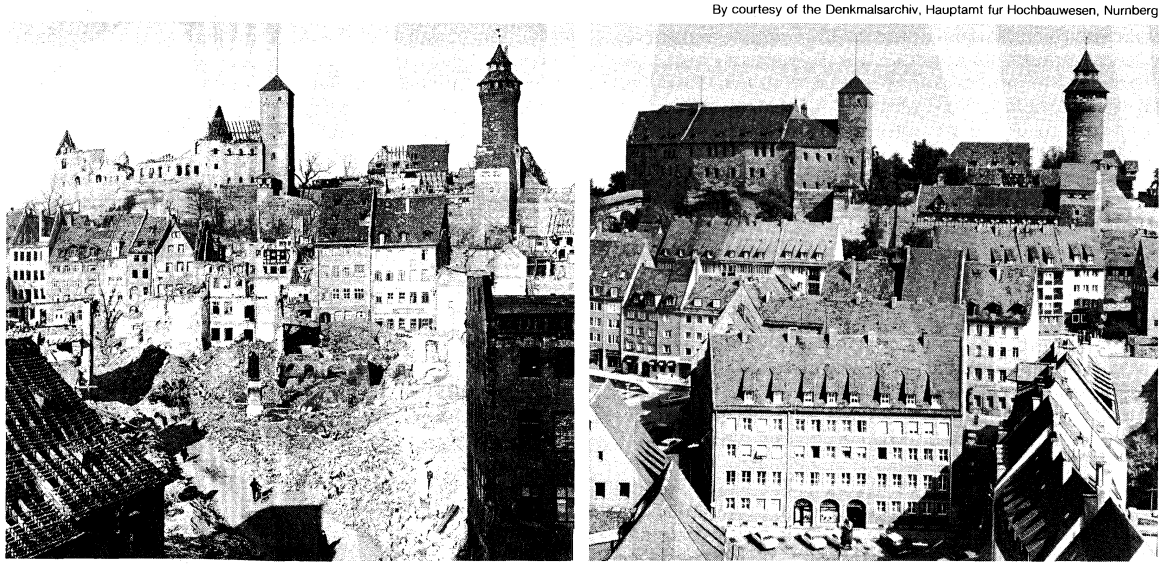
Medieval builders treated the work of their forebears with a healthy lack of awe. Every new Gothic chapel or chantry and virtually every stage in the development of a single Gothic cathedral followed the style of its own day. With the Renaissance in Europe grew a new respect for classical antiquity and a new interest in its architectural forms. By the end of the 18th century a knowledge of archaeology had become an accepted accomplishment of the educated man. Architectural design itself became a matter of "correctness." Old buildings everywhere began to be "restored" to the style of periods especially favoured. The French architect and writer E.-E. Viollet-le-Duc brilliantly restored the Sainte-Chapelle (1840–67) and the cathedral of Notre-Dame de Paris (1845–64). The ancient walls of Carcassonne in France and of Windsor Castle in England were not only repaired but also largely rebuilt.

With the spread of the Industrial Revolution and the increasing reliance on mechanical processes, the labour of hands became more costly, and the value of craftsmanship gained a new significance. Old buildings, which often exhibited the personal touches of master craftsmen, began to command a new respect, and the English art critic John Ruskin (1819–1900) was even able to assert that "the greatest glory of a building is its age." In 1877 the pioneers of the conservation movement, led by the English artist and writer William Morris (1834–96), founded the Society for the Protection of Ancient Buildings (SPAB). Nicknamed Anti-Scrape, the society vehemently opposed the indiscriminate refacing of old stonework and the "conjectural restorations" still so fashionable, such as the new west front of St. Albans Cathedral in England (1880–83). The movement gathered force, and in the 20th century groups throughout the world now devote their efforts to architectural conservation.

An added local impetus has been given by national pride; in countries like Poland, postwar reconstruction became the symbol of national resurgence. Almost every civilized country is increasingly conscious of its heritage of ancient buildings, while cultural bodies such as the United Nations Educational, Scientific and Cultural Organization have lent to the conservation movement a powerful international impetus.

Effects of economic and social change. The development of architecture can be read as a sensitive index of social change. The economic climate and social preoccupations of each age have combined to generate its own architecture and its own towns. Almost every decade of new building displays its own peculiar characteristics and modifies by constant adaptation the buildings and towns of yesterday. But the urban environment is society's investment in its future, and the cycle of renewal is continuous,

By courtesy of the Denkmalsarchiv, Hauptamt fur Hochbauwesen, Nurnberg



Albrecht Dürerplatz, Nürnberg, (left) after bombing in 1945 and (right) after reconstruction.

if often slow. Thus, the problems of building maintenance and renewal are complicated by long-term economic and social change.

Today the most marked trends are still those that brought about the conservation movement itself. First is the accelerated pace of physical growth. Old buildings have become not only relatively rarer but often virtually irreplaceable in terms of labour and craftsmanship and sometimes of materials. In many cases, old buildings give to a locality much of its special character and identity, as, for example, in those English country villages where thatched roofs still predominate. Another and rarer asset is a sheer and intrinsic merit of architectural form. And alongside all these is the tangible evidence that any old building provides for its community of a kind of social and environmental continuity—a reassuring reference point in a constantly changing world.

he factor
land
lue

Under the increasing pressure of population, the value of urban land climbs steeply, with some curious effects on old buildings. Increased demand brings increased values and, at first, better prospects of repair and maintenance. But as values rise higher, the older building must also justify itself in terms of economic efficiency. All over the world, the town houses of the 19th century and earlier serve with varied grace in the 20th century as centres of modern industry and commerce. Their fabric is subjected to new strains, and their room shapes and capacity may become incompatible with new and changed demands. There comes a point at which the old building on a valuable town site can compete no longer with redevelopment. Then it is quickly overtaken, and financial subsidy is powerless. The old building in a deteriorating neighbourhood is at the same time likely to be in no better a situation. Its maintenance may become no longer worthwhile, condemning it to early death by neglect. The destructive effects of both over- and undervalue are clearly displayed side by side in a fine Georgian city like Dublin or in once-distinguished neighbourhoods like Bloomsbury in London or the Marais in Paris. The most successful neighbourhood conservation occurs where values have been held in pace with the architectural capacity of a community, as at Bath in England, or in the Georgetown section of Washington, D.C.

he
ctor of
creased
obility

Another social change is the rapid increase in mobility. The automobile brought better roads and an incentive to use them. Old city centres, after centuries of essentially domestic life, began to be abandoned in favour of ring upon ring of suburbs. This peripheral accretion of cities is allied with their central decay as communities. As a universal result, the twice-daily thrombosis of the highways urges on a constant process of road widening, in which many an intervening historic area has been completely eroded away.

Role of the law. In all conservation of architecture, the first effective step is to decide and define what buildings or sites are worthy of protection. For most countries this has involved a systematic process of inventory and survey. In Great Britain, for example, the Royal Commission on Historical Monuments (RCHM) was set up in 1908, and the Civic Amenities Act of 1967 enabled local planning authorities to define special areas for "conservation and enhancement." In France, the Commission des Secteurs Sauvegardés was set up in 1962 under André Malraux, minister for cultural affairs, to pursue an active program for public protection of historic areas. In the United States, the Historic American Buildings Survey was designed to assemble a national archive of historic American architecture.

riteria
or con-
ervation

Criteria for conservation are rarely well defined. Architectural merit clearly must rank highly—especially in the case of any building that authentically exemplifies its period. Historical associations, such as the birthplace of a famous person, are less easily rated. One pernicious effect of all selection is the way in which it is the most outstanding example of any period, rather than the truly typical, that in the end remains to represent it. Another is that defects as well as merits may be kept warm under the same blanket. This is particularly so in the larger groups of buildings that are coming to be recognized as worthy of conservation.

Once defined, a building's next defense is in specific legal powers for its protection. These may be of varied degree and effectiveness. The most obvious form of legislation is the restriction against demolition. A higher degree of legal sophistication occurs in powers for the annexation of property and its maintenance by the state. Covenanted rights and restrictions are a variant of this principle. Next in the scale of effectiveness comes positive encouragement to owners by means of grants, bringing a public share and interest in the work of repair. In this way, actual legal rights over private property may be confined to a minimum while finance is encouraged from private pockets. Probably the most effective ultimate defense is selective protection, exercised as a regular part of everyday town- and country-planning control.

Negative legislation itself varies in degree. In Italy it is possible to insist upon the return even of certain pictures or chattels illegally dispersed from a building where these are adjudged to be of sufficient national importance. But negative powers are inherently weak. They convey no control over the philistine or intransigent owner and, at best, can only slow down neglect and demolition, whether deliberate or otherwise.

The national acquisition of buildings for conservation in Britain has been carried out chiefly under the Ancient Monuments Consolidation and Amendment Act of 1913, by which suitable unoccupied properties can be "taken into guardianship." A much more rigorous application of the principle is sometimes possible in the United States, whereby the owners of whole groups of buildings held to be of sufficient distinction can in fact be legally dispossessed. These erstwhile owners may then be allowed to remain in residence on condition of the repair and rehabilitation of their buildings to a specified standard. In this way, whole areas of buildings, such as Society Hill in Philadelphia, have been taken over, concentrated redevelopment by high-rise apartments being permitted in selected inner locations, while old buildings with frontage are restored in period styles.

Williamsburg, Virginia

The most exhaustive of all restoration projects is in the United States, at Williamsburg, Virginia. This 170-acre town, the colonial capital of Virginia from 1699 to 1780, has attracted the most expensive restoration program ever undertaken. Commenced in 1926, the project is dedicated to the purpose "that the future may learn from the past." Careful and scholarly restoration has been completed on more than 500 buildings. Environmental management is of a high order. Tourist automobile traffic is excluded from the restored area in season, when a free bus service is provided. The emphasis is frankly educational. The enterprise not only owns its buildings but also staffs them, its employees wearing correct period costume.

One of the most dramatic rescue operations has been in Egypt, where the ancient temples (*c.* 1250 BC) of Abu Simbel were threatened with destruction by the rising waters of the Aswān High Dam. They were sawed into giant blocks and successfully reassembled 200 feet (60 metres) above the original site. This act of preservation was the result of intensive international negotiation and expertise.

Another variant on public ownership may be found in acquisition by a private body, such as the National Trust in Great Britain. Founded in 1895, this property-owning body opens to the public several hundred of its properties. The trust receives no direct government subsidy and relies upon careful economic management, although certain legal preferences operate in its favour. In the United States the National Trust for Historic Preservation operates in a similar way.

Among bodies devoted to grant aid, the Historic Buildings and Monuments Commission for England (as successor to the Historic Buildings Council) disburses grants within a modest annual budget, largely to help building owners penalized by heavy estate duties. These grants are administered to encourage owners to take a pride in their own buildings. The commission is also responsible for the management of more than 400 monuments in the nation's care.

A pioneer training program in architectural conservation has been established by the Faculty of Architecture of

Rome University. Of six months' duration, the course provides specialist training in conservation for architects of all nationalities. In many countries, comparable courses are now available to meet the need for suitably qualified and experienced architects.

Techniques of building conservation. The first requisite in conserving any building is a sensitive assessment of its history and merits. Every building has its own biography. The Parthenon in Athens, originally built (447 to 432 BC) as a temple, subsequently served as a Christian church, a mosque, and a powder magazine before it became one of the world's greatest attractions for the tourist and art lover. A knowledge of the whole life of a building brings an essential understanding of its features and its problems.

Next, the conservator needs a thorough, measured survey. Generally, this is prepared by hand, with tape and rod and level. Modern measuring techniques, including photogrammetry and stereophotogrammetry, are also used and are quick and remarkably accurate.

Assessing the structure's soundness

Third, the architect or surveyor analyzes the structural stability of the subject and its living pattern of movement. No structure is permanently still. Subsoil expands and shrinks, thrust moves against thrust, and materials move with heat and wind. Forceful exercises, like English bell ringing, have an even greater effect on a building's stability. Clay soil is the worst: the building protects the ground underneath but not around; and, with every downpour, a wall on saturated clay may vary the lean of the building. Many ancient buildings had piled foundations—at Winchester, the cathedral was supported on oak piles, which rotted over the centuries. In order to underpin the structure, a diver worked for months in the waterlogged soil. Framed structures can move a great deal. The skeleton of a timber-framed medieval house can be extremely crooked without losing strength, if it is well triangulated and its joints are sound. A wall is theoretically safe until it leans far enough to develop tension on one side, yet even then it may be stiffened by structural cross-walls. Generally, the old, evenly spread load will be stable, and any new point load or thrust will be suspect. The surveyors may check the observations over a period; *e.g.*, by measurement with plumb lines or by simple "tell-tales" (marking devices) set across a crack, or now by electronic measuring devices of remarkable accuracy.

The surveyor lastly tests all services, especially electrical wiring, with its risk of fire; gas lines, with their perils of seepage and explosion; and plumbing, with its danger of leaks. These services are frequently redesigned and simplified as well as improved. Lightning conductors and fire-fighting equipment are an important part of the protection of any ancient building.

The conservator must analyze the good points and bad points of the building, in the context of its current and future use, and define remedies in terms of their relative urgency. He can then prepare a balanced and phased conservation plan, related to the available budget.

Remedying building defects

The first remedial task is to stabilize and consolidate the structure. Ideally, this is best done by restraining, or tying, the point of active thrust and then by replacing, splinting, or in some way giving fresh heart to any failing or defective member. Adding heavy weights such as buttresses can do more harm than good. A load can frequently be spread more widely or more evenly. A structure can, in effect, be corseted by inserting (for example, around a tower) a continuous beam or ring of concrete. This can be done even in delicate masonry and, as in underpinning, by removing alternate sections of a wall, threading in reinforcement, and casting successive sets of concrete stitches, which unite into one strengthening beam. Sometimes a metal rod or tie-bar may be inserted along a direct line of thrust or weakness, linking structural elements in need of support.

After structural movement, the next serious adversary in building conservation is damp. Not only of itself but also allied with almost every other trouble, damp accelerates decay. Weather may be penetrating through whole surfaces, such as porous brickwork, or finding its way through cracks or defects in the roofing. Especially vulnerable are gutters or any part of the rainwater-collecting system. Wet weakens walling, rots timbers, and spoils finishes. The remedy may involve renewing roof finishes. It may entail inserting a continuous moisture barrier, perhaps in a modern material such as stout polyethylene. In this case, special care is needed to avoid future damage by concentrating more trouble at any possible defect. Techniques of waterproofing wet walls include the insertion of high-capillary tubes, designed to draw the moisture to themselves and to expel it, and also the injection of silicone or latex and similar water-repellent solutions into the heart of the walling. Simple methods are best. The traditional ditch, or dry area, drained if necessary, disposes of the water before it reaches the wall. Double or cavity walls, with air between them, are another defense against damp.

Again, dampness compounds decay, and the first attention should be to protective features such as copings. Both in stonework and in brickwork, much harm can be caused by damp, especially when allied with an overly hard mortar jointing. This traps moisture along the lines of the joints, bringing any harmful salts to the surface, where they crystallize and damage the facing. Mortar jointing should always be softer than the brick or stone of a wall.

Much decay is the result of poor construction. Defects are almost always accelerated by the simple contravention of good building practice. In walling, a typical cause of structural instability is a double-skin construction with rough rubble between in which, by uneven loading, one skin has been caused to bulge and to release loose material in the core of the wall. Once on the move, this rapidly gains momentum as a live wedge, forcing apart its two faces. The conservator will insert temporary support, then remedy any uneven loading and rebuild the affected area. In some cases, after loose material is washed out, the unseen cavities can be grouted up, either by gravity or at high pressure, thus strengthening a wall without disturbing the facing stonework.

The roof is a building's first defense. It must be impervious and collect water clear of a building. Roof finishes are commonly either of unit materials such as tiles, slates, or stone, or of boarding covered in sheet metal, such as lead. The failure of unit materials is usually caused by decay of fixings. Iron nails are especially destructive and are best replaced by nonferrous materials, such as copper. The battens that carry the tiles or slates have a longer lifespan but also need periodic renewal. Leadwork failure is usually the result of sheer age. This material has a very long life but, if used in sheets of excessive size, has a tendency to buckle and creep as a result of expansion—especially in sunshine. Leadwork can readily be recast or can be repaired by lead burning a new patch to the original lead. Soldering is less reliable and tends to crack away.

The chief enemies of timber are the natural predators of the forest—fungi and wood-boring insects. The most voracious fungus that attacks building timbers is dry rot (*Merulius lacrymans*). This can spread along infected wood to sound timber, carrying its own moisture supply. It extracts cellulose, which forms the chief part of plant cells, and leaves behind a tindery and useless shell. Stagnant air and warmth accelerate its spread. Eradication must be thorough, or the trouble will rapidly reestablish itself. Modern fungicides are highly effective.

Wood-boring insects include the furniture and deathwatch beetles. From eggs laid in cracks, the larvae tunnel into timber and damage it before emerging as beetles to lay more eggs. The deathwatch beetle inhabits mostly the outer sapwood of oak, when wet or softened by rot. The furniture beetle lives mostly in deal, especially when sappy or damp. Both can be eradicated with modern pesticides.

"Daily care"

Regular maintenance is the key to building conservation; William Morris called this practice "daily care." A building's life can be long, human tenancy relatively short. Yet the cumulative effect of neglect can be desperately damaging. Conversely, a sensitive awareness of a building's needs, with regular attention to them, will extend its life and promote its long enjoyment. The successful conservator identifies himself with a building's life, its structure and demands, with the special needs of an occupant, and with the skills of today's craftsmen. In this spirit, he can hand on to the future the best of the past.

(D.W.I.)

PAINTINGS

The conservator of paintings aims above all at "true conservation," the preservation of the objects in conditions that, as far as possible, will arrest material decay and delay as long as possible the moment when restoration is needed. The correct choice of conditions of display and storage is, therefore, of the first importance. Ideally, each type of painting requires its own special conditions for maximum safety, depending on the original technique and materials used to compose it. Broadly speaking, most paintings can be divided into (1) easel paintings, on either canvas or a solid support, usually wood; (2) wall, or mural, paintings; and (3) painting on paper and ivory.

Easel paintings. More or less portable paintings on canvas or panel are called easel paintings. Basically, they consist of the support (the canvas or panel); the ground, ordinarily a white or tinted pigment or inert substance mixed with either glue or oil; the paint layer itself, which may be complex in structure; and, finally, the surface coating, usually a varnish, to protect the paint and modify its appearance aesthetically. These four layers have many variants but must be constantly borne in mind when considering the problems of conservation.

fects of
midity

Paintings on wood. Wood-panel supports were used almost universally in European art before about 1450, when canvas began to gain ground. Wood has the disadvantage of swelling and shrinking across the grain with variations in the relative humidity of the atmosphere. In northern temperate climates, variations in humidity can be considerable. In England, for example, the seasonal variation in a museum that is centrally heated in the winter can be from 25 percent in midwinter to 90 percent in summer. Although paint has a certain elasticity, it cannot usually take up much movement and generally cracks in a network referred to as craquelure. In continental landmasses, such as the United States, the average relative humidity in dry zones may be consistently low, so that European paintings with wooden supports air-seasoned to a higher humidity may suffer considerably. In both Europe and the United States, the effect of an unsuitable environment of low or changing relative humidity and the restraining effect of the paint layer often produces a permanent bowing of the panel, which is convex at the front surface. To counteract both the shrinkage and the bowing (especially the latter), restorers in the past placed wooden strips called battens or more complex structures across the back of the panel as constraints. This solution, however, often led to severe distortion of the front surface and cracking of the whole panel in lines along the wood grain. Extensive damage to the paint sometimes occurs, and drastic restoration is needed. In terms of preservation, the ideal solution is a form of air conditioning in which the relative humidity is maintained as nearly constant as possible at what is generally agreed to be the most reasonable level; *i.e.,* about 55 percent.

se of
condary
ipports

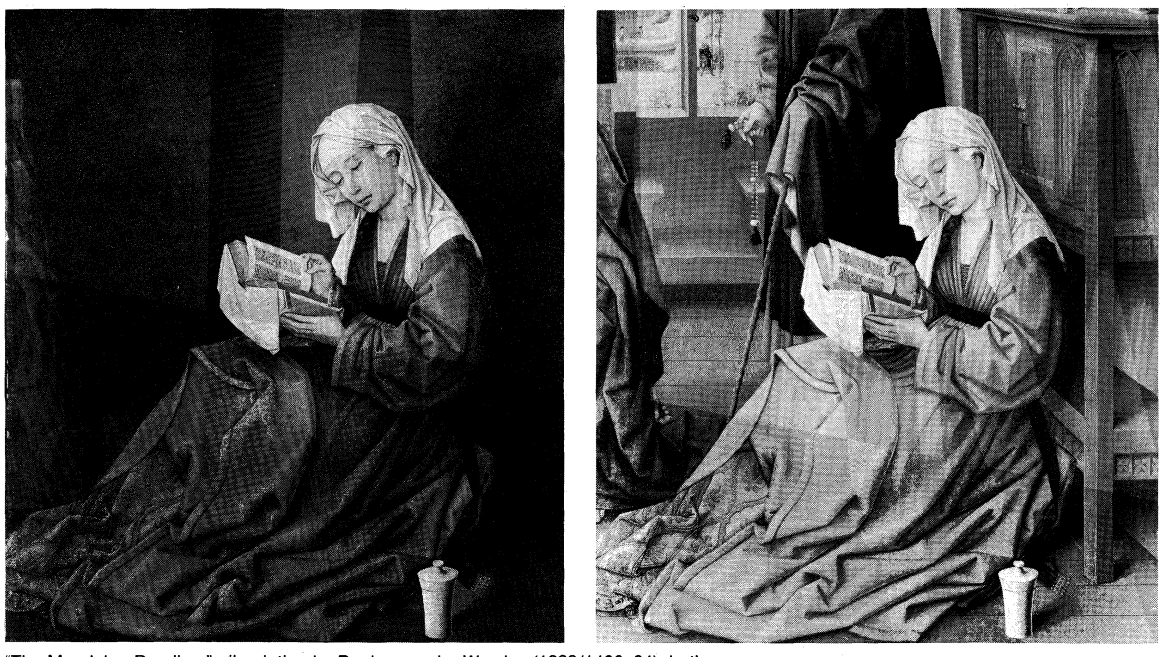
When warping and cracking have already occurred or when the latter seems likely as a result of the mistaken application of secondary supports, such as cross-battens, expert restoration treatment is required. In principle, this consists of removing the cross-battens and applying a reinforcement to the back that imposes a uniform but gentler constraint over the whole surface. It is normal in the 20th century to accept as inevitable some permanent convex curvature. The adhesives used and the composition of the new secondary support take many forms. One consists in backing the panel with strips of a very light, open-textured wood (balsa), using as a cement a mixture of beeswax, a natural resin, such as dammar, and an inert filler. This thermoplastic cement, which is applied as a hot, creamy liquid, solidifies without contraction. The epoxy resins, which also harden without contraction, have been used as well and have the additional advantage of not requiring heat. The material and cement used are chosen according to the nature of the original panel. Some restorers reduce the strength of the original panel, before applying the secondary support, by reducing its thickness. This practice is not universally approved. Occasionally, when the panel is badly worm-eaten or severely cracked, it has to be removed from the paint and ground altogether in the process known as transfer. This is accomplished by pasting a substantial support of paper and, possibly, canvas to the front surface and then gently gouging away the wood on the back. An entirely new, inert support of balsa wood or compressed board is then cemented to the back and the facing removed.

Paintings on canvas. A canvas support expands and contracts with variations in relative humidity, but the effect is not as drastic as with wood. Canvas, however, will deteriorate with age and acid conditions. In many cases, parts of the paint and ground will lift from the surface, a condition described as flaking, blistering, or scaling. In the case of paintings on canvas, the process of transfer is almost never performed. Instead, the canvas is reinforced at the back by attaching a new canvas to the old. This lining process (almost always referred to as relining) can be done in two ways. The traditional method consists of ironing the new canvas to the old, using as adhesive a warm, fluid mixture of animal glue and a farinaceous paste, sometimes with the addition of a small proportion of plasticizer. This method is still used, especially in Italy. It has the advantage that the heat and moisture help to flatten raised paint ("cupping") and local deformations and tears in the canvas. Another method, introduced after the mid-19th century, uses the thermoplastic wax–resin mixture mentioned above, omitting the filler. Originally done with heated irons as is the glue–paste method, it gained in popularity by the introduction, around 1950, of the so-called vacuum hot-table. The canvases are coated with molten adhesive (at about 160° F [70° C]), which is allowed to solidify, and then joined together on an electrically heated platen. They are then covered with a membrane enabling the space between to be evacuated with a pump through holes in the table. Adhesion occurs on cooling. Though the wax protects the canvas from deterioration, the vacuum pressure sometimes makes the texture of the canvas more apparent. Also, wax penetrating the canvas occasionally darkens thin or porous paint layers. To overcome these defects, "heat-seal" adhesives were introduced in the late 1960s. Formulations containing synthetic resins, including polyvinyl acetate, and, increasingly, an ethylene–vinyl acetate copolymer, are applied in solution or dispersion to the surfaces and, after drying, are adhered on the hot table. More recently, cold-setting polymer dispersions in water have been introduced using a "cold-table," from which the water is removed through spaced perforations with a powerful downdraft of air. Pressure-sensitive adhesives also are being evaluated.

Paintings have occasionally in the past been transferred from wood to canvas by a variant of the treatments described above. The reverse of this—*i.e.,* attaching a painting on canvas to a stable rigid support (a process known as *marouflage*)—is still sometimes done for various reasons.

The ground (*i.e.,* the inert paint layer covering the support below the painting itself) can ordinarily be regarded for conservation purposes as part of the painting layers. Occasionally, when the ground is composed of glue and an inert substance such as whiting or gypsum, the glue may deteriorate and the ground lose its adhesion to either the support or the paint layers. In extreme cases, with wood-panel supports, a complete transfer is required, in which not only the support but also the ground must be removed. The restorer has a brief opportunity of seeing the painting or at least its lowest layers in reverse before applying a new ground and support.

The paint layers themselves are subject to a number of maladies as a result of natural decay, faulty original technique, unsuitable conditions, ill treatment, and improper earlier restorations. It must be remembered that, whereas housepaint usually has to be renewed every few years, the paint of easel paintings is required to survive indefinitely and may be already 600 years old. The most prevalent defect, as mentioned above, is flaking, or scaling, where, in local areas of paint, small particles become partly or wholly detached from the support. If the loss is not total, the paint can be secured, according to circumstances, with a dilute gelatin adhesive, the wax–resin adhesive, or a synthetic polymer. The paint is usually pressed firmly into place with an electrically heated spatula. For easel paint-



"The Magdalen Reading," oil painting by Rogier van der Weyden (1399/1400–64). In the National Gallery, London. Cleaning and restoration in 1956 (right) revealed that the painting was a fragment from an altarpiece, not a complete painting as it had appeared (left).

Problems in the original paint

ings the binder for the coloured pigments is usually egg yolk, oil, or, occasionally, glue. The first type of method, called egg-tempera painting, was universal before the mid-15th century, when oil painting began to be used increasingly. The condition of egg-tempera paintings where damage has not been caused by deterioration of support or ground is usually good. The condition of oil paintings is often less satisfactory. Sometimes the original technique of the artist is at fault, and this becomes increasingly so from the 18th century onward. Too much oil may have been used, leading to ineradicable wrinkling, or superimposed layers may have dried at different rates, producing a wide craquelure as a result of unequal shrinkage. An enhanced version of the latter occurred increasingly, as the 19th century progressed, by the use of a brown pigment called bitumen. Bituminous paints never dried completely, producing a surface effect resembling crocodile skin. These defects cannot be cured and can be visually ameliorated only by judicious retouching.

The most notable defect arising from poor conservation is the fading or changing of the pigments by excessive light. Although this is more evident with thin-layer paintings, such as watercolours, it is also visible in oil paintings. The palette of the earlier painters was, in general, stable to light; however, some of the pigments used, notably the lakes, which consisted of vegetable dyestuffs mordanted onto translucent inert materials, often faded easily. A transparent green, copper resinate, much used from the 15th to the 18th century, became a deep chocolate brown after prolonged exposure to light. After the discovery of synthetic dyestuffs in 1856, a further series of pigments was created, some of which were later discovered to fade rapidly. Unfortunately, it is impossible to restore the original colour, and in this case conservation, in its true sense of arresting decay, is important; *i.e.,* to limit the light to the lowest possible level consistent with adequate viewing—in practice about 15 lumens per square foot (15 footcandles; 150 lux).

Almost every painting of any degree of antiquity will have losses and damages, and a painting of earlier than the 19th century in perfect condition will usually be an object of special interest. Before a more conscientious approach to restoration became general in the mid-20th century, areas that had a number of small losses were often—indeed, generally—entirely repainted. It was considered normal in any case to repaint not only losses or gravely damaged areas but also a wide area of surrounding original paint, often with materials that have visibly darkened or faded with time. Large areas with significant detail missing were repainted inventively in what was supposed to be the style of the original artist. It is customary nowadays to repaint only the actual missing areas, matching carefully the artist's technique and paint texture. In some cases, as with skies in which areas have been worn away by injudicious cleaning, very little repainting is done at all.

Inpainting

Some restorers adopt various methods of inpainting in which the surrounding original paint is not imitated. The inpainting is done in a colour or with a texture that is intended to eliminate the shock of seeing a completely lost area without actually deceiving the observer. The aim in inpainting is always to use pigments and mediums that do not change with time. Egg tempera has been preferred, though it is difficult to use, and various stable, modern resins are employed in place of or in addition to tempera. Exact imitation of the original entails close study of the painter's technique, especially the multilayer methods, since the successive layers, being partly translucent, contribute to the final visual effect. Minute details of texture, brushstrokes, and craquelure must also be simulated.

This work of inpainting ordinarily has to be done after the top layer, or the varnish, has been removed. Because all varnishes before about 1930 and many since have undergone changes in colour and transparency, they partially obscure the appearance of the original paint and, therefore, must be taken off.

Varnishing

While the use of varnish was partly to protect the paint from accidental damage and abrasion, its main purpose was to improve the appearance. Oil paint, over the course of time, changes chemically by oxidation and polymerization and becomes harder and more brittle. A remarkable range of injurious cleaning agents, including sand and caustic alkali, is known to have been used for cleaning the surface of the paint in the past. As a consequence, some of the hardened oil medium is lost, and the painting becomes matte, or without lustre, and lifeless. A varnish, visually at least, revives it, and if a varnish itself becomes matte a further coat of varnish revives the former varnish coat, and so on. Unfortunately, the varnishes used consisted of hard resins, such as copal, or, more often, soft resins, such as mastic and dammar. These become yellow, brittle, and slightly opaque and also less soluble in harmless solvents. Occasionally, as in London's National Gallery in the mid-19th century, lead driers were added to the varnish to quench the bloom, a blue haze that covered the varnish as

a consequence of the prevalent coal smoke combined with a high and variable humidity. This varnish, known as the "Gallery Varnish," yellowed even more rapidly than the resins alone. The removal of these disfiguring natural-resin varnishes from paintings is an operation that must be carried out with great skill to avoid damaging the original paint. The work of restorers in removing varnish (usually described as cleaning) has been the subject of occasional vehement public criticism from 1850 onward.

When the varnish is in good condition but covered with grime the restorer may, after close inspection, clean the surface with aqueous solutions of nonionic detergents or mild solvents. This should never be attempted by an amateur. Varnish is almost invariably removed by means of a solvent mixture of which the active ingredient is often one of the lower alcohols. The solvent is sparingly applied with a cotton-wool swab. Choice of solvent mixture and mode of application has always depended on the skill and experience of the restorer, but modern scientific theory has clarified the procedures. For revarnishing, the natural resins such as dammar, although excellent in application and appearance, have mostly been abandoned in favour of synthetics. They are chosen for chemical stability with regard to light and the atmosphere so that they can eventually be removed by safe solvents and will not rapidly discolour nor physically deteriorate. Acrylic copolymers and polycyclohexanones have been the most commonly used since the 1960s. Research continues, however, in order to find the "ideal" varnish, combining ease of application, chemical stability, and an acceptable aesthetic quality.

Wall paintings. From the point of view of conservation, the different types of wall painting have a number of features in common, though the techniques of restoration required for each inevitably differ in detail. Among the wall painting techniques is buon fresco, or true fresco, in which pigments mixed with water are painted onto a freshly prepared layer of damp lime plaster. Fresco secco is a method, often used in conjunction with buon fresco, in which a mixture of pigment and egg tempera is painted onto the dry plaster or is used as a retouching or enhancement of a dried buon fresco painting. Wall paintings are also executed with pigments mixed in oil applied either to a prepared dry plaster wall or on canvas, which is then fixed to the wall.

As far as pure conservation is concerned, there are two outstanding factors. The first, which applies to all methods of wall painting and especially to aqueous, or water-based, mediums, is the exclusion of damp. This can attack the painting from several sources. One source is damp rising through the walls of a building; this first affects the bottom of the wall painting and then spreads upward. This is prevented by inserting a metallic or resinous damp course. New damp courses in old buildings are often prohibitively expensive, in which case a possible amelioration is to dig out exterior soil to a depth of at least six inches below the interior floor. The second source of damp is from the outside wall. It is important at least to avoid treating the painting with a water-impermeable material, such as wax or silicates, so that the damp can penetrate freely without meeting a barrier at the inner surface. The third source is condensation on the inner surface, which is particularly prevalent in churches that are heated only on weekends. More continuous and uniform heat is the solution, provided that the air is not dried out so rapidly that efflorescence, the formation of a powdery surface, occurs. The fourth and most easily remedied source, though often neglected, is from leaking roofs and clogged drainpipes.

Deterioration of lime

The second important hazard is more insidious. It affects solely those murals painted on lime mortar, which inevitably, by the action of air, becomes calcium carbonate. Since 1900, with the increasing use of motor vehicles and of fuel-burning industries, the percentage of sulfur dioxide in the atmosphere has greatly increased. In the presence of moisture the calcium carbonate is changed to calcium sulfate, whose volume is almost twice that of the original carbonate of the mural. As a result, disintegration in some areas of a mural can be rapid. In Italy this sort of disintegration has greatly increased and has made necessary the development of drastic though highly expert methods of transfer of frescoes from the original walls. These range from the method of *strappo* to that of *stacco*. While in practice they are not always clearly distinguishable, *strappo*, the more usual method, consists in gluing canvas firmly to the surface of the fresco, followed by pulling and easing away with long spatulas a thin layer of the plaster that contains the pigment particles of the fresco. The bond between the facing and the fresco must be stronger than the internal cohesion of the plaster. Excess plaster is removed, revealing the fresco in reverse. This is then fixed to a rigid support with synthetic resins, using inert substances mixed with resins as an intermediate layer to simulate optically the original underlying plaster. In the *stacco* method, a thicker layer of plaster is removed with the fresco and is smoothed flat on its back surface before sticking the rigid composite layer to a board. Where possible, consolidation without detachment is performed. The removal of previous repaintings and overlying whitewash is often the most tedious part of the work.

In humid, temperate climates, such as England's, limewater is usually used as a consolidant. Earlier consolidations, often of wax or natural resins, are not only difficult to remove but also have frequently accelerated deterioration. In dry parts of the world, synthetic resins such as polyvinyl acetate have been used with success as consolidants.

Paintings on paper and ivory. Environmental conservation for these objects, which are ordinarily painted in an aqueous medium, consists in maintaining a stable relative humidity in the region of 50–60 percent. At lower humidities, both paper and ivory (the latter often used as a thin layer for portrait miniatures) tend to shrink, and the former becomes more brittle. The thin ivory of miniatures, which often tends to crack, may crack along the grain if constrained under conditions of varying humidity. At higher humidities, there is a possibility, especially when ventilation is poor, of mold growth, which can occur above about 68 percent relative humidity. Watercolour paintings are particularly vulnerable to light, which ideally should not exceed 5–10 lumens per square foot (5–10 footcandles, 50–100 lux). Some pigments fade rapidly, whereas others do not alter, and there is inevitably not only a loss of colour but also a distortion of the artist's intention. It should be noted that a warm light, as from an ordinary incandescent lamp, is less damaging in general than an equal amount of daylight or light from a fluorescent lamp. Daylight should preferably be avoided. The ultraviolet component should, in any event, be removed. Ultraviolet filters are available for windows and fluorescent tubes.

Restoration of paintings on paper has many detailed variations. After removal of the material on which the paintings are mounted, local brown stains, usually known as foxing, are sometimes reduced. The painting is freshened by washing gently in water with or without a little neutral detergent (which should not be of the household variety). Often a watercolour painting will resist washing without loss of colour, but it is generally advisable merely to damp the back before proceeding to reduce the stains locally with an oxidizing bleach. A mild form of bleaching agent known as chloramine-T is sometimes used. Other, stronger oxidizing bleaches can be used subsequently, but there are various disadvantages. Stains other than the characteristic foxing must be identified and the specific solvents used. Japanese prints may be treated similarly, though with even more care, since some colours (notably, a range of mauves) must never be damped. Portrait miniatures on ivory require expert treatment, and it is even possible to damage them irrevocably in removing them from their lockets.

The conservation of fine prints is dealt with in the article PRINTMAKING. (N.S.B.)

SCULPTURE

Until the mid-1960s, painting conservators led the whole field of conservation with their technical expertise and experience. Today that imbalance has shifted, and it is in the field of sculpture conservation that many of the most complex and exciting technical developments are taking place. This change can be attributed partly to the growing international concern with the problems of stone decay

and partly to the rapid development of more sophisticated synthetic resins for use in repair.

The realization that the heritage of stone sculpture and buildings might not remain in a recognizable form for more than another 50 years has stimulated an interest in the conservation of sculpture that would not have occurred were the problems merely confined to museum collections. New pressures also are being exerted on museums. As the main centres of conservation expertise, they are called upon to lend their aid to the organizations dealing with these problems in cathedrals, churches, and historic houses. They also act as places of refuge for endangered sculptures. The scale of the problem (the rapid increase in pollution worldwide and the vast number of sculptures involved) has caused the profession of sculpture conservation to develop rapidly. Although it has been possible to borrow from painting conservation many surface cleaning techniques for use on terra-cotta, plaster, and polychrome wood sculpture, very few of these techniques are suitable for marble and limestone, with their particular susceptibility to damage from water and soluble salt migration.

The main problems facing the stone conservator are stabilization, consolidation, and further protection against pollutant gases and soluble salts. Stone is extraordinarily unstable in the modern environment. Once it has been attacked by pollutant gases, such as sulfur dioxide, or migrating salts, such as nitrates or chlorides, it is difficult to return the stone to a stable condition, even when it is placed in a museum environment. Although some temporary stability may be achieved by putting a damaged sculpture in a temperature- and humidity-controlled glass case, it is commonly found that degradation will continue and, in certain instances, even accelerate.

The mechanism by which soluble salts cause damage in stone and marble is complex, but the broad effect can be simply characterized. These salts, which can be derived from pollutant gases, a marine climate, or natural ground salts, dissolve in water and seep through the pores of the stone. The water may derive from the ground, from the atmosphere, or from oversaturation of the stone by inappropriate water-washing. As the salts move to the drier air at the surface of the stone, they begin to crystallize either on the surface (efflorescence) or beneath the surface (subflorescence). It is this crystallization and resultant expansion of the salts that breaks open the pores of the stone and creates the damage.

To have any hope of halting this activity, the stone conservator must interfere with the deep structure of the stone, sealing it against moisture movement and strengthening it against salt damage to the pore structure. Probably the most popular means of stabilizing stone is the introduction of a consolidant. In the past, consolidants such as wax and shellac have been tried. These do not penetrate deeply into the stone and often aggravate the problem. Various synthetic resins, such as acrylics, epoxies, polyesters, and silicones, have been used with greater success. By far the most successful, however, have been the alkoxy–silanes. These have several distinct advantages over other consolidants. They penetrate deeply into the stone (two to three inches in some limestones), and they deposit a hard, almost indestructible network of silica in the pore structure of the stone, which waterproofs and strengthens it.

There are many forms of alkoxy–silanes in use and many ways of applying them. The commonest methods are simple brushing, spraying, and vacuum impregnation. Of these, the first is the most controllable and delicate approach, while the last is the least controllable and most potentially dangerous.

The full treatment of a sculpture must, of course, include cleaning. Any consolidation treatment or attempt to remove salts from stone must be carefully integrated with an appropriate cleaning system. In the past, the most common way to clean and desalinate stone was to immerse it in a tank of water for a period of weeks or months. This process can cause considerable damage because it loosens friable stone and pigment from the stone surface. A better method was developed in the 1960s, by which a clay poultice (magnesium silicate and deionized water) is used to suspend a thin layer of water over the surface of the sculpture, like a cosmetic mudpack, sucking out both dirt and salts. This treatment minimizes the contact with water and also does less harm to the fragile surface of the sculpture. The use of sophisticated tools and techniques such as ultrasonic dental descalers and abrasion by air-blasted microscopic glass beads helps to give the conservator much greater control over the cleaning process. Lasers were first used for removing pollution deposits from stone in 1970. Improved laser technology, decreasing cost, and the concurrent development of fibre optics suggests that it may soon be possible to produce a flexible precision tool that is capable of removing dirt and other encrustations from the surface of sculpture by vaporization, without harming the stone itself.

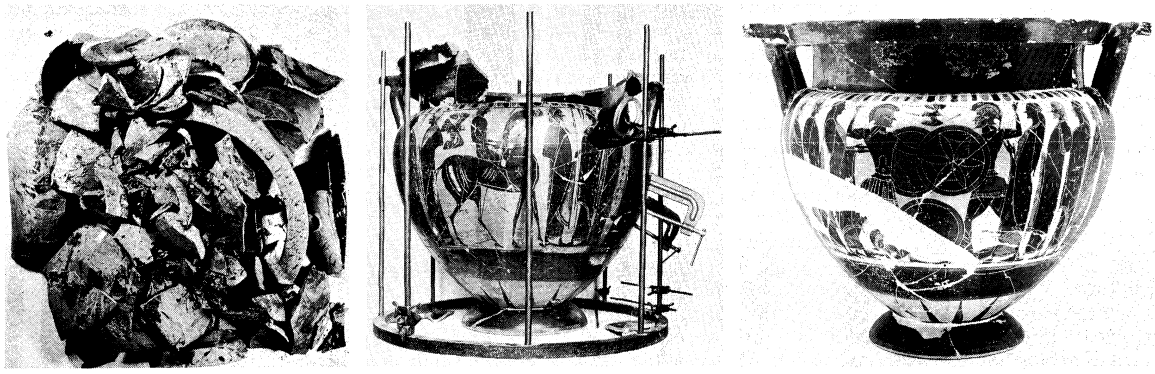
The other main advance in sculpture conservation has been the growing use of the binocular microscope. When the surface of a sculpture is examined under a surgical microscope of from 10× to 40× magnification, the immense damage that can be inflicted on sculpture by indiscriminate cleaning becomes strikingly apparent. Tiny fragments of original pigment often remain on sculptures that to the naked eye appear completely unpainted. From these pinpricks of paint, technicians can determine the exact composition of ancient sculptural pigments and their binding mediums. (J.H.L.)

DECORATIVE ARTS

Furniture. Apart from physical damage, effects of woodworm, and failure of glued joints, deterioration of furniture today is mainly attributable to the dry air (*i.e.*, low relative humidity) of centrally heated rooms in winter. In the past, the air in houses was not much different from that of the cabinetmaker's workshop. Dry conditions, however, cause the carcass wood to warp and split, joints to loosen, and surface decorations such as veneer to detach. Further damage can be eliminated by humidity control (within 50–60 percent relative humidity) the year round; a simpler alternative is the use of humidifiers in winter. Furniture should not be situated close to either humidifiers or sources of heat.

Restoration of fine furniture requires a range of skills similar to those of the original cabinetmaker, coupled with restraint and judgment with regard to the integrity of the object. Replacements required for mechanical or aesthetic reasons are preferably of matching material finished to simulate the original patina. Replacement of worm-eaten wood can now often be avoided by impregnation of the damaged original with resin, usually an epoxy. For live woodworms there are proprietary liquid pesticides, although care must be exercised during application to avoid damaging original finishes. A gas chamber using, for example, methyl bromide or a mixture containing ethylene oxide is more effective. Repair requiring specialized skills may be needed for a range of materials. These include tortoiseshell, ivory, pewter, mother-of-pearl, and the materials of upholstery. Oriental lacquer presents unsolved problems that are still the subject of international discussion.

Stained glass. Stained glass windows may include pieces of coloured glass, uncoloured glass to which a thin coloured layer has been applied (flashed glass), and, in examples from the 15th century and later, uncoloured glass with a painted and fired design of coloured enamel. Deterioration other than physical damage results mainly from rain and condensation and consists of overall corrosion on both sides and pitting, generally on the outside only. Susceptibility to corrosion varies with glass composition. The corrosion layer darkens the glass, but its removal is a matter of some controversy. A variety of methods of local abrasion may be employed. Missing pieces can be replaced with new coloured glass and glass enamelled and fired in accord with the design. Original glass from which enamel has flaked owing to imperfect firing cannot be refired and has to be retouched with a cold-setting paint. The tendency of the enamel to flake makes the simplest operation—grime removal by washing—a matter for particular care. Breaks, formerly mended with so-called strap leads, are now fixed with epoxy resins. Sometimes badly broken pieces are dry-plated with cover glasses, the pieces



Greek black-figure vase from Orvieto destroyed during the flood of 1966 in Florence, shown (left to right) before, during, and after restoration.
By courtesy of the Soprintendenza alle Antichita d'Etruria, Florence

being inserted together into the leading. At the Cologne cathedral workshop, all the pieces are plated, using a clear resin adhesive. Deterioration of leading makes releading necessary every century or so.

Organic surface coatings have been used for protection from the weather, but opinion is turning toward isothermal glazing, in which the window is replaced with plain glass, and the stained glass panel is hung inside with a narrow gap between the two, open to the interior atmosphere.

Textiles. Environmental requirements for textile preservation are similar to those for paintings on paper, but neglect of textiles is in general more damaging. Fading is a serious problem, but light also weakens the fibres of the material, especially silk. Gaseous air pollution is harmful, and soiling from airborne grime leads to the need for washing, which is best avoided. Where washing is necessary, nonionic detergent formulations are used, never ordinary commercial detergents. Dry cleaning with selected solvents may be substituted in particular cases. Handling and storage of fragile textiles require special care: loose wrapping with acid-free tissue paper; storage containers ventilated to avoid local humidity buildup; folding with sharp edges avoided; for tapestries, rolling with weft (design weave) along the axis; and so forth. New acquisitions and stored material require inspection for insect infestation. The feasibility of insect poisons and repellents in textile preservation remains uncertain.

Restoration of valuable textiles, generally by means of skilled needlework, does not normally involve the replacement of worn or decayed materials. When this has to be done for structural reasons informed judgment is required. Material that is so decayed that it cannot be reinforced by stitching to a backing material may require an adhesive bond. After decades of discussion over the use of synthetics, research now points to hydrolyzed starch (an old Japanese recipe) or, when use of water is inadvisable, methylcellulose in an organic solvent.

Ceramics. Ceramic restoration, generally of breakages and losses, sometimes has to begin with the often difficult removal of material from old repairs, and the reduction of ingrained dirt and stains. Rivets and dowels (from a former method of repair) are always removed. Choice of adhesive depends on type of object and probable degrees of stress; epoxy and polyester resins and polyvinyl acetate emulsions are among those used. For hard-bodied ceramics, missing portions or decorative details may be replaced with a suitably bodied and pigmented epoxy. A proprietary plaster filler is preferable for earthenware. Sticking and filling operations require skill to secure an exact fit and a perfect surface. Retouching, with brush or spray, is equally exacting; medium and pigments must be lightstable and the hardened coating physically durable. In museum practice the extension of the retouching to nearby original surfaces is avoided and only cold-setting media are used. Heat-curing risks damage to original glazes.

The apparently simple process of washing ceramics should in fact be carried out with care. Porous and soft-paste ceramics should not be immersed but cleaned with swabs of cotton-wool dampened with lukewarm water and, if necessary, a small amount of nonionic detergent. Hard-paste ceramics may be similarly cleaned but can be immersed unless there is gold decoration (which must be cleaned with special care) or metal mounts, which should never be wetted. Biscuit ware with ingrained dirt requires expert treatment. (N.S.B.)

Arthropods

Arthropoda is the largest phylum in the animal kingdom and includes such familiar forms as lobsters, crabs, spiders, insects, centipedes, and millipedes. About 84 percent of the known species of animals are members of this phylum, and they are very diverse in structure, in life-styles, and in types of habitat.

The distinguishing feature of arthropods is the presence of a skeletal covering composed of chitin (a complex sugar) bound to protein. This nonliving exoskeleton is secreted by the underlying epidermis (which corresponds to the skin of other animals). The body is usually segmented, and the segments bear paired, jointed appendages, from which the name arthropod ("jointed feet") is derived. More than 879,000 arthropod species have been described, of which about 86 percent are insects. This number, however, may be only a fraction of the total. Based on the number of undescribed species collected from the treetops of tropical forests, zoologists have estimated the total number of insect species alone to be as high as 10,000,000. The 30,000 described species of mites, another group of arthropods, may also represent only a fraction of the existing number.

The phylum Arthropoda may be divided into four subphyla: Trilobita, Chelicerata, Crustacea, and Uniramia. The subphylum Trilobita contains only the trilobites, which were the dominant arthropods in the early Paleozoic seas (570,000,000 to 225,000,000 years ago) but became extinct during the Permian Period (280,000,000 to 225,000,000 years ago), at the end of the Paleozoic Era.

Most members of the subphylum Chelicerata belong to the class Arachnida, containing the spiders, scorpions, ticks, and mites. They are largely terrestrial arthropods, living beneath stones and logs, in leaf mold, and in vegetation, but there are some aquatic mites that live in fresh water and in the sea. There are also many parasitic mites. Two small classes of chelicerates, the Merostomata, containing the horseshoe crabs, and the Pycnogonida, containing the sea spiders, are entirely marine. The merostomes are an ancient group and probably gave rise to the arachnids. Indeed, the earliest known fossil scorpions were aquatic.

The subphylum Crustacea contains mostly marine arthropods though many of its members, such as the crayfish, have invaded fresh water, and one group, the pill bugs (sow bugs) has become terrestrial, living beneath stones and logs and in leaf mold. In the sea, large crustaceans such as crabs and shrimps are common bottom-dwelling arthropods. Many minute species of crustaceans are an important component of the zooplankton (floating or weakly swimming animals) and serve as food for other invertebrates, fishes, and even whales.

Uniramia is the largest of the arthropod subphyla. It contains not only the class Insecta but also four closely related classes of long-bodied arthropods collectively known as myriapods: class Chilopoda (centipedes); class Symphyla (symphylans); class Diplopoda (millipedes); and class Pauropoda (pauropods). They are mostly terrestrial and, in contrast to the other arthropod subphyla, the uniramians are believed to have had a terrestrial origin. Centipedes, symphylans, millipedes, and pauropods live beneath stones and logs and in leaf mold; insects are found in all types of terrestrial habitats and some have invaded fresh water. The sea has remained the domain of the crustaceans, however, and only at its very edges are insects found.

This article discusses the arthropods as a group; for specific information on the most significant subphyla and classes of arthropods, see the *Macropædia* articles CRUSTACEANS; ARACHNIDS; and INSECTS; see also the *Micropædia* article MYRIAPOD.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 313.

The article is divided into the following sections:

GENERAL FEATURES

Size range. Representative groups of arthropods are shown in Figure 1. Most arthropods are small animals. Only aquatic forms are able to attain substantial sizes, because their bodies are supported in part by the surrounding water. The extinct chelicerate Eurypterida, for example, reached a length of 1.8 metres (5.9 feet), and some modern spider crabs may weigh up to 6.4 kilograms (14 pounds) and span 3.8 metres. Terrestrial arthropods do not grow very large. The largest insects and spiders do not weigh more than 100 grams (0.22 pound). The beetle *Goliathus regius* measures 15 centimetres (5.9 inches) in length and 10 centimetres in width, while the butterfly *Ornithoptera victoriae* of the Solomon Islands has a wing span exceeding 30 centimetres. One of the longest insects is the phasmid (walkingstick) *Pharnacia serratipes,* which reaches a length of 33 centimetres. The smallest arthropods include some parasitic wasps, beetles of the family Ptiliidae, and mites that are less than 0.25 millimetre (0.01 inch) in length, despite their complex structures.

Terrestrial arthropods

Distribution and abundance. Arthropods are found in almost all of the habitats that cover the Earth's surface. Many crustaceans live in the sea at depths exceeding 4,000 metres, while the insect collembolans and jumping spiders have been found on Mount Everest at heights exceeding 6,700 metres. Collembolans and the oribatid mites are among the permanent inhabitants of Antarctica. Brine shrimp are found in some saltwater lakes, and beetles, mites, and various crustaceans have been taken from hot springs. Minute crustaceans inhabit underground waters in many parts of the world, and deserts support a large arthropod fauna, especially insects and arachnids.

The numbers and diversity of arthropod insect pests are enormous. A bag filled with leaf mold from a forest floor, for example, will contain hundreds of arthropods, including mites, spiders, false scorpions, myriapods, a great variety of insects, and crustacean pill bugs. In the spring a temporary pool often teems with minute crustaceans. Planktonic copepods, which range in length from less than 0.5 millimetre to at least 10 millimetres, can reach densities of 30,000 individuals per cubic metre in surface waters of productive oceans, as around the Antarctic.

Insect pests

Importance. Arthropods are of great direct and indirect importance to humans. The larger crustaceans—shrimps, lobsters, and crabs—are used as food throughout the world. Small planktonic crustaceans, such as copepods, water fleas, and krill, are a major link in the food chain between the photosynthetic phytoplankton and the larger carnivores, such as many fish and whales. Although many species of insects and mites attack food crops and timber,

arthropods are of enormous benefit to human agriculture. Approximately two-thirds of all flowering plants (angiosperms) are pollinated by insects, and soil and leaf-mold arthropods, which include insects, mites, myriapods, and some crustaceans (pill bugs), play an important role in the formation of humus from decomposed leaf litter and wood.

The stings and bites of arthropods may be irritating or painful, but very few inject dangerous toxins. Medically, arthropods are more significant as carriers of diseases such as malaria, yellow fever, dengue fever, and elephantiasis (via mosquitos), African sleeping sickness (via tsetse flies), typhus fever (via lice), bubonic plague (via fleas), and Rocky Mountain spotted fever and Lyme disease (via ticks). Many diseases of domesticated animals are also transmitted by arthropods.

FORM AND FUNCTION

The exoskeleton and molting. The success of arthropods derives in large part from the evolution of their unique, nonliving, organic exoskeleton (Figure 2), which not only functions in support but also provides protection and, with the muscle system, contributes to locomotion. The exoskeleton is composed of a thin, outer protein layer, the epicuticle, and a thick, inner, chitin–protein layer, the procuticle. In most terrestrial arthropods, such as insects and spiders, the epicuticle contains waxes that aid in reducing evaporative water loss. The procuticle consists of an outer exocuticle and an inner endocuticle. In the exocuticle there is cross-bonding of the chitin–protein chains (tanning), which provides additional strength to the skeletal material. The hardness of various parts of the exoskeleton in different arthropods is related to the thickness and degree of tanning of the exocuticle. In crustaceans, additional rigidity is achieved by having the exoskeleton impregnated with varying amounts of calcium carbonate.

Epicuticle and procuticle

The formation of an exoskeleton required the simultaneous solution of two functional problems in the evolution of arthropods: If the animal is encased in a rigid covering, how can it grow and how can it move? The problem of growth is solved in arthropods by molting, or ecdysis, the periodic shedding of the old exoskeleton (Figure 3). The underlying cells release enzymes that digest the base of the old exoskeleton (much of the endocuticle) and then secrete a new exoskeleton beneath the old one. At the time of actual shedding, the old skeleton splits along specific lines characteristic of the group, and the animal pulls out of the old skeleton as from a suit of clothes. The old skeleton is usually abandoned but in some species is eaten. The new exoskeleton, which is soft and flexible, is then stretched by localized, elevated blood pressure augmented by the intake of water or air. Hardening occurs by stretching and especially by tanning within a number of hours of molting. In crustaceans, calcium carbonate is deposited into the new procuticle. (Soft-shell crabs are simply newly molted crabs.) Additional endocuticle may be added to the exoskeleton for some days or weeks following molting.

Molting is under hormonal control, and there is a long preparatory phase that precedes the process. The steroid hormone ecdysone, secreted by specific endocrine centres and circulated in the blood, is the direct initiator of molting. The timing, however, is controlled by other hormones and commonly by environmental factors. The interval between molts is called an instar. Because of the frequency of molts, instars are short early in life but grow longer with increasing age. Some arthropods, such as most spiders and insects, stop molting when they reach sexual maturity; others, like lobsters and crabs, molt throughout their lives. Most of the larger spiders of temperate regions, for example, molt about 10 times before reaching sexual maturity. As a result of molting, the length and volume of an arthropod display steplike increases over the life span, but internal tissue growth is continual as in other animals.

Instars

Loss of a limb is a common hazard in the life of many arthropods. Indeed, some arthropods, such as crabs, are capable of amputating an appendage if it is seized by a predator. The limb is then regenerated from a small, nipplelike rudiment formed at the site of the lost limb. The new limb develops beneath the old exoskeleton during the premolt period and then appears when the animal molts.

Muscles, appendages, and locomotion. The problem that a rigid external covering imposes on movement has been solved by having the exoskeleton divided into plates over the body and through a series of cylinders around the appendages. At the junction, or joints, between the plates and cylinders the exoskeleton is thin and flexible because it lacks the exocuticle and because it is folded. The folds provide additional surface area as the joints are bent. The arthropod's exoskeleton is therefore somewhat analogous to the armour encasing a medieval knight.

Most arthropods move by means of their segmental appendages, and the exoskeleton and the muscles, which attach to the inside of the skeleton, act together as a lever system, as is also true in vertebrates. The external skeleton of arthropods is a highly efficient system for small animals. The exoskeleton provides a large surface area for

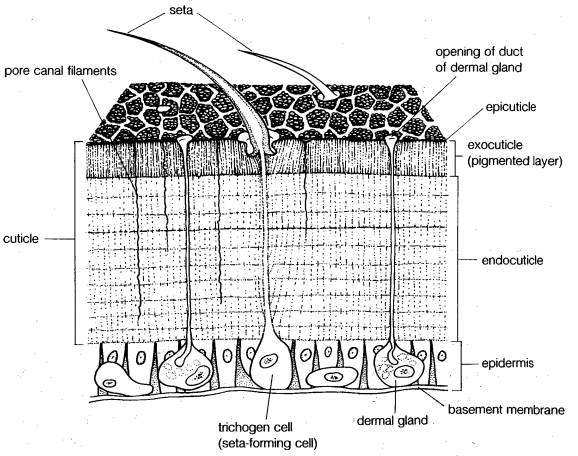

Figure 2: Diagrammatic section through the arthropod integument.

From *Invertebrate Zoology*, 5th ed. (Figure 12-3) by R.D. Barnes, copyright © 1987 by Saunders College Publishing, a division of Holt, Rinehart and Winston, Inc., reprinted by permission of the publisher, after R.H. Hackman in M. Florkin and B.T. Scheer (eds.), *Chemical Zoology*, vol. 6 (1971), Academic Press

the attachment of muscles and, in addition to functioning in support and movement, also provides protection from the external environment. The cylindrical design resists bending, and only a relatively small amount of skeletal material need be invested in thickness to prevent buckling. The external skeleton imposes limits on the maximum size of an arthropod, especially in those that live on land. The largest arthropods live in the sea, where they gain considerable support from the buoyance of seawater. On land, an excessive amount of skeleton would be required to support a large bulk and, in addition, the new soft skeleton might collapse following a molt.

Appendages

Appendages of arthropods have been adapted for all types of locomotion—walking, pushing, running, swimming, and burrowing. In most arthropods the legs move alternately on the two sides of the body; *i.e.,* when one leg is in a power stroke, its mate on the opposite side of the body is in the recovery stroke (the same is true of mammals when walking). The legs in front or back are a little ahead or behind in the movement sequence. Because of the lateral position of the legs, the body of an arthropod tends to hang between them. Leg interference and trunk wobble tend to be problems in an animal with a long trunk and many legs, such as a millipede or centipede. Most arthropods have evolved more compact bodies and a smaller number of legs. The number of pairs of legs used in walking is not more than seven (crustacean pill bugs), four or five (shrimps and crabs), four (arachnids), and three (insects). This reduces the problem of mechanical interference. When a ghost crab, for example, is running rapidly across a beach or dune, only the second, third, and fourth pairs of the five pairs of legs (counting the claws) are employed. Leg interference is further reduced in most arthropods by varying limb length and placement. For example, in *Scutigera,* the centipede commonly seen in houses, the legs increase in length from front to back and thus pass over or under one another in stepping. The tendency for the trunk to wobble has been reduced in some centipedes by having overlapping dorsal plates and in millipedes by having pairs of segments fused to form double segments. Many arthropods are capable of walking on vertical surfaces. Some simply grip minute surface irregularities with the claws at the end of the legs. Others, such as certain spiders and flies, have an array of specialized gripping hairs at the ends of the legs.

Insect wings

Insect wings are not segmental appendages as are the legs. The paired wings arise as lateral folds of the integument, one pair above each of the last two pairs of legs. Each wing thus consists of an upper and lower sheet of exoskeleton closely applied to each other. The two skeletal sheets are separated at various places, forming tubular supporting veins. Unlike the wings of an airplane, the wings of insects are flat plates, and lift is obtained by changing the angle at which the front margin of the wing meets the oncoming air stream. The evolution of flight is one of several adaptations that have enabled insects to become the most diverse and populous group of terrestrial animals.

A burrowing habit has evolved in some insects, such as mole crickets and ants, but the largest burrowers are crustaceans. Mole crabs and box crabs are rapid burrowers in soft marine sands, and various species of mantis shrimps, mud shrimps, and snapping shrimps create elaborate burrows below the bottom surface. Crustaceans also include the largest number of arthropod tube dwellers, surpassed only by certain marine worms (polychaetes). Most of the tube-dwelling crustaceans are amphipods. Their tubes are usually composed of sand or mud particles secreted together and attached to bottom objects; there are, however, some amphipods that carry their tubes with them like a portable house.

Digestive system and feeding. Arthropods exhibit every type of feeding mode. They include carnivores, herbivores, detritus feeders, filter feeders, and parasites, and there are specializations within these major categories. Typically, paired appendages around the mouth are used for collecting and handling food and are usually specialized in accordance with the particular diet of the animal. For example, the insect family Aphididae has mouthparts adapted for piercing vegetation and sucking out plant juices. The crustacean fiddler crabs, which emerge from burrows on sand flats at low tide, scoop up the surface sand with their small claws (only one in the male) and place the sand within their mouthparts, where it is sifted with fine hairs. The organic material is consumed, and the mineral material is ejected as a small "spitball." Where there is a large population of crabs, ejected material may cover the surface of a flat by the end of the low-tide period. The crustacean mole crabs, or sand crabs, of surf beaches use their antennae to filter plankton from the receding waves after reburying themselves. Planktonic crustacean copepods only a few millimetres long can collect up to several hundred thousand diatoms every 24 hours with certain appendages (maxillae) near the mouth. A number of carnivorous arthropods, notably spiders, pseudoscorpions, and centipedes, capture prey with poison, which is usually delivered with a pair of appendages; scorpions use a single stinger at the tip of the tail. In spiders, the poison is introduced through a pair of fangs (chelicerae) flanking the mouth, and in centipedes the poison claws lie beneath the head. Few of these species have a venom that is fatal to humans (see the *Micropædia:* MYRIAPOD).

The front and back parts of the digestive tract (foregut and hindgut) are lined with the same skeletal material that is found on the outside of the body and that is molted with the rest of the skeleton. Only the relatively small middle section (midgut) lacks a chitinous lining. The digestive tract varies greatly in structure, depending upon the diet

Barnes, copyright © 1987 by Saunders College Publishing, a division of Holt, Rinehart and Winston, Inc., reprinted by permission of the publisher, modified from M. Locke in J. Bereiter-Hahn, A.G. Matoltsy, and K.S. Richards (eds.), *Biology of the Integument* (1984), Springer-Verlag, Berlin

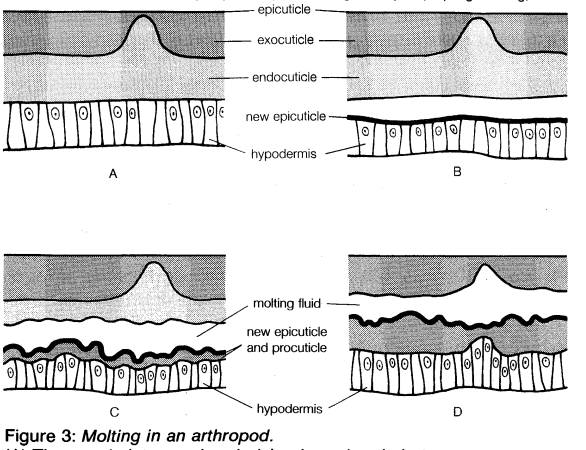

Figure 3: *Molting in an arthropod.*
(A) The exoskeleton and underlying hypodermis between molts. (B) The hypodermis separates, and the molting fluid and a new epicuticle are secreted. (C) The old cuticle is digested and a new procuticle is secreted. (D) Just before molting, the animal is encased in new and old skeleton.

and feeding mode of the animal. In general, however, the midgut region is the principal site of enzyme production and absorption of digested food. The enzymes may pass forward into the front part of the gut and even outside into the body of the prey, in the case of spiders.

Respiratory system. Aquatic arthropods (crustaceans and the chelicerate horseshoe crabs) possess gills for respiration. Although they vary in structure and location, the gills are always outgrowths of the integument (skin) and are therefore covered by the exoskeleton, which is thin in this area and not a barrier to the exchange of gases. Terrestrial arthropods possess tracheae and book lungs as respiratory organs. Tracheae are a system of tiny tubes that permit passage of gases into the interior of the body. In some arthropods the tracheal tubes are bathed by blood, but in insects the minute terminal endings (tracheoles) are embedded in the tissues, even within muscle cells. The tracheal tubes (but not the tracheoles) are molted along with the rest of the exoskeleton. Tracheae are a unique arthropod invention and undoubtedly evolved numerous times in the phylum, for they are found in myriapods, insects, and arachnids. Tracheal systems are highly efficient for these small, terrestrial animals. The small, external openings (spiracles) reduce water loss, the chitinous lining prevents collapse, and the small size of the arthropod and consequent short length of the tubule eliminates the need for moving gases in and out by active ventilation (diffusion usually being sufficient). Book lungs are chitin-lined internal pockets containing many blood-filled plates over which air circulates. Most spiders possess tracheae and book lungs, but large spiders (such as tarantulas) and scorpions possess book lungs alone.

Tracheae

Circulatory system. Arthropods possess an open circulatory system consisting of a dorsal heart and a system of arteries that may be very limited (as in insects) or extensive (as in crabs). The arteries deliver blood into tissue spaces (hemocoels), from which it eventually drains back to a large pericardial sinus surrounding the heart. A varying number of paired openings (ostia) are located along the length of the heart and permit blood to flow in when the valves are open. When the heart is contracting, closed valves prohibit the blood from flowing back and force it into the arteries of the tissues, from which it flows to other hemocoels. In the larger crustaceans, the blood then passes through the gills (where it becomes oxygenated) on its return to the heart. The blood of large arachnids and crustaceans contains the blue, oxygen-carrying pigment hemocyanin; insects lack a respiratory pigment since the tracheal system delivers oxygen directly to the tissues. A few insect larvae and some small crustaceans have blood containing hemoglobin.

Hemocoels

Excretory system and water balance. Crustaceans and arachnids possess paired excretory organs (maxillary, antennal, or coxal glands) that open at the bases of certain appendages. Myriapods, insects, and some arachnids, such as spiders and mites, possess another type of excretory organ, Malpighian tubules, which open into the intestine. Thus in these animals both excretory and digestive wastes exit from the anus.

Water loss through evaporation is a major problem for animals that live on land, especially small ones like arthropods, and an array of defenses against desiccation have evolved. Both arachnids and insects possess waxy compounds in the epicuticle, the outer layer of the exoskeleton, which greatly reduce evaporative water loss. Arthropods that lack a waxy epicuticle, such as the pill bugs, and very small arthropods, such as mites, pseudoscorpions, and collembolans, live in leaf mold and soil, beneath logs, under stones, and in other areas where the danger of desiccation is reduced. The waxes in the epicuticle not only reduce water loss but can also act as a water repellent, reducing the danger of submersion in droplets of rain or dew. This resistance to wetting enables aquatic insects, such as beetles, to carry below the surface a film of air, which can then be used in respiration. It also contributes to the ability of water striders to move over the surface of water without breaking through the surface film.

Both insects and spiders eliminate their nitrogenous wastes as compounds insoluble in water (uric acid, guanine), thereby not requiring that water be excreted. Insects share with birds and mammals the ability to produce a urine that is saltier than the blood, which is of great value in conserving water because it permits the production of a concentrated urine.

Nervous system and organs of sensation. The arthropod nervous system consists of a dorsal brain and a ventral, ganglionated longitudinal nerve cord (primitively paired) from which lateral nerves extend in each segment. The system is similar to that of annelid worms, from which arthropods may have evolved. The neuromuscular organization of arthropods is quite different from that of vertebrates, in which one neuron supplies a number of muscle cells, together forming a functional motor unit. The small size of the muscles prohibits such an organization in arthropods. Instead, the state of contraction of an arthropod muscle is determined by which of several different types of neurons supplying one muscle cell are fired.

The sense organs (sensilla) on the body surface involve some specialization of the exoskeleton barrier. The sensory nerve endings are lodged in cuticular hairs (setae), peglike projections, cones, pits, or slits, which may occur in large numbers on antennae, mouthparts, joints, and leg tips. Changes in the tension of the surrounding cuticle stimulate the nerve endings. For example, the legs of spiders and scorpions possess slits in the exoskeleton that are covered by a thin membrane to which a neuronal receptor is attached below. Tension changes in the exoskeleton cause slight movements in the cuticular membrane and stimulate the receptors. Slits of varying length may be grouped together like the strings of a harp. Slit sense organs enable spiders to detect web vibrations produced by trapped insects, and they permit scorpions to detect ground vibrations produced by approaching prey. Chemoreceptive sensilla (taste and smell) have holes in the cuticle permitting the chemical substances being monitored to enter.

Most arthropods possess eyes, but in most species they function only to detect the intensity of light and the direction of the light source. The ability to detect objects is more restricted. Among arthropods the greatest visual acuity is found in the predaceous mantis shrimp, some crabs, and many insects, all of which possess compound eyes. Compound eyes are effective in detecting motion. The eight eyes of spiders are not of the compound type, but in the case of the cursorial (hunting) wolf spiders and jumping spiders they are effective in locating and tracking prey.

Eyes

Reproductive system and life cycle. With few exceptions, the sexes are separate in arthropods; *i.e.,* there are both male and female individuals. The paired sex organs, or gonads, of each sex are connected directly to ducts that open onto the ventral surface of the trunk, the precise location depending upon the arthropod group.

In arthropods, sperm are commonly transferred to the female within sealed packets known as spermatophores. In this method of transfer the sperm are not diluted by the surrounding medium, in the case of aquatic forms, nor do they suffer from rapid desiccation on land. Among some arachnids, such as scorpions, pseudoscorpions, and some mites, the stalked spermatophore is deposited on the ground. Either the female is attracted to the spermatophore chemically or the deposition of the spermatophore occurs during the course of a nuptial dance, and the male afterward maneuvers the female into a position in which she can take up the spermatophore within her genital opening. Centipedes also utilize spermatophores with an accompanying courtship behaviour. Among insects there are some primitive wingless groups, such as collembolans and thysanurans, in which the spermatophore is deposited on the ground, but in most insects the spermatophores are placed directly into the female genital opening by the male during copulation. Many arthropods transfer free sperm rather than spermatophores. These include many crustaceans, millipedes, some insects (such as dipterans and hemipterans), spiders, and some mites.

Spermatophores

Arthropod eggs are usually rich in yolk, but in all groups there are species whose eggs have little yolk. Some specialized methods of reproduction found among certain arthropods include the development of unfertilized eggs

(parthenogenesis), the birth of living young (viviparity), and the formation of several embryos from a single fertilized egg (polyembryony).

The eggs of many crustaceans hatch into larvae which have fewer segments than the adult. The earliest larval hatching stage is a minute nauplius larva, which possesses only the first three pairs of appendages. Additional segments and appendages then appear at regular intervals with molting. There are several advantages of larval stages in the development of aquatic animals: Currents disperse the larvae, enabling some to settle in different locations from the parents; because many larvae are capable of feeding, less yolk is required in the egg; and, moreover, planktonic larvae do not compete with benthic adults.

In most chelicerates and insects, almost all of the segments are present at hatching, although in insects the body form may differ from that of the adult. Primitive insects, such as collembolans, have the adult form on hatching. Many insects, such as grasshoppers, crickets, and true bugs, hatch as nymphs, which superficially resemble the adult but lack wings. They gradually acquire these adult features during the nymphal instars. Other insects, such as beetles, butterflies, moths, flies, and wasps, hatch as larvae (grubs, caterpillars, maggots) that differ markedly from the adult. The larvae inhabit different environments and eat different foods than the adults. In these insects a pupal stage with metamorphosis bridges the gap between the larva and the adult form.

Nymphs

Myriapods have the general body form of the adult on hatching though they may lack some of the segments. Most millipedes hatch with only seven trunk segments. Some centipedes hatch with all of the adult trunk segments, but others have fewer than the adult.

The young of most arachnids are similar to the adult. The female scorpion gives birth to her young, which immediately climb onto her back. Female wolf spiders also carry their young, and prior to hatching they carry the white egg case attached to the posterior spinnerets. Unlike other arachnids, mites and ticks hatch as six-legged larvae, which acquire the fourth pair of legs at a later molt.

EVOLUTION AND PALEONTOLOGY

The arthropods share many features with the phylum Annelida. Both are segmented, and members of the annelid class Polychaeta have a pair of appendages on each segment. The plan of the nervous system in arthropods is very similar to that of annelids, and the basic plan in both groups shows a tubular, dorsal heart, which is then lost or modified in some. Annelids possess a coelom, which in arthropods is present only in the embryo. Its absence is probably related to the evolution of the exoskeleton and to the change in the mode of locomotion.

The first fossil arthropods appear in the Cambrian Period (570,000,000 to 500,000,000 years ago) and are represented by trilobites, merostomes, and crustaceans. Also present are some enigmatic arthropods that do not fit into any of the existing subphyla. The earliest terrestrial arachnid is from the Devonian Period (395,000,000 to 345,000,000 years ago), but it does not belong to any living order. Though a myriapod-like fossil has been found from the Devonian Period, it is not until the Carboniferous Period (345,000,000 to 280,000,000 years ago) that there is a good record of centipedes, millipedes, and insects.

Most zoologists recognize the trilobites, chelicerates, crustaceans, and uniramians as four major lines of arthropod evolution, but there is little agreement as to how these lines are related to one another or, indeed, if they had independent evolutionary origins from the annelids. The Uniramia takes its name from the proposition that the appendages of these arthropods are primitively unbranched. This idea is not accepted by all zoologists, especially some entomologists.

CLASSIFICATION

Distinguishing taxonomic features. Modification, specialization, number, and appearance of body segments and appendages (especially anterior ones such as antennae and mouthparts) are important criteria in distinguishing arthropod classes. Other structural features of taxonomic importance include location of the gonopores, structure of the head, and adaptations of the respiratory and excretory systems. In the classification below, the group marked with a dagger (†) is wholly extinct and known only from fossils.

Annotated classification.

PHYLUM ARTHROPODA

Bilaterally symmetrical invertebrates with jointed exoskeleton covering body and appendages; cilia absent; body segmented, though segmentation commonly reduced as a result of fusion; appendages typically specialized for different functions; coelom greatly reduced; nervous system consists of dorsal brain and a double or single (fused) ventral nerve cord; eggs typically rich in yolk; development highly modified.

†Subphylum Trilobita (trilobites)

Extinct; head (or cephalon) composed of 5 segments bearing a pair of antennae and compound eyes; oval, flattened body composed of cephalon, thorax, and pygidium, each segmented; dorsal surface molded longitudinally into 3 lobes; each segment bears a pair of similar, branched appendages; marine; Cambrian Period to the end of the Paleozoic Era; more than 4,000 fossil species known.

Subphylum Chelicerata

Body divided into prosoma (cephalothorax) and opisthosoma (abdomen); no antennae; first pair of appendages consists of chelicerae flanking the mouth; in most chelicerates the other prosomal appendages are a pair of pedipalps and four pairs of legs.

Class Merostomata

Large marine chelicerates with book gills on the underside of the opisthosoma; prosoma covered by a dorsal carapace; opisthosoma bears a long terminal spine; 2 orders, Xiphosura (horseshoe crabs, 4 species) and Eurypterida (Gigantostraca), which is extinct and includes 200 fossil species from the Paleozoic Era.

Class Arachnida (scorpions, spiders, ticks, mites)

Chiefly terrestrial; book lungs and/or tracheae as gas exchange organs; opisthosoma (abdomen) segmented or unsegmented externally and broadly or narrowly joined to the prosoma; prosomal appendages consist of 1 pair of chelicerae, 1 pair of pedipalps, and 4 pairs of legs; gonopore always on the lower side of second abdominal segment; about 70,750 species; 0.25 mm–18 cm.

Class Pycnogonida (sea spiders)

Marine; narrow trunk of 4 to 6 segments; greatly reduced abdomen; cephalon (head) with proboscis bearing a pair of chelicerae, palpi, and egg-carrying legs; usually 4 pairs of walking legs attached to lateral projections of the trunk; tubercle with 4 eyes located dorsally between the first pair of legs; no gas respiratory organs; commonly found crawling over sessile animals, such as hydroids and bryozoans; about 1,000 described species; 1 mm–10 cm.

Subphylum Crustacea

Chiefly aquatic; head bearing 2 pairs of antennae, a pair of mandibles, and 2 pairs of maxillae; trunk highly variable but commonly covered in part or entirely by a posteriorly directed fold of the head (carapace); paired appendages biramous, often with 1 branch lost; 2 stalked or stalkless compound eyes present in most; when present, gas exchange organs are gills; mostly marine, but many freshwater species; some isopods terrestrial; 44,000 described species in up to 10 classes.

Suphylum Uniramia

Chiefly terrestrial; segmental appendages primitively unbranched; head appendages comprise a pair of antennae, a pair of mandibles, and 1 or 2 pairs of maxillae; trunk and appendages variable; respiratory organs are tracheae.

Class Chilopoda (centipedes)

Elongate; many trunk segments, each with 1 pair of legs; 2 pairs of maxillae covered by a large pair of poison claws representing the first pair of trunk appendages; eyes, if present, are simple ocelli; gonopore on last segment; 5 mm to almost 30 cm; about 2,500 living species.

Class Symphyla

Mouthparts consist of a pair of mandibles and 2 pairs of maxillae; 12 leg-bearing trunk segments; terminal segment carries a pair of spinnerets; gonopore on fourth segment; 1–8 mm; about 160 living species.

Class Diplopoda (millipedes)

Elongate; trunk containing many diplosegments, each bearing 2 pairs of legs and spiracles; single pair of maxillae fused to form a flattened plate (gnathochilarium); first 4 trunk segments not diplosegments, and third bears the gonopores; simple eyes (ocelli) present or absent; 2 mm–28 cm; about 10,000 living species.

Class Pauropoda

Antennae branched; a pair of maxillae; 9–11 trunk segments bearing legs; gonopores on third trunk segment as in diplopods; 0.5–1.5 mm; about 500 described species.

Class Insecta

Body composed of a head, thorax, and abdomen; head bears simple eyes and usually a pair of lateral compound eyes; 2 pairs of maxillae, the second pair fused (labium); thorax of 3 segments, each with a pair of legs, and the second and third usually bearing wings; abdomen of 11 segments without appendages in the adult; gonopore at end of abdomen; 0.25 mm–33 cm; about 751,000 described species.

Critical appraisal. The classification adopted above is the most widely accepted system and the one followed in *Synopsis and Classification of Living Organisms* edited by Sybil P. Parker. An older and frequently encountered system unites all of the mandibulate arthropods (crustaceans and uniramians) within one subphylum, the Mandibulata, but since crustaceans and uniramians are now believed to constitute independent lines of evolution, the Mandibulata is an artificial taxon. If the four major lines of arthropod evolution—trilobites, chelicerates, crustaceans, and uniramians—evolved independently from annelidan ancestors, then each should constitute a separate phylum and the Arthropoda, a superphylum.

Most zoologists agree that the myriapod classes, which contain the uniramians with long trunks, are related to insects, but the precise interrelationships of these five classes are still unknown. Members of the phylum Onychophora, caterpillar-like animals of the tropics and the Southern Hemisphere, are believed to be near the ancestors of the uniramians, and they are sometimes included within the Arthropoda. Onychophorans, however, lack a well-developed exoskeleton, the most basic feature of the phylum.

Members of the phylum Tardigrada, called water bears, are microscopic animals living in algae, soil, and moss. Although they have sometimes been included within the Arthropoda, the similarity to arthropods is probably superficial, and they are relegated to a separate phylum by most zoologists. Another group sometimes called an arthropod subphylum or class is the Pentastomida (Linguatulida), wormlike parasites that live in the lungs, gut, and coelom of reptiles, birds, and mammals. The body is ringed, and there is no chitinous exoskeleton; on the side of the head are four hooks, but the mouth region lacks jaws and other appendages. These peculiarities are undoubtedly related to their endoparasitic habit; if they are aberrant arthropods, their relationship to the other classes is uncertain.

BIBLIOGRAPHY. Introductory texts include ROBERT D. BARNES, *Invertebrate Zoology,* 5th ed. (1987); VICKI PEARSE *et al., Living Invertebrates* (1987); RICHARD S. BOARDMAN, ALAN H. CHEETHAM, and ALBERT J. ROWELL (eds.), *Fossil Invertebrates* (1987); ALFRED KAESTNER, *Invertebrate Zoology,* vol. 2 and 3, trans. from German and adapted by HERBERT W. and LORNA R. LEVI (1968–70); "Arthropoda," in SYBIL P. PARKER (ed.), *Synopsis and Classification of Living Organisms,* vol. 2 (1982), pp. 71–728, taxonomic classifications; and FRIEDRICH SCHALLER, *Soil Animals* (1968; originally published in German, 1962). Advanced treatments of arthropod characteristics include KENNETH U. CLARKE, *The Biology of the Arthropoda* (1973), emphasizing the unity of functions among arthropods; CLYDE F. HERREID II and CHARLES R. FOURTNER (eds.), *Locomotion and Energetics in Arthropods* (1981); ANTHONY C. NEVILLE, *Biology of the Arthropod Cuticle* (1975), on the phylogeny, physical properties, and physiology of cuticle; and J. BEREITER-HAHN, A.G. MATOLTSKY, and K. SYLVIA RICHARDS (eds.), *Biology of the Integument* (1984), vol. 1, *Invertebrates,* with several chapters on the arthropod integument. Opposing viewpoints on the evolution of arthropods are presented by H. BRUCE BOUDREAUX, *Arthropod Phylogeny with Special Reference to Insects* (1979), favouring a monophyletic or single-ancestor origin; and S.M. MANTON, *The Arthropoda: Habits, Functional Morphology, and Evolution* (1977), taking a polyphyletic origin.

(R.D.Ba.)

Classification of the Arts

As long as the name arts is given to a realm so vast and indefinite as to embrace literature, music and dance, theatre and film, the visual and decorative arts, and other equally diverse activities, their classification—the ways in which each is regarded as being either unique or like others—will remain a controversial but necessary undertaking. Classification is a useful approach to the organization of knowledge in any field: the classification of plants and animals in the 18th century led to the discovery of evolution in the 19th. In the arts, classification can be of immense help in understanding the interrelations between the arts and in drawing attention to characteristics of each that might otherwise go unnoticed. Whether it is consciously devised or largely unconscious, some sort of classification is implicit in any serious exploration of the arts. Related to it is an appraisal of the importance and value of each of the arts. Admirers of a particular art often feel that it is unique and deny that it is like any other. Logically, however, anything correctly described as a work of art, whether a poem, a picture, or a sonata, belongs to that class and hence resembles other members of the class to some extent. Some works or types of art are more nearly unique than others in resembling fewer others or in resembling others in fewer respects. On the other hand, no type or example is exactly like any other, but the differences may be negligible for all practical purposes.

There is no one correct way of making a classification. The aims and interests of the person making the classification, and his philosophical orientation, are usually significant factors. The emphasis may be placed on sensory qualities, for example, or on moral and religious ideals. Regardless what classification is used, however, as it is subdivided into smaller groups, detailed similarities and differences are brought out in the emotional, intellectual, and social features of the works or art involved.

The classification of the arts is closely related to subjects that receive more extensive treatment in the articles AESTHETICS; PHILOSOPHIES OF THE BRANCHES OF KNOWLEDGE; and ARTS, CRITICISM OF THE. Discussions of specific classification systems are in ARTS, STYLE IN THE; FOLK ARTS; and ARTS, PRACTICE AND PROFESSION OF THE. The relationship between the arts within a given culture is discussed in SOUTH ASIAN ARTS and comparable articles on the arts of other peoples.

The article that follows will attempt only to draw the reader's attention to the importance of the subject of classification in the study of the arts and to offer him means of applying thoughtful scrutiny to a process that has too often remained subconscious.

It is divided into the following sections:

BASES OF CLASSIFICATION

To classify things is to arrange them in groups or sequences according to a plan, especially on the basis of some characteristic that they are thought to have in common. Thus, the names in a directory may be arranged according to the letter of the alphabet with which each last name begins. A biologist classifies the kinds of animal or

plant within a certain area. A museum of art may place its sculptures in one gallery, its paintings in another. It may also classify them according to historical period, such as Italian Renaissance or 18th-century French.

A base or basis of classification is a concept of what the members of a certain class are thought to have in common, a factor that can be used either for grouping them or for separating them from other classes. "Subject represented" is one such base: it may be used to separate "paintings" into three or more groups, such as portraits, landscapes, and narrative scenes. This involves classification in a narrow sense; that is, as grouping items or subgroups together under certain headings. It also involves division, which can be regarded as the opposite of classification, but the latter is usually made to cover both processes. A large, complex art such as literature can be divided into smaller ones, such as poetry and prose. Each of these also can be subdivided, as into epic, dramatic, and lyric poetry. A relatively complex, detailed division and classification of the arts from a philosophic point of view is called a system of the arts.

Taxonomy in the arts

The study and scientific practice of classifying phenomena in an extensive field is called taxonomy. In biology and other exact sciences, it is highly complex and consistent, with precise definitions. Thus a "genus" in biology comes between a "family" and a "species." In classifying arts, however, such terms are used more loosely. Thus, genus can mean, in aesthetics, any fairly large, inclusive group, capable of including subgroups and also of being subsumed under a still larger group. A species, in the broad sense, is one of the main divisions of a genus, and the traits or characteristics of a genus are generic traits. Differentiae are ways in which individuals or subgroups in a larger group are significantly unlike. Aristotle distinguishes between epics and tragedies in poetry in terms of differentiae.

To define or locate a particular example or subgroup in a system of classification, it must be ascertained, first, what genus (inclusive group) or genera it belongs to and then how it differs from others in that group or groups. A species is one of the main divisions of a genus, but it may also act as a genus (in the broader sense of that word) by including smaller groups.

Problems of definition. What are the arts, and what is art in general? This is still a controversial question after centuries of debate. No particular definition commands universal assent. Several meanings are still frequently used, of which the oldest is the broad, technical sense. In this sense, the English word art and its equivalents in Greek and Latin covered not only what are now called "fine arts" or "aesthetic arts" but any kind of transmitted, useful skill, such as agriculture, medicine, and war. This sense of "art" survives in such terms as Bachelor of Arts, a degree that is often awarded for a course of study that involves no aesthetic arts at all.

In the 18th century, the so-called beaux arts, the beautiful or high arts (also called "elegant" or "polite" arts), were distinguished from the merely useful arts on the ground that they were aimed at giving aesthetic pleasure to the beholder. In the 19th and 20th centuries, there has been a tendency to abandon the name art in speaking of the purely utilitarian skills and to call them instead "industries," "technics," "branches of engineering," or "applied sciences." Without the prefix fine, the word art alone is now commonly understood to mean the fine or aesthetic arts. To produce an experience of beauty or aesthetic satisfaction is said to be their distinguishing function or characteristic but not necessarily their only one. In this moderately broad, technical sense, some, but not all, architecture, furniture, and clothing can qualify as arts in spite of their useful purposes. They can be called useful arts, rather than merely useful skills, because they combine aesthetic and utilitarian forms and functions. On the other hand, such technics as coal mining and placing metal pipes underground do not qualify as arts at all, since they do not ordinarily involve aesthetic perception.

In psychology, anthropology, and other sciences, a particular product or performance does not have to be beautiful or aesthetically satisfying to qualify as art. The same can be said of much primitive art, children's art, and art produced by the insane. They may be classed as art if they belong to types of product or performance that have been socially recognized as having an aesthetic function. In this sense, any picture, clay figure, dance, or traditional song can be accepted as a work of art, whether beautiful or not. Being nonevaluative, this conception makes it possible for the scientist to study the arts as a field of cultural phenomena for investigation, without having to show in advance that they are pleasant, good, or beautiful.

In another sense of "art," called the expressionist theory, art has been defined as the expression and transmission of remembered emotion. This definition is not inconsistent with the technical meanings, but it puts an emphasis on the artist's procedure rather than on the effects and functions of the product.

In a third sense (an extremely narrow one), the concept of art is limited to painting and drawing alone, sometimes to the visual arts alone. This definition has the disadvantage of excluding music, poetry, dance, and many other arts that have long been recognized as "fine" or "aesthetic." It is confusing in that painting and the other visual, manual arts were themselves long excluded from the category of "liberal arts."

Decorative and industrial arts

The decorative arts are a species of visual art whose main function is to combine utility with beauty or aesthetic satisfaction. They tend to emphasize visual ornamentation and design along with fitness for some useful end or ends. Although Western painting and sculpture in the past traditionally tended to emphasize representation, the decorative arts used both abstract and representational design. Utility, design, and representation appear with varying degrees of emphasis in such arts as medieval book illumination, jewelry, Greek or Chinese vase painting, Persian rugs, and French rococo furniture. Some styles of decorative art are comparatively plain and simple in order to achieve an effect of visual design without superficial ornament.

Ironworking is usually classed as an industry not an art, because most of its activity is devoted to products that have no aesthetic intent. A small branch of the industry, however, may be devoted to making decorative designs in iron and steel, perhaps for use in architecture. This branch may be called a useful art or a decorative art; the two categories overlap. If old-fashioned hand methods are used there, the term handicraft is also applicable.

The term industrial art is now applied chiefly to arts in which machinery and mass production are commonly employed, with many specialized workers cooperating, as in motion pictures. It may be applied to the process of making large numbers of colour-print reproductions from paintings. Such art used for advertising, however, as in newspaper layouts and street posters, is called "commercial art." The industrial arts include many types of large-scale manufacture in which an aesthetic appeal is sought, as in the manufacture of books, magazines, refrigerators, typewriters, furniture, television sets, automobiles, airplanes, or appliances. The aesthetic factor in such work is sometimes called "styling."

Bases in status. Until the 18th century, the most common basis for classifying the arts was in terms of their social and psychological status. This system, which was devised by the ancient Greek philosophers, involved a wide separation between the so-called liberal and servile arts. In ancient Greece and Rome, the liberal arts were conceived as: (1) those that befitted a freeman and were thus comparatively noble, aristocratic, or genteel; (2) those requiring the exercise of superior mental ability, rather than mere hand labour, however skillful; and (3) those tending to elevate the minds of the artist and of his patrons, rather than merely providing material comforts, pleasures, and conveniences. The servile arts were those befitting only a person of a lower class, at least as far as the work itself was concerned. It was beneath the dignity of a lady or gentleman to work in them but not to use and enjoy such products. For the wealthy aristocrat, even to practice painting as a hobby exposed him to ridicule. Aristotle notes that even if the gentleman practices music for his own pleasure, he should not do it too well.

Liberal and servile arts

From the medieval period through the Renaissance, the

class distinction between liberal and servile was retained in modified form. The "seven liberal arts" of the Middle Ages were composed of the trivium, or literary group—consisting of grammar, dialectic, and rhetoric—and the quadrivium, or mathematical group—consisting of arithmetic, geometry, music, and astronomy. Music was theoretical in emphasis, with little attention to its sound and much to the numerical relations among the tones. In the 12th century, literature, including poetry, tales, and dramas, was classed as a mere supplement or aid to philosophy. Modern taste admires the visual arts of the Middle Ages, but many churchmen and philosophers of the time condemned them as sensuous, perhaps idolatrous. The artist in a material medium such as stone or metal was low in social status until well along in the Renaissance.

In and after the Renaissance, art was conceived as being more hedonistic, more devoted to providing aesthetic pleasure through the sensuous perception of beautiful forms. This conception partly replaced the emphasis on moral and intellectual qualities in the ancient Greek and Roman traditions. The manual arts of decoration and design gradually rose in prestige, along with the arts of music, poetry, ballet, and theatre. Visual artists in such media as architecture, landscape, design, and pageantry gained in respect and in financial rewards. High status in them depended more on success in pleasing a luxury-loving aristocracy than on moral and intellectual virtues. But some philosophers urged that art at its best combines both sets of values.

Elite and popular arts

A hint of social status persists today in the distinction between "elite" and "popular" art, which includes products of the "mass media" such as film, newspaper and magazine illustration, radio, and television. But this distinction refers more to the level of taste and education supposedly required to appreciate these arts, and to their different publics, than to social or financial status.

Certain arts have been grouped from time to time as "lively," suggesting animation and gaiety, in contrast with the supposed solemnity of classical, "highbrow" art. Such arts are, on the whole, suited to popular taste, though often appealing also to the scholarly. They often are easy to grasp and involve a simple narrative. The comic strip is static, but it suggests movement, often playfully exaggerated into mock violence. Some, but not all, lively arts involve directly presented motion, as in the film, which has rapidly ascended from a popular to a serious art. At its best, it can achieve all types of aesthetic value, including emotional expression, character, and plot, but it does not always try to avoid banality.

Major and minor arts

The antithesis between "major" and "minor" arts is partly dependent on the social status and cultural context of the arts concerned, though it is often mentioned as if certain arts were inherently and permanently greater than others. The ground of superiority of an art, according to some philosophers, is its greater ability to express thoughts and feelings of universal, lasting value. Poetry and other forms of literature have been regarded as superior in this respect to the decorative arts, which were associated with superficial, thoughtless luxuries. As the decorative and useful arts rose in critical esteem, however, a tendency to reject these evaluations has become evident. A Persian rug or a sonata, it is said, is not necessarily inferior in aesthetic, moral, or spiritual values to a poem, play, or novel. Its value depends on what it does in its own medium. What seems at first to be mere trivial ornament may have deep, symbolic meanings for the culture in which it originated. Certainly the relative size of the products provides no sure measure of value, as, for instance, between a badly designed cathedral and a well-designed miniature painting. The major–minor antithesis may be useful if applied to the relative status of an art in its own cultural context. The status of an art may change within a culture and differ widely from one culture to another. Tattooing has been a major art in some primitive cultures, notably among the Maori people of New Zealand. Mosaic was a major art in Byzantine culture. Poetry, for the present, has declined in importance in Western civilization. The creative energies of man flow at different times through different channels.

Mode of presentation as a base. One way to avoid questions of value in a descriptive classification of the arts is to use as a base the concept of the sense to which the work is primarily addressed, instead of fineness or beauty. Painting, sculpture, and architecture are said to be addressed primarily to the sense of vision; hence they are now increasingly known as "visual arts." Music is an "auditory" art. Opera and sound film with colour are "audiovisual." An armchair is addressed not only to vision but also to the sense of touch and to muscular sensations of comfort and fitness for the posture or range of postures desired. Thus, a throne, a theatre seat, and a dentist's chair will have somewhat different forms and functions. From the aesthetic standpoint, the visual characteristics of physical objects are usually emphasized. Some philosophers have pursued this approach into the realm of "lower senses," providing for the "gustatory" art of cuisine and the "olfactory" art of smell, as in perfume and ritual incense.

Painting is one species of visual art, and it can be subdivided in various ways. One is according to style, such as baroque or romantic. Another is based on the amount of representation, whether the work is realistic, abstract, or nonobjective. The words abstract and nonobjective are sometimes used interchangeably, to mean nonrepresentational or intentionally devoid of resemblance to any outside object. At other times, an abstract painting is said to be one that started with a representational conception but omitted some or all its representational details, while a nonobjective picture is one conceived and executed from the beginning in terms of lines and colours without any definite outside reference.

Abstract and nonobjective art

Painting can also be divided according to the subject represented; that is, into portraiture, landscape, fantasy, and so on. Some paintings are colouristic in style; others are linear. Some emphasize perspective, with imaginary vistas into deep space. The other arts can be similarly divided; narrative literature can be in prose or verse; prose narrative can be divided into novels, short stories, and so on.

Poetry is sometimes presented aurally, as in speaking it aloud; at other times, visually, as in reading it silently; at still other times, tactually, as in reading Braille type for the blind. In opera, poetry is presented audiovisually. Originally, when few persons could read, it was presented to the sense of hearing. Now, it is more often read silently. A poem is fundamentally the same whether read silently or heard. In reading it silently, the word sounds are imagined rather than heard. For purposes of classification, the art of poetry may be described as primarily auditory, but now, often visual or audiovisual; in short, it is variable.

The "performing arts" are so designated because of the ways in which they are presented to the attention of observers. Most of the visual arts perform automatically, so to speak. The artist who created the painting or statue did his performing once and for all time, when he made it. There is a temporal sequence in perceiving any complex, three-dimensional work of art, especially a large one such as a cathedral, since the observer must walk around it and perhaps inside it in order to see it fully as a three-dimensional form. The form itself may change in appearance from moment to moment, through changes in sunshine, atmosphere, and shadows. Such changes are usually considered to be indeterminate and superficial, however, not enough to characterize the work of art itself as mobile. In mobile sculpture, such as that of the modern American Alexander Calder, the form as a whole changes in accord with air currents and other pressures from outside. Unless moved in a definite way, as by a motor, the succession of arrangements in mobile sculpture is somewhat indeterminate.

Mobile and static arts

Arts in which the objects do not ordinarily have to move or change radically in order to be properly observed have been called "static arts," "space arts," or "arts of rest," in contrast with "mobile," "dynamic," or "time" arts such as music and dance. Some arts, notably cinema and ballet, unfold actively in both space and time. In cinema, the product—the film projected on the screen—is made to perform automatically; the operator does not have to influence the showing unless something goes wrong. The main performance was done permanently in the photographing, editing, and other processes involved in produc-

ing it. Much the same can be said of a phonograph record or tape, since the performance was completed by the musician before the record was made or marketed. Slight adjustments in tone, balance, volume, and the like may be required at the start; after that, the record performs automatically.

What is meant in speaking of "performing arts," however, is, for example, what the actor does in speaking his lines and moving or gesturing as directed, what the musician does in playing a certain sonata on his piano or violin, and what the dancer does in moving his body as required by the choreography. In these examples, there is usually a set of directions, prepared by the designer, the creative artist or group of artists, and made available to the performer. As a rule such directions allow some scope for original interpretation or minor departures from the score, so that the performance is not purely automatic. Different performances of the same script or printed score may vary considerably as to nuances of expression and yet be recognizable as renditions of the same composition. Such variations help to distinguish an original interpretation (good or bad) from a merely mechanical reproduction. Of course, a creative performer may at times compose his own score or improvise without the aid of any directions.

Early theories contrasted "arts of motion" with "arts of rest" and put painting in the latter category. With the advent of the film, especially such works as Walt Disney's "animated cartoons" in colour, photography and painting began their rapid development as arts of time. They are now arts of both space and time, rest and motion. This development illustrates the need for flexibility in classification, to allow for the accelerating evolution and unpredictable variation of the arts.

Arts in which works are shown or sounded in a definite temporal sequence tend to acquire an appropriate notation to guide that sequence. Chief among these are the performing arts of spoken literature (especially poetry and drama), music, dance, pantomime, and other temporal arts of the theatre. Stage design, costume, and lighting are sometimes classed as theatre arts but are not necessarily shown in temporal order.

The first notation of art

Poetry was the first art for which a definite notation, that of writing and literature in general, was developed. As sung or recited by the ancient bards, poetry left a great deal to be supplied by tradition and individual taste. Indications of rhythmic variation—by separating lines, sentences, and phrases with the aid of punctuation, capital letters, and italics—were slowly developed. Some of the earliest musical notation consisted of a few conventional marks above the words of a poem. Dance steps, which were simple and regulated by tradition with the aid of music in songs and rituals, remained long without notation.

The notations of music, from the Renaissance to the mid-20th century, became very precise in directing pitch, melody, chord structure and progression, rhythm, metre, phrasing, dynamics (loud and soft), and many nuances of expression. Because of its scope, precision, and adaptability to many styles of music, the printed score was widely used as a framework for forms that combined music with words, such as song, cantata, oratorio, or opera. It was found impossible, however, to record Oriental, primitive, and other exotic styles of music and dance in Western musical notation. Such music includes pitches that cannot be precisely indicated in Western scales; its rhythms tend to overflow European bar lines, and the timbres of its instruments and voices cannot be exactly described in conventional Western notation. Such limitations were even more keenly felt as Western avant-garde composers sought to use a great variety of sounds, instrumental and otherwise, that had not been previously used in serious music—sounds of nature, city life and countryside, birdsongs and traffic noises, flowing water, thunder and lightning, and many new sounds derived from electronic machinery. In music of the 20th century, timbre and tone quality tended to be emphasized rather than conventional melodic and chordal progressions. Timbre, rather than rhythm or pitch, became the principal component of experimental music. Physical scientists cooperated with composers in adapting the new knowledge of electronic sound to music.

For the dance also, conventional musical notation came in the 20th century to seem less than adequate for guiding movements. Traditionally, the mobile designs of dance had been based on a set of conventional postures and movements, mostly devised in the 18th century. Light and graceful whirls, leaps, and glides on tiptoe could be fairly well symbolized in a simple choreographic notation, which is still used to some extent in traditional solo dance and ballet. As in music, however, style leaders felt the need of a more flexible notation, capable of recording new types of emotional expression.

Another motive for breaking with the past in this regard was the feeling that dance should not be a handmaid to music or limited to expressing musical forms and feelings in bodily movement. Experiments were tried in dancing without music or with rhythm alone, and new bases were sought for recording the moods and movements of the dance in visual symbols.

Imperfections of notation

It would be unreasonable to expect a perfect notation in so complex an art as modern ballet. Even in such a long established notation as the printing of poetry, many qualities—*e.g.*, tempo—cannot be specified. Verbal notation is always incomplete, partly because both poet and reader usually prefer to have much of the word-sound content, along with other meanings, left to the imagination. Printed words are enough to start the reader on an approximate path toward understanding. The sound film and the phonograph offer new, partial substitutes for printed notation as guides to performing the temporal arts.

Other types of base. Three main types of base for classification and division of the arts may be distinguished. They may also serve as aids in defining particular arts or be combined into one system of the arts.

The first is that of medium or material. It is used in the names of such arts as painting, metalwork, woodcarving, jewelry, and ceramics. These refer to the physical materials out of which the work of art is made. Sound waves in music and light waves in cinema are also physical media. Tools and instruments, such as pianos, voices, brushes and canvas, chisels and marble, the human body (as in dance), are all distinctive materials of the various arts. Perceptual qualities such as rhythm, pitch, and colour are parts of the medium of sound film. Poetry also uses rhythm.

The second type of base is that of the process or technic employed, for example, the hands or other parts of the body, or instruments or machines, such as the cameras and projectors used in motion pictures. Shaping, sounding, and verbalizing are three main types of artistic process. They often overlap and combine in various arts.

When photography is conceived merely in terms of operating a camera, it is a medium of art rather than an art itself. It can be used either for purposes of art, as a scientific instrument, as a means of recreation, or in other ways. It approaches art when used as a device for giving someone an aesthetic, visual experience by means of the resultant picture.

Some technics are overt, as in dance, employing the whole body; others are mental and inner, as in memorizing a dramatic role. Some artistic skills are professional or managerial, some mechanical or manual. An architect plans and oversees the construction of buildings and the making of plans and specifications. A landscape architect works with plants, roads, levels of ground, hills and valleys, roads, lawns, bridges, and sprinkler systems. An author may do little that is overt muscular work but much dictating or typewriting.

Some art production is solitary, some cooperative. Some emphasizes visual shaping; some sounding; some verbalizing, usually organizing words and meanings approximately in accord with the rules of grammar and syntax in the language employed.

The third type of base is that of the form, design, and functions of the product, including its function as an aesthetic object; that is, as a stimulus to aesthetic perception and imagination. Arts can be grouped or distinguished as to the amount of emphasis on the following: (1) Presentative (*i.e.*, directly perceptible) and suggestive factors; (2) modes of suggestion (*e.g.*, mimesis symbolism, common association); (3) components in aesthetic form (*e.g.*, melo-

Types of formal emphasis

dy, harmony, rhythm, perspective, plot, characterization); and (4) modes of composition: utilitarian (*e.g.,* as church or palace), representational (*e.g.,* narrative, dramatic, lyric), expository (*e.g.,* essay, symbolic picture), or thematic design (*e.g.,* fugue, sonata, Persian rug, sonnet).

HISTORICAL DEVELOPMENT

In European philosophy, the classification of the arts, or "system" of the arts as it is usually called, has formed an integral part not only of the philosophy of art but of philosophic systems in general. This has been especially true since the work of the late 18th-century German philosopher Immanuel Kant. European philosophers have not limited themselves to making superficial, verbal arrangements but have undertaken to show the role of each art in the mind of man, in world history, and in civilization. A system of the arts may also be used in an attempt to evaluate the arts and to list them in a hierarchy according to their metaphysical and moral roles. In the Western democracies, the classification of the arts has usually been given a more modest, secondary role in philosophy, limited to showing empirical relations.

Thinkers as different as Saint Augustine of Hippo (AD 354–430), one of the chief influences in Christian thought, and Francis Bacon (1561–1626), the English philosopher who was instrumental in the development of modern science, felt the need of a systematic survey of the aesthetic arts as part of a general survey of human knowledge and experience. Separated by more than 1,000 years, Augustine and Bacon disagreed on the value of worldly knowledge obtained through empirical science. Augustine disapproved of such knowledge, while Bacon approved of it. Looking back over his youth, Augustine found much to regret and repent in the pleasures afforded by the various arts to the five senses. Bacon, in his monumental survey the *Advancement of Learning,* admired the progress of the sciences and foresaw their future benefits to man; to poetry, painting, and music he gave a fairly high place, but in the "voluptuary arts," which appeal to the lower senses, he found little to praise.

Kant, writing toward the end of the 18th century, covered the field in a tolerant, empirical way, avoiding moral and metaphysical dogmatism. Beginning with "art" in general (in the broad, technical sense including all transmitted human skill), he distinguished it from nature, science, and paid handicrafts. He then distinguished between aesthetic art and mechanical art, the first of which he subdivided into fine, or beautiful, art and agreeable, or pleasant, art. His division of fine art into the arts of speech, the shaping arts, and the arts involving the beautiful play of sensations led him eventually to further subdivisions into poetry, music, landscape gardening, the art of colour, buildings, and furniture. Under agreeable art, he assigned a place for dinner music, table arrangement, and entertaining narrative.

Georg Wilhelm Friedrich Hegel (1770–1831), another German philosopher who was vitally concerned with the arts, offered a system combining the ancient Greek philosophical conception of a cosmic mind (which embraced all man recognizes as reality) with the theory of evolution. In the world process envisaged in his scheme, he assigned an important role to the arts: architecture is most capable of expressing the early, symbolic stage in world history; sculpture, the classic stage; painting, music, and poetry, the romantic stage.

The symbolic, classical, and romantic stages

The article on the Fine Arts, in the 11th edition of the *Encyclopædia Britannica* (1910–11), by the English man of letters Sir Sidney Colvin, is one of the few attempts in English to deal with the subject in a detailed, systematic way. He proposed three main divisions: the first, into shaping, moving, and speaking arts; the second, into imitative and nonimitative arts; and the third, into serviceable and nonserviceable arts. This triple division expressed Colvin's belief that no one formula could adequately describe the manifold interrelations of the arts.

On the other hand, Max Dessoir, a leading German aesthetician in the first part of the 20th century, tried to combine several bases in one pattern. In his construct, space and time arts are arranged in two vertical columns, with sculpture, painting, architecture, and plastic arts listed under "space" and mimicry, poetry, music, and poetic arts under "time." A third parallel column contrasts the arts "of imitation and definite associations" with the "free arts of indefinite associations." He commits the same error that many previous writers made in supposing that the space arts coincide with the arts of rest and the time arts with the arts of movement and succession and that sculpture and painting are necessarily imitative (*i.e.,* representational). He did not recognize the extent to which the traditional arts had changed, making new modes of classification necessary.

Instead of rectangular diagrams, Étienne Souriau, a French aesthetician of the mid-20th century, offered a wheel-shaped one. By means of this form, he showed how seven basic types of perceptible data (lines, volumes, colours, sounds, and so forth) were developed into complex arts. Using concentric circles, he showed how each type of datum developed into a nonrepresentational and a representational art. Though no such diagram can offer a complete picture, Souriau presents a large number of interrelations in a simple pattern.

BIBLIOGRAPHY. ST. AUGUSTINE, *Confessions,* trans. by E.B. PUSEY, pp. 223–239 (1838), one of the earliest extant classifications of the arts, was made in disapproving of them on moral and religious grounds; FRANCIS BACON, *De Augmentis Scientiarum,* is an enlargement in Latin of *The Advancement of Learning,* bk. 2, ch. 1, vol. 4 of *The Works of Francis Bacon* (1858), a profound, far-reaching survey of the state of science and technology in the early 17th century, which includes a short classification of the arts; SIDNEY COLVIN, "Fine Arts," in *Encyclopædia Britannica,* 11th ed., vol. 10, pp. 355–375 (1910–11), is one of the few attempts in English at a detailed, systematic classification of the arts on various grounds; MAX DESSOIR, *Ästhetik und allgemeine Kunstwissenschaft* (1906; Eng. trans. by S.A. EMERY, *Aesthetics and Theory of Art,* 1970), is a system of the arts reduced to a short, neat pattern, by a leading German aesthetician; G.W.F. HEGEL, *Vorlesungen über die Aesthetik,* trans. by F.P.B. OSMASTON, *Philosophy of Fine Art: Introduction* (1920), is a system that is remarkable for its cosmic breadth; IMMANUEL KANT, *Kritik der Urteilskraft,* part of this work trans. by J.C. MEREDITH as *Critique of Aesthetic Judgment* (1911), is a pre-evolutionary empirical system, based on common sense and broadly tolerant toward the many manifestations of art in his time; THOMAS MUNRO, *The Arts and Their Interrelations,* rev. ed. (1967), is a critical survey of the various classifications of the arts up to the mid-20th century, with reference to more than 400 arts and types of art; *Oriental Aesthetics* (1965), on types and classifications of the arts in India, China, and Japan; and ETIENNE SOURIAU, *La Correspondance des arts* (1947): a wheel-shaped diagram exhibits the system of the arts from a modern French point of view.

(Th.M.)

Criticism of the Arts

Criticism of literature, of music, of the visual arts, or of any other of the arts can be a controversial enterprise. For one thing, disputes arise about the purpose and nature of the judgments made by critics; for another, disputes arise about the nature and properties of what it is that critics discuss—the works of art themselves; and for still another, disputes arise about the possibility of generalizing about *all* the arts, each of which differs significantly from the others in many respects.

Each of these disputes is really a complex cluster, involving nearly all of the persistent issues involved in the practice of criticism. Although this article cannot pursue all of these issues, it will attempt to provide an orientation that will facilitate their investigation.

The article is divided into the following sections:

THE NATURE OF AESTHETIC CRITICISM

The concerns of the critic. It may be safely said that criticism in all the arts is concerned with the description and assessment of particular works. Although some hold that the critic's proper function is only the appraisal or evaluation of works of art, it is certain that nothing can be evaluated unless it is describable beforehand. Accuracy of description can in fact be so extremely difficult, particularly for complex or unfamiliar works and traditions, that some critics devote their efforts largely to matters of a descriptive sort.

It may also be said that all critics of the arts are concerned with the description and evaluation of works of art *as works of art,* even if they are more interested in moral, political, religious, ideological, or other considerations. For example, the moral criticism of works of art presupposes that the actual properties and features of a given work first may be fixed and then may be examined further according to moral considerations. Similarly, religious, political, or other considerations can only follow some relatively objective determination of what it is that is being examined. It is in this sense that criticism of the arts is primarily aesthetic. Although the objectivity of a description or an evaluation may be argued, as well as the propriety of concentrating on only the aesthetic aspects of a work, the central point is not open to dispute; *if* given works of art are to be appraised on any grounds, they must be independently describable beforehand. One cannot judge what one cannot identify and describe.

Primacy of aesthetic issues

The properties of works of art. Quarrels also arise about what may rightly be construed as the properties of works of art. For example, to say that a novel *expresses* a certain Gothic longing or that a painting *symbolizes* the end of feudalism or that a work of sculpture *represents* a bird in flight presupposes some theory of what a work of art is. The object cannot be described truthfully unless it is of a sort that can exhibit the properties ascribed, and quarrels often arise about what may rightly be construed as the properties of works of art as such. To see this is to see the sense in which descriptive statements are theory-laden. The theory of criticism and the theory of the nature of a work of art are largely aspects of the same question.

Provisionally, then, the criticism of works of art may be considered, at least minimally, as aesthetic criticism—that is, centred on the actual properties of the works considered. Correspondingly, appreciation of art may be said to be aesthetic when the art is savoured or enjoyed in terms of the properties that may be discriminated in it. Appreciation, in this sense of the term, may be informed by criticism, since both are focussed on the same properties. This point should be emphasized because it has been held by Leo Tolstoy and others that a genuine appreciation of art must be a naïve, direct, or uninformed response. If serious thought and labour go into the creation of works of art, however, there is no reason why a similar effort will not be needed to appreciate or criticize them.

Identifying and describing works of art. The crucial conceptual issues in criticism of the arts are what is meant by a work of art and how its properties may be ascertained. The difficulties involved in these issues are principally of two sorts. One concerns the identity and individuation of works of art. For example, different performances of the same piece of music may be perceived to differ from one another. A given piece may be transposed for different instruments, or it may be performed on instruments that have been modified since the date of composition, and performances by different artists will regularly exhibit noticeably different qualities. Nevertheless, it is normally considered one and the same piece of music as long as it is identified by reference to a particular score, even though aesthetically there may be more interest in the subtle variations in the performances than in what they have in common. Some critics hold that all distinct performances must be compatible with some ideal performance or that all admissible performances must correspond to the fundamental score, and deviations from it result in serious logical paradoxes. It does seem possible, however, to admit as instances of the same work performances so different from each other as to appear incompatible with any idealized performance.

The same conclusion may be drawn for all the arts that rely on a notational scheme. Variant versions of a poem, for example, may count as instances of the same poem, and analogous instances may be found in theatre, dance, film, and in view of the increasing importance of the blueprint, architecture. Analogies may be found in the plastic arts as well.

The referent of criticism

It is important to emphasize that an entire range of questions regarding the objectivity of criticism rests on puzzles respecting the referent of criticism. Both in describing and in evaluating particular works, it must be made clear whether different versions of the same work of art or several distinct works of art are being discussed. Identity may sometimes be established by detailed analysis, for example, by providing evidence on notational and cultural grounds that what seemed to be different folk songs may be construed as variant versions of the same song.

The principal issues of criticism concern not the identification of works of art but their description and evaluation. It is not possible to segregate entirely what may be correctly said about a given work of art and what it is that individuates that work of art—that is, makes it a distinct entity within a class of related entities.

To illustrate this point, imagine that the central image of a given work may be construed in two radically different ways. Some of Anton Chekhov's plays, for example, may be construed as either comedies or tragedies, depending on whether the views of the author or those of the director Konstantin Stanislavsky are preferred. If the possibility of such competing views be admitted (even though the mere admission of them presupposes a certain theory of criticism), then any account of what a critic does must accommodate this possibility.

When critics say what a certain image means and their

(defensible) accounts conflict with each other, it is clear that they cannot be *describing* the work at hand. It should be possible to confirm a description by an independent study of the object described. Obviously, it is not possible to confirm descriptions that are incompatible.

It might be argued that the differences in conflicting critical accounts are merely apparent, as a coin might be described as circular from one view and elliptical from another. To resolve such an apparent difference in a physical object like a coin, one could invoke some commonly accepted canon such as saying that when it is seen "under normal circumstances" the differences disappear. In criticism of the arts, however, there is no such common canon in terms of which the competing views may be sorted. Moreover, in some schools of criticism, such conflicting views would not be ruled out as impossible.

Interpreting works of art. The solution is to distinguish between *describing* works of art and *interpreting* works of art: a critic's description may be true or false of the work in question, but his interpretation of the work can be only plausible or implausible. Each of several incompatible interpretations may be plausible, but they cannot all be true. In rendering an interpretation of a work of art, then, the critic must be imputing to it properties that cannot with certainty be found in it. This view of critical practice implies a theory of the nature of a work of art that allows some properties to be considered either truly in the work or only plausibly imputed to it.

Distinction between description and interpretation

A substantial body of criticism is intelligible only if the critics who purport to be describing given works—incorporating analysis, comparison, historical or biographical explanation, and the like—are, to some extent at least, interpreting those works. The enormous body of criticism of the greatest poetry, drama, and fiction shows how dissimilar the apparently descriptive efforts of critics may be. The mere existence of this vast body of diverse views would appear to refute the claim that interpretation is merely the unearthing of what is descriptively true of a work of art. It may include this but it must be more.

Interpretive criticism would be unintelligible without a counterpart theory of the nature of a work of art. The key to that theory lies in not confusing works of art with the physical objects associated with them. Physical objects having different physical properties cannot be the same object. As has been noted, however, works of art with different physical properties, and even critical aesthetic differences, may count as instances of the same work of art. This fact is most easily seen in literature, drama, music, and, to some extent, dance and architecture, arts in which the identity of a given work depends on some notational system. It is less easily seen in the visual arts, even though different tokens of the same work, as in etching, may be admitted there too. Clearly, then, works of art are individuated in ways that substantially depart from those of physical objects and in ways that vary from art to art.

A further consideration is that a work of art is a purposive system, whose internal organization may be seen to reflect the systematic decisions of the artist. Criticism explicates this purposive organization, and critics are sometimes obliged to impute a design to a work of art rather than merely to find it inhering in the work. Under those circumstances, the critic turns from description to interpretation. Thus, the very nature of art leads to interpretation as a legitimate, and even inescapable, practice of critics.

An even more decisive difference between physical objects and works of art lies in the sorts of properties that are normally attributed to them. For instance, *expressive* qualities may be assigned to works of art: a novel such as Gustave Flaubert's *Madame Bovary* may be said to express a certain "bourgeois consciousness." Or *symbolic* qualities may be assigned: the castle in Franz Kafka's novel of that name has been said to symbolize divine redemption. Or, *representational* qualities may be assigned: Pablo Picasso's painting "Guernica" is called a representation of the horrors of war. Also, *meanings* may be assigned in various ways: in William Shakespeare's *Hamlet,* for example, the meaning of Laertes' exchanges with Polonius and Claudius is said to be in their contrast with Hamlet's self-doubt; and the meaning of Bigger Thomas' dilemma in Richard Wright's novel *Native Son* is said to derive from the plight of the Negro in America.

As has been noted, it is difficult to say whether properties such as these are to be found *in* works of arts or only may be imputed *to* them. Out of respect for the artist, critics may assume their own role is subsidiary—*i.e.,* that of identifying properties of a work that might not otherwise be appreciated. Because it cannot be said with certainty, however, whether expressive, symbolic, or representational qualities or meanings and the like are actually *in* works of art, criticism must go beyond the severer canons of description to those of interpretation. This issue of the autonomy of criticism has been debated in the works of T.S. Eliot, Oscar Wilde, and many others.

Thus, as has been shown, critics may well offer incompatible accounts that purport to describe the same work. Even in cases in which the identity of a work of art is closely associated with its physical properties, as a work of sculpture might be associated with a mass of cast bronze, pure description may be adequate only for its physical properties but not for the properties that may be ascribed to a work of art. If a line in a painting is called "humorous," it is not always clear whether the line is being described or interpreted. What is clear is that critical interpretation must conform to certain minimal constraints. It must be compatible with whatever is descriptively true of the work in question; any interpretation that is compatible only with what is descriptively false is inadmissible. Interpretation, therefore, depends on some indisputable range of critical description.

Constraints on interpretation

The limits of this range, however, are not easy to establish. To do so requires deciding which among competing critical practices is the correct one. Such a comparison of critical hypotheses leads to metacriticism—that is, to the evaluation of the critical norms themselves, an extremely difficult matter. Without becoming entangled in this problem, some pragmatic rules of critical practice may be laid down: it should be possible to formulate its canons, these canons should be used by a community of practitioners, they should be effective in confirming or denying relevant claims, and it should not be necessary to distort them to examine new works or works that were not anticipated when they were adopted.

These rules permit a number of critical approaches and, therefore, allow alternative and incompatible interpretations of given works of art. It would be difficult, however, to justify the restriction of critical practice to any highly specialized way of proceeding. In literary criticism, for example, it would be difficult to reject out of hand the legitimacy of many diverse but fruitful approaches, such as the archetypal criticism of the Canadian critic Northrop Frye or the Marxist criticism of the Hungarian statesman and writer György Lukács or the Freudian criticism of the British psychiatrist Ernest Jones or the neo-Aristotelian criticism of the U.S. critic Ronald S. Crane or countless others.

An extreme view of criticism holds that the interpretation to be preferred is the one that maximizes the value of the work in question. This view, however, does not recognize the rigour and independence of criticism or its obvious analogies to other endeavours, such as science, that are concerned with claims to truth and validity.

The objectivity of critical practice may be conceded not only to description but also to interpretation. Since interpretation is concerned with plausibility rather than with truth, plural approaches to works of art may reasonably be tolerated. The appreciation of a given work may entail a canvass of all plausible ways of construing it. Moreover, different schools of criticism may prove variously fruitful for each of the arts or for the movements within them. A Freudian approach to music or architecture, for example, promises less than formalist approaches; without question, however, the Freudian approach would be more fruitful in literature than in architecture. To examine the diversity of tenable critical practices (and there are new ones all the time) is to doubt that all but those consistent with some supreme critical principle can be disqualified.

Evaluating works of art. In addition to the identification, description, and interpretation of works of art, the

problem of their evaluation has been the subject of a number of disputes. The issues are those of value theory in general: there seems little reason to suppose that value judgments of works of art differ significantly from those of conduct, for instance. Immanuel Kant held that aesthetic and moral judgments are of fundamentally different logical kinds, but he was chiefly concerned with taste (which, despite Kant, appears in the moral, as well as the aesthetic, domain, in judging such matters as tact, decency, and personal ideals) and he failed to consider the implications of professional criticism and connoisseurship.

Nature of values

Although all the basic issues of the nature of values are not within the scope of this article, two fundamental issues are vital to a survey of the theory of criticism. For one thing, expressing one's tastes, preferences, likes, and dislikes must be carefully distinguished from judging merit. And for another, the principal varieties of value judgments must be sorted out. Quarrels about the critic's appraisal and evaluation of works of art are linked to these issues.

There is no prevalent philosophical view regarding value judgments that can be formulated in a simple and straightforward way. The account that follows puts forward one viable thesis, which may clarify how disputes about values can or cannot be resolved in a domain dominated by considerations of taste.

Value judgments are such in virtue of their predicates—that is, what they affirm or deny about the subject at hand. The predicates themselves, however, are not inherently valuational or nonvaluational; they are construed either way on the basis of governing theories. For example, to judge that Peter is tubercular may constitute a value judgment if good health is accepted as a norm. If tuberculosis is not regarded as a normative concept, however, but as a purely biological phenomenon, the judgment remains factual though not valuative. Factual judgments may be assigned truth values—that is, they may be determined to be true or false. Value judgments, on the other hand, are judgments that entail reference to a norm, or standard of merit. Some value judgments may also be factual judgments as well, as in the case of the judgment about Peter's tuberculosis.

Statements about one's likes or dislikes—one's tastes, in short—are usually not considered normative statements but statements of fact. They concern an aspect of a person's disposition and behaviour.

In making value judgments, however, the person puts a value on things by judging them in accord with norms that usually lie outside his own tastes. Of course it is possible that the values he places depend entirely on his tastes—his likes, dislikes, preferences—but it is not necessary. Herein lies a crucial distinction, for value judgments that depend on personal tastes are strikingly different from those that do not. Value judgments that depend upon taste may be called appreciative judgments and those that do not may be called findings.

Findings differ from factual judgments only insofar as they are linked to standards of merit; otherwise they are alike. In principle, critical judgments of the merit of a work of art, like other value judgments, may be as rigorously objective and confirmable as judgments of fact. Logically, findings are judgments of fact, in that truth values may be assigned to them.

It should be emphasized that questions of the relativity of values, or of their variability, are not relevant here. The logical properties of findings are not affected by the nature of socially institutionalized values. Value judgments about beauty or fashion may well derive from the prevailing tastes of a community, but, as findings, they will be made in accordance with those norms and not with one's personal taste (if we disregard coincidence).

In contrast, appreciative judgments are based entirely on one's own tastes. The well-known Latin maxim *de gustibus non est disputandum,* "there is no disputing concerning taste," applies to appreciative judgments only; it does not bear at all on findings.

Distinguishing between these two fundamentally different kinds of value judgments permits some rational debate respecting the merit of a given work of art. To the extent that a critical tradition is standardized (as the standards of wine tasting or of dog breeding have been established), critical findings may be regarded as objective relative to such a tradition. (The entire system may be challenged, of course, but that is another matter.) But appreciative judgments cannot be objective in that way; they cannot be simply true or false. Appreciative judgments depend on personal tastes, which vary greatly among individuals, so that seemingly contradictory judgments are common. If these judgments were treated as findings, such contradictory judgments might be found to be jointly true, a logical impossibility. If such a contradiction were resolved by regarding each judgment as true relative to given taste, then appreciative judgments could not be distinguished from mere statements about one's tastes. Since this distinctive kind of value judgment is prominent in aesthetic criticism, appreciative judgments may be conceded much weaker confirmation than findings. In a finding, one holds that a given work has (or lacks) a certain merit; the matter can be decided by attention to relevant criteria and evidence, as factual matters are. In an appreciative judgment, one assigns a certain value to a work in accord with one's personal likes, dislikes, and preferences. In findings, the supporting reasons must be publicly compelling; in appreciative judgments, the supporting reasons need only be relevant and reasonable to a critical public. The public may attest to the coherence of an appreciative judgment and its supporting reasons, but, because of differences in taste, it is not bound to share that judgment, as it must in the case of findings.

The problem of conflicting judgments

Incompatible findings, like incompatible descriptions, are inadmissible. Seemingly incompatible appreciative judgments, however, are admissible insofar as they are coherent (in accord with informal canons of such judgments) and compatible with the actual properties of the given work. In the context of an academic tradition, judgments of beauty may well be findings; but, in the context of personal taste, judging beauty is rendering an appreciative judgment. One may (appreciatively) say that a certain woman is beautiful and offer supporting reasons that may seem forceful or not. But, if one claims, in the mode of findings, that a certain woman *is* beautiful relative to a particular tradition of values, the evidence will serve flatly to confirm or deny the claim.

Disputes may arise about judgments of both sorts, and there are procedures for appraising each type. The precept about the pointlessness of arguing about taste should therefore be amended to say that the kind of rational dispute possible for findings is not possible for appreciative judgments, or judgments of taste. Nonetheless, rational dispute of a different sort is possible for appreciative judgments as well.

The two types of judgment—findings and appreciative judgments—cannot be segregated on the basis of their respective range of predicates; an assertion that something is beautiful, for example, may be construed as either type of judgment. The conditions under which relevant claims may be confirmed is the key factor in distinguishing between the two types.

Other aspects of value judgment

There are, of course, deeper questions about values than can be treated in this article. Especially pertinent is this question: are values discoverable in nature, or the real world, or can they be construed only as an expression of the interests of a particular community? If it were possible to prove the existence of "true" or "real" values, there would be no need to account for appreciative judgments; practicing critics would be concerned only with findings—that is, with making judgments that are in accord with those true values. In fact, however, no such true values have been proved, and the critic is chiefly concerned with appreciative judgments, in which his personal tastes are systematically articulated. In any culture there may be a number of critics operating at cross purposes, each imprinting his own distinctive taste on a community of enthusiasts. Revolutionary tendencies in taste appear, however, resulting in significant alterations in critical practice. Thus, the judgments of critics tend to be informal and variable; because of the logical properties of their appreciative judgments and the conventional nature of the norms that support their findings, it could not be otherwise.

These, then, are the principal conceptual issues bearing on the systematic practice of criticism of the arts. The critic's judgments may be either valuational or nonvaluational. With respect to the former—that is, his value judgments—findings must be distinguished from appreciative judgments; with respect to the latter, the nonvaluational judgments, descriptive judgments must be distinguished from interpretive judgments. Because appreciative and interpretive judgments do not allow truth values to be assigned to them in the way that findings and descriptions do, the critic must tolerate logically weak judgments at the heart of his enterprise. This tolerance, however, should not be misconstrued as a lack of rigour in applying critical canons. On the contrary, rigorous critical practice requires such tolerance.

EXTERNAL INFLUENCES ON AESTHETIC CRITICISM

The influence of doctrine and ideology. Actual critical practice raises certain technical questions that tend to divide considerations that are internal from those that are external to aesthetic criticism—that is, those that bear on the work of art as such from those that involve ulterior appraisals or characterizations. In spite of disputes regarding the proper scope and orientation of criticism, the diverse schools of criticism exhibit broadly parallel practices in both the internal and the external considerations to which they address themselves. For example, Marxist critics such as Lukács and Christopher Caudwell use the socioeconomic categories of their philosophy to analyze works of art as art, to characterize the artist's life, and to study the role of the work within the dynamics of social change. Clearly, it is not always easy to discriminate between internal and external criticism.

The issue here is conceptual; it is not open to ideological quarrel. For instance, it has been said that the ancient Greek dramatist Aeschylus in his trilogy the *Oresteia* was presenting an idealized version of emerging notions of political justice. This external interpretation presupposes an internal interpretation of the work that does not violate any canons of aesthetic criticism, or it would not be tenable. Precisely the same consideration applies to the attempt by the Freudian critic Jones to psychoanalyze Shakespeare on the basis of *Hamlet* or Sigmund Freud's attempt to analyze Leonardo da Vinci from his drawings and paintings. The principle that the external and the internal criticism must match remains the same whether the criticism is concerned with libidinal conflicts as are the Freudians, with archetypes as are the followers of the Swiss psychologist Carl Gustav Jung, with class conflicts as are the Marxists, or with theological and moral resolutions of modern poetry as is the French Thomist philosopher Jacques Maritain. In the light of the pluralism of viewpoints that has already been shown inevitable, it is not surprising that internal and external criticism cannot be sharply opposed to each other. Although adherents of some particular approach may disagree, it is difficult to see how any one approach can be exclusively vindicated. In a very real sense, the preference for any given approach may be construed as an appreciative judgment in itself.

Advantages of pluralism

It is not at all necessary that a theory about some aspect of human society be true in order for it to be fruitful and defensible in criticism. In describing, interpreting, and evaluating a work, the critic requires only that the theory is relevant to it. For instance, the critic may appropriately characterize or appraise a work in terms of Marxist, Freudian, Jungian, or Thomist doctrines to the extent that the imagination of either the artist or the audience is informed by such doctrines. Such doctrines need only be recognizable and socially significant to be useful in criticism; scientifically valid theories, on the other hand, may be entirely uninstructive when applied to the description and interpretation of a work of art. False theories may be so rewarding in discussing particular works that they cannot be dismissed solely because they are not true. To understand William Wordsworth in terms of some version of Platonism is not to subscribe to Platonism itself, and to read the *Oresteia* in Marxist terms need not presuppose that Aeschylus held similar sociological convictions. The truth, or at least the plausibility, of the descriptive, interpretive, and evaluative judgments of critics must be carefully distinguished from the truth of the doctrines advanced by them or by artists. The validity of Thomism, for instance, is an entirely separate issue from the validity of interpretations of Dante from the Thomist point of view.

Those critics who believe they subscribe to a science of values, whether it may be Freudian, Thomist, Marxist, or some other, would quarrel against such a use of diverse doctrines. Inasmuch as the foundations of their beliefs do not compel the belief of all others, however, the use of doctrines of doubtful validity in criticism must be tolerated.

A doctrine may be applied by a critic if it is compatible with his own practice of criticism and if it provides an account of the design of that work, especially those elements that seem to call for interpretation.

In sum, the discipline of criticism has been shown to exhibit significant rigour, despite the logical weaknesses of the judgments of interpretive criticism and the uncertainty of the doctrines it applies. Contributing to this rigour are the requirements that an interpretation not deny any descriptive elements; that it be plausible; and that it deal with the traditionally salient problems of the work—that is, the interpretive puzzles that obstruct the assignment of a coherent and comprehensive internal order to the work.

Historical and biographical influences. A final issue may serve to round out this account of the criticism of the arts. As has been seen, an interpretation must be compatible with what is descriptively true of a given work of art. It is sometimes supposed that both description and interpretation should be similarly constrained by historical and biographical considerations. In fact, some versions of this thesis hold that interpretations prove to be no more than description provided under relatively difficult conditions of discovery. In the historical thesis, the "meaning" (*i.e.*, the correct characterization) of a work of art is the one that accords with its critical reception in the culture in which it was produced. The biographical thesis holds that "meaning" is what accords with the artist's intention.

Historical and biographical criticism

A number of things may be said about both theses. For one thing, the two theses may be construed as the same wherever the artist's intention is interpreted in terms of the conventions governing such works rather than in terms of his own avowals of what he intended. It is extremely difficult, however, to suppose that one and only one construction can be put on a given work, especially in complex societies in which artists often intentionally depart from academic or other conventions. The problem of plausible alternative interpretations haunts critical practice even when the problem is confined within historical limits, even though the elimination of such alternatives is often claimed to be an advantage of historical criticism.

Furthermore, plausible interpretations that are put forward long after the work of art is produced may also be construed as the work of historical criticism; the restriction of interpretation to the period in which the artist worked represents a somewhat arbitrary constraint on the practice of criticism. Some works of art attract critics and audiences over generations, or even ages, without requiring close attention to historical or biographical origins. The force of accurate historical criticism cannot be denied, but criticism that ignores the *evolving* historical reception of a work of art unjustifiably restricts the scope of criticism.

A historical hypothesis, particularly one concerned with cultural significance, bears a striking similarity to interpretive criticism; like interpretive criticism, history as a discipline must rely substantially on criteria of plausibility. It should be noted that the same arguments that apply to historical and biographical criticism also apply to criticism based on cultural anthropology or the history of ideas.

Historical misunderstandings and inaccuracy about a given work of art must be distinguished from the historically changing significance of that work. A Freudian interpretation of *Hamlet,* for example, cannot be dismissed solely because the Freudian system was unknown to Shakespeare. If audiences that share Shakespeare's cultural and linguistic traditions are deeply influenced by the Freudian outlook, then a Freudian reading of his work, if independently plausible, cannot be regarded as a historical mistake. Interpretations that are constrained by *special*

historical and biographical considerations must be distinguished from those that are not. Interpretations of both sorts may be welcomed.

Intentional criticism

Further objections may be raised against biographical criticism that narrowly construes the artist's intention as what may be documented in conversation, letters, and the like. Quite often, there is simply no such documented knowledge of the artist's intention. Even when there is, it may prove vague and ambiguous or even irrelevant to the appreciation of the work. In any case, any interpretation based on a statement of the artist's intention is subject to precisely the same sort of confirmation that other interpretations would be. Intentional criticism may be viewed as a form of historical criticism that assumes certain types and modes of artistic endeavour within a tradition (to which the artist's intentions are said to correspond).

Some critics opposing what the American critics W.K. Wimsatt and Monroe C. Beardsley called the "Intentional Fallacy" would not admit any criticism based on the artist's intention; they would rule it out on the grounds that it violates the proper aesthetic concern of the critic. In view of what has already been said in this article about the nature of a work of art and of its boundaries, however, intentional criticism may be viewed as simply another selective mode of critical practice, one that is by no means exclusively correct but not for that reason inadmissible.

In conclusion, then, the principal issues affecting critical practices in the arts may be said to be (1) the identity and individuation of works of art; (2) the nature and characteristic properties of works of art; (3) their description and interpretation; (4) value judgments about them; and (5) the admissible varieties of, and constraints upon, criticism of the arts.

BIBLIOGRAPHY. Perhaps the most comprehensive canvassing of the current philosophical literature respecting criticism of the arts is to be found in M.C. BEARDSLEY, *Aesthetics: Problems in the Philosophy of Criticism* (1958); and J. MARGOLIS, *The Language of Art and Art Criticism: Analytic Questions in Aesthetics* (1965). Each of these two books (with extensive bibliographies) proposes its own theory of criticism; the first reduces interpretation to description, while the second opposes such reduction. Of relatively recent theories of art bearing on the problems of criticism, the following are among the most penetrating: N. GOODMAN, *Languages of Art: An Approach to a Theory of Symbols* (1968), primarily addressed to notational problems in identifying works of art; R. WOLLHEIM, *Art and Its Objects* (1968), pursues the paradoxes of numerical identity regarding works of art; S.K. LANGER, *Feeling and Form* (1953), attempts a systematic ordering of the different arts in terms of symbolic form; and H. OSBORNE, *Aesthetics and Criticism* (1955), construes criticism primarily in evaluative terms and the work of art as the object of such practice. Recent anthologies of the most widely discussed papers include: W. ELTON (ed.), *Aesthetics and Language* (1954), a linguistically oriented attack on the Italian philosopher Benedetto Croce and on Idealist aesthetics; and J. MARGOLIS (ed.), *Philosophy Looks at the Arts: Contemporary Readings in Aesthetics* (1962).

(J.Ms.)

Practice and Profession of the Arts

The practice of the arts goes back to the remote prehistory of mankind; the profession of the artist is of more recent origin. The oldest surviving works of art such as the cave paintings at Lascaux, France, and Altamira, Spain, dating from the late Paleolithic Period between 10,000 and 15,000 BC, were presumably made by men who never thought of themselves as artists. Though these works can be viewed as art today, it is probable that their creators were intent only on executing a magic ritual designed to aid them in the hunt.

At some point in the development and differentiation of human society, the professional artist emerged. The monumental buildings and stone carvings of ancient Egypt or Assyria and the intricately decorated pottery and elegant murals of Crete were undoubtedly done by trained and experienced craftsmen. They were no longer occasional practitioners of art, as the cave painters had been, but full professionals—*i.e.,* men skilled in a specialized occupation, practicing it full-time and probably earning all of their livelihood from it.

But even the relatively simple definition of a professional as a person receiving pay for carrying out a specialized occupation on a full-time basis is difficult to apply to the arts. In no other field do the categories of professional and amateur so overlap. One of the 20th century's major poets, Wallace Stevens, and one of its most innovative composers, Charles Ives, earned their living as insurance executives. By every criterion of proficiency and accomplishment, both deserve to be ranked as professional artists, yet in a real sense, both were amateurs. Similarly, it is difficult to classify Thomas Jefferson as a professional architect, even though he designed some of the most beautiful buildings of his time.

The phenomenon of amateurism in the arts represents only one of the key problems in an attempt to discuss the professional artist. There is also the question as to whether the arts are professions, as distinct from crafts or skills. This aspect of the concept involves consideration of matters of the status or prestige of the arts and decisions on what constitutes proper preparation for careers in them. On these issues, attitudes have varied enormously from one art to another, from one historical period to another, and from one culture to another. Nearly everywhere and always, music, architecture, and poetry have been regarded as professions, while pottery making has been regarded as an art and granted the dignity of a profession only in some non-Western cultures.

Since antiquity, there has been a continuing debate as to whether painting and sculpture demand skills of eye and hand alone or intellectual grasp and training as well. The painter has often spoken contemptuously of the sculptor, describing him as a mere stonecutter, and the sculptor, in turn, has looked at the painter as simply an illusionist and trickster.

The attempt to gain for some of the arts the status of learned or quasi-learned professions resulted in a distinction between "the fine arts" and "the applied arts," a distinction that has done harm to both. The notion that a painter has a profession, but a cabinetmaker or silversmith only a craft, helped to isolate the former from everyday life and to limit the creative enterprise of the latter. The gradual breakdown of the attitude that permitted such exclusive categories to be created and the general rejection of the false distinctions between art and utility may be among the most encouraging developments in the arts in recent times.

Of even greater importance has been the lessening of the separation that exists between the professional and the practitioner. The "cultural explosion" following World War II not only made the arts more readily accessible to the general public but also stimulated artistic activity in great numbers of people. Never have there been so many professional artists active in so many fields, and never have there been so many nonprofessional practitioners of the arts.

The present article treats the practice and profession of the arts in terms of training, working conditions, and social and economic roles and influences. The phenomenon of fraudulence in the arts is also discussed. The principles of aesthetics and other theoretical aspects of the arts are treated in the articles AESTHETICS and PHILOSOPHIES OF THE BRANCHES OF KNOWLEDGE: *Philosophy of art.*

This article is divided into the following sections:

Preparation of the artist

Formal education for a profession in the arts is a relatively new development. The school of art or architecture, the conservatory of music, the academy of dramatic art, and the university's creative-writing program have emerged in modern times, some within the last generation or two. To most artists of the past it would have seemed incomprehensible that they should go to school to learn their profession. Neither would any of the great educational institutions before this century have thought it part of their function to teach artists. Indeed, serious doubts continue to be expressed as to whether academic schooling is the best training for most branches of the arts.

Formal instruction in the visual arts—painting, drawing, sculpture, and architecture, as well as the many arts of decoration and design—has the longest and most diversified history. A consideration of the patterns of development that have occurred in these related fields will reveal the general directions of training in all the arts as well as many of the basic problems running throughout the history of art education.

THE VISUAL ARTS

The ideal of the universally trained artist

Throughout much of history, the insistence that the artist be learned in many fields has constituted a deliberate attempt to raise his status, to rank him as a practitioner of the liberal rather than the mechanical arts. The Roman architectural theorist Vitruvius (flourished 1st century BC) declared:

> [The architect] should be a man of letters, a skilful draughtsman, a mathematician, familiar with historical studies, a diligent student of philosophy, acquainted with music; not ignorant of medicine, learned in the responses of jurisconsults, familiar with astronomical calculations . . . (From *De Architectura,* F. Granger [tr.], Harvard University Press, 1962.)

Such a prescription represented the ideal of the universally trained artist, and, so far as is known, no institution existed in antiquity to provide this or any other kind of formal training in the arts.

The traditions of apprenticeship. Until the 16th century, when the earliest academies of the arts appeared, the artist acquired his skills mainly through various systems of apprenticeship. He learned his trade as he practiced it under the instruction and supervision of a master. Sometimes the apprenticeship was regulated by a craft guild. Typically, a boy was bound to a master at the age of 14 and served for seven years. This system was in force throughout most of the Renaissance, and it was under such rules that Michelangelo entered the workshop of Ghirlandajo and Leonardo da Vinci that of Andrea del Verrocchio. Gradually the system changed so that, in the 17th century, the beginning artist came to be considered a pupil rather than an apprentice. He lived and studied in the home of a master for an indefinite period and was free to leave when he felt he had learned enough.

Functioning of the systems. Whether as apprentice or more informally attached pupil, however, the young artist was trained on the job by his master. As an apprentice, he began by doing the most menial jobs: grinding the colours, cleaning the brushes, or preparing the wood panel or the plastered wall. Gradually, he was trusted with more responsible tasks, given instruction in the technique of the art itself, and allowed to paint in some of the decorative details of an altarpiece or fill in large neutral areas of a fresco. Finally, he might be assigned the subordinate figures or landscape background of a painting by the master. It is said that Leonardo as an apprentice painted so beautiful an angel in a "Baptism of Christ" by his master that the master resolved to renounce painting and devote himself to sculpture.

The student, from menial to master

Strengths and weaknesses of the system. The training of an apprentice in a Renaissance workshop was not confined to a single art. The workshop of Antonio and Piero Pollaiuolo, perhaps the most active art establishment in Florence of the mid-1400s, accepted commissions in sculpture as well as in painting of all sorts. The graduate of such a workshop, then, if he had kept his eyes open and his hands busy, could have developed a wide range of artistic skills. The apprentice system, however, had serious weaknesses. In a good workshop run by a conscientious master, an apprentice could receive excellent training. Far too many apprentices, however, undoubtedly were condemned to years of repetitious drudgery, receiving little systematic instruction and, at best, being trained purely as craftsmen. Moreover, the guilds deliberately limited the number of apprentices.

Academies and the artistic elite. The founding of the first academies of art, in the late 16th and early 17th centuries, was a step forward. Although later such institutions became restrictive and rigid, they were designed to break the monopoly of the guilds, to regularize the training of artists, and to lift artists from the category of mere craftsmen by liberalizing their education.

The French Academy as model. The most famous and influential of all academies of art was the Académie Royale, commonly known as the French Academy, founded in 1648 in imitation of the Accademia di S. Luca, which had been set up in Rome in 1593. Under the patronage of Louis XIV's great minister, Jean-Baptiste Colbert, the French Academy by the 1660s had become a major force. Under the directorship of the painter-decorator Charles Le Brun after 1683, it exerted a virtual dictatorship over French art. Its success inspired the creation in other countries of official academies that aped its organization and program.

Curriculum and rewards. The curriculum of the French Academy, fixed under Colbert and Le Brun, centred around drawing. The student drew from the drawings of his professors, then from casts, and finally from life. In addition, he attended academic lectures, analyzing pictures from the royal collection. These discourses were designed to instill in the student certain aesthetic criteria and a fixed hierarchy of values in which subject matter played a leading role. In the scale, historical paintings were regarded as the noblest, still lifes as the meanest.

The academy's students competed for a series of prizes culminating in the Prix de Rome, a four-year scholarship

in Rome that assured its holder a successful career at the top of his profession. Even those who won no prizes could anticipate a secure future in the service of the state or of individual patrons, for the steady production of uniformly trained and indoctrinated artists was of great importance to the regime.

The academy performed a great service in breaking the stranglehold of the guilds on the training of artists, in raising the standards of art instruction, and in improving the status of artists. On the other hand, it locked the artist into a closed system, made conformity a virtue, and treated individualism and originality of style as sins to be avoided at all costs. By standardizing methods of instruction, it also standardized the bases of critical judgment. By admitting only 200 students and thus creating a small artistic elite, it neglected the need for trained artists and designers in the decorative and applied arts. Academicism established above all the principle that the artist succeeded not through native genius but through a correctness of technique that could only be acquired through proper training.

Academicism as a negative force

The English Royal Academy. In England, a number of schools of art were established during the early 18th century, notably one founded by the painter and caricaturist William Hogarth. In the employment of female models, these schools went beyond anything yet attempted in France. It was not until 1768, however, that the patronage of the crown was obtained for a Royal Academy. By the end of the century, this academy had achieved immense prestige and influence, and a painter who could sign the coveted "R.A." after his name was certain of a prosperous career. The *Discourses* delivered over a period of 15 years by the painter Sir Joshua Reynolds, the academy's first president, remain the best statement of the academic philosophy.

As a teaching institution, however, the Royal Academy fell far short of its French prototype. The limitation to 40 on the number of academicians increased the social and economic desirability of membership but narrowed the scope of the academy's teaching functions. The restrictive curriculum and the discouragement of "eccentricity" of style were not calculated to foster true talent. Of the outstanding English artists of the early 19th century, only J.M.W. Turner was trained and supported by the Royal Academy. The painter-poet William Blake despised it, and landscapist John Constable became an R.A. only late in his career.

Countermovements: the applied arts and crafts. It was not only its self-perpetuating and oligarchical exclusiveness that provoked criticism of the Royal Academy. With the growing impact of the Industrial Revolution, the academy was attacked by reformers in and out of Parliament for its failures to encourage the applied arts and to remedy the growing shortage of trained artisans in such fields as china manufacturing, ornamental metalwork and plastering, and carving in wood and stone. Parliamentary hearings sharply critical of the Royal Academy led in 1837 to the establishment of a government School of Design and an accompanying museum.

Schools and museums of design. The School of Design and its branch schools were succeeded, after 1852, by a network of art schools under a government Department of Practical Art. By 1864 there were 90 such schools instructing about 16,000 students. The founding, in 1852, of the Victoria and Albert Museum, which came to have vast collections of design in all fields, was an important step forward in art education. This combination of schools and museums of applied art was soon imitated in many of the leading cities of Europe, especially in Austria, Germany, and The Netherlands. Despite attacks on the basic principle of separating schools for the applied arts from those for the fine arts, such schools continued to flourish in the 20th century. Most of them, however, modified their curricula to include such studies as art history and aesthetics.

Waning of academic dominance. In painting and sculpture, however, the academic idea lost some of its vitality and dominant influence in the 19th century. By the mid-18th century, the French Académie Royale was under attack from the philosophers of the Enlightenment, and in 1793, at the height of the Reign of Terror following the French Revolution, it was dissolved and its functions handed over to a Commune des Arts led by the painter Jacques-Louis David. The Institut de France, set up in 1795 to supervise the arts, revived the academy in everything but name. The academic establishment, under different forms, remained a powerful though no longer controlling force in the French art world. As the École Nationale Supérieure des Beaux-Arts, it continues today to train artists to compete for the Grand Prix de Rome.

Continued influence of the masters. Even in the heyday of the academy, the system of training the artist in the master's studio had continued to flourish. In 1771 the Irish painter James Barry estimated that 5,500 persons were receiving some kind of art instruction in Paris alone and that of these, 1,500 were being trained to work in such industrial enterprises as the Gobelin tapestry works. Thus most artists were still trained in the studios of established artists or in elementary technical institutes, such as an industrial school founded by Jean-Jacques Bachelier in 1762. France's dominant position in the decorative arts during the 18th and 19th centuries can be attributed in large part to the effectiveness of the Bachelier school and similar training centres.

During the second half of the 19th century, the demand for training in painting and sculpture grew so great that large numbers of beginners congregated in such studios, or ateliers, as the famous Académie Suisse in Paris, where they painted from a model under the often cursory supervision of a well-known teacher.

Copying the old masters

Another training method became important during the 19th century. Much earlier, copying of frescoes such as those by Masaccio in the Brancacci Chapel in Florence had been a major source of instruction for later painters. With the opening to the public of such great museums as the Louvre, the practice of painting from the old masters again became a basic feature of the artist's training. Even so sophisticated a painter as Paul Cézanne was devoted to this method of teaching himself.

Synthesis of art and craft. Despite 19th-century advances in the formal training of artists in all fields, sharp criticisms of prevailing art education were made, notably by the critic John Ruskin and the poet-craftsman William Morris. They opposed the separation between training for the applied arts and education for the fine arts. Morris saw the division as creating a group of designers who turned out standardized patterns for machine-made objects and a group of fine artists who were constrained from producing things needed by people for an aesthetically pleasing environment in daily life.

As a direct result of Morris' teachings, a number of art schools were established in England to revive handicrafts and to bridge the gap between the applied and the fine arts. The most successful of these schools was the London Central School of Arts and Crafts, founded in 1896. After 1900, however, the leadership in the movement to reform art education passed from England to Germany, where there was a decisive change in emphasis. Contrary to Morris' rejection of the machine, an attempt was made to realize the aesthetic possibilities of machine-made objects and also to create a new architecture.

Impact of the Bauhaus. The major figures in 20th-century art education were the Germans Bruno Paul and Walter Gropius. It was Paul's strong conviction that art schools had a responsibility to artists and to society: to train artists in fields in which they could both earn a living and be socially useful. After World War I, he combined the Berlin Academy of Art with the School of Decorative Art. In a pamphlet on art education published in 1918, he declared that all students, whether they intended to become fine artists or applied artists, should receive basically the same training. He stated also that no one should be admitted to an art school without first having learned a trade in a workshop or trade school.

Walter Gropius, in his early career in Germany and his later work in the United States, exerted an incalculable influence not only on art education but also on the whole development of modern art and architecture. Already a well-known architect in 1914, he became principal of the Weimar School of Arts and Crafts. After service in World

War I, he returned to Weimar and in 1919 founded the Staatliches Bauhaus (State Architecture House), a school merging the Weimar art school with the arts and crafts school. In 1925 the Bauhaus was moved to Dessau.

Unison of arts and crafts

The Bauhaus ideal was to unite all arts and crafts to create a new architecture that comprised a living environment; to break down the false separation between the applied arts and the fine arts, between art and utility; and to train artists in the creative possibilities of machine design.

To these ends, the Bauhaus curriculum emphasized the use of different tools and materials, as well as academic instruction in geometry, principles of construction and design, and the history of art. Instruction was divided into three stages. The first, lasting for six months, covered an elementary survey of Bauhaus principles and methods. The second, taking three years, was the basic practical and academic course in which the student, in addition to the general training he received, was required to specialize in a trade under the supervision of a particular master. At the end of this course, the student had to pass one of the regular city trade examinations before, finally, he entered the third phase, *Baulehre* ("building instruction"), in which he took an active part in one of the Bauhaus' projects.

During its short life, which ended in 1933, the Bauhaus achieved remarkable results and assembled an extraordinary faculty that included such leaders and innovators as painter-photographer László Moholy-Nagy, architect Marcel Breuer, and painters Wassily Kandinsky and Paul Klee. It had created the ideal of a new type of art education and proved that it was workable. John Ruskin, as Slade Professor of Art at Oxford in the 1870s, had taken his students out to repair roads, but it remained for the Bauhaus to transform Ruskin's experiments into a coherent program.

Acceptance of the arts in higher education. Though the Bauhaus had no immediate successor, it affected the teaching of art in many schools in following decades. Such education achieved notable growth in university-based or university-sponsored schools of art, especially in the United States. Such schools attempt, in many instances, to combine a four-year academic education with studio work in drawing, painting, sculpture, and other media. Many offer specialized work in such fields as industrial design, book illustration, advertising art, and costume design. The graduates of these schools usually are granted bachelor's or master's of fine arts degrees. None of the schools, however, has attempted to realize the Bauhaus ideal of a student completely trained in both the fine and applied arts.

The same is true of schools of architecture, most of which are connected with universities. In these, the academic curriculum is generally more rigorous than in schools of art. A degree is usually granted after a five-year course, which includes considerable work in traditional liberal arts subjects. A number of schools offer special concentrations in city planning. Few if any, however, see architecture as Gropius did, as a discipline unifying all of the crafts.

THE OTHER ARTS

Music. Next to schools for the visual arts and architecture, the most widespread of contemporary schools for the arts are those for the training of musicians, whether composers or performers. Like the school of art, the school of music has a long history.

The Paris Conservatoire model. The first full-fledged music school of modern times was the Conservatoire de Musique, founded in Paris in 1795 by the revolutionary National Convention as a successor to the earlier École Royale de Chant et de Déclamation and Institut National de Musique. In 1797 it had 125 professors and 600 pupils. It has had a continuous and distinguished history to the present day.

Development of the music curriculum

The curriculum developed at the Paris Conservatoire has been followed with slight variations in schools of music elsewhere. Originally, classes in composition, harmony, singing, and instrumental performance were given. Later, classes in music history were added, and an increased emphasis was given to training in sight reading. Still later, instruction in aesthetics and musical analysis became part of the standard curriculum.

The success of the Paris Conservatoire and the greatly increased demand for trained musicians during the 19th century led to the creation of conservatories in major European and American cities. In the United States, the Boston Conservatory of Music was founded in 1867, the Peabody Conservatory in Baltimore in 1857 (first classes in 1868), and, later, others in New York, Philadelphia, and elsewhere. Some of these schools have remained independent, whereas others have become part of universities.

Private and institutional study. The conservatories of music have not altogether supplanted the older system under which a student worked under a particular master, as Ludwig van Beethoven did under Joseph Haydn at the end of the 18th century. Such a famous teacher of composition as Nadia Boulanger attracted students from all over the world, and singers and instrumentalists often prefer to attach themselves to the studio of a favourite teacher. Increasingly, however, the conservatories have absorbed the master's classes.

Literature. The idea that the college-bred writer is superior to the one who has not had a liberal arts training goes back at least as far as the Elizabethan Age, when Robert Greene, one of the so-called university wits, sneered at Shakespeare as an upstart crow. The notion that creative writing, as distinguished from the ancient discipline of rhetoric, is something that can be taught in an academic environment is a recent development.

In the United States, especially, many creative writing programs have developed in higher education, usually in conjunction with the appointment of a well-known writer in residence as a member of the faculty. The creative-writing student typically receives more broadly based, and less technical, training than the student at a school of art or music.

Theatre and dance. The training of dramatists has taken a direction somewhat different from that of other writers. It has been combined with practical work and experience in the crafts of the theatre.

Academic teaching and apprenticeship. The workshop set up at Harvard by George Pierce Baker and the Yale School of Drama, which he founded in 1925, served as models for later drama schools. In recent years, some university-based schools of theatre arts have developed very elaborate programs, with professional courses in scenic design, lighting, and direction, as well as in playwriting and acting. They often sponsor highly trained repertory companies that present new and often controversial plays as well as the classics.

There also exist separate schools for actors outside the university establishment. Among the best known of these is the Royal Academy of Dramatic Art in London, which has trained many successful actors. The Actors Studio in New York City has enrolled fledgling actors as well as established actors who wish to keep their skills sharp.

Training the performer

The old apprenticeship system remains more a vital factor in the training of actors than in any other of the performing arts. Particularly in countries in which repertory companies are well established, as in England, France, Germany, and the Soviet Union, actors can learn and gain experience in their craft by progressing from walk-on roles to more demanding ones. Often the actor can start in a provincial repertory company and move to one of the national companies. For the experienced actor, the repertory company provides the opportunity to do a variety of roles, and to go from a major to a minor part from week to week, as a member of an integrated and continuing ensemble. The system goes back to the beginning of stable acting companies in the Europe of the 16th and 17th centuries, when actors might enroll as boys and live out their lives as members of the same company.

Formal education for the dance in modern times dates from the establishment by Louis XIV of the Académie Royale de Danse in 1661. In 1669, the Académie Royale de Musique was founded, and a school to train professional dancers was added in 1672. These institutions made Paris, and specifically the Paris Opéra, the world centre of ballet training and performance in the 19th century.

Formal demands of the dance. Training for the dance has made less headway in universities than that for oth-

er of the performing arts. A few colleges in the United States offer a fully developed dance curriculum, and some schools of fine arts include programs in dance, but the professional instruction of the dancer, whether in ballet or modern dance, usually is carried on in the 19th-century tradition of teaching in schools associated with ballet companies or opera houses. It has changed little from the time when Edgar Degas painted the young dancers of the Paris Opéra at practice. With few exceptions, training for the dance has remained a relatively narrow and physically demanding regimen.

The technologically based arts. Relatively little attention has been paid to the development of professional curricula in photography. More than any other art, it has been treated as a hobby to be learned without formal instruction. Where it is taught, the focus is on photographic technique rather than on photography as an art. There are, however, signs of a growing acceptance of photography as an important and expressive art form, and it is now becoming part of the curriculum not simply of schools of journalism but of schools of fine arts as well.

The new arts of the 20th century—film, radio, and television—still depend largely upon people trained in the older arts. The foundation in recent decades of film institutes associated with universities, notably in New York state and California, has been a significant step. A few radio and television programs exist, sometimes as parts of a department of communication arts or outside academic settings. Most of the directors, actors, and writers in film and television either have developed in the theatre or the literary world or have grown up in the industry without formal instruction.

THE SELF-TAUGHT ARTIST

With all of the many systems and institutions for formal training in the arts that have come into being over the centuries, there always have been self-taught artists. This is especially true of writers, the overwhelming majority of whom, from Homer to the present day, have had no specific training in their art and many of whom, in fact, like Shakespeare or George Bernard Shaw, had comparatively little schooling of any sort. They have learned their trade by studying other writers and life itself, and by proceeding from imitation to original creation. Many people have turned to writing after education for careers in other fields. Medicine alone has produced such outstanding writers as the Englishmen Sir Thomas Browne and W. Somerset Maugham and the American William Carlos Williams.

Art without schooling

Self-trained artists have also achieved prominence in other fields, though far less frequently than in writing. The history of architecture, perhaps of all the arts the one that seems most to demand strict technical training, contains two spectacular instances of the self-trained professional. Sir Christopher Wren, among the greatest of English architects, was a mathematician and professor of astronomy at Oxford before he took up architecture. But whereas Wren was grounded in the principles of the exact sciences, Sir John Vanbrugh, the architect of Blenheim Palace, had been a soldier and a dramatist before he turned to architecture at the age of 35.

The completely self-trained professional artist is a rarity in painting and sculpture. More than any other kind of artist, the painter especially must learn from and with other painters. Although such painters as Paul Cézanne, Vincent Van Gogh, and Paul Gauguin were in many respects self-taught, they absorbed a great deal from studies of, and interactions with, their fellow artists. Occasionally a true "primitive" such as Henri Rousseau, unhampered by conventional instruction, has produced a style with extraordinary power and directness as well as naïveté.

TRAINING OUTSIDE THE WEST

In non-Western cultures also, professional training in the arts has had a long history. Much of it has been carried out under systems of apprenticeship similar to those found in the West. Both in the Orient and in Africa, the profession of the arts has often been a hereditary one, sometimes, as in the case of bronze casters and ceramics workers in China, with secret techniques passed on from one generation to another. Similarly, Japanese Nō and kabuki actors long passed their craft from father to son, with the aristocratic Nō being regarded for centuries as a secret tradition. In West Africa, an entire village frequently has specialized in the production of a particular kind or style of art object.

Oriental and African art practices

Education in the arts has also been diffused through written treatises. In China a number of practical manuals on painting are extant, the two most famous ones dating from the 17th century. In India there were noted teachers of arts and crafts as early as the 1st century. Most recently, art schools similar to those in the West have been founded in a number of Eastern countries, notably in Japan, where a conscious attempt has been made to combine ancient traditions and modern styles. During the period of French colonial rule in Southeast Asia, an influential École des Beaux Arts was set up in Hanoi. In many primitive and folk societies, however, such arts as dance have been passed on by imitative learning.

Conditions of work in the arts

In no way can artists be stereotyped as shivering recluses, painfully pursuing their craft in dimly lit garrets; as well-fed hangers-on to the coattails and whims of the wealthy; or as irresponsible wastrels, lurking in the outskirts and subcellars of respectable society. The conditions of their work and life have been shaped in large measure by the regard of their society for the arts in general or for their art in particular. High regard has not always brought success or satisfaction, however, and artists have turned into many different avenues in search of tangible or other rewards for their art.

THE STATUS OF THE ARTIST

The social and intellectual status of artists has differed considerably from one field to another, from one culture to another, and from one historical period to another. They have been regarded as entertainers, artisans, seers and prophets, and, often, as dangerous cranks or misfits. The history of each of the arts has been marked by a determined effort on the part of its practitioners to raise their status and to be accepted as honoured members of their society.

Prehistory. In preliterate cultures, the poet preserved and transmitted the beliefs and traditions that gave the culture its sense of identity and purpose. Less an original creator than a storyteller and singer, he kept alive the works that had grown up by gradual accretion and refinement, and often he contributed to the process. The Homeric epics of ancient Greece probably developed in this way over generations, though in the form in which they have survived they almost certainly were shaped by one or more supreme geniuses.

The primitive bard

The primitive bard seems to have occupied an anomalous position, held in awe because of his seemingly divine powers but without a fixed place in the social hierarchy—existing as a dependent of a tribal ruler or as a wandering beggar. It is no accident that the Greeks represented Homer as blind, thereby symbolizing not only the poet's inward-directed vision but also his separation from ordinary men. The peculiar contradiction that poets have complained of bitterly, that their gifts are venerated but that they themselves are neglected, has its most famous statement in the couplet, "Seven cities warred for Homer being dead,/Who living had no roof to shroud his head," by the English poet Thomas Heywood.

Antiquity. In the great age of classical Greece and, later, of Rome, the artist lost some of his legendary quality as seer, but he gained considerably in the area of social acceptance.

Greek poets, sculptors, and designers. The skill of the dramatist, like that of the athlete, was tested in competition and rewarded by prizes. The bard gave way to the historically defined individual. Sophocles, in the fifth century before Christ, was no blind beggar but a respected citizen, a soldier, and politician, as well as a tragic poet. Above all, the intellectual role of the writer was recognized and his claim to respect was validated by the celebrated

Emergence of the known artist

dictum of Aristotle that poetry is more philosophical than history. Aristotle's defense of poetry was perhaps a deliberate response to the celebrated attack by Plato in *The Republic* on the creative artist as a potential threat to the stability of the state.

In other fields, too, artists began at the same time to emerge from anonymity and to achieve social acceptance. The nameless artisans and stonecutters who erected the first crude Doric temples and carved the cult images that they housed were succeeded by renowned architects such as Ictinus (flourished 5th century BC) and Callicrates and by master sculptors such as Phidias (flourished 475–430 BC), who supervised the rebuilding of the Athenian Acropolis. Phidias is alleged to have represented himself and the Athenian tyrant Pericles on the shield of Athena. Such self-glorification would have been beyond the imagination of earlier generations.

The great mass of Greek sculptors of the classical and Hellenistic periods, however, continued to be regarded as craftsmen, paid standard wages for a day's work or for a specific piece. To Plato, for example, sculptors were common workmen. Even the recognized masters were expected to turn their hands to whatever their patrons demanded.

Rome and service to the state. Under the late Roman Republic and the empire, the artist continued to enjoy a favoured status. The great Roman dramatist Terence (flourished 2nd century BC) began his career as a slave, but his achievements earned him freedom and admission to the leading intellectual circles of his time. The organizing genius of the Romans enlisted poets, architects, and sculptors in the service of the state. Gaius Maecenas (died 8 BC), the first of the wealthy patrons of the arts, encouraged and supported such poets as Virgil and Horace. Vast building and engineering projects throughout the empire gave employment and prestige to many architects.

This was the age, too, that saw the emergence of the art connoisseur and the tourist in search of cultural treasures. The esteem for artists in Rome is reflected in the eagerness with which Pliny the Elder sought out and recorded biographical information on the great artists of Greece. For the first time the artist was felt to merit the same attention as the statesman or soldier. A similar rise in the prestige of the writer was signalized by the founding of such great libraries as the one at Alexandria, devoted to preserving the literature of the past.

The musician of antiquity. Much is known about the musician in antiquity, although practically none of the music itself has survived. There is considerable testimony to show that music itself apparently was considered among the highest of human accomplishments; in fact, of divine origin. The legend of Marsyas, the human being who dared to challenge Apollo to a musical contest and was flayed for his pains, was a favorite subject of Hellenistic sculpture. The myth of Orpheus, whose playing on the lyre could move even inanimate things to wonder and delight, reveals the almost superstitious awe in which the Greeks held the powers of the musician. Musical theory, with its close relationship to mathematics, was regarded as a branch of philosophy. The philosopher Pythagoras (flourished *c.* 530 BC), who saw the whole universe as a harmony of the spheres, was only one of many who gave the highest intellectual ranking to the study of music. The special status given to music in antiquity continued into the Middle Ages, when music alone, of all the arts, was ranked among the seven branches of learning.

Music as the highest art

In Greece, there emerged for the first time the distinction between the gentleman amateur and the paid professional that was to play so large a role in the later history of the arts. Every educated Greek was expected to be able to play an instrument, to sing acceptably, and to discourse on the theory of harmony. On a much lower intellectual and social level were the professional entertainers who competed for prizes at great public concerts, who performed in the dramas, and who supplied the musical accompaniment for athletic games.

Actors, dancers, and rhetoricians. The distinction between the creative artist and the entertainer or interpreter, which continues to be made even today, seems already to have existed in ancient civilization. The accomplishments of the actor-dancer were admired and applauded, but, aside from the citizen-dancer of the Greek festivals of tragedy, he had a relatively low intellectual and social status. The names and other details of some of the famous actors of this period are known, but references to them are in a tone altogether different from references to a Phidias or a Virgil, and everything indicates that actors were regarded as belonging to an inferior class.

One art virtually unpracticed today, that of the orator or rhetorician seeking to persuade, by speech or writing and according to a detailed formulistic pattern, occupied an especially favoured place in antiquity. The principles of the art were expounded in treatises by Aristotle, Quintilian, and others, and its greatest practitioners, Demosthenes among the Greeks and Cicero (first century before Christ) among the Romans, were accorded the same respect given to the poets. In the twilight of the Roman Empire, the young St. Augustine supported himself as a teacher of rhetoric. The prestige of rhetoric as a noble and useful art reached its highest point during the Renaissance, when every court had its master rhetoricians and orators.

The lost art of persuasion

The Dark and Middle Ages. With the collapse of the Roman Empire in the West in the 5th century, the professional artist virtually disappeared in Europe. Until the revival of Western culture under Charlemagne about 800, the practice of the arts was confined mainly to scattered monastic enclaves, which kept alive the traditions of a written literature and began to develop a new architectural style. Some of the arts, such as the written drama, were lost altogether, only to be revived later from church ritual and folk ceremonies. The sophisticated poet, a product of the stable and assured civilization of antiquity, vanished from the scene to be succeeded by anonymous bards, such as the creator of the Anglo-Saxon *Beowulf,* who, as in Homeric days, put into final form the results of centuries of oral shaping of legend and history. Only in the Byzantine Empire and, after the 7th century, in the rapidly growing world of Islām, was the professional artist able to flourish.

The rich burgeoning of medieval civilization following the early 9th-century Carolingian renaissance produced a magnificent harvest in the arts, but for the most part the creators remain unknown. The superlatively beautiful so-called Book of Kells from 9th-century Ireland was decorated, page by page, by a monk or group of monks who saw the task as their gift to God, their way of living their vocation. It is doubtful that they were conscious of themselves as artists or that they were so regarded by their fellows.

The builders and sculptors of the great Romanesque and Gothic churches were journeymen masons and carvers who worked under the driving direction of a forceful churchman, such as the remarkable Frenchmen Hugh of Semur, Abbot of Cluny from 1049 to 1109, and Abbot Suger, who built the Abbey Church of St. Denis from 1140 on. The radiant stained-glass windows of the Gothic cathedrals were made in the workshops of Chartres and other centres. Only rarely did a particular craftsman, such as the sculptor Giselbertus of Autun or the sculptor-decorator Nicholas of Verdun, emerge from anonymity.

The Renaissance and Baroque. An enormous increase in the prestige of the artist came about with the beginnings of the Renaissance in 14th-century Italy. The veneration for antiquity that so dominated intellectual life was in large measure a veneration for the arts of antiquity, for a life-style in which the written and spoken word, the visual image, the public monument, and those who created them were seemingly central elements.

Reverence for the artist

New stance of the poet. The crowning with laurel of the poet Petrarch at Rome in 1341 was a ceremony intended to establish a link with ancient civilization. Almost immediately after the death of Dante, *The Divine Comedy* became the object of an intense scholarly and critical study equal to that given the great epics of antiquity.

Throughout Italy, but especially in Florence, the humanist of the 15th century was dedicated to the purification and preservation of Latin as a living universal language. He gave to the profession of writer and scholar a distinction it had not had since the collapse of Rome nearly a millennium earlier. Men of letters were held in an esteem

that—in the case of that shown the Dutch humanist Desiderius Erasmus—approached reverence.

Regnancy of the visual arts. The new Renaissance attitudes were most striking in the visual arts. The painter and architect Giorgio Vasari, in his *Lives of the Most Eminent Architects, Painters, and Sculptors* (1550), saw the development of the arts in Tuscany as the working out of a divine plan. According to Vasari, God sent Michelangelo to the world endowed with so great a universality of power in each art that he might be considered of a divine rather than human nature. A century earlier, no one would have considered artists deserving of extended biographical treatment.

The artist had fought for this new status, however, from Filippo Brunelleschi, who stoutly defended his independence as an architect from the meddling of the Florentine government, to Michelangelo, in his defiance of Pope Julius II. Leonardo resented bitterly the placing of painting among "the mechanical arts" and attempted to raise the status of painting by deliberately downgrading sculpture, which he called a sweaty and fatiguing job for workmen. Even after he had become a world-famous artist, Michelangelo felt it necessary to defend his social and intellectual position. Forbidding his nephew to address letters to him as "Michelangelo the Sculptor," he insisted he had never been a painter or sculptor such as those for whom it was a business.

Status and the academy

The first academies of fine art were founded not primarily as teaching institutions but as means of enhancing the standing of artists. Florence's Accademia del Disegno, founded by Vasari in 1563, was headed jointly by a prince and an artist—the Grand Duke Cosimo and Michelangelo. In 1564 the academy publicly demonstrated the honour being paid to artists in its elaborate funeral ceremonies for Michelangelo. Such leading Venetian artists as the painters Titian and Tintoretto and the architect Andrea Palladio were glad to apply for membership in the Florentine Academy, and its advice on the design of the Escorial Palace was requested by King Philip II of Spain.

Particularly in northern Europe, however, the average painter, as distinct from the outstanding genius, continued to be regarded as a craftsman throughout the 16th century. In 1590 the Guild of St. Luke in Haarlem included not only painters, wood-carvers, and goldsmiths but also printers, slate layers, plumbers, and lantern makers. This extreme situation was bitterly complained of by a leading Dutch painter and theorist of the period, but it illuminates the attitude toward painting still held by many.

In the 17th century the intellectual and social status of the artist reached perhaps the highest level it has ever attained. Two of the greatest Baroque artists, the Flemish painter Peter Paul Rubens and the Italian sculptor Gian Lorenzo Bernini, lived like princes. Both were accepted in leading intellectual circles and were completely at home in this environment. The Spanish master Diego Velázquez enjoyed lifelong security as the favourite painter and friend of King Philip IV, who, despite the grumbling of many aristocrats, awarded him the Noble Order of Santiago.

Writers and performers. The change in the status of the writer during the Renaissance and Baroque periods was not nearly as spectacular. The poet and rhetorician were treated with respect, but it was still necessary for Sir Philip Sidney about 1581 to write *An Apologie for Poetrie* (first published in 1595), and the poet Edmund Spenser, like many poets of lesser stature, had to beg for patronage from powerful nobles. Shakespeare published his narrative poems with obsequious dedications to his patron, the Earl of Southampton.

Practitioners of such newer literary forms as the novella and the popular drama never achieved full social or intellectual acceptance in this period. The dramatist, in particular, linked as he was with the day-to-day commerce of the theatre, and often himself an actor, was considered simply as a hack writer. His plays were regarded lightly as literature, and when Ben Jonson dared to publish his plays as his *Workes* in 1616, he was jeered at for his pretensions. Actors, though they were loved and admired as entertainers, had escaped only recently from being classed as "rogues and vagabonds," and technically they were regarded as household servants of the nobility. An occasional actor, such as Edward Alleyn or Shakespeare, was able to attain the position of a gentleman if he was a manager as well or had powerful patrons.

The theatre as mere entertainment

Only in the France of Louis XIV did the dramatist attain the status of an honoured man of letters, and then only by adhering to the rigidly defined neoclassical standards of dramaturgy. The drama, like all the arts, was closely integrated into the political structure, and powerful ministers of the crown carefully supervised the work of the playwright. Leading dramatists such as Jean Racine were victims of political intrigues, but if they survived them, they could look forward to the ultimate reward of election to the Académie Française. Molière, however, who was an actor and theatre manager as well as a dramatist, was regarded socially as a member of Louis's household.

Revolutionary impetus. The great social and political changes of the late 18th century, climaxing in 1789 in the French Revolution, were as decisive for the artists as for other groups of men. The emphasis on personal freedom and the desire to break loose from mind-forged manacles as well as social shackles were key elements in the Romantic movement that dominated the arts for almost 100 years. A wide gulf separated the attitudes of Haydn from those of Mozart, though the two were only a generation apart in age. Haydn was content to serve as music master for the Esterházy family in Hungary from 1760 to 1790. Mozart could easily have made a similar career, but he rebelled against being a servant to the Archbishop of Salzburg. He determined to earn his living as an independent musician, and for a time his career flourished. The day of the free-lance composer had not yet dawned, however, and he died early, in poverty and loneliness.

For the first time in history, under the impetus of the French Revolution, there emerged the phenomenon of the revolutionary artist committed to an active political role. The most conspicuous example was the Neoclassical painter Jacques-Louis David, who not only expressed the ideology of the Revolution in his works and organized its great public festivals but was a political leader and a friend and ally of the Revolutionary leaders Marat and Robespierre. The ambivalent attitude expressed in the 20th century toward political activity by artists was illustrated earlier when David was caught up in Robespierre's downfall in 1794. Unlike other of Robespierre's followers who were executed summarily, David, after a stay in prison, was pardoned and restored to favour as virtual dictator of the arts. A similar situation befell the Spanish painter Francisco Goya, who had partially cooperated with the French puppet government in Spain. When the Napoleonic armies were driven out in 1814, he regained his position as court painter. There may have been in both cases an unwillingness to dispense with the services of a great artist. In addition, however, there also may have been at work the feeling, expressed even in this present century, that the artist is not to be taken altogether seriously as a politician.

The artist as political activist

The developing setting of modern art. A characteristic feature of artistic activity in the 19th and 20th centuries is that no generalizations about the status of the artist can be made. Trends are divergent and often completely contradictory. On the one hand, the artist became one of the representatives of the acquisitive society, a successful businessman satisfying the demands of the market. Whether he was a man of genius, such as the English novelist Charles Dickens and the French novelist Honoré de Balzac, or a talented and industrious hack, he wrote for a vastly expanded audience created by mass literacy and growing leisure. The English writer Anthony Trollope, sitting in his club and turning out his fixed quota of words, finishing a novel one day and beginning another the next, was a perfect embodiment of the respectable, punctual, middle-class writer.

Similarly, the official artist was recognized by the national academy and hung at the salon exhibitions. He created a standardized and approved product—whether portrait, landscape, or sentimental illustration—to meet the great demands of a newly rich clientele eager for culture but unsure of its tastes. The American portraitist John Singer Sargent not only answered completely the artistic needs

of his upper class patrons but identified with them as a person. At this point the social distinction between patron and artist virtually has disappeared.

On the other hand, the 19th century was above all the period of the alienated artist, the deliberate exile from society. The tone was set early in the century by the English poets Lord Byron and Shelley, both born aristocrats, who flouted the standards and conventions of their class. The contempt for accepted social behaviour and the adoption of the pose of the outcast are seen at midcentury in the French poet Baudelaire and in the closing decades in the French painter Gauguin. *Épater la bourgeoisie,* "to dumbfound the middle class," became the slogan of a whole group of French Romantics. The doom-ridden artist propelling himself toward destruction by drink, drugs, or a furious excess of behaviour became a characteristic figure of modern times, from Edgar Allan Poe to Jackson Pollock and many "pop" singers of the 1960s and 1970s.

Emergence of the alienated artist

Somewhat related to this phenomenon was the distrust with which the middle class came to view artists, above all painters and musicians. This is especially true of attitudes toward the avant-garde artist, whose rejection of academic conventions within his own art makes him suspect as an enemy of society itself. Napoleon III's superintendent of fine arts summed up for all time the attitude of officialdom toward such artists when he expressed his displeasure and disgust with their work, characterizing them as democrats who do not change their linen and hope to put themselves over on the world.

Impact of scientific dominance. As science became a dominant force, the intellectual prestige of the artist declined. The role of the prophet continued to be played by such writers as Thomas Carlyle and John Ruskin, both of whom were skeptical of the benefits of science and technology. No creative artist since Goethe, however, has gained the intellectual respect accorded to scientists. Modern art has produced no men of universal interests and abilities to match such Renaissance geniuses as Leon Battista Alberti or Leonardo, whose work and thought carried them into virtually every area of human activity.

The ideological gap between scientists and artists, between "the two cultures," as the English novelist C.P. Snow has called them, has widened dangerously over the past century. A number of artists, however, attempted to incorporate into their own work some of the methodology of science and to gain for themselves the intellectual status of the scientist. In a famous essay of 1880, *The Experimental Novel,* Émile Zola argued for a literature governed by science and claimed for the novelist the function of a biologist of society. The French Postimpressionist painter Georges Seurat, who set for himself the reconciling of art and science, believed that properly applied scientific theory could replace intuition as the basis of art. In the 20th century, apologists of Cubism, though not its leading practitioners, saw in it the artistic expression of the fragmented world of modern physics. Recently, electronic music, created mainly by university-based composers, has provided a new union of technology and art.

New areas of respectability. The actor-manager David Garrick had helped to make the theatrical profession respectable, but during the early 19th century, actors and actresses, however applauded or financially successful, continued to be regarded by many as slightly disreputable. By the end of the century, however, the situation had so changed that in 1895 Queen Victoria knighted Henry Irving, the first actor to be so honoured. Such an accolade became almost commonplace in following years, and in both Europe and America the actor is now accorded considerable respect.

The new arts of the 20th century—cinema, radio, television, and recording—have all produced their mass idols. The fantastic adulation lavished on film stars or pop singers, however, has often been accompanied by an openly or covertly expressed intellectual contempt. Of all the artists involved in the creation of a film, only the director seems so far to have achieved intellectual respectability. Such directors as the Italian Federico Fellini, the Swede Ingmar Bergman, and the Frenchman Jean-Luc Godard became subjects of a serious aesthetic discussion comparable to that focussed on the most important of contemporary writers or visual artists.

Artists of the new arts

In music, the last 100 years have featured the virtuoso performer, the pianist, the violinist, the soprano, or the conductor. The separation of composer from performer began early in the 19th century, and instead of a Bach, Mozart, or Beethoven performing his own works, there is the virtuoso who interprets the compositions of others. The most publicized musician of the 20th century and the one most widely admired for his intellectual gifts was not a composer but the conductor Arturo Toscanini. The famous pianist Ignacy Paderewski, when he served briefly as premier of Poland in 1919, became the first professional artist to head a national government. One of the most striking phenomena of the rock music of the 1950s and 1960s was the closing again of the gap between composer-lyricist and performer.

Another important development in this century was the growing activity of black artists and women artists to break down the social and intellectual discrimination that historically has been directed against them. There has been, as a result, not only increased public knowledge of the contributions made by both groups but also a greater understanding of the artist as an individual who is directly involved in—and in much of his work reflects—the problems and stresses of his society.

THE ARTIST'S LIVELIHOOD

Throughout history, the economic status of the artist has varied as widely as his social and intellectual status, though changes in the one have not necessarily paralleled changes in the other. Since conditions favouring one art may have been unpropitious for another, artists in different fields often did not experience the same measure of economic security at any given time. Similarly, though artistic activity in general has followed the economic development of a society, there have been periods in which a society has experienced great prosperity while at the same time artists have starved.

Forms of patronage. Until recently, artists in most fields were directly dependent upon patronage—whether governmental, church, or private—for their livelihood. They produced works specifically commissioned for a particular need or occasion or designed to appeal to the tastes of a well-defined group or known individual. The notion of an artist working to please himself and then attempting to sell his product on the open market, either directly or through an intermediary, is a comparatively modern one. In such fields as architecture and serious music the artist even now remains almost completely dependent on direct commissions.

The system of patronage has had a profound effect on the work of art itself. The idea that institutional sponsorship always produces bad works of art is refuted by the facts. The buildings on the Acropolis of Athens, the Gothic cathedrals throughout Europe, the Sistine Chapel frescoes in Rome, and the sculptures of the Benin kingdom of West Africa, for example, were all commissioned by a governmental or religious body. Artists working to express a shared system of ideas and beliefs for a community of which they are an integral part are likely also to share a common and stable style. The rapid shifts of style that characterized the arts in modern times reflect, to a certain extent, the new economic status of the artist as well as the present instability of artistic traditions.

Quality and patronage

The open marketplace. Nevertheless, many artists of the past have chafed at the loss of individual freedom entailed by institutional support. This was particulary true during the 16th and 17th centuries, when the intellectual and social status of the artist was improving. When artists gradually freed themselves from the tyranny of patronage, they often discovered that they had submitted to the equally confining tyranny of the marketplace. In 17th-century Holland, for the first time in the history of art, painters began to produce works to be sold at auction or in art markets. The dependence on commissions did not cease, but direct patronage was no longer the only source of the artist's income. Most of Rembrandt's work, for example, was probably done to order, but many of

his surviving works, including more than 60 self-portraits, probably were done without immediate commission.

In the 19th century, a number of artists attempted to capitalize directly on their own work, not by selling individual paintings to particular buyers but by exhibiting them for a fee to a mass audience. The American artist Rembrandt Peale earned $9,000 from the showing of his painting "The Court of Death," which was seen by 32,000 people during a 13-month tour in 1820–21. At virtually the same time, the French painter Théodore Géricault was exhibiting his famous, "The Raft of the Medusa" throughout England and Ireland. In 1855, Gustave Courbet constructed his own Pavillon du Réalisme at the Universal Exposition in Paris, charging the public an entrance fee to view 50 of his paintings.

In the other arts as well, the artist emerges as an individual entrepreneur from the 16th century. Alexander Pope was perhaps the first poet in history to earn a living entirely from the public sale of his work. The new commercial orientation of the writer was summed up in the famous aphorism of Samuel Johnson, "No man but a blockhead ever wrote, except for money."

Institutional patronage has never, even in modern times, lost its importance for the artist. Eugène Delacroix, the supreme French Romantic painter, accepted a number of commissions for large murals from the French government. One of the most celebrated paintings of the 20th century, the "Guernica" by Pablo Picasso, was done for the Spanish Pavilion at the Paris Exposition of 1937. Both Marc Chagall and Henri Matisse created masterpieces of religious art on commission.

Artists in the modern period have had, nevertheless, to appeal to the general public in order to survive. For those who succeeded, the rewards were great, and many artists, both academic and avant-garde, became wealthy. On the other hand, innumerable other arguably good artists have been driven to despair by lack of public recognition and support.

Governmental and other subsidies. Various attempts have been made to provide some kind of governmental subsidy for artists. Among the most conspicuous of these were the Works Projects Administration (WPA) programs for painters, writers, actors, and other artists supported by the United States government during the depression of the 1930s. These projects were attacked bitterly by some politicians and eventually discontinued.

State-supported performing companies

Today, the principle of government support for the arts is widely accepted. Most European countries have state theatres and opera houses, and they support symphony orchestras, ballet companies, and other groups of artists. The British government grants sizable subsidies to the National Theatre and the Royal Shakespeare Company. In the United States, the federal government and some state governments have given financial aid to artists through such organizations as the National Endowment for the Arts and the New York State Council on the Arts. Universities and some private foundations have become important sources of economic support for the artist. Poets, painters, and composers in residence are now found in many universities, sometimes with teaching duties, sometimes free simply to create.

Conditions outside the West. The social forms of non-Western cultures have varied so widely, from place to place and from period to period, that it is impossible to make any valid generalizations about the economic position of the artist in such cultures. At one end of the scale, in simple nomadic or agricultural communities, the artist hardly has existed as a specialized person. Such crafts as pottery making or weaving generally have been diffused throughout the community, sometimes limited to one sex or another. In the sophisticated and highly developed imperial, monarchial, or tribal societies of China, India, or Africa, on the other hand, the trained artist has always been regarded as a valued servant of the ruling or priestly group and has been integrated completely into the economic structure of the state. With the vast social and political upheavals in the Orient and in Africa in recent decades, a period of rapid change in the economic and social status of the artist has set in.

INTERACTIONS AMONG ARTISTS AND WITH THEIR PUBLICS

The mingling of artists working in the same or different mediums always has provided a leavening element for their creative energies and imagination. Similarly, collective or collaborative work, criticism and appreciation, and national and international awards, as well as collective action for the benefit of the artistic community, have contributed to artistic life and work.

The artist's working environment. The act of artistic creation is usually a solitary one, whether carried out in an isolated cell or in a crowded room. Most artists, however, have sought the stimulus of some special kind of environment, generally one in which they could have regular interaction with their peers. Only rarely has an artist who is cut off from others, by necessity or choice, been able to produce great work. It has been suggested that the American poet Emily Dickinson might have developed her poetic gifts even more significantly if she had not been so isolated from other writers. The battles of wit between Shakespeare and Ben Jonson at London's Mermaid Tavern may be apocryphal, but they describe a situation typical of the literary life.

A deliberately and formally organized artistic environment has proved only rarely to be conducive to creative work. Art colonies, either specifically limited to artists or existing within Utopian communities, have tended to fall apart rather quickly. One of the longest lasting of these, the MacDowell Colony at Peterborough, New Hampshire, has endured mainly because it offers a pleasant and quiet summer retreat for the artist. Brook Farm in Massachusetts, which Nathaniel Hawthorne joined briefly in 1841, and the Helicon Home Colony in New Jersey, founded by Upton Sinclair, were both short-lived.

The university has come to play an important role as a fostering environment for the artist. The many temporary or permanent positions it offers have provided not only a measure of economic security for artists but also an intellectually stimulating setting. There is some feeling, however, that permanent immersion in an academic environment may insulate the artist too much, eventually depriving him of his vital sources of inspiration.

Centres and schools of artistic activity

Historically, most artists seem to have thrived best in a city that is the centre of vigorous political, economic, and intellectual activity and in which they could interact with other artists when and where they chose. Florence in the 15th century, London in the Elizabethan era, Vienna in the late 18th and early 19th centuries, and Paris from the Revolution until World War II were such places. The Café Guerbois in Paris was the scene of innumerable heated discussions in the 1860s and the 1870s between many of the leading painters and writers of the period. Such interchanges undoubtedly provided much creative impetus for their art.

Sometimes, artists brought together by similar views have mutually inspired each other and worked in tandem to develop new styles. This was true probably of Giorgione and Titian in Venice, and certainly of Georges Braque and Picasso during the elaboration of Cubism in the early 20th century. There have also been looser groupings of artists with common interests, such as the Impressionist painters who exhibited together from 1874 to 1886. More recently, such groups as the Dadaists of immediately after World War I and the Surrealists of the 1920s for a time united various artists of sometimes diverse tendencies.

Artists have on occasion, particularly during the 19th century, combined out of a sense of shared poverty and neglect to express a common contempt for accepted values. They have formed a separate society of their own, a "bohemia" characterized by deliberately outrageous costume and behaviour. The ultimate expression of the bohemian disdain for middle class conventions was the glorification of suicide, and young French bohemians actually founded a Suicide Club in 1846 as a gesture of defiance.

Social integration outside the West

Such bohemian excesses generally have been unknown in non-Western cultures. In societies where the role of the artist has been clearly defined and established by long tradition, the notion of the alienated artist would be virtually incomprehensible. Like the European craftsman of

the Middle Ages, the non-Western artist has functioned not in a special environment set apart from his society but as a respected member of the community. Here again, of course, as in other aspects of the profession of the arts, the very recent period has begun to see a breakdown in traditional values and relationships.

Multiple creators. Related to the question of the artistic environment is that of group creativity. A collective approach has proved far less viable in the arts than in such fields as scientific research. In the performing arts, film, and architecture, however, cooperative activity has been not only possible but often necessary, although usually there is one guiding vision—that of the director or the chief architect, for example. Many great buildings, such as St. Peter's Basilica in Rome, represent the effort of a number of different architects. Almost always, however, these architects have been in charge successively rather than at the same time.

Collaboration

More successful in most arts has been the collaboration of two individuals. The Parthenon was the product of the architects Ictinus and Callicrates. Collaboration was a common procedure among Elizabethan dramatists, a most notable example being the works of Francis Beaumont and John Fletcher. A collaboration between composer and librettist, such as that between Mozart and Lorenzo da Ponte, created many great operas.

Art collectives have been organized, with varying degrees of success, in many of the Socialist or Communist states, particularly in the immediate post-Revolutionary periods. In such countries as China, North Vietnam, and Cuba, deliberate emphasis has been placed on "the democratization of art," an attack on the notion of art as the province of the individual genius, and an attempt to create a collective and anonymous art. Numerous political events, such as the 1968 student strike in France, stimulated collective activity in the production of propaganda posters and the organization of guerrilla-theatre companies that gave informal but impassioned performances usually on social or political themes.

Guilds and unions. Artists have also banded together for very practical purposes. It was, for instance, during the later Middle Ages and the Renaissance that European artists, like all other craftsmen, were organized into guilds that looked after their economic interests and regulated trade procedures. The bronze workers of the great African kingdom of Benin, which flourished in the 16th century, also had their guild.

Attempts to organize creative artists into modern trade unions generally have failed. During the depression in the United States, artists' and writers' unions enjoyed a brief period of growth, and during the 1960s black artists and women artists formed their own groups. Performing artists, in contrast to creative artists, have formed strong unions that have been able to exert considerable pressure to better their economic situation. American Actors' Equity Association and British Actors' Equity Association are probably the best known of these unions, and there are similar organizations in radio and television and in the film industry. On an international scale, there have been various attempts to bring together artists for political or economic activity. International PEN (*P*oets and playwrights, *E*ssayists and editors, and *N*ovelists) is an organization of writers that has taken vigorous public positions on matters of concern to professional men and women of letters. Founded in 1921 and actively supported in its early days by such prominent figures as H.G. Wells, Bernard Shaw, Anatole France, and Thomas Mann, the organization includes today more than 8,000 writers from 58 countries.

Impacts of criticism and appreciation. Among the necessary conditions of work for most artists are public criticism and appreciation. Although artists often have pretended to be scornful of critics, generally they have flourished best in an atmosphere in which their work was studied, understood, and encouraged. Almost every important artistic movement of modern times has had its critical spokesman and defender. Conspicuous among such champions have been the Frenchmen Émile Zola, for the Impressionists, and Guillaume Apollinaire, for the Cubists, as well as the American critic John Martin, for the modern dance movement.

Many creative artists have been discouraged, however, by lack of appreciation of their work. The great Baroque architect Francesco Borromini committed suicide at least partly because of critical neglect and attack. A legend that the English poet John Keats died because of savage criticism of *Endymion* is false, but Keats was affected seriously by the attacks. Cézanne, in his later years, was deeply hurt by what he thought was complete public disregard of his achievement.

National and international honours

Like individuals of distinction in other fields, artists have been singled out for awards of various sorts. The most prestigious of these honours is the Nobel Prize for Literature, which, with two exceptions (1914 and 1943), has been awarded annually since 1901. The prize has sometimes been refused, notably because of political pressure, but the writers chosen usually have regarded it as the climax of their careers. There is no comparable award in the other arts.

In the United States, the Pulitzer Prizes annually honour outstanding work in drama, fiction, poetry, and musical composition, as well as in scholarly and journalistic writings. The National Book Awards also honour literary work in the different genres.

In other countries, artists are given prizes or other marks of merit for distinguished achievement. The Prix Goncourt is the best known of French literary awards. Many creative and performing artists appear each year on the honours list in Great Britain, as recipients of knighthoods or other distinctions. In the Soviet Union, the title of Honoured Artist is conferred as a badge of accomplishment, and in Japan, actors are often honoured with such titles as National Living Treasure, indicating the prestige they have acquired.

Artists are also eligible for election to honorary societies, some of which are limited to the arts. The greatest tribute that can be paid to an artist or intellectual in France is elevation to membership in the Académie Française, the famous company of "immortals." In the United States, the National Institute of Arts and Letters constitutes the chief honorary society of the arts.

THE ROLES OF THE AMATEUR

Amateurism has always been an important factor in the development of the arts. In the oldest sense of the term, the "amateur of art" is simply the lover of art. He need not necessarily be a practitioner of any of the arts himself, functioning instead to encourage and support the arts in every way possible. What distinguishes this kind of amateurism from passive art appreciation is its active commitment. From its ranks come the students, the connoisseurs, and the patrons of art.

There is also a more common sense in which the term amateurism applies to the arts. There are vast numbers of people who, without special talent or extensive training, write, paint, or play musical instruments primarily for their own pleasure or as a leisure occupation. Often such amateurs band together in musical groups or theatrical companies that perform for themselves and their friends. The line of demarcation between amateurs of this kind and professionals is usually clear, although their economic contributions in the form of royalties are often important for playwrights, film performers, and the composers of popular music. Few Sunday painters, unlike Gauguin, ever abandon their businesses and families to risk everything on their talents.

The idea of the gentleman artist

Another kind of amateurism—rare today, though historically it has been of great significance—goes back to an idea that appeared first in antiquity and acquired force during the Renaissance: namely that proficiency in an art, particularly music or poetry, is an (ennobling) attribute of the gentleman. Art is valued as an accomplishment of the educated man, but not as a profession. Unlike the art amateur who practices an art simply for his personal enjoyment and basically is not concerned with how well or how badly he does it, the gentleman amateur aims at excellence. His ideal is the quality of *sprezzatura,* or effortless grace, described by Baldassare Castiglione in his

Courtier (1528) as one of the chief characteristics of the Renaissance courtier.

Chinese culture always has been unique in considering painting as the special avocation of the noble amateur. The man of letters, the statesman, and the upper-class gentleman have traditionally been trained in and expected to be proficient in the art of painting, and especially in calligraphy. In India, too, training in the arts has been considered a necessary part of the education of members of the highest caste.

The amateur in all of these senses has made invaluable contributions to the preservation and dissemination of art. The devotee of art has encouraged and supported artists, has collected and handed on works of art, and has founded museums, libraries, and schools for the arts. Above all, he has set a standard of taste in every generation, sometimes a false or artificial one but one that often has raised the level of artistic performance. If the skilled amateur at times has introduced a measure of snobbism into the appreciation of the arts, he has compensated for this by his defense of art against those who have attacked it as immoral, dangerous, or frivolous. Most of all, however, artists are indebted to the millions of amateur practitioners of art who, having experienced its value for themselves, can respond to it as practiced on the highest professional level. (Si.T.)

Social and economic aspects of the arts

It is necessary to begin a sociological analysis of the arts by identifying the various social frameworks within which artistic activities have been conducted and the influences that these frameworks have had on the style and content of the arts, the levels of creative attainment, the mode of living of the artists, and the uses to which their art has been put by society. This mode of analysis is not concerned, as the histories of the various arts are, with describing how the particular arts have historically evolved and what they have meant to their users. Rather, it is aimed at discerning the basic alternative patterns of organizing artistic activities and the consequences, for society and for the arts, of adopting one or another of them.

Most of the necessary knowledge for recognizing these patterns is still lacking or is ambiguous in its implications. Indeed, there is no generally accepted theoretical basis for encompassing all the arts in relation to all sociological variables in all types of societies, from the simplest to the most complex. There is, furthermore, hardly any other field in the whole area between the humanities and the social sciences as inviting to partisan sensibilities as the relationship between art and society. Any general statements about relationships between art and society must therefore be treated cautiously, not as established knowledge but as tentative hypotheses.

THE FIELD OF ART

There are two possible ways to conceive of art sociologically. In the nonhistorical view, art must be conceived as that which is defined by a society, or an artistically relevant part thereof, as art. This could be called the "labelling" view. The work itself may or may not claim to be art; it is recognized as such by those with an authority to do so (in modern societies, by artists and art critics) or by anyone interested. This definition implies that art did not exist in preliterate societies until it was recognized by the moderns, since what now appears to be art has been treated mostly as religious or utilitarian artifacts in such societies. In the absence of the label art, imposed by later cultures, these objects are indeed only utilitarian or religious artifacts. Art arises merely in our perception of them, but does not exist in the intrinsic qualities of the objects themselves.

Historical conception of art

The second, historical view of art is based on the assumption that art is what survives a series of "tests" given to objects that function as art. When such an object is initially presented to the view of people other than its creator, it could be viewed as representing a "claim to art." When it is accepted by large numbers of people in a society or by its established elites or by other artists and art critics, it could be said to have become a popularly, or authoritatively, or professionally validated work of art. But the ultimate test of its artistic quality is whether it can transcend the boundaries of time and space and be accepted by other peoples in other areas.

The historical conception of art implies that art represents a universe with *some* shared characteristics that are everywhere recognizable as artistic (whether or not the concept of "art" is consciously acknowledged). Experimental psychological studies provide some support for this view. It has been found, for example, that traditional Japanese potters agree to a high degree with U.S. art students on the relative merits of a series of works of art shown to them. The agreement is closer than that between American art and nonart students. Thus, practitioners of art appear to agree across cultural boundaries on the quality of artistic attainments.

The agreement on what constitutes a work of art has the following characteristics:

1. It is partial. Each society and period has its own particular standards, as well as generally accepted criteria, by which it judges works of art. The patrons and publics of art (and even art critics) probably insist on these special standards to a greater extent than do the artists themselves. Hence, local criteria should have greater weight in judging works of art when the artistic enterprise is dominated by nonartists. This is one reason for the great fluctuations over time in the economic evaluations of particular works of art, for persons who are not artists usually determine these judgments.
2. The artistic consensus is hierarchical. When artists are left alone, they can, in the long run, roughly agree on the ranking of individual works of art. This happens even in quite egalitarian societies, such as the Australian Aborigines, where most men participate in artistic activities but differences in the quality of achievements and in individual capacities are recognized. The notion of a hierarchy of artistic qualities is therefore not a superimposition of a social hierarchy on artistic experiences.
3. The consensus on art has expandable boundaries. The artists of a society can incorporate works they have been unfamiliar with into their notion of the "field" of art, with a discriminating sensitivity as to their merits. The entrance of new claims to art generates efforts at evaluation, clashes of particularistic values, and the rise of artistic schools and movements. Such claims are ultimately tested in terms of what is considered to be the total structure of the field of art. In turn this structure evolves, by a process of self-testing, through the evaluations it gives to works claiming the right to enter it.

THE AESTHETIC FUNCTION

The nature of the system of art seems to derive from sustained experience with the practical problems of making objects or acts that perform the functions of art and from a sense, which craftsmanship seems to generate, for what transcends mere craftsmanship. A mid-20th-century survey in the United States has shown that craftsmanship by itself is more highly regarded, in judging works of art, by nonexperts than by artists and art scholars.

Art and craftsmanship

Since craftsmanship is a purposeful activity, it appears that the art public is more apt to judge art by some presumed purpose, while artists judge it in terms of what transcends any presumed purpose. If it is ultimately the consensus of artists that determines what is included in the field of art, artistic value must lie in something that is not recognized, even by the artists themselves, as "the purpose" of art.

It follows that works of art cannot be understood by the manifest functions they have been specifically intended to perform. Where they function most purely as works of art, they perform latent functions—unintended and unrecognized. If this observation is valid, art could be regarded as the generalized system of the society for the performance of unintended and unrecognized (but nevertheless needed) psychological and cultural functions. If these functions are effectively performed by other systems of the society, art can remain implicit in them. To the extent that other systems become explicit about the functions they perform and rationalize them to exclude everything that does not

clearly contribute to their purpose, art has to emerge as an autonomous system.

The autonomy of art from the social forces that would control it derives, as an immediate consequence, from the structural requirements of good design peculiar only to art; and, ultimately, from the origin of the aesthetic function in the intuitive organization of unintended and unrecognized functions of an interrelated psychological and cultural nature. To the extent that art performs an aesthetic function, it is not subject to intentional social control. A variety of consequences follow from this conception of the aesthetic function:

1. If its very essence arises from performing unrecognized functions, art must be a less self-conscious, a less "rationalized," and indeed a less professionalized activity than any other in the cultural sphere.
2. Since it must be ready to perform unrecognized functions as they unpredictably arise, the system of the arts cannot be a specialized one, adapted to a particular set of circumstances. It must remain generalized, to some extent maladapted to the existing state of society, and able to function in a wide range of areas of ambiguity.
3. The survival over time, and perhaps the aesthetic quality, of works of art depends on how wide a range of unintended and unrecognized functions they can effectively perform. It is because they have a wide aesthetic range, in this sense, that great works of art function for us even when it is not known exactly what they have meant for their producers, as is the case with prehistoric art. The latent functioning of a work of art is not dependent on the grasp of its intended meanings.
4. It could be argued that an effective organization of any unrecognized function constitutes the aesthetic aspect of the social or psychological system in which it is embedded. Thus, scholars could analyze successful works of art as diagrams of effectively constructed but hidden psychological processes occurring in personalities individually or collectively, and could discern how these diagrams are used, by artists and art consumers, to deal with otherwise raw and chaotic psychological processes. The diagrams may be seen as providing rehearsals for effective organization of these psychological processes or as suggesting alternative models for them or as providing focal points around which they can crystallize.

If aesthetic value depends on consciously unrecognized functions, does an explication of these functions erase the possibility of an aesthetic experience (or prevent it from arising for those who will, in the future, be conscious of the functions the work of art presumably performs)? Not necessarily—if the work of art, after one or more of its functions have been explicated, can still function effectively in other unrecognized and unintended ways. The interpretation of art could be viewed, then, as a struggle against its inexhaustibility, but the functions that have been fully explicated would seem to become more cognitive than aesthetic.

SOCIAL USES OF ART

Relation of art to other disciplines

While, to be artistically effective, art must function as art—filling many unrecognized and unintended functions—it does not generally operate as "pure" art. First, it may overlap other cultural systems—religion, philosophy, science, a secular ideology—and perform, in part, the more clearly identifiable functions of these systems. It is then shaped, to some degree, by the superimposed functions it performs as a part of those systems.

In general, art tends to become increasingly differentiated from other cultural systems in the course of social evolution. Yet in some periods a closer integration of art and some other cultural system may be sought. Thus, the system of science has, in most cases indirectly, affected much of modern visual art. It cannot be taken for granted that the most complete differentiation of art from other cultural systems is most conducive to its authenticity. Nor does a self-conscious "integration" of art with another cultural system enhance art, as is shown by the failure of Socialist Realism, tightly bound to Communist ideology. It could be inferred from the notion of the aesthetic function that an indirect, unintended mutual interaction between art and some other cultural system would be most stimulating to the arts.

Second, art may be used by various social agencies or groups to perform functions these agencies are interested in. Such use of art by social agencies structures the content and style of art and influences its level of creative attainment and its total repertoire of functions. Again, it is not to be taken for granted that it is necessarily disastrous for art to be used for extra-artistic purposes. On the one hand, by using art to fulfill their purposes, social agencies may restrict art's capacity to function as art. This seems likely to happen to the extent to which social agencies successfully limit art to performing any set of consciously recognized and intended purposes.

On the other hand, by using art for their own purposes, social agencies may also stretch art's limits in directions that artists might not otherwise have been inclined to explore, enhance certain of its expressive potentialities at the cost of others, and increase its capacity to communicate with contemporaries while perhaps reducing its ability to communicate transhistorically and cross-culturally. By being forced to struggle against purposes imposed from the outside, artists may become more aware of what is both peculiar and essential to art.

Like other symbolic systems, art can function as a means of attaining the purposes of any system of society. Thus in the economy, art can be used as a means for attaining or symbolizing the possession of wealth but also as a critique of particular ways of using it. In the political system, it can encourage or condemn a particular distribution or use of power. In the community, it can be used as a means of reinforcing or protesting against the existing order of sensibilities, expectations, social rankings, and social distances. In an ideological system, it can operate to strengthen the hold of established values by filling the imagination with forms or content suggestive of these values—or to question them by presenting forms and content that are irreconcilable with existing values. But even if art "objectively" functions to promote particular social ends, it is not necessarily consciously employed to promote these ends.

Extra-artistic functions

None of these extra-artistic uses of art seems by necessity aesthetically superior to any other. What seems important is whether artists accept the legitimacy of the extra-artistic expectations directed to their work and incorporate them, unselfconsciously, into their own notion of the artistic task. If they do so, they should be able to produce good art regardless of the type of extra-artistic expectations imposed on it.

The critical question, nevertheless, in evaluating the aesthetic quality of works of art is whether they can resist or transcend the social uses to which they have been put by their makers and whether they retain their own character and transmit their own message even when manipulated to serve the purposes of their sponsors. An art that has not been subjected to manipulation during its making could well be deprived of a powerful stimulus for acquiring a "resistable" character, an artistic toughness that ensures its aesthetic survival.

THE COGNITIVE CHARACTER OF ART

To what extent do the particular social uses of art shape its content and style? To what extent do content and style, therefore, correctly reflect or distort the "objective" realities of the society in which they have been produced? Does use of art by a social agency or group necessarily imply a distortion, in its interests, of the reality that art may be presumed to reflect? Or can some groups (as, in the Marxist views, the "progressive" ones, which identify themselves with the direction of history) use art in their own interests without thereby forcing it to distort reality?

The most general response to these queries is probably that art reflects either subjective affirmations or subjective denials, symbolic invalidations, of the existing reality. It can therefore be read only as a record of the history of subjective attitudes toward objectively existing reality. The ways in which art has been used can be assumed to influence the subjective responses it will express. The subjective responses that exist in the environment in which art is produced but that are not "useful" to the groups

Inherent subjectivity of art

or individuals that provide resources for art creation, or for the artists themselves, are less likely to be reflected in art. Yet, insofar as art necessarily performs unintended and unrecognized functions as well, it may reflect even the subjective responses that it is not useful to anyone involved in the artistic process to reflect. These responses may contradict the conscious intentions of the artist. Art is never an objective record, and it is never fully controlled by those who use it—or it ceases to be art.

The most significant art may well express both the most striking characteristics of objective social reality and the sense of what is most missed in it—reflections of reality as well as utopian denials of it. The significance of such art may arise from its discovery of ways to articulate these mutually contradictory subjective responses to social reality, without suppressing one in favour of the other. Cognitive distortions in art arise not from an introduction of subjective attitudes but from a denial of the ineradicable contradiction between existing "objective" realities and their possible "subjective" negations. Art distorts the totality of human experience, in any social setting, when it is biassed in favour of either "objective" recording or "subjective" expression.

Art reflects, or compensates for the deficiencies of, objective reality not only in its content but also in style. Even completely nonrepresentational arts therefore have a cognitive character, and subjective orientations to social reality can be inferred from them.

Easily swayed modes of art

Some arts lend themselves more easily to deliberate manipulation in the interest of consciously distorting the ways in which they reflect reality—whether in style or in content. Fiction, the theatre, painting, and sculpture are more vulnerable to such manipulation than music or lyrical poetry. Representational styles lend themselves more easily to manipulation than highly symbolic or completely nonrepresentational ones. Indeed, one reason for moving toward the latter styles, in modern societies, is the desire of artists to escape manipulation. The mass arts are particularly susceptible to imposed distortions. It is deliberate manipulation, rather than merely the use of art by social agencies and groups, that would appear to give rise to distortions in the way works of art reflect reality in its interrelated social and emotional aspects.

SOCIAL DYNAMICS OF ARTISTIC CREATIVITY

If art performs unintended and unrecognized functions, the creation of artistic values should be affected by the degree to which art is needed, in particular social settings or by particular individuals, to perform these functions. That is, for artistic creativity to become possible, there must be many psychic needs that are neither met by existing social arrangements nor can be consciously identified and purposefully dealt with by means of social policy.

Conditions favourable to artistic creativity arise when rapid changes in either the organization of society or in the emotions of its members produce a sharply sensed disjunction between personal emotion and objective social structure. But while the need for art increases during such periods, the possibility of creating it also depends on the availability of resources for creating art. The supply of such resources tends to be diminished in the phase of most intense action of periods of radical change. This phase occurs during rapid economic accumulation, technological transformation, the high points of religious (or secular ideological) reformations, and struggles for imperial consolidation, national liberation, or change of political system. Artistic creativity is enhanced when an increased social need for art coincides with an ample supply of resources for artistic production—thus before and after, but not during, the most intense phase of any cycle of technological, political, ideological, or communal change in the society. Activistic social movements are unlikely to be artistically creative, but they increase the need for art—after they have succeeded or failed to transform society.

Creativity and social resources

Conscious social policy can affect artistic creativity by supplying, or failing to supply, social resources for artistic production commensurate with the existing social need for art. Not all such resources, however, can be controlled at will—the supply of cultural symbolism, for example, depends on its existence in any social system in a form appealing to the imagination of artists. It does not depend on the immediate policies of governments, churches, or parties, although these institutions can, to a high degree, determine the allocation of economic resources to artistic activities. But while a deficiency of such resources may prevent the creation of works of art for which the potential exists in a society, economic resources cannot generate artistic values if the social need for art is not sufficiently intense, as during periods of general cultural quiescence and social complacency, when existing conditions are taken for granted by most members of a society (as in 18th-century Italy); if the creative people are too widely scattered in a large population or too isolated from each other by ethnic, ideological, class, or disciplinary barriers to attain a necessary density of interaction; if an appropriate social organization for producing art, particularly important for the large-scale arts and the film, is not established; or if the general symbolic design of a civilization is not sufficiently developed or is already too "completed" to sustain efforts at producing great artistic designs.

In modern societies, perhaps especially in the large nations, two threats to artistic creativity have emerged in the possible bureaucratic overorganization of the artistic enterprise, leaving too little space for the unintended and unrecognized in art, and the early popularization by the mass media of new artistic movements before they have had time to mature their contributions. Once artistic movements become widely popular, they tend to drop what they have been doing, since the modern cult of originality discourages a continued exploration of what others have become familiar with. Hence, what a style is potentially capable of may never be developed.

SOCIAL ROLE OF THE ARTIST

Variables in defining the artist's role

The two main variables in defining the social role of the artist are that role's degree of specialization and the extent to which it is conceived as involving manual labour or some sort of "spiritual expression."

By their nature, all the literary arts involve less visible manual labour than the traditional visual arts, and the sculptor or painter has been generally more easily and closely assimilated to the traditions of skilled manual craftsmanship. The poet has tended to be associated with the realm of religious ceremony and, later on, with record keeping within or outside the various church organizations. Thus, some of the prestige of literacy in traditional civilizations has attached to the poet's role. Yet it was originally literacy in the service of a god as well as an illiterate aristocracy, and there is still some tendency to expect writers, more than other artists, both to entertain the classes that have become their sponsors in place of the aristocracy and to serve a moral purpose. It is they, of all the artists, who are expected to be "the moral conscience" of society. But besides this clerical tradition, there is also the more anarchic one of vagabond poets, who live "beyond good and evil."

In music, he who composes a work is frequently—at least since the German composer Beethoven—perceived as partaking of a more "spiritual" role, and he who performs it, particularly in groups of performers, has been frequently seen as more of a "craftsman." In the theatre, the actor is a physical labourer insofar as he uses his own body, but, in performing his role, his body assumes and acts out "spiritual substances" originally alien, and possibly greatly superior, to it. This is one reason for the ambiguities in the social treatment of the actor, who, like the singer and the dancer, has been the most exalted and the most despised of artists.

Within the limits shaped by the nature of the particular artistic medium, the social role of artists has been affected by developments in the organization of society and its value system. The main evolutionary trend has been toward increasing professionalization of artistic roles. In the preliterate societies of a more egalitarian character, all adult members of a society (or all members of one sex and a few of the other) may be engaged in activities of producing objects or performances that, in addition to their consciously intended functions, have some kind of aesthetic aspect

(superfluous from a purely utilitarian point of view). But some individuals are recognized by their peers as more competent carvers, potters, or dancers, and their products or performances, though not superior in a utilitarian way, are more highly esteemed; their authors receive a superior compensation in prestige and, less frequently, in material valuables. Yet even the best of tribal artists are spare-time specialists who devote most of their time to meeting obligations incumbent on all members of their society of their own sex and age.

Full-time specialization

It is only with the development of a hierarchic type of social organization that, for male artists, full-time specialization becomes possible, if their society is both interested in art and sufficiently prosperous to sustain a demand for full-time specialists. Women tend to remain semispecialists or "folk" artists, and, the more professionalized the artistic enterprise, the lesser their part in it. In the primitive states or hierarchically organized chiefdoms is formed the main pattern that has governed artistic enterprise in classical civilizations: the division between "high" and "low" art, the specialization of male artists, formalization of their training, patronage by clients, and general subordination of art to the politically ruling class and the religious establishments.

This pattern has occasionally been modified in mature preindustrial civilizations. The basic hierarchic pattern, however, has been radically challenged only in consequence of the Industrial Revolution and the rise of a civilization associated with it, in which aspirations to universal participation appear. This transition is still going on. But "high" art has already become detached from its almost exclusive dependence on the ruling elite. It is now visible, through the mass media, to almost everyone and is intensely experienced by a recently developed loose coalition of artists and intellectuals. This coalition is the primary audience, even for art that has been explicitly produced for other social classes. An example is the Mexican murals of the 1920s that were intended to revolutionize the proletariat but are appreciated mainly by a bourgeoisified intelligentsia. With respect to art, the socially dominant class tends to lose confidence in its own taste and to become "culturally" subordinate to this coalition. From a symbol of privilege, art changes into a symbol of emotional aliveness; hence, the boundary between "high" and "low" art becomes blurred. But the artistic enterprise itself remains highly stratified in accordance with the prestige granted the type of activity the artist engages in and his personal achievement in it. Women once again return to greater participation in the fully specialized production of the "creative" arts. As for the performing arts, women have either always possessed or regained at an earlier time fully specialized roles in them. This is especially true of the dance, except in those cases where religious asceticism or some comparable influence has eliminated them from the performing arts as well.

"Cult of the genius"

Historically, the most significant single illustration of the ways in which the value system of a society affects artistic roles is the Western "cult of the genius." It developed under the influence of the great achievements and the striking personalities of artists like Michelangelo and Leonardo da Vinci in the Renaissance—a civilization that generally placed a very high value on achievement and expression of individual personality. Comparably great achievements in less "individualistic" cultures have not produced any similarly powerful notions of genius. The cult of the genius had the long-term effects of assimilating all the creative, and at a later date even the performing, arts to the "spiritual expression" of poetry; legitimating the demand for creative autonomy on the part of the men whose genius has been perceived as transcending the dimensions of established custom; and, on the basis of the above two changes, transforming those arts previously treated as crafts (and organized in guilds, etc.) into a peculiar kind of free profession.

All professions are corporate bodies of practitioners in a skilled activity who are devoted to an ethical purpose superior to the mere pursuit of wealth, power, or pleasure for themselves. The professions set their own standards, determine admissions to them, and judge their own members accused of transgressions against the profession's ethical code. Modern artists constitute a peculiar profession in that they do all this without necessarily being organized into an association that encompasses all of its members (as the medieval guilds did) and without necessarily being held accountable to public authorities for its activities. The ethos of the artistic profession, as it has emerged in the West since the Renaissance, is opposed to both general organization and any kind of public accountability of artists. Even with the evaporation of the cult of genius, in the 20th century, the conception of the artist's role as that of a free professional has remained as the ideal expectation. There are evident tendencies, from the latter part of the 19th century on, toward a partial collectivization of the role of the professional artist—whether in artistic movements in which several artists interact in producing individual innovations that have something in common (as did the French Impressionist painters of the 1870s) or in artistic workshops in which several artists cooperate in producing the same, or the same type of, works of art (as in the Bauhaus school of design in Germany, 1919–33). Yet it is a collectivization of a free profession, not a return to the guild structures, that *some* artists of industrial societies are willing voluntarily to accept.

Even as a liberal profession, the artistic enterprise remains professionalized to a lesser extent than other recognized professions. The artists are *morally* a profession, but the degree to which they *economically* depend on it as their main source of income varies tremendously. Most professional artists in modern societies do not derive the bulk of their income from the direct exercise of their profession, particularly where they have to sell their products under conditions of a free market.

Professional incomes

Estimates made at the beginning of the 1970s suggest that no more than one-half of 1 percent of the professional painters and sculptors in Paris and in West Germany receive a regular and sufficient income from the sale of their works. Some arts have retained, even in the self-perceptions of the artists, the character of vocations rather than professions: it is still awkward to describe someone as a professional poet.

It is conceivable that, in the more affluent and leisurely societies predicted for the future on the basis of technological progress, well-trained amateurs might again, as in the past in China, begin producing art of respectable quality. The nature of the aesthetic function sets limits on the extent to which a professionalization of the artistic enterprise can be sustained without aesthetic loss.

ARTISTIC CULTURES

Artistic cultures are the various basic situations in which art is produced. Each such culture involves a distinct type of social organization of artistic activities that is associated with a distinguishable attitude of artists toward their work. Artistic cultures arise from artists' relationships with other artists, their publics, their means of earning a living, and agencies affecting artistic activity; from their involvements with cultural systems not specifically artistic; and from artists' technologies, shared emotions, and ideologies. Changes in any of these variables modify artistic cultures and give rise to new variants of them.

Once the artistically undifferentiated unity of the tribal society has come to an end, several variants of "traditional" and "modern" types of artistic cultures can be distinguished.

Traditional artistic cultures. At least seven highly distinct types of artistic cultures can be identified in traditional (preindustrial) societies.

The folk culture. Artists are nonspecialized members of their community of residence and closely involved with all of its activities. Their art deals with typical experiences, concerns, or needs of ordinary members of that community. The real-life references are, however, linked with elements of highly utopian imagination (folktales, in which an attitude critical of the existing reality is frequently expressed), abstract stylization (geometric ornamentation of utensils), or symbolizing lyricism (folk songs). The artist is one of the people, but living more powerfully in the imagination than the others. Artists create by following or

elaborating on traditional patterns. Much art is produced spontaneously for oneself or in friendship or for communal enjoyment, rather than for pay.

The artisan culture. The artist is a specialist—possibly a member of a specialized collectivity such as a guild or a workshop set up by a state or a church—who works on order and for pay (or on command) only. He develops the pride of good craftsmanship and habits of regularity and reliability in his work. He does whatever style or content is required by his client without asking about his intentions. Whatever individual needs he expresses in his work, his conscious ideology is that he is a skilled worker who respects high standards of craftsmanship and produces to earn a living. He belongs, not permanently to his community, but temporarily to his client, wherever the latter may be located, and perhaps to his clan or guild of fellow artisans who share his craft ethic. To the extent that his client is his local community, however, he becomes a "civic" artist, whose highest purpose is, on command, to celebrate his community, as in the cities of the Mediterranean civilizations. (In modern society, this culture survives most nearly, perhaps, among orchestral musicians.)

Specialized craftsmen

The clerical culture. The artist is very much a craftsman, but his craftsmanship is subordinated to a highly valued tradition of a literate civilization, which he is committed to serve and to defend by his work. By his association with this tradition, he gains in prestige, but he also acquires a moral responsibility which the pure craftsman is not bound by. He belongs to a moral community, not necessarily localized, that provides him with criteria for judging which works of art are worth making. In this can be discerned the potential beginnings of an artistic consciousness and of a critical attitude of the artist toward society and its artistic ideologies. Most of the time, the clerical artist (for example, the medieval manuscript illuminator) is submissive to the discipline of the moral community of which he is a part, but, in the conception of the artist as a civilized servant of a higher moral purpose, there is, at least, a potentiality of criticism of the organization to which he belongs.

The ecstatic culture. This is a general term suggested for situations in which some type of artistic creation—though it is usually more than merely artistic—occurs in the midst of a mediumistic trance performed for religious or magical purposes, during an orgiastic happening, as a consequence of a mystical experience, or even as an element of prophecy. Art, performing or literary, arises from emotionally intense experiences, "divine madnesses," which are perceived to have high symbolic significance but over which the individual (or, sometimes, the group) that has them imposes no critical controls. Traditions that generate ecstatic art creation, such as the Dionysian ritual (performed by followers of the cult of the god Dionysus) in ancient Greece or the poetry of Hebrew prophecy, usually arise in loosely structured societies (as do the mediumistic priest-doctors known as shamans) or in times of social crisis (as mystics and prophets are likely to do). The shaman tends to be conservative with respect to his society, the mystic apathetic, the prophet radically innovative. Numerically, these types constitute a small part of the artistic cultures of the well-ordered literate civilizations and are least important in the visual arts dependent on organized patronage. But they have been sources of revitalizing impulses for established traditions. In the ecstatic culture, the artist is a nonspecialist who opens up higher, or more truthful, realms of existence and transcends the norms of everyday life. Theories of "artistic inspiration" and of the artist as martyr (or scapegoat) arise from this culture and continue to be generated in it.

Sources of revitalization

The courtly culture. The artist, who may be an aristocratic poet or a craftsman of ordinary social standing, is directly dependent upon a secular royal court or a household of the high nobility (or, by extension, plutocracy). To some extent, he is even socially involved with this household as a vassal, royal favourite, or court artist. He therefore not only produces for but also spiritually identifies with the high aristocracy for which he works, without actually being a member of it. The artist is a man ennobled by his art; his art must therefore be permeated with "noble" attitudes: heroic exaltation, fashionable late-medieval despair, or refined Rococo or Rājput sensuousness. While this art, by glorifying the establishment, reinforces its privileges, it may at the same time educate its—and other people's—emotions in novel ways.

The gentlemanly culture. When men of high social standing and independent economic means become active in the production of art, a tradition of gentlemanly art may arise (as is exemplified in much of the calligraphy and landscape painting in historic China). Art tends to be contemplative, subjective, aestheticizing—but not consciously "ennobling," since artists already possess sufficient "nobility" (as courtly artists do not). The artist is a man of independence who observes and contemplates without desire (an attitude that has been influential in modern aesthetic philosophies, frequently produced by such men).

The vagabond culture. All the traditional types of artistic cultures presuppose a firm social location of the artist in relation to a community, except where the artist is a vagabond adventurer who roams the countryside producing or performing works of art—comical tricks, storytelling, lyrical songs (for example, the medieval minstrels or the 15th-century French poet François Villon). In origin, he may be an uprooted folk artist, who belongs only to temporary communities. He is neither an apprentice journeyman nor a gentleman (who may also travel widely) but an impecunious amateur master unconcerned with material gain. (Masterful amateurism in the arts has two sources: the gentleman and the vagabond.) In contrast to the ecstatic artist, the vagabond does not assume that his works possess any higher symbolic significance. They are plays of fancy that amuse the fancier and whoever cares to join him. Individual vagabond artists have probably always existed, but vagabond cultures can arise only in the fringe areas of cities (for example, a transitional zone between industrial and residential quarters) or where nomadic tribes like the gypsies travel over a settled countryside. Travelling theatrical groups exemplify both conditions. Whatever the effect of vagabond artists on society, they, like the ecstatic artists, tend to have a liberating effect on the arts in which they engage.

Modern artistic cultures. Several types of artistic cultures, in some cases anticipated in earlier periods, have come to a full development in industrial societies. Some older types have been transformed and new ones evolved. In the advanced industrial societies, artistic cultures tend to become fluid—composed of overlapping and fluctuating elements, components of a mixed orientation rather than rigidly separated alternatives. Nevertheless, several types can be distinguished.

Artistic cultures in industrial societies

The genius culture. The product of a conjunction of the artisan, clerical, and courtly cultures, the cult of genius emerged in the early 16th century during the High Renaissance and became more fully developed in the age of Romanticism at the beginning of the 19th century. The artist conceives himself as the "unacknowledged legislator of the world" (in the words of the English poet Percy Bysshe Shelley), an autonomous, godlike creator of new orders of reality obedient only to his perceptions and the categories of his mind. He is superior to the specializations of the sciences and the crafts: he creates the unifying symbols of a developing civilization. He is self-confident, a proclaimer of new values rather than a critic of the established ones. Historically, perhaps the greatest significance of the genius has been in the legitimation he has provided for the developing conception of the professional artist.

The professional culture. The most essential characteristic of the artistic professional is that he himself chooses what to produce or perform. But, unlike the gentleman artist, the professional produces in order to sell. His art is the activity of a specialist competent in the techniques of expressing subjective perceptions. In the visual and the literary arts, the professional usually works in his own studio, at times of his own choice. In the performing arts—which are less "professionalized"—he is dependent on facilities provided for him by entrepreneurs and impresarios. He may have an agent who represents his economic interests in any case. But the essential point, in the artistic profession, is not the ownership of the means of production; it

is the artist's sense that he can, and indeed must, depend upon his personal aesthetic sense. This is the predominant image of the writer in modern Western societies.

A sociologically important distinction can be made between private and public professionals. The first have originated in the gentlemanly culture, the second in the salon-coffeehouse-journal circuit of the 18th and 19th centuries, in which the enlightened aristocracy and the increasingly popular press joined forces in supporting a socially critical collectivity of middle-class artists, journalists, and hangers-on. In this public culture, it was most important to be up to date and to respond to current issues by one's wit. As this culture began to disintegrate, the distinction between private and public professionals was partly replaced by the distinction that exists between bohemian and radical avant-gardists.

The applied-arts culture. The old artisan tradition has continued in the modern applied arts (for example, industrial design, advertising). The artist is, however, not usually in a guild but, rather, is employed in a white-collar type of job by large business firms or governmental organizations, sometimes by "artistic firms," which, in their management, are not very different from other business firms. But while the applied artist is employed as a craftsman, his attitudes have been affected by the culture of professional art. He may therefore be a craftsman with aspirations to professionalism and may tend to perceive himself as failing to realize his artistic aspirations, regardless of financial success and social recognition. Applied artists with the self-conception of professionals provide one of the main supports for movements of radical criticism of contemporary society and culture.

White-collar artists

A development toward the applied arts may be occurring at present in such an established profession as architecture: the increasing costs over which he has little control, the various restraints over his activity (zoning codes, labour union regulations, and the like), and group pressures to which he must respond are tending to transform the architect into a high-level organizational craftsman. As their opportunities for being artistic professionals decline, architects tend to conceive of themselves increasingly in the image of social engineers—a trend noticeable also in the other arts.

The mass-arts culture. The notion of the mass arts implies that the artist communicates with his public through the mediation of some type of mechanical or electronic machinery; that he does not kno even the kinds of people of whom his public will eventually consist and may be unfamiliar with the characteristic experiences ofmost of his actual public. Furthermore, the responses that he will get from his public will probably also be, in most cases, mediated either in a mechanical manner (statistics of sales) or by professional intermediaries (newspaper critics). Film, television, mass-periodical fiction, and recorded music represent the clearest cases of mass art. Insofar as the mass media deal with any art, they tend to assimilate it to a greater or lesser extent to the mass arts. Because of the conditions under which he operates, the mass artist lacks a sense of general standards—other than the purely technical ones of craftsmanship—by which to orient his artistic activity. Nor, since he is dependent on large, impersonal audiences, can he trust his own convictions to guide him. His typical solution is to cultivate an "image" that has proved to be popular with a mass audience and that, once established, is "forced" on him by his public. He becomes a victim of his own image, in the sense that he is trapped within its confines. He is an uncertain specialist in the symbolic manipulation of diffuse audiences.

Cultivation of a popular image

Avant-garde cultures. Another characteristically modern artistic culture is definable by two aspects: a principled sense of alienation from significant aspects of existing reality and a conscious commitment to overcoming the deficiencies of existing reality by artistic means of a completely novel character. One of the distinguishable types of this artistic culture is the bohemian avant-garde, which tends to be alienated from all rational and utilitarian aspects of social organization and cultural tradition and aims to create a new kind of exaggeratedly irrational art and, perhaps even more important, an irrational style of life. (Typical of this group is the French poet and critic Charles Baudelaire.) Its behaviour centres on the ambivalent and the self-consciously paradoxical: a tradition of pursuit of the new, the cultivation of a pleasureless hedonism, the development of systems for the liberation of spontaneity. Another type of this culture is the radical (politically committed) avant-garde, which regards itself as alienated from "oppressive" and "exploitative" political and economic institutions and tries to create a new kind of art intended to undermine faith in these institutions and to provide a basis for their abolition or reconstruction (an example is the German poet and playwright Bertolt Brecht). These two avant-garde cultures overlap, and, over time, one may change into the other. The alienated type is more influential among artists when faith in ideological utopias declines generally in their society. Perhaps because of its tendency to limit itself to consciously recognized and intended purposes, the aesthetic achievements of the radical avant-garde (the "prophets") have been less significant, so far, than those of the alienated avant-garde (the "mystics").

More recently, a third type has emerged: the anti-artistic avant-garde, which is alienated from the very notion of art and its practice as heretofore conceived, even (or perhaps especially) in the other versions of the avant-garde culture. Art itself is perceived as "oppressive" and "exploitative," and the obligation of the artist (and of the art critic) is seen as the promotion of the "end of art"—its diffusion into a "life" of childlike impulsivity. The very coherence of art is felt to be an imposition of an arbitrary system on the immediacy of "aesthetic experiences," which are to be pursued with a self-conscious repudiation of any deliberate control.

All the avant-garde cultures can be seen as diverse outgrowths of the culture of genius, with which the peculiarly modern developments in the arts began. But the bohemian and radical version of the avant-garde culture are also reactions, by artists and aesthetically sensitized intellectuals, to the development of the modern industrial society—a society highly rationalized and, in spite of its ideology celebrating the "common people," continuingly stratified. The anti-artistic avant-garde appears to be a "shamanistic" reaction against the professionalization of art, and, like the mediumistic trances of traditional cultures, its efforts may prove to be a socially innocuous (or conserving) ritual that is perhaps psychologically refreshing.

Total-command cultures. Hitler's Germany and Stalin's Soviet Union still provide the best examples of what happens when a modern artistic enterprise is subordinated to a political ideology that has the monopoly of organized power in a society. Artists are forced back into clerical roles—with the difference that the moral responsibility for upholding an ideology is imposed on them without its necessarily corresponding with their own convictions; and, even when it does correspond with their ideological views, it conflicts with the conception of the professional role that they, as modern artists, regard as their primary orientation within the sphere of art. An artistic enterprise can be effectively politicized, without losing most of its aesthetic qualities, only if artists are content with assuming the role of "clerics" illustrating, with appropriate technical means, the manuscripts of a political ideology, yet do so without limiting their imagination to service in its mission.

Politicalization of art

The scientific-technological culture. Partly under the influence of imaginative developments in science and technology and partly out of disillusionment with the avant-garde cultures of art, an artistic culture in which the artist is assimilated to the role of a scientific researcher has arisen. The artist is a strategist of concepts, a deviser of technical systems for others to build, and a manager who invents ways for workers to relate technological or natural processes to each other. His difference from the scientist is that he seeks not new understandings but new perceptions; his difference from the technological experimenter is that the systems constructed are expected to have no utility. They are frequently evanescent or self-destructive. This type of artistic culture requires large financial outlays and tends to result mainly in entertaining decorative effects. It is neutral with respect to the particular institutions of a

society but tends to glorify the technological and economic achievements that enable it to sustain such works of art. Thus it is the equivalent, in a technological civilization, to the monumental art by which absolute monarchs had been glorified in the agricultural empires, such as ancient Egypt.

Movement cultures. Artistic situations that arise in spontaneous movements of a general cultural, rather than specifically artistic or primarily political, character (such as youth movements) may generate an immediacy and intimacy of the relationship between producers and consumers of art that is rare anywhere else in modern societies. The effect on the arts is to simplify aesthetic structures and integrate them more closely with the experiences of the many. The arts most frequently involved are poetry, music, and some form of theatre. The movements themselves are not highly productive of enduring artistic achievements. Their main significance is in opening up large audiences to a sensitive responsiveness to art or to particular kinds of art—a sensitivity anesthetized by the mass arts.

Amateur art making. With the increase in leisure time, amateur art making has become increasingly popular in advanced industrial societies, as had amateur musical performances in the European upper and middle classes in the 16th and 17th centuries. This phenomenon contributes to the blurring of the traditional distinctions between producers and consumers of art and to the involvement of larger numbers of people in a more active manner with the artistic enterprise, strengthening the social anchoring of art in the modern society.

ECONOMIC EVALUATION OF THE ARTS

Factors in the allocation of wealth to the arts

The economic evaluation of the arts in general is indicated either by the absolute amount of economic resources put into their production, acquisition, distribution, and consumption or by the relative share of the total income of an individual, group, or society that these allocations represent.

While the absolute size of expenditures may be determined more by the level of wealth than by the degree of interest in art, it yet has a significant effect on the artistic enterprise, perhaps especially on art collection and prices of artworks. When the absolute amount of funds available for the arts is very large, it produces the phenomenon of "cultural imperialism": it enables the powerful, whatever the degree of their interest in art or their own creative attainments, to dominate and overwhelm the cultural activities of the financially less well endowed, unless the latter remain isolated or protect themselves by consciously designed cultural policies.

The percentage of the income devoted to art, on the other hand, bears a closer relationship to interest in art, and it could therefore be expected to be more closely associated with the level of artistic creativity—which does not necessarily require large economic resources to sustain it. Some of the finest works of primitive art, for example, have been produced in places where life is economically precarious, such as the swampy areas of New Guinea. The percentage of wealth devoted to the arts tends to be greatest in economically comfortable societies that have passed their peak of economic expansion—Italy after the middle of the 14th century and Spain in the late 16th and 17th centuries, to cite two instances.

The economic valuation of art is also affected by the degree of its association with activities that are regarded as possessing great importance in a particular society. Actual importance of an activity can be measured, in economic terms, by the size of economic allocations for its pursuit. The closer art is integrated with the activities (typically, the economic, political, religious, and military) getting the major share of available funds, the larger tends to be its own share. In the advanced industrial societies, a major financial basis of contemporary arts is their integration with the growing leisure industry (as in the Broadway theatre or the arts in the mass media) and with education (as in the widespread employment of artists in schools and universities). It is partly for this reason that modern states tend to allocate larger sums for the support of the performing than of the object-making arts and for the dissemination than for the production of art objects.

To the extent that art itself is a prestigious activity, individuals, groups, cities, or whole societies may compete for supporting its most important living practitioners or acquiring the most famous works. This motive has probably been present, to some degree, in all elite-oriented societies, but its significance tends to increase in civilizations that have many centres rather than a single "imperial" one—in Renaissance Italy, in Germany before its unification, and in the modern world in general. Competition of would-be patrons for the prestige of living artists increases not only the economic allocations to art but also the freedom of "elite" artists. Modern state support for the performing arts, in particular, rests to a high degree on competition for internationally recognized cultural reputations.

The value of art as an investment of wealth, either for ensuring its preservation or for increasing it, grows in periods of social and political instability and currency fluctuation. Small-scale artworks made either of precious materials or by prestigious old masters become the safest investment in times of trouble. This has been an important motive for the collection of art by the rich in the Renaissance as well as in the 20th century. It is characteristic of this system that a high economic valuation of art does not necessarily correlate with the income received by living artists, since the object of speculative interest is the reputation of a master, who is frequently dead, rather than the aesthetic merits of the work itself. It is a system in which artists, instead of being supported by the rich in the pursuit of aesthetic values, support the rich in their pursuit of further enrichment, since an artist may endure a lifetime of poverty to produce works that then become tokens of steadily increasing worth. As a consequence, the system encourages capital accumulation rather than artistic creativity. It has little effect on the performing arts or literature but is currently a major source of discontent among practitioners of the visual arts.

Relation of achievement to value

Increases in the social status of artists and in the prices their works fetch on the market have, in the past, tended to follow increases in the creative attainments of an artistic tradition. Thus, in England, an increase in artistic creativity in the early part of the 18th century (as exemplified by the paintings and engravings of William Hogarth) was not followed by a significant increase in the social and economic status of some artists until the 1780s. During the late 19th century, however, when contemporary English art was admired above that of any other period or society and highly rewarded, it produced only minor achievements. Clearly, economic allocations do not guarantee artistic efflorescences, and inferior art may be ascribed high economic value. Great artistic achievements, nevertheless, appear to increase the economic value of art, though perhaps not immediately. While the economic value of particular objects of art depends in part on their historical significance, uniqueness, and fashion, the economic valuation of art itself is, in the long run, not altogether unrelated to the presence in a society of large numbers of aesthetically meritorious works.

SYSTEMS OF FINANCING ARTISTIC ACTIVITIES

The economic support of artistic activities can be provided by the artist himself, who derives his income from sources other than the rewards he receives for producing art, or it can be furnished by nonartists supplying the economic means for the artist to survive while he is making works of art.

Self-financing of artistic activities has always been, and still is, considerable. The gentlemanly type of artistic culture is wholly supported by artists of independent means. The writing of lyrical poetry has very generally been a leisure-time activity of persons deriving the bulk of their income from other sources. In modern times, self-financing is present when the artist survives from an activity that does not require him to produce works of art, or when his income from producing works of art is significantly lower than what he could earn by being employed in a legitimate alternative occupation accessible to him. The dance is heavily self-financed in the second sense.

Sponsorship of artistic activities may be said to occur when the artist draws upon the economic support of individuals or organizations that do not necessarily expect to get anything for themselves in return for it. They support the artist because they are committed to art for its own sake or to a particular artist. In this specific sense, artistic activities may be sponsored by government agencies supporting art as a "social service" for the people, by private foundations, by individual sponsors, by relatives who support the artist while he is economically unsuccessful, or by friends and acquaintances whom an artist "sponges on." Sponsorship may thus be, in some cases, unintentional.

Financing outside of the market system

Self-financing and sponsorship are economically "abnormal" systems of financing the production of goods and services that potentially possess an economic value to people other than their producers. These modes of financing are found principally in the "cultural" activities, above all religion and art (but also in "ideological" politics), and they occur because artists are not treated as if they were engaged only in the production of economic values. They produce economic values, but there is also a "religious" aspect in their activity that requires to be supported for its own sake. If the arts were to be supported entirely by a market economy, this aspect might well disappear: art would then become purely a commodity.

The arrangements of economic support that have traditionally carried the main burden of sustaining artistic activities are the three types of normal economic systems into which the arts may be integrated like any other productive activity: the exchange, command, and market economies.

The exchange economy. An artist in the exchange economy produces for a customer familiar to him who, in turn, directly or through a series of similar exchanges, provides him with a desired good or service of equivalent value. The transaction between the producer and consumer is, ideally, a ritualized exchange of gifts, and, in addition to providing the goods that each needs, it reinforces their social relationship. This type of economy prevails in the egalitarian type of preliterate societies and in the folk type of artistic cultures.

In more advanced societies, this becomes a minor part of the economic support structure of the arts; it tends to be limited to the private circle of artists and their friends. The economic rewards to artists within this system are small, fairly continuous, and not greatly differentiated in magnitude.

The command economy. The artist in the command economy depends on a consumer—an individual or organization—of superior status who has extracted a great deal of wealth from the producers in the economy and can distribute it, perhaps within the boundaries established by tradition, as he sees fit. This economic system is dominant in a range of societies extending from the Kwakiutl Indians of the northwest coast of North America through the classical absolutist monarchies to modern totalitarian states. Usually, however, it does not completely displace elements of other economic systems.

Patron systems

In this system, the artist depends for his support on relatively few patrons, who are far more powerful and socially resourceful than he is. He may be well rewarded by them, but he must produce works that will be regarded as possessing high value—usually both aesthetic and economic—by his patron. He is paid well if he produces economically valuable aesthetic goods and services. (A significant exception to this principle has been built into the situation of women in the performing arts: in male-dominated societies, they tended to be well paid if they performed sexual as well as artistic services.) Before the modern age, all artists who produced expensive works of art were supported by economies of this type. Even today, architecture—to the extent that it is an art—and the large-scale "technological" arts are supported in this manner.

The market economy. In the market economy, many artists compete for the favour of numerous customers not greatly differing in their purchasing power and not personally known to artists. Since artists are not familiar with their customers, their products become acts either of self-expression or of appeal to an image, an abstract stereotype, of the "average customer." In reality, market economies in the arts only approach this condition to varying degrees: some publics are known to their artists, and there are always elements of the command economy limiting the operations of market economies. There are always economic or political elites or powerful business and political organizations, at whose command, to varying degrees, artists must be in order to achieve "success" even in market economies. And in the modern system of art trade, the mass media have assumed the character of a command element in a market system. To be able to compete for numerous potential buyers, artists must first ingratiate themselves into the favour of a relatively few taste makers in positions of power within the system of mass communications. The more centralized this system is, the more of a command character it acquires.

In a pure case of market economy, the artist's freedom is great, but his rewards are highly unpredictable and uneven; his uncertainty and sense of alienation from his public is a natural consequence. In market economies, the arts are particularly dependent on support through the economically "abnormal" systems of self-financing and sponsorship. These systems typically provide the economic basis for radically new departures in the arts in market economies. They also subsidize the established arts when their costs are too high to be supported by the market (symphony orchestras, for example).

Competition for the "best"

When there are several basically independent command economies in adjoining areas, all interested in art, they are likely to compete with each other for possessing the "best" living artists (as well as the works of the most prestigious dead masters). This competition is apt to favour artistic creativity in a way that pure market economies, concerned with the production of the most usable rather than the most perfect, seem to be less capable of. First of all, pure market economies are hard put to concentrate sufficiently large economic resources to finance expensive artistic achievements (except where they can be immediately "consumed" by large numbers of people, such as in filmmaking). Beyond that, the expectation, typical of command economies, that the artist will produce the most perfect object he is capable of producing may actually increase his motivation (and consequently his capacity) for doing so. Market economies do not hold forth any such expectation. No longer economically supported, expectations of the artist's commitment to excellence in a market economy come to depend mainly on the professional integrity of the artist.

It seems probable that a given allocation of funds to artistic activities can be more directly translated into high artistic achievements in command economies than in market economies—provided, however, that the command economy, in addition to insisting that an artist produce the most perfect, also permits him to do what he is best at. It is in the latter respect that the command economies of modern totalitarian states have fallen short: they have prescribed for their artists a manner of working in which the latter could not do their best work. Mass-media "command economies" may also work to that effect.

Market economies are potentially more capable than command economies of integrating art into the private life of ordinary members of society, and not only into the life-style of the elite. But market economies seem less capable, by themselves, of generating high artistic achievements (as well as producing artistic public environments). There is, therefore, likely to be an increasing demand for art in market economies but a reduction in the quality of what is being produced. There may be other, quite powerful stimuli to artistic creativity in societies with market-type economies, including the creative entrepreneurs who succeed in joining the market mechanism to an artistic purpose. But the impersonal workings of the economic system of the market itself appear to interfere with the accumulation of the "creative capital" while encouraging its dissemination.

THE ART MARKET

The art market is a complex system, with roots in preliterate societies and historical civilizations, by means of

which artistic activities are organized as profit-making enterprises. Expectably, this system is most fully developed in capitalist economies, but, since economic enterprises generally have to take profitability into account, even in state-managed economies, the art market has some degree of existence wherever art is treated as an economic good that is offered, for a price, on a market.

The operations of the art market are determined both by the general dynamics of market systems and by the peculiar character of art as a commodity.

Sellers' options

People buy art for various reasons. But the organizations that specialize in selling art (or also in producing it for sale, as theatrical companies) are built in most cases on one of two assumptions about the motivations that propel people into spending their money on art. There is an elite market that sells reputation and a popular market that sells entertainment.

Selling entertainment. The popular market provides art for customers who seek primarily entertainment. It must, therefore, adjust to the prevailing popularly defined conceptions of what is entertainment or shape such conceptions to correspond with the product it is capable of providing. It conducts market research into audience preferences, but it also manipulates these preferences by spreading the impression, through its publicity agents and the mass media of communication, that entertainment is what the popular art market dispenses: not only its finished productions but the whole behaviour of the people involved with them is "entertaining." The artist must "sell" not only his art but also his behaviour outside of the art system. The implicit aim is absorbing everything that appears to the mass audience to be entertainment into the ambience of the popular art market—by transmuting the entertaining aspects of life into salable works of art, by associating entertaining people who are not artists with the popular art market, and so on.

Conversely, whatever cannot be regarded as entertaining tends to be forced out of the works of art or artistic performances handled by this system. It puts a premium on "slickness," the glittering or sensational packaging, and discounts both high seriousness and unique sensibility, unless they can be seen as "entertaining." Its influence spreads even beyond the arts it deals with, affecting the character of art that people highly exposed, from their early years, to this system produce and consume even when they operate outside of it.

Selling reputation. If the popular market sells entertainment (an important means of overcoming sensory deprivation), the elite market sells reputation (an important resource for legitimating high social status or aspiration). It is, therefore, involved only with customers concerned with reputation. Such customers may be individuals or organizations. While the "masses" are mainly involved with the popular market, organizations, including states, tend to be more closely linked with the elite market. This market attunes itself to the prevailing hierarchies of artistic reputation, but it also reinforces these hierarchies by spreading the news of the high prices (or prizes) fetched by the works of art handled by it, by encouraging competition among buyers (or supporters) of unique art objects, and by subsidizing the work of scholars and critics that is likely to draw the attention of purchasing elite groups to their goods, increasing their cultural reputation.

Transforming cultural significance into economic value

The elite market has a monopoly of the "measuring rods" used to transform cultural significance into economic value. For the buyers, these scales of measurement indicate the degree of their "cultivation." If impresarios in the popular market have the role of tastemakers (as well as organizers of a complex set of productive activities in the performing arts), dealers in the elite market operate as cultivation makers, cultivation being economically definable as the rate at which cultural reputations are paid for. Art sellers for the elite do not create the reputations, but they prosper by increasing the price of acquiring cultivation.

On the living artist, the elite market has the effect of encouraging him to produce a reputation that, highly paid for, identifies the purchaser as a person of cultivation. The artist's works must be the opposite of what the popular market deals with—they must be *not* entertaining but, rather, culturally "significant" (in accordance with current conceptions of cultural significance). In the 20th century, cultural significance is regarded as virtually equivalent to being innovative.

Interaction of popular and elite markets. Markets that are oriented to elites but deal in mechanically reproduced multiples, such as the publishing of "serious" (as contrasted to "popular") books, represent a special case in between elite and popular markets. The objects they deal in are not inherently "entertaining," and yet the cultural significance an individual object is seen to possess does not lend itself, when the object is multiplied many times over, to being transmuted into inflated prices on the market for reputations. Publishing costs have become so high that any published book, unless subsidized, must enter a popular or semipopular market. The transformation of book publishing into an industry oriented to a fully popular market has been encouraged by the paperback revolution and the profitability of motion-picture rights for both publishers and writers. A peculiarity of the book market is that it has developed semicaptive publics, in the form of book clubs, which the other arts have not been as successful in organizing.

The motion-picture industry is in the popular market. So are all the "spectacular" arts, such as the opera and the ballet, insofar as they are economically dependent on a market—even though their markets have been, by tradition, smaller and more selective than those of the cinema. The smaller and more select a market of the popular type is, the more important seems to be the influence of professional critics on it. And the more influential the critics, the more closely does a popular market approximate an elite market.

Relation of selling to quality

As the history of the opera and the ballet indicate, it is not to be assumed that a market concerned more with selling entertainment than with selling reputation does not permit the production of high artistic values. Even though a public is presumed to be spending its money for entertainment, entertainment is not necessarily what the artists think they are selling—one reason for the alienation of the artist from his public. The great impresario in the popular market is the one (such as Sergey Diaghilev) who arranges for artists to sell their best art to a public convinced it is getting glorious entertainment. Pioneering in new forms of entertainment may both change notions of entertainment and produce objects that will enter the elite market. It is not primarily by the objects produced but, rather, by the manner of their economic operation that one may distinguish between the popular and the elite market in the arts.

Popular and elite markets are not wholly separate. Prices of paintings by old masters in the elite market tend to be increased by their pleasing appearance and are usually reduced when they depict inelegant scenes of suffering. The elite market operates most purely, in terms of reputations, when art museums are involved. Conversely, any "respectable" popular market uses (and manufactures) reputations to increase the economic value of its product. Only anonymous entertainment—by "nameless" artists—can constitute a purely popular market.

The popular market, by treating art as entertainment, imposes on consumers' contact with art the expectation of fleeting experiences and of the absence of any cultural significance transcending them. The elite market imposes the expectation of enduring values and of the presence of the highest kind of significance. In both cases, the market exercises an influence over the definitions of art held by the art consumer (and even by the artist, for that matter, to the extent he is governed by his market situation rather than other elements of the artistic role). The effectiveness of the influence depends on the degree to which market considerations alone govern artistic experiences and activities.

In both the popular and the elite markets, contrary to the usual dynamics of the marketplace, increases in the number of artists and in the amount of their production, relative to the size of the demand for their work, do not necessarily reduce the prices of works of art. In modern societies, these trends produce a focussing of attention on a few (who receive very high rewards) and the neglect of

the rest of art producers, many of whom may be only slightly inferior (or not inferior at all) to the "stars."

Publicity in the mass media, which both the popular and the elite markets manipulate and benefit from, reinforces this tendency by promoting celebrity cults. The objects of these cults may be intrinsically meritorious or not, but the cult, in either case, destroys proportionality between merit and reward. Mass media tend to promote in the arts a phenomenon similar to the medieval cult of sacred relics. Current profitability of investments in art objects rests, perhaps mainly, on a cult of this sort.

Artists' unions

Trade unions of artists—a recent phenomenon—are important mainly in the popular art market. They establish lower limits for the incomes of working artists but also increase the cost of full-scale artistic productions, particularly in the performing arts. In effect, they seek to eliminate the need for the performing artists to finance their art by accepting an income less than commensurate with what they could get from an alternative occupation. But the increases in costs of artistic performances render the performing arts more dependent on sponsorship systems. Neither the European theatre nor symphony orchestras anywhere could survive in a perfect market system. While increasing the economic security of employed artists, artistic trade unions tend also to promote the unemployment or the underemployment of the performing artists and the growth of a "serious amateur" system (for example, the off-off-Broadway theatre and other experimental fringe theatres), which, in addition to developing a style alternative to that of the professional theatre, may also nurture fresh talent and feed it into the professional system. Artists working for the elite market have been less concerned with establishing trade unions. They either survive as celebrities—or fail to survive.

Marginal phenomena. In addition to the two major types of art markets, one can distinguish two currently marginal phenomena: traditional (that is, noneconomic) elements in the art market, such as ideological commitments to particular types of art or group commitments to particular artists, and the various "little" markets, at present increasingly numerous in Western societies, in which art is sold not exclusively, or not mainly, for profit and which may indeed be partly financed by proprietors or participants from income not derived from the sale of art or through their own unpaid services (little magazines, artists' cooperatives, the U.S. "underground" cinema at its beginnings). Little markets may be individual or cooperative, expert or amateurish, and built on the most varying motives. While their cultural role may be important, particularly in nurturing difficult artistic innovations, the little markets collectively cover only a minor part of the art market. If they become economically successful, they tend to be incorporated into one of the two major systems of art trade.

Incorporation of traditional elements into art markets

The "traditional" elements are usually incorporated into one of the three types of art markets and limit the intrinsic logic of their operation. In the elite markets, nation states impose restrictions on the export of historically significant works of art; all respectable book publishers print a certain number of worthy books they expect to be altogether unprofitable. In the popular markets, traditional criteria establish limits of "proper" and "improper" entertainment (performances of avant-garde musical works, for example, are consistently less profitable, both in Europe and the United States, than those featuring more traditional ones). On the little markets, which tend to lack economic staying power, commitments to an identifiable tradition exert a stabilizing effect.

REMUNERATION OF ARTISTS AND PROTECTION OF THEIR RIGHTS

Methods of remunerating artists depend on whether they are involuntarily bound (serf artists) or, with their own consent, are attached (palace artists) to a consumer or organization that uses their works, or are free to sell them on the market.

Bound artists are provided with subsistence by their lords; attached artists receive regular salaries (which may be high in the case of palace favourites and academicians) and additional bonuses for particular successful works of art. Freedom to sell on a market may be unlimited, as in modern societies, or it may be conditional on membership in a socially recognized group of producers (the medieval guild system). To the extent that it approaches a perfect market (numerous artists of approximately equal artistic reputation competing for numerous customers of approximately equal purchasing power), the economic transaction takes the form of a sale; in command economics it is more usually a commission. In guild systems, the association of producers may itself transact the sale or at least regulate the conditions of sale, by its members, of their products. In a dealer system, which was known in classical antiquity but (in the visual arts) has developed most fully since the 17th century (in the Netherlands) and the 19th (in France), a group of commercial intermediaries—dealers and artist's agents—has stepped in between individual artists and individual purchasers. Their task is to introduce the one to the other and conduct the economic transaction in accordance with the practices of good business. (Some art dealers and their literary equivalents—writers' agents—have operated also as patrons and even sponsors of young artists.)

Methods of payment

In market systems, methods of remunerating artists depend on the traditional cultural reputation of the art they practice, the degree to which the artists' rights of authorship are legally recognized in an economically consequential manner, and the technological requirements for transacting the sale of an artwork.

When the traditional cultural reputation of an art is high, the artists who engage in it, while not necessarily highly rewarded in economic terms, tend to acquire a moral right to a socially recognized authorship of their works. Their names are affixed to the works they have produced; these are no longer products of anonymous craftsmen or works signed by the supervisors of art workshops, as were lacquerworks from the imperial workshops of China.

The conception of individual authorship began developing in Greece around 700 BC and in China more than 1,000 years later. It was known in the medieval West and India, but the notion of individual authorship remained undeveloped in the Byzantine civilization. This conception is directly dependent on the development of a professional or gentlemanly or genius type of artistic culture. Indirectly, it is supported by a strong stress on individualistic values in a cultural tradition, but, as in eastern Asia, the notion of authorship could arise even in the absence of any strong commitment to individualism.

The notion of a legally protected intellectual property of an art creator in his work, which he retains even after he has sold his work to a user, presupposes a conception of authorship but extends beyond it. Historically, it is a much later development. It began in the West in the late Middle Ages and has been encouraged by technological inventions facilitating the reproduction of works of art (before book printing, possession of a manuscript implied the right to reproduce it); the growth of a competitive market in such reproductions, which needed to be regulated (the most prominent motive in the early phases of the copyright law was the desire to protect the economic interests of the book publishers, rather than the intellectual rights of the authors); and the image of the artist as a man of genius who may sell, like other producers, the works of his labour but retains a right to the spiritual substance, uniquely his own, that he has invested in them. What the copyright and unfair-competition laws protect are tangible contributions to a product that remain identifiably individual. The artist has a legal right only to what he has worked out; the law protects the labour of elaboration, not the idea or intuition. Yet, once the notion of a legally protected intellectual ownership has taken root, it tends to become self-perpetuating, even in the absence of the conditions that have favoured its development.

Implication of intellectual ownership

The retention of a moral right in the artistic product provides the rationale for an author's sharing in the income that the buyer derives from the use of his work and from the appreciation of its value over time. The logic of this system has been worked out most fully in the publishing and the mass-communications industries (radio, film,

and television). In the visual arts, efforts are being made to extend the economic implications of the recognition of the author's moral right to his work by developing a model contract for the sale of a work of art that will not only guarantee to the artist control over the reproduction of his work but also provide for his share in any profits from the resale of his work. U.S. copyright law provides that ownership of a copyright is distinct from ownership of any material object in which the work is embodied, thus giving the artist control over its reproduction, and that the transfer of a material object, in the absence of an agreement in writing to the contrary, does not transfer ownership of the copyright of any work embodied in the object.

The contemporary copyright system guarantees to the writers covered by it that their incomes will be proportional to the current economic value of their works (the total income from their sale). Visual artists' income, on the other hand, is unrelated to the current economic value of their works once these have been sold (except indirectly, as the prices of the works they will sell in the future are affected by appreciation or depreciation of the works sold earlier). Thus, there is a disproportionality in the effects of the law on the relationship between the artist and his product in literature and the visual arts.

In the performing arts, unless the performance is recorded, the performing artist cannot be guaranteed any direct economic benefits from being recognized as the author of his performance, because the performance "vanishes" after it is completed. It is only what is being performed (the text, choreography, musical composition), and not the performance itself, that can be protected by custom or the law. There is thus a difference between the legal rights of performing and "producing" artists in their art, and this difference may well affect their overall social status and self-esteem.

Legal rights in the mass arts

The development of the mass-arts industry has made it possible for performing artists to enjoy the benefits of legal protection of their continued "intellectual possession" of their performances, if they have been made to be recorded and can be reproduced. Recordings of live performances have remained unprotected by copyright law and frequently are "pirated," or reproduced without permission. In 1971 an international convention prohibited piracy of musical recordings, and member countries then began developing legislation on the matter. The U.S. copyright law was amended in 1972 to prohibit the unauthorized duplication of sound recordings. If only in the mass-arts industry, the situation of performing artists has been made similar to that of such "producing" artists as writers and composers, who receive royalties on their past work. The performers in a film continue to receive a set rate of payment from each showing of that film and residuals from reruns on television. While in this way they have a type of continuing property right in their performances, as specified in their contract, performers have no moral right of authorship that would permit them to control the manner in which their work is presented to the public (as writers of books do). This right is usually vested in the film director, and even then, only if it is specifically assured to him in his contract.

Whether the legal protection of artistic property has in fact encouraged the production of high-quality art appears debatable: the system does not distinguish between high- and low-quality products. The operation of the legal-protection systems in the arts must be judged by the degree to which it helps artists both to earn an income and to derive self-respect from their work. It must, however, also be judged by inquiring whether its provisions result in larger benefits to the artists collectively or to the sellers of their works collectively.

ART COLLECTING

Art collecting and the building of architectural ensembles, such as churches and palaces, which can be regarded as immobile "art collections," have probably provided the most important source of income for the major visual artists, particularly in command economies. Once artworks enter a collection, however, they tend to stay there for long periods of time, potentially reducing the space and the demand for the works of later artists. There is thus a certain ambiguity in the attitude of artists toward art collections and museums, particularly in societies that possess well-stocked ones, such as Italy or, by now, the United States. Museums that tend to "enshrine" artists are in this respect worse, from the living artist's point of view, than private collections, which get reshuffled every once in a while—a process encouraged, at all times, by defeats in war, social upheavals, economic troubles, and, in modern societies, by high inheritance taxes. In contemporary societies, collecting by nonartistic organizations—governmental agencies, business firms, universities—seems likely to become increasingly important. This would mean a greater incorporation of art into real-life (as contrasted with museum) environments. As an encouragement for living artists, collecting seems to be most effective when any particular collection is intended to be temporary: that is, when it is established, exhibited, and then dispersed to make room for a different one.

Relations between museums and living artists

Purposeful collecting of works of art is most eagerly pursued in periods of great affluence and a reduction of the creative drive—in the Hellenistic age (323–30 BC), in ancient Rome, and in 18th-century Europe. The relationship between art collecting and political power has been more ambiguous. On the one hand, the powerful have liked to surround themselves with the grandeur emanated by an "overpowering" collection of art. On the other hand, states have compensated for their loss of power by cultivating an image of their cultural grandeur and refinement; art collections serve this purpose, too. But art collecting is also an appropriate response to great outbursts of creativity that have occurred in the past. And it establishes reservoirs from which later artistic efflorescences will, in part, be fed: art collections, if open to the public, provide a place for young artists to study their craft and for people in general to develop an interest in the arts.

Collecting of the art of the past may be encouraged by a lack, or loss, of faith in the creative accomplishments of living artists; by the proved prestige of the works of the past (important when the newly rich collector has neither taste nor understanding to judge by himself); and, particularly in contemporary society, by the profitability of economic investments in famous works of art. It is estimated that art prices in general have multiplied more than 10 times since the early 1950s.

The rise in art prices

Private art collecting on a smaller scale has been developing in the middle classes since the beginning of the modern age. Currently it shades off into "temporary collections" of multiples from the popular market, such as musical records or posters used to decorate student rooms. Attitudes derived from this practice are spreading even into sophisticated responses to art (*e.g.*, conceptions of the social function of museums).

SOCIAL CONTROL OF ART

Little art, except perhaps in the "intimate" genres such as lyrical poetry, can have been created, until the latter part of the 19th century, without some degree of social control—that is, influence exerted by nonartists—over its creation. The influence has varied greatly in degree, in the groups and agencies exerting control, and in the means used. Six basic types of social control of art can be distinguished: (1) suppressive censorship by agencies in total control of channels of possible expression (the "medieval system"); (2) product specification by a relatively few customers, each of whom is not in total control of channels of artistic expression (the "Renaissance system"); (3) administrative restriction of the artist's access to his potential audience without a complete withdrawal of his opportunity to communicate and without destruction of his works ("enlightened censorship"); (4) organizational incorporation of artists into either nonartistic institutions, such as churches or business firms, artistic groups under the authority of nonartistic agencies, such as the academy under the French king Louis XIV (reigned 1643–1715), or state artists' unions (the "organizational system"); (5) expression of preferences of taste by large numbers of individual art consumers not differing greatly in the power to

command and to purchase (the "democratic system"); and (6) criticism by experts specializing in sustained analysis and evaluation of individual works of art (the "intellectual system").

Censorship compared with criticism. Of the six modes of control, censorship is the most severe and least sensitive to the aesthetic merits of works of art. Art is on principle judged in terms extrinsic to artistic values and subordinated to explicitly utilitarian considerations of political, religious, or "moral" character. Criticism, at the other extreme, at least uses the means of imagination, rather than of power, to control products of the imagination and mediates between artists and groups of users of art (however small) whose standards particular critics articulate. Thus, criticism helps to relate artists to the subcultures in which their work is most responsively consumed and to reveal the character of these subcultures to their own members. At best, criticism expands the artist's experience in areas relevant to his understanding of how art operates in the minds of people and increases the consciousness of the community to which the critic "speaks." At the same time, the artist can avoid being influenced by critical interpretations (at the risk of not learning what they reveal) by the simple decision not to read the reviews. Scientific research into empirically demonstrable effects of particular kinds of art on particular types of personalities, under specified conditions, can be treated as a newly evolved element of artistic criticism.

Benefits derived from criticism

Censorship of the arts has been typically justified by "clerical" or "civic" conceptions of art—the view that art has a moral obligation to defend a cultural tradition higher than art itself or a civic obligation to celebrate the community that supports the artist. The first view is usually espoused by various ideological elites, but the second can be quite popular and widely supported, even in a democracy. The clerical conception of art also generally implies the assumption that art has a great power to corrupt or to save. It is, indeed, this tendency to overestimate the power of art that leads to demands for censorship. The civic attitude toward art presupposes merely a tendency to suppress anything that offends local self-esteem.

Whatever the conception of art, censorship becomes "necessary" only when an established clerical or civic view of art is powerfully challenged by other artistic cultures—the ecstatic, the vagabond, the genius, the professional, or the avant-garde. It is perhaps from such challenges to civic and clerical assumptions by ecstatic (Dionysian) or emerging professional types of artists that the first explicit philosophical defense of artistic censorship, by the philosopher Plato, emerged in classical Athens. A conflict between two clerical cultures, the Catholic and the Protestant, together with the invention of the printing press (which made literature more "dangerous"), led to the great development of formal, organized religious and political censorship in 16th-century Europe. Censorship declined, especially in the Anglo-Saxon countries, in the 18th century, with the establishment of religious tolerance and in conjunction with the displacement of clerical by professional conceptions of the writer.

Targets of censorship. Censorship has been mainly directed against the ideological (stated or implied views) or depictive (represented scenes) content of the arts, thus primarily against the arts in which content is more important—literature, the theatre, and the visual arts (including the film and, to a lesser degree, photography). But whole types of art have been outlawed. The ancient Spartans expunged music and dance, as well as poetry, on the grounds that they might promote effeminacy and license in a population that had to be hardened for heroic militarism. Early Christianity suppressed the theatre and fictional literature of the Greco-Roman civilization. Muslims, Calvinists, and in some periods the Byzantine iconoclasts outlawed religious visual art.

Suppression of content

While, in general, secular states have been concerned only with the content of art, ideological organizations have been sensitive, especially in 20th-century totalitarian systems, to the attitudes and values suggested also in style. It was primarily by stylistic characteristics that "degenerate" art was defined in Nazi Germany. Totalitarian movements have not only prohibited some styles but have also prescribed others for their artists to work in (for example, Socialist Realism in the Soviet Union between the 1930s and the 1950s).

The 17th-century absolutist state also perceived the value implications of artistic styles, but (like the medieval Catholic Church in its approach to the visual arts) it relied more on the techniques of product specification—patronage, by a royal court, and promotion, by an official art academy—rather than on prohibition, enforced by police power, against working in particular styles and having works in these styles exposed, in some manner, to artists' customers. As a mode of control, product specification is more congenial to artistic creativity than is censorship; and 17th-century France sustained creative attainments of a high order, even in the visual arts in which the court specified its demands most insistently. But it achieved still more in dramatic literature, over which the court had a less direct influence.

In the 20th century, the large economic organizations that have come to dominate the mass arts have acquired a capacity to exercise a private kind of censorship by depriving artists of their means of work. In the "image" industries, the reason for such blacklisting, as in the U.S. film industry after World War II, has tended to be the political image of the artist rather than either the style or the content of the work he was proposing or had done in the past. In the democratic societies, private watchdog and pressure groups are likely to be more effective in imposing their demands for censorship on the mass-arts industries or on the business firms whose advertising sustains them financially than in influencing governmental agencies. The newer mass media are, because of their dependence on public licensing (television stations), more vulnerable to governmental pressures than the traditional arts.

Self-censorship

Self-censorship by artistic enterprises (for example, the movie rating system of the U.S. film industry) has developed largely in response to the influences private pressure groups have brought to bear on the culture industries, by threatening their mass sales. A different variety of self-censorship is practiced by art museums when they ban types of art with contents that are not congenial to the economic or political interests of the business leaders who usually control their boards of trustees, or that seem capable of causing libel suits, or that appear to conflict too sharply with the traditional conceptions of what art museums should exhibit.

In neither of these two situations does "censorship" completely prevent public exposition of the works censored or terminate the public career of the artist concerned. These cases thus do not represent true, suppressive censorship but, rather, a system of limiting the public's opportunities for viewing certain types of art. Prohibition of the sale of certain types of art to juveniles also represents restrictive censorship. In respect to the arts, the Western democracies have by now virtually abandoned suppressive censorship in favour of the restrictive.

In the U.S.S.R., there have been some trends after the death of Joseph Stalin (1953) toward a transformation of the system of suppressive censorship into a de facto system of administrative restriction: allowing for privileged exhibitions of modernistic art in scientific institutes, showings of avant-garde foreign films to select circles (partly specialists and partly political elite), publication in small editions or in recondite journals. But a somewhat relaxed suppressive censorship is still in operation. China has a completely suppressive system.

In contrast to the censorship practiced by the ideological organizations, style is usually of no concern to the economic interest and private pressure groups endeavouring to subject art, or what is presented as art, to censorship either by pressuring the mass-arts industries and large artistic enterprises or by demanding action by government agencies (in the United States, most frequently on grounds of "obscenity").

CONDITIONS FOR SOCIAL CONTROL

In general, the arts seem to be most susceptible to social control when artists are dependent on a relatively few im-

portant consumers or on a great mass audience of a fairly homogeneous social character, and when their works are either very expensive "uniques" or highly profitable "multiples." The susceptibility of artists to social control thus depends, to some extent, on the kinds of art they choose to produce. This susceptibility tends to decline when there is a differentiated, heterogeneous public with political institutions permitting a free expression of individual choices and an inexpensive access to a wide range of works of art. If access to art is provided at public expense, however, artists again become susceptible to social control—this time by the intermediaries staffing the cultural organizations, such as museums and state publishing houses, that determine which artists and which works will be exposed to the public.

Factors in the susceptibility to restraints

Art is least susceptible to social control when it is sponsored and financially supported by other artists, who acquire their income in some manner other than through the sale of their works (for example, through teaching). The institutionalization of the professional conception of art is perhaps, in the long run, the most reliable defense, from within the artistic enterprise, against deliberate manipulation of the arts by social agencies. But a purely professional tradition of art is so inoffensive as to appear dehumanized, and artists themselves may seek to overthrow it, opening themselves up to deliberate manipulation by those (frequently political movements) they align with to achieve this goal.

IMPLICATIONS OF SOCIAL CONTROL

The issue of censorship and other kinds of deliberate manipulation of art has ultimately to be dealt with in terms of moral and political assumptions about human nature and the proper character of the artistic enterprise, not primarily in terms of the effects of these policies on artistic creativity. The effects of social restraints, or their absence, on artistic creativity seem, in any case, somewhat ambiguous. In general, no direct relationship seems to exist between the degree of personal freedom enjoyed by the artist and the aesthetic quality of his work. The tolerance and cultivation of the art patrons in Italy during the 17th and 18th centuries did not prevent a decline in creativity. On the other hand, a general cultural repressiveness does not always preclude an artistic efflorescence: the period of the most intense activity of the Spanish Inquisition in the 16th and 17th centuries coincided with El Siglo de Oro (The Golden Age), one of Spain's most important periods of artistic creativity.

Freedom, however, may have become a necessary—though not sufficient—condition for artistic creativity in industrial societies. Artists, particularly those who have been affected by artistic developments in the West since the Renaissance, have come to expect creative freedom and cannot help but feel illegitimately constricted in its absence. Their personalities are no longer sufficiently congruent with an authoritarian structure of external controls, as the personalities of medieval artists may have been, to be able to produce aesthetically significant work when subjected to such controls. By abolishing artistic freedom, both the Soviet Union and Nazi Germany destroyed flourishing artistic movements and proved unable to generate aesthetically valid substitutes for them. But a relaxation of earlier rigid controls may be more conducive to artistic creativity than the maximum of freedom, because under restrictive controls an unspent tension accumulates, which is then available to be released in an explosion of creative activity when pressures are relaxed. Under complete external freedom, such energy may never accumulate; unless the artists possess an extraordinary degree of self-discipline, their energies tend to be immediately used up through a variety of outlets.

Effect of easing controls

What seems to be specifically fatal to artistic creativity is not social control of the arts but an imposition, whether by outsiders or indeed by the artists themselves, of a completely intentional conception of the artistic enterprise: that is, its successful limitation to the expression of any set of recognized and intended functions.

If there is to be any social control over the arts, which many artists would dispute, its least objectionable form would seem to be one limited to a combination of expressions of preference by large numbers of interested art users with analysis and reasoned evaluation by art critics and scholars. The two modes of control in conjunction balance each other's biases and increase the range of options available to artists. These controls can be dismissed from consideration only if it is assumed that art is totally irrelevant even to the people most interested in it (other than the artists themselves). Art would then have to be treated as either a private affair of the artists or as pure entertainment without any cultural significance.

SOCIAL RELATIONSHIPS

In both preliterate societies and historic civilizations, the arts have frequently, but not always, had a close relationship with religion. In the past, this relationship has tended to be less direct when art objects were being produced by women, such as the pottery of the Pueblo Indians of the southwestern United States. Women, who have rarely been the religious specialists of their societies, have mostly produced an art of decorated utilitarian artifacts or of personal intimate expression, in either case not characterized by high cultural symbolism. Men have been more frequently disposed, or constrained, to justify their aesthetic interests by relating them to a metaphysical purpose. In effect, this means that men have had more reasons, in most preliterate and historical societies, for making art than women did.

Interaction of art and religion. An explanation for the frequently close relationship between art and religion may be found in the areas in which they are similar or overlap. In both art and religion, there is much concern with the basic needs of the imagination and with a valid perception of subtle qualities of experience, and there is no binding requirement that they provide references to demonstrable fact for their insights (as there is in science). The similarity means that the arts and religion might, in part, operate as functional substitutes for each other: the more successfully one system functions, the less need for the other, and the less successfully, the more need. This may be one reason for the modern growth of interest in the arts, especially among the intelligentsia and the alienated of the middle class.

Religious and artistic similarities

Religion, however, tends to be more dependent than the arts on those aspects of culture that are communal, involved with abstract ideas, and concerned with standards of conduct. It must provide guidelines for action that whole communities (as well as individual persons) could live with. While the arts can perform such "religious" functions, they can also survive quite well without performing them: inherently, the arts have a less direct, less intentional, less "responsible" relationship to social action than does religion. In their specifically aesthetic essence, the arts are more private, more individualizing, less binding than religion. There is more play than obligation in the arts. The opposite is true of religion. Popular interest in the arts tends to decline, and interest in religion to increase, during life-threatening historical crises, such as the Black Death of 1348–50 in Europe or destructive wars. Interest in art frequently increases after such periods. Religion is more of a crisis-management phenomenon, art that of postcrisis integration.

The impact of art on its consumers is likely to be magnified by its association with religion or even, in the absence of any formal association with organized churches, by its perception in terms appropriate to religious experiences. If close alliance between the arts and religion means that they are "used" by religion, the arts become collective liturgies, providing sensuous elements to increase the hold of a religious doctrine over the more private aspects of human experience. If, on the other hand, the arts "interact" with religion, if artists can have an influence on the development of religious orientations (instead of merely being "guided" by them), religion might acquire some of the characteristics of an art—become less systematized, more private, less dogmatic in its claims, more individualizing in the experiences it permits. The medieval Catholic Church, by and large, "used" the arts, while the Asian religions—other than Confucianism—tended to "interact" with the

arts. In classical Greece, the arts became so emancipated from religion that they can be said to have "used" it, with more enduring benefits for the arts than for religion.

Separation of religion from art. A sharp separation of religion from the arts, such as tended to occur during the Protestant Reformation, promotes the rise of a rationalized, "disenchanted" religious world view and an anarchically romantic tradition of the arts. Like the Reformers, religions generally have been willing to accept some kinds of music and literature and have varied mainly in their attitudes toward the visual and the "bodily" arts—the dance and the theatre. Attitudes toward the religious significance of the materially existent underlie this variation. But religions have also varied in the degree to which they made use of, or interacted with, the arts. "Aesthetically deprived" religions lose one sort of appeal to potential adherents and, perhaps especially in times of widespread discontent and cultural crisis, do not compete well for popular support with religions that possess more powerful aesthetic (or mythological) resources. Soviet explanations of the survival of religion in the U.S.S.R. stress increasingly its aesthetic aspect—a problem for Marxist ideologists, who are beginning to perceive a lack of this element in their own system of faith.

Effect of separating art from religion

A religion or a secular ideology without the arts loses one type of symbolic resource for its perpetuation and a possible source of modification of its doctrine. In addition, the arts represent one possible way of testing human significance of various aspects of the message of a religion or secular ideology. Do they survive, when artistically treated, without the support of enforcement by the established authorities of a church (or party)? It has been suggested that some ideological and religious concepts failed to be retained in the popular consciousness because they never received an effective artistic elaboration.

For the arts, a complete separation from religion or secular ideology means, on the one hand, a release from the obligation to serve a tradition regarded as superior to art itself and from its various efforts at social control—including censorship—over artistic expression. On the other hand, the separation of art from religion or ideology means: (1) the loss of a symbolic resource that either can be used directly in art creation or that stimulates artistic creativity indirectly by "disturbing" the imagination of artists; (2) the loss of one type of opportunity to create art that is both appreciatively used by large numbers of people and regarded as significant by them; and (3) the loss of a type of patronage that has historically been more continuously interested in the arts (other than literature), in times good and bad, than any other and that has tended to exhibit more concern even for the aesthetic merits of art than did the two most important types of patrons—the high bourgeoisie and the secular state—that followed the virtual demise of church patronage.

Attitudes toward patronage

A preoccupation with patronage, however, has not always governed the behaviour of artists. Even though painters could expect to lose their most important kind of patronage if the iconoclastic Protestant Reformation succeeded, a surprising number of them supported the Reformation. Historically, literature has been least dependent on religious patronage; music (because of its almost ubiquitous linkage with ritual), perhaps most.

AESTHETIC INFLUENCES

A strong influence of doctrinal religion over the artistic enterprise disposes it toward a "clerical" conception of its task: the upholding of a cultural tradition regarded as higher than art itself. It also tends to eliminate women from roles, except auxiliary, in the artistic enterprise—as in organized religion. But the *mystical* streak of religious experience has frequently influenced the artistic enterprise in a generally liberating direction, producing an ecstatic type of artistic culture. Any kind of direct religious influence on the arts tends to give them a more consciously symbolic character, but the doctrinal religions tend to impose on them an authoritarian rigidity (for example, the Romanesque style current in Europe from the 11th to the 12th centuries), whereas the mystical religions produce tendencies toward a more fluid style that could be interpreted as more egalitarian (Buddhist wall paintings at Ajantā in Mahārāshtra State, India). Mystical religions may also open the arts more equally to both sexes, as it did for such women mystic writers of the late Middle Ages as the English Julian of Norwich and the Italian St. Catherine of Siena.

Feeling-oriented religions like Buddhism tend to produce preferences, in the personalities influenced by such religions, for sensuous styles of art; belief-oriented religions like Calvinism favour austerity in art styles.

Confucianism has also tended to favour austerity, but the Chinese Confucian gentlemen painters drew most of their artistic inspiration from Taoism and variants of Buddhism. Perceptual tendencies may persist even after the religious tradition that has shaped them is no longer consciously adhered to.

Changes in the religious system have, in strongly religious periods, provided impulses for subsequent artistic changes. Periods of increased artistic creativity have frequently followed those of intense religious struggle—conversions of nations, great heretical movements, successes or failures of popular reformations, even iconoclasm. But this is not an effect peculiar to religious changes: other types of intense social action have also preceded artistic efflorescences. A more specifically religious influence on artistic creativity is suggested in the historic tendency for artistic efflorescences to occur after periods of great religious creativity. This suggests that the arts benefit from a partial secularization of intensely religious traditions or that religious efflorescences shape symbolic or emotional resources that are most usable for artistic expression when they have aged ("mellowed") somewhat but have not been completely discarded from the living experience of a people. Expirations of previously potent religious traditions, as of Buddhism in India, have coincided with declines in artistic creativity.

Inferior influence of secular "religions"

The modern secular equivalents of religion have generally been quite inferior to it in their effects on the arts. This may be partly because most of the "secular religions" of 19th-century origin have been rationalistic, purposive ideologies with little mythological content to disturb and stimulate the artistic imagination. In fact, artists have been most affected by the drama of events (or "theatre") brought into being by secular religions, rather than by their "mythology."

A great many modern artists have been willing to let themselves be influenced by the secular ideologies or by the more ancient religious traditions of their own civilization or by religions of cultures alien and exotic to them. The latter two influences have generally been aesthetically more auspicious than the former, but most artists do not experience even these influences with sufficient intensity to be "disturbed" by them and tend to exploit, almost at random, their more superficial characteristics.

It would be difficult to demonstrate that developments in the sphere of art have had any independent effects on religion. Throughout much of history, art has not been sufficiently independent from religion to be perceived as a "cause" of religious developments. More likely, it may have given focus, a tangible concreteness, a dramatic shape, a memorable melody, to abstract religious notions or shapeless feeling states and provided means for celebrating and transmitting them—rather than initiating the experiences and the notions themselves.

The impact of fantasy

It seems likely that the cultural attitudes of the growing number of alienated intelligentsia of the West are greatly affected by its artistic culture. The conception of the "revolution" as espoused by the New Left has, in many ways, been a "surrealistic" one ("all power to the imagination," etc.). Fascism, too, has been considered by some observers to be an aesthetic phenomenon almost as much as a political one. It is, in any case, through the shaping of fantasy dispositions—congenial modes of perception—that art can influence the development of general value orientations, which in turn dispose people to favour particular religious or political ideologies, when choice between alternatives is possible.

Yet the shaping of fantasy dispositions is not a foolproof method of manipulation, particularly in modern societies:

it may provoke a subjective rejection of overly insistent attempts to influence—an anarchic response to the rigid authoritarianism of the "classical" styles or, conversely, a demand for new dogmas and rituals in response to more ambiguity, suggested by the arts, than an individual can live with in his own life.

INFLUENCE OF TECHNOLOGY ON ART

To varying degrees, the arts depend on technological evolution for the very techniques used to create works of art—literature least, music considerably, and architecture most of all. The cinema has been made possible only by recent technological developments.

The arts also depend on technology for the dissemination of the creative product. Book printing has made possible the development of a mass reading public, which in turn has facilitated the rise of new literary genres, such as the novel. Modern techniques rendered objects of visual art mechanically reproducible, hence perceived and treated as less "unique" than they had been in the past. The film is a peculiar art in that the technique of production and the technique of dissemination immediately imply each other, both having been produced by the same technological development.

Beyond these direct technological influences on the arts, there is an indirect one, mediated through the effects that particular technologies have on the imagination of artists or of larger populations.

Effect on content. Generally, the arts do not mirror, in any direct manner, the technological developments occurring in the society in which they have been produced. In their contents, the visual arts are more likely to touch upon the consequences of technological developments that have become intimately familiar (for example, the artifacts represented in still-life painting) but are not necessarily its objectively most important result; or perhaps upon the more vividly visible agents of technological development (such as draft animals, machines, or electronic processes) rather than on the whole system of technology or the basic principles underlying it.

In other words, the arts focus on those aspects of technology that "grasp the senses." Thus, they frequently dwell on technological innovations in a very early stage of their development, then let them drop as subjects for artistic concern after they have become fully developed, attained a dominant role in the economy, and are taken for granted emotionally.

Art as a celebration of the absent

But it is also what technological change has eliminated or does not permit to exist that can grasp the artists' imagination; they will then be concerned with what they miss in a particular technological system and will depict, perhaps, the opposite of what they see as existing in it. It has been found that in preliterate societies where the house shape is circular, straight lines are preferred in art style and that, conversely, where the house type is rectangular, art styles tend toward the curved line. This finding suggests either that art supplies what is most lacking in the technological environment or that one art must provide what another art does not.

Technological developments may both suggest new contents for art and encourage the elimination of old ones. Thus, the invention of photography has virtually eliminated the need for realistic portraiture.

Effect on style. In the development of styles of art, technological factors appear to be more important than they are in the choice of subject matter. Certain styles have been made possible only by particular technological developments (electronic music). In other cases, technological developments (new types of paints) have converged with new scientific theories (in optics) and perhaps psychological changes (the decline of middle class democratic militance) to produce a particular style, such as Impressionism in French painting.

In still other cases, a style may be regarded as a symbolic projection of psychological attitudes inherently linked with a technological process. It has been argued that tendencies toward more geometric styles of visual art have emerged in connection with both of the major technological transformations of society—the agricultural and the industrial revolutions, while periods that have preceded these transformations have favoured more "realistic" styles (*e.g.*, Paleolithic cave paintings and the figurative arts of urban pre-industrial civilizations). A possible explanation of the linkage of the technological revolutions with more abstract styles of art may be the alienation from nature or a sense of mastery over it suggested by the geometric styles. Through them man imposes "his own" type of order on nature, where no such geometricism can be found. This attitude is also implied by the great technological transformations through which man has objectively increased his control over the forces of nature.

This process could have started in the imagination of artists inventing the notion of mastery over nature as a dream; in the attitudes of the people or of the religious, economic, or political leaders, reflected in both technological and artistic changes; or in the process of technological transformation, which, by its success, led to a widespread sense of mastery, projected into artistic style.

Industrial mastery and style

In the industrial transition the apparent sequence has been change in popular or elite attitudes, encouraged by the Protestant Reformation; speeding up of technological changes; and the rise of geometric styles of visual art. Music has "lagged behind" the technological transition even more than have the visual arts, but literature may, in certain respects, have anticipated it.

Thus, it could be argued that the poetry of courtly love and of religious affective mysticism of the late Middle Ages suggested an attitude of mastery over nature (over sexual impulses, limits of time and space). Even if this interpretation were accepted, however, it could not be concluded that literature is necessarily a more sensitive indicator of underlying psychological changes than the other arts. It may be in periods in which the other arts are heavily dependent upon organized patronage and a guild organization, and literature is comparatively free of such encumbrances, that it registers psychological changes more sensitively and at an earlier date. Technology, in this perspective, appears not as the "ultimate" determinant of artistic expression but as an aspect of basic psychological and cultural change—an aspect that became crucial at a certain point.

The interest of artists in science appears to have been greatest on the threshold of the Industrial Revolution, in the 17th century, and toward its end—when technological developments, particularly in the field of electronics, have altered the material basis of advanced societies in the second half of the 20th century. In between, artists, especially writers, tended to be repelled by technology and its effects on people and the environment (and by the science they associated with these effects).

In the latter part of the 20th century, the attitude of repulsion still tends to hold with respect to the machine technology, but a distinction is made between it and the electronic (and cybernetic) technology, which is viewed more optimistically. Electronic technology, by the miracles of its circuitry that exhibits an almost human responsiveness, is expected to overcome the chasm between the "mechanical" and the "spiritual" that the Industrial Revolution had deepened.

Changes in the character of science during the 20th century, its recognition of the principles of relativity and indeterminacy and of the importance of the researcher's subjectivity, have contributed much to the revived appeal of science to artists and to their high expectations with respect to the technology based on this kind of science. In the 20th century, psychoanalysis and several perspectives in the social sciences have also been influential in the arts.

The response of the arts to science

In the long run, it is likely that the artists' response to the sciences and technologies of advanced industrial societies will follow the usual logic of the workings of the artistic imagination. That is, scientific technology should influence the arts through the artists' choices between affirming it and modelling their own work after it or repudiating it and concentrating on what it cannot recognize or suppresses or, if left to itself, would tend to destroy. The power, mathematical clarity, and systematic nature of the sciences and technologies may produce an artistic response in the form of sensuous, amorphous styles, car-

rying suggestions of impotence, of mysticism, of unique experiences.

There is no reason to anticipate that, in the long run, artists will be overwhelmed by science and assimilated into its mode of operation. Indeed, the more science and technology develop, the more they may be subjectively taken for granted, the more imagination may be captured by what science and technology cannot encompass, and the more an art that has not been overwhelmed will be needed. Artists tend to be overwhelmed by a great increase in the technical possibilities of expression only when they have no reason of their own—a mode of perception, a value commitment—to express anything in particular.

Effect on creativity. An essentially descriptive science may influence artistic creativity favourably when it fuses with an older tradition of an artistic craft, as anatomical and optical research vitalized painting in the Italian Renaissance. But a highly abstract science, removed in its formulations from directly perceivable realities, seems to be of most benefit to artists when they permit their imaginations to be stimulated by the general atmosphere of scientific discovery, of the revision of concepts about the nature of reality, or of new perceptions, rather than when artists have set out to apply scientific principles consciously to their work. Even an incorrect interpretation of scientific models by artists can be artistically productive (and perhaps scientifically suggestive).

Other aspects of the relationship. To what extent the arts can influence the sciences is still uncertain. If "visual thinking" precedes conceptual thought, or if there is a basic background element common to both visual and conceptual thought, changes in perceptions that art either reflects or stimulates may generate responses in conceptual theorizing and, in this manner, affect developments in science as well as in philosophy. But it is on social and psychological theory and on the perceived shape of history that developments in the arts may be expected to have the strongest effect.

Effect of art on the social sciences

The association of artists with technology, especially in the visual arts and architecture, has been far closer and more durable than it has been with science, and the requirements and achievements of artists have often led to technological discoveries. Literary artists, on the other hand, have, particularly in the periods of great scientific discovery, such as the 17th century, been influenced more by science than by technology.

It might seem that the new technologies of the mass media of communication, by permitting more pervasive dissemination of particular works of art throughout society, are likely to increase the impact of art on people's personalities and modes of existence. But the mass media may also have the opposite effect: by making of art a commonplace occurrence that is taken for granted but does not generate an enduring emotional response, by assimilating it more completely to "entertainment," the mass media may decrease the effects of works of art on people and, indeed, on the artists themselves and on their aesthetic experiences.

At the same time, the media may be increasing the psychological impact of nonartistic events, particularly those that resist being assimilated to entertainment, such as wars in a foreign country, which were easier to take for granted before the electronic media became fully developed. This has led to tendencies to substitute, especially in the visual arts, the structures of events or of social systems for aesthetic structures (for example, an art exhibition consisting of photographs of slum buildings and landlords' names).

While it is debatable whether the mass media have enhanced the impact of art, they have certainly increased the social status of the performing artists (and tend to transform all artists whom they capture into performers).

AESTHETIC EDUCATION

The broad and narrow views of aesthetic education

In the broad sense, aesthetic education refers to everything that art is, or may be, used for in the education of nonartists. In the narrower sense, aesthetic education is the developing of a sensitivity to aesthetic qualities and works of art and of an understanding of the criteria by which some works of art are regarded, by artists and art critics, as possessing more highly valued aesthetic qualities than others. Aesthetic education could hardly avoid, but it does not need to be limited to, what is implied in the term's narrower meaning. Approaches to aesthetic education vary mainly in how they conceive of its "broader" responsibilities.

As soon as art is created and exposed to others, it always educates in some way. A study could well be made of the implicit philosophies of aesthetic education, inherent in the manner in which art is used and particularly in the manner in which the growing individual is exposed to it, of the preliterate societies in which the role of an art educator—as distinguished from the practicing artists—does not exist.

The formal development of aesthetic education, like the formalization of all education, has occurred in the classical civilizations. In the Western tradition, four basic conceptions of aesthetic education for the nonartist have been sociologically most important, although in practice they frequently overlap.

Didactic. The didactic theory regards art as a means for shaping a particular type of personality (the view of the Greek philosopher Plato). Modern notions of proletarian, black, or feminine "consciousness raising" by means of art, insofar as they presuppose that art is to be used for developing an attitude specified in advance, represent variants of the didactic approach to aesthetic education. But even when the goal is developing a particular type of aesthetic taste (as, for example, a taste for the "classical" styles or for "modern" art), a philosophy of education is didactic, albeit in a more subtle way. The didactic theory implies that if art does not do the task assigned to it, it has either no place in education or a subordinate one; and it may lead to justifying censorship of the arts, "to protect the innocent from corruption." This view of aesthetic education is most congruent with the "clerical" conception of art.

Therapeutic. The therapeutic theory views art as the supplier, for individuals or groups, of experiences that everyday life in society fails to provide but that are assumed to be necessary for a "whole" and "healthy" existence. In a highly rationalized society, art supplies or reveals the irrational, supplementing or confronting reason and duty with spontaneity and sensuousness. Or, in a more sophisticated conception, art reconnects reason with sensuousness, which had first to be separated from each other, for man's self-awareness to advance itself.

Since this philosophy of art as therapy developed in an early phase of the Industrial Revolution, it usually conceives the deficiencies of society in terms of what was becoming suppressed then—needs for emotional expression—or what was promised ideologically but has not been adequately delivered in reality even in the most modernized societies, such as equality and participation. But what appear to be increasingly missed in the advanced industrial societies are credible designs for the symbolic coherence of life; a sense for experiences and objects that resist being used up and are immune to planned obsolescence. The therapeutic function of aesthetic education may be changing accordingly.

Changes in the therapeutic function since the Industrial Revolution

The objective of a "therapeutic" aesthetic education is to use art to bring out the missing elements and either to promote their integration with the existing state of affairs or to overthrow the latter. The task may be conceived as "sociotherapeutic" or "psychotherapeutic"—overcoming the deficiencies of a whole civilization or those of an individual personality. In contrast to the didactic approach, only the initial problem and the general direction of the effort but not the final solution—a specified type of personality or society—are presupposed. Artworks can be judged, in a general way, by the degree to which they fulfill the therapeutic task set to art by the character of the society or the stage of the evolution of civilization contemporaneous with it. But no artwork can be in principle excluded from aesthetic education, since any work may be "therapeutic" for someone.

Developmental. The developmental theory aims at making it possible for anyone to choose from the realm of art whatever he needs to develop his unique potentialities.

The evolution of society has not given rise to any particular type of need that art should be meeting in a given social context. The task of aesthetic education is, perhaps, to increase the range of exposure to art so that every individual will choose on the basis of a more complete knowledge, more intelligently, how to develop his own self aesthetically.

This is a liberating educational philosophy, particularly in a tradition dominated by didactic approaches. But it has three unintended effects: (1) Since it puts the emphasis on what a person gets from a work of art for himself, it destroys the reason for trying to understand the work of art in itself and the ways it has functioned for other people, including its author. (2) While this approach permits individual experiences and descriptions of such experiences, it eliminates the basis for a more generalized critical evaluation of works of art. (3) By its emphasis solely on the individual's aesthetic experience, it eliminates the need for art. What have the works of art got that "aesthetic experiences" on a crowded street or in one's dreamworld do not give?

The developmental approach applied to children

The developmental approach is most applicable to the aesthetic education of children, where it is provided with a sense of direction by the psychologists' notion of the stages of intellectual and perceptual development of the personality, each offering distinctive possibilities and limits to aesthetic education. In the aesthetic education of adults, however, by implying that neither art nor the society nor history are particularly important as compared with a person's "experiences," this approach defines itself as a luxury object, likely to appeal to a social group that is prosperous but impotent to shape its destiny; it needs to be balanced by various other kinds of aesthetic education.

Culture-critical education. The purpose of another form of aesthetic education is criticism of culture, in the broad, anthropological sense, through analysis of concrete works of art and of their functions in the life histories of individuals and in the historical existence of societies (and particular groups within them). This culture-critical approach differs from the therapeutic in that it is based less on the personal feelings and cast of mind of the educator and anchored more in the empirical study of culture history and of people's relationships to the symbolic expression of their experiences. It considers art in the context of all human experience, not just in the narrow social setting of an individual perceiver of art (as the developmental theory necessarily does). It is not concerned with recapitulating human experiences in the technical detail of historical monographs. Instead, it is involved with the recognition of patterns in which experiences are "fitted together"—externally influenced, intuitively structured, and their qualities and meanings interpreted to affect later experiences.

Aesthetic education as culture criticism is concerned with producing an ability to make aesthetic judgments that are founded on the knowledge of the ways in which whole civilizations, as well as everything involved with them, have been working. An analytical understanding of parts and of particular relationships is encouraged to grow into a capacity to perceive and evaluate the overall connectedness of a civilization.

Aesthetic education as culture analysis is a method that can be adequately used only with adults; but it can be placed at the very centre of the education of adults, including college students. Its purpose is not to produce art critics but, rather, persons more competent of judging civilizations, including their own, on the basis of an increasing understanding of what they have done, or failed to do, to human sensibilities.

Supplementary approaches. The culture-critical approach to aesthetic education is predominantly analytical. It needs to be supplemented, for most people, by practice in the making of works of art. The writing and performing of dramatic works permit an exploration of the potentialities of social interaction and its limits, which a person has either had no experience with in his own life and yet senses as potentially significant or which he has experienced in an "incomplete" manner and whose full logic and his own design for interpreting it he wishes to work out. Other kinds of literature seem to have a similar role in aesthetic education. Music and dance clarify the dynamic rhythms in terms of which personal experiences and the character of civilizations are perceived, while the visual arts crystallize images of the emotional qualities these experiences and civilizations are sensed to possess. The film provides a potential basis for integrating the functions that literature, music, and the visual arts have in aesthetic education, but the separate experience of these arts provides a clearer understanding of such functions.

Architecture, with its commitment to relating dispositions of the imagination to the practical exigencies of life—and therefore to social policy—in a viable overall design of aesthetic merit, deserves, perhaps, a central place in aesthetic education that has not been recognized in any large-scale educational system. It may have a particularly important role in the education of those who refuse to recognize the linkages of their imaginations with the requirements of actuality.

The importance of aesthetic education beyond purely artistic considerations

It would appear to be arbitrary and self-defeating to limit aesthetic education entirely to considering the work of art in its isolation. It also must give some attention to the ways in which societies organize, or fail to organize, themselves to build aesthetically adequate whole environments (physical, social, and even "spiritual"). It must demonstrate how individuals can demand and, by their own political actions and spending patterns, support the building of such environments. A complete program of aesthetic education should include a consideration of the costs of building and tearing down (or maintaining) aesthetically inadequate environments as compared with the costs of building environments capable of adequately performing a great many cultural functions for the people inhabiting them. And it must teach the techniques of social action for insisting effectively that the kind of aesthetic environment needed is provided.

The importance of immediate contact with practicing artists in the aesthetic education of nonartists is not primarily in the teaching of the technical skills of making art, which the practicing artists are not necessarily superior to "art educators" in transmitting. What good practicing artists can provide for aesthetic education is the demonstration of how "aesthetic structures" (meaningful connections between disparate elements of experience) arise from skilled labour under the constant judgment of a personal sensibility. Good artists also reveal in workaday practice how the nature of a subject, a design, a genre evolves in the process of elaborating its implications and simultaneously develops intrinsic requirements of its own, a set of "norms," a "logic," that the artist cannot disregard without diminishing his creative attainment. In this way, practicing artists transmit a sobering sense for what is required of creators by the inner logic of their works.

The role of the art critic in aesthetic education is to clarify the criteria by which he judges the aesthetic fitness of works of art and distinguishes between artistic successes and failures. The critic should be distinguished from the art interpreter, who explicates the meanings that a work of art has for him. The aesthetic philosopher's most productive role in aesthetic education would be to compare, in some systematic manner, the criteria of the critics, the meanings of the interpreters, and the intentions and the practices of the artists of various societies. In practice, the aesthetic philosophers mainly study each other. Partly for this reason, a role in aesthetic education has been opening up for the sociologists and psychologists of art, who are concerned with how art actually functions in the life of societies and personalities.

Since different individuals are likely to benefit most from different aspects of aesthetic education, it would seem to be a mistake to have a single model of aesthetic education for everyone.

THE NATURE OF ART PRESERVATION

Art preservation in preliterate societies

Even in preliterate societies, not all art is created for the occasion of its use and then abandoned. First of all, the basic design of the work of art survives in the collective memory of the tribe, or of its more artistically inclined members, and can be reproduced from this recollection, frequently with creative modifications. This principle of

preservation operates most clearly in oral literature, but it gives continuity also to the other arts, both performing and objectifying. And this sort of preservation is not limited to preliterate societies.

In some cultures, art objects may also be preserved either for their utility or for their religious significance. Cave paintings have been continuously "refreshed"—that is, restored by overpainting—over long periods of time by the Australian Aborigines to retain the benefit of their magical effectiveness.

Even before the rise of literate civilizations, art collecting had become a symbolic exhibition of wealth and power. Forms of writing, which made easier the collection and preservation of literature, probably also were developed, in the classical civilizations, for their utility in economic management, the pursuit of religiously significant activities such as astronomy, and the more effective exercise of political power. But once traditions of collecting works of art and of literacy have evolved, they have tended to acquire a degree of autonomy from the purposes they may originally have been associated with. Systems of musical notation have evolved later than literacy and without any significant economic or political motives to necessitate their development; it was encouraged, however, by a religious need to stabilize the liturgical uses of music. Systems of dance notation have been produced for purely artistic purposes. Systems of photographic, sound, and motion recording have been provided by the progress of modern technology. The development of these systems has been propelled more by curiosity than by the anticipation of the great profits they eventually proved capable of producing.

Collections of manuscripts existed in the ancient world, and a system of state and school libraries was established in Rome. But a network of public libraries has evolved only since the middle of the 19th century. The notion of a collection of books has not been as closely associated with the aristocracy as that of a collection of works of visual art: the chief connection of libraries has been with scholarship and its practical applications (in preaching, in administration, and, in modern times, in self-advancement through education).

Art collecting in the industrial age

The nature of art collecting has also changed in the age of industrialization and the democratic revolutions that started in the second half of the 18th century. Art collections, which previously had been possessions of the monarchy, privileged classes, and the church and (except for the visible part of church art) were rarely opened to the public, became, in most cases, public museums.

The traditional association of high art and art collecting with class privilege has led some of the revolutionaries and avant-gardists of the 19th and 20th centuries to conclude that the establishment of a democratic culture requires the destruction of the monuments to an aristocratic culture collected in the museums—and of the museums themselves as repositories of that type of culture.

Not only art museums but also symphony orchestras and even the theatre (in contrast to Elizabethan times, 1568–1603) have, in Western societies, little attraction for the working and lower middle classes. A study made in France in the 1960s found that 1 percent of museum attenders were agricultural labourers, 4 percent industrial workers, 5 percent artisans and tradesmen, the rest white-collar workers and higher social classes. In eastern Europe, where there is more of a tradition of high culture being in alliance or, indeed, in secret emotional conspiracy with the people (an attitude of the folk culture that has been retained), working class attendance at performances or exhibitions of high culture is higher. But even though it is encouraged by government, party, and trade-union agencies (and indirectly by the monotony of much of the officially sponsored "popular" culture), interest in high culture is still stratified by class.

This lack of interest by manual labourers in art poses a contradiction. Works of art, by whomever they have been sponsored or collected, have always been produced by craftsmen who surpassed mere craftsmanship. They represent a conjunction of craftsmanship and sensibility of the men and women who have been in the vital centre of their own times, working and imagining. If there is a monument to the immortality of manual labour, it is a museum of art.

Museums of modern art

Museums devoted to contemporary art have developed only in the 20th century. Instead of preserving what has survived repeated tests of critical judgment over the ages, museums of contemporary art delve into the flux of ongoing artistic developments, at best endeavouring to sort them out into intelligible patterns and to enlighten the public's consciousness of its own times. Frequently, however, such museums have become powerful trend setters for the fashionable, producing an ephemeral new "movement" each year and becoming, in effect, adjuncts of the mass media of communication rather than seekers for the surviving values of art. In the 1960s, there developed demands that contemporary-art museums be conceived of as "houses of controversy"—where anything arousing concern of contemporary artists could be exhibited, whether it is art in the traditional sense or not. There are tendencies toward differentiation between two types of art museums: one engaged in controversy and the other a repository of art-historical collections whose holdings are critically evaluated for their aesthetic merit. There also seems to be an increasing need for museums in which all the arts of a period or a historic group could be shown together, to reveal the overall cultural atmosphere of the period or group and the interconnections of its arts, placed within their sociological context.

For each living generation to preserve artworks implies the desire not to deprive future generations of the kinds of human experiences that the circumstances of the past and present have generated and the future may no longer be able to produce. Possession of what one is not able to produce stretches the mind in ways that, in the absence of these possessions, could not even be imagined. By not preserving works of art, a society would lose much of its awareness of the limits of its own imagination and would tend to treat its present modes of existence and of aspiration as though they were absolute.

Unselective preservation of everything that has claimed to be art would, however, very quickly overload the depositories of culture. A decision to preserve therefore implies a criterion of selection to determine what is worth preserving. Such criteria may be the aesthetic merit of the work of art or its historical significance for a nation, a church, a political movement, or a family lineage. Preserving samples of the "popular culture"—presumably lacking in aesthetic merit but representative of the character of a period—is also justifiable. Since judgments of aesthetic merit are revised and possibly improved over long historical periods, "accidental" preservation of works that have not been judged by their contemporaries to possess aesthetic merit can also become important.

The greater part of the art produced by the preliterate societies and historic civilizations has been lost due to neglect and historical misfortune. Only 12 percent of the tragedies said to have been written by Aeschylus, Sophocles, and Euripides in Greece during the 5th century BC have survived. Of the period that the Chinese traditionally regard as representing the historical peak of their painting—the T'ang (AD 618–907)—hardly any paintings have been preserved. Many works of art have been intentionally destroyed by organizations or individuals (for example, medieval peasants burning classical marble statues for lime to fertilize their fields). Among the major social organizations, the churches have probably done more for the preservation of works of art than any other, but they have also destroyed art in religious wars and campaigns for the eradication of heresy. States have both protected and destroyed. Business organizations, on the other hand, rank among the major destroyers of architectural monuments, particularly in contemporary societies. Only by governmental regulation can the popular market, whether capitalist or Socialist, be restrained from destroying unique works of art to build parking lots.

Destruction of art

SYSTEMS OF DISSEMINATION

At least seven types of systems through which artistic products are disseminated to art consumers may be identified. These systems differ in the manner in which contact

with art is established and the attitude with which it is approached.

1. Ritualistic systems. Art is incorporated into the conduct of special, repetitive occasions and presented as an integral part of them (for example, church services and political rituals in which particular kinds of music are performed). Highly specific types of art receive wide exposure on an occasional basis. An air of the extraordinary, of festivity, is attached to these types of art. The modern opera has inherited some of the trappings of the ritualistic system. Certain avant-garde occasions may approach it. So do art festivals, by breaking with the routine of permanent museum collections or environments, which gives art the character of being taken for granted.

2. Environmental systems. Art is incorporated into the organization of the everyday, stable environment visible to everyone in the normal course of his life. Architectural works, landscaping, public monuments, and private libraries are cases in point. Transmitted in this way, art influences the perceptual expectations of most everyone, but it tends to be taken for granted, to become "invisible." In modern societies, economic organizations and governmental agencies are primarily responsible for the dissemination of art (bad as well as good) through this system. Governments could, indeed, do more for aesthetic education by controlling the environmental system than through their hold over aesthetic education in the schools.

Art in everyday utilitarian objects

3. The utilitarian system. Art is incorporated into the small, usually portable objects of everyday use, from eating utensils to automobile designs. In its effects, this system is comparable to the environmental system. But it is industry, rather than the government, that is in a strategic position to affect art's distribution through the utilitarian system.

4. The art-trade system. Art objects are produced for and sold on the market specialized for goods of their nature. Depending on their cost, they may appeal to a "mass" or a "class" public but, in any case, to those possessed of a purchasing power they can devote to objects of no material utility and who have a tradition of buying such objects. In practice, the system of trade in the objects of fine art tends most frequently to become oriented to economically privileged groups. The market for music records and tapes is, however, creating a tradition of buying art objects even among the underprivileged. The book trade, particularly after the development of the paperback in 19th-century Germany, is oriented to a broader section of the population than is the art trade; the book market tends to divide into an elite-oriented and a popular component, but the two overlap.

5. The mass-entertainment system. Artworks are constantly exposed, at low cost, to large audiences, but not as a stable and integral part of their everyday environment (as in the environmental and utilitarian systems) nor with an attitude of the extraordinary attaching to it (as in the ritualistic system). The ubiquity of exposure, the fleetingness of the occasions of exposure, and the general atmosphere of fun and games surrounding the operations of this system have the effect of obliterating the unique significance of any particular object of art. Everything processed through the mass-entertainment system tends to become like everything else.

6. The educational system. This is the concern not only of schools but also of modern museums and libraries. Works of art are collected and disseminated with an educational intent—in schools potentially to everyone in the right age groups, in museums and libraries to those who choose to make use of the education offered. Museums, however, have not been fully assimilated to the educational system. In the United States, they are still not regarded, in their claims for public support (or for an automatic tax exemption by virtue of their status), as quite equivalent to schools. There are also notable tendencies in the latter half of the 20th century to incorporate museums into the mass-entertainment system. On the other hand, a politically controlled system of "mass entertainment," as in totalitarian states, is in fact heavily "educational," in a didactic manner. The street theatre of the "counterculture" is also intended to be educational.

The educational system typically lacks the power inherent in environmental or utilitarian systems and the intensity characteristic of ritualistic systems. Possibly for these reasons, the art disseminated through the educational system tends to acquire connotations of what in the upper middle class of Western societies used to be perceived as "femininity"—a refined irrelevance to the world of affairs. The possession of "real life" power by the large art museums constitutes one of their educational advantages over art teaching in the schools, where the art teacher is still frequently treated as an inferior type of educator.

7. Movement systems. There are indications that a new system of dissemination of art may be emerging in the youth movement and perhaps other popular movements of a basically "cultural" (rather than traditional "political" or "economic") character that have become a feature of advanced industrial societies. Any particular movement system is temporary, but, while it lasts, it generates an intense audience response to certain kinds of art, and the audience may even be drawn into the collective production of works of art. The dividing line between producer and consumer of artworks becomes attenuated. Art can be consumed without waiting for a set occasion, but its consumption always has an aura of rebellious celebration attaching to it. If movement systems are successful, however, they tend to be assimilated into mass-entertainment systems—revitalizing them, but at the same time losing their own vitality.

While all known societies produce (and therefore presumably need) some kind of art, not all their individual members use art or exhibit any kind of response to it, even when it is offered to them at no cost and in an environment that is not intimidating. Therefore, all societies have some system, or a combination of systems, for the dissemination of works of art, but not all of their members are involved with such systems. While art-dissemination systems might aim at a universal exposure to works of art, they cannot be blamed for not generating a universal response to art.

The sources of the responsiveness to art lie partly outside of the whole artistic enterprise, in the structures of individual personalities and in their experiences in confronting social systems and historical processes. In this sense, an individual's contact with art starts not with society's systems of art dissemination but with the character of his existence. (V.Ka.)

Fraudulence in the arts

The most common type of fraudulence in art is forgery—making a work or offering one for sale with the intent to defraud, usually by falsely attributing it to an artist whose works command high prices. Other fraudulent practices include plagiarism, the false presentation of another's work as one's own, and piracy, the unauthorized use of someone else's work, such as the publication of a book without permission of the author; both practices are generally in violation of copyright laws.

Types of fraudulence

Forgery most often occurs with works of painting, sculpture, decorative art, and literature; less often with music. Plagiarism is more difficult to prove as fraud, since the possibility of coincidence must be weighed against evidence of stealing. Piracy is more often a business than an artistic fraud; it frequently occurs in the publication of editions of foreign books in countries that have no copyright agreement with the nation in which the work was copyrighted. A stage production, the reproduction of a painting, the performance of a musical composition, and analogous practices of other kinds of works without authorization and royalty payments also fall into this category.

The fundamental consideration in determining forgery is "intent to deceive." The act of copying a painting or other work of art is in itself not forgery, nor is the creation of a work "in the style" of a recognized painter, composer, or writer or of a particular historical period. Forgery may be the act not of the creator himself but of the dealer who adds a fraudulent signature or in some way alters the appearance of a painting or manuscript. Restoration of a damaged painting or manuscript, however, is not

considered forgery even if the restorer in his work creates a significant part of the total work. Misattributions may result either from honest errors in scholarship—as in the attribution of a work to a well-known artist when the work was in fact done by a painter in his workshop, a pupil, or a later follower—or from a deliberate fraud.

Excluded from the category of literary forgeries is the copy made in good faith for purposes of study. In the matter of autographs, manuscripts in the handwriting of their authors, forgeries must be distinguished from facsimiles, copies made by lithography or other reproductive processes. Some early editions of Byron's work, for example, contained a facsimile of an autograph letter of the poet. If such facsimiles are detached from the volumes that they were intended to illustrate, they may deceive the unwary.

Motivations for fraudulence

The commonest motivation for fraudulence is monetary gain. Fraudulence is most likely to occur when the demand for a certain kind of work coincides with scarcity and thus raises the market prices. Unprincipled dealers have encouraged technically skilled artists to create forgeries, occasionally guiding them to supply the precise demands of collectors or museums. This is by no means a modern phenomenon: in the 1st and 2nd centuries AD, sculptors working in Rome made replicas of Grecian works to satisfy the demands for the greatly admired Grecian sculpture of the preceding five centuries. These copies or adaptations apparently were not offered as contemporary work but as booty from Greece at the extraordinarily high prices paid for such works in imperial Rome. Similar circumstances may account for the "discovery" of a manuscript or autograph by a dead author or composer, although many such finds are quite legitimate and have been authenticated.

The history of the arts reveals instances of persons who have used forgery either to gain recognition of their own craftsmanship or to enjoy deceiving the critics who had rejected their genuine work. A legend told about Michelangelo illustrates this point. At the age of 21, he carved in marble a small sleeping Eros, or Cupid, based on ancient Roman works that he admired. Some time later this carving was sold as an antique to the well-known collector Cardinal Riario, who prized it highly. When Michelangelo stepped forward and claimed the work as his own he won immediate fame as a young man who could rival the work of the greatly venerated ancient sculptors.

Two further motivations behind forgery must be noted: forged documents have been produced from time to time to exalt or malign some religion, political party, or race; and forgeries are sometimes created as a hoax. Some hoaxes are intended to confound or ridicule the experts; others are intended to parody or burlesque an artist or genre.

Three methods of forgery

There are basically three methods of producing a forgery: by an exact copy, by a composite of parts, and by a work done in the style of an artist or period and given a deliberately false attribution. These methods apply most directly to the visual arts but can be discerned in literature and music as well. (Ed.)

LITERARY FORGERY

Financial gain is the most common motive for literary forgery, the one responsible for the numerous forged autographs that appear on the market. The popularity of such authors as the Romantic poets Burns, Shelley, and Byron led to the fabrication of numerous forgeries of their autographs, some of which remain in circulation. These forgeries were usually made by men who had access to only one or two genuine specimens, which they began by tracing. Their forgeries are stiff, exaggeratedly uniform, and lacking in the fluency and spontaneity of genuine autographs.

Instances of literary forgery. Occasionally a forger appears with a certain specious glamour like Constantine Simonides (1824–67), a Greek adventurer who varied his trade in perfectly genuine manuscripts with the sale of strange concoctions of his own. Maj. George de Luna Byron, alias de Gibler, who claimed to be a natural son of Byron by a Spanish countess, successfully produced and disposed of large quantities of forgeries ascribed to his alleged father and to Shelley, Keats, and others. More commonplace is the forgery encountered in the case of the Edinburgh forger A.H. ("Antique") Smith, who was responsible for forgeries of Robert Burns, Sir Walter Scott, Mary Stuart, and other persons from Scottish literature and history—a feat that ultimately earned him 12 months' imprisonment.

Particularly notorious was the case of the Wise forgeries. Thomas James Wise (1859–1937) had the reputation of being one of the most distinguished private book collectors on either side of the Atlantic, and his Ashley Library in London became a place of pilgrimage for scholars from Europe and the U.S. He constantly exposed piracies and forgeries and always denied that he was a dealer. The shock was accordingly the greater in 1934 when John W. Carter and Henry Graham Pollard published *An Enquiry into the Nature of Certain Nineteenth Century Pamphlets,* proving that about 40 or 50 of these, commanding high prices, were forgeries, and that all could be traced to Wise. Subsequent research confirmed the finding of Carter and Pollard and indicted Wise for other and more serious offenses, including the sophistication of many of his own copies of early printed books with leaves stolen from copies in the British Museum.

No forgery to attain recognition is better known than the "Thomas Rowley" poems of Thomas Chatterton (1752–70), which the youthful author attempted to pass off as the work of a medieval cleric. These poems, which caused a scholarly feud for many years, were influential in the Gothic revival. Chatterton, however, enjoys a place in English letters as a creative genius in his own right. The more conventional forger William Henry Ireland (1777–1835) cheerfully manufactured Shakespearean documents until his forged "lost" tragedy *Vortigern and Rowena* was laughed off the stage at the Drury Lane Theatre, London, in 1796. More fortunate was Charles Bertram, who produced an account of Roman Britain by "Richard of Westminster," an imaginary monk. Bertram's dupe, the eccentric antiquary Dr. William Stukeley, identified the monk with the chronicler Richard of Cirencester, known to have resided at Westminster in the 14th century. Bertram's forgery (cunningly published in a volume containing the works of two genuine ancient authors, Gildas and Nennius) had an enormous influence upon historians of Roman Britain, lasting into the 20th century. Equally influential were the Ossianic poems of James Macpherson (1736–96), which influenced the early period of the Romantic movement. To what degree Macpherson's poems are to be regarded as spurious is not certain. Denounced in his own day they were possibly, as he claimed, based upon a genuine oral tradition of Scottish Gaelic poetry; but there can be little doubt that they were carefully edited and interpolated by their collector.

Among the forgers who have tried to make the experts look foolish is George Psalmanazar (1679?–1763). A Frenchman, he went to England where he pretended, with great success, to be a native of Formosa (Taiwan), and published a book about that island, which he had never visited. Another is William Lauder, who attempted to prove Milton guilty of plagiarism by quoting 17th-century poets who wrote in Latin, into whose works he had interpolated Latin translations from *Paradise Lost.* A forgery made as a joke but taken seriously was the "Ern Malley" poems, offered to an Australian magazine in 1944 as the work of a recently dead poet. Actually it was composed by two young soldiers who wished to ridicule certain aspects of contemporary poetry.

The pure fabrication is a kind of forgery that defies classification, often because there is no false attribution and the motives are difficult to ascertain. An example of this is the *Historia regum Britanniae* (*c.* 1135) of Geoffrey of Monmouth (died 1155), a pseudo-historian who compounded stories from Celtic mythology and classical and biblical sources into a fictitious history of ancient Britain. The book became one of the most popular of the Middle Ages and was the basis for some Arthurian legends recounted in medieval romance and epic.

Detection of literary forgeries. The scientific examination of a forged document may demonstrate its spurious character by showing that the parchment, paper, or ink cannot belong to the period to which they pretend. A

skillful forger takes care, however, to secure appropriate materials; and in any case, scientific examination will not avail against the contemporary forger, living in the same age as his victim. Accordingly, other tests must be employed.

Forgeries may be detected by the methods of examination formulated by Jean Mabillon, in his great work *De re diplomatica* (1681), for determining the authenticity of a document by the writing and the style of the terminology. These techniques have developed during three centuries into the modern sciences of paleography and diplomatic, by which various scripts and formulas can be assigned to particular ages and localities, and effective comparison can be made between two examples of handwriting purporting to come from the same pen. Thus it is possible to state that a particular document could not have been written at the date that it bears. In dealing with printed texts, analogous methods are employed.

Nevertheless, a forgery may pretend to be no more than a copy of a genuine original. It then becomes necessary to examine the language and style in which it is written and to look for anachronisms or for statements that conflict with known authorities. This is the method of textual criticism brilliantly employed by Richard Bentley in his *Dissertation upon the Epistles of Phalaris* (1699), which proved that these letters, far from being written by a Sicilian tyrant of the 6th century BC, were, in fact, the work of a Greek sophist of the 2nd century AD.

While the detection of the careful forger may require an expert, forged literary autographs can often be detected by anyone taking the trouble to compare them with an authentic example. Many collectors have been deceived by their own credulity, because they wished to believe that they were getting a good bargain and subconsciously suppressed their critical faculty. A classic case is that of the French forger Vrain-Denis Lucas, who sold a collection of forgeries including a letter of St. Mary Magdalene, written in French on paper made in France. (Ge.B.)

FORGERY IN THE VISUAL ARTS

Any art object—paintings, sculpture, jewelry, ceramics, fine furniture, and decorative pieces of all kinds—can be forged. The difficulty of forging, however, is as important as market price in determining what is forged. Probably fewer than 1 percent of stone sculptures are false because they require so much labour to make and their market is limited, but as many as 10 percent of modern French paintings on the market may be forgeries. The technical difficulties in making a convincing imitation of an ancient Greek vase are so great that forgeries are almost nonexistent. In contrast the forgery level of tiny archaic Greek and Cretan bronze statuettes, which are simple to cast, is possibly as high as 50 percent. A forger is most likely to succeed with a mediocre piece in the middle price range because such a piece probably will never be subjected to definitive examination. Although the price should be low enough to allay suspicion, the object can still yield a fair return for the effort expended by the forger.

Copies

The copy is the easiest forgery to make and is usually the easiest to detect. When a duplicate has appeared the problem is merely to determine which is the original and which is the copy. At least a dozen excellent replicas of Leonardo da Vinci's "Mona Lisa" exist, many of them by his students. Various owners of these copies have at various times claimed that they possess the original. The Louvre is satisfied that it owns the painting by Leonardo because close examination reveals slight changes in the composition underneath the outermost layer of paint, and because this painting has an unbroken record of ownership from the time that the artist painted it.

A monumental sculptural forgery was a copy based on a Greek bronze statuette of a warrior of 470 BC, only five inches high and located in the Antikenabteilung, Berlin. The forgers made an eight-foot-high reproduction of it in terra-cotta and offered it as an Etruscan masterpiece. The resemblance was noted by the experts, who thought it to be an example of an Etruscan artist borrowing a Greek design motif. In 1961, after it had been in the Metropolitan Museum of Art in New York for 40 years, an analysis was made of the black glaze that covered the figure. It was found that the glaze contained as a colouring agent manganese, which never was used for this purpose in ancient times. Finally, Alfredo Adolfo Fioravanti confessed that he was the sole survivor of the three forgers.

Fine examples of pottery and porcelain have always commanded high prices, which have, in turn, encouraged the making of forgeries and reproductions. Since many European factories tried to imitate Italian majolica during the 19th century when it was especially popular, forgeries are common. The work of Urbino, Castel Durante, Faenza, and Gubbio was copied freely, and, to a lesser extent, so were the wares of Orvieto and Florence. Most of these forgeries are not close enough to deceive a reasonably expert eye. Potters used natural deposits the impurities of which, for good or ill, often affected the final result; until recently it has been impossible to procure materials in a pure state. In all but a few isolated instances (some German stoneware reproductions, for example) the forger no longer has access to these original deposits and he has to imitate the effect of the impurities as best he can. Although the best forgeries are often remarkably close to the originals, they are not very numerous.

Composition fraud

In the composite fraud, or *pastiche,* the forger combines copies of various parts of another artist's work to form a new composition and adds a few connecting elements of his own to make it a convincing presentation. This type of forgery is more difficult to detect than the copy. Such a combining of various elements from different pieces can be very deceptive, because a creative artist often borrows from his own work. In fact, the similarity of a figure or an object in a forgery to that in a well-known work of art often adds to the believability of the new creation.

The Dutch forger Hans van Meegeren employed a combined composite and stylistic procedure when he created seven paintings between 1936 and 1942 based on the work of Jan Vermeer. In "Christ at Emmaus" he combined figures, heads, hands, plates, and a wine jar from various early genuine Vermeers; it was hailed as a masterpiece and the earliest known Vermeer. Ironically, Van Meegeren never was detected as a forger. At the end of World War II he was arrested for having sold a painting attributed to Vermeer to one of the enemy, and was accused of being a collaborator. He chose to reveal himself as a forger, which was a lesser offense, and proved his confession by painting another "Vermeer" while in prison.

A variation in composite forgery, quite common with inlaid French furniture, involves the use of parts from damaged but genuine pieces to create a single complete piece that may or may not resemble one of the pieces from which it has been made. These made-up pieces are still considered forgeries. In composites of archaeological material only one part may be ancient, the balance being made up to complete the object. The head of a small terra-cotta figure may be ancient, the body and limbs of modern workmanship. A single ancient element in a composite forgery will help to deceive the buyer.

Stylistic fraud

Most difficult of all to detect is the forgery done in the style of a particular artist or age. If the forger is skillful and is able to absorb the attitudes, conventions, and techniques of the period, he can often create a very successful piece of duplicity.

The work of the Italian Alceo Dossena belongs in this class. He very competently forged works that were acquired by collectors and museums throughout the world. From 1916 to 1928 he produced hundreds of forgeries created as original expressions of archaic Greek, medieval, and Renaissance sculptors.

A newly discovered type of art inevitably brings on a flood of forgeries. At the end of the 19th century, when the first small, attractive Tanagra figurines were found in Greece, the market very shortly was flooded with a myriad of fraudulent Tanagra terra-cotta statuettes. In the mid-20th century, African primitive art became very popular, and woodcarvers from Italy to Scandinavia responded to supply the demand. Later, a very early civilization was discovered in Turkey, and the few genuine Anatolian ceramic pieces that appeared on the market were followed immediately by very competent forgeries apparently made

in the same location as the ancient pieces. The lack of knowledge about genuine pieces made detection extremely difficult.

Detection of forgeries in the visual arts. The key to detecting forgery of unique objects lies in the fact that every object has within itself evidence of the time and the place in which it was made. The two main approaches, stylistic and technical analysis, are complementary and are best used together.

tylistic nalysis

Stylistic analysis is subjective: it rests on the astute eye of the art historian. Each artist has a style, a flair, a verve unique to himself, and this can be recognized. His style will undergo change throughout his career, and this, too, can be stylistically analyzed and documented from his known works. When an unknown work purporting to be by a certain artist is discovered, the art historian attempts to fit it into the overall body of works by this artist. The subject matter, the brushwork, the choice of colours, and the type of composition are all consistent elements in a given artist's production. Any variation immediately arouses suspicion. When the idiosyncrasies of an artist's brushwork are studied, a fraud can sometimes be detected in much the same way a handwriting forgery is proven. In ancient works, particularly in antiquities, the scholar must examine the iconography of a piece. Forgers rarely have the scholarly background to combine iconographic elements correctly, and their errors often betray them.

An object must also be studied for its purpose. Ancient works were made for functional purposes. A forger usually makes an attractive piece often inconsistent with that purpose. As they were used most ancient pieces developed signs of wear. These rubbed and worn areas should appear in logical places on the object.

Documentation is also an important area of investigation. The apparent authenticity of many spurious pieces is bolstered by false documents to attest to the point of origin, former owners, and expert opinions concerning the pieces. A careful examination of these records often detects the forgery.

The hardest deception to detect is usually one that has been made recently. The forgery is a product of the time in which it was made, and the forger is closer to current understanding of the artist or period forged. The forgery, therefore, is often more appealing than a genuine work of art. As a forgery ages, viewpoints and tastes shift, and there is a new basis of understanding. Consequently, a forgery rarely survives more than a generation.

Technical analysis

Technical analysis, an objective approach, rests on an arsenal of equipment and tests. The fundamental principle is the comparison of a suspected work with a genuine work of the same artist or period. The suspected piece must show the same pigments or materials used and comparable age deterioration. Inconsistencies automatically cause the piece to be suspect. Oil paintings dry out and develop a crackle, bronzes oxidize, and ancient glass buried in the ground develops iridescent layers. The microscope is the most useful basic tool: a close examination of the physical condition often will show if the aging is genuine or has been artificially induced. The type of tools used by the artist can be detected from an examination of their telltale traces.

Ultraviolet rays readily reveal additions or alterations to a painting, since the varnish layers and some of the paint layers fluoresce to different colours. Ultraviolet is also used in the examination of marble sculpture. Old marble develops a surface that will fluoresce to a yellow-greenish colour, whereas a modern piece or an old surface recently recut will fluoresce to a bright violet. Infrared rays can penetrate thin paint layers in an oil painting to reveal underpainting that may disclose an earlier painting on the same canvas, or perhaps a signature that has been painted out and covered by a more profitable one. X-rays are used to examine the internal structure of an object. A carved wooden Virgin supposedly of the 15th century but revealing modern machine-made nails deep inside is obviously a fraud. A forger usually works for the surface effect and is not concerned with the internal structures.

Sometimes it is necessary to remove small bits of materials from a work and subject them to various analyses. Chemical analysis is particularly valuable in determining the pigment used because many of the paints available to the modern forger were unknown in earlier times. Today titanium, a 20th-century product, is used to make the white pigment in most oil paints, whereas white lead was the element used in the time of Rembrandt. Many ancient colours were manufactured by grinding natural minerals such as lapis lazuli for blue and malachite for green. Today cheaper synthetic chemicals are used. Some chemical tests, however, require the removal of more ancient material than is desirable. In that event a speck as small as the head of a pin can be analyzed spectrographically. From the burning of a minute sample a photographic record of the spectrum of the light emitted is analyzed to reveal the elements present and their relative percentages.

The dating of an object by the study of radioactive decay of carbon-14 has had little application in the detection of art forgery because of the large quantities of material that must be destroyed. Thermoluminescent dating is based on the slight damage to all matter, including clays, by the faint nuclear radiation present in the earth. Magnetic dating of ceramic objects is based on the slow but perceptible shift of the earth's magnetic field over the centuries.

Considerations of aesthetics and risk. One may logically question the real meaning of the difference between a genuine and a spurious work of art when in many cases it requires such expert study to detect the difference between the two. Or to phrase it another way, what is the difference in value of a work of art that has been on view in a museum for 40 years, after it has been proved to be false? This is a somewhat philosophical point in that the object itself has not changed, only our opinion of it. Its monetary value has been reduced from that of a rare, expensive, original piece to that of an attractive but spurious imitation. Its aesthetic quality has become a real danger, as it is a perversion of the truth. The forgery presents a false understanding of the work of an artist or an ancient culture, one which has been perverted in its modern translation. To appreciate the work of ancient artists their work must be studied alone and not be diverted by forgeries, or one will be inexorably misguided.

Despite all the studies and technical tests available, forgeries will still be made. The 20th-century art forger is far better equipped and much more knowledgeable than his predecessor. The demand for rare works of art has increased, and he will attempt to supply them. In collecting, whether by the private collector or by a museum, there comes a point when, after all the studies and all the tests are conducted, a decision has to be made as to whether or not to purchase a piece in question. The element of risk can be minimized but not eliminated. At this point, the collector should be ready to back his opinion with the purchase price. In order to acquire great pieces, particularly from newly discovered and relatively unknown cultures, it is necessary to take a calculated chance. The collector who has never bought a forgery probably has never bought a great piece of art. (J.V.N.)

BIBLIOGRAPHY

Preparation of the artist and conditions of work in the arts. There is no one book that satisfactorily covers all of the issues discussed in these sections. There are, however, a number of excellent works that deal in detail with one or another phase of the subject. CARL ROEBUCK (ed.), *The Muses at Work: Arts, Crafts, and Professions in Ancient Greece and Rome* (1969), contains a mass of fascinating information. RUDOLF and MARGOT WITTKOWER, *Born Under Saturn: The Character and Conduct of Artists: A Documented History from Antiquity to the French Revolution* (1963), is an invaluable work. NIKOLAUS PEVSNER, *Academies of Art: Past and Present* (1940), is not only the standard book on its subject but also contains many penetrating observations on the profession of the arts generally. QUENTIN BELL, *The Schools of Design* (1963), adds much interesting and useful detail to Pevsner's book and explores some new ground. CESAR GRANA, *Modernity and its Discontents: French Society and the French Man of Letters in the Nineteenth Century* (1967), is a brilliant study that was originally published in 1964 as *Bohemian Versus Bourgeois.* Much information about the profession of the arts may also be found in books on the history of the various arts, such as the volumes in the "Pelican History of Art" series; or JOHN REWALD'S magnificent two books on *The History of Impressionism,* rev. ed. (1961),

and *Post-Impressionism* (1962). DONALD DREW EGBERT, *Social Radicalism and the Arts: Western Europe* (1970), provides a very full treatment of the effect of radical thought on the arts from the French Revolution to the present.

(Si.T.)

Social and economic aspects of the arts. *Anthologies:* On the visual arts in preliterate societies, see CAROL F. JOPLING (ed.), *Art and Aesthetics in Primitive Societies: A Critical Anthology* (1971), an important reader. On the arts in historic societies, MILTON C. ALBRECHT, JAMES H. BARNETT, and MASON GRIFF (eds.), *The Sociology of Art and Literature* (1970), has very extensive coverage and bibliographies. The best overview of the sociology of literature is LEO LOWENTHAL, "Literature and Sociology," in JAMES THORPE (ed.), *Relations of Literary Study: Essays on Interdisciplinary Contributions,* pp. 89–110 (1967).

Art and society: ROBERT ESCARPIT, *Sociology of Literature* (1970); I.C. JARVIE, *Movies and Society* (British title, *Towards a Sociology of the Cinema,* 1970); and ALPHONS SILBERMANN, *Wovon lebt die Musik?* (1957; Eng. trans., *The Sociology of Music,* 1963), provide overall analyses of the social organization of particular arts. CESAR GRANA, *Bohemian versus Bourgeois: French Society and the French Man of Letters in the Nineteenth Century* (1964); FRANCIS HASKELL, *Patrons and Painters: A Study in the Relations Between Italian Art and Society in the Age of the Baroque* (1963); BARRINGTON KAYE, *The Development of the Architectural Profession in Britain: A Sociological Study* (1960); HARRISON C. and CYNTHIA A. WHITE, *Canvases and careers: Institutional Change in the French Painting World* (1965), are studies of changes in the social role of particular types of artists. An account of a social setting in the performing arts (the Broadway theatre) is SAMUEL W. LITTLE and ARTHUR CANTOR, *The Playmakers* (1971).

Basic works on social factors in the style and content of the arts: WALTER ABELL, *The Collective Dream in Art: A Psycho-Historical Theory of Culture Based on Relations Between the Arts, Psychology and the Social Sciences* (1957); PIERRE FRANCASTEL, *La Réalité figurative: éléments structurels de sociologie de l'art* (1965); ARNOLD HAUSER, *Sozialgeschichte der Kunst und Literatur,* 2 vol. (1953; Eng. trans. of vol. 1, *The Social History of Art,* 2 vol., 1957); VYTAUTAS KAVOLIS, *Artistic Expression: A Sociological Analysis* (1968); ALAN LOMAX, *Folk Song Style and Culture* (1968); LEO LOWENTHAL, *Literature and the Image of Man: Sociological Studies of the European Drama and Novel, 1600–1900* (1957); RENATO POGGIOLI, *Teoria dell'arte d'avanguardia* (1962; Eng. trans., *The Theory of the Avant-Garde,* 1968); PITIRIM A. SOROKIN, *Social and Cultural Dynamics,* vol. 1, *Fluctuation of Forms of Art* (1937); and MAX WEBER, *The Rational and Social Foundations of Music,* ed. by D. MARTINDALE, J. RIEDEL, and G. NEUWIRTH (Eng. trans. 1958). For studies of historic cases see LUCIEN GOLDMANN, *Le Dieu caché: étude sur la vision tragique dans les Pensées de Pascal et dans le théâtre de Racine* (1956; Eng. trans., *The Hidden God: A Study of Tragic Vision in the Pensées of Pascal and the Tragedies of Racine,* 1964); PHILIP E. SLATER, *The Glory of Hera: Greek Mythology and the Greek Family* (1968).

Social conditions of artistic creativity have been studied in VYTAUTAS KAVOLIS, *History on Art's Side: Social Dynamics in Artistic Efflorescences* (1972); and A.L. KROEBER, *Configurations of Culture Growth* (1944). Influences of art on society are theorized in HUGH DALZIEL DUNCAN, *Communication and Social Order* (1962); and RADHAKAMAL MUKERJEE, *The Social Function of Art* (1948). VICTOR W. TURNER, *The Ritual Process: Structure and Anti-Structure* (1969), provides a framework for analyzing the social effects of the performing arts. For a survey of some empirical findings, see JOSEPH T. KLAPPER, *The Effects of Mass Communication* (1960).

Art and economics: There is no basic overall inquiry into the role of economics in the development of art. Good historical studies of art collecting are FRANCIS HENRY TAYLOR, *The Taste of Angels: A History of Art Collecting from Rameses to Napoleon* (1948); and NEILS VON HOLST, *Künstler, Sammler, Publikum* (1960; Eng. trans., *Creators, Collectors, Connoisseurs: The Anatomy of Artistic Taste from Antiquity to the Present Day,* 1967). For trends in art prices, see GERALD REITLINGER, *The Economics of Taste,* 3 vol. (1961–70); and GERALDINE KEENE, *Money and Art: A Study Based on the Times-Sotheby Index* (1971). On economic support of contemporary arts in the United States, see WILLIAM J. BAUMOL and WILLIAM G. BOWEN, *Performing Arts: The Economic Dilemma* (1966); and WILLIAM JACKSON LORD, *How Authors Make a Living: An Analysis of Free Lance Writers' Incomes, 1953–1957* (1962). In nine western European nations, see FREDERICK DORIAN, *Commitment to Culture: Art Patronage in Europe, Its Significance for America* (1964). On both the development and the current status of the legal rights of artists, see BRUCE W. BUGBEE, *Genesis of American Patent and Copyright Law* (1967); BORIS I. GOROKHOFF, *Publishing in the U.S.S.R.* (1959); GEORGE HAVEN PUTNAM, *Books and Their Makers During the Middle Ages,* vol. 2 (1897); HOWARD WALLS, *The Copyright Handbook of Fine and Applied Arts* (1963).

Art and politics: There is no reliable survey of relationships between art and politics. Good examples of monographic studies of particular historic cases include: HUGH DALZIEL DUNCAN, *Culture and Democracy: The Struggle for Form in Society and Architecture in Chicago and the Middle West During the Life and Times of Louis H. Sullivan* (1965); DONALD DREW EGBERT, *Social Radicalism and the Arts, Western Europe: A Cultural History from the French Revolution to 1968* (1970); JAMES A. LEITH, *The Idea of Art As Propaganda in France, 1750–1799* (1965); GEORGE LACHMANN MOSSE (ed.), *Nazi Culture: Intellectual, Cultural, and Social Life in the Third Reich* (Eng. trans. 1966); HAROLD SWAYZE, *Political Control of Literature in the USSR, 1946–1959* (1962).

Art and religion: Relationships between religion and the arts are surveyed in GERARDUS VAN DER LEEUW, *Vom Heiligen in der Kunst* (1957; Eng. trans., *Sacred and Profane Beauty: The Holy in Art,* 1963). For sociological studies of religion and the visual arts, see the works of Abell, Francastel, Kavolis, and Sorokin listed above. Of numerous historical studies, G.G. COULTON, *Art and the Reformation,* 2nd ed. (1953); and JEAN GIMPEL, *Les Batisseurs de cathédrales* (1958; Eng. trans., *The Cathedral Builders,* 1961), deal with the effects of religion in organizing the arts, while HELEN GARDNER, *Religion and Literature* (1971); and ANDRE MALRAUX, *La Métamorphose des dieux* (1957; Eng. trans., *The Metamorphosis of the Gods* 1964), with the "spirit" of religion in art.

Art, technology, and science: A historical survey is provided in CYRIL STANLEY SMITH, "Art, Technology, and Science: Notes on their Historical Interaction," *Technology and Culture,* 11:493–549 (1970). On the impact of contemporary science and technology on the visual arts, see JACK BURNHAM, *Beyond Modern Sculpture: The Effects of Science and Technology on the Sculpture of This Century* (1968); and C.H. WADDINGTON, *Behind Appearance: A Study of the Relations Between Painting and the Natural Sciences in This Century* (1969). On the influence of science on poetry, see DOUGLAS BUSH, *Science and English Poetry: A Historical Sketch, 1590–1950* (1950); and MARJORIE NICOLSON, *Science and Imagination* (1956).

Art and education: The most influential recent prescriptions for aesthetic education have been JOHN DEWEY, *Art As Experience* (1934); and HERBERT EDWARD READ, *Education Through Art* (1943). For psychological studies of perception and imagination in art, see RUDOLF ARNHEIM, *Visual Thinking* (1969); and ANTON EHRENZWEIG, *The Hidden Order of Art: A Study in the Psychology of Artistic Imagination* (1967). The utopian and the analytical dimensions of aesthetic philosophy may be illustrated by HERBERT MARCUSE, *Eros and Civilization: A Philosophical Inquiry into Freud* (1962); and RALPH A. SMITH (ed.), *Aesthetic Concepts and Education* (1970). See also *The Journal of Aesthetic Education* (quarterly).

(V.Ka.)

Fraudulence in the arts. *Literary forgery:* J.A. FARRER, *Literary Forgeries* (1907, reprinted 1969), provides a good introduction, which may be supplemented by H.T.F. RHODES, *The Craft of Forgery* (1934); and S. COLE, *Counterfeit* (1955). For individual forgers and forgeries, see E.H.W. MEYERSTEIN, *A Life of Thomas Chatterton* (1930); T.G. EHRSAM, *Major Byron* (1951); A.N.L. MUNBY, *Phillipps Studies,* vol. 4 (1956), on Constantine Simonides; and B.A. MORRISSETTE, *The Great Rimbaud Forgery* (1956). E.J. GOODSPEED, *Modern Apocrypha* (1956), gives an authoritative account of modern forgeries of Christian writings. On medieval forgeries, see the classic essay by T.F. TOUT, "Medieval Forgers and Forgeries," *John Rylands Library Bulletin,* 5:208–234 (1919); and for an example of forged charters, R.W. SOUTHERN, "The Canterbury Forgeries," *English Historical Review,* 73:193–226 (1958). On the detection of forgeries see W.R. HARRISON, *Suspect Documents: Their Scientific Examination* (1958), and *Forgery Detection: A Practical Guide* (1964); and J.V.P. CONWAY, *Evidential Documents* (1959).

Forgery in the visual arts: SEPP SCHULLER, *Fälscher, Händler und Experten* (1959; Eng. trans., *Forgers, Dealers, Experts,* 1960); and HEINRICH SCHMITT (pseudonym FRANK ARNAU), *Kunst der Fälscher, Fälscher der Kunst* (1959; Eng. trans., *Three Thousand Years of Deception in Arts and Antiques,* 1961), are both standard anthologies. DIETRICH VON BOTHMER and JOSEPH V. NOBLE, *An Inquiry into the Forgery of the Etruscan Terracotta Warriors in the Metropolitan Museum of Art* (1961), is the exhaustive technical and art historical study of an important group of clever forgeries. A similar article is JOSEPH V. NOBLE, "The Forgery of Our Greek Bronze Horse," *Bulletin of the Metropolitan Museum of Art,* 26:253–256 (1968). Stories of frauds told from the viewpoint of the forgers are given in LAWRENCE JEPPSON, *The Fabulous Frauds* (1970).

(J.V.N./Ge.B.)

Style in the Arts

Like much of the vocabulary of aesthetics, the word style resists straightforward definition. The word may point to little more than a mode or form of artistic production; or it can designate traits regarded simply as aids in the task of dating, grouping, and attributing works of art; it can imply skill, grace, or some other sort of excellence; it can mean a manner sanctioned by a standard; it refers to a mode, form, manner, tone, theme, subject, or quality—or a combination of such—that is felt to be characteristic enough to evoke a person, a group, a class, a nation, a place, a period, or a civilization; often also the reference is to features that are said to express an outlook, a doctrine, or a program. As a rule, even in the most carefully controlled context, several meanings will be present; and the tidy meanings will tend to bloom, or decay, into the untidy. Thus, although "sonata style," strictly constructed, should point only to a mode of musical production, in fact it will usually suggest a Classical outlook, the European 18th century, and perhaps the compositions of Haydn. Although to a field archaeologist "Late Helladic III" may designate merely a device for classifying pots of the ancient Greek city of Mycenae, in many imaginations the phrase is apt to inspire a vision of an entire culture, or perhaps of the legendary King Agamemnon bleeding in his bath after being murdered by his wife, as related in Aeschylus' tragedy.

The resulting confusion in thinking and talking about art is often deplored. One art historian likens style to a rainbow, a phenomenon of perception governed by the coincidence of certain physical conditions, which vanishes in the attempt to approach it. Another scholar takes the view that an adequate theory of style awaits a deeper knowledge of the principles of form construction and expression and a unified social theory comprising the practical means of life as well as emotional behaviour.

Such comments have not, however, had much effect; the majority of artists, critics, historians, and ordinary appreciators have continued to employ, loosely but confidently, the familiar term. And this persistence is not indefensible. Rainbows, after all, do exist; the chaser who fails to catch one demonstrates nothing except a mistake about their mode of existence. Also, in talking about art one can always cite the principle, first enunciated by Aristotle, that every study has its own degree of certainty and that a well-educated man will not ask for an unsuitable degree.

With that principle serving as a point of departure, the present article undertakes to expand and combine the several meanings of "style" into a discussion concerning the inner nature, the varieties, and the dynamics of the phenomenon as it manifests itself in all of the arts. (By "dynamics" is meant the patterns of movement and change that are the concern of style-conscious historians and biographers.) The whole discussion is presented on the level of a general theoretical introduction; material from the history of art and the history of aesthetics appears only in the form of examples, which are intended to provide clarification and some historical perspective.

The article is divided into the following sections:

The nature of style

General suppositions

It is easy to suppose that present notions about the nature of style are as old as the human ability to perceive differences, and a sampling of reasonably ancient cultural activity can seem to confirm the supposition. Much of the history of Chinese painting, for example, seems unthinkable without something like a modern critical apparatus for sorting out the dynastic periods, the local schools, and the copiers of venerated masters. Must not the ancient Greeks have been thinking of style when they noted the differences between Doric and Ionic orders in architecture? The way in which ancient Athenians contrasted the "rational" sound of the stringed cithara and the "irrational" reed-pipe wail of the aulos suggests the distinction between classical and romantic styles that was made in the 19th century, and the parodies of the tragic dramatist Euripides by the Athenian comic playwright Aristophanes imply modern conceptions of a personal style.

Much of what is now called stylistics seems to have existed already in the long succession of ancient Greek and Latin treatises that dealt with rhetoric. In sum, examples from both East and West can seem to support the assumption that there has always been something in the arts that may be called style.

INVENTION AND DISCOVERY

That "seem," however, needs very heavy emphasis. Throughout the history of art some unexpected facts have resided below the surface of the sort of sampling that has just been cited—facts that are open to more than one interpretation, but certainly not wide open.

Historical background. The admirer of Chinese painting who consults the old texts on the subject will find illuminating accounts of brushwork and much wisdom about the creative process but practically no discussion of style in the full modern sense of the word. In Indian aesthetics since ancient times, the doctrine of *rasa* (Sanskrit:

"essence") has been used in reference to the flavour or sentiment of works of art and to the modes of affective response to them, but not to what is properly called style. In the West, ancient writers on art exhibit a similar and finally rather enigmatic failure ever to focus squarely on the subject. Linguistic evidence, while inconclusive, suggests that in the Greco-Roman world there was no word that meant quite what is now generally meant by "style."

Vitruvius, the Roman authority on architecture, writing sometime during the 1st century BC about the Doric, Ionic, Corinthian, and Tuscan orders, avoided even the Latin word *ordo* ("arrangement") and contented himself with *opus* ("work") and *genus* ("kind"). The Greek traveller Pausanias, writing about the visual arts in the 2nd century AD, used *kataskeuē* ("device" or "method of fitting out") and *ergasia* ("work"). Among writers on literature and rhetoric a parallel tendency is apparent. Speaking of the style of an author, Aristotle was likely to refer simply to *lexis* ("speech" or "word"), and he was also likely to be talking merely about lucidity. The unidentified Greek critic known as Demetrius, writing probably in the Hellenistic era, used *charaktēr* ("quality" or "mark"), but the noun carried overtones from the verb meaning merely to scratch or engrave. The anonymous Latin text called the *Ad Herennium,* dating from around 85 BC, used *figura* ("figure"). A generation later Cicero used an arsenal of terms that included, with greatly varying degrees of precision, *figura, color, habitus* ("condition," "character"), *dictio* ("diction"), *elocutio* ("elocution," in a very general sense), and *genus.*

"Style" and *stilus*

Only in Late Latin does *stilus,* the word for the sharp-pointed instrument for writing, usually on wax, begin to mean also a manner of writing, as "pen" now does in such expressions as "a fluent pen" and "an acid pen"; and even here modern readers must be alert, for the derivation of English "style" from *stilus* does not prove that *stilus* always meant "style." The Latin term was reserved entirely for discussions of writing and speaking and usually for treatises on rhetoric; moreover, it seems to have implied little more than style in the sense of a skill or grace, and of a manner sanctioned by a standard. Apparently an author or orator in the closing years of the Roman Empire, in the 5th century AD, could have a periodic, loose, effective, ineffective, elevated, elegant, plain, high, middle, or low *stilus* but only very exceptionally, if ever, an idiosyncratic *stilus* that expressed a personality. And, again apparently, an architect, painter, sculptor, or musician could not have a *stilus* at all.

No important change in the usage thus established can be detected during the European Middle Ages. Words that suggest a kind, category, or mode of artistic production continued to be used in contexts in which a modern critic or historian might think in terms of a characteristic or expressive manner, or style. In architecture and the other visual arts, *opus* continued to be favoured; the French Gothic style of building was called Opus Francigenum, and English-style embroidery was know on the Continent simply as Opus Anglicanum. In music, the stylistic change apparent at the beginning of the 14th century, especially in France, was referred to as a new art: Ars Nova. The Latin *stilus*—and eventually its derivatives in other languages—was used only for talking about writing and speaking, and normally in the old rhetoricians' sense of a nonpersonal style sanctioned by a standard. When Dante (*Purgatorio,* xxiv) refers to the *dolce stil nuovo* ("sweet new style") that appeared in Italian poetry at the end of the 13th century, he stresses the importance not of the authors' personalities but of making the manner suit the matter and the occasion. The Host in Chaucer's *Canterbury Tales,* of the late 14th century, has this sense in mind when he addresses the Clerk of Oxford, in the prologue to the latter's tale:

> Your termes, your colours, and your figures,
> Kepe hem in stoor till so be ye endyte
> Heigh style, as whan that men to kinges wryte.
> Speketh so pleyn at this tyme, I yow preye,
> That we may understonde what ye seye.

In Renaissance Italy a shift in attitudes is apparent. Giorgio Vasari, for instance, in his widely influential *Lives of the Most Eminent Italian Painters, Sculptors and Architects* . . . (first edition in 1550, enlarged edition in 1568), built up a fairly consistent terminology on the basis of the word *maniera* ("manner"); his *maniera tedesca* ("German manner") refers to Gothic architecture, *buona maniera greca antica* ("good antique Greek manner") to ancient classical architecture, *maniera vecchia* ("old manner") to Byzantine or Byzantine-influenced painting, and *maniera moderna* to Renaissance architecture and painting. The *stilus* of the rhetoricians, *stile* in Italian, was still, however, reserved for literature. Not until around 1600 did musicians use such expressions as *stile moderno* and *stile rappresentativo,* and *stile* in criticism of the visual arts came still later.

In Britain, the equivalent extension of usage does not occur until the 18th century; the *Oxford English Dictionary* gives 1706 for the earliest reference to "style" in painting and 1728 for the earliest application of the term to music. Concerning the earliest English application to architecture there is some disagreement involving connotations, but a case has been made for a passage in Henry Fielding's novel *Tom Jones,* written in 1749: "The Gothic style of building could produce nothing nobler than Mr. Allworthy's house."

Earliest English usage of "style"

After that there was an era of the refinement of labels. A sharpened distinction between the art of ancient Greece and that of Rome began to be made in the 1760s. The division of British medieval architecture into Norman, Early English, Decorated, and Perpendicular styles dates from 1817. The term "roman" (Romanesque), referring to the architecture of western Europe before the Gothic, appeared in French criticism around 1820. Around 1850, "Rococo," after a career in slang, became a serious term for the style of the 18th century. The idea of the Renaissance as a cultural period, and not just an artistic movement, became fully-fledged around 1860. Definitions of the post-Renaissance styles of Mannerism and the Baroque were elaborated in the late 19th century. By the early 20th century, journalists were applying their own coinages to the styles discernible in modern painting and poetry.

Contemporary thought. The interpretation of the centuries-old mass of mostly semantic data on style is difficult and, for many people, exasperating. How is it possible to reconcile seemingly adequate perceptions of style throughout history with the long lack of adequate terms for it? How can the apparently adequate term, *stilus* or a derivative, be reconciled with inadequate perception of what it now connotes? Assuming that Chaucer's pilgrims reached their destination, what did the Host, familiar as he was with the figures and the high style of the rhetoricians, think when he was confronted by the Frenchness of Canterbury Cathedral?

Retrospective interpretations

Some historians have taken the easy course of assuming that when their ancestors used such words as "kind," or "work," or "speech" in certain contexts they somehow actually meant not what such words normally meant but what is now meant by "style." When *stilus* or a derivative was used, according to these historians, it somehow actually meant not what the rhetoricians meant but what is now meant in references to the composer Igor Stravinsky's or the novelist Ernest Hemingway's personal style. More rigorous minds have decided that style, viewed in the perspective of linguistic and general cultural history, is a will-o'-the-wisp. The majority of scholars, however, to judge from published essays, are reluctant to tamper with the evidence or to indulge themselves in a comfortable skepticism. They might therefore agree with the position that will be adopted in this article, which is that style in the arts is to a considerable extent a discovery, and to a large extent an invention, of a surprisingly late date.

Like many another cultural invention-discovery, style had a basis in human behaviour, but the distance between an ordinary ability to recognize things and what is meant by style in the arts is about as great as the distance between ordinary human memory and what is meant by history. Again like many another invention-discovery, style had a long phase during which some important levers and gears were already in place and more or less functioning. But the main job of assembling and powering the apparatus has been done since the end of the Middle Ages. Con-

tributing to this development were Renaissance ideas of the importance of the individual personality, as opposed to medieval collectivism; 18th-century ideas of order and taxonomy in the natural sciences; and 19th-century ideas of biology, history, and, of course, aesthetics, all of which provided analogues for stylistic perceptions. The inventing and discovering are still going on, with much help from the experiments of artists and from such disciplines as archaeology, anthropology, psychology, sociology, and linguistics.

Philosophical questions on the nature of style

To talk of the nature of style in these terms is to raise some difficult philosophical questions, ranging from those posed by ancient thinkers down to those of recent logicians. For although in practical affairs it may be willingly granted that every invention is to some extent also a discovery and that every discovery involves some invention, the fact is that the word "invention" implies one sort of being and the word "discovery" quite another sort. Moreover, by a curious reversal of what happens in many inquiries, the philosophical questions that are thus raised for art critics, historians, and appreciators tend to be less pressing in regard to style as a concept or a collective noun than to style as it is actually experienced. People speculate calmly, if at all, about the nature of their comprehensive stylistic assumptions and become heated about the alleged reality or unreality of the style of the 19th-century French sculptor Rodin or of the *style galant* in 18th-century music or of the style of the Renaissance.

Can anything useful be said in this realm? Certainly any attempt to deal thoroughly with the issues would lead far beyond the scope of this article and deep into problems for which professional philosophers have not yet found accepted solutions. But it seems legitimate to confront antistyle "realists" with the suggestion that a style is no less real, or no more unreal, than a work of art, which is also a kind of invention-discovery, and to add that this degree of certainty is all that a well-tutored man should expect. Works of art can be, among other things, physical objects, imaginary objects, enduring possibilities, realized possibilities, sensible phenomena, insensible phenomena, sheer processes, and even, according to respectable opinion, transcendental entities. They can also have—and this is important to the argument—what has been called an emergent mode of existence and might be called a "do it yourself" mode; a picture, for instance, emerges from the blobs of pigment on a canvas when the viewer steps back and perhaps squints, and a symphony emerges from blobs of sound in the same way. All these modes of existence, and the emergent in particular, can be found among styles. Rodin's style emerges when a sufficient number of his works are contemplated from a certain psychic distance, and it is also a bronze entity in one of his statues of Balzac. The *style galant* emerges from compositions by Bach's sons, and it is also in a single Mozart serenade, which itself exists on paper, in performances, and, above all, as an enduring possibility. The Renaissance style, according to the scholar Arnold Hauser, "is at once more and less than what has actually been expressed in the works of the Renaissance masters. It is something like a musical theme of which only variations are known." In short, it is probably most usefully thought of as having an emergent mode of existence.

All this might be summarized by remarking that the process of invention and discovery that produced the general notion of style over a period of centuries is constantly being recapitulated by individuals, sometimes over a period very brief indeed, for particular styles. From this, one might hastily conclude that practically anyone can invent-discover what will pass unchallenged as a style; and anyone acquainted with modern art scholarship and art publicity must grant that there is a measure of truth in the conclusion. But in the long run, of course, there are certain limits to what can pass as style, just as there are certain limits to what can pass as a work of art; eventually opinion accumulates to the effect that the invention-discovery in question does not work well enough, or is simply not important enough, to qualify for the standard label. The annals of archaeology in Latin America and the eastern Mediterranean are strewn with styles that broke down, often after extensive repairs by their inventors. And, in fact, the world's major accepted styles turn out on examination to have more rigour and clarity in their nature than might be supposed. They have a number of recurring features that can be extracted and combined so as to constitute a working model of style, a sort of metastyle, that can be used for dealing critically with new labels.

PRINCIPAL ASPECTS OF STYLE

These recurring features can be grouped and considered under the headings of value aspects, poietic (or creative) aspects, morphological (or formal) aspects, metaphorical aspects, polar aspects, and measurable aspects. The word "aspect" is preferable to "feature" or "element" or some other possibility, for it must be kept in mind that a style is an invention-discovery with several modes of existence. Moreover, in each instance, what is being talked about is likely to be affected by the different viewpoints of producers, consumers, historians, critics, and other observers.

Value aspects. The first group on the list is logically defective, since all the other aspects have value aspects, but it is important enough to merit some separate preliminary treatment. That styles are regarded as desirable is evident from common usage. Merely to say that an artist, a work, or a period has style is to judge him or it favourably; merely to use "style" in preference to such words as "manner" or "fashion" is to imply value; even to say that a thing is in a poor style is often to suggest that it does not have enough style. And that styles are actually worthwhile is difficult to doubt. They provide the art appreciator with the pleasure of recognizing somebody or something, a pleasure that is certainly among the basic ones of human existence: witness the popularity of handbooks that tell how to distinguish Tang from Sung styles in Chinese art or Louis Quinze from Louis Seize in French art. Styles provide the artist with the pleasure of being recognized, and they do so without the self-display of a signature. They are like codes; in the language of information theory, they help obtain an invariant output from a variable input, and nearly all art history, which is a comparatively recent phenomenon, and much criticism makes use of them. They also have many less evident sorts of value. They function as the signs and, to some extent, as the agents of integration in individual artists, groups of artists, and sometimes whole cultures; they are brakes on alienation. They are appetizing and preservative, like spices; they have saved from oblivion a number of great minds whose ideas have lost their fascination. To cite only a few examples from British critical and historical literature, it is hard to imagine anyone still reading much of Dr. Samuel Johnson, Edward Gibbon, Thomas Babington Macaulay, Thomas Carlyle, or John Ruskin for content alone.

Evidence from common usage

These positive aspects are accompanied, of course, by some negative ones, and the latter have been worrying critics increasingly during recent decades. Since styles stress similarities and work partly as codes, they tend to blur differences and to simplify excessively; they encourage many viewers to see, for example, merely "a Picasso" or "Cubism" where one ought to see the rich uniqueness of a painting. The pleasure of being recognized, and the money that may come with it, can encourage some artists to develop a mere trademark. Successful period styles of the past may foster, as they did among 19th-century European architects, an absurd amount of eclecticism and fancy-dress historicism. Successful current styles can generate an equally absurd amount of imitation among artists. The difficulty of defining specific styles and style in general creates serious problems in art history, which will be discussed in the last section of this article.

Negative aspects

Do these negative aspects outweigh the positive? The majority opinion is clearly that they do not, for there is no prospect of a return to the supposed innocence of the centuries before the massive, intricate, dangerous, useful invention-discovery got up steam.

Creative aspects. One of the complaints, however, is very legitimate: it is that people who talk about style do so too often from the viewpoint of an appreciator. The same complaint can be made about art discussions in general;

a good deal is heard, for instance, about disinterested contemplation, which is fair enough from an appreciator's viewpoint but close to wild calumny from an artist's viewpoint. The hardworking men who built the Parthenon were certainly not disinterested in any usual way, nor were John Milton in writing *Paradise Lost,* Michelangelo in painting the frescoes for the Sistine Chapel, Richard Wagner in composing the opera *Tristan und Isolde,* and Leo Tolstoy in creating *War and Peace,* and what they were doing can scarcely be called contemplation. It was rather what the Greeks called *poiēsis* ("creation," or simply "making").

Style, then, has what can be called poietic aspects; the adjective brushes jargon but lacks the Romantic connotations of "creative" and the matter-of-factness of such an alternative as "productive." The existence of these aspects can be posited etymologically, with the risk inherent in arguing from dead metaphors; *stilus,* as has been noted, originally meant a writing instrument; and such near equivalents for "style" as "manner" (Latin *manuarius,* "of the hand") and "fashion" (Latin *facere,* "to make") also have clearly poietic pedigrees. Moreover, in some contexts "style" still means little more than a mode of artistic production.

But here an attempt to sharpen common usage seems to be called for, since a style in its poietic aspects is not the whole of an act of making. A style is only the part of the act that represents a deviation from a norm and that, as such, is apparent enough to offer the pleasure of recognition. The norm may be provided by a more inclusive style, by a tradition, by material conditions, or by some other frame of reference within which artists work. The norm may also be assumed, more or less arbitrarily, by observers. For example the personal style of the 17th-century Flemish painter Peter Paul Rubens is not, poietically speaking, the whole of his way of applying paint to canvas; his personal style is merely that part of his way that constitutes a recognizable deviation from a norm—the Baroque style—in which he worked. The Baroque, to continue the illustration, is not the whole of the Baroque painters' ways of applying paint to canvas; it refers to merely the part of their ways that constitutes a recognizable deviation from another norm, the general style that prevailed in European painting from roughly the middle of the 15th century to the end of the 19th, though in many histories of art the norm from which the Baroque deviated is instead assumed to be the High Renaissance style as exemplified by Raphael.

The role of norms

One can conclude that style is dependent on originality and the will to exercise it. But much depends also on the norm. In the first place, many norms are imposed, sometimes by accepted authority, sometimes by social pressure, and most often by unawareness of an alternative; the average Western composer, for instance, between Bach in the 18th century and Schoenberg in the 20th, seems to have regarded the tonal-style norm—the organization of tones and chords in a composition in relation to a keynote—as something like a law of nature. In the second place, certain norms contain fewer variables than others and therefore offer fewer opportunities for deviation; a Byzantine mosaicist had no possibility of developing a marked personal style. And, finally, there are the supernorms constituted by each art, by artistic materials, by languages, and by much else; at this level the number of variables may be decisive. Traditional sculpture offers fewer variables than painting and hence has yielded a much smaller number of styles. Granite offers fewer variables than bronze and hence has what might be called a lower yield in terms of style. Specialists in stylistics—the branch of linguistics that studies the variables in a language and their manipulation—have noted that one of the secrets of the 20th-century Welsh poet Dylan Thomas's strongly personal style was his discovery of unsuspected variables in English: thus where the norm had seemed to insist on nouns of temporal, or linear, measurement he could write "All the sun long," "A grief ago," and "farmyards away." In "Spelt from Sibyl's Leaves," the 19th-century English priest Gerard Manley Hopkins showed a comparable talent for finding possibilities of deviation:

> Earnest, earthless, equal, attuneable, vaulty, voluminous . . . stupendous
> Evening strains to be time's vast, womb-of-all, home-of-all, hearse-of-all night.

Formal aspects. Much of the above might have been put under the heading of the morphological—or "formal," if certain connotations are ignored—aspects of style, and much that is traditionally morphological is equally poietic. The form of a work of art can be regarded as the record left behind by the making process; this idea, implicit in ancient rhetoricians' descriptions of prose and poetry (*e.g.,* as laboured), has been prominent in modern criticism since the appearance in the 1950s of such process-emphasizing accomplishments as Action painting, in which the brush strokes and textures may be regarded as a record of the creation of the work; aleatoric music, in which the notes or sounds are selected by chance; and Brutalist architecture, the sort that leaves the concrete raw and plank marked.

The making process, however, involves the whole work, whereas form may be regarded as excluding content and including only shape, volume, space, structure, pattern, organization, texture, rhythm, imagery, emphasis, balance, and the like. This separation is often denounced by careful critics, and a successful work of art, when contemplated in a properly focussed and expanded state of awareness, does indeed present itself with form and content organically tangled. But there is little likelihood that art appreciation suffers when things are untangled for discussion, since most persons are quite capable of distinguishing between the critical analysis of a work and actual aesthetic experience. So it seems safe to accept common usage concerning "form" and then to agree with commentators who have been assuming for centuries that style has purely morphological aspects—without joining them in assuming that it has practically no other aspects.

Separating form and content

Immediately an apparently drastic shift in emphasis occurs, from one of variables and deviations to one of repetitions and conformity. In fact, style can be reasonably, if incompletely, defined as constant formal elements and their combinations, with content excluded except in certain circumstances. But the shift in emphasis is obviously just a result of the play of aspects. A style is always generated by the manipulation of available variables in such a way as to yield a recognizable deviation from a given or an assumed norm. If, however, the deviation is to be recognized as something more than an accident or a solitary impulse, it must be repeated, either identically or in a recognizable variation. It must become understandable, which a unique event—an accident—cannot be.

Thus a style is always, when perceived from what can be called the poietic stance, rather surprising; the Baroque norm and the English-language norm do not lead to any expectation of Rubens' fleshly swirl and Thomas' "A grief ago." But thus also a style is always, when perceived from the morphological stance, rather familiar; what was unexpected in terms of the act of making becomes expected in terms of form. Again the illustration can be continued above the level of personal style: the energized masses found in Baroque painting of the 17th century are constant in their deviation from the balance of High Renaissance paintings of the 16th century. In sum, an artist, or a group of artists, is obliged by the nature of style to move freely into constraint, and heretically into orthodoxy.

Metaphorical aspects. Hence certain styles are commonly said to be "characteristic," or "expressive." An aesthetic deviation, repeated sufficiently, may become converted into a form and yield recognition pleasure. The result may fairly be described as a manifestation of personality. The flame shapes in El Greco's paintings may be thought of as a handwriting, Bach's driving rhythms as a gait, Proust's long sentences as a voice; and usually no harm is done to understanding.

Such metaphors, however, along with the words "characteristic" and "expressive," can become whimsical or misleading in many situations. Moreover, the stylistic aspects in question are best perceived in depth and in the aggregate by noticing that nearly every style is itself a metaphor, functionally speaking. It implies, as Aristotle said a good metaphor does, an intuitive perception of the similarity in

Similarity in dissimilars

dissimilars. It works, as an ordinary simile does, by seizing striking likenesses and neglecting differences; to see that the 18th-century English poet William Cowper wrote in a Miltonic style resembles, as process, seeing that Robert Burns's sweetheart was "like a red red rose." There is a substitution of a part for a whole, as in synecdoche; in many eyes a pointed arch and a flying buttress are enough to evoke the Gothic style, and for many ears a single chord can summon up Beethoven.

Most importantly, in nearly every stylistic context, and not just in those involving personal and "characteristic" styles, there are two sections, like the two sections in the comparing process of metaphor; these can be thought of as the "window" and the "view." In the simplest situations the view through the window of the style is of an individual artist, or of a well-defined group; the 19th-century French poet Stéphane Mallarmé may be sensed through his repetition of the word *azur,* and the contemporaneous group of Impressionist painters that surrounded Claude Monet are recognizable through their deviant, flickering brushwork. The situation, however, is seldom quite that simple. Through Mallarmé's style as well as through Impressionism the view may be of a doctrine or a program; in other situations it may be of a class, a nation, a place, a period. There are styles that bear a functional resemblance to myths, if the latter are thought of as communal metaphors. The view that looms through the symmetrical frontality of the rigidly posed figures in ancient Egyptian sculpture is of an entire culture, a culture that is dramatically different from the one that looms through the asymmetrical twist, the contrapposto, of figures in Italian Renaissance statues.

These remarks have to be qualified, for if common usage is accepted there are styles that seem to have no metaphorical aspects, that are practically opaque. Possible examples are procedural styles in general: those described by the ancient rhetoricians, those associated with the fixed forms of music and poetry, those that are just simplifications, often geometrical, of natural forms.

Polar aspects. Common usage also provides evidence for the existence of certain structural or self-defining tendencies in style that can be grouped under a single heading as polar aspects. These have long been noticed; Hellenistic and Roman literary critics have a lot to say about the flowery, redundant oratorical prose known as Asiatic, which is presented as the diametrical opposite of the plain, economical Attic. The invention or discovery of such polarities did not get seriously under way, however, until the 18th century in western Europe; and most of it has been accomplished, mainly by German thinkers and largely in the visual arts, since the late 1800s.

Among the great number of such contrasting pairs that could be mentioned are haptic–optic (*i.e.,* oriented to the sense of touch as opposed to sight orientation), idealistic–naturalistic, multifarious–unitary, closed–open, linear–painterly, and many more. It will be noticed that the trend is toward all-inclusive world styles, or at least toward constantly recurring stylistic features, and that the emphasis is strongly on morphological aspects. This emphasis, although open to the usual objections to "formalism," has compensated handsomely, in terms of instrumental value, for the sometimes naïve scientism and general overconfidence implicit in the labelling. Indeed, it is not an exaggeration to say that the best visual-art criticism and history published since World War I could not have been written without the help of polar analysis of form.

Applicability of polarization

But pairs like the rather abstruse ones mentioned are not the whole story. Any style, including the familiar established ones, may be polarized; the 19th-century French painter Delacroix's Romantic style may be paired with his older contemporary Ingres' Neoclassical style, the Gothic with the Renaissance, the French with the English, the Christian with the Islāmic, the Eastern with the Western. Each member of each pair is defined in terms of what the other member is not; each is at once the deviant from the other and the norm for the other. Often in such pairs the forms are not seriously analyzed; mere diametrical opposition, as in traditional political parties, is felt to be enough. This peculiarity may be especially evident in connection with a modern style, which is always polar to begin with and which may stay that way until in its turn it begins to cease to be modern. Only then may historians have a good chance to cut through the partisan propaganda, get at the constant forms, and decide if the style is internally consistent enough to merit a label of its own and a place in the parade that began some 40,000 years ago.

Measurable aspects. The historian who undertakes such a task is not likely to approach the constant forms with a yardstick, for in general the measurable aspects of style are not very highly considered by artists and art critics. But such aspects do exist.

The differences between Doric and Ionic orders in classical architecture are not only in the abacuses and volutes that decorate the columns and their capitals but also in proportions and in the number of flutes on a column. The 20th-century French architect Le Corbusier performed his subtle manipulation of architectural variables with the help of a system of proportion, which he called the *modulor,* based on the human figure. Sculpture styles were influenced for centuries by the canon (now lost) of Polyclitus, a Greek sculptor of the 5th century BC who believed that "the beautiful comes about little by little, through many numbers." In a portrait in the Mannerist style of mid-16th-century Italy, much of what makes it Mannerist may be a matter of how long the body is. Some of Hogarth's pictures can be analyzed in terms of what he called "the line of beauty," obtainable by winding a "precise serpentine line around the figure of a cone." Painters of the 20th century have revived the interest Renaissance artists had in the proportion (about 8:13) known as the golden section. An important part of the stylistic difference between a movie director of around 1930 and one of around 1970 may be discovered by simply noting the smaller number of camera shots and sequences used by the latter. Styles in poetry can be specified, often with surprising results, by counts of images, rhymes, run-on lines, and metrical variations; and such methods are accurate enough to help date Shakespeare's plays. Prose styles are, for certain modern linguists, a matter of the statistical averaging of the use of certain words, performed with the help of a computer. That musical styles have measurable aspects has been clear, of course, since at least the time of Pythagoras, who discovered in the 6th century BC the relationship of musical intervals to the lengths of strings; and the fact has become freshly clear under the impact of 20th-century science and technology. Computers have become standard equipment for many composers; synthesizers have become generators of styles translatable into mathematics; Beethoven's poietic deviations from a norm have turned out to be quantifiable in somewhat the same way as the unforeseeables studied by information theorists.

Qualifications on quantification

Some qualifications are in order. The analysis of a style is not the same as the experience of a style: the whole of a work of art is certainly not the sum of its measurable parts. While it may be true that under certain conditions quantity turns into quality, it does not follow that every quality can be quantified; and certain conditions—Beethoven's genius, for instance—remain to plague the quantifier. But all this does not alter the fact that styles do have certain measurable aspects. Nor does it excuse the neglect of these aspects by some art appreciators, critics, and historians. Perhaps the remedy both for the shortcomings of the quantity-minded and for the attitude of the quality-minded will eventually be found in interdisciplinary work on aesthetic problems.

The varieties of style

Since it is part of the nature of style to provide recognition pleasure, and since this pleasure is usually accompanied by an irrepressible impulse to name, one can suppose that unlabelled styles are rare. Would that they were not, an archaeologist may say; would that there were an opportunity to classify works of art scientifically and to substitute numbers or New Latin labels for such misnomers as "Gothic" (which is unrelated to the Goths) and "Cubist" (which has little to do with cubes). Actually, however, the downright mistaken or merely derisive la-

bels are neither very numerous nor very misleading; to anybody who knows enough to be interested, "Gothic" is likely to mean something like "Medieval West European III," and "Cubist" something like "genus, partly abstract; species, Picasso–Braque 1907–14." And if the majority of style names are not scientifically descriptive, they do as a rule offer adequate clues not only to the thing being talked about but also to the class, or classes, to which the thing belongs. In other words, the familiar nomenclature, although accumulated apparently haphazardly through the centuries, has taxonomic—more precisely, typological—implications. To speak of Rembrandt's style is not only to refer to certain poietic deviations from a norm and to certain recurring formal elements; it is also to imply the existence of a personal variety of style plus a more general sort that includes the personal variety. To speak of a realistic style, or of one of its several polar opposites, is to imply a different variety and a correspondingly different general sort.

When such implications are grouped, they yield some 13 varieties of style in the arts. (The "some" is inserted here to allow for reasonable differences of opinion as to where the dividing lines should be drawn.) These 13 varieties are clearly of two general sorts, which emerge from two types of "view" beyond the metaphorical "windows" that styles create in a sufficiently knowledgeable imagination. The first general sort, to which Rembrandt's style belongs, affords views that focus on single cultures; the second sort, to which a realistic style may belong, affords views that cut across cultures. It will be noticed that a given style may move from one category to another; more will be said later about this mobility. But most styles are reasonably stable, and for the moment it is convenient to assume that the others have certain recognizable home categories. Even a slightly unstable classification can stiffen discussion.

Two types of "view"

SINGLE-CULTURE VARIETIES

Single-culture styles are usually inhabited, so to speak. They usually evoke, more or less in the foreground of the contemplating imagination, either a person, a school, a social class, an ethnic division, a regional community, a nation, an ecological division, a religious community, or the generations that constitute a period. Rembrandt's style usually evokes the bulb-nosed, sad-eyed person known through dozens of remarkably self-searching self-portraits; the Venetian style usually evokes the 16th-century masters Giorgione, Titian, Tintoretto, and Veronese; each style in African sculpture usually evokes a tribe; and so on down the list. Single-culture styles are therefore frequently said to be "characteristic," or "expressive," of a particular people; and in this context these familiar terms of interpretative art criticism may seem to triumph over the mild objection raised earlier, in the discussion of the general metaphorical aspects of style. In fact, these adjectives, and also the noun "people," raise some awkward problems even here.

Personal styles. No variety of style seems, at first thought, quite as vividly, specifically, indubitably inhabited as the personal variety. Quoting the celebrated and seldom-read *Discours sur le style* (1753), by the Comte de Buffon, and neglecting his qualifying remarks, many appreciators assume confidently that "the style is the man himself." In a somewhat modified form, the same assumption can be found as far back as the 1st century in the Stoic moralizing of the Roman philosopher Seneca. In a somewhat pseudoscientific form it has produced some disturbingly glib psychoanalysis of works of art. In its plebeian form it has led to such suppositions as that the flame shapes in El Greco's paintings are evidence of astigmatism, the long sentences in Proust's novels evidence of asthma, the rhetoric of Liszt's piano pieces evidence of Gypsy blood, and the right angles of Mies van der Rohe's architecture evidence of a subtle totalitarianism. The notion may be said to have reached one of the peaks of its career in 1935 in the earnest excogitation of the literary scholar Caroline Spurgeon; after counting and sorting Shakespeare's images, she concluded that the poet was

Style and the man

> a compactly well-built man, probably on the slight side, extraordinarily well coordinated, lithe and nimble of body, quick and accurate of eye . . . probably fair-skinned and of a fresh color, which in youth came and went easily . . . very sensitive to dirt and evil smells . . . gentle, kindly, honest, brave and true.

She also saw, through the obviously wide-open window of the personal style, a man who at 35 had "probably experienced heartburn as a result of acidity."

It is easy to call this sort of interpretation wrong and not easy to explain exactly why it is wrong. After all, everyone indulges in it to a degree. Spurgeon, of course, went a bit too far; she was neglectful of complexity and of the possible differences between a dramatist and his personages. But her counting and sorting of images was a valuable and influential piece of research; it demonstrated, in an irrefutable way, the existence of some of the deviations and constants that make up Shakespeare's personal style. If the person who is certainly recognizable in this personal style is not quite the Stratford man himself, who is he?

When the question is asked about a large enough number of personal styles, a tentative answer may emerge. The style, it appears, is not the man himself but the artist himself—mostly, at least. Naturally, the artist is to a considerable extent the man; he has much of the latter's native capacities, acquired skills, secret drives, and painful defects. But the artist is a professional role, a programmatic personage, a cultural configuration, a persona; in sum, he is a remarkably, often deliberately, synthetic personality. Further, he is conditioned by much besides the man himself and notably by the work of other artists. To put all this another way, every personal style is in part sheer performance, and every artist as such is in a sense (not a pejorative one) a performer. Mies the man went on living in his relatively old-fashioned Chicago apartment, while Mies the artist was "performing" with gleaming right angles in the tall apartment buildings he designed for Chicago's fashionable Lake Shore Drive; Mozart the man disliked flute music, while Mozart the artist "performed" by composing flute music; Petrarch himself philandered, while Petrarch the poet "performed" as a faithful worshipper from afar of the idealized Laura.

The person and the performer

Hence, in the opinion of many modern critics, the once-popular problem of personal stylistic sincerity is meaningless; to pose it is to mistake art for life. Hence also the distinction that is often made between creative personal styles and performing personal (or group) styles should not be too categorical. Although a dramatic text, a musical score, or a notated ballet may seem to constitute a norm that offers a very small number of variables, in practice a competent actor, musician, dancer, conductor, or director usually manages to produce enough deviations to have an easily recognizable personal style. No opera-record collector is likely to confuse an interpretation by the intensely dramatic soprano Maria Callas with one of the same role by the serenely lyrical soprano Renata Tebaldi; and ballet literature suggests that the ethereal 19th-century ballerina Marie Taglioni was as different from her rival the sensuous Fanny Elssler as the 19th-century Italian operas of Vincenzo Bellini were from those of his contemporary Gaetano Donizetti. Moreover, an interpreter has about the same choice as a creator among the more inclusive styles that can always be recognized simultaneously with a personal one; he can be modern, traditional, Classical, Romantic, Baroque, or whatever. And finally, if he tries to be as faithful as possible to his text, the result will approach another personal "performing" style, that of the artist who composed the work. To succeed in producing *Phèdre* exactly as it was conceived would be to play the player Jean Racine.

These remarks should not be interpreted as a complete denial of the presence of "the man himself" behind a personal style—into the polar opposite of Spurgeon's error. Since the artist is partly conditioned by the man, so, of course, is the style; and stylistic evidence can often be made to match biographical information in an enlightening way. Friends of Mies noticed in his manners and dress a certain fastidiousness and a love of good material that reminded them of his architecture. The reported simplicity, honesty, and modesty of Haydn are an agreeable match for qualities in his musical style. Most readers probably sense an authentic personality, a real voice, behind the

sprung rhythm and breathless rush of the verse of Hopkins. Also, some quite successful methods of stylistic analysis apparently depend on a strict correspondence between the manner and the man himself; a fascinating example is the technique for attributing paintings, developed by the Italian art critic Giovanni Morelli in the 19th century, which assumes that the touch of a particular master can best be detected in unimportant details, such as the ears in a portrait, that were presumably painted without taking much thought.

None of the counter-evidence, however, seriously shakes the argument that the person in a personal style is mostly the artist as such, and some of it does not stand up very well under scrutiny. Fastidiousness, simplicity, and vehemence do not become meaningful in this context until they are given energy and focus by the artist; and the telltale details used for attributing paintings may have about as much aesthetic interest as fingerprints.

School styles. When artists are considered as a stylistic group, or school, all the problems raised by personal styles reappear in new guises in the company of other problems; and one of the more nettling of the latter is the precise meaning of "school." For there is no denying that this part of the apparatus of criticism has got badly out of hand since its invention and discovery in the 18th century (largely by the pioneer Italian archaeologist Luigi Lanzi). Art critics, historians, and especially painting-museum curators have acquired the habit of using the term as an elegant variation for what usually turns out to be merely a country of residence; thus J.M.W. Turner is said to be a painter of the British school and Thomas Eakins of the American school. Sometimes the geographical designation is narrowed, with a commensurate gain in stylistic information; thus Mantegna is said to belong to the North Italian school and Perugino to the Umbrian school. The gain, however, may be in confusion; the division between the so-called Northern and Southern Sung schools of Chinese painting, for example, has been called the most misleading and arbitrary in art history. Sometimes geography is abandoned for a general stylistic designation; thus the 18th-century French painter Jean-Baptiste Chardin is said to belong to the Realist school. Sometimes the stylistic designation is narrowed drastically, and then a gallery visitor may be confronted by a brass plaque attributing a 15th-century Florentine painting to the school of Fra Angelico, for instance; this can mean that documents point to the studio or to a follower of Fra Angelico; or that the picture is an ancient, and therefore respectable, copy; or that it looks rather like a genuine Fra Angelico without his customary quality—the unstated premise being that all pictures by Fra Angelico are first class.

The meaning of "school"

The situation is regrettable not only because one word is being forced to do things other words can do better but also because "school" has its own work to do. Musicologists can profitably use the term to talk about the centres of musical activity that existed in the 12th century at such places as Paris, Compostela, Padua, and Winchester; or about the late-16th-century amateur "academy" known as the Florentine Camerata, in which the monodic style that led to opera was fostered; or about the group of composers of atonal music that surrounded Arnold Schoenberg in 20th-century Vienna. Painting historians must refer to the Tours school of Carolingian miniaturists, the Shen Chou school of 15th-century Chinese ink artists, the Barbizon school of 19th-century French landscape painters. Literary historians must consider such schools of poetry as those of the 16th-century French Pléiade, the English Lake poets of around 1800, the Tokyo (then Edo) haiku masters of the 17th and 18th centuries, the American Imagists of around 1914. Even architectural historians, who tend to think in large units, have to take account of such phenomena as the Burlington group of Palladianists in 18th-century London, the Glasgow School in the 19th century, the slightly later Chicago School, and so on. Each of these examples, and of the hundreds of others that could be cited, involves a well-defined and usually not large geographical area, a relatively short time span, and a relatively small number of artists working in a describable shared style; here are the essential requirements for using the term "school" profitably. Of course, a curator, in announcing that Turner is of the British school, may really intend to commit his museum to the proposition that a nationally shared painting style has been perceptible in Great Britain down through the centuries. Such is not usually the intention, however, and when it is, it should be made explicit.

The confusion is worth dwelling on because in many works of art a school style, defined as the shared style of a relatively small number of artists, is as striking as a personal style. It is a "window" that affords a "view" inhabited by a synthetic personality, a programmatic personage, almost (but not quite) vivid enough to justify thinking in terms of something like an overartist, as some German philosophers have. Moreover, in the interaction between a personal style and a school style, there is a model, manageable for study, of the complex relations that emerge when several styles are found together in a given work. The personal style of John Donne, the 17th-century English poet of the Metaphysical school, is recognizable in the dense, macabre imagery, the sometimes violently wrenched metre, and the self-dramatizing switch of the following lines from his "Nocturnall upon St. Lucies Day, being the shortest day":

Interaction of artist and school

> The world's whole sap is sunke:
> The generalle balme th' hydroptique earth hath drunke,
> Whither, as to the beds-feet, life is shrunke,
> Dead and enterr'd; yet all these seeme to laugh,
> Compar'd with mee who am their epitaph.

At the same time, the style of the Metaphysical school is apparent in the rather conversational tone, the compact syntax, and the use of extravagant poetic conceits. Deviations and a norm solicit attention, and the solicitations will multiply if the recognition process is continued into the maze of styles—the Elizabethan, the Jacobean, the English, the religious, the aristocratic, the Mannerist, the formal, the haptic, etc.—which a sufficiently subtle and patient critic may discover in Donne's poetry. The common reader, in Dr. Johnson's sense, can be excusably irritated at a certain point by the game of hide-and-seek between the different and the same, the self and the other. But, in fact, such simultaneous recognitions are normal in the actual experience of art; and they are no more mysterious than recognizing, with confidence and usually without being able to say exactly why, that a given face is of an individual, a family, a region, a nation, and a race—is at once itself and not itself.

Social styles. On a scale of recognizability, many critics would probably put social styles—those associated with a particular class or section of society—directly after personal and school styles, at least when much of the art of the centuries before the Industrial Revolution is being considered. Even an untrained appreciator can sense courtly styles in the intricate fixed forms of troubadour verse, the stiff etiquette of a Louis XIV portrait, and the languors of medieval Japan's *Tale of Genji,* by Murasaki Shikibu; bourgeois styles in the solid forms of 17th-century Dutch still-lifes, the uncomplicated rhythm and harmony of a Protestant hymn, and the matter-of-fact, 18th-century English prose of Daniel Defoe; and peasant or proletarian styles—often more accurately described as traditions—in songs, carvings, and embroidery. In the 20th century such clear-cut social styles have become less and less noticeable, partly because class distinctions have become much less evident in the technologically more advanced nations. Also, artists have ceased to know for whom they work, the art market having replaced, except on special occasions that are most frequent for architects, the old system of direct commissioning by patrons. Nevertheless, a sophisticated, or merely mischievous, critic can point to contemporary social styles; some evoke the established families, others the new millionaires. A number are related to young people, who since the 1960s have exhibited many of the economic and cultural characteristics of a separate class. Politicians in all countries throughout the 20th century have occasionally attempted, sometimes on a totalitarian scale, to impose on artists one of the old courtly or bourgeois styles; and a few dictators, notably Hitler and Mussolini, have temporarily revived an imperial-court style with the parvenu touch, familiar to art historians in such

Tradition and class distinction

outsized forms as those of Darius's palace at Persepolis in ancient Persia and Napoleon's church (originally temple) of the Madeleine in Paris.

Here two concessions seem called for. The first is that in talking about social styles it is often impossible, even for the purpose of cold analysis, to keep morphological aspects separate from content. The second is that throughout history the artist as such has been remarkably, sometimes depressingly, available for the "expression" or "characterization" of a social stratum other than that of the man himself. Perhaps the artist as such—shaman, bard, craftsman, entertainer, 19th-century demiurge, 20th-century iconoclast—has been rather more of a performer than has already been suggested.

Ethnic styles. Like social styles, ethnic styles have become less noticeable in the modern era. Their formerly high level of recognizability, their complex morphological aspects, and their surprising persistence over long periods have made them, however, favourite subjects for study among both archaeologists and aesthetics. Good examples are plentiful in the Indian arts of North America; the sculpture, painting, and music of black Africa; the pottery of the ancient Middle East and east Asia; and the surviving decorated objects, mostly metalwork, of the so-called barbarian peoples who moved across Asia and Europe between roughly the 6th century BC and the time of Charlemagne, at the end of the 8th century AD. In some instances scholars have been able to trace the borrowing of motifs; the Germanic animal styles of the migration period, for example, show the influence of Roman figurative art and Mediterranean ribbon ornament. But the borrowed motif is invariably transformed by a repeated deviation into one of the morphological constants of the borrowing tribe, and the reasons for this enduring assimilative capacity are not well understood.

Theories of stylistic disposition

The notion of a physically inherited stylistic disposition has long since been discredited, and archetypes in a collective unconscious, as postulated by the 20th-century Swiss psychologist Carl Jung, have been dismissed by the majority of professional historians. Among the more attractive theories are some that point to analogies with the inertia and the assimilative capacity of a language; yet even these seem inadequate before such a fact as that the Eskimo ethnic style has lasted for about two millennia. Another attractive theory links the lack of stylistic change to a general lack of history—or at least to a general lack of awareness of history. But if this theory is plausible in a North American or an African context, it is much less so in the context of the Asian and European migrating peoples, who managed to pass through an immense amount of history without making important changes in the design of their crowns, buckles, and other useful objects.

Regional and national styles. The problem of stylistic stability reappears in the consideration of regional and lagnational styles, which are partly just ethnic styles that have settled down. But they are always more than that. The high—and polar—recognizability of Oriental and Occidental styles cannot be satisfactorily accounted for by references to ancient tribes and by linguistic analogies; nor can the long preoccupation in the Mediterranean basin with human forms; the long preoccupation in northern Europe with animal, zoomorphic, fantastic, symbolic, and abstract forms; the rigidity of Egyptian pictorial and sculptural forms during some 3,000 years; the persistently emotional, romantic, and expressionist tendencies in German music, painting, and literature; the French emphasis on structure in architecture, painting, and poetry; the English linear and decorative tendency that runs through medieval miniature painting, Perpendicular Gothic architecture, the drawings of William Blake, and Art Nouveau. Common sense, of course, is needed in thinking about such styles; the theorizer who sets out to show that all French art is rational and all German art emotional will be in trouble immediately. Also, a certain vagueness is often suitable, for the distinctive features of a regional or national style may be of the sort better described as qualities than as morphological aspects. Recurring differences, however, finally add up to recognizability, and a quality hard to define can be strongly felt.

Climate and landscape were formerly popular as explanations for regional and national styles (for all styles, as a matter of fact); Gothic architecture was supposed to have emerged in northern Europe because of the many forests. Evocations of some kind of permanent national outlook were also frequent; Russian musical styles were thought to be inhabited by a Slav soul. Such ideas are now perhaps too much out of fashion; it is not quite unthinkable that an English stone carver's affection for linear pattern was encouraged by the frequent absence of bright, shadow-casting sunlight in England and that the symmetry of much French architecture and painting corresponds to the average Frenchman's enduring attachment to order. But eventually, of course, an explanation must include an entire regional or national culture and environment and at the same time take note of the fact that an art may have an existence of its own. To neglect this latter possibility would be to repeat on a large scale Spurgeon's confusion of men with writers.

Ecological styles. A subvariety of the regional variety is perhaps distinct enough to be classed separately as the ecological: here, that is, the style in question evokes in fairly specific ways the relationship of human organisms to their environment. Here also there are likely to be strong polarities; typical contrasting pairs are urban–rural, mountain–plain, hunting–farming, inland–seaboard, nomadic–sedentary, capital–provincial (in some ways), and (at least in comic strips and science fiction) earth–space. Such styles are most recognizable in architecture, painting, and the making of such useful objects as furniture, tools, and weapons. But they may be recognized more distantly in the dance, in music, and in poetry: the imagery of the Parisian poet Charles Baudelaire is urban; that of the New England farmer-poet Robert Frost is rural; while Homer's is seaboard, at least in the *Odyssey*.

Influence on appreciation

It is probable, too, that a well-defined ecological pattern affects in subtle respects the appreciation of foreign styles and hence the emergence of new local ones. Psychologists have found that the Zulus of South Africa, for instance, who live in a "circular culture" of windowless round huts and meandering paths, are relatively immune to visual illusions seen by people who have been conditioned by the right-angled, straight-perspective, so-called carpentered world of European and American cities.

Religious styles. Conditioning also undoubtedly affects recognition of religious styles. The problem of hard-to-define "qualities" that contribute to recognizability, mentioned above in connection with regional and national styles, also returns here to vex a conscientious historian. So does the problem of the separation of form and content, plus the false problem of the sincerity of the artist as such—of the artist as mere "performer." Strictly speaking, in terms of forms and their combinations, one must grant that a vast number of profoundly moving works of religious art are not recognizably in religious styles. One can plausibly argue, for example, that there has been no religious style at all in Western painting since about the 15th century; later painters of religious subjects, such as Van Eyck, Raphael, Rubens, and their successors, painted the Virgin much as they painted their wives and mistresses. A similar point can be made about Western post-Renaissance music; Bach's sacred works sound much like his secular ones, and Giuseppe Verdi's magnificent *Requiem* (1874) has sounded to many ears like his operas. Even in the European Middle Ages and in the worlds of the great Eastern religions, the evidence is not always clear; the style that seems to yearn toward God in the 13th-century Gothic cathedral at Chartres, France, served also for town halls and ivory combs.

Style conditioned by content

The point, of course, should not be exaggerated, partly because other styles often make use of borrowed forms and principally because many religious stylistic elements do exist in their own right, even though their secular ancestry can sometimes be traced. In architecture, examples of religious style can be seen in the basilican plan of Christian churches, the cosmic-mountain form of Hindu temples, the rectangular and cruciform plans of mosques, the needle shape of the minaret; in music, the single vocal line and free rhythm of Gregorian chant, the florid

melody of Islāmic chant; in painting, the free brushwork of Zen Buddhists, the abstract arabesques of Islām, the nonillusionistic kinds of pictorial space favoured by medieval Christians. But when the list of such elements is completed, the fact still remains that the average appreciator recognizes a religious style primarily because it is tinged by long association with religious texts, ritual, and iconography. In brief, it has for him a quality that seems to emanate from content.

Period styles. A style belonging to one of the single-culture varieties may be divided, conventionally or arbitrarily, into periods. Beethoven's personal style is usually split into early, middle, and late; the ethnic style of the migrating Germanic peoples may be referred to as Animal I, II, and III.

The adjective period is often reserved, however, for a distinct variety of style: the one in which the metaphorical "windows" afford "views" inhabited by generations whose cultural and other activities appear to constitute definable units of history. Familiar examples are the Gothic period style, the Renaissance, and, in general, all styles that bear the names of rulers or dynasties: the Victorian style, the Carolingian, the Sung. Frequently the period style is itself "periodized," the Gothic is Early and Late, the Renaissance is Early and High. The issues raised by periodization of all sorts will be discussed in the last section of this article (see below *The dynamics of style*). But period styles have their place in this part the classification, for they are clearly, often emphatically, of the single-culture sort.

CROSS-CULTURAL VARIETIES

Cross-cultural styles are usually uninhabited, in contrast to personal styles. They do not, in any event, call up into the foreground of the appreciator's imagination a John Donne, a Metaphysical school of versifiers, a Murasaki Shikibu in an ancient Japanese court, a Germanic tribe on the march, a succession of English stone carvers expressing their Englishness, a Baudelaire in an urban twilight, a medieval monk singing for God, or a group of eminent Victorians.

Uninhabited, unmetaphorical styles

In a sense, then, cross-cultural styles are relatively unmetaphorical; they tend to focus attention on themselves. They have modes of existence that lie outside of history, and they often are not so much aesthetic terms as general-utility adjectives: almost anything, and not just works of art, can be "classical," for instance, or "organic," or "abstract." Cross-cultural styles in art, however, are by no means without implications; they can evoke outlooks, contexts, methods, and professions.

Outlook styles. Any style, of course, can be said to express an outlook or an attitude along with whatever else it expresses. Michelangelo's personal style expresses the outlook of Michelangelo; the Biedermeier style in furniture and decoration expresses the outlook of the German and Austrian middle classes between the Congress of Vienna in 1814–15 and the Revolution of 1848. Certain cross-cultural styles, however, can be said to specialize in general outlooks and attitudes that recur everywhere in all arts in all eras. There is a Classical style—a deviation toward clear, logical, nobly impersonal, carefully proportioned forms—that is recognizable not only in works that are ordinarily labelled "Classical" or "Neoclassical," such as the sculpture of the Parthenon of 5th-century-BC Athens and the plays of Pierre Corneille of 17th-century France, but also in the 13th-century sculpture of Reims Cathedral, the 20th-century Symbolist poetry of Paul Valéry, the 18th-century English portraits of Sir Joshua Reynolds, a Japanese screen, a Chinese vase, and some buildings on Fifth Avenue in New York City. There is a Romantic style—a deviation toward restless, alogical, nobly personal, intensely expressive forms—that is recognizable not only in works of the Romantic period of the early 19th century, such as the music of Frédéric Chopin or a poem by Heinrich Heine, but also in the Italian baroque architecture of Francesco Borromini, the fantasy painting of Paul Klee, Shakespeare's *King Lear,* a Hindu stone relief, a Hellenistic mosaic, and an avant-garde dancer. The same sort of thing can be said about such styles as the realistic, the fantastic, the expressionistic, and the idealistic, each of which implies an attitude toward life and the world. And perhaps the list should be rounded out with the academic style, into which the other outlook styles tend to sink when they are reduced to a set of teachable rules.

Classical and Romantic styles

Since these styles cross every aesthetic, geographical, or temporal frontier, embrace common human attitudes, and exhibit strong polar aspects, they have tempted many critics into an effort to arrange them all into two contrasting groups: the classical and the romantic, the conservative and the liberal, the idealistic (here the classical joins forces with the romantic) and the realistic, the rational and the emotional, and so on. Such arrangements have the advantage of breaking up traditional divisions and freshening awareness along with the disadvantage of not exhausting the evidence.

Contextual styles. At first glance the outlook styles may seem capable of annexing the contextual, which include the traditional genres and kinds of art—such styles as the tragic, the comic, the satiric, the pastoral, the heroic, and the melodramatic. But here the outlooks, when they exist, are at one or two removes from those of real life and the real world.

A tragic style evokes not a death in the family but a work by Sophocles, Shakespeare, or some other playwright; a pastoral style evokes not herdsmen in the Alps but swains in a mythical Arcadia; a heroic couplet evokes not a brave warrior but the practice of John Dryden and others of using units of two rhyming lines of iambic pentameter in their "heroic" drama. Moreover, when the context—the genre, or kind of art—is not literary, the contextual style may evoke nothing that can properly be called an outlook. The operatic style in Verdi's *Requiem,* cited above, is a contextual style; so is the landscape style, with its hints of land, horizon, and sky, that is sometimes recognizable, like a ghost from Dutch paintings of the 17th century, in modern abstract paintings. So are the sculptural styles recognizable in the bizarre 20th-century architecture of the Spaniard Antonio Gaudí, the painterly styles in the Italian baroque sculpture of Gian Lorenzo Bernini and in certain Cubist sculpture of the 20th century, the musical styles of the poetry of Edgar Allan Poe and Alfred Lord Tennyson.

Procedural styles. Procedural cross-cultural styles are similar to but not quite the same as the contextual. For the term "procedural" is here meant to refer to ways of making art, to varieties of *poiēsis,* that may be shared by several arts and, in fact, are often shared by all. Hence, when the point of view is that of appreciators, procedural styles are commonly called "formalistic." Familiar examples of such styles are the mimetic, the representational, the naturalistic, the abstract, the geometric, the organic, the linear, the optical, the haptical (or tactile), and the plastic; some of these can be regarded, not always profitably, as subvarieties of others, and all of them can be regarded as members of polar pairs.

Formalistic members of polar pairs

Traditionally, certain procedural styles are associated with certain arts, but they need not be. Mimetic, or representational, styles, for example, are most often associated with painting and sculpture (*e.g.,* Gilbert Stuart's lifelike 18th-century portraits of George Washington or a Sumerian animal statue of the 3rd millennium BC), but they can also be recognized in the resemblance of Frank Lloyd Wright's mid-20th-century Guggenheim Museum to a snail, in the similarities of Nikolay Rimsky-Korsakov's musical composition *The Flight of the Bumble Bee* to the buzzing of a bee, and in Tennyson's frequently quoted lines in *The Princess:*

> The moan of doves in immemorial elms,
> And murmuring of innumerable bees . . .

which employ onomatopoeia, the use of words that actually sound like what the words represent.

Similarly, linear styles can be recognized not only in such obvious places as a line engraving by the 16th-century German master Albrecht Dürer or in the linear patterns of Plateresque ornament of 16th-century Spain but also in the vocal line of an Italian Renaissance madrigal or in a modern building by the American architectural firm of Skidmore, Owings, & Merrill.

Traditionally also certain procedural styles are associated with certain cross-cultural outlook styles, but again they

need not be. Mimetic styles are accompanied by Classical in the serene 17th-century landscapes of Nicolas Poussin, by Romantic in the turbulent 19th-century seascapes of Turner, by Realistic in Caravaggio's works of 16th-century Italy; by fantastic in the 20th-century Surrealistic compositions of René Magritte, and by Expressionistic in the tortured figures of Matthias Grünewald's Isenheim Altarpiece of the early 16th century. Abstract styles in 20th-century painting are accompanied by Classical in Piet Mondrian's use of pure lines and rectilinear shapes, by Romantic in Wassily Kandinsky's watercolours of his Blaue Reiter period, by Realistic (of a sort) in Frank Stella's striped, "objective" works, by the fantastic in Yves Tanguy's Surrealistic vistas, and by Expressionistic in Willem de Kooning's often violent canvases. The point is worth some emphasis, for even the most careful critic is likely to slip into the error of assuming that the classical, the romantic, and especially the realistic styles call for eternally fixed methods of production.

Professional styles. When the context of a contextual style or the procedure of a procedural style is derived from somewhere outside the arts in a sufficiently recognizable way or form, the result may be called—at the risk of some confusion—a professional style. Every artist, of course, has a professional style insofar as he is indeed an artist. But the critical occasions for talking about an "art" style in a meaningful fashion are rare; they are likely to arise only when an emphatic distinction is needed between two levels of artistry or when, as during the 19th-century English Aesthetic movement, artists and allied nonartists are waging war against alleged Philistines.

Styles from non-artistic professions

On the other hand, artistic styles derived from nonartistic professions have never been rare and have recently been plentiful. An engineering style is easily recognizable in Roman, Gothic, and modern architecture and also in several kinds of modern sculpture and painting. Many novelists, from the beginning of the genre, have borrowed the styles of historians, and many the styles of journalists; directors of fictional films have worked in documentary styles, composers of modern music in the styles of experimental science and electronic-age technology. Occasionally the stylistic trend among 20th-century artists toward outside professions has been noticeable enough to lead a few observers, always promptly challenged by others, to conclude that the traditional arts were running low on unmanipulated variables.

The dynamics of style

This article has considered styles more or less as a panorama in which all the features are contemporaneous with each other and with the appreciator. The approach, to borrow a term from modern linguistics, has been largely "synchronic"; and such an approach has evident advantages. It gives an explicator a chance to classify, to structuralize, without worrying overmuch about the randomness of history. More importantly, it corresponds in a sense with an appreciator's actual experience of works of art, which is, of course, always synchronic, always in the present; experientially speaking, the Gothic style of the 13th century is not a second older than the style of Skidmore, Owings, & Merrill of the 20th. The historical, or diachronic, approach can offer, however, its own set of advantages. Facts and speculation concerning styles as they occur or change over a period of time can have the same sort of value as political or military history, and in addition they can contribute greatly to the recognition pleasure that is basic in an appreciation of styles.

Difficulties of stylistic history

The pleasure, it should be said right away, is normally accompanied by some peculiarly daunting doubts. Like all history, stylistic history is at once a branch of knowledge that tries to explain significant past events, a chronological record of such events, and somehow the past events themselves, in all their intractable uniqueness. But whereas the members of the trinity can usually be kept reasonably distinct in political or military history, they can usually be found in a state of oneness in stylistic history; the beginning of the Renaissance style, for instance, is notoriously a blend of theoretical explanation, selective records, and such "events" as surviving paintings, poems, and buildings. Also, whereas elections and battles have their fixed times and places, many styles do not; romanticism can leave the ahistorical limbo of cross-cultural styles to become the single-culture 19th-century Romanticism and then suddenly materialize, to some historians, as a phase of late Greco-Roman single-culture Classicism. In sum, the emergent mode of existence to which styles are disposed may make impossible a clean distinction between conceptions and historical facts and may expose the most conscientious of art historians to the charge of merely manoeuvring with private abstractions.

Another difficulty, which was glanced at in connection with the measurable in style, can be mentioned again here. It is the familiar one of overspecialized interpretations presented as general theory. Much of the terminology and nearly all of the chronological framework for the history of style are inventions of specialists in the study of the visual arts. Fortunately, the terminology and the framework can be adapted, with the help of some stretched meanings, to the study of music and literature. In what follows, a strong possibility of visual-art bias should be kept in mind during the discussion, which will concern origins, diffusion, and change and duration of art styles.

HISTORICAL ORIGINS

The question of the origins of styles has already been raised. From an appreciator's strictly synchronic point of view, to raise such a question is often to be irrelevant, or to get into a round of tautologies and to confuse the merely relational with the causal. The origins of the courtly style, of the Eskimo style, and of personal styles are by definition courts, Eskimo, and artists, respectively.

The relational and the causal

There is something to be said, however, for the elaborated tautology as a form of analysis and also for the fact that adding the space-time of history makes a difference: it is one thing to point to an emphasis on order in the French national style and another thing to account for the advent of the Gothic style at the abbey of Saint-Denis in 1140. Moreover, art historians do not usually mean anything as determinative as a cause when they refer to the origins of a style; they merely mean a set of conditioning historical factors. And when they disagree they usually do so over the relative importance to be assigned to one of four sorts of factors: the politico-economic, the cultural, the technical, and the artistic.

Politico-economic factors. The most evident sort is the politico-economic. If the ancient Greeks had lost the Persian Wars in the 5th century BC, the columns of the temples on the Acropolis would probably be taller. If the Great Depression in the United States had begun earlier, the Empire State Building and other skyscrapers in New York of the 1920s and 1930s would probably have been shorter. The styles of Chinese blue and white porcelain were perceptibly influenced by export possibilities. Films are an industry as well as an art. The Italian Renaissance cannot be fully understood without references to the personality cults of monarchs, petty tyrants, and usurping mercenary leaders, to the capital accumulated in the bank of the Medici family of Florence and the coffers of the Vatican, to the expansion of international trade, and to the loosening of feudal ties. Such examples, along with more subtle ones, can be multiplied into a solidly factual kind of stylistic history.

Cultural factors. Nothing quite so solid is likely to come out of a consideration of contributing cultural factors; here one is obliged to weigh such imponderables as changes in manners, morals, psychologies, philosophies, and that pervasive sensibility system known as "the spirit of the age" and then to try to match these changes with the arrival times and the formal elements of presumably new styles. Thus it can be argued that the new period style gradually apparent at the close of the Greco-Roman era—the lack of naturalism, for instance, in painting—reflects Christian otherworldliness.

The question of the "spirit of the age"

Similarly, it might be claimed that the exuberantly enumerative prose style of the French satirist François Rabelais has roots in the widespread 16th-century zest for learning and discovery. To take still another example, the

development of the orchestral crescendo in the middle of the 18th century, principally at Mannheim, Germany, has been said to reflect a new kind of human self-assertion, one destined for importance in all the arts with the arrival of 19th-century Romanticism.

Technical factors. The presence of politico-economic or of cultural factors need not, of course, rule out the technical sort, and examples of the latter are plentiful. The stylistic change from 14th-century to 15th-century European painting coincides with a new utilization, although not the invention, of the oil technique. The refinement of volumes and of implied movement in Renaissance bronze sculpture is linked to a new skill in casting techniques acquired in the making of artillery. Chopin's personal style and significant improvements in the piano both date from the 1830s.

Sometimes the technical factors are partly disguised by a change of material; the Doric order in architecture is a wood style in stone. Sometimes, too, the technical factors must be understood in a large sense that embraces the functional, and they may then be accompanied by moralizing; thus, some 20th-century architects have maintained that it is "honesty" to let a building reveal its construction and use. Usually more than one set of technical factors can be discovered; a poet's style that mixes true rhyme with eye rhyme (similarity only of spellings) has origins—rather remote—both in ancient oral mnemonics and in the silent reading fostered by printing.

Artistic factors. Explanations of stylistic origins involving politico-economic, cultural, and technical factors tend to have in common the defect of not providing very exclusive matchings of formal elements with supposed sources. Many times and places have had ambitious princes and accumulated capital equal to those of 16th-century Italy without producing anything like the smoky style, the sfumato, of Leonardo da Vinci's paintings, or the clarity and solemnity of Bramante's architecture. If a lack of naturalism goes well with early Christian otherworldliness, it also seems to go somehow with the reputed this-worldliness of the 20th century. If the perfected piano can be matched with the smooth 19th-century compositions of Chopin, it can also be matched with the staccato 20th-century music of Béla Bartók. To be sure, these are only contributing factors, not specific causes. Even so, the versatility of the factors mentioned usually leads an art historian to add some relatively direct, purely artistic factors and eventually to postulate a group of ancestors and influential cousins for a given style. Thus Leonardo's style is said to be derived partly from his early master Verrocchio's, early Christian from ancient Roman and Syrian, Chopin's from the styles of other Polish pianists and from the Irish-born John Field. Art historians of this persuasion do not, as is sometimes alleged, reject the hypothesis that an artist may think up a style partly on his own; they merely regard it as lying outside the concerns of scholarship.

Matching causes and effects

Here another difficulty in the writing of stylistic history has to be mentioned. In which painting did Leonardo's personal style become his own and not Verrocchio's? At what date did the early Christian style cease to be Roman and Syrian? Questions of this sort, if pressed far enough, can raise the suspicion that a discussion supposedly about the origins of a certain style is actually about the arbitrary periodization of a more inclusive style.

DIFFUSION

Periodization is always, although the fact is not always made clear by periodizers, a spatiotemporal operation: it poses questions of where as well as of when. The Gothic period can be said, if dates are used with convenient recklessness, to end around 1420 in Italy, around 1530 in France, and a generation later in England. Moreover, the "where" may be not only a point in geographical space but also a zone in the imaginary space constituted by any classification of the arts.

The factor of place in diffusion

The Italian Renaissance can be said to begin in painting around 1300 with Giotto; in poetry around 1330 with Petrarch; in architecture around 1420 with Brunelleschi; and in music around 1525 with madrigal composers, or perhaps around 1600 with Monteverdi. In sum, staggered dates, distinct localities, and the separation of the arts combine to involve the student of period styles in a complex problem of assumed or alleged correspondences and sometimes in unexpected variants of the problem of stylistic origins.

Correspondences in real space. Like their colleagues in other branches of cultural history, art historians sometimes are obliged to choose between diffusionism and theories of spontaneous development; the striking similarity between a motif on a Chinese bronze and one on an Aztec temple, for instance, may be attributed to prehistoric migration, to analogous stages of civilization, or to chance. Normally, however, and for good reasons, art historians rely on diffusion from a creative centre in their attempts to explain stylistic correspondences in even widely separated areas; and they rely on it almost exclusively in discussing period styles.

It is fairly easy to trace the movement of Andrea Palladio's style from the buildings he designed in Vicenza, Italy, in the 16th century to Inigo Jones's Banqueting House in London in the 17th century, of opera buffa from Naples to Vienna in the 18th century, or of Cubism from Paris to Prague and New York in the 20th century. A difficulty in this sort of history is that diffusion implies receptivity, and stylistic receptivity implies at least a degree of spontaneous development.

Correspondences in the arts. There are a number of problems in attempts to deal with stylistic correspondences in different arts. One of the most common is the difficulty of making a distinction between a period style and a period of time when the same label is used for both—and perhaps for each in more than one sense. Thus, a historian who refers to Baroque music without explanation may mean that the music in question has certain stylistic affinities with the theatricality of Bernini's sculpture, with the full-blooded movement and illusionism of Pietro da Cortona's painting, with the undulations of Borromini's architecture, and with the cadences of Sir Thomas Browne's prose; instead, or also, he may mean, as many musicologists would, that the music carries the technical eramark of a basso continuo part; again he may mean that the music evokes the manners, public life, science, and general culture of "the Age of the Baroque"; and finally he may mean nothing more than that the piece was composed in the 17th century. If he does mean that the music has stylistic affinities with Baroque sculpture, painting, architecture, and prose, then other difficulties appear. He must manage to translate each art into the others, construct a convincing historical pattern, and explain the correspondences.

Problems and ambiguities of correspondences

Nevertheless, there is considerable agreement among art historians that such correspondences do exist—not in every period but often enough to merit attention. In addition to those of the Baroque, which are frequently cited, one can mention those between musical and visual-art proportions during the Renaissance, those among nearly all the arts during the Gothic period, and those among painting, sculpture, architecture, and music during the 20th century. Persuasive arguments for correspondences between art and other disciplines have been advanced, notably in a comparison of Gothic architecture with scholasticism, the contemporaneous church-oriented philosophy, and by several commentators in comparisons of Leibniz's highly complex but integrated philosophy to Baroque art.

CHANGE AND DURATION

The already mentioned problem of distinguishing between the origins of a distinct style and the periodization of a more inclusive one complicates every discussion of stylistic change and duration. It can be argued that whenever a style moves into a new period or phase it becomes a new style; and a few modern historians have drawn the conclusion that the concept of style should be kept out of art history and be reserved for synchronic structuring and critical analysis. They feel that one can usefully take a cross section of Baroque, for example, and study it horizontally, out of time, but that to talk about the historical antecedents of Baroque, or about phases of Baroque, is to fall into logical contradiction. Such historians, however,

are very much a minority. Most of their colleagues are committed not only to stylistic change and duration but also, if often only implicitly, to various theories about supposedly typical stages in the stylistic historical process.

Cyclical theories. In the preface to his *Lives,* Vasari remarked that the arts, like human beings, "are born, grow up, become old, and die." Four centuries later, the infinitely more knowledgeable and sophisticated art historian Henri Focillon entitled an essay on style *The Life of Forms in Art* (1934). André Malraux, in his *Voices of Silence* (1951), refers to

> these imaginary super-artists we call styles, each of which has an obscure birth, an adventurous life, including both triumphs and surrenders to the lure of the gaudy or the meretricious, a death-agony and a resurrection.

References to the "maturity" or the "decay" of styles are part of nearly everybody's art criticism. In sum, the biological metaphor for style has become commonplace. But it once was a serious theory of the historical process, and as such it perhaps still deserves some denunciation for having been frequently both a misrepresentation of facts and a source of prejudice against estimable works of art—Hellenistic, late Gothic, Mannerist, Baroque, and so on—which were believed to belong to the "decadent" part of "the life cycle" of a style.

In an effort to get closer to the observed course of events, some historians have favoured, in whole or in part, a cyclical theory that pictures each major single-culture style as going through the same irreversible series of cross-cultural styles, which is usually given as archaic, classic, baroque, impressionist, and archaistic. Thus the first, or archaic, phase of the Greco-Roman cycle is supposed to correspond with the first phase of the Gothic and of the Renaissance cycles; and one can speak of third-phase baroque Greek, third-phase baroque Gothic, even third-phase baroque Baroque. The theory has some fascination, and occasionally it works well enough to shed light on the actual historical behaviour of styles. But often it works only because one has been careful to start the cycle in the right place, and far too often it does not work at all.

Dialectical theories. The notion that history is a pendulum, with left inevitably followed by right, occurs to everyone, and it is especially likely to occur to art historians because of the polar aspects of style. Sometimes the pendulum is imagined as swinging forever between cross-cultural outlook styles: classical then romantic, idealistic then realistic. Historians who are inclined to feel that outlook styles are too vague and too laden with value implications may favour the idea of swings between cross-cultural procedural styles: mimetic then abstract, organic then geometric.

The pendulum notion of history

The influential theory devised by the Swiss art historian Heinrich Wölfflin (1864–1945) postulates an elaborate dialectic involving pairs such as linear–painterly and closed–open. A theory devised by the German critic Paul Frankl (1878–1962) combines a movement between styles of being and becoming with a cyclical development through preclassic, classic, and postclassic stages. Another theory, devised by the Austrian scholar Alois Riegl (1858–1905), postulates cycles of evolution within a long swing across the centuries from an early haptic to a later optic phase. All these models of the stylistic historical process break down eventually, but they can provide useful categories for organizing the flux of artistic events.

Sequential theories. Historians who refuse to believe that styles are haunted by destiny may be willing to grant that within short periods and mostly in terms of technique something that looks like a preordained evolution can occur. Thus it is possible to discern in Gothic architecture a predictable movement toward lighter construction, in Early Renaissance painting a movement toward a desired illusionism, in 16th-century European music a movement toward the tonal system that emerged in the following century. But beyond this concession, such historians are likely to rely on simple sequences devoid of any trace of determinism. Their works often consist of a sequence of biographies of artists and a sequence of centuries.

Do such theoretical methods suggest that art historians are engaged in mere chronicling rather than history? Perhaps partly to answer such a question, a theory advanced by the contemporary U.S. historian James S. Ackerman presents stylistic change as a "process" of a sort, although not one that is preordained; art history is envisaged as a series of steps away from the past, but not toward the future. "Each step," Ackerman says, "for the artist who takes it, is final and definitive; he cannot consciously make a transition to a succeeding step, for if he visualizes something he regards as preferable to what he is doing, he presumably will proceed to do it. . . . "

Satiation theories. Why does the artist take a step away from the past? A common explanation is that he, or his audience, has become overly familiar with the prevailing style. The phenomenon is similar to what psychologists call semantic satiation—the loss of meaningfulness in repeated words. According to one theory, stylistic satiation is hastened by comparison; thus when much was changing at the beginning of the 20th century, many painters felt that their old styles were intolerably familiar. According to another theory, satiation is always merely temporary. To revert to part of the biological metaphor, styles are born, but they never really die.

BIBLIOGRAPHY

Theoretical surveys: An excellent critical résumé of early 20th-century speculation, with emphasis on the visual arts, is M. SCHAPIRO, "Style," in A.L. KROEBER (ed.), *Anthropology Today* (1953). J.S. ACKERMAN, "Theory of Style," *Journal of Aesthetics and Art Criticism,* 20:227–237 (1962), stresses relational values and offers a lucid critique of evolutionary notions. R.L. SCRANTON, *Aesthetic Aspects of Ancient Art* (1964), analyzes in sharp detail the structure of style and applies his conclusions to specific works, including literature. HERBERT READ, in the introduction to *The Styles of European Art* (1965), emphasizes the psychological aspects of the subject. RENE WELLEK and AUSTIN WARREN, *Theory of Literature,* 3rd rev. ed. (1966), have much to say about style in passing, from the standpoint of Anglo-American New Criticism. GEORGE KUBLER, *The Shape of Time* (1962), wages brilliant war on conventional art history and presents a formal substitute for the concept of style. BRUCE ALLSOPP, *Style in the Visual Arts* (1956), reviews the history of the concept and stresses the allegedly damaging effects of style on contemporary artistic activity.

Special studies: ERWIN PANOFSKY, *Renaissance and Renascences in Western Art,* 2nd ed., 2 vol. (1965), examines the idea of rebirth in Italy and discusses the significance of medieval renascences; his *Meaning in the Visual Arts* (1955), although focussed on iconography, has extensive reflections on style; his *Gothic Architecture and Scholasticism* (1951) is a study in correspondence. ETIENNE SOURIAU, *La Correspondance des Arts* (1947), presents a basis for comparative aesthetics. WYLIE SYPHER, *Four Stages of Renaissance Style* (1955) and *Rococo to Cubism in Art and Literature* (1960), make good use of stylistic polarities in an analysis of painting, sculpture, architecture, and literature. RUDOLF WITTKOWER, *Architectural Principles in the Age of Humanism,* 3rd ed. rev. (1962), deals in depth with problems of symbolism, optics, and harmony in Renaissance buildings. NIKOLAUS PEVSNER, *The Englishness of English Art* (1956), offers one of the few instances of a serious historian taking the idea of a national style seriously. G.M.A. GRUBE, *The Greek and Roman Critics* (1965), discusses stylistic theories from Homer to the 3rd century AD. WALTER WIORA, *Die vier Weltalter der Musik* (1961; Eng. trans., *The Four Ages of Music,* 1965), presents a panorama of the world's musical styles from ancient times to the 20th century.

Classical studies: FRANZ BOAS, *Primitive Art* (1927, new ed., 1962); H. FOCILLON, *Vie des formes* (1934; Eng. trans., *The Life of Forms in Art,* 2nd ed., 1948); P. FRANKL, *Das System der Kunstwissenschaft* (1938); A. RIEGL, *Stilfragen: Grundlegungen zu einer Geschichte der Ornamentik* (1893; 2nd ed., 1923); HEINRICH WOLFFLIN, *Renaissance und Barock* (1888; Eng. trans., *Renaissance and Baroque,* 1964); *Die klassische Kunst* (1899; Eng. trans., *Classic Art,* 1952, reprinted 1968); and *Kunstgeschichtliche Grundbegriffe* (1915; Eng. trans., *Principles of Art History,* 1932).

Bibliographies: Useful short lists of theoretical works on style may be found in the above-mentioned publications of Schapiro and Scranton. Longer lists, mixed with other material, may be found in those of Panofsky, Sypher, and Wellek and Warren.

Aschelminths

The phylum Aschelminthes (or Nemathelminthes) includes five diverse classes of wormlike animals, mostly of microscopic size: Nematoda (or Nemata), Rotifera, Gastrotricha, Kinorhyncha (or Echinodera), and Nematomorpha. The American zoologist Libbie H. Hyman, in her classic textbooks on the invertebrates, originally included Priapulida as a class of the aschelminths, but Priapulida are usually not now included. Aschelminths have in common a body cavity, the pseudocoel, that arises in the embryo in a way different from that found in more advanced animals and that has no epithelial lining—*i.e.*, it is not a true coelom. Priapulids possess such an epithelial lining and are therefore coelomates. Aschelminths are bilaterally symmetrical, have a tough external covering, the cuticle, and, except for the kinorhynchs, lack segmentation.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 313.

This article is divided into the following sections:

GENERAL FEATURES

Size range and diversity of structure. The five classes of aschelminths are of different sizes and varying importance. The nematodes are by far the largest group, with 13,000 to 14,000 named species and many times that number undescribed. Most of the described species are parasites of human beings, domestic animals, or cultivated plants and are therefore of great importance in medicine and agriculture. Typically, nematodes have a simple wormlike body, elongated, without appendages or segmentation, which moves with a characteristic sinuous movement, though there are exceptions. Parasitic nematodes may be large enough to be seen with the naked eye, with a few 50 centimetres (20 inches) or longer and are often referred to as roundworms. Most are not parasites and are microscopic, between 0.1 and two millimetres (.004 and .08 inch) when fully grown, living in soil or aquatic muds or sands.

The rotifers, with about 2,000 known species, are common microscopic animals in lakes and ponds but also occur in the sea and damp soil. Generally between 0.1 and 0.5 millimetre long, they are usually recognizable under the microscope by the water currents set up by rows of beating hairlike cilia, which are used to collect food, on their heads (the corona).

The gastrotrichs, with at least 450 named species, and of a size range similar to rotifers, creep or swim by cilia but do not possess a corona. They are found in fresh waters and marine mud sand or among plants. The kinorhynchs, with about 150 described species, and less than one millimetre long, are little known but not uncommon in marine sands and muds. The body is segmented and spiny, with a retractable head. The nematomorphs, with several hundred species, are, when juvenile, parasites of insects, spiders, centipedes, or marine shrimps. The adults, which may be as long as 0.5 to one metre, were formerly called horsehair worms because it was believed that they arose from horses' hair that had fallen into the water. Because they can become tangled in knots, they are also sometimes called gordian worms. Nematomorphs are long, thin worms with a brown, leathery body. They swim or crawl with a sinuous movement superficially resembling that of nematodes.

Horsehair worms

Distribution and abundance. Nematodes are the most abundant of all multicellular animals and are found wherever life can be supported. They reach their greatest numbers in estuarine mud flats, up to 20,000,000 per square metre, decreasing in density in marine muds and sands but often reaching one to several million per square metre. Typical densities for terrestrial soils, including forests, grasslands, agricultural land, and even arctic tundra, number several million per square metre. Though basically aquatic, as are all aschelminths, nematodes can be found in deserts and polar regions because of the ability of some to survive drying or freezing conditions in an inactive state (cryptobiosis [see below *Adaptations*]), a capacity shared with some rotifers. Unlike many rotifers, however, nematodes are not adapted to a free-swimming planktonic life.

Rotifers are common in the surface waters of lakes and ponds, often showing short-lived seasonal blooms of several thousand per litre. Others attach themselves to aquatic plants (sessile rotifers) at even greater densities (tens of thousands per litre). Some inhabit the interstices of aquatic sediments; at one lake more than 1,000,000 per litre were found. They also may be found in the soil and in the sea.

Importance. The aschelminths are primarily particle feeders, grazing on bacteria, microfungi, algae, and protozoans, though some are predators on other aschelminths. As such they play important roles in recycling nutrients, which then become available for plant growth, and in promoting the decomposition of dead organic matter. Aschelminths are at the base of many food chains.

The nematodes, however, have a much more direct impact on human welfare as parasites. In agriculture they cause great losses in the production of cereals, root crops, and many other plants. Crop rotations, the application of potentially toxic nematocides, and the development of resistant cultivars are required to control their activities. One nematode, *Bursaphelenchus xylophilus,* in association with beetles, even destroys pine forests. Nematodes can be used in the biological control of some insect pests.

Effects on agriculture

Nematodes cause several of the most serious tropical diseases, such as, for example, filariasis, an infestation of the lymphatics and subcutaneous and deep tissues that causes inflammation and scarring. Filariasis is transmitted by biting insects.

Filariasis

Many nematode parasites live in the alimentary canal and are spread as infective eggs. *Ascaris lumbricoides,* a human intestinal parasite, is common wherever human sewage is used as a fertilizer because its eggs contaminate food. Even in the most hygienic countries, most people suffer at some time from the human pinworm *Enterobius vermicularis,* an innocuous inhabitant of the bowel whose eggs are passed from person to person. Some species for which a human is not the normal host can invade humans and cause diseases. For example, the dog roundworm, *Toxocara canis,* can only mature in the dog's intestine, but the microscopic larvae from dog feces can invade human tissues and occasionally can cause blindness.

NATURAL HISTORY

Reproduction and development. Most aschelminths are bisexual; the male inseminates the female during copu-

lation so that she lays fertilized shelled eggs. In some cases, these eggs may have started to develop before being laid. Parthenogenesis, by which the female's eggs develop without fertilization, is common. In most rotifers (*i.e.,* the order Monogononta) males are smaller and less frequent than females. Monogonot females are of two kinds: amictic or mictic. Amictic females produce amictic eggs, which develop without being fertilized (parthenogenesis). Mictic females lay mictic eggs, which develop into males if unfertilized or into amictic females after a period of dormancy if fertilized. Of the remaining orders of rotifers, males are unknown in the order Bdelloidea, and the order Seisonidea is bisexual.

Amictic and mictic females

In some terrestrial nematodes, individuals of female appearance first produce spermatozoa, which are stored and then used to fertilize eggs produced by the same gonad; such individuals are called protandrous hermaphrodites. Normal functional males may occur much less frequently in the same population. Parthenogenesis also occurs in nematodes, sometimes with environmental factors determining whether the female's eggs will develop parthenogenetically or require fertilization by a male. Some gastrotrichs are parthenogenetic; others are protandrous hermaphrodites. Nematomorphs and kinorhynchs are bisexual.

Generally, aschelminth eggs have relatively little yolk, and their embryonic development may be technically described as holoblastic cleavage (*i.e.,* division of the entire egg into separate though contiguous cells), during which a blastula (a hollow, single-layered ball of cells) is formed, followed by the formation of a gastrula (a hollow, two-layered ball of cells). Gastrulation brings the cells destined to form the adult organs, derived from mesodermal and endodermal layers, and the reproductive cells into the interior. The earliest stages of embryonic development in rotifers show a limited form of spiral cleavage, also found among the flatworms and segmented worms, but such a pattern is much less apparent in other aschelminths.

Determinate development

Development is highly determinate, giving rise to a body with a relatively constant number of cells in highly characteristic positions, little, if any, powers of regeneration of lost parts, and lack of capacity for asexual reproduction. The cuticle, which covers the body, is molted as the body grows in nematodes, nematomorphs, and kinorhynchs. In nematodes there are four molts separating four juvenile (or larval) stages preceding sexual maturity. Sometimes there may be substantial growth after the last molt. In kinorhynchs a larva of three segments adds more segments as it grows.

The terrestrial bacteria-feeding nematode *Caenorhabditis elegans* is of interest to developmental biologists because unique features have made it invaluable for the analysis of the genetics of development and for other aspects. A generation may take as little as 3½ days to develop, and each hermaphrodite lays between 200 and 300 eggs. The sequence of cell divisions and differentiations that transforms the fertilized egg into an adult worm is known in precise detail. A highly predictable sequence of divisions gives about 550 cells by the time the juvenile worm hatches, with all of its organs formed apart from the sexual organs. The place and function of each cell, muscle, or nerve, for example, are determined largely by its place in the invariant sequence of binary cell divisions (*i.e.,* its cell lineage) as well as by chemical messages from other cells. There are 811 cells in the hermaphrodite and 971 in the male, in addition to the eggs and sperm. The juvenile (or larva) sheds and replaces its cuticle four times before becoming a sexually mature adult.

Experimental studies

Hundreds of experimentally induced mutated individuals have been bred as self-fertilizing genetically identical clones, which are invaluable for the study of the genetics (inheritance) of developmental processes. The clones can be stored indefinitely at very low temperatures until required and have been used to study a wide range of biologic processes. Self-fertilization by hermaphrodites facilitates isolating mutated individuals, while crossing females with males makes it possible to map the genes on the five pairs of non-sex chromosomes and on the one pair of sex chromosomes in the female or on the unpaired chromosomes in the male. The DNA of *C. elegans* has some 80,000,000 base pairs, about 4,000 genes. Genetically speaking, it is a very simple animal.

Locomotion. Nematodes have a characteristic sinuous movement in which waves travel along the body, which generally lies on its side, backward waves driving the body forward, forward waves driving it backward. These waves are brought about by successive contractions of longitudinal body wall muscles, in dorsal and ventral blocks, acting out of phase. The muscles increase the hydrostatic pressure in the internal tissues, causing the flexible, but not very extensible, cuticle to bend and producing graceful body curves. The body waves enable nematodes to move efficiently through the fluid-filled interstices of mud, sand, and soil or to crawl in thin films of water, using the resistance offered by surface tension. Nematodes also swim with body waves but not so efficiently, some of their effort being dissipated as turbulence. Nematomorphs move in a way similar to nematodes.

Rotifers and gastrotrichs swim by means of beating cilia (protoplasmic hairs), which in rotifers also generate food-collecting currents. Many rotifers swim continuously close to the water surface, while others loop along over surfaces, alternately attaching the corona of the head and the toes of the tip of the foot to the surface. Some rotifers are sessile, remaining attached to an object, sometimes building a tube by gluing together particles with body secretions so that only the head projects. Gastrotrichs glide by using cilia to propel themselves over surfaces. The kinorhynchs use the repeated eversion and retraction of the spiny front end of the body, coupled with muscle contraction, to pull themselves forward.

Behaviour. Although their nervous systems are simple, aschelminths can respond to a range of environmental stimuli by, for example, attraction, avoidance, feeding, or copulation. They respond to touch, temperature gradients, chemicals, and light. Some species in each class have two or more pairs of simple eyes capable of indicating the direction and intensity of light but unable to form an image.

Many nematode males are attracted to females by chemical attractants (pheromones) released by the female. Plant-feeding nematodes are attracted to the roots of host plants. *C. elegans,* a soil inhabitant, is attracted to a number of dissolved salts (sodium, potassium, magnesium, and chlorine), some amino acids, cyclic nucleic acids, basic solutions (OH^-), pyridine, and the products of its bacterial food. Other chemicals are repellent. Nematodes respond with changes in the pattern of body waves and in the frequency with which their direction of movement is altered.

Adaptations. The ability of some nematodes and rotifers to survive drying or freezing conditions in a state of suspended animation, *i.e.,* cryptobiosis or anabiosis, has enabled them to inhabit the driest deserts and the coldest polar regions, as long as free water occurs occasionally and for long enough periods of time for them to reproduce. This ability also allows both groups to inhabit large areas of the world where the soil is seasonally arid or frozen. The plant-parasitic nematode *Ditylenchus dipsaci* has been revived after 23 years in dried plant material. The animal responds to negative environmental signs by changing the hydration of its proteins and cell membranes, synthesizing antifreezes, such as trehalose or glycerol, and storing energy. It is possible to store *C. elegans,* which does not naturally tolerate freezing, in a liquid-nitrogen refrigerator at very low temperatures and later to revive it after artificially infusing glycerol.

Cryptobiosis

Plant- and animal-parasitic nematodes often have infective stages that remain quiescent for long periods. *A. lumbricoides* eggs may infect a host after remaining for several years in the soil. The eggs of the cereal cyst nematode *Heterodera avenae* may have to experience winter chill before they will hatch in the spring. After long periods of inactivity, the eggs of the potato cyst nematode *Globodera rostochiensis* hatch when stimulated by substances diffusing from the roots of potatoes.

Nematodes from two different orders, Tylenchida and Dorylaimida, have mouthparts forming a hollow needle, made of cuticle, that acts like a hypodermic syringe (Figure 1). Digestive juices from pharyngeal glands can be pumped out through the stylet and plant and animal juices

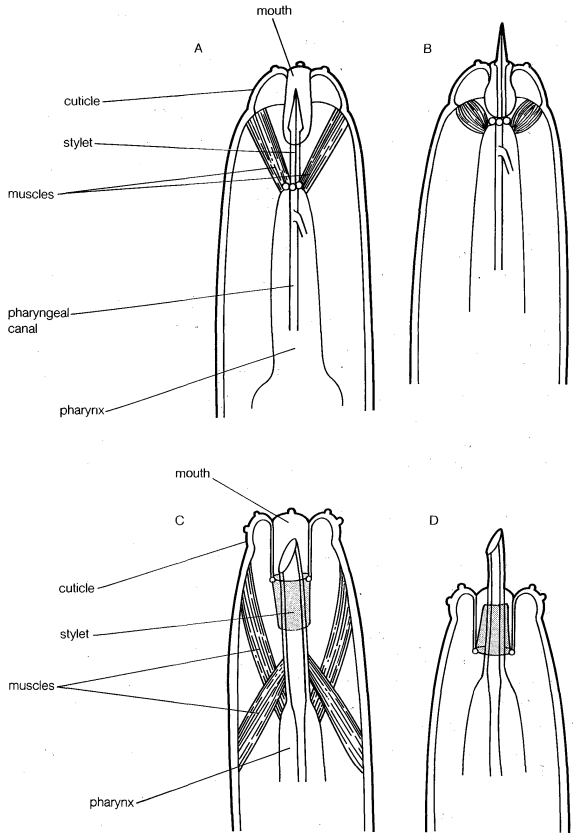

Figure 1: *The heads of stylet-feeding nematodes.* Tylenchid with (A) stylet withdrawn and (B) stylet protruded as in feeding. Dorylaimid with (C) stylet withdrawn and (D) stylet protruded.

pumped back into the pharynx. Many species from these two orders feed on plant roots, puncturing plant cell walls with their stylets, but others are predatory or parasites of invertebrate animals. Some tylenchids invade plant tissues to feed as endoparasites.

Associations. Bacteria form mutually beneficial associations (symbiosis) with nematodes. The insect-pathogenic nematodes *Steinernema* and *Heterorhabditis* carry different species of *Xenorhabdus* in their intestines, which their soil-living infective juveniles inject into any insect they can invade. Bacterial toxins kill the insect, and the nematodes then multiply for several generations, feeding on the bacteria that proliferate in the cadaver. Some stylet-feeding dorylaimids aquire plant-pathogenic viruses, which they transmit to new plant hosts while feeding.

Predatory fungi

Many nematodes feed on fungi, while many soil fungi specifically attack nematodes. Some soil fungi possess sticky traps for nematodes, and others form loops, which close tightly around a nematode that pokes its head into the trap. The loops respond to specific chemicals on the surface of the nematode cuticle. The nematode is then digested. Some fungi only form such traps when nematodes are in the vicinity.

The pine-wilt nematode *B. xylophilus* feeds and multiplies on fungi but can also feed on pine tissues. After a period of reproduction some juveniles enter a stage in which they can invade the wood-boring larvae of certain beetles (Cerambycidae). When they become adults, these flying insects carry the nematodes to new pine trees, spreading the infection and in due course killing the trees.

FORM AND FUNCTION

General form and external features. The great majority of nematodes have slender, elongated cylindrical bodies, without obvious external appendages, that move in graceful curves (see Figure 2). The external cuticle that covers the whole body is often transparent and may be smooth, but it usually has closely spaced grooves, which at high magnification can be seen encircling the body (annulation) and which give the animal a segmented appearance. Some have a thicker cuticle with obvious annulation, or they may have rows of pits, knobs, ridges, bristles, or other ornamentation. The mouth, at the anterior end, usually leads into a cuticle-lined buccal cavity that may be armed with a variety of teeth, jaws, or stylets, depending on the kind of food usually ingested. The anus is near the posterior end, with a short or long, thin post-anal tail, the latter facilitating swimming. Most marine nematodes have caudal glands in the tail that secrete mucus through a pore or spinneret, enabling the worm to maintain a hold on an object and not be washed away. The female sexual opening (vulva) is usually mid-ventral but may be anywhere between the head or anus. The male sexual organs usually open adjacent to the anus. Two cuticular rods, the spicules, used to open the female's vulva, open into the anus. Occasionally, cuticular flaps that surround the male sexual opening also clasp the female during copulation.

Darkening of the cuticle

The adult nematomorph has an elongated cylindrical body resembling a nematode. When the fully grown worm escapes from the body of its host it has a rough, thick cuticle that becomes darkly coloured. The tip of the head is pale and the hind end is lobed where the anal sex organs open. When it hatches from the egg, the head of the larva possesses a proboscis with stylets that enable it to penetrate the body of an appropriate invertebrate host, often an insect, in which it completes its growth.

Gastrotrichs have a short body that swims smoothly by means of cilia, which typically are arranged in bunches on the head and in bands along the ventral surface of the body (Figure 3). The cuticle may be spiny or form plates or scales. Adhesive tubes, the outlet of glands, are a feature of gastrotrichs also found in kinorhynchs and a few unusual nematodes (*e.g., Draconema*). In gastrotrichs there may be many adhesive tubes situated along the sides of the body or merely two at the tips of a forked hind end of the body. Kinorhynchs have a short body of 13 to 14 segments with cuticular body spines (Figure 3). There is an oral cone at the front armed with stylets, and there are further hinged spines around the first segment. The first segment together with the spines and stylets can be completely withdrawn into the second and third segments.

Rotifers show a great diversity of body form (Figure 3). Cilia surround the anterior end of the body and mouth, forming the corona. Cilia may form circumoral rings or two or more ciliated lobes or be arranged in other ways. In some sessile rotifers the corona, which takes the form of a ring of long, thin lobes bordered by stiff bristles, replaces beating cilia and serves to entrap prey. Behind the head, with its corona, is a trunk region leading, in

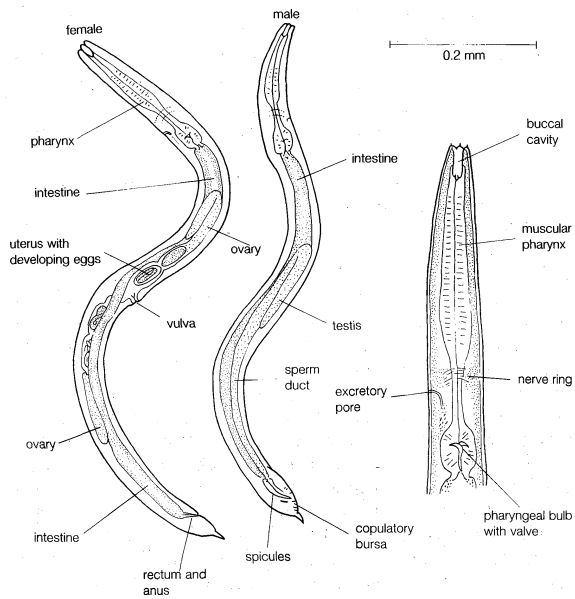

Figure 2: Female and male *Rhabditis oxycerca*, a free-living soil and freshwater bacteria-feeding nematode; enlarged head of female at right.

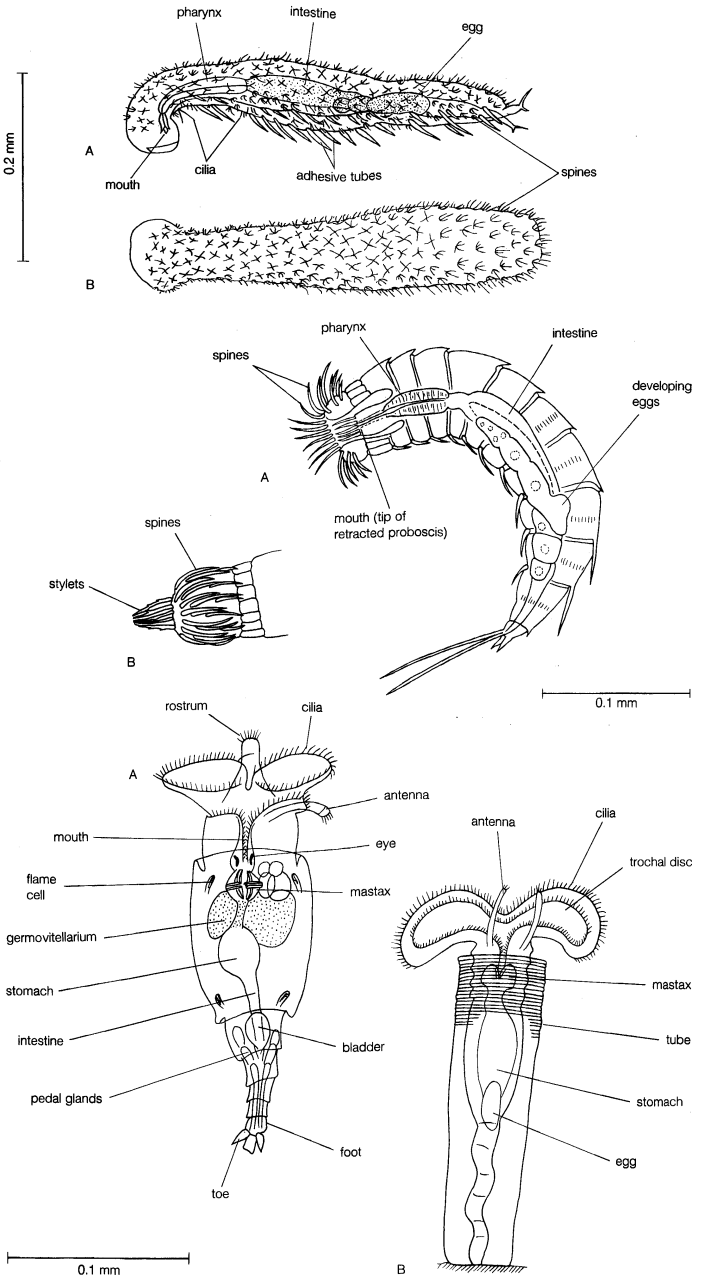

Figure 3: *Representative selection of aschelminths.* (Top) A marine gastrotrich (Macrodasyida) from a sandy beach seen from (A) the side and (B) above. (Centre) A marine kinorhynch from estuarine sand with proboscis (A) retracted and (B) protruded. (Bottom) Rotifers showing (A) a freshwater bdelloid and (B) a sessile flosculurid.

many, to a narrower tail, or foot, often ending in two or more toes. The foot often has a pair of mucus-secreting glands opening on the toes and the cuticle can be annulated, superficially appearing to form segments. Some free-swimming rotifers have a spherical trunk, sometimes with long spines extending from it. Many have the trunk cuticle strengthened to enclose the body in armour (the lorica).

Internal features. The graceful body waves by which nematodes move are brought about by the alternating contraction of dorsal and ventral longitudinal muscles acting on the cuticle and opposed by hydrostatic pressure in the body tissues. This hydraulic skeleton affects all aspects of the nematode. The cuticle must resist stretching in length and circumference and yet remain flexible. The cuticle is a multilayered structure strengthened by an internal system of fibres, struts, or plates. It is secreted by the layer of underlying cells, the hypodermis, before each molt. The longitudinal muscles are obliquely striated. *C. elegans* possesses the same molecular and biochemical machinery in its muscle cells as do higher animals, such as vertebrates, but is arranged somewhat differently. The cross-banding characteristic of striated muscle fibres in vertebrates is replaced by bands making a small angle to the long axis of the cell. The sarcomeres (the structural units of striated muscle that shorten as the muscle contracts) of nematode body wall muscles in adjacent cells are staggered, instead of being arranged side by side. Obliquely striated muscles contract more slowly than cross-striated muscles, but they can maintain tension when stretched to a greater degree, which is important in an animal that must coil and uncoil a long body. The mouth leads into a pharynx (or esophagus), which is a muscular pump opened by intrinsic radial muscles and closed by the elastic cuticular lining and fluid pressure. The pharynx has a triradiate symmetry (Figure 4). It forces food through the straight non-muscular intestine. A short rectum leads from the intestine to the anus.

The cuticle

The alimentary canal of gastrotrichs and kinorhynchs is like that of nematodes. A buccal cavity leads into a muscular pharyngeal pump, which is triangular in cross section. It is followed by a simple intestine, without glands, the rectum, and the anus. In the nematomorphs the gut is greatly reduced, and during their growth as endoparasites food is probably absorbed through the body surface.

The alimentary canal of rotifers is quite different. The funnellike mouth leads into a pharynx armed with a complex cuticular organ, the mastax, or trophi, which serves to masticate food. (The muscular pharynx is called a mastax; hard jaws within the pharynx are called trophi.) It takes many different forms but basically possesses a fulcrum and movable lateral opposable pieces. Food then travels via an esophagus to a saclike stomach, from which it passes to an intestine and finally to a dorsal anus. The rotifer alimentary canal is unlike that of other aschelminths, with, for example, the digestive glands opening into the stomach instead of the pharynx. The mastax is unique to rotifers.

The cuticle is secreted by a hypodermis. Instead of blocks of longitudinal muscles, there are discrete strands of muscle in the body cavity, and there are also muscles around the stomach. There is a spacious body cavity. Excretory organs, known as protonephridia, are found in rotifers, many gastrotrichs, and kinorhynchs; they are not found in nematodes or nematomorphs. Protonephridia are tubes, usually paired, sometimes branching, that end blindly within a cell. The cells, called flame cells from their appearance, set up a water current with waving protoplasmic hairs (cilia or flagella). Their primary function is not excretion but the expulsion of excess water to the exterior through an excretory pore (*i.e.,* osmoregulation). Nematodes and nematomorphs lack flame cells, but nematodes possess one or more ventral cells that contain canals running along both sides of the body. These canals open to the exterior by a ventral pore.

Flame cells

Aschelminths have a simple brain and systems of ganglionated nerves coordinating the muscles and serving the sense organs. In nematodes the brain forms a nerve ring around the pharynx. Sense organs take the form of nerve endings associated with sensitive hairs or papillae concentrated on the head and around the copulatory organs. Sensory ciliated pits probably are chemoreceptors.

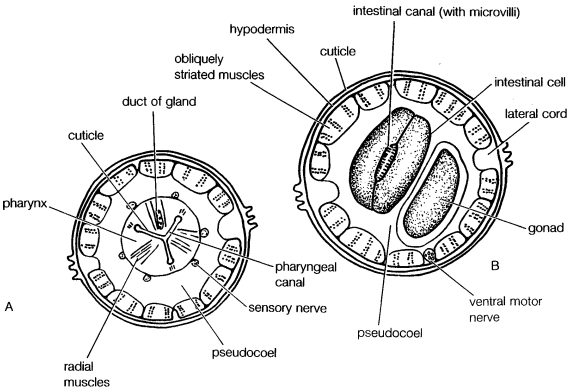

Figure 4: Diagrammatic transverse sections through (A) the pharyngeal and (B) the intestinal regions of a nematode.

In nematodes there are two deep pockets opening near the mouth, each containing a gland and a number of sensory nerve endings, the amphids. The structure of nematode sense organs shows them to be modified cilia, whereas normal locomotory cilia do not occur in nematodes. Aschelminth eyes, one or more pairs, located on the head or within the pharynx, possess a pigment cup, nerve endings, and a simple lens.

Reproductive organs

The reproductive organs are usually paired and tubular. The female organs consist of an ovary, an oviduct, a receptacle for sperm, and a gonopore to the exterior. There may be accessory glands and muscles. The eggs are fertilized within the gonad following copulation and then secrete a shell. The egg may contain yolk, as in nematodes, or enclose separate yolk cells produced in a separate organ, as in rotifers. The testis, which may be single or double, passes sperm down a sperm duct to the male pore. Often this opens together with the anus. There often are accessory copulatory organs forming a kind of penis, as in many rotifers. Nematodes have a pair of cuticular rods, the spicules, to open the female pore, the vulva, which may be located ventrally anywhere between the head and the anus. Nematode sperm, rather than swimming with a protoplasmic hair (flagellum), crawl (amoeboid movement).

EVOLUTION AND PALEONTOLOGY

The only aschelminth fossils known are some nematodes in amber, but these are, in geologic terms, recent fossils, being not more than about 100,000,000 years old. They are similar to, or the same as, living aschelminths. More recent still are parasitic nematodes in fossilized feces.

In the absence of useful fossils, the evolutionary history of the aschelminths can only tentatively and incompletely be reconstructed from their structure and development. There are strong similarities in the pharynx, except in rotifers, and in the adhesive tubes or caudal glands. There are sufficient similarities between gastrotrichs and nematodes, especially in their digestive organs, to suggest a remote common ancestor. One hypothesis suggests that in the Precambrian seas these aschelminths inhabited marine sediments, but, whereas the gastrotrichs preserved the primitive ciliary form of locomotion, the nematodes lost functional cilia (though their sense organs show evidence of derivation from cilia) and adopted sinuous movements powered by muscles to move through the spaces between sand, mud, and soil particles. Both invaded fresh waters, and the nematodes further invaded the soil. The kinorhynchs also resemble both groups in a number of organ systems, but segmentation and the retractable head are unique. Their affinities are much less clear, though they remain inhabitants of marine sediments.

Parasitism

The adoption of parasitism has been accompanied by a great increase in the size of some nematodes and nematomorphs. There are sufficient similarities between nematomorphs and nematodes to make a distant common ancestor likely. The marine nematomorphs are probably the most primitive. Reduction of the alimentary canal is often associated with parasitism. Of the two nematode subclasses, the Adenophorea are the most diverse and, except for the Dorylaimida, primarily marine and not parasitic, while the second subclass, the Secernentea, are primarily freshwater and terrestrial, with many parasitic species. Perhaps the Dorylaimida and Secernentea evolved with the rise of the land flora and fauna, many becoming parasites of plants and animals.

The evolution of the rotifers is not clear. They show some resemblance to the smallest flatworms (Turbellaria). The most primitive are probably the few marine seisonids, with the freshwater forms being more advanced.

Protonephridial organs, present in rotifers, gastrotrichs, and kinorhynchs, are probably lacking in nematodes and nematomorphs because the locomotory system requires higher internal hydrostatic pressure. The characteristic, determinate pattern of cell division in the embryo giving rise to an adult of few cells, even in the larger parasites such as *A. lumbricoides,* perhaps can be explained as a primitive feature on an ancestral aschelminth adapted to life in the small spaces in marine sediments, where miniaturization was an advantage.

CLASSIFICATION

Annotated classification.

PHYLUM ASCHELMINTHES (or Nemathelminthes)

Multicellular; bilaterally symmetrical; triploblastic; mostly microscopic, though some parasitic species many centimetres long; body surface, mouth, and pharynx covered by the cuticle, sometimes with spines, scales, or mouthparts; pseudocoelom; includes a mouth, pharynx, intestine, anus, simple brain, and sensory and motor nerves; some with protonephridial osmoregulatory organs; some possess simple eyes; without respiratory or circulatory systems; reproduction bisexual, parthenogenetic, or hermaphroditic, but not asexual. Development determinate, with small numbers of cells in predetermined, predictable positions in each species.

Class Rotifera

Microscopic free-swimming, crawling, or sedentary animals; feeding and swimming by cilia (beating protoplasmic hairs); a ciliated organ, the corona, of diverse form, on the head; the pharynx, with mastax; body form very diverse, often with an elongated foot.

Order Seisonidea. Marine species on the surface of Crustacea; not parasitic; weakly developed corona; bisexual.

Order Monogononta. Mostly freshwater; free-swimming or sessile; males smaller and less common than females, often seasonal; female with single gonad.

Order Bdelloidea. Mostly freshwater; swimming or crawling; corona in two parts; retractable head; female gonad paired; no males.

Class Gastrotricha

Microscopic; swimming or crawling by means of cilia, often in tufts on the head or in bands on the ventral surface of the body; cuticle, often with spines, scales, or plates; muscular triradiate pharynx, but without corona or mastax.

Order Macrodasyida. Marine; adhesive tubes, often numerous, along the body.

Order Chaetonotida. Mostly freshwater; distinct head and forked hind end on the tips of which caudal glands open; protonephridia.

Class Kinorhyncha (or Echinodera)

Marine; microscopic; body with 13 or 14 segments; first segment (the head) with stylets and spines withdraws into the following segments; movement by protruding and retracting head.

Class Nematoda (or Nemata)

Elongated; cylindrical; crawling or swimming by sinuous movements; no functional cilia or flagella; usually less than 2 mm long; parasitic species may be larger; cuticle smooth, annulated, or otherwise ornamented; triradiate muscular pharynx; no protonephridia.

Subclass Adenophorea

Mostly marine; nonparasitic, except Dorylaimida; usually with caudal glands and a single ventral excretory cell and pore; amphids (lateral cephalic sense organs) posterior to lips.

Order Chromadorida. Mostly marine and nonparasitic; amphids spiral or circular; each ovary usually folded back on oviduct.

Order Monhysterida. Mostly marine and nonparasitic; amphids spiral or circular; single or paired ovaries outstretched.

Order Enoplida. Mostly marine and nonparasitic; amphids pocket-shaped; characteristic stretch receptors (metanemes).

Order Dorylaimida. Mostly soil-inhabiting; many feed by means of hollow stylet, others by teeth; amphids a slit or pocket; includes parasites of invertebrates and vertebrates; large glands (stichosomes) associated with pharynx.

Subclass Secernentea

Mostly terrestrial or parasitic; without caudal glands; excretory organs often intracellular canals running along sides of the body, opening by ventral pore; amphids inconspicuous pores on lips.

Order Rhabditida. Mostly nonparasitic; terrestrial; bacteria-feeding; pharynx expands posteriorly into a muscular bulb with valve.

Order Diplogasterida. Soil-inhabiting; bacteria-feeding or predaceous; pharyngeal bulb; mouth often with teeth.

Order Tylenchida. Many feed on higher plants, others on fungi or predatory, using stylet; others, insect parasites; mostly terrestrial; characteristic hollow, slender mouth stylet; pharynx with bulb, valve, and prominent glands.

Order Ascaridida. Very large intestinal parasites; club-shaped or cylindrical pharynx.

Order Oxyurida. Intestinal parasites; pharynx with posterior valved bulb.

Order Strongylida. Parasitic; often with nonparasitic larvae; males with characteristic copulatory muscular flaps (bursa).

Order Spirurida. Parasites of vertebrates; larval stage in invertebrate host; pharynx with muscular and glandular parts; includes Filarioidea transmitted by insects.

Class Nematomorpha

Develop as parasites of invertebrates; free-living; reproduce sexually as adults; up to 1 m long; elongated; cylindrical; swimming or crawling by sinuous movements.

Order Gordioidea. Freshwater or terrestrial; single ventral hypodermal cord; cell-filled body cavity.

Order Nectonematoidea. Marine; dorsal and ventral hypodermal cords; fluid-filled body cavity.

Critical appraisal. The true evolutionary relationships of the five aschelminth classes is a problem because it is difficult to reconstruct a possible common ancestor and because there are no relevant fossils. Since it is a fundamental principle of zoology that the classification of animals should be based on their evolutionary history, some zoologists treat each of the five classes as a phylum, thereby implying that they are not necessarily more closely related to one another than to some other simple invertebrates. Except for the Nematoda, there is little difficulty in subdividing the classes into orders (or separate phyla into classes).

With the Nematoda it is difficult to give a satisfactory classification. One reason for this is that those most concerned, marine biologists, plant pathologists, and animal parasitologists, have worked in isolation, each putting forward classifications that raise the ranks and increase the subdivisions of the nematode groups on which they work, while combining and reducing the importance of other groups. The leading authorities have proposed irreconcilable hypotheses on the evolutionary history of the nematodes, which underline the different classifications.

BIBLIOGRAPHY. Two comprehensive classical works on the aschelminths are L.H. HYMAN, *The Invertebrates,* vol. 3, *Acanthocephala, Aschelminthes, and Entoprocta, the Pseudocoelomate Bilateria* (1951); and PIERRE P. GRASSÉ (ed.), *Traité de zoologie: anatomie, systématique, biologie,* vol. 4, fascicle 2, *Nèmathelminthes (nèmatodes),* and fascicle 3, *Nèmathelminthes (nèmatodes, gordiacés), rotifères, gastrotriches, kinorhynques* (1965). More recent accounts include PAUL A. MEGLITSCH, *Invertebrate Zoology,* 2nd ed. (1972); and VICKI PEARSE *et al., Living Invertebrates* (1987), especially ch. 12 and 13. Papers on various aspects of rotifers are collected in the published proceedings of the INTERNATIONAL ROTIFER SYMPOSIUM; four meetings had been held by 1987.

There is a much larger literature on the nematodes than other aschelminths because of their importance to humans. Introductory works include NEIL A. CROLL and BERNARD E. MATTHEWS, *Biology of Nematodes* (1977); ARMAND MAGGENTI, *General Nematology* (1981); WARWICK L. NICHOLAS, *The Biology of Free-Living Nematodes,* 2nd ed. (1984); and GEORGE O. POINAR, JR., *The Natural History of Nematodes* (1983). Parasitic forms are discussed in WILLIAM R. NICKLE (ed.), *Plant and Insect Nematodes* (1984); GERALD D. SCHMIDT and LARRY S. ROBERTS, *Foundations of Parasitology,* 3rd ed. (1985); and NORMAN D. LEVINE, *Nematode Parasites of Domestic Animals and Man* (1980). Nematodes in biologic research are the subject of BERT M. ZUCKERMAN (ed.), *Nematodes as Biological Models,* 2 vol. (1980).

(W.L.N.)

Asia

Asia is more a geographical term than a homogeneous continent. The most diverse of all continents, it extends over a latitudinal range of 92° from north to south, has the greatest range of land height of any continent, is subject to climates ranging from Arctic to tropical, and produces the most varied forms of vegetation and animal life in consequence. Similarly, its patterns of human adaptation range from the lives of the nomads of Arabia and Central Asia to those of the crowded cities of the Yangtze Basin and the Gangetic Plain.

Asia is the largest continent, occupying 30 percent of the world's land area, with a mainland area of approximately 17,000,000 square miles (44,000,000 square kilometres). To the east the Pacific Ocean forms its natural boundary; the chains of islands that include the component territories of Japan, Taiwan, the Philippines, and Indonesia are part of Asia. To the west the boundary is generally regarded as running southward along the eastern slope of the Ural Mountains, after which it turns approximately southwestward to the northern shore of the Caspian Sea, from where it again runs generally southwestward to the Kuma River, thence following the Kumo-Manych Depression northwestward to the Sea of Azov; from the Black Sea, the coast of Asia Minor and the Mediterranean coast of the Levant form Asia's western limits, after which the boundary runs south across the Isthmus of Suez and along the coast of the Arabian Peninsula.

This article treats the physical and human geography of Asia, followed by discussion of geographical features of special interest. For discussion of individual countries of the continent, see specific articles by name, *e.g.,* CHINA, INDIA, and JAPAN. Other Asian countries are treated in articles on regions under the titles ARABIA and SOUTHEAST ASIA, MAINLAND. For discussion of major cities of the continent, see specific articles by name, *e.g.,* DELHI, PEKING, and TOKYO–YOKOHAMA METROPOLITAN AREA. For discussion of the history of specific Asian regions, see the articles PALESTINE and ISLĀMIC WORLD, THE. Related topics are discussed in articles on religion (*e.g.,* BUDDHISM, THE BUDDHA AND; HINDUISM; and ISLĀM, MUḤAMMAD AND THE RELIGION OF) and arts and literature (*e.g.,* CHINESE LITERATURE; JAPANESE LITERATURE; and SOUTH ASIAN ARTS). For further references, see also the entries for these topics in the *Index.*

The article is divided into the following sections:

PHYSICAL AND HUMAN GEOGRAPHY

General considerations

Asia is the most populous of the continents, containing more than half the human race. The continent includes the two most populous countries in the world—China and India—in addition to Japan and Indonesia, each of which has a densely packed population; among non-Asian nations these last two countries are surpassed in numbers only by the populations of the Soviet Union (the territory of which also extends into Asia) and the United States. Two other Asian countries with very large populations are Bangladesh and Pakistan. During most of the 20th century the population of Asia grew at a rate faster than the world average. There is a general awareness in Asia, especially in the most populous countries, of the need for some regulation of growth. Nevertheless, it appears that—barring an unexpected breakthrough in the acceptance of birth control—the population of Asia may reach 3,400,000,000 by the year 2000.

Origin of the name Asia

The name Asia is very ancient, and its origin has been variously explained. The Greeks used it to designate the lands situated to the east of their homeland. It is also believed that the name may be derived from the Assyrian word *asu,* meaning "east." Another possible explanation

is that it was originally a local name given to the plains of Ephesus and gradually extended to include Anatolia (contemporary Asia Minor) and the rest of the continent.

Geological development has resulted in a configuration that includes the Arabian massif and the plains of Iraq; the mountain belts of Tūrkey, Iran, and Afghanistan; the great Himalayan mountain chain stretching from Afghanistan to the Burmese peninsula; the Indo-Pakistan subcontinent; Central Asia; the vast Siberian lowlands extending from the Urals to the Pacific; and the great island chains that sweep in arcs from Japan to Indonesia.

As a result of this configuration Asia's population is unevenly distributed. Thus, while there has been a concentration of population on the Arabian plains and river valleys, in the Indo-Pakistan subcontinent, in Central Asia, especially China, and to some extent in the Pacific borderlands and on the islands, there are vast areas with a low density of population.

Siberia, which represents approximately one-third of the land area of Asia, has an estimated population of about 11 persons per square mile (four persons per square kilometre), compared with an average density of 156 persons per square mile in the rest of Asia.

The mountain systems of Central Asia not only have provided the great rivers with water from their melting snows but also have formed a forbidding natural barrier that has influenced the movement of peoples into the area. Migration is possible only through mountain passes. As a result the historic movement of population has been broadly from the arid zones of Central Asia through the mountain passes into the Indo-Pakistan subcontinent, from China through Southeast Asia to modern Indonesia and Malaysia, and from the Arabian Peninsula and from India across the Bay of Bengal into Indonesia and Malaysia. The Japanese people and, to a lesser extent, the Chinese have remained ethnologically more homogeneous than the populations of other Asian countries.

Asia's religious heritage

Asia has been the birthplace of all the great world religions, including Buddhism, Christianity, Hinduism, Islām, Judaism, Sikhism, Taoism, and Zoroastrianism. Of these, only Christianity moved westward; it subsequently exerted little influence, in its religious aspects, on Asia, although many Asian countries have Christian minorities. Buddhism has had a greater impact outside its birthplace in India and is prevalent in various forms in China, Korea, Japan, the Southeast Asian countries, and Sri Lanka. Islām has spread out of Arabia eastward to Afghanistan, Pakistan, and India, and thence to Malaysia and Indonesia, as well as west and south to several areas of Africa. Hinduism, basically a non-proselytizing religion, has been mostly confined to the Indian subcontinent.

Before the Industrial Revolution in the 18th and 19th centuries, most principal technical achievements began in Asia. Three millennia before Christ, Asians knew the arts of cooking and pottery and the use of fire for the smelting of ores. They had already progressed from nomads to cultivators, using irrigation and practicing crop rotation. They had learned to domesticate animals and had invented the wheel, the harness, the saddle, and the chariot. They had begun to use a form of paper and had developed elaborate scripts. Early Asians were familiar with wood carving, stonecutting, and the casting of metals and left monuments of stone and metal that still evoke admiration and astonishment. They used the art of calculation, including the decimal system, and employed means of measurement. Various indigenous systems of medicine were developed, many of which are still in use. In ancient times major Asian empire-states arose, employing intricate systems of laws and regulations and delegating power and authority to institutions of government at various levels.

The impact of the West

In the 15th century Asia's material advances were envied by people in Europe. The fabled prosperity of Asia prompted the movement of adventurous spirits from Western nations to Asia and led to the eventual conquest of many Asian countries. The Western impact on the civilizations of these Asian countries, on their attitudes, and on the development of their political institutions and economic systems will only be referred to briefly here. Even though almost all Asian countries have attained their independence, the era of European conquest and colonization has left an indelible mark on much of Asia. The Asian countries received many benefits by way of the establishment of an infrastructure, a system of posts and telegraphs, railway and road networks, ports and harbours, public health systems, modernized educational systems, and the rudiments of an apparatus of modern Western-style government—civil, judicial, and military—as well as the impetus for publishing newspapers and magazines. On the other hand, there was little progress in industrialization. The effect of the neglect of industrial development during these years of colonization is still noticeable in commercial relations among many Asian countries. Broadly, it may be said that the role of most Asian countries—with the exception of Japan and a few others that did not feel the impact of conquest and colonization—was that of primary producers exporting their products to the metropolitan countries, where they were turned into finished products and reexported back to the Asian countries. As a result, most Asian countries have economies that are imbalanced, and efforts to produce greater economic integration and coordination among Asian countries have had only limited success.

In addition to the uncertain economic situation, the lack of any ethnic, religious, or cultural homogeneity among the Asian peoples has made it difficult for a common Asian political consciousness to arise. In the struggle for independence most of the Asian countries developed a political philosophy favouring nationalism. Furthermore, since achieving independence, many Asian countries seem to have lost the unifying force of emergent nationalism and are groping to find a substitute for it. Even the doctrine of nonalignment, which formerly seemed to be common to several Asian countries, has lost its impetus.

In the economic field Asian countries are caught between two conflicting forces. On the one hand, the need to ensure improved levels of living has led to a desire to move toward orderly and planned economic and social development. On the other hand, many countries there have a long tradition of otherworldliness and austerity. This conflict of forces may produce a new philosophy of economic development in Asia that will reconcile the need for material progress with the imperative of not abandoning spiritual and religious values.

Asia's entry into the nuclear age

The political forces that are emerging in Asia cannot be ignored. China has begun to play an important role in world affairs; until 1974 it was the only nuclear power in Asia. Japan has become one of the great industrial nations of the world and clearly has the capability to develop into a nuclear power, although the Japanese, in the light of their own experience at the end of World War II, have accepted a constitution renouncing war as a sovereign right of the nation and abjuring the threat or use of force as a means of settling international disputes. India became a nuclear power in 1974. Nuclear proliferation in Asia, coupled with the region's political instability, is a matter of growing international concern.

The modern political history of the continent has resulted in part from the political vacuum created by the withdrawal of the colonial powers. The continuing disturbed political situation in the Middle East illustrates this fact. The difficulties that arose between India and Pakistan after their independence in 1947 and between Indonesia and Malaysia from 1963 to 1968 are clearly part of the same pattern, as are the conflicts that, during the 1960s, 1970s, and 1980s, produced war in the countries of Indochina.

With a new awakening of political consciousness, with a new spirit of regional cooperation, and with a new urge at the grassroots level for the improvement of living standards, there are positive factors at work that could make possible a resurgence of Asia. The high rate of population growth throughout most of Asia constitutes perhaps the greatest negative factor. Several Asian countries have shown, however, that even under existing circumstances great progress can be made in the limitation of population growth. If this trend becomes more widespread, the chance that Asia will become economically stronger and socially better developed will be correspondingly increased.

Geological history

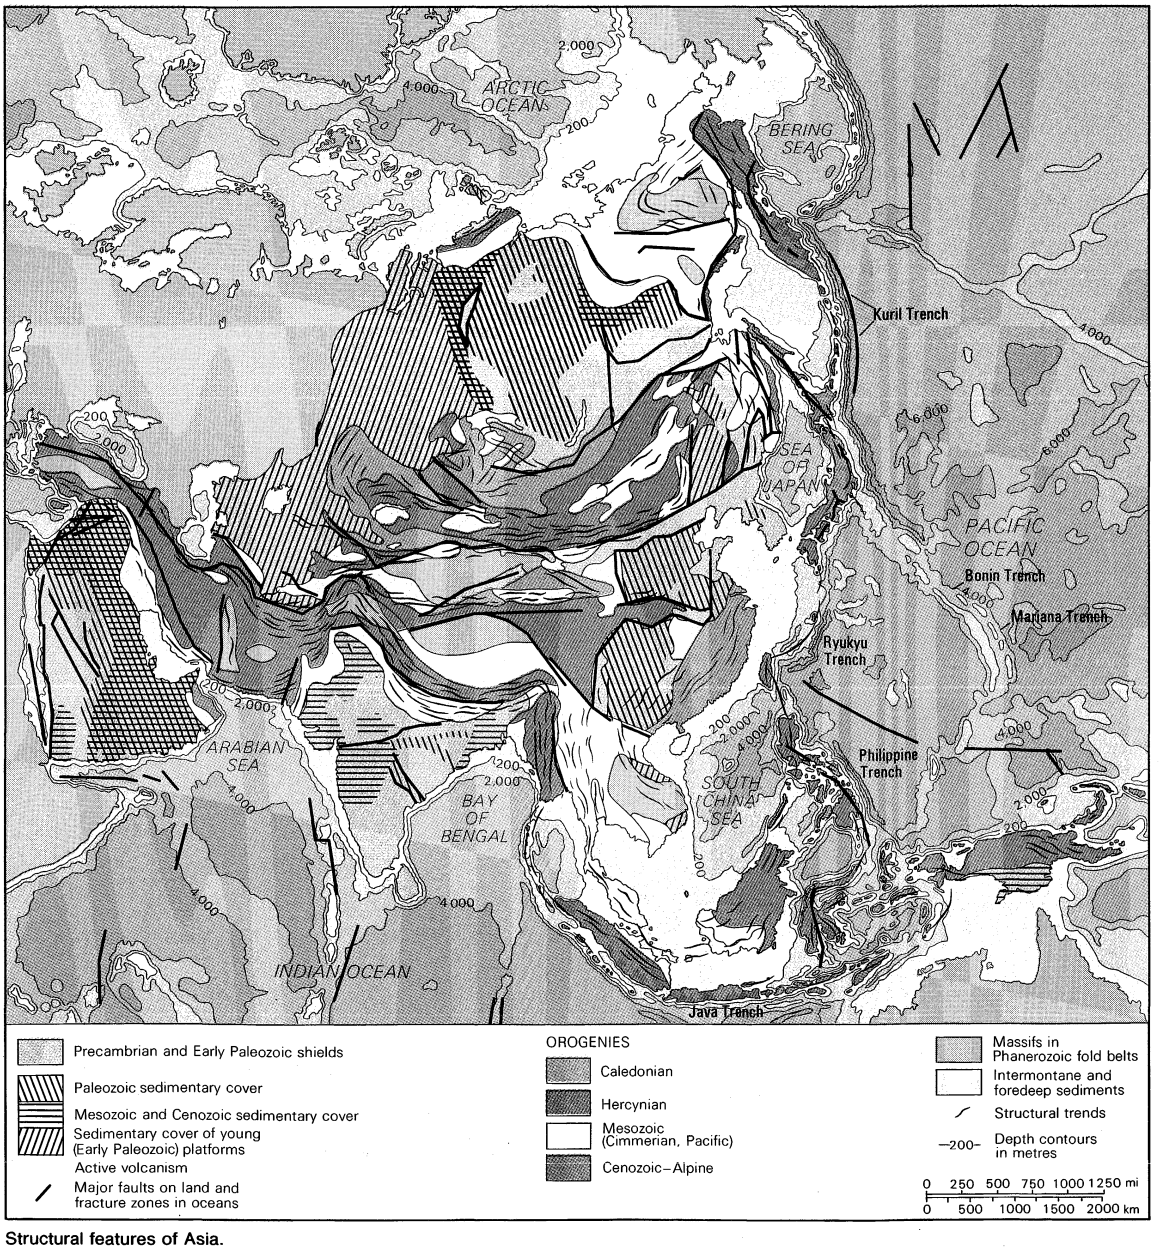
ELEMENTS AND PROCESSES IN THE MAKING OF THE CONTINENT

Platforms, shields, and geosynclines. Asia consists, in part, of several platforms that have been subjected to almost no folding since the Precambrian Era, which lasted from 4,600,000,000 to 570,000,000 years ago. It also consists of vast regions of folding, formed later in various periods or ages, that originated in geosynclines (large and generally linear troughs that gradually subsided over long periods of time and subsequently became filled with thick accumulations of sediments). Contemporary geosyncline systems, still not consolidated by folding, join the shores of the Asian mainland to the Malay Archipelago, underlie bordering seas such as the Sea of Japan and the Sea of Okhotsk, and extend to the island arcs of the Pacific Ocean.

The four continental platforms

The principal continental platforms of Asia are the Siberian Platform in the north, the Chinese Platform in the east, the Indian Platform in the south, and the Arabian Platform in the southwest. Those parts of the platforms where the Precambrian crystalline bedrock is not covered by a sedimentary deposit are called shields; almost all the shield areas were dry land during the last 500,000,000 years and include the Aldan Shield in eastern Siberia, the North Chinese Shield, the Indian Shield in peninsular India, and a large part of the Arabian Shield. In addition, the Russian Platform has played an important role in the geological history of western Asia. Along its western edge the folded structures of the Urals and of Kazakhstan were formed at the end of the Paleozoic Era (which lasted from 570,000,000 to 225,000,000 years ago).

Endogenetic and exogenetic forces. Two geological forces have molded the Asian continent into its present configuration. On the one hand are the endogenetic forces, which represent vertical or lateral forces originating deep within the Earth and that produce fissures in the Earth's crust through which magma, or molten rock, wells up in the form of lava or forms intrusive bodies; when it solidifies, this rock, called basalt, is described as igneous (rock solidified from the molten state). Exogenetic forces, on the other hand, represent those endless processes of erosion and sedimentation that take place on the Earth's surface, where rocks are subjected to weathering and denudation. Associated with these two forces is a principle of equilibrium called isostasy, which represents a theoretical balance maintained between large sections of the Earth's crust, which act as though they were floating on a denser underlying layer. In maintaining this equilibrium, less



Structural features of Asia.

dense material rises vertically while denser material sinks.

The mountain-building process. Mountain building, or orogenesis, is the result of folding or thrusting, which occurs when thousands of feet of sediment accumulate in geosynclines, causing them to sink deeper, thus either activating, or interacting with, vertical or lateral endogenetic forces. In this way the geosynclines themselves, representing zones of structural weakness between crustal blocks or platforms, are folded upward into new mountain systems—a process associated with the upwelling of granitic magma and the deformation of metamorphic rock (rock that has been altered in composition, texture, or internal structure as a result of heat and pressure).

THE TERRITORIAL FORMATION OF ASIA

Blocks and zones of folding

As a result of folding, the intrusion of granite, the swelling of the Earth's crust in response to pressures, the isostatic uplifting (uplifting caused by equal pressure on all sides) of mountains, and the drying up of marine basins that lay in the geosynclinal regions between the continental platforms, ancient blocks of the Earth's crust and weaker zones of folding were united to form the Asian continent. From the formerly inundated geosynclines, several belts of folding—including the Alpine-Himalayan belt—were formed in the Late Paleozoic Era, the Mesozoic Era (from 225,000,000 to 65,000,000 years ago), and the Cenozoic Era (which is dated from 65,000,000 years ago to the present time).

The composition of the continental platforms. *The Siberian Platform.* Greatly deformed schists (metamorphic rocks containing micaceous minerals), gneisses (rocks in which bands rich in granular minerals alternate with bands containing schistose materials), and granites of the Precambrian form the basement of the Siberian Platform. Extending between the river basins of the Yenisey and the Lena, it surfaces within the boundaries of the Aldan Shield, north of the Stanovoy Mountains, and the Anabar Massif (mountainous mass), west of the Lena River and south of the Arctic. In other areas the crystalline bedrock is overlain almost horizontally by sedimentary rock, including marine and salt lagoon deposits from the Cambrian Period (from 570,000,000 to 500,000,000 years ago), marine deposits from the Ordovician Period (from 500,000,000 to 430,000,000 years ago) and the Silurian Period (from 430,000,000 to 395,000,000 years ago), as well as deposits from the Permian Period (from 280,000,000 to 225,000,000 years ago) containing strata of coal. In the western part of the platform, primarily along the edges and in the centre of the broad Tungus syncline (a basin formed by a downward bend of rock strata), east of the Yenisey River, the Paleozoic strata are cut by numerous intrusive sills (layers) of a dark, fine-grained, basaltic rock known as traprock, locally associated with copper and nickel ores and volcanic pipes (cylindrical veins of volcanic origin) containing diamond-bearing kimberlite (an ultrabasic rock of a subcrustal origin). In the southern part of the platform, the lower layers of the sedimentary cover consist of thick layers of Precambrian marine sediments analogous to the Sinian System in China. They were slightly disturbed at the time of the Baikal folding, which occurred at the end of the Precambrian and during the Cambrian Period. Along the northern and eastern edges of the platform, there is widespread distribution of coal-bearing deposits from the Jurassic Period (from 190,000,000 to 136,000,000 years ago) and the Cretaceous Period (from 136,000,000 to 65,000,000 years ago). Mesozoic sedimentary series reach particularly great thickness in the depressions of the Vilyuy River and in the depression near the Verkhoyansk Mountains, which run parallel to the Lena River, both areas having natural gas deposits.

The Chinese Platform. The Chinese Platform consists of four separate massifs—the North Chinese, the South Chinese, the Tarim, and the Tibetan—which probably constituted a single platform in the Precambrian. This platform appears to have broken up at the beginning of the Paleozoic Era, at which time geosynclinal downwarps were formed between the separated blocks. As a result of the folding that took place in these downwarps during the Paleozoic and Mesozoic eras, mountain ranges arose, including the Kunlun and the Tsinling (both in China). The Precambrian bedrock is exposed on the surface primarily within the boundaries of the North Chinese massif, which contains large deposits of ferruginous (iron-bearing) quartzite.

The four Chinese massifs

During the Silurian Period and the Devonian Period (from 395,000,000 to 345,000,000 years ago), the southern part of the platform—as well as almost all of it during the later part of the Cretaceous Period—was subjected to folding and faulting deformations that were considerably more intense than those experienced by platforms elsewhere in the world. These deformations were accompanied by intrusions of ore-bearing granite.

The sedimentary rocks overlying the folded bedrock (basement) of the Chinese Platform represent, for the most part, marine sediments of the Precambrian and Lower Paleozoic (Cambrian, Ordovician, and Silurian) eras; marine and continental deposits from the Devonian, Carboniferous (from 345,000,000 to 280,000,000 years ago), and Permian periods, some of which are coal-bearing; and thick layers of rocks of the Mesozoic Era, as well as layers from the Cenozoic Era in some of the depressions. Among the Mesozoic deposits there is an abundance of red fragmented rocks that were formed when the prevailing climate was hot and dry. The sedimentary cover is thickest in the synclines of the Ordos Desert region of Inner Mongolia, of the Chinese province of Szechwan, and of the Lower Huang Ho, as well as in the Mesozoic downwarp of southeastern Korea.

The Arabian Platform. The Arabian Platform, like the Indian Platform, is usually considered to have formed a part of the continent of Gondwana, which began to split apart during the Paleozoic Era. Gondwana is believed to have included Africa, Australia, South America, and possibly Antarctica, and the two platforms do have much in common with these continents. The ancient basement of Arabia is composed of Precambrian crystalline rocks, which crop out in the western part of the peninsula as the Arabian Shield. To the north and east the bedrock is buried under thick layers of horizontal or only slightly disturbed Paleozoic rocks; these are mainly sediments

The crystalline bedrock

from the Jurassic and Cretaceous periods and from the earlier part of the Cenozoic Era. These sedimentary strata lie within the bounds of the Mesopotamian downwarp, which occurs in the Persian Gulf region; here the bedrock has sunk to a depth of about two and a half miles and contains large amounts of petroleum.

The Indian Platform. The Indian Platform covers a large part of peninsular India and Sri Lanka. It consists of a Precambrian crystalline shield in which broad grabens (blocks that have been downthrown along faults in the rock on either side) along the Godāvari River and along the Dāmodar River farther to the northeast are overlain by horizontal deposits of the Gondwana system. These were laid down between early Carboniferous and late Jurassic time. The Deccan Plateau, which forms the backbone of peninsular India, is itself overlain by basaltic lavas (traprock from the Late Cretaceous Period and the Early Cenozoic Era). Along the edges of the platform the bedrock is covered by marine deposits from the Jurassic, Cretaceous, and Tertiary (from 65,000,000 to 2,500,000 years ago) periods; in the Gulf of Cambay region, off the west coast of India, these contain petroleum deposits. To the north, the bedrock lies under Cenozoic deposits that reach their greatest thickness in the northern part of the Ganges River Basin, in the marginal downwarp at the foot of the Himalayas, and in the Indus Basin. Deposits of gas and petroleum are associated with the Cenozoic marine and continental sediments, while the Precambrian rocks of the shield contain iron and manganese ores. A small Precambrian outcrop, the Shillong Plateau massif, occupies the eastern part of the platform.

Mountain folding. *The Late Precambrian and the Paleozoic eras.* Those Asian zones that were folded during the Late Precambrian and Early Paleozoic eras consist of various kinds of weakly and strongly metamorphosed volcanic and sedimentary rocks. They are cut by intrusions of granite, granodiorite (a quartz-bearing rock formed at great depth), gabbro (a coarse-grained, dark igneous rock), diabase (a rock of basaltic composition), and serpentinous ultrabasic rocks (*i.e.,* igneous rocks containing less than 45 percent of silica). Deposits of gold, copper, tungsten, polymetallic (*i.e.,* containing many metals), and other ores are associated with these rocks in many areas.

Regions of Late Precambrian and Early Paleozoic folding border the Siberian Platform to the west and south. They compose the Yenisey Ridge, the Eastern and Western Sayan ranges, the Kuznetsk Alatau, the higher (alpine) part of the Soviet Altai, the Mongolian Altai, and a considerable part of the Khangay and Tannu-Ola ranges. Caledonian folding—which is to say, folding that took place during the Caledonian (*i.e.,* Silurian–Devonian) orogeny (mountain-building process)—is also found in the Taymyr Peninsula and on the Severnaya Zemlya Islands, in central Kazakhstan, in the northern chains of the Tien Shan, in the Kunlun Range, and in southeastern China. In the portion of the Caledonian orogeny that occurred during the Devonian Period, a number of large depressions were formed. These included the Kuznetsk and Minusinsk basins and the depressions in the central part of Tuva. Large reserves of coal are concentrated in the deposits laid down in these regions in the Carboniferous and Permian periods.

Areas of depression

The fold structures of the Hercynian orogeny were formed as the result of tectonic activity (movements of the Earth's crust) that occurred during the Middle Paleozoic (Devonian) and Late Paleozoic (Carboniferous and Permian) eras; these constitute a broad arc traversing the central part of the continent. The Hercynian fold structures have a northeasterly and southerly trend between the Russian and Siberian platforms, and a northwest trend in Kazakhstan, along the Salair Ridge, and in the southern Altai; run east to west in the Tien Shan, Kunlun, and Tsinling ranges; and run northeast in northeastern China. According to geophysical data, the Hercynian fold system of the Urals, covered toward the south by a horizontal layer of Mesozoic and Cenozoic deposits, is joined with the Tien Shan. In addition, a branch proceeds from it which passes through the Mangyshlak Peninsula toward the Donets Basin.

A considerable area of the original Paleozoic fold zones was levelled by erosion and subsequently sank, forming large depressions that were filled to an overall depth of between one and four miles with virtually undisturbed marine and continental sediments of the Mesozoic and Cenozoic eras. Associated with these depressions are the vast West Siberian Plain; the Turgay Downwarp, located to the east of the southern Urals; the Turan Platform in the Amu Darya and Syrdarya basins; the depressions of Lake Balkhash and of the lower course of the I-li Ho (river); the Dzungarian Basin; the Fergana and Turfan depressions; the Tsaidam Basin; the Tungliao or Manchurian lowlands in the Sungari River Basin; and others. Only the intermontane depressions, those of Fergana and Turfan, were affected by slight folding; in the other depressions the strata lie almost horizontal. Deposits of petroleum and gas are found in almost all these depressions, from Western Siberia to the Tsaidam Basin and Manchurian Plain in China.

The Mesozoic Era. The belt of Mesozoic folding includes northeastern Siberia (the Verkhoyansk and Chersk ranges), the Sikhote-Alin Range in the Amur region, a large part of Indochina, and possibly the Trans-Himalayas. Folded structures, intersected by numerous granite intrusions, were formed in all these areas as a result of the crumpling of thick layers of geosynclinal deposits of the Permian, Triassic (from 225,000,000 to 190,000,000 years ago), Jurassic, and Early Cretaceous periods. Associated with these folding belts are gold, tin, and polymetallic ores. Moderately large blocks—such as the Kolyma, Indosinian, and other massifs, which resemble the Precambrian or Paleozoic platforms in their structure—are enclosed between the branches of the broad Mesozoic folding zones.

Mesozoic folding zones

Mesozoic folding and the upwelling of magma (molten rock) also affected adjacent areas, such as the Hercynian mountain zone of Mongolia and the Transbaikalia, the Caledonian zone of South China, and a considerable part of the Chinese Platform. Deposits of tungsten, tin, mercury, and other metals are found in these areas.

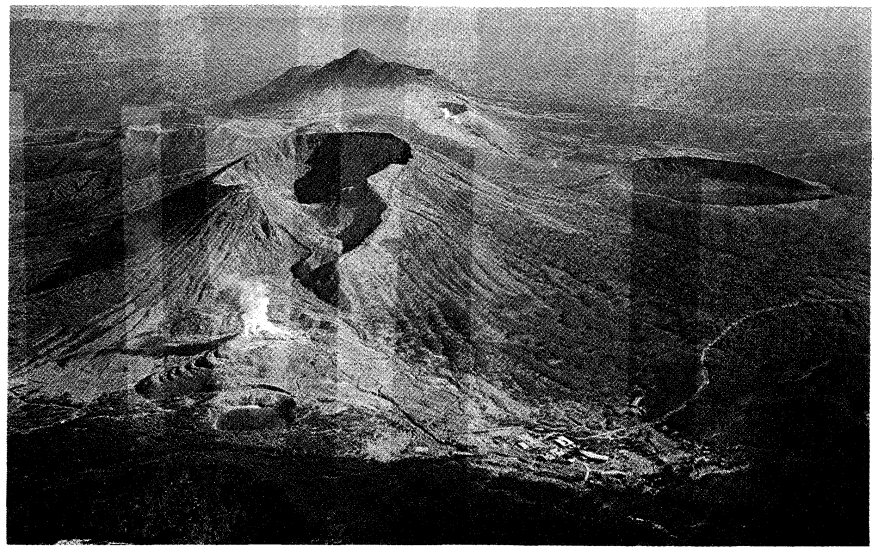
The Cenozoic Era. During the Early Cenozoic Era, a volcanic belt was formed that extends from the Chukotsk Peninsula and the shores of the Sea of Okhotsk through the eastern slopes of the Sikhote-Alin Range, in South Korea, to the southeast coast of China. It runs approximately along the border of the Mesozoic and Cenozoic fold zones. This volcanic belt is composed of massive accumulations of basaltic, andesitic, and acidic lavas dating from the Cretaceous and Early Tertiary periods, with many granite intrusions. It would seem that a series of volcanoes extended through this belt in a long arc, resembling the volcanic island chains of East Asia.

The two Cenozoic fold belts

Areas of Cenozoic folding are confined to two zones—the Alpine–Himalayan belt that traverses Asia from west to east, and the Pacific Ocean belt that runs through the island arcs to unite with the Alpine–Himalayan belt in Indonesia. The Alpine–Himalayan belt was essentially formed on the site of the extensive Tethys Geosyncline. This geosynclinal ocean, the remains of which are to be seen in the Mediterranean and Black seas and in the marine basins of Indonesia, divided two distinct continents—Gondwanaland and Angara, or Angarida—during the Paleozoic, Mesozoic, and Early Cenozoic eras. In the Alpine–Himalayan belt itself there may be distinguished two—and in places three—curving folded mountain ranges; at times these are close together, and at times they diverge. These ranges represent slabs or blocks that were overthrust onto one another or onto the edges of the neighbouring platforms, forming gigantic and complex anticlines (convex folds). The internal parts of their folded structures were sometimes already formed during the Mesozoic Era from Mesozoic and Paleozoic sediments that had accumulated in the Tethys Geosyncline, while some slopes and foothills were formed of Tertiary deposits as a result of less violent folding. The thick sand–clay strata of the Cenozoic Era, which accumulated at the base of the mountains and in depressions in front of them, often contain gas and petroleum.

Northern and southern anticlinoria

The northern series of alpine anticlinoria (*i.e.,* series of anticlines and synclines so arranged that together they form a general arch or anticline) is formed by the Greater



Kirishima Range on Kyushu, Japan's southernmost island; it includes several active volcanoes.
Kokunai Jigyo Kouku

Caucasus Mountains between the Black and Caspian seas; the Turkmen–Khorasan ranges east of the Caspian; and the Selseleh-ye Safīd Kūh (Paropamisus), Pamir, Gissar, and Alai ranges. West of this system of ranges runs still another series of folded structures, separated from the first series by deep troughs. These consist of the Pontic Mountains, the Lesser Caucasus, and the Elburz Mountains. In the related depressions—the Black Sea, the Kolkhida (Rion) and Kura-Aras Lowland, and the South Caspian basin—are concentrated layers, from three to six miles thick, of Cenozoic deposits, which are folded along the edges of the depressions. The southern series of anticlinoria is composed of the ranges of the Taurus, Zagros, Makran and Soleymān mountains, the Hindu Kush, and the Himalayas. Between the northern and southern series of folded mountain ranges are situated the massifs of Menderes and Kirşehir in Turkey, and the central Iranian massif. The small Georgian block occupies a similar position between the Greater and Lesser Caucasus. All these massifs represent regions consolidated by Precambrian or Paleozoic folding, with surface outcrops of bedrock in some places; in others, the bedrock is covered by weakly folded sedimentary deposits of the Paleozoic, Mesozoic, and Cenozoic periods.

Mountain folding in progress. In the folded ranges of Burma, Malaysia, and Indonesia there occurs a transition from the belt of alpine folding—formed on the site of geosynclines that were already landlocked and drained—to a contemporary geosyncline system in which folding is not yet complete. This system, the youngest, occupies the area between the Asian continent itself and the Pacific Ocean and includes the folded systems of the Koryak Range; the Kamchatka Peninsula; Sakhalin Island; Borneo; Celebes Island; the archipelagoes of the Komandorskiye (Commander), Aleutian, and Kuril islands; and the islands of Japan, the Ryukyus, Taiwan, the Philippines, the Moluccas, and the Sundas. Within its structure, geoanticlinal uplifts, consisting of island arcs and mountainous peninsulas, may be distinguished, as well as intermontane troughs, the contemporary geosynclinal downwarps of the seas bordering Asia, and deep-sea trenches on the periphery of the Pacific and Indian oceans. The axial parts of the folded ranges and island arcs in this zone are usually composed of Mesozoic and Upper Paleozoic deposits; they are cut by recent (Tertiary) intrusions and are crowned with a series of active volcanoes. The Tertiary deposits of the intermontane troughs attain great thickness and contain petroleum deposits, such as those of Sakhalin, Japan, and Indonesia; they were folded during the Miocene Epoch (from 26,000,000 to 7,000,000 years ago) and the Pliocene Epoch (from 7,000,000 to 2,500,000 years ago). In some places there are folds in the deposits sedimented in the Quaternary Period (which began 2,500,000 years ago), and as a result of large and recent fractures, Cenozoic lavas consisting of basalts and andesites cover vast areas of the island regions of East Asia.

The youngest geosyncline system

The Alpine–Himalayan belt and, in particular, the Pacific Ocean belt are both characterized by the active tectonic processes peculiar to geosynclinal systems. A comparatively rapid horizontal shifting of different parts of the Earth's crust at a speed of between one-quarter and three-quarters of an inch a year is taking place, according to geodetic measurements taken in Japan and Tadzhikistan. Also characteristic is intensive vertical movement. This occurs in the form of the uplifting of geoanticlines, accompanied by the sinking of neighbouring depressions and strong seismic activity. Disturbances of the isostatic equilibrium are concentrated in zones where the contrasting nature of the vertical movement is the most clearly manifest. The foci of earthquake shocks are not confined only to those fractures that rupture the Earth's crust but include also the deeply buried zones of folding that are associated with fractures. These zones are tilted from the deepwater trenches of the Indian and Pacific oceans toward the Asian continent at angles of from 20° to 70°. The sources of the earthquake shocks lie from 10 to 450 miles (16 to 720 kilometres) deep (about 150 miles deep in the Hindu Kush region). The characteristic movement originating from these foci is overthrust folding and upthrusting, and it indicates extreme compression of the Earth's crust. It is assumed that along the deep fractures there occurs an overthrusting of the island arcs onto the floor of the Pacific Ocean, an underthrusting of the Indian Platform under the Himalayas, and an analogous movement along the buckled edges of all the other outlying downwarps and deep-sea trenches. A considerable thickening of the Earth's crust is taking place in the high mountain regions of Central Asia and the Himalayas; here the Earth's crust is up to 40 or 50 miles thick, as opposed to 20 to 25 miles thick on the low plains and flatlands. This thickening may also be related to the lateral compression that is folding the Cenozoic strata.

Foci of earthquake shocks

THE PATTERN OF ASIA'S PALEOGEOGRAPHIC DEVELOPMENT

The Precambrian era. Although, on the crystalline shields of Asia, rocks may be found that are known to have been formed 3,000,000,000 years ago, an adequate description of the paleogeography of the continent—that is to say, of its geography in different eras and periods of geological time—can be given only for the last 1,000,000,000 years. At the beginning of this period, primitive forms of animal and plant life appeared, primarily as algae, when the vast marine basins of the Precambrian covered the

Asian seas of the Precambrian

Geological structure of Asia and (inset) New Guinea.

geosynclinal regions of the Urals, the Tien Shan, the Altai, the Western Sayans, and South China, as well as the southern parts of the Siberian Platform and the entire Iranian Massif. At that time continental sediments, including glacial deposits, accumulated over a considerable part of the Chinese Platform, while regions of erosion where detrital material was removed were represented by the shields.

The Cambrian and Ordovician periods. During the Early Cambrian Period, the seas began to transgress, covering almost all of the Siberian Platform, a large part of the Chi-

nese Platform, and the northern parts of the Arabian and Indian platforms. The transgression reached its maximum extent in the middle of the Cambrian Period, and the seas began to recede during the Late Cambrian, particularly from the Siberian Platform. But the sea advanced again during the Early Ordovician Period, covering almost the entire area of the Chinese Platform. The Cambrian and Ordovician deposits on the platforms were primarily limestone, but there were also red sand–clay rocks. Deposits of rock salt were associated with the sand–clay rocks in the southern part of the Siberian Platform, in the northwestern part of the Indian Platform, and in the eastern part of the Arabian Platform. Such deposits, and the nature of the marine animal life known from the fossil record, indicate that these three platforms were situated in a hot climatic zone; judging from the paleomagnetic data, the Equator then passed through the southern part of the Siberian Platform.

The Silurian Period. The seas receded during the course of the Silurian Period; red sediments and evaporites (sediments formed as a result of evaporation) continued to be laid down in the western half of the Siberian Platform and in other areas. At the end of the Silurian Period and in the course of the Devonian Period, all the platforms were uplifted and became dry land, except for some of the marginal areas and freshwater basins. Meanwhile, during the Cambrian, Ordovician, and Silurian periods, marine sandy-clayey and carbonate sediments, tuffs (rocks formed of compacted volcanic fragments), and lavas continued to be deposited in the geosynclines that separated the Russian, Siberian, and Chinese platforms from each other, as well as from Gondwanaland. The basins, which were separated from each other by islands, gradually dried up as the result of the Baikal and Caledonian folding; these included the basins of the Sayans, a considerable part of the Altai, the Khangarulsk, Tannu-Ola, central Kazakhstan, Kunlun, and South China. Large land areas were also subjected to volcanic activity.

The Devonian, Carboniferous, and Permian periods. The paleogeography of the Late Devonian, Carboniferous, and Permian periods is somewhat similar. In place of the present continent of Asia there existed, as before, the separate, small continental blocks of the three northern platforms, with the enormous continent of Gondwanaland to the south of them. Carbonaceous, detrital, and volcanic rocks continued to be deposited in the seas of the geosynclines separating these blocks. Calcareous sediments were also characteristic of the seas covering the massifs of Iran and Turkey, part of the Siberian Platform during the Devonian Period, and the southern half of the Chinese Platform in the Carboniferous Period. But the area of the marine geosynclinal basins was greatly reduced as a result of subsequent Hercynian folding. The basins between the Russian, Siberian, and Chinese platforms almost disappeared toward the middle of the Permian Period, at which time the area of present-day Mongolia and Western Siberia dried up. Coal-bearing strata that accumulated during the Late Carboniferous and Early Permian periods on the Indian, Chinese, and Siberian platforms and in the intermontane Kuznetsk, Minusinsk, and Tuva basins provide evidence that a humid climate then prevailed. In India these strata are underlain by glacial deposits of the Carboniferous Period.

Virtual disappearance of the landlocked basins

The Triassic and Jurassic periods. From the beginning of the Triassic Period, the northern platforms, together with the folded mountain ranges from the Paleozoic Era, formed a large continent embracing three-quarters of modern Eurasia. At the same time Gondwanaland split up into several gigantic blocks, separated from each other by a series of basins, some of which broadened and coalesced to form the Indian Ocean. The geosynclinal basins of the Mesozoic Era survived in the Tethys Sea, in Northeastern Siberia, in the Amur region, in Indochina, and in the belt of island arcs located in East and Southeast Asia. Shallow seas or coal-bearing freshwater basins and swamps, especially numerous during the Jurassic Period, at times covered the lowlands of Western Siberia, the Turan Plain, the Iranian Massif, and the Ordos Desert and Szechwan Basin.

The Cretaceous Period and the Cenozoic Era. Toward the middle of the Cretaceous Period, the areas of Mesozoic folding—located in what are now the Verkhoyansk Mountains, Sikhote-Alin, and Indochina—dried up, while in the course of the Late Cretaceous Period and the Early Cenozoic Era a rapid reduction in the size of the Tethys Sea took place. Finally, toward the beginning of the Early Cenozoic Era, folding in the Himalayas united India with the remainder of the continent, and Asia acquired approximately the outlines it has today. The island arcs and the basins of the marginal seas were shaped at the same time.

The joining of India and Asia

The Cretaceous Period and the Cenozoic Era were marked by mighty volcanic phenomena throughout East Asia. The Pliocene Epoch and Quaternary Period were times of vigorous tectonic movements that not only led to the uplifting of folded mountain ranges in the Alpine-Himalayan belt and in the island arcs but also rejuvenated the relief of the ancient folded mountains of the Urals, the Tien Shan, the Altai, the Sayans, and other ranges. Today an active belt of contemporary seismic activity stretches from the Hindu Kush through the Tien Shan, Mongolia, and the Baikal region to the Sea of Okhotsk.

Contemporary developments. The paleoclimatic and paleomagnetic data indicate that considerable shifting was taking place—in relation to the North and South poles as well as to each other—of those blocks from which the Eurasian continent was gradually formed. During the course of the early and middle periods of the Paleozoic Era, a considerable rapprochement (bringing together) of the Russian and Siberian platforms occurred. In the Late Carboniferous and Permian periods the Indian Platform was situated much closer to the South Pole and was partially subjected to glaciation. The Siberian Platform, on the other hand, was at that time located in the northern humid zone; in the Triassic Period the North Pole evidently lay at its northeastern edge. At the end of the Paleozoic Era the Tethys Sea was several times broader than the belt of folding that was formed within it in the course of the Mesozoic and Cenozoic eras. There are indications of the drift of the island arcs toward the shores of the Pacific Ocean and of the spreading of the bottoms of the marginal seas, such as the Sea of Japan and others, which originally developed and deepened in the middle of the Mesozoic Era.

(P.N.K.)

The land

RELIEF

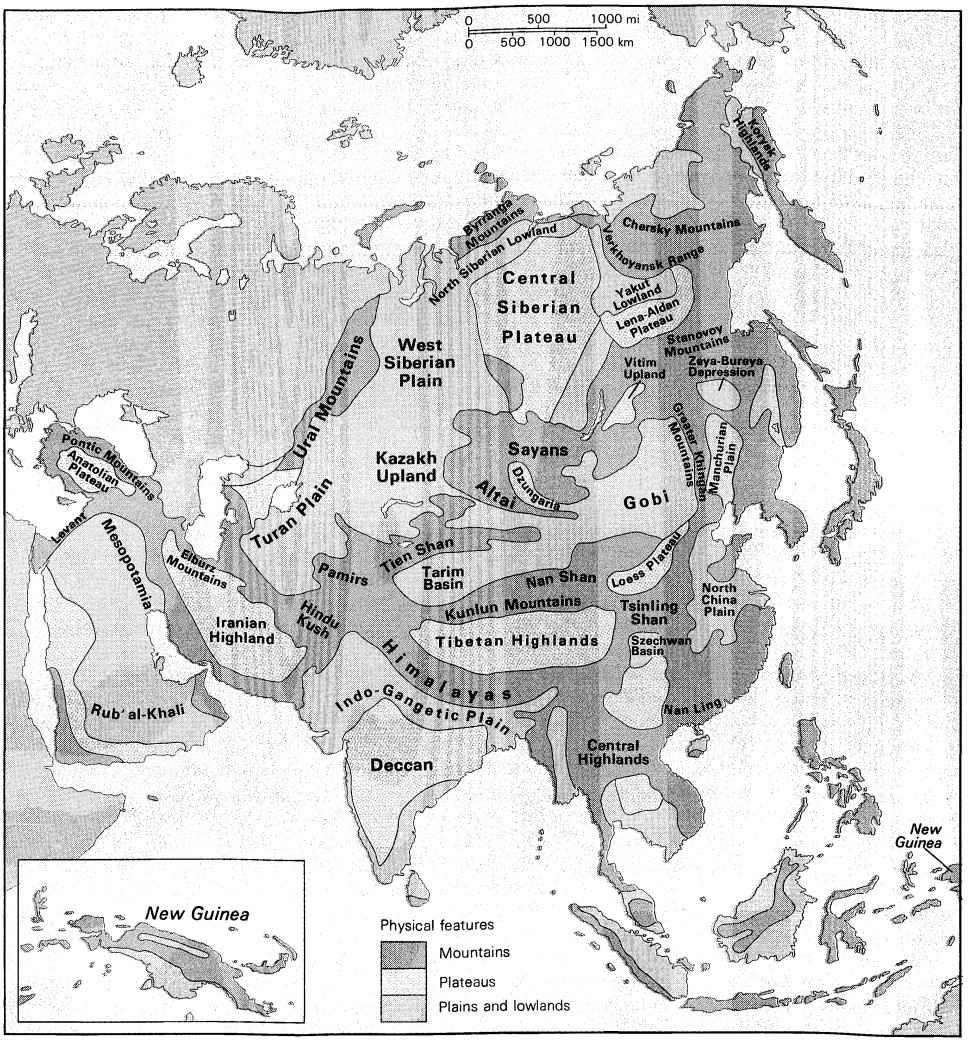
Asia is the highest of the continents and contains the sharpest relief. The highest peak in the world, Mt. Everest, which is 29,028 feet (8,848 metres) high; the lowest place on the Earth's land surface, the Dead Sea, which is approximately 1,300 feet (400 metres) below sea level; and the world's deepest continental trough, occupied by Lake Baikal, which is 5,315 feet (1,620 metres) deep and whose bottom lies at 4,250 feet (1,295 metres) below sea level, are all located in Asia.

Asia is also the most extensive of the continents. The farthest terminal points of the Asian mainland are Cape Chelyuskin in the Soviet Union (77° 43′ N) to the north; the tip of the Malay Peninsula, Cape Piai, or Bulus (1° 16′ N), to the south; Cape Baba in Turkey (26° 4′ E) to the west; and Cape Dezhnyova, or East Cape (169° 40′ W), also in the Soviet Union, overlooking the Bering Strait, to the east. The shores of Asia are washed by the Arctic Ocean on the north, the Pacific Ocean on the east, the Indian Ocean and the marginal seas of the Indian and Pacific oceans on the south, and by the seas of the Atlantic Ocean—the Mediterranean, the Aegean, the Sea of Marmara, the Black Sea, and the Azov Sea—as well as by the landlocked Caspian Sea, on the west.

The continent's extremities

Asia is separated from Australia to the southeast by the mingled waters of the Indian and Pacific oceans, and from North America on the northeast by the Bering Strait. The Isthmus of Suez unites Asia with Africa, and it is generally agreed that the Suez Canal forms the border between them.

The boundary between Asia and Europe is a historical–cultural concept that has changed more than once and is



Physiographic regions of Asia.

only as a matter of agreement tied to a specific borderline. The most convenient geographic boundary is a line drawn along the eastern slope of the Urals, then turning west along the Emba River to the Caspian Sea; west of the Caspian, the boundary follows the Manych River and the Kerch Strait to the Black Sea. From a statistical–economic point of view, the boundary is taken to run along those political–administrative borders of the republics and *oblasti* of the Soviet Union that most closely approximate this line, which is to say, along the eastern borders of the Komi Autonomous Soviet Socialist Republic; the *oblasti* of Arkhangelsk, Sverdlovsk, and Chelyabinsk; the western border of the Kazakh S.S.R.; and along the northern borders of the *kraya* (territories) of Stavropol and Krasnodar. Some authorities consider, however, that the boundary runs along the border between the Russian Soviet Federated Socialist Republic and the Transcaucasian republics (the Georgian S.S.R. and the Azerbaijan S.S.R.).

The area of mainland Asia, including the Caucasian isthmus, amounts to about 16,750,000 square miles (43,400,000 square kilometres), of which the peninsulas—Asia Minor to the west; the Arabian Peninsula, peninsular India, Indochina, and the Malay Peninsula to the south; Korea, Kamchatka, and the Chukotsk Peninsula to the east; Taymyr and Yamal to the north—make up about 3,000,000 square miles.

The islands—Cyprus, Sri Lanka, the Andamans, the Malay Archipelago, the Philippines, Hainan, Taiwan, the Ryukyus, Japan, the Kurils, Sakhalin, Wrangel Island, the New Siberian Islands, and Severnaya Zemlya—account for another 770,000 square miles.

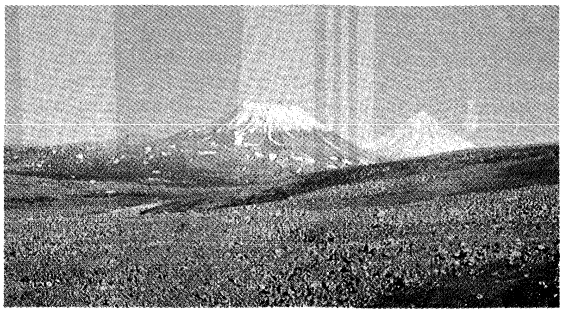
Asia's coastline is, variously, high and mountainous; low and alluvial; terraced as the result of the land being uplifted; or "drowned," where the land has subsided. The specific features of the coastline in some areas—especially in the east and southeast—are the result of active volcanism; of thermal abrasion (resulting from a combination of action by sea breakers and of thawing) by the subterranean fossilized ice (consisting of fossil ice, subsurface ice, and ice-formed rock), as in northeastern Siberia; and coral building, as in the south-southeastern area.

A characteristic of the surface of Asia is the predominance of mountains and plateaus, which form about three-quarters of the total area. The highest mountains and plateaus occur in Central Asia (Mongolia, Dzungaria, the Kashgar region, and Tibet) and Middle Asia (Turkmenia, Uzbekistan, Tadzhikistan, Kirgiziya, and Kazakhstan), which are also characterized by the vastness of their interior drainage basins.

Asia's mountain ranges

The mountain belts. The mountains are grouped in two large belts. One extends from the Chukchi Peninsula at the eastern extremity of Asia through the Kolyma Highlands, the Dzhugdzhur Mountains, and the Stanovoy Mountains to the mountains of Southern Siberia (the Stanovoy Uplands, the Sayans, and the Altai) and to the Tien Shan and Gissar-Alai. The Chersk and Verkhoyansk ranges are the western spurs of this belt.

The second belt, in the west, runs in a latitudinal direction and includes the West Asian highlands, the Pamirs, Karakoram, the Tibetan Highlands, and the Himalayas; it then turns to the south and southeast, running through the Arakan Mountains to the islands of the Malay Archipelago. A generally latitudinal branch springs from it in the Pamirs region and runs eastward through the Kunlun, Nan Shan, and Tsinling mountains. The western part of the second mountain belt consists, for a considerable distance, of two



Sopka (volcano) Krasheninnikova on the Kamchatka Peninsula in Northeastern Siberia.
Novosti Press Agency

series of mountain chains that converge in dense knots in the highlands of Armenia, in the Pamirs, and in the southeast of the Tibetan Highlands; the two chains then diverge to encompass the interior plateaus—the highlands of Asia Minor together with the Anatolian Plateau, and the Iranian and Tibetan highlands. At the margins of the highlands the mountain chains change direction abruptly in the congested mountain knots, but in the intervening areas they curve in flowing arcs.

Along the edges of the Central Asian plateaus extend the elongated mountain chains of the Greater Khingan, T'aihang Shan, and the Sino-Tibetan ranges. The Khingan–Bureya mountains (Bureya and Lesser Khingan mountains) demarcate the Zeya-Bureya Depression; the Manchurian–Korean mountains and the Sikhote-Alin ranges separate the plains of the Amur–Sungari, the Lake Khanka lowland, and the Manchurian Plain. The coastal ranges in the southeast consist of the Nan Ling (South China) and Annam mountains. In the east, the Koryak Highlands rise in the northern section of the Kamchatka–Koryak arc; in its southern portion they form the Central Range (Sredinny Khrebet) of Kamchatka. The marginal seas of the Pacific Ocean are bordered by the East Asian islands, which form the line of arcs that also extends partly onto the continent, running from Borneo to Taiwan, through the Ryukyu Islands to Korea, from Honshu to Sakhalin, and from the Kuril Islands to Kamchatka.

Detailed discussion of the Altai Mountains, Himalayas, Hindu Kush, Karakoram Range, Kunlun Mountains, Pamirs, and Tien Shan can be found at the end of this article.

The distribution of plains and lowlands

The plains and lowlands. Low plains occupy approximately a quarter of Asia, particularly the vast West Siberian and Turan plains of the interior. The remaining lowlands are distributed either in the maritime regions, such as Northern Siberia, the Yana-Indigirka lowland, Kolyma, and the Chinese coastal mainland, or in the piedmont depressions of Mesopotamia, the Indo-Gangetic Plain, and mainland Southeast Asia. In addition, there are the intermontane plains of Kashgaria, Dzungaria, Tsaidam, and Fergana and the plateaus of middle Siberia and the Gobi. The plateaus inside Tibet, the Tien Shan, and the Pamirs lie at altitudes as high as 12,000 feet. Many ranges in Middle and Central Asia reach elevations of 21,000 to 24,000 feet, but in other mountain chains and massifs they rarely exceed 12,000 feet. To the south of the zone of piedmont depressions, partially occupied by seas—the Arabian Sea, the Bay of Bengal, the Gulf of Oman, the Persian Gulf, and, in the Mediterranean, the Cyprus Basin—lie extensive tablelands and plateaus, including the Deccan Plateau in India and the Syrian–Arabian Plateau in the west; these are enclosed by marginal mountain ranges, such as the Western Ghāts in India; the Oman, Hadramawt, Yemen, and Hejaz mountains on the Arabian Peninsula; and the Lebanon and Anti-Lebanon mountains in the Levant. In Central Siberia are the isolated and uplifted Putorana Mountains and, situated to the north of them, the Byrrangas Mountains.

The islands. A large part of the islands of Asia are mountainous. The highlands of Sri Lanka rise to 8,279 feet (2,524 metres), Mt. Kinabalu in Malaysia reaches 13,451 feet (4,101 metres), Fuji-san on the Japanese island of Honshu has an altitude of 12,385 feet (3,776 metres), and many volcanoes of Sumatra, Java, and Mindanao reach 10,000 feet (3,000 metres). The Kuril–Kamchatka island arc, which extends onto the Kamchatka Peninsula, comprises the Vostochny (East) volcanic range. Especially high is the Klyuchevsk group of volcanoes, where the highest active volcano in Asia—Klyuchevskaya Sopka—rises 15,580 feet (4,750 metres).

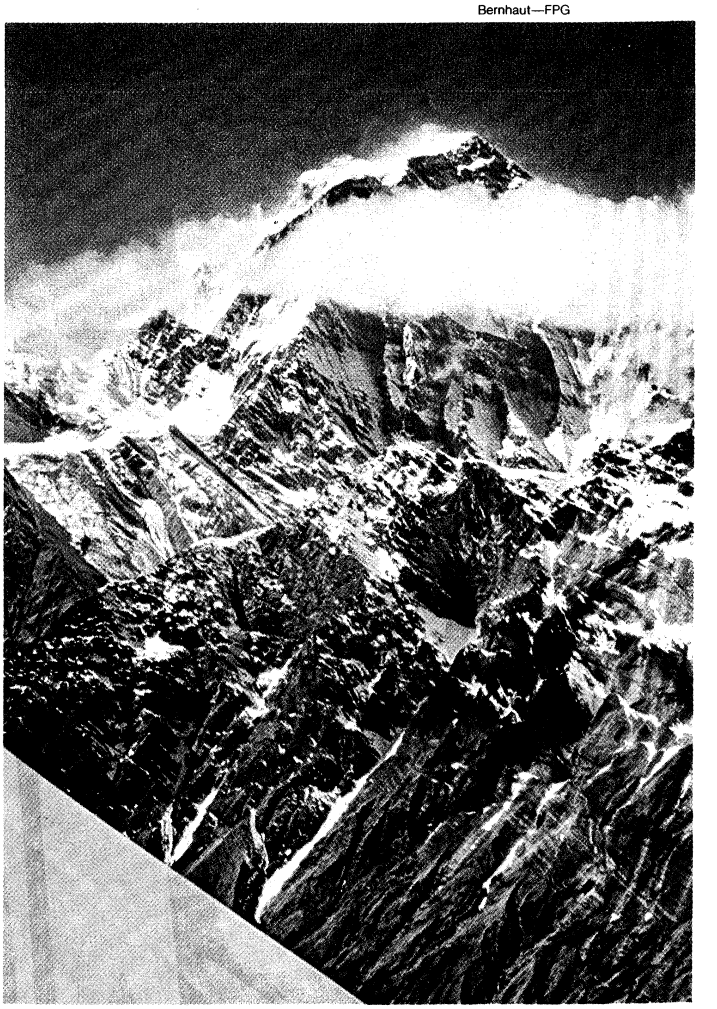
Forces shaping Asia's relief

Geologic and climatic influences. Mesozoic and Alpine foldings created boundaries between basic types of mountains over vast areas of Asia. The contemporary relief of Asia was molded primarily under the influences of: (1) ancient processes of planation (levelling); (2) larger vertical movements of the surface during the later Tertiary and Quaternary periods; and (3) severe erosive dissection of the edges of the uplifted highlands with the accompanying accumulation of alluvium in low-lying troughs, which were either settling downward or being uplifted more slowly than the adjoining heights.

The interior parts of the uplifted highlands, and the plateaus and tablelands of peninsular India, Arabia, Syria, and Eastern Siberia, which are relatively low-lying but composed of resistant rock, have largely preserved their ancient peneplaned (levelled) surfaces. Particularly spectacular uplifting occurred in Central Asia, where for the last 30,000,000 years the amplitude of this uplift of the mountain ranges of Tibet, the Pamirs, and the Himalayas has exceeded 13,000 feet. The eastern margin, meanwhile, underwent subsidences of up to 2,300 feet. Uplifting as a result of fractures at great depths, of which the Kopet-Dag and Ferghan mountains provide examples, and of folding over a large radius, of which examples may be seen in the Tien Shan and Gissar-Alai, played a large role.

Erosional dissection transformed many ancient plateaus into mountainous regions. Majestic gorges were carved

Bernhaut—FPG



Dhaulāgiri, in the Great Himalayas, Nepal, rising to a height of 26,810 feet.

into the highlands of the western Pamirs and southeastern Tibet; the Himalayas, the Kunluns, the Sayans, the Stanovoy Highlands, the Cherski Mountains, and the marginal ranges of the West Asian highlands were deeply cut by the rivers, creating deep superimposed gorges and canyons. In many areas, and especially in those regions with dry climates, erosion clearly exposed the structural forms, including rock layers of different erosional resistance.

Vast areas of Middle, Central, and East Asia, particularly in the Huang Ho Basin, are covered with loess (a loamy unstratified deposit formed by wind or by glacial meltwater deposition). There are broad expanses of badlands, eolian (wind-produced) relief, and karst topography (limestone terrain associated with vertical and underground drainage), and features associated with ancient glaciation.

olian
elief

The mantle of Quaternary glaciation embraced northwestern Asia only to 60° N. East of the Khatanga River, which flows from Siberia into the Arctic Ocean, only isolated glaciation of the mantle debris and of the mountains occurred because of the extremely dry climate that existed in the northeast even at that time. The high mountain regions experienced mainly mountain glaciation. There are traces of several periods during which the glaciers advanced—periods separated by warmer interglacial epochs. Glaciation continues in many of the mountainous areas and on the Severnaya Zemlya archipelago. Karakoram, the Pamirs, the Tien Shan, the Himalayas, and the eastern Hindu Kush are noted for the immensity of their contemporary glaciers.

There is an enormous area of permafrost in northern Asia that extends to lower latitudes than in any other part of the world. Little snowfall occurs, due to the aridity, and deep freezing of the soil takes place.

Several lowlands, primarily coastal plains, are covered with marine sediments as the result of recent advances of seas, such as the Caspian and the northern seas.

Volcanism added broad lava plateaus and chains of young volcanic cones to the relief of Asia. Ancient lavas and intrusions of magma, exposed by later erosion, cover the terraced plateaus of peninsular India and Central Siberia. Extensive zones of young volcanic relief and contemporary volcanism, however, are confined to the unstable arcs of the East Asian islands, together with Kamchatka, the Philippines, and the Greater and Lesser Sunda Islands.

olcanic
ones

Recent volcanism is also characteristic of the West Asian highlands, the Caucasus, Mongolia, the Manchurian–Korean mountains, and the Syrian-Arabian Plateau. In historic times eruptions have also occurred in the interior of the continent in the Lesser Khingan Mountains and the Anyuy highlands.

The regions of Asia. In geographical literature the practice of dividing Asia into large regions, each grouping together a number of countries, is common. These divisions usually consist of North Asia, including Siberia and the northeastern edges of the continent; East Asia, including the continental part of the southern Soviet Far East, the East Asian islands, Korea, and eastern and northeastern China; Central Asia, including the Tibetan Highlands, Dzungaria and Kashgaria in the Sinkiang Uighur Autonomous Region, Inner Mongolia, the Gobi, and the Sino-Tibetan ranges; Middle Asia, including the Turanian Plain, the Pamirs, the Gissar-Alai, and the Tien Shan; South Asia, including the Philippine and the Malay archipelagoes, Indochina and the Indian Peninsula, the Indo-Gangetic Plain, and the Himalayas; and West Asia, including the West Asian highlands (Asia Minor, Armenia, and Iran), the Levant, and the Arabian Peninsula. On occasion, the Philippines, the Malay Archipelago, and the Indochina peninsula, instead of being considered as part of South Asia, are grouped separately as Southeast Asia; the Arabian Peninsula and the Levant are also sometimes grouped together separately as Southwest Asia.

North Asia. The North Asia region includes platform plains, plateaus, and folded mountain ranges. Frost weathering and permafrost have influenced relief.

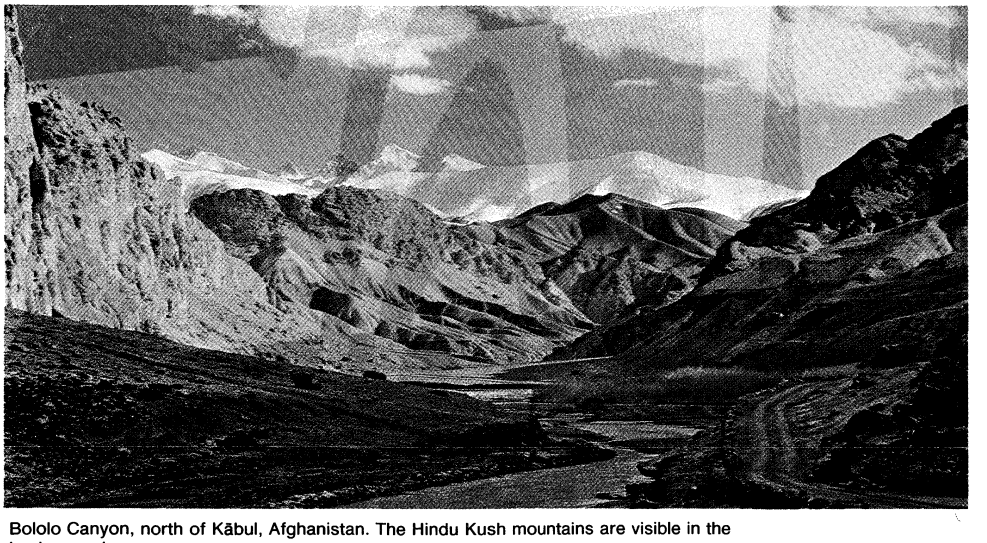
In Northeast Siberia are found faulted and folded mountains of moderate height, such as the Verkhoyansk, Chersk, and Okhotsk-Chaun mountain arcs, formed of Mesozoic structures rejuvenated by neo-tectonic uplifting; the Koryak Mountains, formed of Cenozoic structures, are also in this region. Volcanic activity took place in these areas during the Cenozoic Era. Some plateaus are found in the areas of the ancient massifs, such as the Kolyma massif. Traces of several former centres of mountain glaciers remain, as well as traces of lowland originally covered by the sea, such as the New Siberian Islands. The Aldan Plateau—an ancient peneplain resting on the underlying platform that sometimes outcrops on the surface as the Aldan Shield—is located in the region. Traces of ancient glaciation are also to be distinguished.

Northeast Siberia

The North Siberian plains consist of the Middle Siberian Tableland and the Lena–Vilyuy lowlands, which are platform plateaus and stratified plains that were uplifted in the Cenozoic Era. They are composed of terraced and dissected mesas with exposed horizontal volcanic intrusions; plains formed from uplifted Precambrian blocks; a young uplifted mesa, dissected at the edges and partly covered with traprock (Putorana Mountains); and the peripheral North Siberian lowland, covered with its original marine deposits.

The West Siberian Plain is stratified and is composed of Early Cenozoic sediments deposited over thicknesses of Mesozoic material, in addition to folded bedrock that is Hercynian in the west and Caledonian in the east. The northern part was earlier subjected to several periods of glaciation; in the south the predominant deposits are those laid down by glacier streams, as well as alluvial deposits.

Harrison Forman



Bololo Canyon, north of Kābul, Afghanistan. The Hindu Kush mountains are visible in the background.

In the northern part of the region are the mountains and islands of the Asian Arctic. The archipelago of Severnaya Zemlya is formed of fragments of fractured Paleozoic folded structures. Throughout the region vigorous contemporary glaciation has occurred.

East Asia. Mountains and plains are characteristic of the northern part of continental East Asia. The main features in the northern region include the Khingan–Burein mountains; the Sikhote-Alin ranges of Khabarovsk and Primorsky *kraya* (territories) in the Soviet Union; the Manchurian–Korean highlands running along North Korea's border with China; the East Korean range of the Korean Peninsula; the Zeya-Bureya Depression of Amur *oblast* in the Soviet Union; the Liao Ho in Liaoning Province, China; the Manchurian Plain and the North China Plain; and the Amur and Sungari rivers and the Lake Khanka lowlands. Most of these features were formed by folding, faulting, or broad zonal subsidence. The mountains are separated by alluvial lowlands in areas where recent subsidence has occurred.

The mountains of southeastern China were formed from Precambrian and Caledonian remnants of the Chinese Platform by folding and faulting that occurred during the Mesozoic and Cenozoic eras. The mountain ranges are numerous, are of low or moderate altitude, and occupy most of the surface area, leaving only small, irregular-shaped plains.

The East Asian islands

The islands off the coast of East Asia and the Kamchatka Peninsula are related formations. The Ryukyu Islands, Japan, Sakhalin, and the Kuril Islands are fragments, uplifted in varying degrees, of the Ryukyu–Korean, Honshu–Sakhalin, and Kuril–Kamchatka mountain-island arcs. Dating from the Mesozoic and Cenozoic eras, these arcs have complex knots at their junctions, represented by the topography of Kyushu and Hokkaido. The mountains are of low or moderate height and are formed of folded and faulted blocks; some volcanic mountains and small alluvial lowlands are also to be found.

Kamchatka is a mountainous peninsula, formed from fragments of the Kamchatka–Koryakskaya and Kurilo–Kamchatskaya arcs, which occur in parallel ranges. The young folds enclose rigid ancient structures. Cenozoic (including contemporary) volcanism is pronounced. Vast plains exist that are composed of alluvia with volcanic ashes.

Central Asia and South Siberia. Central Asia consists of mountains, plateaus, and tablelands formed from fragments of the Siberian and Chinese platforms, peripherally surrounded by a folded area formed in the Paleozoic and Mesozoic eras.

The mountains of Southern Siberia and Mongolia were formed by renewed uplift of old faulted and folded blocks; ranges are separated by intermontane troughs. The alpine mountains—the Altai, the Mongolian Altai, and the Sayano-Tuvan and Stanovoy highlands—are particularly noticeable. They have clearly defined features resulting from ancient glaciation; contemporary glaciation is also very active.

The Central Asian plains and tablelands include the Takla Makan Desert, the Gobi, and the Ordos Desert. Relief features vary from surfaces levelled by erosion in the Mesozoic and Cenozoic eras to stratified plateaus with low mountains, eroded plateaus on which loess had accumulated, and vast sandy deserts covered with windborne alluvium and lacustrine deposits.

Alpine Asia—sometimes known as High Asia—includes the Pamirs and the eastern Hindu Kush, the Kunlun Mountains, the Tien Shan, the Gissar-Alai Mountains, the Tibetan Highlands, the Karakoram Range, and the Himalayas.

The Pamirs and the eastern Hindu Kush are sharply uplifted mountains dissected into ridges and gorges in the west. There is thick glacial cover; alpine deserts occur on the plateaus.

The Kunlun Mountains, the Tien Shan, and the Gissar-Alai Mountains belong to an alpine region that was formed from folded structures of Paleozoic age. There are glaciers of impressive size centred in this alpine region.

The Tibetan Highlands

The Tibetan Highlands represent a fractured alpine zone in which Mesozoic and Cenozoic structures that surround an older mass in the centre have experienced more recent uplifting. Some of the highlands are covered with detrital desert; elsewhere in this region, alpine highlands are dissected by erosion or are covered with glaciers.

The Karakoram Range and the Himalayas include the highest mountains in the world; they were formed by uplifting that took place in a zone of Cenozoic folds and Mesozoic partially folded areas containing outcrops of the ancient bedrock. Contemporary glaciation in the region is vigorous.

South Asia. South Asia, in the limited sense of the term, consists of peninsular India and Sri Lanka and the Indo-Gangetic Plain.

Peninsular India and Sri Lanka are formed of platform plateaus and tablelands uplifted in the Mesozoic and Cenozoic eras and subjected to humid-climate erosion ever since. Tablelands with uplifted margins and terraced and dissected plateaus with lava mantles or intrusions may be distinguished.

The Indo-Gangetic Plain is formed from the combined alluvial plains of the Indus, Ganges, and Brahmaputra rivers, which lie in a deep marginal depression running north of and parallel to the main range of the Himalayas. It is an area of immature subsidence, in which thick accumulations of earlier marine sediments and later continental deposits that washed down from the mountains have been transformed into sandy deserts in the western arid region.

Southeast Asia. Southeast Asia comprises the Indochina Peninsula and the islands and peninsulas to the southeast of the Asian continent.

Indochina

The mainland consists of the western mountain area and

Brian Blake—Rapho/Photo Researchers

The Ch'iang-t'ang plain of northern Tibet, bordered by the Kunlun Mountains.

the central and eastern mountains and plains. The western mountain area of Burma is a zone of Cenozoic folding. Mountains of medium altitude are formed of folded blocks that decrease in size and altitude to the south; the valleys are alluvial and broaden out to the south. The central and eastern region of Thailand and of Vietnam is characterized by mountains of low and moderate height that have been moderately fractured. The region is one of Mesozoic structures surrounding an ancient mass known as the Cambodian saucer, with which are associated plateaus and lowlands filled with accumulated alluvial deposits.

Archipelagoes border the southeastern margin of Asia, consisting mainly of island arcs with which peninsulas are associated. The island arcs are bordered by very deep oceanic trenches. These arcs are characteristically very unstable and are volcanically active.

The Indian Ocean arcs—the island chains of Sumatra, Java, and the Lesser Sunda Islands—consist of fragments of alpine folds formed from materials of different ages. Cenozoic and contemporary volcanic activity is manifest, and volcanic mountains as well as alluvial lowlands may be distinguished.

Borneo and the Malay Peninsula are formed from fractured continental land situated at the junction of the Alpine–Himalayan and East Asiatic geosynclinal regions; contemporary volcanism is absent. The mountains are composed of folded and faulted blocks; the lowlands are alluvial.

The Pacific Ocean island arcs, including Celebes, the Moluccas, the Philippine Islands, and Taiwan, are fragments of folded alpine structures that were built up by volcanic products during the Cenozoic Era. Volcanic activity and the building of coral reefs continue. Mountain areas of moderate height, volcanic ranges, alluvial lowlands, and coral reef islets may all be distinguished in the region.

Middle Asia. Middle Asia includes the plains and hills lying between the Caspian Sea to the west and Lake Balkhash to the east.

The area between the Caspian and Lake Balkhash is composed of flat plains on continental platforms of folded Paleozoic and Mesozoic bedrock. Individual uplifted portions form low rounded hills (*melkosopochniks*) in the Kazakh region; low mountains on the Mangyshlak and Krasnovodsk peninsulas of the Caspian Sea; and mesas (isolated hills with level summits and steeply sloping sides) in areas of earlier marine sedimentation, such as the Ustyurt Plateau and the Kara-Kum Desert. Thick accumulations of alluvium have been transported by the wind, forming sandy deserts in the south. Original marine and lacustrine sediments adjoin the shores of the Caspian and Aral seas and Lake Balkhash.

West Asia. West Asia includes the highlands of Asia Minor, and the Armenian and Iranian highlands.

The highlands of Asia Minor—the Pontic mountain system that parallels the Black Sea, and the Taurus and Anatolian tablelands—are areas of severe fragmentation, heightened erosional dissection, and isolated occurrences of volcanism.

The Armenian Highlands

The Armenian Highlands, which include the Little Caucasus and the Kurd mountains, are severely fragmented. Recent uplifting, in the form of a knot of mountain arcs, took place during a period of vigorous volcanism that occurred in the Cenozoic Era.

The Iranian Highlands represent a combination of mountain arcs (in the north, the Elburz and Turkmen-Khorasan mountains, the Selseleh-ye Safīd Kūh, and the western Hindu Kush; in the south, the Zagros, Makran, Soleymān, and Kirthar mountains), together with the tablelands of the interior, and the Central Iranian, Eastern Iranian, and Central Afghanistan mountains. There are isolated Cenozoic volcanoes, a predominance of accumulated remnants resulting from ancient erosion, and saline and sandy deserts in the depressions and on the tablelands.

Southwest Asia. Southwest Asia, like much of southern Asia, is made up of an ancient platform—the northern fragments of Gondwanaland—in which sloping plains occur in the marginal downwarps. Its principal components are the Arabian Peninsula and Mesopotamia.

The Arabian Peninsula is a tilted platform, highest along the Red Sea, on which the stratified plains have undergone erosion under arid conditions. Block tablelands with uplifted margins, Cenozoic lava plateaus, stratified plains, and cuestas (long, low ridges with a steep face on one side and a long gentle slope on the other) may all be distinguished. Ancient marine sands and alluvia, resulting from previous subsidence and sedimentation, now take the form of sandy deserts.

Mesopotamia consists of the Tigris and Euphrates floodplains and of the deltas from Baghdad to the Persian Gulf. The original lowland is covered with late Cenozoic and Quaternary sedimentation; the elevated plain, on the other hand, has been dissected by erosion and denudation under the continental conditions prevailing in the Late Cenozoic Era.

CLIMATE

Air masses and wind patterns. The enormous expanse of Asia and the abundance of mountain barriers and inland depressions have resulted in great differences in existing conditions of solar radiation, atmospheric circulation, and climate as a whole. A continental climate, associated with large landmasses and characterized by an extreme annual range of temperature, prevails over a large part of Asia. Air reaching Asia from the Atlantic Ocean, after passing over Europe or Africa, has had time to be transformed into continental air. As a result of the prevalent easterly movement of the air masses, as well as the isolating effect of the marginal mountain ranges, the influence of sea air from the Pacific Ocean extends only to the eastern edge of Asia. From the north, Arctic air has unimpeded access into the continent. In the south, tropical and equatorial air masses predominate, but their penetration to the centre of Asia is restricted by the ridges of the latitudinal belt of highlands; in the winter months—November through March—such penetration is further impeded by the density of the cold air masses over the interior.

The continental climate

The contrast between the strong heating of the landmasses in the summer months from May to September and the chilling in winter produces sharp seasonal variations in the atmospheric circulation and also enhances the role of local centres of atmospheric activity. Winter chilling of the Asian landmass develops a persistent high-pressure winter anticyclone over Siberia, Mongolia, and Tibet, which is normally centred southwest of Lake Baikal. Within the zone of the anticyclone there is relatively little strong air movement in protected basins and lowlands, but strong winds may affect the higher mountains and passes. The anticyclone is fed by subsiding upper air, by bursts of Arctic air flowing in from the north, and by the persistent westerly air drift that accompanies the gusty cyclonic low-pressure cells operating within the Northern Hemisphere cyclonic storm system. Drifts of cold, dry air move eastward and southward out of the continent, affecting eastern and southern Asia during the winter. Only a few of the winter cyclonic lows moving eastward out of Europe carry clear across Asia, but they do bring greater periodic change in weather in Western Siberia than is typical in Central Siberia. The zone of lowest temperature—the so-called cold pole—is found in the northeast, near Verkhoyansk, where temperatures as low as −90° F (−68° C) are recorded. The outward drift of winter air creates a sharp temperature anomaly on Asia's eastern margin, where the climate is colder than the characteristic average for each given latitude. But episodic intrusions of oceanic air from the east and southeast moderate this anomaly, so that temperatures are not as severe here as in the centre of the anticyclone.

The polar front

The zone where the temperate and tropical air masses are in contact—called the polar front—shifts southward in winter. This movement is caused by a displacement, in the same direction, of the entire system of atmospheric circulation—a displacement resulting from the powerful climatic influence exerted by the chilled continent. The winter rainy season in the southern parts of the West Asian highlands, which is characteristic of the Mediterranean climate, is associated with this southerly movement of the polar front. In the more northerly areas of West and Middle Asia, the effect of cyclonic action is particularly

strong in the spring, causing the maximum in annual precipitation to occur at this season. In summer, the polar front shifts northward, causing cyclonic rains in the mountains of Southern Siberia. In West, Middle, and Central Asia, a hot, dry, dusty, continental tropical wind blows at this time. Over the basin of the Indus River the heating creates a low-pressure area, known as the South Asian (or Iranian) low. The southern monsoon (a rain-bearing wind) advances along its southern edge, bringing copious rainfall to peninsular India, the southern Himalayas, and mainland Southeast Asia. Farther to the west the hot, dry air of North Africa and the katabatic (downward) current of air from Europe, blowing from the northwest, sweep in the direction of this low-pressure area. The aridity of the desert-tropical climate of Arabia and Pakistan is related to this phenomenon.

In eastern Asia the Pacific Ocean polar front creates atmospheric disturbances during the summer. From the warm sectors of cyclones moving westward through this region, the warm and moist summer monsoon blows toward the continent. Becoming chilled as it passes over cold ocean currents, this air brings fogs and drizzling rains. To the south of 38° N, where the warm Kuroshio (Japan) current approaches the coast of Japan, the summer monsoon brings protracted rains and high humidity; together with high temperatures, this creates a hothouse atmosphere.

The summer period over China is a time of variable air movement out of the South Pacific. If that drift is strong and the summer continental low-pressure zone is marked, a strong summer monsoon may carry moisture well into Mongolia. If neither the drift nor the continental low is strong, the China summer monsoon may fail, falter over eastern China, or cause irregular weather patterns that may threaten China proper with crop failure.

Typhoons and monsoons

Tropical cyclones, or typhoons, occur along the East Asian weather fronts throughout the year but are most severe during the autumn months. These typhoons are accompanied by very strong winds and torrential rains so heavy that the maximum precipitation from the typhoons locally may exceed the total amounts received during the normal summer monsoons.

In winter the Pacific Ocean polar front is driven back to tropical latitudes by a steady drift of cold, dry Siberian air. On the East Asian islands the effect of the winter continental monsoon is tempered by the surrounding seas. In passing over them, it becomes warmed and saturated with moisture; then waters the northwestern slopes of the island arcs. Occasionally, however, strong bursts of cold air carry cold spells as far south as Hong Kong and Manila.

In winter, continental tropical air prevails in subequatorial Asia; in summer it is replaced by equatorial ocean air. The winter season's dry and warm winds, directed toward the equatorial low-pressure axis, are analogous to trade winds but simultaneously act as the South Asian continental monsoon. The dry spring that follows changes abruptly and dramatically into the rainy summer with the onset of the monsoon. The summer monsoon brings enormous amounts of rain (up to about 25 inches [635 millimetres] in a month). Over the areas of Asia close to the Equator—southern Sri Lanka, Malaysia, and the Greater Sunda Islands—equatorial air prevails continuously, accompanied by even temperatures and abundant rainfall at all seasons. The Lesser Sunda Islands have a subequatorial monsoon climate; their wet and dry seasons are regulated by the calendar rhythm of the Southern Hemisphere, which is characterized by a wet summer from November to February and a dry winter from June to October.

The influence of topography. Differences between the climatic conditions of the various regions of Asia are determined to a considerable degree by topography. Different altitudinal climatic zones are most clearly defined on the southern slopes of the Himalayas, where they vary from the subequatorial and tropical climates of the foothills, at the lowest levels, to the snowy climate of the peaks, at the highest altitudes. The degree of exposure also plays a large role—the different orientation of the opposite slopes of the ridges in relation to compass directions and to the prevailing winds. The sunny southern slopes differ from the shady northern ones, and windward slopes exposed to moist ocean winds differ from leeward slopes, which, lying in the wind (and rain) shadow, are necessarily drier. In addition to the physical isolation of the leeward slopes from the moisture-laden winds, the foehn effect is also found here. This occurs when a strong wind traverses a mountain range and is deflected downward as a warm, dry, gusty, erratic wind. Contrasts of climate resulting from exposure are manifested clearly in the Himalayas, the Elburz Mountains, Japan, Taiwan, the Philippines, the Tien Shan, the Transbaikalia, and many other places.

The foehn effect

The isolating barrier effect of the relief on the climate appears clearly in the West Asian highlands and in Central Asia. In these regions the surrounding mountains isolate the tablelands of the interior from the moisture-laden winds. The massiveness of the interior highlands is also a significant factor; it favours the formation of local anticyclones over them during the cold months of the year.

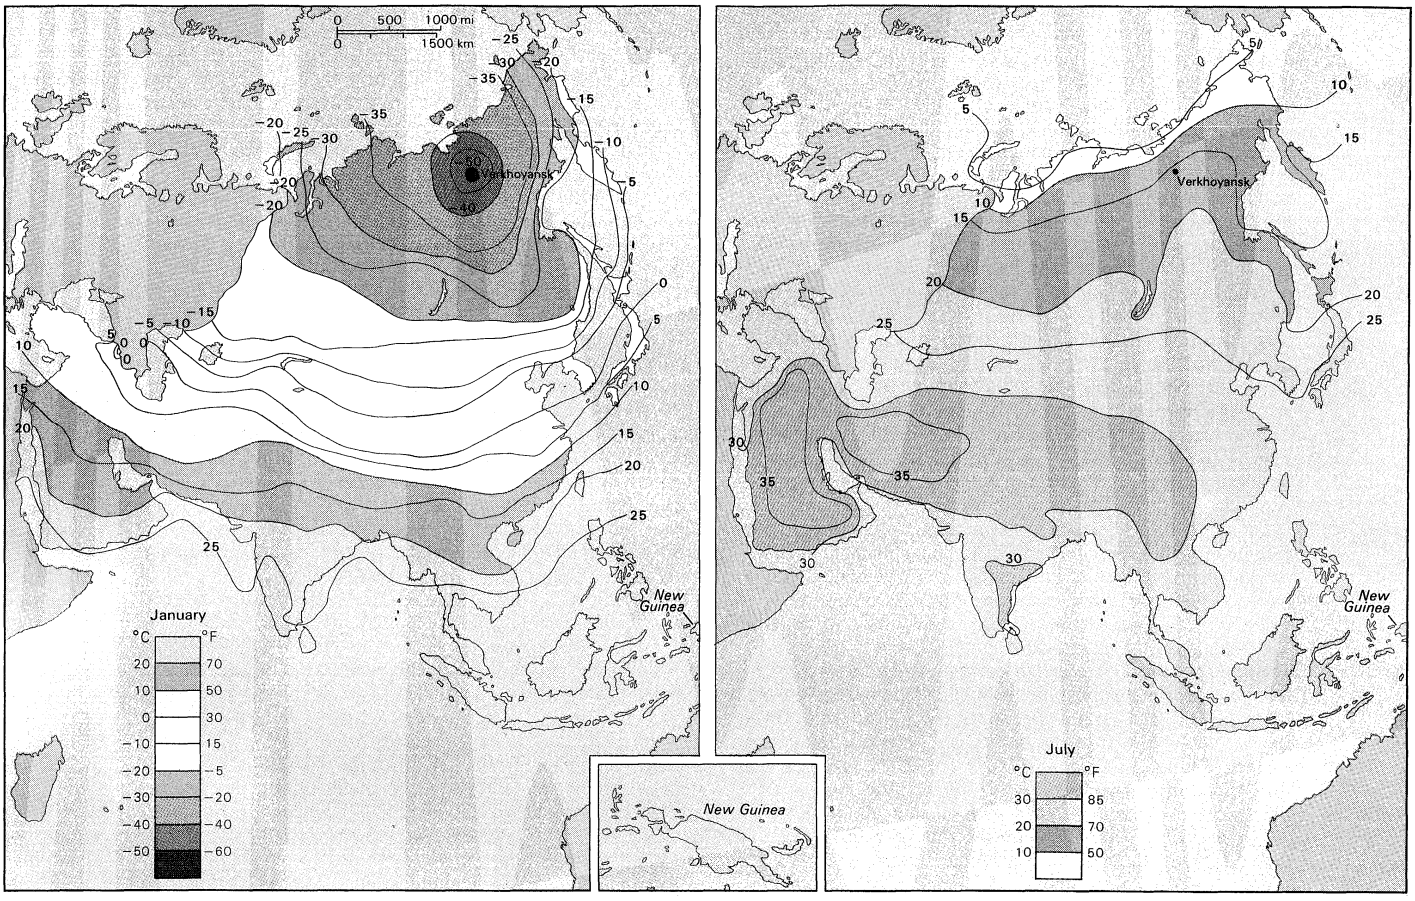
During the winter season some of the cyclonic storms that move eastward through the Mediterranean Basin are deflected south of the Tibetan Highlands, crossing northern India and southwestern China and then turning northeastward to return to the northern cyclic path. Such storms do not often bring winter rain, but they create short periods of cloudy, cool, or gusty weather and bring snow to the higher mountain ranges.

Temperature. The average January temperature over a considerable part of Siberia is below −4° F (−20° C), and in the Verkhoyansk region it reaches −58° F (−50° C). Along the coastal areas, the proximity of the Pacific Ocean moderates the temperatures to from 23° F to 5° F (−5° C to −15° C). The January isotherm (a line connecting points of equal temperature) of 32° F (0° C) passes through Samarkand, Peking, and the island of Honshu. An isotherm of 68° F (20° C) is traced along the Tropic of Cancer and one of 77° F (25° C) along the Equator. In July, when the average temperature is 86° F (30° C), the maximum temperatures are found in West Asia and in the Thar and Takla Makan deserts. The 68° F (20° C) isotherm moves as far as 55° to 60° N, but near the cool Pacific Ocean it bends to the south. Along the northern coasts of Asia the average temperature in July is below 50° F (10° C), which is typical for a tundra climate. The greatest amplitude in annual temperature range occurs near the "cold pole," which has surprisingly warm summers; the annual range may exceed 175° F (97° C).

Rainfall. Annual rainfall in the equatorial belt is approximately 80 inches (2,000 millimetres); it is 80 to 120 inches and more (300 to 500 inches in places) on the windward maritime slopes in South and East Asia. In Cherrapunji (Meghalaya) 900 inches of rain fell in seven months in 1891. Precipitation is less than 40 inches on the lee slopes of the subequatorial regions. In the subtropical and temperate monsoon climates there is adequate rainfall, amounting to about 24 to 40 inches. Precipitation is less than 10 inches in Eastern Siberia and averages six to eight inches (but may be less than four inches in some places) in the deserts of West, Middle, and Central Asia.

Climatic regions. The distribution pattern of rainfall throughout the year is varied. Relatively uniform moisture is characteristic of the Asian equatorial zone. Maximum summer precipitation and minimum winter precipitation are the rule in the subequatorial zones and in other regions with monsoon climates, as well as in those areas where there is summer movement of the fronts—the polar front in the mountains of Southern Siberia and the Arctic front in the subarctic regions. Wet winters and dry summers are typical of the Mediterranean climatic region in West Asia, where precipitation is associated with the winter activity of the polar front. This polar front activity, accompanied by maximum precipitation, occurs in the spring in the interior parts of the West Asian highlands. Summer and winter precipitation merges in some parts of Asia. In the Kolkhida climate the summer rains—brought by the northwesterly Atlantic air currents—merge with the cyclonic Mediterranean winter rains. In some areas of Japan and eastern China there is uniform precipitation when, in addition to the summer monsoon, the winter monsoon brings moisture.

As the aggregate result of these various meteorological



Average temperatures for January and July in degrees Celsius for Asia.

Types of climate

patterns, the following types of climate may be distinguished in Asia: the tundra climate (associated with the cold, treeless plains of the Arctic lowlands of Asia); the cold, sharply continental climate of Eastern Siberia; the cold, moderately humid Western Siberian climate; the humid, subtropical Kolkhida climate; the desert climate of the temperate zone; the Mediterranean subtropical climate of the western edge of West Asia; the subtropical desert climate; the mountain-steppe highland subtropical climate of West and Central Asia; the alpine desert climate; the climate of the Eastern Pamirs, Karakoram Mountains, and Tibetan Highlands; the climate of the tropical deserts; the temperate monsoon climate of the Soviet part of the Far East, and northern parts of Japan and East China; the subtropical monsoon climate of Southern Japan and of Southeastern China; the subequatorial monsoon climate of South Asia, eastern Java, and the Lesser Sunda Islands; and the equatorial climate of the Greater Sunda Islands.

Many climatic variants can be distinguished that are associated with such local topographical features as the degree of exposure of the slopes, the protective effect of the mountains, and altitudinal zonality, with temperatures dropping as the altitude increases. Low temperatures, however, are also found in low hollows where cold air stagnates or on coasts where air is chilled by cold ocean currents. The mountain climates, evidently, represent variants of those climates that are determined by latitude. All the various features of the types of climate mentioned exert a strong influence on other natural conditions, as well as on the landscape as a whole.

Urban climate. Distinctive variations of climatic characteristics result from the cultural and economic activities of human society. One example of this is provided by the microclimates associated with the cities and with large industrial complexes. The emission by the cities of quantities of dust and gases produces alterations of temperatures and changes in wind patterns. Such conditions are characteristic, for example, of Tokyo and the industrial region of northern Kyushu in Japan, of Calcutta and the industrial area of the northeastern part of peninsular India, and of the industrial regions of the Kuznetsk Basin in the Soviet Union.

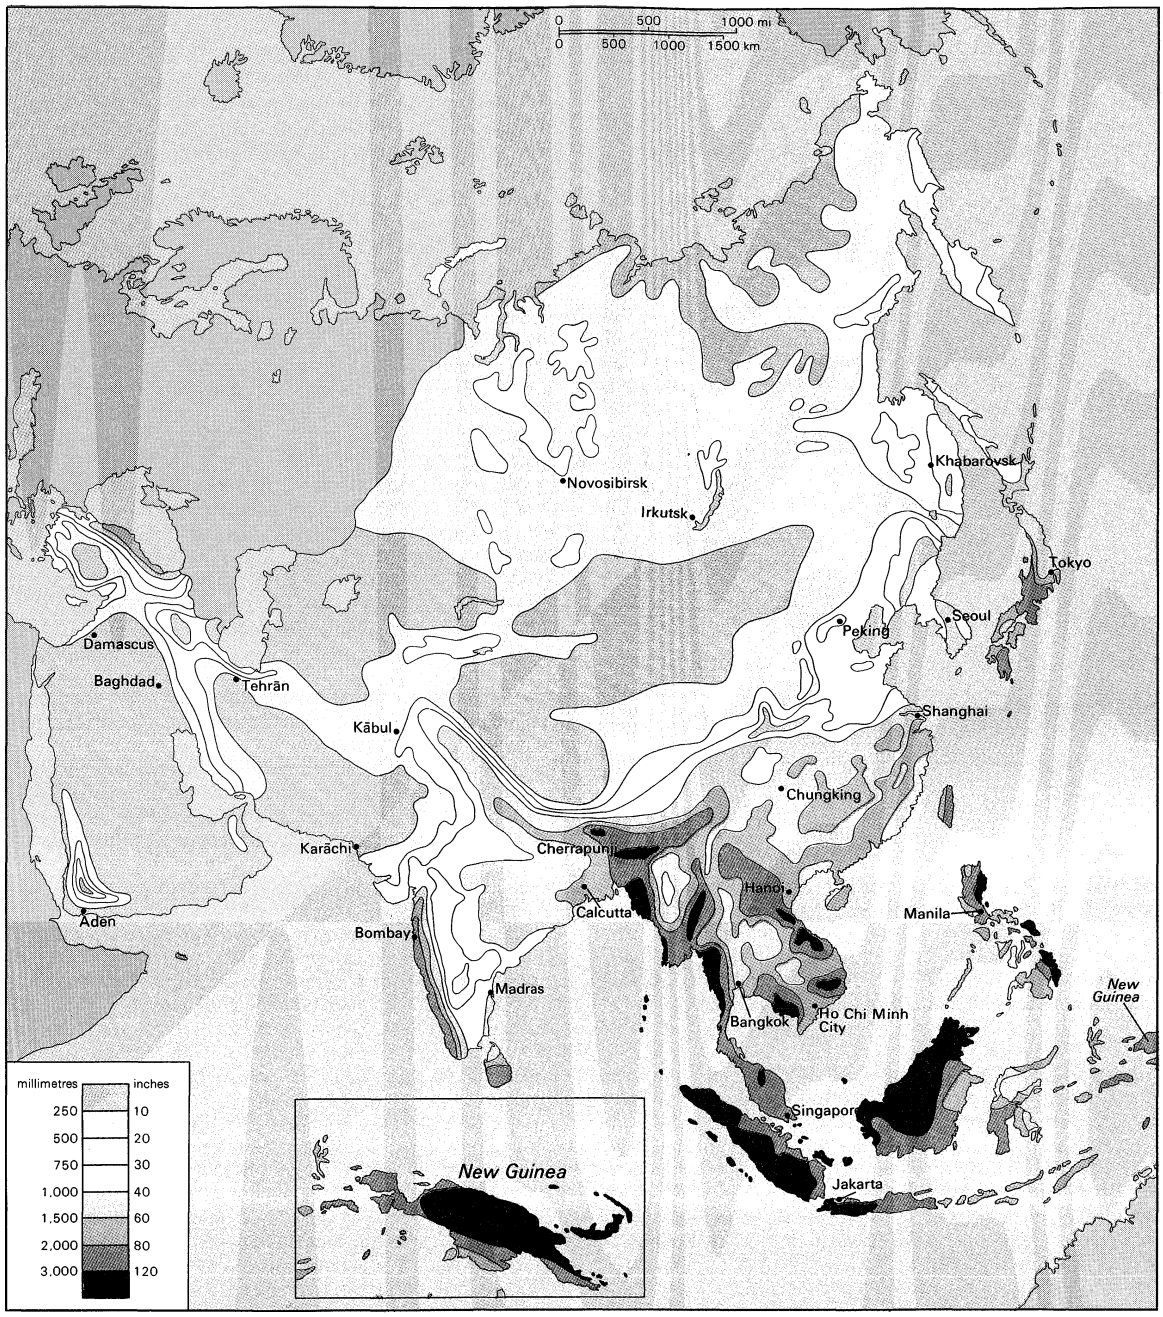
DRAINAGE

Rivers. Asia is a land of great rivers. The Ob, the Irtysh, the Yenisey with the Angara, the Lena (with the waters of the Aldan and the Vilyuy), the Yana, the Indigirka, and the Kolyma rivers all flow into the Arctic Ocean. Among rivers draining into the Pacific Ocean are the Anadyr, the Amur (combined with the Sungari and the Ussuri), the Huang Ho, the Yangtze, the Hsi, the Red River (Song Hong), the Mekong, and the Chao Phraya. The Salween, the Irrawaddy, the Brahmaputra, the Ganges, the Godāvari, the Krishna, and the Indus flow into the Indian Ocean, as also does the Shatt al-Arab, which is the confluence of the Tigris and Euphrates rivers. Only small mountain rivers flow from Asia into the Caspian, the Sea of Azov, the Black Sea, and the Mediterranean. The Amu Darya, the Syrdarya, the I-li, the Chu, the Tarim, the Helmand, and the Tedzhen rivers empty into vast interior basins. Some of these rivers end in lakes, some end in dry deltas in the sands or salt marshes, and some flow into oases, where all the water is used to irrigate fields or else it evaporates.

Rivers of the Pacific

All the Siberian rivers freeze over in the winter, and some freeze to the bottom. In spring widespread flooding occurs. These rivers are important communication routes, being used by boats during the summer and as roads for sleighs in winter; they also teem with fish.

In the dry regions, where drainage is landlocked, the only large rivers are temporary ones fed by snow and glacier water in the mountains; they reach their peak water levels in summer. Rivers that are not fed by mountain runoff have little water; their levels vary sharply, and periodically or occasionally they dry up. The rivers of the monsoon climate regions reach their maximum volume in summer and are utilized for irrigating the rice fields. The Asian rivers in the vicinity of the Mediterranean that are not fed



Average annual precipitation for Asia.

by mountain snows grow shallow in summer and sometimes even dry up. In the equatorial regions, however, the rivers are perennially full of water.

Lakes. The many lakes of Asia vary considerably in size and origin. The largest of them—the Caspian and Aral seas—are the remains of larger seas. Lakes Baikal, Issyk-Kul, and Hövsgöl (Khubsugul), the Dead Sea, and others lie in tectonic depressions. The basins of Lakes Van, Sevan, and Urmia are, furthermore, encircled by lava, and Lake Telets was gouged out by ancient glaciation. A number of lakes were formed as the result of landslides (Lake Sarez in the Pamirs); karst processes (the lakes of the western Taurus, in Turkey); or the formation of lava dams (Tsin Bokhu in Northeast China, and several lakes in the Kuril Islands). In the volcanic regions of the eastern Asian islands, in the Philippines, and in the Malay Archipelago, lakes have formed in craters and calderas. The subarctic has a particularly large number of lakes; in addition to lakes formed as a result of permafrost and subsidence, there are also ancient glacial moraine lakes. Many lagunal lakes occur along low coastlines.

The lakes in the internal drainage basins—such as Koko Nor, Tuz, and others—are usually saline. Lake Balkhash has fresh water in the west and brackish water in the east. Lakes through which rivers flow are freshwater and regulate the flow of the rivers that issue from them or flow into them; examples of these are Lake Baikal, associated with the Angara River; Lake Khanka (the Sungacha and Ussuri rivers); Tung-t'ing Hu and P'o-yang Hu (the Yangtze River); and Tonle Sap (the Mekong). Large reservoirs have also been created by the construction of hydroelectric stations.

Subterranean water. In arid regions, subterranean water is often the only source of water supply. Large accumulations are known to exist in artesian basins and beneath the dipping plains at the foot of mountains; these are associated with the extensive oases of Middle Asia, Kashgaria, and many other regions.

Detailed discussion of Asia's drainage systems and waterways, arranged generally from south to north, can be found at the end of this article. The discussion for Southwest Asia includes the Caspian Sea, Persian Gulf, Red Sea,

The Ganges River winds through the fertile plain east of Delhi, in northern India.
Harrison Forman

and Tigris and Euphrates rivers. Treatment of South Asia includes the Arabian Sea, Bay of Bengal, Brahmaputra River, Ganges River, Indus River, and Irrawaddy River. For East and Southeast Asia, the Amur River, China Sea, Huang Ho, Sea of Japan, Mekong Delta, Yangtze River, and Yellow Sea are covered. Discussion of Siberia's waterways includes the Lena, Ob, and Yenisey rivers.

SOILS

The soils of Asia are distinctly marked by the combined effects of climate, topography, hydrology, organic nature, and the economic activities of man. The horizontal zonality of the climate, the drainage conditions, the existing plant and animal life, and agriculture are each related to the considerable meridional extension of Asia, which is accompanied, of course, by a horizontal zonality of the soil cover, which is especially clearly defined in the plains of the continental sector.

The Arctic zone. In the Arctic, where glacial and Arctic deserts predominate, the processes of soil building are manifested only in rudimentary form. The soils are saturated and are low in humus. The subarctic north of Asia is occupied by a timberless zone of tundra vegetation. Beneath the tundras, specifically tundra-type soils are formed, which are characterized by poor drainage (associated with the proximity of permafrost) and only a short period in which the decomposition of organic substances is possible. This results in the accumulation of undecomposed organic residues in the form of particles of peat. The poor drainage creates an oxygen-free medium in which the bluish substance known as gley is formed. Thus, peaty-gley soils are most characteristic of the tundra. There are widespread occurrences of movement by mud glaciers; heaving of the ground because of frost; settling or caving in of the ground from thawing; and the formation of stone rings around central areas of debris in bouldery regions.

The forest tundra. Farther south stretches the transitional belt of the forest tundra, where tundra and sparse forest alternate with regularity. Tundra soils alternate with the soils of the taiga (the cold, swampy forested region to the south of the tundra, characterized by very low temperatures). The soils below the frozen taiga are called cryogenic (*i.e.,* having very low temperatures). In the mountainous regions the peaty-gley soils are replaced by mountain tundra and weakly developed, often embryonic soils of detritus and stony fragments.

The forest zone. The forest zone occupies the largest part of the temperate zone. Characteristic of soil formation in the forest zone is the leaching process. The forest leaves and needles that fall, together with dead remains of the sparse grass cover, are subjected to decomposition by organic acids in the litter of the forest floor; the duration of the summer season and the amount of precipitation are sufficient for complete decomposition of the soluble soil components; the soil solutions transport them and leach them into deeper soil horizons (layers). The undecomposed quartz grains remain in the upper horizon, which is therefore infertile; this layer resembles light-gray ashes, which is the reason soils of this type are called podzols ("under ashes"). The various subzones of the forest zone are subjected to different degrees of leaching. A dense, rusty-brown horizon of wash-down (deposition in an underlying layer of soil) underlies the podzolic portion of the soil profile (vertical section of the soil); its colour is related to the accumulation of iron and aluminum oxides. This layer, called orstein, or iron pan, is impervious to water and contributes to the self-swamping of the taiga forests. East of the Yenisey River, where the forest zone for its entire breadth is in the grip of permafrost, soil drainage (and consequently the leaching process) is made more difficult; the transfer of substances is complicated by freezing and thawing, and therefore the typical podzols are replaced by specific cryogenic taiga soils. Marshes and bog-type soils are widely distributed over a considerable part of the taiga subzones.

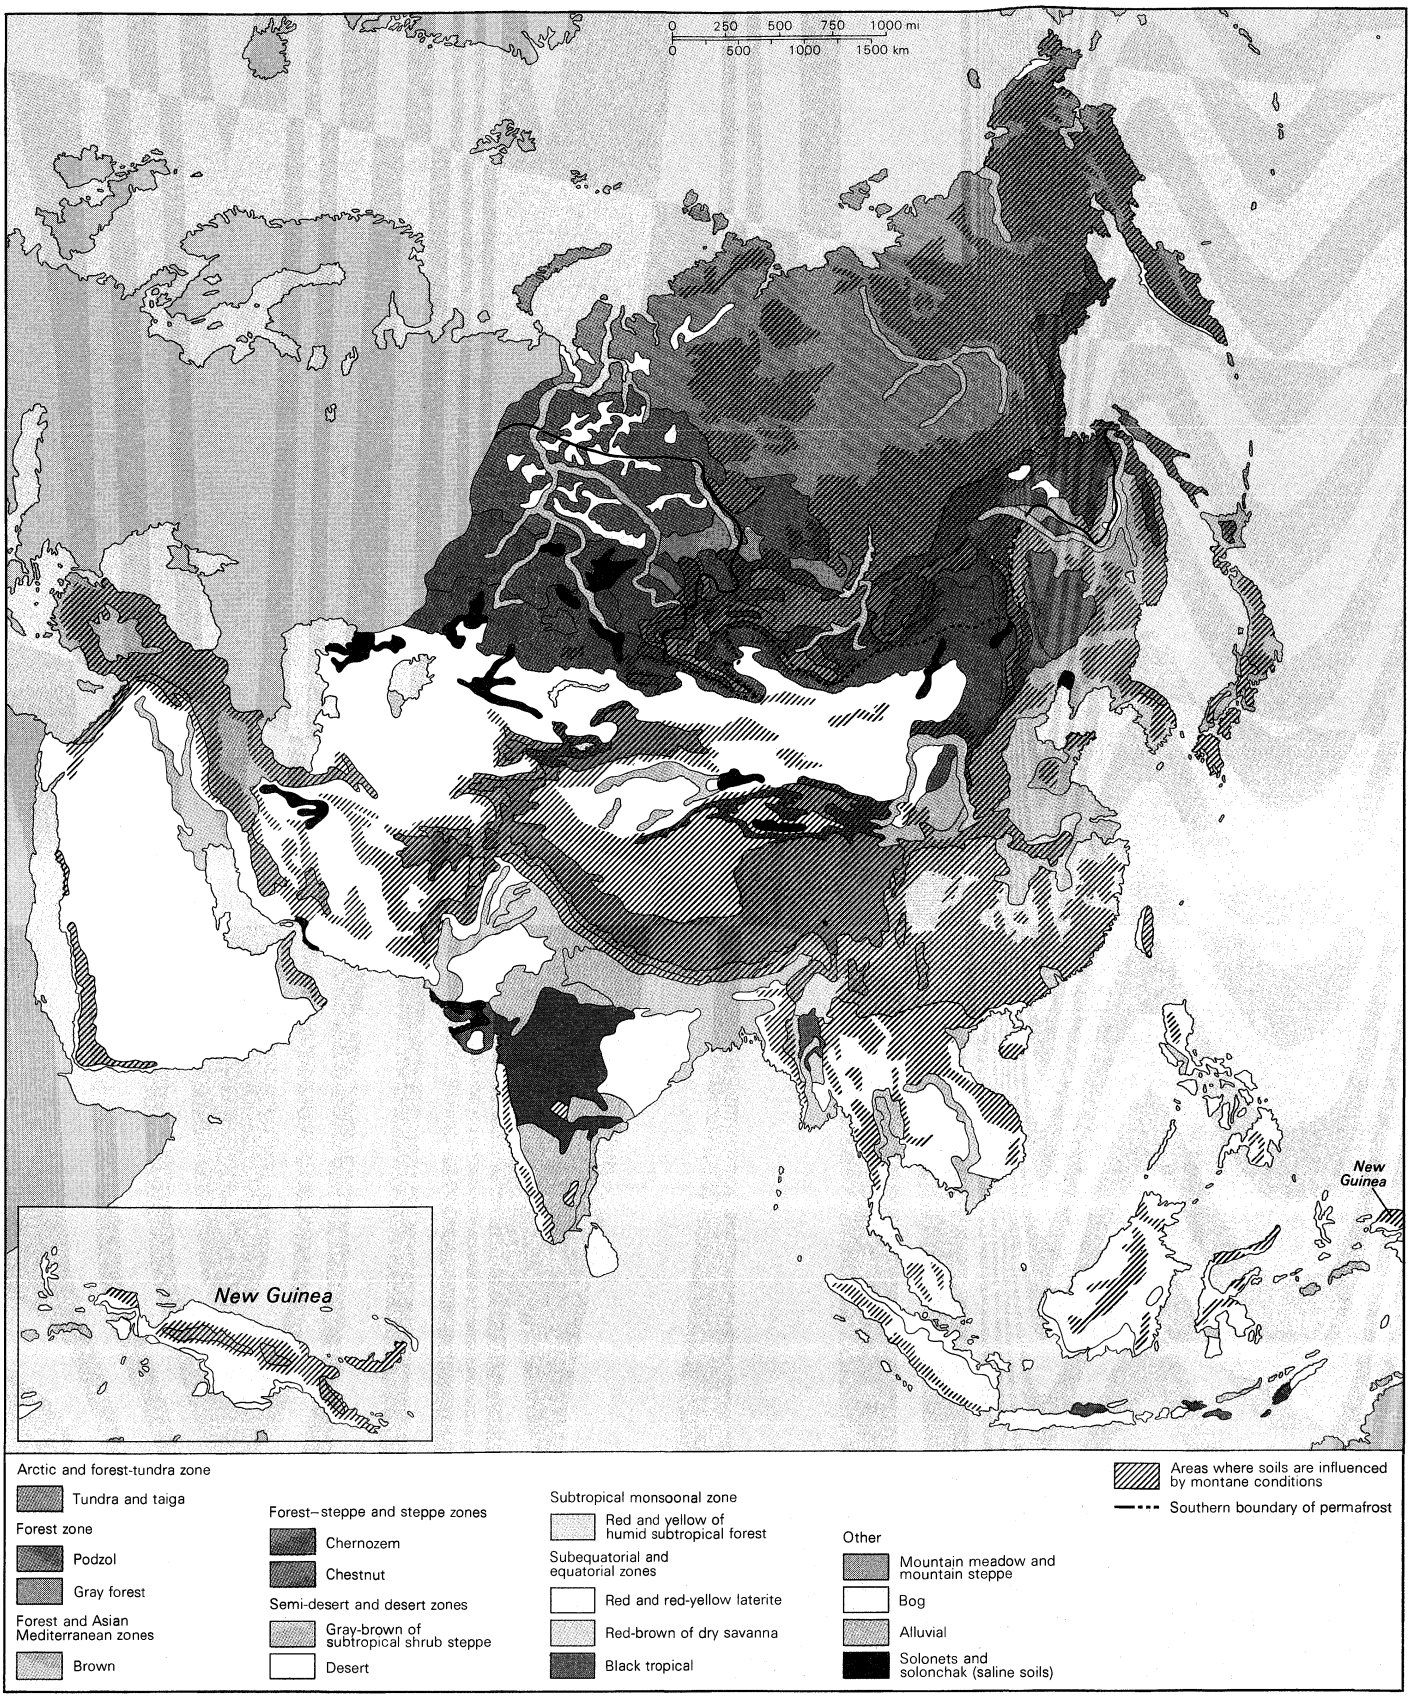
The leaching process

The deciduous forest subzones of Asia form two distinct areas. In Western Siberia there are small-leafed, primarily birch or aspen, forests on gray forest soils. They are more gray in colour than the podzols because of the greater amount of organic substances—such as tree leaves and a more abundant grass cover—feeding these soils. This explains their higher content of humus, as well as their greater fertility. The second section of the deciduous forest subzone has survived in the Far East, stretching from the Lesser Khingan Mountains in the north to the Japanese island of Honshu; in this subzone abundant warmth and moisture intensify chemical weathering, and iron oxides accumulate even in the surface soil horizons. In this manner brown forest soils, known as forest burozems, are formed.

The forest-steppe and steppe. Soil cover in the forest-steppe region is formed when the ratio of precipitation to evaporation is in equilibrium and as the leaching process of the wet season alternates with the upward flow of the soil solutions during the dry period. Under these conditions, with abundant organic material resulting from the dense vegetation, intensive accumulation of humus takes place in the soil, and dark-coloured soils are formed that are the most fertile in all of Asia; known as chernozems, they are the most fertile as well as the thickest of the forest-steppe and mixed grass subzones. Characteristic of the wooded-meadow plains of the Amur Basin (the "Amur prairies") are meadow soils that are dark, semiboggy, and often composed of blue gley. In the drier steppes, where vegetation is sparse, the amount of humus is reduced and the content of unleached mineral salts is increased; transport of the dissolved salts to the surface by the upward flow of soil solutions is also intensified. Associated with this process is a bleaching and salinization of the soil. The drier steppes thus form a transitional zone from the shallow southern chernozems to the chestnut soils. Broad expanses of the forest-steppe and steppe are under cultivation and serve as rich granaries for the cultivation of grain crops. Severe wind erosion occurs during the hot, dry seasons. In many areas impoverishment of the soil has also developed as the result of surface washout and gully erosion, despite the preventive efforts that have been made.

Soils rich in humus

Semidesert and desert. Through inner Kazakhstan and Mongolia stretches a zone of semidesert, and through Middle Asia, Dzungaria, Takla Makan, and Inner Mongolia a belt of temperate zone deserts. A belt of subtropical deserts extends through the Levant, the Iranian highlands, and the



Soils of Asia.

southern edge of Middle Asia. Beneath the semideserts, with their mosaic of desert and arid-steppe vegetation, light-chestnut and light-brown semidesert soils form; these are low in humus but contain an abundance of strongly alkaline soil. Beneath the deserts, where the supply of organic substances, as well as the humus content, is extremely low, gray-brown soils form in the temperate zone; gray desert soils (sierozems) form in the arid subtropics. Here there is a great deal of saline soil, and agriculture is possible only with the use of irrigation, which is feasible in the infrequent oases, where specific cultivated types of sierozems have formed.

Only in western Asia is the tropical desert zone clearly defined. Broad expanses of this area are characterized by embryonic soils and desert crusts, as well as by blowing sands.

Iron-bearing soils

The Asian Mediterranean. In the maritime areas of the Asiatic Mediterranean—Asia Minor and the Levant—xerophytic vegetation (vegetation structurally adapted to exist with very little water) of the Mediterranean scrub-woodland types, known as maquis (evergreen), shiblyak (an association of bushes and scrub characteristic of the Balkan Peninsula in Europe), and frigana (low-growing, prickly, and cushion-like bushes), is prevalent. The predominant soils under such vegetation are brown; they have accumulated iron as a result of the intense chemical weathering during the wet Mediterranean winter and of the upward flow of soil solutions during the dry summer. Frigana vegetation, characterized by thorn bushes, is widely represented in the West Asian semidesert highlands. Here soils have developed that are transitional between the brown soils and the sierozems.

Detailed discussion of the Arabian Desert, the Gobi, the Kara-Kum, and the Takla Makan can be found at the end of this article.

The subtropical monsoonal regions. Typical of the monsoon subtropics are the evergreen forests of the southern portion of the Korean Peninsula, of southwestern Japan, and of southeastern China. Intensive chemical weathering during the simultaneously warm and wet summer monsoon season results—as it also does in the more southerly torrid zones—in the decomposition and carrying away from the soil of many minerals, the accumulation of residual iron and aluminum oxides, and the consequent predominance of red and yellow soils as well as of podzolized soils. Agriculture, with the irrigation of rice fields, is especially widespread on the alluvial soils of the plains, which have been cultivated continuously by farmers for thousands of years. Terracing of the slopes is a widely applied practice.

The subequatorial and equatorial regions. The subequatorial zones of Asia are covered by savannas (grassy parklands) and dry-tropical deciduous forests, primarily situated in the rain shadow on the leeward slopes, and by wet-tropical evergreen forests on the rainy windward slopes facing the sea. Intensive leaching followed by evaporation is characteristic of these soils. Under the wet tropical forests, red-yellow lateritic (leached and hardened iron-bearing) soils predominate; beneath the savannas and dry tropical forests there are red lateritic soils that change, with increasing aridity, to red-brown and desert brown soils. Beneath the dry savannas of peninsular India there are unique black soils called regurs that are thought to be developed from basalt country rock.

Charles Lenars—Atlas

Tropical vegetation surrounding fertile rice paddies on the island of Java, Indonesia. The active volcano Gunung Merapi rises above the clouds in the background.

In the equatorial zone (southern Malaysia and the Greater Sunda Islands), typical tropical rain forests have developed. In southwestern Sri Lanka and in Java they have been almost entirely replaced by an agricultural landscape in which mountain slopes and hills are covered with plantations of tea, coconut palms, and rubber trees. The soils are lateritic and are red-yellow or brick-red, with marginal degrees of laterization.

In the valleys of the subequatorial and equatorial zones, alluvial soils predominate; they have been developed by thousands of years of cultivation and irrigation of the rice fields. Artificial terracing of the slopes is practiced on a very large scale in the mountainous regions, both for purposes of irrigation and in order to prevent soil erosion.

Underdeveloped mountain soils

The mountains. In the mountains, zones of different soil types are found at different altitudes. As a rule they are skeletal, underdeveloped soils, clearly reflecting the differences in rock structure and origin and in the degree of exposure of the slopes. The boundaries of the vertical zones become higher from north to south; the number of zones increases. Mountain soils also correspond to the different vegetation zones occurring at different altitudes. Under the mountain forests of the northern portion of the temperate zone are mountain-podzolic soils. Mountain variants of the gray forest soils and taiga-cryogenic soils have also developed; above the tree line they are replaced by mountain-tundra soils. Mountain chernozem and mountain chestnut soils develop beneath the mountain steppes in the southern part of the temperate zone; brown mountain-forest soils are found in the wetter regions; beneath the alpine and subalpine meadows the soils are of the mountain-meadow type. Mountain red podzolized, yellow earth, and other lateritic soils are predominant in the wet areas of the lower latitudes; in the dry areas mountain brown and gray-brown soils, as well as mountain gray soils, occur. The alpine steppe and desert soils of Central Asia have a number of distinctive characteristics.

The correlation of the vertical soil zones and of the landscape zones varies with the whole spectrum of vertical zonality. A zone of forest, followed higher up by meadows, with snow cover at the highest altitudes, is characteristic of the western maritime regions. On lower slopes in the western Caucasus, for example, broad-leafed mountain forests occur on brown mountain-forest soils; above these are coniferous forests on mountain podzolic soils, followed by stunted trees, followed in turn by subalpine and alpine meadows on mountain-meadow soils, while near the highest ridges perennial snow and glaciers are found. Associations of desert, steppe, meadowland, and snow zones are widespread in the interior of Asia and sometimes include mountain-forest zones. Thus, characteristic of the Tien Shan, for example, is the predominance of mountain-desert and semidesert landscapes, which occur in association with gray-brown and brown mountain soils in the foothills of the ranges, while higher up are mountain steppes associated with mountain chestnut soils and mountain chernozems. Under parts of the mountain forest-steppe and the mountain forests, the soils are podzolized. Above the stunted forest zone in the maritime sector, mountain-meadow soils occur beneath the meadows, but here, too, a distinctive snowy type of landscape occurs in the vicinity of the ridges.

Typical of the mountains of Eastern Siberia are the taiga-tundra spectra that occur in vertical zones; thus, mountain taiga on taiga-cryogenic soils is followed by a zone of dwarfed trees, followed by mountain tundra, and then finally by bald peaks.

In eastern Asia, the subalpine and alpine meadow zones with mountain-meadow soils usually disappear; instead, mountain-forest landscape extends as far up as the vicinity of the crests and is succeeded only by a zone of stunted trees. The spectra of the alpine regions of South Asia (the

Himalayas) are distinguished by the most complex variety of vegetation and soil types. (Y.K.Y.)

PLANT LIFE

In Asia an immense range of vegetation is found, resulting from the continent's wide diversity of latitude, altitude, and climate. Natural conditions, however, are not entirely responsible for the associations of trees, plants, and grasses of Asia; natural landscapes have been transformed by 80 centuries of farming.

The geographic pattern of vegetation. *North Asia.* The natural landscape has been least affected by man in sparsely populated North Asia. Vast plains, continentality, and the nearness of the Arctic Ocean explain the presence here of a zone of tundra—cold, treeless plains with permanently frozen subsoil—similar to that found in the western Soviet Union and in Canada. In more flourishing parts the tundra has a discontinuous covering of lichens, mosses, sedges, rushes, some grasses, cushions of bilberries, and dwarf trees of willow and birch; in the far north, lichens grow on favourable hillsides. Thanks to the greater number of hours of daylight during the summer solstice in June, when the Arctic Circle receives the same amount of light energy as the tropics, the tundra at this season is covered with bright flowers. Nevertheless, climate conditions are extreme; in Severnaya Zemlya, along the Arctic coast, thawing begins in May and frosts begin in August, although in some years frosts may occur at night throughout the short summer. The soil never thaws below a depth of two or three feet; consequently, hollows are badly drained and turn into peat bogs. Windy conditions speed up evaporation, and the frozen soil cannot absorb water to compensate for this, so that surface drought often allows wind erosion and the transport of sediments deposited by annual riverine floods.

The tundra

The tundra belt extends still farther south on higher ground. In the Arctic Urals tundra begins at about 3,000 feet, but at latitude 53° N it begins at 4,250 feet. Tundra extends over large areas of the Chersk, Verkhoyansk, and the Kamchatka mountains.

The taiga

The taiga zone—a belt of coniferous forest—begins south of the tundra, after a transitional zone of "wooded tundra" and forest galleries, found along streams between the tundra-covered watersheds. Taiga, although essentially coniferous, is mixed with hardy deciduous trees such as aspen and birch; there are sections of grass and shrub steppe in the drier zones. Larches account for 37 percent of the Siberian forest, which covers 2,700,000 square miles; pines cover 24 percent and spruce 4 percent. The geographic distribution of particular types of vegetation is determined chiefly by climate. Spruce, for example, unable to survive temperatures below −36° F (−38° C), is not found east of the Yenisey River. The taiga has a thin undergrowth of cranberries and bilberries, and there are numerous extensive peat bogs.

Sovfoto

Taiga vegetation growing on the Siberian Lowland of south central Siberia.

In Soviet Asia broadleaf deciduous forest does not extend eastward beyond the Yenisey River, where it gives way to the coniferous forests of Central Siberia, reappearing in Eastern Siberia near the Okhotsk Sea; here poplars, birches, and alders are numerous, as well as various conifers and larches. Forests around the Ussuri River include maples, ashes, walnut, elms, and lindens, in addition to species already mentioned. In the direction of China, as described below, the landscape becomes transitional.

South of the Siberian forest, the zone of prairie (continuous herbaceous cover) is not uninterrupted; forest frequently gives way to steppe (discontinuous cover).

Tibet, which is chiefly dry and cold, has a scattered vegetation of halophilic bushes (bushes flourishing in a salty environment) and Artemisia's tufts.

The Far East. In the Far East, the monsoon climate brings hot and rainy summers, giving rise to a great variety of temperate and tropical vegetation. China has the most varied vegetation of any country in the world, with about 15,000 species, excluding mushrooms and mosses. Far Eastern forests are fascinating to botanists because of the variety of their plant life; many trees have large, bright evergreen leaves, and there is a dense undergrowth with abundant creepers.

Japan has 68 percent of its area under forest, whereas China is almost entirely deforested, although sizable tracts remain untouched in the remote, rugged regions and many small areas have been reforested. The reason for this is that Japanese scenery was traditionally respected, and strict forestry regulations were severely enforced. The best examples of Far Eastern forest are found in Japan; for example, in the Kii Peninsula. Conifers are the principal species used for reforestation in Japan's policy of restoring its forests in order to meet the industrial need for wood.

The "true" Chinese forest

North of the Yangtze River, much of China was covered by primeval deciduous forest, most of which has been removed through farming. South of the Yangtze the "true" Chinese forest was prevalent before 1800. A wild growth of trees and shrubs survives, however, throughout the cultivated areas, and park-like tree growth and stands of bamboo are widespread. The "true" forest included 60 different genera of tall trees, including—among the temperate genera—oak and maple, linden, chestnut, hornbeam, and a species of hickory. Tropical genera included magnolia, the tulip tree, the camphor tree, the Spanish cedar, liquid ambar (a tropical tree of China), catalpa, and lianas (vines). A variety of conifers of both hemispheres was also to be found, and in the mountains of eastern Szechwan there grew a rare and ancient Chinese conifer, the metasequoia. Palm trees are found throughout South China and South Korea as well as in the southern half of Japan; many varieties of bamboo are also found in these regions.

The Peking government is proceeding energetically with a program of reforestation. The new forests, however, consisting largely of pines, do not resemble the primeval Chinese forest.

South Asia. The wettest parts of peninsular India, such as the Western Ghāts, and of Southeast Asia have magnificent forests noteworthy for the variety of their plant life. The culturally controlled forests of Java and Sumatra alone include over 3,000 species of trees. The variety of tropical vegetation is accentuated by the diversity of influences, such as that of altitude upon climate. Temperate pines are found in Sumatra and in the Philippines, where eucalyptus also thrives; oaks occur in the mountains of New Guinea; and austral *Podocarpus* (evergreen trees with a pulpy fruit) in the eastern Himalayas. In the seasonal monsoonal climatic zone of central Indonesia, Thailand, Burma, and southern India, the teak forest thrives as an open park-like cover with little underbrush.

A notable feature of South Asian vegetation is the Dipterocarpacea family (yielding aromatic oils and resins), which

Vegetation zones of Asia.

is here represented by more than 500 species. Mangrove thrives in muddy deltas along the South Asian coastline. In the southernmost areas, the bogs on the land-side edges of the mangrove swamps abound with the semi-aquatic nipa palm, the leaf fronds of which are widely used for thatching.

Hevea brasiliensis, the most successful rubber plant, is found in tropical Southeast Asia, where it was introduced from South America in the 1870s; it is particularly important in plantations in Malaysia and Indonesia.

Primeval evergreen rain forest remains in a few parts of South Asia. Secondary forest, which develops where temporary clearings have been made in the original forest, covers a much larger area. In drier tropical areas, secondary forest is deciduous; where the dry season is particularly long, park forest, with trees spaced at wide intervals, is found, as in the "sal" (East Indian hardwood) forests of India. Extensive fires in such areas have resulted in a herbaceous landscape, as in the cogonales (areas of coarse tall grasses, used for thatching) of the Philippines.

Mountain vegetation

In the higher mountains of Southeast Asia the cooler humid tropical climate gives rise to deciduous and coniferous temperate forest at altitudes of between about 4,250 feet and 10,000 feet. Above this level, low forests of plants, mostly shrubs of the heath family, are often found. Diverse types of trees grow in the mountain forests of the region. The Arakan Mountains of Burma, for example, are covered with a thick mantle of little bamboos. In the eastern Himalayas sal is intermingled with *Castanopsis* (a small genus of nut-bearing trees) and pines. Above these are found forests of shrubs and trees of the laurel family and, higher still, oaks and conifers; between about 10,000 feet and 13,000 feet, forests of firs occur. The central Himalayas present strikingly beautiful landscapes in the following upward succession: dry sal forest; pine forest; cedars, spruces, pines, and oaks; firs, birches, and tall rhododendrons; above 13,000 feet, bushes of rhododendrons, together with junipers; above 16,000 feet, perpetual snows.

West Asia. In western Asia naturally wild vegetation no longer occurs in clearly defined zones but is dispersed in small areas. The region is predominantly arid: desertlike depressions such as the Kyzylkum in the Kazakh and Uzbek regions of the Soviet Union and the Rub' al-Khali (Empty Quarter) of the Arabian Peninsula contrast with the moist, well-forested mountains that lie between them. Three climatic zones, however, characterize western Asia: a continental climate in the northern regions; a dry zone, except where northerly winds bring moisture to the mountains, to the south; and a Mediterranean climate along the western edges.

A few examples of the variety of vegetation associated with these climatic zones may be cited. In the valleys of the dead rivers of the Kara-Kum Desert grows a strange tree, the saxaul, which is oddly shaped, gnarled, and leafless; between the galleries of saxauls the desert is interspersed at very wide intervals with bushes and tufts of grass. A fringe of steppe covers the area between the Fertile Crescent (which sweeps in an arc from the Tigris–Euphrates Valley to the Mediterranean) and the north and west of the Syrian Desert. With more than 2,000 species of plants—more than in the whole of the Sahara—the borders of the latter desert are noteworthy for their floral variety. The moist northern slopes of the Pontic Mountains in northern Turkey are covered by magnificent forests of beeches and conifers, with an undergrowth of tall cherrylowels, hollies, and creepers. This type of forest is also found in Georgia and on the northern slopes of the Elburz Mountains in Iran. Along the Mediterranean border of Asia the vegetation is similar to that in other parts of the Mediterranean region: holm oak (an evergreen oak), Aleppo pine (characteristic of the city of Aleppo), cistus, mastic tree (which yields mastic, used as a chewing gum), and other species are found in landscapes of thick underbrush and open scrubland.

"Pontic" forest

Man and vegetation. *Vegetation in traditional civilization.* Asia's indigenous vegetation has provided many edible products, such as stone fruits, citrus fruits, bananas, mangoes, soybeans, and tea; building materials, such as wood, bamboo, and thatch; cotton and straw for clothing; bamboo, widely used in the making of utensils; and the bark of the paper mulberry, used for making bark cloth and paper. In addition, silkworms are fed upon mulberry leaves; lacquer is made from *Rhus vernicifera* (lacquer tree); and a multitude of other items are obtained from plants, including a styptic for stopping hemorrhage, an anti-asthmatic agent made from mahuang (a plant yielding ephedrine), and a fine fibre, extensively used in weaving, derived from ramie, a plant of the nettle family.

Similarly, the forested areas of Southeast Asia provide the sparse population with a wide variety of products: firewood; timber for construction; foodstuffs from a variety of trees, plants, and fungi, including sago, taro (a plant with an edible, starchy, tuberous rootstock), and mushroom; scented resins from sandalwood and eaglewood (an East Indian tree with soft resinous wood); and dyes from a variety of tubers. Probably the irrigated cultivation of taro and rice began in Southeast Asia.

Wheat is indigenous to the humid hill margins of western Asia; it still grows spontaneously in the hilly fringes of Asia Minor. Cherry, peach, and pistachio trees, as well as vines, were domesticated in the mountains of western Asia. The large acorn cups from the forests of *Quercus aegilops*—a species of oak, in western Asia Minor—are valued for the abundant tannin they contain.

Commercial forestry. China and the Indian subcontinent, with their enormous populations, are today poor in timber resources. The best resources of timber for building and for paper manufacture are in Siberia. Japan produces about 1,600,000,000 cubic feet (45,000,000 cubic metres) of timber annually from its controlled forests. The tropical and equatorial forests of South Asia are difficult to exploit; because of the diversity of species found in these forests, commercially valuable trees are mixed with a majority that is of no economic value. Some deciduous forests, however, are of commercial interest since they are more homogeneous and consist of good quality trees. Included in this category are the forests of teak, sal, and ironwood. Such forests are important in the Burmese economy, timber being among the more important exports. The countries of Indochina, as well as Thailand, Malaysia, and the Philippines, are covered with extensive forests, but only a small fraction of their timber resources are commercially exploited. As in Burma, teak is the most valuable wood, but much of the remaining natural timber is of low quality and not easily marketable. It is, nevertheless, increasingly being recognized that the forests of these countries form potentially valuable resources. Malaysia, in particular, is encouraging the development of forestry, and although overshadowed by rubber and tin, forestry is one of the most important Malaysian industries. In western Asia, Turkey has launched a program to increase production from its forests and thus reduce lumber imports. (P.Gu./Ed.)

Timber

ANIMAL LIFE

The Himalayas, stretching from east to west, form a barrier largely preventing the movement of animals southward or northward. Thus, Asia north of the Himalayas, with parts of western Asia and most of the Far East, belongs to the Palearctic (literally "ancient Arctic") zoogeographical region. Asia south of the Himalayas is called the Oriental, or Indian, Region. The boundary dividing these zones east and west of the Himalayas is not well marked, however, as there the mountain chains often have a north–south trend facilitating migration of animals between them.

The Palearctic Region. A distinction can be made between the animal life of the tundra in the north and that of the adjacent taiga farther south; the taiga in turn merges into the steppes, which have their own distinctive forms of animal life. The tundra subsoil is frozen throughout the year; hence, burrowing animals cannot live there, and, as the tundra is partly free from snow only during the short summer, conditions for life are poor. Most animals, including reindeer, Arctic hare, Arctic fox, and wolf, live here in summer only and migrate in autumn, but the lemmings (small rodents of circumpolar distribution) stay, feeding on the herbage buried beneath the snow. Hibernation is impossible, for the short summer does not allow the necessary accumulation of food reserve in the body.

During the summer, birds are numerous but they also desert the tundra in winter, except for such birds as the willow grouse and the ptarmigan, which live in tunnels in the snow, feeding on berries and leaves. Many species of waders, such as the gray plover, the sanderling, and several kinds of sandpipers, migrate to the tundra and breed there in the summers, feeding principally on the mosquitoes in the wet areas. Mosquitoes are also the staple food of passerine birds (true perching birds), such as the snow bunting and the Lapland bunting. Gyrfalcons (a subgenus of large Arctic falcons), rough-legged buzzards, and skuas (large, dark-coloured rapacious birds of northern seas) prey on these smaller birds and on lemmings. Several kinds of geese and ducks, Arctic tern, and three species of divers occupy the moist parts.

The taiga fauna

The taiga fauna is much richer than that of the tundra. The taiga is the haunt of brown bear, wolf, glutton (a kind of wolverine), otter, ermine, sable, lynx, elk, forest reindeer, hare, and several kinds of squirrel. Birds include various kinds of grouse and woodpecker, pine grosbeak, crossbill, siskin, redpoll, red-spotted bluethroat, rubythroat, redwing, fieldfare (a medium-sized thrush), nutcracker, Siberian jay, and others. Wading birds include the terek sandpiper, which frequents marshes and pools.

The rivers of North Asia are inhabited by many common freshwater fishes and by several kinds of sturgeons, including the sterlet. Lake Baikal has a peculiar animal life, including many native species of sponges, worms, and crustaceans and a native species of seal.

The animal life of the steppes differs as much from that of the taiga as that of the tundra. It includes many burrowing rodents, such as jerboas, marmots, and piping hares, and, among larger animals, large numbers of antelope. The steppes were the original home of the northern cattle (*Bos taurus*), the horse, and probably the Bactrian (two-humped) camel; it is doubtful that any of these remain as truly wild animals. Typical birds are bustards, quails, sand grouse, and the red-legged hobby. Hoopoes and rollers are common locally, and bee eaters and the common sand martin nest along riverbanks. Waterfowl inhabit the reed beds of the great rivers, as do locusts, which migrate in almost unbelievably large numbers, devastating crops.

Wild sheep and goats live in the mountains and on the plateau to the north of the Himalayas. Tibet is the home of the wild yak, which is in great danger of extermination, although the domesticated yak survives.

The eastern part of the region, comprising Northeast and eastern China, has several peculiar kinds of deer. The Siberian tiger, originally native to southeastern Siberia, Manchuria, and Korea, has spread southward through eastern China into all of Southeast Asia and northern India. The giant panda inhabits the lower mountain margin of China bordering Tibet; the lesser panda is a Himalayan animal. Associated with the wastelands of the higher Himalayas is a legendary form of higher animal life—the yeti, or "Abominable Snowman." Some species of animals are peculiar to Japan, including a monkey related to the tailless Barbary ape of Gibraltar.

The large rivers of China have a rich fish life, among which *Psephurus gladius* (paddlefish) from the Yangtze and Huang Ho is of interest, as it is one of the two survivors of an otherwise extinct family, the other remnant of which is the paddlefish of North America. Another freshwater animal is the giant salamander, found in Japanese waters. Southeast Asia and southern China are the home of most of the carp family, from which the various forms of goldfish are derived.

The animal life of Asia Minor is much like that of other Mediterranean countries, but that of Israel, Syria, and Arabia also includes an African element, such as a species of coney and—in Lake Tiberias and the Dead Sea—fishes of the African genus *Tilapia* (the Nile perch). The donkey may have been domesticated in Southwest Asia, and the dromedary (one-humped) camel was originally native to the drier portions of Transcaspia.

The Oriental Region. The greater part of the Oriental Region is tropical. The northwestern part is dry and partly desert, so that animal life is chiefly confined to the forms related to those of the dry parts of the Ethiopian and Palearctic regions. Elsewhere, monkeys are common. Apes are found only in tropical rain forests—being represented by gibbons in Assam, Burma, the southeastern peninsula, and the Greater Sunda Islands—whereas the orangutan is restricted to Sumatra and Borneo, where it is in danger of extermination.

Large game animals

The Asiatic distribution of the African lion is now confined to the Gir Forest of the Kāthiāwār Peninsula in India, where it is protected, but a few specimens may still occur in southeast Iran. The tiger is now found from the Himalayas to Sumatra, Java, and Bali, but not in Borneo or Sri Lanka. Panthers range all over the region, except in Sumatra. Civets and mongooses are numerous. Among badgers, the ratel lives in the hilly districts of peninsular India and is even to be seen as far west as Israel. Jackals are plentiful in India; the striped hyena is confined to drier parts. Both are absent from the east.

Flying and ordinary squirrels are common in woodlands; the gaur (a large wild ox) is found in India and Burma, the banteng (the Malayan wild ox) in Burma and south to Borneo and Java, but not in Sumatra.

The most common antelope is the black buck, found in open brush-covered wild areas and cultivated plains all over India, except on the Malabār Coast; the nilgai, or blue bull, and the chousingha (a four-horned antelope of northern India) occupy hilly regions south of the Himalayas. Species of deer include musk deer in the pine zone of Kashmir, Nepal, and Sikkim; sambar deer practically over the whole region; and barking deer ranging northward into southernmost China.

Chevrotains (very small, hornless, deerlike ruminants) are typical, and wild pigs are also widely distributed. The Indian one-horned rhinoceros is protected and confined to Nepal and Assam; the Javanese rhinoceros is now restricted to Malaya, southern Sumatra, and western Java; the two-horned rhinoceros ranges from Burma to Sumatra. The Indian tapir lives in dense forests in southern Tenasserim, Malaya, and Sumatra. The Indian elephant is found throughout the region. Scaly anteaters, or pangolins—also found in Africa—are characteristic. The tropical cattle (*Bos indicus*), known as Zebu or Brahman cattle and recognizable by its shoulder humps, was domesticated in India, as was the water buffalo, which is now distributed from Egypt to central China and the Philippines.

Birds

Game birds are important. The Indian peacock can be seen throughout India, whereas another species of peacock (*Pavo muticus*) is restricted to Java. Numerous species of pheasants live in the forests of Burma, Thailand, Indochina, Malaya, Sumatra, and Borneo. Jungle fowl are unique to the Oriental Region and are the source of all domesticated chickens. Pigeons occur in great variety, but the number of species of parrots is small compared with other tropical regions. Water and wood kingfishers are represented by many species. Hornbills show their greatest development in the Oriental Region. The Indian hoopoe is common in India but is only a migratory bird in the southeastern part of the region. Among cuckoos the brain-fever bird—an Asian hawk cuckoo that takes its name from the suggested effect of its repetitious cry—is well known. Eagles, osprey, falcons, hawks, kites, and buzzards all occur; in the western part vultures are numerous and are found even in towns. The forests are inhabited by many species of woodpeckers. The barbets (loud-voiced tropical birds) are characteristic, the best known being the coppersmith bird. Bee eaters and rollers are common in India, but whereas the former can be found as far as the Malay Archipelago and beyond, rollers are absent in the southeast except in Celebes and beyond. The passerine birds are very numerous. The house crow, the Indian grackle, and the common mynah are familiar birds in India. Drongos (Old World passerines, usually black with hooked bills), flycatchers, bulbuls, tailorbirds, orioles, and many others are widely distributed, and broadbills are typical. Among the herons the white cattle egret is common throughout the region, whereas spoonbills, cranes, and gulls are mostly confined to the western part.

Of the crocodiles the gavial, which has long slender jaws and a soft, inflatable nose tip, is restricted to the large rivers of northern India; a species of an allied genus

is found in Sumatra and Borneo; and the mugger (the common freshwater crocodile) and the estuarine crocodile have a wider distribution. Freshwater turtles and land tortoises are well represented. Lizards are numerous, and flying lizards are also typical of the region. Chameleons are chiefly African, but one species is found in peninsular India and Sri Lanka. Snakes are numerous, among them the poisonous krait, cobra, and Russell's viper. Frogs and toads are abundant.

The freshwater fish life of the Oriental Region is rich. The carp and catfish families have many native genera and species. The labyrinth fishes (so named for a labyrinthine outpocketing of the gill chamber that permits them to take oxygen from air as well as from water), to which the climbing perch and the gourami belong, are characteristic of the fish life of the region, as are spiny eels.

Insects, arachnoids (scorpions, spiders, and mites), mollusks, and other invertebrates inhabit this region in great numbers. Large bird-winged butterflies, allied to the well-represented swallowtails, are typical. Almost all known families of scorpions are present. Among land shells the absence of Helicidae (a family of land snails having lungs), common in the Palearctic Region, is noteworthy. Their place is taken by other forms, such as *Hemiplecta,* and by land mollusks having horny or shelly plates on their posterior dorsal surfaces. (L.F.deB.)

The people

A discussion of Asia and its peoples cannot entirely exclude other parts of the Old World when the origins of man, his ethnic divergence, and his migrational wanderings, or the evolution and historic development of his linguistic and culture systems are considered. The relatively modern division of the largest of the continents into Europe and Asia derives from arbitrary decisions made by peoples living in the western part of the peninsula of Europe; this division has only minor significance in relation to the historic patterns of human occupation of the continent. The ethnic and linguistic diversity of Asia is greater than that of any other continent, because it represents ethnic types and linguistic systems that have evolved in separated regional homelands, as well as repeated patterns of modification and intermixture, resulting from both peaceful and militant migrations. Ethnically and linguistically, some territories have become highly diversified mosaics in which there are mixed and overlapping elements.

EVOLUTION OF ETHNIC PATTERNS

The three major racial stocks

Original racial stocks. The peoples of Asia include all the three major racial stocks of *Homo sapiens*—Congoid (Negroid), Caucasoid, and Mongoloid. The view is here taken that Congoid racial stocks derived from tropical origins in the zone extending from Africa eastward through the Indonesian Archipelago. It would, however, appear that to the east of Africa their original numbers were insufficient to ensure that they became the predominant element among the populations of South and Southeast Asia. The contrary belief that Congoid groups east of Africa originated in Africa leads to the conclusion that the migrating Congoids scattered out very thinly to the eastward and were able to contribute only to the skin pigmentation of South India and part of Southeast Asia. Whatever their origin, Congoid racial stocks at no time seem to have penetrated deeply into the Asian mainland. At the present time they constitute an element in ethnic stocks only in the southern peninsular fringes of Asia. The view here taken is that the Caucasoid racial stocks derive from a western Eurasian racial hearth, or region of origin, that also includes North Africa, and that Mongoloid racial stocks derive from an eastern Eurasian racial hearth. A very simplified view of the history of man in Eurasia, then, is that the western zone of the continent came to be populated primarily by the Caucasoid, or white, ethnic groups; that the eastern zone was populated primarily by the Mongoloid, or yellow, ethnic groups; and that the southern fringes of the continent were lightly occupied in early time by the Congoid, or black, ethnic groups. This pattern was apparently derived from the evolutionary beginnings of *Homo sapiens* possibly about 40,000 years ago, out of predecessor racial stocks, since the basic differentiation of the human species predates both modern man and the last glacial era. In considering modern man in Asia we cannot speak of distinct races in any definite way, as repeated migrational movements since the last glacial era have resulted in such intermixed racial stocks that the modern Asian cannot be racially defined. While it is possible to give a general description of an Indian, a Chinese, or a European, this can be done only in terms that connote ultimate regional origin in the broadest sense. In discussing Asian ethnology, therefore, we cannot refer to races but only to ethnic groups that speak particular languages and that have particular cultural characteristics. Thus, a Hunan Chinese from central China may be compared to a Czech from central Europe, or a Japanese from the southern island of Kyushu may be compared to an Iranian from southern Iran. All four belong to the single species but show marked differences in physique, language, and culture. It is, nevertheless, convenient to stereotype Chinese, Japanese, Czechs, and Iranians as members of "geographic races," meaning members of normally separated breeding populations.

Prehistoric migrations

Ancient migrations. The two primary prehistoric centres from which migrations over the continent took place were Southwest Asia and a region comprising the Mongolian plateaus and North China.

From prehistoric to historic times, possibly beginning as early as 30,000 years ago, movements from Southwest Asia continued toward Europe and into Central Asia; significant movements also took place into India. There were probably small divergent migrational movements in other directions that became swallowed up in later patterns of mixing. The Greeks were one of the late groups moving westward, about 2100 to 1900 BC, as were the Aryans who moved east to invade India from 1600 to 1500 BC. Mongoloid migrational movements have always been primarily toward Southeast Asia.

Important Mongoloid components, however, also moved westward through Central Asia toward the European peninsula. Such movements must have begun as early as 10,000 years ago, but they continued into the Christian Era as Mongols pushed Turkic peoples westward, setting off additional displacements of such peoples as the Finns and the Magyars. These westward Mongoloid movements also produced, over a period of time, much mixing of early Caucasoid and Mongoloid stocks in Central and West Asia. Northern Eurasia continued to be inhabited chiefly by thinly distributed residual elements of very early eastern Asian stocks, although some fairly late northward movements of Turkic peoples did take place.

There have been many small-stream movements away from the main trends, and these have often complicated the ethnic picture of any one region. At least one prehistoric Caucasoid movement penetrated East Asia and today is represented by the historic aboriginal population of Japan known as the Ainu. A countermovement out of India by a nomadic ethnic stock about AD 1000 contributed the Gypsy strain now so widespread in Europe.

Prehistoric countermovements along the China coast carried early Mongoloid migrants of Southeast Asia northward again into southern Korea and Japan, to leaven the later Mongoloid and Ainu stocks, from all three of which modern Japanese are derived. Similar northward drifts of early Mongoloid Indonesians account for a significant share of the ethnic ancestry of the population of the Philippines. Within the broad zone of Central Asia, prehistoric and historic movements have often retraced older migratory routes, creating overlapping and fragmented distributions of stocks that have yielded the many ethnic groups found there today. Secondary and tertiary intermixing of many of these regionally derived ethnic groupings has resulted in the emergence of regionally and physically distinct ethnic groups. Thus, the Uzbeks may originally have derived from a Mongoloid stock; some of them migrated westward to near the Volga River at an early date, then moved southward to become intermixed with Caucasoid-derived stocks. Uzbeks are now widely distributed in Central Asia and show considerable physical and linguistic variation.

Modern movements of peoples. Within historic time the aggressive expansion of particular ethnic groups has either driven weaker groups away from their territory or has resulted in the newcomers' assuming control of the territory and reducing the older inhabitants to the status of ethnic minorities. Some of these weaker ethnic stocks eventually became so diluted by intermixture as virtually to lose their identity. In some instances a new and variant ethnic stock with a different dialect resulted from the mixing. Some areas are now given over to distinct enclaves occupied by several diverse ethnic stocks, each following its own way of life. Thus, in Southeast Asia, from the riverine and coastal lowlands to the higher mountain uplands, different ethnic stocks have been migrating southward to become resident in separate altitudinal layers, one above the other. Some of this migrational movement in Southeast Asia is as late as the 19th century, but it has been going on for thousands of years. Within what are now India and Pakistan the general trend, for many centuries, has been eastward and southward, producing very discontinuous patterns. Discontinuity also characterizes the ethnic patterns in Central and Southwest Asia.

The mixture of ethnic groups

Militant campaigns of Arabs spread Islām and Arab political structures out of Arabia westward into Africa and Spain and eastward through the Levant into Asia Minor, Transcaspia, and India. Beginning in the 7th century AD and lasting until the 16th century, these efforts spread Arab ethnic elements widely in Southwest Asia and northern Africa.

Within recent times, movements of Caucasoid European Russians eastward along the Central Asian routes of exploration, and the penetration of the oceanic fringes of South and East Asia by Caucasoid western Europeans, have carried Caucasoids to all parts of the Eurasian continent. This has resulted in an interbreeding that has produced many local and variant mixtures. Since the 17th century, intermarriage between Europeans and indigenous Asians has produced many mixtures, including the Anglo-Indians of India and the Burghers of Sri Lanka. Intermarriage between Chinese men and local women has produced many hybrid strains in Indonesia, Malaysia, Thailand, and the Philippines. The introduction of American white and black soldiers to East and Southeast Asia, during and after World War II, has further complicated the ethnic mosaic in China, Korea, Japan, Vietnam, and the Philippines. Such modern racial mixings are often viewed apart from the historic patterns of migration and racial mixing, but essentially they form a part of them.

POPULATION DISTRIBUTION AND REGIONAL ECOLOGY

The background. Around 1750 the distribution of ethnic groups was relatively easy to describe. The whole of northern Eurasia was rather lightly populated by diverse ethnic groups of Paleo-Asiatic, Tungusic, and Turkic peoples who engaged in hunting, collecting, fishing, or herding; some groups, such as the Samoyed, Yakut, and Chukchi, had somewhat distinctive single economies or had economies that were seasonally mixed. Central Asia, Tibet, and Mongolia formed a mixed zone dominated by nomadic pastoralism, but the lower plateaus and lowlands were sprinkled with agricultural oases in which towns and villages were occupied by sedentary crop growers. Population was relatively light; mountain regions were occupied only in summer, but there were locally dense populations centred on such large oases as Tashkent, Samarkand, Kashgar, and Urumchi, with smaller groupings around lesser sources of water. The Buriat Mongols and the Kirgiz were pastoral, whereas the Tadzhiks, Uighurs, and Uzbeks were sedentary oasis dwellers. Southwest Asia was then inhabited by Iranian, Arab, and Turkish peoples, with a scattering of minority ethnic stocks, practicing either traditional pastoralism or the agricultural economy of the oasis. Population was concentrated around cultivable areas, water resources, or grass pastures.

Life-styles in the 18th century

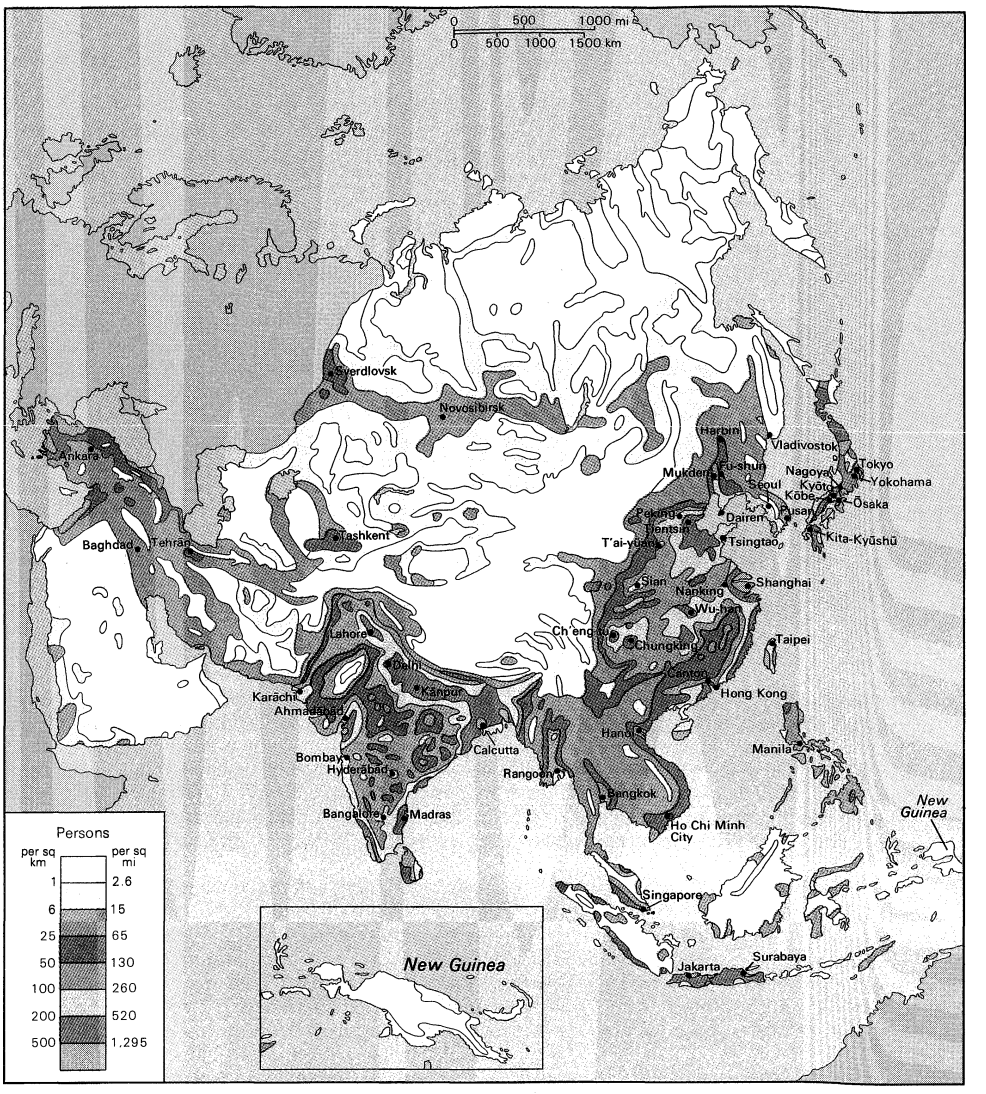
South and East Asia showed a more complex dual set of patterns. The largest components consisted of the highly civilized lowland populations, long settled on their land and engaged in sedentary agriculture and handicraft manufacturing. Market towns and cities were scattered over the countryside, and many small port towns dotted the seacoasts. Population density was heaviest in the best agricultural lowlands, which had also been occupied the longest, such as the North China Plain, southern Japan, coastal Vietnam, and the Ganges Valley.

Lesser components included the many diverse ethnic groups scattered in wet deltaic lowlands such as those of the Ganges, Irrawaddy, Chao Phraya, and Mekong rivers; the central plain of Luzon Island in the Philippines; and the north coast of Sumatra. Groups were also scattered throughout most of the hill and lower mountain country. Their living systems varied from simple hunting and collecting economies to more complex systems in which, apart from shifting cultivation (the shifting of cultivation to new land after a crop has been raised), hunting and collecting are also practiced. Generally these lesser areas had small populations scattered in hamlets or village settlements sustained by subsistence economies; only a little handicraft manufacturing took place, and trade was confined to minor products. The Nāga of northeast India, the upland Karen of Burma, and the Miao of Laos exemplified this life-style. Toward the end of the 18th century, European colonial efforts were beginning to shape the production systems of eastern Eurasia to conform to patterns of integrated world trade. The supplying of Europe with raw materials, which was to characterize the early 20th century, was also begun at this time.

The pattern of ethnic distribution. By the late 20th century, great changes had taken place in both the ethnic patterns and the associated life-styles in Asia. The divisions that prevailed in the 18th century were dissolving as the Soviet Union and China extended their economic and political control over Siberia and Central Asia, as the former colonial lands of South Asia established political independence, and as some of the component territories of the old Ottoman Empire were reshaped into the modern nations of Southwest Asia. Many of the hundreds of small ethnic groups were being absorbed into the populations of nation-states, many old languages were declining, and many formerly distinctive living systems were remaining in existence only as remnants or artificially preserved societies. The expansion of dominant ethnic groups was steadily restricting the territory available for older, simpler societies; and aspects of modern economic development were replacing the earlier systems. It is possible, still, to identify the region in which the Yukaghir formerly lived as a separate culture group in Eastern Siberia, but—for the few hundred Yukaghir who remain—political absorption, modernizing acculturation, and internal social decay have made the classic description of the group largely a historic one. Many former horse-riding, tent-dwelling, sheep-herding Kara-Kirgiz today ride tractors on Soviet state grain farms, live in permanent villages, and speak Russian in public. Some men of the Chotanāgpur hill region of eastern India, who formerly engaged in hunting and practiced shifting cultivation, today work in the steel mills of Jamshedpur. The remnant Ainu of northern Japan today are gathered into "cultural villages" where their continued woodcarving and bear dances attract a flow of tourists from southern Japan.

Social changes of the 20th century

Contemporary developments. Population densities have everywhere increased, and planned programs of modernized agriculture, mineral exploitation, and industrialization are bringing cultural change. Some of the small ethnic groups are dying out, but larger groups have often accepted change and are again increasing in numbers. In South and East Asia, increasing lowland populations are pressing hard upon the available land as population densities exceed 2,000 persons per square mile. In Central Asia, both Chinese and Russian settlement programs are moving peoples from heavily populated regions into frontier zones, in order to develop both agricultural and industrial resources. In Southern Siberia the Soviet settlement program has spread a thick wedge of European Russians and assorted ethnic minorities eastward to the Pacific and northward along every river valley to the Arctic Ocean. As a result, the Paleosiberian ethnic remnants are being submerged and absorbed. Old trading posts, oasis towns, and



Population density of Asia.

the few old cities of Southern Siberia and Soviet Central Asia are being developed into modern industrial centres; these are linked to modern transport systems by which raw materials and manufactured products flow back to the European regions. Most new cities are populated largely by European Russians, with the former Asian ethnic stocks remaining chiefly in the rural areas. The modernization of Southwestern Asia, through the renascence of Turkey and the impact of petroleum exploitation on the Arabian Peninsula, has altered many of the old patterns of ethnic groupings in these areas. A further alteration of the historic pattern came in 1948 with the creation of the State of Israel, to which more than 1,500,000 Jews from the Middle East, Europe, and North America have migrated.

Urbanism

Urbanism is becoming marked in many parts of Asia, thus heightening regional contrasts in population densities. Israel and Japan are among the most highly urbanized countries in the world. Asia's cities are among the largest in the world, and many of the newer cities resemble those of the West in terms of population, buildings, facilities, and congestion.

Ecological factors. Agriculture remains the mainstay of Asia, though the percentage of the population engaged in agriculture is steadily declining.

Although marginal lands in many parts of South and East Asia have been brought under cultivation, and many former pastoral ranges in Southwest and Central Asia are now irrigated, the broad ecological factors touched upon above continue to give rise to zonal distinctions in population and economic activity. Parts of South and East Asia can support dense populations. Favoured localities in the southwest—for example, in Turkey and northern Iran—support large populations. In Southwest and Central Asia in general, however, agricultural productivity and population density vary markedly with the regional pattern of rainfall or the availability of water from humid highlands nearby. In the Soviet sector the older pastoral nomadism has been transformed into organized transhumance (seasonal migration of stock between lowlands and mountains); consequently, the families that were formerly nomadic have become permanent residents in villages, and only herders accompany the flocks and herds. Northern Asia remains a semi-developed frontier region with short-season crop growing in favoured southern localities, even though breeding of newer varieties has extended agriculture northward. The Arctic fringe is being developed on the basis of mineral resource exploitation, but only in particular localities. Siberia continues to be lightly populated, with the population primarily grouped around local centres.

The importance of water

The pattern of language distribution. Language maps of an area tend to reflect conditions of the past because speech systems are constantly undergoing change. In the past, language maps for the Eurasian continent have often shown eight languages—Turkic, Slavic, Tungusic, Chinese, Tibeto-Burman, Indo-Aryan, Iranian, and Mongol—almost blanketing the main portion of Asia and leaving other languages predominating only on peninsular appendages, island fringes, and in small pockets. Except for the large eastward expansion of the Slavic group, the map

reflects distributional patterns that prevailed in the 18th century. At that time, by far the largest language groups, by number of speakers, were the Chinese and Indo-Aryan, but the Tungusic languages were probably used over wider areas. In recent times many of the small ethnic-group languages have, for practical purposes, been dying out, to be preserved only by professional linguists. The Tungusic group shows this decrease in usage, in spite of the Soviet practice of publishing books and newspapers in regional languages and the encouragement given to the preservation of the more important ethnic languages. Russian is now the dominant public language throughout the Soviet Union, and in the Asian territories it is spoken by large numbers of non-Slavic inhabitants. Similarly, Mandarin Chinese is expanding in China at the expense of local languages and dialects. In India, however, local languages are not losing ground, and language has become a territorial political issue. Meanwhile, the Indian government continues to use English as an official language. In Indonesia, which has many local languages and dialects, Bahasa Indonesia (the national language) has not yet spread throughout the Indonesian state. English remains the most commonly spoken single language in the Philippines, despite the adoption of a national Pilipino language.

The loss of small ethnic languages

Whereas many languages are dying out, as ethnic groups disappear or become merged into larger groups, some ethnic populations are increasing in numbers, thus increasing the relative importance of their languages. The large increase in the population of China now means that Mandarin Chinese is the world's leading language by number of speakers. The marked increases in population in Japan and the island of Java mean that Japanese and Javanese rank much higher on the list of languages, by speakers, than formerly. Similarly, Western Hindi, spoken in northern India, is one of the larger languages by number of speakers. Though many of the Paleosiberian (Paleo-Asiatic) languages are dying out as their ethnic users decline in numbers, the Uzbeks and the Tadzhiks, for example, have adjusted to Russian control and are again increasing in numbers, forming significant ethnic components of the Soviet Union, with the result that their languages are being maintained. It appears that many ancient languages spoken in Asia have disappeared within the last millennium and that others have been greatly modified by linguistic change.

Regional situations have sometimes produced multiple and overlapping language patterns. Around some of the old Central Asian oases and in Southern Siberia, migrants from Russia and exiled ethnic groups have created ethnically mixed regional populations. A comparable pattern may be discerned in Chinese Central Asia. Such large cities as Manila, Singapore, and Bombay show complex linguistic patterns. As European Russians have moved into the new cities in Transcaspia and Western Siberia, Russian has become the language of the cities; the older languages have been confined chiefly to the countryside.

FORMS OF ETHNIC ADMINISTRATION

Imperial administration. The older forms of administration, by which political states controlled adjacent and frontier ethnic groups, generally used local native leaders, who normally were given honorific subordinate titles and made responsible for the orderly control of their territories. The Chinese Empire sometimes entered into treaty-like agreements with subordinate states on its periphery and either subsidized the non-Chinese states or exacted tribute as a token of subordinate or feudatory status. The British in India and Burma, the Dutch in Indonesia, and the French in Indochina developed systems of frontier agencies that employed resident officials to supervise local leaders, who exercised autonomy over what amounted to ethnolinguistic groups. The Thai maintained their control of Siam (now Thailand) as a buffer state between the French and British regions but in their northern area maintained the older form of control through native leaders. Beyond the reach of these larger imperial states simpler ethnic groups maintained their local sovereignty under the rule of chiefs, shamans, or clan leaders, sometimes forming limited confederations.

Multiethnic states. The development of modern forms of political administration among Asian states has produced some distinctive regional patterns. The Soviet Union was the first state to organize administrative districts on an ethnolinguistic basis. There are about 100 separate ethnic groups publicly recognized in the Soviet Union, as well as some minority groups never identified, and about 60 of these are represented by political administrative territories at major or minor levels. China under the Communist regime has adapted this system and has modified the Imperial political structure in regions containing ethnic or linguistic minorities—primarily in South and Southwest China, Northwest China, and Central Asia. In the Soviet Union such ethnic territorialism is relatively fixed and stable, but in China there continue to be changes in spatial arrangements of autonomous regions as various pressures are exerted, for not all minorities have yet been given internal territorial autonomy.

Ethnolinguistic political units

In India, with several hundred languages and many varieties of ethnic groupings, ethnolinguistic recognition is made only at the state level. Several of the political states of the Indian Union are now bounded by linguistic limits. Many minorities are not recognized at present, and the question of spatial ethnic and linguistic autonomy has given rise to considerable unrest within the Indian Union. The former northeastern Nāga tribal agency, however, has become a full state on the basis of its cultural unity. In Pakistan the tribal and frontier agencies formed during British Indian rule are still preserved; in these agencies, spatial autonomy derives from the ethnolinguistic situation. Burma worked to resolve the problems of integrating ethnic minorities into a modern political structure after several upland ethnic minority groups expressed militant opposition to the forms of limited territorial autonomy offered by the government. Throughout the rest of Southeast Asia, except for Malaysia, ethnic minorities have generally not received formal recognition, and each country has tended to adopt different means of integrating its minorities into the national life.

Malaysia is a multi-ethnic state in which Malays total just less than half the total population; Chinese total just over one-third; and Indians, Pakistanis, and tribal groups almost equally split the remainder. The constitution makes no recognition of the plural ethnic composition; Malay is the official language; Islām is a state religion (although religious freedom is guaranteed); and the head of state must be a Malay. Quasi-legal political parties, however, represent ethnic groupings, and there are—in practice—many ways in which all ethnic elements are represented.

In Southwest Asia, minor populations exist in most political states without formal recognition of their status, the minority position deriving from ethnic, linguistic, or religious factors. Only in Saudi Arabia and Yemen (Aden) is there homogeneity in the three elements. Lebanon is ethnically and linguistically Arabic, but its population is almost equally divided between Christians and Muslims. Israel has a sizable Arab minority, and Iran is only half Persian in ethnic and linguistic terms. Most other states in Southwest Asia have comparable ethnic conditions.

(J.O.Es.)

DEMOGRAPHIC PATTERNS

Asia, which covers about a third of the total land area of the world, has a population of more than half the world total. Asia includes the two countries that have the largest populations in the world, China and India; these two countries alone have populations that together are estimated to comprise more than a third of the world's people.

The age structure of Asia's population, particularly in the developing countries, is predominantly young. One consequence of this is that the number of dependents—particularly children—is disproportionately large in relation to the number of employed adults. Another is that, in view of the high birth rate, the age structure favours large additions in the future to the massive population already in existence.

Youth of population

Several Asian countries, aware of demographic trends and their adverse effect on economic growth and social progress, have embarked on official birth control pro-

grams, which have met with considerable success. Japan's program has perhaps been the most effective. In operation since World War II, it includes well-publicized family-planning services, legalized abortion, and the provision of all forms of contraceptive devices. Programs in China, South Korea, Taiwan, India, Pakistan, and Sri Lanka offer family-planning services, birth-control clinics, vasectomies, and contraceptives (including intrauterine devices). The Soviet Union has an ambivalent population control policy, and birth rates in Soviet Asia continue to be relatively high. The Southeast and Southwest Asian countries lag behind in formal programs, but public consciousness and basic planning have grown.

In nearly all countries of the world, more male than female babies are born. In advanced industrialized countries, where maternal mortality is low and where infant girls receive as much care as do boys, the male death rates are higher than female death rates at every stage of life; the numerical excess of males at birth is, in consequence, gradually reduced until females outnumber males in the older age groups.

Some Asian countries, particularly India and Sri Lanka, as well as Pakistan and a few predominantly Muslim countries, have a high sex ratio—*i.e.,* the number of males per thousand females—in the sense that males outnumber females in all age groups, even though in a few categories of the population females predominate at birth. This sex ratio is unusual, and there is controversy about its cause. In some countries social attitudes are held to be responsible for the difference in mortality rates of the sexes after birth. Early marriages—if not quite child marriages—increase the initial balance in favour of males because of the relatively high mortality rate of mothers in childbirth.

While Asia and Europe are the two most densely populated continents, Asia is slightly less overcrowded than Europe. The distribution of Asia's population has traditionally followed a pattern of dense settlement in river valleys, where the soil is fertile because of perennial irrigation and where double-cropping (the harvesting of two crops a year) can sustain large numbers. This traditional pattern still exists, despite the emergence of another pattern, represented by the attraction of large and congested industrialized cities such as Tokyo, Calcutta, Bombay, and Shanghai—cities to which the underemployed rural population often migrates. The depressed rural economy, the periodic failure of the monsoon, and the near-famine conditions that result have contributed to the continual drift of population to the towns and cities; often, however, the shortage of available jobs results in many unskilled village farmers, who come to the city in search of work, ending up in slums rather than as operators of factory machines.

While haphazard, unplanned urbanization is proceeding in many Asian countries, the population in general remains predominantly rural. Asia's population is most urban in the Middle East, and in East Asia. (S.Ch./Ed.)

Traditional cultures

Within each area of Asia, different traditional peoples and their patterns can be identified, described, and classified together in many ways. The following represents simply one of many useful classifications.

SIBERIA

The main discussion of Siberian cultures is to be found in the section on *Siberia* in the article UNION OF SOVIET SOCIALIST REPUBLICS. Only a sketch is offered here.

Located east of the Ural Mountains, Siberia lies in a transitional area in which tundra or treeless plain becomes taiga or swampy coniferous forest. Farther south, the taiga blends into a forest steppe with alternating stands of trees and open, seasonal grasslands. Summers, except in the extreme south, are too short to permit agriculture; spring floods often inundate the taiga. Farther north are the Altai (Kirgiz) and Sayan (Kazakh) mountains, which abut Central Asia in the west and the Mongolian People's Republic in the east. Farther east are the mixed broadleaf forests of the Amur-Ussuri valleys, with hot summers and severe winters. The Pacific maritime coast and Sakhalin Island complete the geographic picture. The northeastern region of China (formerly called Manchuria) sits to the south.

Mongoloids of Siberia

The indigenous populations are primarily Mongoloid racially, although generally they are outnumbered in most areas by Russian, Ukrainian, and Belorussian immigrants. The aborigines still live mainly in separate, virtually endogamous villages, though many groups (including reindeer herders) have been collectivized by the Soviets. They speak several languages and dialects of the Uralic-Altaic family, among them Samoyedic, Tungusic, Mongolian, and Yakut (or other Turkic dialects).

The main economic pursuits include small-scale reindeer herding (seven to 10 reindeer per herd, small when compared to groups farther north), hunting (deer, elk, squirrel), trapping (sable, fox), and fishing. Traditionally, the inhabitants have lived either in longhouses and semi-subterranean huts in permanent villages or in conical, bark-covered tepees at temporary campsites and, for transportation, have used canoes, rowboats, skis and snowshoes, sleds drawn by reindeer or dogs, and, in the east, horses. Many aborigines now work in mines and other Siberian industrial projects.

Most aboriginal groups are small. The 80,000 Evenki (Tungusic-speaking reindeer herders), for example, live and wander in an area about the size of the continental United States.

CENTRAL ASIA

The main treatment of Central Asian cultures is given in the section on *Soviet Central Asia* in the article UNION OF SOVIET SOCIALIST REPUBLICS. Only a brief characterization is offered here.

Central Asia extends from western Manchuria to the Caspian Sea, along the grasslands, mountains, and plateaus of Inner and Outer Mongolia, Tibet, the Central Asian Muslim republics of the U.S.S.R. (Kirgiziya, Tajikistan, Uzbekistan, Kazakhstan, and Turkmenistan), and Afghanistan north of the watershed of the mountain range of the Hindu Kush. An interesting man-made boundary, the Great Wall of China, exists in the east. Altitudes and local ecology vary considerably from region to region and even within regions. The western Turkistan deserts and steppes lie close to sea level, whereas the upland Mongolian steppes often exceed 5,000 feet (1,500 metres) above sea level. Basically, Central Asia is an arid zone that has inland drainage and a continental climate.

Mongoloids of Central Asia

Racially, all Central Asians are Mongoloid variations, more Caucasoid to the west (Slavic) and southwest (Mediterranean subvariant). Most speak Ural-Altaic languages—usually Turkic dialects but also Mongolian. Other language families include Sino-Tibetan (Tibetan in Tibet and Chinese near the eastern and southern borderlands) and Indo-European (Tadzhik and Dari Persian). Cyrillic has replaced the Arabic script in Soviet Central Asia and Mongolian in Mongolia. Inner Mongolians now use simplified Chinese characters, but Tibetans, though under great pressure from the Chinese, cling to their own traditional script.

Islām pressed into Central Asia early in the 8th century AD, culminating in the Arab sack of Samarkand in 712. Most people as far east as Outer Mongolia and south into Chinese Sinkiang became Sunnī Muslims, constituting the main orthodox school of Islām, but pockets of Ismāʿīlīs, who consider the Aga Khan as their leader, live scattered in such mountainous areas as the Pamirs and the Hindu Kush. Buddhism centring on teachers known as lamas and heavily laden with animistic and shamanistic beliefs and practices dominates Tibet and neighbouring parts of Mongolia and China. Anti-religious drives by the Communists of the U.S.S.R. and China have been only partly successful.

Often called the belt of "pastoral nomadism," Central Asia also includes sizable sedentary agriculturists, usually existing in the loose-knit symbiotic system described earlier, with modifications wherever Communism has introduced collectivization of herds and land. Political ties are largely kin oriented, and a loosely stratified class system exists along with a hereditary nobility. Slavery was common until the Russians and British virtually wiped it out in the 19th century. Mongol nomadic patterns dominate:

groups move year-round within well-defined territories; there are few fixed economic centres.

Local ecology greatly influences livestock distribution. Fundamentally, sheep and goats are mountain animals (though sheep prove to be less adaptable than goats and tend to flounder in snow); cattle and camels appear more numerously in transitional forest steppes and semideserts. Yak and yak-bovine hybrids become important in the Pamirs and the higher mountains of Sinkiang, Mongolia, and Tibet. Donkeys and mules are found mainly in the west, where Central Asia nudges the Middle East. Horses, prestige animals throughout Central Asia, are ridden, and sometimes their milk is drunk, often as koumiss (fermented mare's milk). (Ed.)

SOUTH ASIA

The subcontinent of South Asia lies south of the Himalayas and Afghanistan. It comprises the countries of India, Pakistan, Bangladesh, Sri Lanka (Ceylon), Nepal, and Bhutan. While these countries together may be thought of as constituting a single region, they contain a multitude of ethnic groups. The peoples of the Himalayas have Mongoloid features. The upper-caste groups of the Indo-Gangetic Plains are basically Mediterranean in appearance. The tribal and semi-tribal populations of middle and southern India have dark skins, flat noses, and wavy or curly hair. The Pashtun (Pathan), Kashmiri, and Sindhi of the northwest are tall with long heads, white complexions, and wavy hair. The Kadar of Cochin, the Andamanese and Onge of the Andaman Islands, and the Vedda of Sri Lanka have the Negrito characteristics of dark skins, small stature, and frizzly hair. The tribes of the jungles of Bihār, Orissa, and Madhya Pradesh share certain characteristics with the aboriginals of Australia and are sometimes referred to as Proto-Australoid; some of them (the Oraon and the various tribes of Gonds) speak Dravidian languages, while others (the Mundas, the Santāl, and the Ho) speak Austro-Asiatic languages.

The South Asian population may be divided into tribal and nontribal peoples. The tribes are somewhat detached from the mainstream of civilization, having been isolated in the forests and hills. They constitute about 6 or 7 percent of the total population of India and varying proportions of the populations of the other countries.

A vast number of languages are spoken in South Asia, belonging to four different families of languages. In India alone there are more than 100 separate languages, of which 15 have been designated as national languages.

Selected ethnic communities of South Asia.

The South Asians are predominantly religious in their outlook. Their religious orientation pervades every sphere, from social and economic life to science, literature, and art. Whether one thinks of Hinduism in India, Islām in Pakistan, Buddhism in the Himalayan states, or tribal religions in the hilly areas, one cannot escape the fact that the traditional way of life is largely determined by ritual and belief. Along with this religious outlook there appears to go a tendency to fatalism, a sense that every course of action as well as its outcome is up to the gods. This is true not only of Hindus and Buddhists but even of Muslims; as S.M.H. Zaidi observed in *The Village Culture in Transition: A Study of East Pakistan Rural Society* (1970), the Muslims "have a predominantly fatalistic attitude to change, believing that no human hand without the will of God can change anything."

Another characteristic of the South Asian peoples is that they are predominantly peasants. More than 90 percent of them live in villages and depend on simple agriculture for their livelihood. The average person lives his whole life in the same village. There is much interaction between the village societies and the important religious cities such as Vārānasi (Benares), Mathurā, Ayodhyā, Gayā, Prayāga (Allāhābād), Rāmeswaram, Madurai, Cape Comorin (the southernmost tip of India), Dwārkā, and Kāmākhya.

Caste groups and tribes. South Asian society is characterized by a hierarchical social system with a vast efflorescence of caste groupings. A caste group is hereditary, usually localized, and associated with a particular occupation; its members do not marry outside the group. There are complex relationships of superiority and inferiority among caste groups, including restrictions on eating and drinking with one another. At the bottom are the so-called scheduled castes, or untouchables; in India these amount to about 15 percent of the population. These groups engage in various "impure" occupations such as scavenging, sweeping, cattle herding, and leather working.

At the lower levels of society, caste groups are not easy to distinguish from tribes. Many scholars, in fact, have suggested that caste groups evolved from primitive tribal groups. One difference is that while caste groups are endogamous (the members of a group do not marry outside it), the marital rules among tribal groups are somewhat more complex. Each tribal group confines its marriage relations to the same tribe or subtribe. But each tribe is divided into clans or moieties, often named after animals, birds, or plants, and these groups are exogamous; *i.e.,* the members of a clan must marry outside it. Such division of a tribe into several social groups or clans is found both in matrilineal tribes like the Garo and Khāsi of Meghalaya and in patrilineal tribes like the Nāga, the Munda, the Santāl, the Bhīl, and the Gond. Some tribes of southern India have a complex social organization. The Urāli, for example, who are matrilineal, have two sets of clans: brother clans, among whom marriage is prohibited, and brother-in-law clans, among whom marriage is sanctioned.

Tribal organization

Even among the tribes of the Himalayas, where there is a great tolerance of casual sex relations, both premarital and extramarital, the rule of clan exogamy is strictly followed. Among the Sherpa of Nepal, the term for clan is *ru* ("bone"), implying that the members belong to the same father's bone or blood. A recent study of this tribe failed to reveal even a fleeting amorous attachment between members of the same clan and no marriage between members of brother clans. The Dimasā Kachāri of Assam have different sets of clans for different sexes: there are 40 male clans and 42 female clans, all practicing the system of double descent, by which the male child is given the clanship of his father while the female child inherits the mother's clan. Very few tribes lack the totemic clan division. The Saora (Savara) and Māler of middle India have territorial divisions rather than clans, and their marriage relations are exogamous within these divisions. The Saoras are divided into 17 such exogamous units.

Certain tribes of middle India have clans organized in groups or moieties. Among the Gond of Bastar, for example, the moieties are composed of 96 and 69 clans. The Rāj Gond Ādilābād have four groups of clans, and the Muria have five.

While most tribes lead a peaceful life, there have been some warring groups. The Baluchi nomadic groups used to fight among themselves over pastureland, leadership rights, and women. Descriptions of the Nāga tell of their weapons, their methods of warfare, and their custom of head-hunting.

Caste and social structure

The basis of the social structure in South Asia is the caste system. Although it is Hindu in origin, the caste system has had a pervasive influence on all South Asian society, whether based on tribalism, Islām, Buddhism, Sikhism, or Christianity.

In Nepal both Hindus and Buddhists are subject to the code of the caste system. Among the Hindus of Nepal there are high castes such as the Brahmins, Ṭhākurs, and Chetris. The followers of Buddhism in Nepal are also divided into three main caste groups. There are the Barnas, the Udās, and a mixed caste of heterodox Buddhists. The Barnas enjoy a status equal to that of the Hindu Brahmins and observe the same rules of commensality and intermarriage. The Udās are inferior to the Barnas in the caste hierarchy. The third group of mixed castes includes numerous occupational castes (barber, carrier of light, etc.) and professional castes considered to be equivalent to the untouchables among the Hindus. The tribes also have several categories: the Gurung and Magar are at the top; the Newār are in second place followed by the Kiranti, the Khambu, the Limbu, and the Yākhas; below them are the Sunwar and Tamang (Mūrmi), who are given approximately equal status, while the Tibetan tribes including the Sherpa are ranked slightly below them; at the bottom of the scale are the Tharu, the Thami, the Hayu, the Thakali, and numerous other minor tribes.

In Sri Lanka the Goyigama (cultivators) enjoy the highest position, while the castes of potters and washermen are ranked low. These caste groups are endogamous.

The caste hierarchy, even in the traditional system, was not entirely rigid. It was possible for caste groups to move upward, although slowly. Even tribes have been able to acquire an appropriate place in the caste hierarchy. The Rāj Gond of central India, for instance, successfully claimed for themselves the rank of Kṣatriyas (a ruling and warrior class) on the basis of their acquisition of political power. Recent researches have revealed how caste-like groups such as the Bhumij, the Mahali, the Bauri in West Bengal, the Cheros, the Kharwār, and the Manjhi in Bihār, as well as various sections of the Bhīl and the Gond, have been assigned appropriate status in the Hindu caste systems in their regions.

Islām's claim of equality for all those who profess the faith has been greatly weakened in South Asia because of caste practices. The Muslim caste system, unlike the Hindu, is not based on purity and pollution concepts; nor is it sanctioned by religious ideas. Among the Muslim castes, the highest are the sayyids and the lowest are the sweepers. In Bangladesh the landholding groups of foreign (Persian or Arabian) descent are generally ranked high, while those who do manual labour that involves ritual contamination are ranked lowest.

The hierarchical system in Pakistan may meaningfully be compared to the Hindu caste system. In Swāt in northern Pakistan there are seven social groups; they are, in order of descending rank: (1) persons of holy descent, (2) landowners and administrators, (3) priests, (4) craftsmen, (5) agricultural tenants and labourers, (6) herders, (7) the despised group.

Sikhism also, despite its emphasis on equality, has a caste structure. The Sikhs are broadly divided into Sardars and Mazhabis, the former consisting of higher caste groups and the latter of sweepers. Caste restrictions are also rigidly observed among the Christians of the west coast, particularly in marriages.

The joint family

Kinship patterns. The joint family is another basic institution in the societies of South Asia. In India the joint family has existed since prehistoric times. The coming of Islām failed to modify the structure of this most ancient institution. Despite the industrial revolution and other modernizing influences, the joint family continues to exist on a large scale.

There are two types of joint families. In the northern

type, the family unit includes three or four generations of males and their dependents: one's grandfather and his brothers, one's father and his brothers, one's own brothers and cousins, one's sons, and the nephews and wives of all these male relatives plus one's own unmarried sisters and daughters. The southern type of joint family includes one's mother's mother and her sisters and brothers, one's mother and her sisters and brothers, one's own brothers and sisters, one's mother's sister's sons and daughters, and the children of one's sisters. The husbands of the women of the family live in the houses of their mothers, occasionally visiting their wives and children. Throughout Nepal the members of several generations in the father's line maintain common arrangements for cooking and have joint ownership of property under a single head. As in India, in some families the relatives on the mother's side may also live with the household in an extended family. Throughout Nepal, the kitchen is regarded as a symbol of family unity.

In Bangladesh the largest unit of family organization is the patrilocal extended family, in which two or three generations may live together. The extended family includes two or more nuclear or joint families united by male kinship bonds and living in a cluster of adjacent dwellings. It may have as many as 50 or 100 members or as few as seven or eight, the average being about 20. The extended family includes a number of component property-holding units such as the nuclear family, the joint family, and the irregular family (centred around a widow or a widow and her unmarried children). As long as the father remains alive after his son's marriage, the joint family is the rule rather than the exception. It is clearly related to the system of inheritance, by which land is allotted to the son only after his father's death. The joint family is slightly less frequent in Bangladesh than in West Bengal but more common than in Pakistan.

In Sri Lanka the nuclear family prevails. A Sinhalese family generally consists of a husband and wife and their unmarried children. It leads an economically self-sufficient life under the benevolent and mildly patriarchal rule of the father-husband.

Most tribal societies in South Asia have a nuclear family.

Marriage. Patterns of family organization can also be viewed in terms of the marriage relationship, the kinship system, and the position of the women in the family. The organization of the family throughout northern India is that of the patriarchal family. The traditional rule of avoiding marriage with somebody who is removed by less than seven degrees from the father and five degrees from the mother is practiced by all castes, from the highest to the lowest. In southern India a man preferably marries his maternal cross-cousin—*i.e.,* his mother's brother's daughter.

Polyandry among the Sherpa

Among the tribes of the high Himalayas, such as the Sherpa, the Bhutia (Bhotia), and the Lepchā, it is common to have more than one husband, usually brothers. The Sherpa believe that a polyandrous union is desirable because it prevents the fragmentation of property and fosters solidarity among brothers. It has been observed that since such a marriage improves a woman's economic prospects and assures her the advantage of a younger husband in later years, she prefers to marry two brothers. The Sherpa style of polyandry differs from the Tibetan practice that permits any number of younger brothers to share an elder brother's wife; this is also prevalent among the Khāsa, the Toda, and the Nāyar, who allow more than two younger brothers to share the same woman.

The custom of paying a bride price is prevalent among almost all the tribes of South Asia. The bride price may be livestock, food, clothing, or even service by the bridegroom in the bride's father's house. The ease of acquiring wives and the freedom of sex relations in the tribal communities make divorce an easy process.

In Islāmic law, marriage is essentially a contract rather than a sacrament, as it is among the Hindus. The rules of marriage prescribed by the Qur'ān have been modified in parts of India by the customs of the particular region. Marriage among the Muslims as among the Hindus is an important family affair, arranged by the elders of the family. Marriage is possible between almost any boy and girl under Muslim law, even within an extended family and between cousins. While traditional Muslim law does not sanction dowry, the Hindu influence compels it. The bridegroom's family expects the bride's father to give enough in dowry to establish a home for the couple. A Muslim can divorce his wife at his own will, but no such privilege is accorded to the wife. The custom of *pardah* (wearing the veil) is observed strictly among the Muslims of South Asia.

Socialization and education. The birth of a child in the societies of South Asia is considered a divine blessing. A childless woman is viewed unfavourably. In Hindu society a very important ceremony called *śrāddha,* conducted after a person's death, can be performed only by a son. It is believed that without this ceremony the departed soul is not likely to attain salvation. To the peasantry of South Asia, a male child means a pair of extra hands to help on the farm. Girls are not highly regarded; having a female child is preferred only to remaining childless.

Rites of passage

In Hindu society an individual passes through a series of rites from his conception to his death. Several rites are performed before the birth of a child to ensure his safe arrival. After the child is born, other ceremonies are conducted to provide the incarnating soul with a good body and prepare it for life.

Next are the rites known as *vidyārambha* (commencement of education), *upanayana* (the sacred-thread ceremony), *vedārambha* (commencement of Vedic recitation) and *samāvartana* (convocation). Traditionally a Hindu boy was taught by the guru in the *gurukula,* where he led a life of rigorous discipline and purity. He was then ready to undergo the ceremony of marriage and become a householder in his joint family. A man's death is mourned by the members of the family, his kinsmen, and other members of his larger communities. A series of death rituals are observed by his eldest son in cooperation with the kin groups to ensure the deceased freedom from rebirth. The Indian joint family continues to practice some of the traditional rites or *saṃskāras,* especially the birth rites, the sacred-thread ceremony, the marriage ceremony, and the death rites.

Most of the Muslim communities are converts from the Hindu religion, and there is considerable similarity in the methods of child rearing. One important difference is the Muslim ritual of circumcision that usually takes place between the ages of three and five.

The tribal communities have relatively informal relationships among kinsmen, in contrast to the highly formalized Hindu relationships. The youth dormitory so common among the tribes is the traditional institution of the unmarried boys and girls; it provides training in folk songs and dances, the moral code, customs and manners, and sexual relations. The young learn the arts of life mostly by observation and imitation.

Economic life. *Villages and settlements.* Most of the people of South Asia still live in villages and follow the traditional pursuits of an agricultural and pastoral economy. In the high Himalayas the tribespeople live with their flocks in established summer and winter encampments, each of which remains unoccupied for some months in a year. The pastoral nomads of the Baluchi tribe in Pakistan generally have only temporary encampments. The Dafla, Apa Tani, Gallong, and other tribes of Assam site their villages on the highest parts of the hills, from whence the whole valley below is visible. Many tribes site their villages in accordance with the will of God as interpreted by their shamans. Hundreds of villages of the Santāl, Munda, and Ho tribes in middle India are in the forest clearings. In southern India many tribal villages are located in dense forest, and their economy revolves around the forest. In western Rājasthān there are dispersed settlements in desert or semidesert areas.

In the deltaic plains of West Bengal and Bangladesh, the countless rivers and streams have given birth to compact, nucleated settlements. More typical of the area are clusters of houses scattered along the banks of streams and rivulets. Each cluster usually forms a separate residential unit consisting of a number of huts built around a courtyard.

The linear settlement is much in evidence in the plain areas of Orissa, Madhya Pradesh, Andhra Pradesh, Kerala, and Tamil Nadu. The abundance of river valleys and the prevalence of the *jajmānī* system (in which lower castes perform specialized artisan services for the landowners and cultivators) serve to maintain the traditional linear settlement pattern. The linear settlement is also found in fishing villages on the sea, or estuaries, or along big rivers.

Villages vary in size from more than 1,000 people to fewer than 50. The villages of the rich agricultural plain areas are usually larger, while those of the hills and forests are smaller. Some tribal villages are temporary encampments of five to 10 huts that provide accommodation for up to 30 persons. The tribal villages of the Hill Māler, the Hill Khariā, or the Bondo highlanders in middle India are slightly bigger, composed of 10 to 30 huts accommodating 30 to 100 persons. Large villages like those of the Waromung in Nāgāland, having a population of 1,600, are exceptional.

The villages of the settled cultivators are large and somewhat elaborate in layout. Depending on the extent and fertility of the land, the population of an average village varies from 100 to 500 persons. Hindu villages, especially those in the Indo-Gangetic Plain, may have as many as 5,000 inhabitants, divided into a number of hamlets. The central part of a village is occupied by the dominant castes, while the untouchables live in a far-removed area. Every village has a temple located near the settlement of the high castes. The houses of the landlords are elaborate, while those of the tenants are simple. Most houses are built of mud and tiles, with courtyards and parlours.

Food getting. Almost all of South Asia lies in the monsoon belt, and its agriculture depends on the torrential rains associated with the monsoon. The vagaries of the weather pose a great problem to the peasantry. When there is a lack of rain they turn to the rain god, Indra. In Nepal the guardian deity Machendranāth, who presides over agricultural affairs, is elaborately worshipped; the ritual of asking for rain is observed collectively by the villagers, who go from shrine to shrine in a procession, shouting, "O Lord Mahādeo, give us rain!"

Agricultural organization

Agricultural technology is still very simple. While among the forest tribes the primitive occupations of hunting, food gathering, and collecting still predominate, the basis of the South Asian economy is the plow. The Indo-Gangetic Plain, extending from the Punjab in the west to Bangladesh in the east, along with the coastal deltaic regions of eastern India and Sri Lanka, is the largest rice-growing zone in the world. In Nepal, Sikkim state of India, and Bhutan, intensive plow cultivation is practiced in the valleys and plains, but a primitive slash-and-burn type of cultivation is found in the hills. Pastoral pursuits are supplemental to agriculture in most South Asian villages. There are, however, communities, such as those of the Pathan and Baluchi in northwestern Pakistan and of the Gūjar and Gaddi in the western Himalayan districts, whose entire economy revolves around pastoral nomadism. During the summer they move up the mountains in search of pasture, returning in wintertime to the foothills.

The economy of the tribal peoples is based on hunting and gathering. They eat edible roots, fruits, vegetables, honey, insects, fish, and various kinds of birds and game. Some tribes such as the Birhor in Bihār, the Chenchu in Andhra Pradesh, the Juang in Orissa, the Kadar in Kerala, and the Paliyan and Paniyans in Tamil Nadu depend on the forest as their primary source of food. The tribes of the Assam Hills, of Orissa, of Madhya Pradesh, and of Nepal, who practice shifting cultivation (moving from one location to another), supplement their economy with occasional hunting and gathering. Even agricultural tribes such as the Munda, the Oraon, and the Ho of the Chota Nāgpur Plateau depend on the forest to supplement their harvests.

The hunting tribes use various types of bows and arrows and trapping devices. They also have simple missiles such as the throwing stick of the Oraon and the nonreturning boomerang of the Bhīl. Slings are also used to throw stones and hardened clay balls. Spears with iron heads and wooden shafts are very common. The Buna use multipronged harpoons with barbs for fishing. The Jarawa of the Andaman Islands poison their spearheads.

There are many forms of land tenure in South Asia, ranging from common ownership by villagers to individual ownership by the head of a nuclear family. In the past, many landlords gained their property under British occupation when they were given tax-collecting rights; the tax-farming system led to a great stratification of the peasantry. At the same time, the pressure of the population upon the land produced a fragmentation of holdings in some areas. Since independence there have been various attempts at land reform.

The *jajmānī* system

A common institution of Indian village life is the Hindu *jajmānī* system, practiced all over India under different names. Each caste group within a village gives certain standardized services to the families of other castes. A member of a carpenter or a barber caste, for instance, works for a particular family or group of families with which he has hereditary ties. The association passes from father to son. The system serves to reduce the need for money and to minimize competition. It also tends to assure a stable labour supply for the dominant agricultural caste in a particular region by severely limiting the mobility of the lower castes. If a worker leaves his village, he must supply a substitute, usually a member of the same joint family; but the system gives him rights and advantages that make him reluctant to leave and endanger his social and economic security.

Another traditional element of economic organization is the local market. The weekly or biweekly markets are located in open areas between villages where the means of communication provide a central place for the economic exchange of the region. In the nonmonetary economy of the tribal areas of India and Bangladesh, villagers exchange their produce for clothes, utensils, spices, and other necessities. Occupational specialists such as barbers, tailors, blacksmiths, and potters provide their goods and services. The agricultural produce from the surrounding regions is collected here and sold. The intertribal market is also a centre of social, religious, and political life.

Moneylending is an integral part of the agrarian economic structure of South Asia. In Bangladesh, the so-called middle-class farmers lend out their surplus money. In Indian villages the moneylenders come mainly from business castes and traders who have settled in the tribal villages.

The worship of spirits

Religion and art. Life in South Asia revolves around religious belief and practice. Belief in supernatural entities is strongest among the tribal communities; they believe that disease and death, failure in hunting or cultivation, and all the other hazards of life are caused by ghosts and spirits who can be propitiated with the sacrifice of animals. A study of the religion of the Ho and other tribes of the Mundari group has shown that this belief in the power of spirits to control the nature and destiny of man is basic to their religion. The Buddhist Sherpa observe certain rites to protect themselves and their land from evil spirits. Among the Muslims of South Asia, the matrix of primitive faith is found in the worship of *pīr*s, or saints, a practice for which there is no authority in the Qur'ān.

The tribes and also the Hindus worship certain forest and tree spirits, water spirits, and other spirits in natural objects. Among the agricultural tribes, every village has in its vicinity a grove (*sarna*) reputed to be a remnant of the primitive forest left intact for the local gods when the clearing was done. This sacred grove is the chief village shrine among many Mundari and Dravidian tribes of middle India. These tribes have special festivals associated with trees. In the festival of Karma, a branch of a sacred tree is cut and planted in the village assembly ground, and the unmarried young of both sexes dance around it. The Karma festival is also observed by Hindus in north Indian villages.

The Hindus consider the pipal tree (*Ficus religiosa*) sacred, believing that its trunk provides a habitation for Brahmā, its twigs for Vishnu, and its leaves for other gods. Water is poured on its roots by pious people after their morning bath. The bel tree (*Aegle marmelos*) is associated with the Śiva (Shiva) cult. The small plant tulsi (*Ocimum sanctum*) is associated with Vishnu, and its leaves are of-

fered to him during worship. The presence of a tulsi plant in the courtyard is the mark of a pious Hindu house.

The worship of rivers and springs is of great significance among the tribal people, who believe that the indwelling spirit causes the water to move. The tribes of Chota Nāgpur offer sacrifices to the water spirits. The people of the plain consider some of the rivers, particularly the Ganges, to be sacred. The spirit of the Ganges is recognized by many Hindus as one of the wives of Śiva, and there are periodic rituals involving bathing in the Ganges and other rivers. The non-Aryan hill tribes worship mountains.

Worship of the sun has been common among both the tribes and the Hindus. The supreme spirit of the tribes of middle India is Singh Bonga (Sun God). Some temples have been erected to the sun, notably those at Konārak near Puri in Orissa and at Deo near Gayā.

Many tribal peoples and Hindus also worship the mother earth. Pious Hindus offer a prayer to her before walking in the early morning, and some farmers offer a sacrifice in her name before digging the land. Hindu mythology and folklore hold that the mother earth rests on the hood of a cobra; he is also considered sacred, and a festival is devoted to him. Some deities are associated with certain diseases, as the goddesses of smallpox (Sītalā) and of cholera (Olābibi), who are worshipped by singing devotional songs in their praise.

According to the scriptures, the Hindu pantheon has 330,000,000 deities, although even the most detailed texts have never tried to list all of them or even all the categories of them. There are many shrines to gods such as Śiva, Vishnu, Gaṇeśa, and their wives, as well as to the mother goddess Śakti (Kālī or Durgā). A shrine may be a pile of stones set up under the village tree or an elaborate iconographic creation in stone, marble, bronze, copper, silver, or gold. The latter are found at places of pilgrimage. The ancient Kṣetra (sacred grounds) celebrated in the scriptures have played a significant role in bringing together peoples from north and south and from different sociolinguistic groups.

Types of priesthood

Diverse types of priesthood are found among the tribal and Hindu communities of India. There used to be tribes such as the Korwa and other primitive communities that had no priests because they had no gods, their worship being confined to the spirits of their ancestors. Some tribes such as the Munda, the Oraon, and the Gond have their traditional priests, who perform ceremonial observances. There are also shamans who are said to have the power to cure diseases or other evils caused by malignant spirits. They give statements believed to be oracular.

In the Hindu religious system the highest caste group of Brahmins are traditionally and professionally the priests. Every orthodox Hindu of clean caste must have a Brahmin family priest to whom he pays customary dues in return for services at weddings, funerals, and other ceremonial occasions. The sacred specialists popularly known as *paṇḍā* are found at places of pilgrimage. Hindu religious organizations also sanction a number of ascetic orders, mainly at places of pilgrimage.

Islām as a religion is optimistic and transcendentalist; it does not favour either asceticism or extremes of ecstasy as does Hinduism. Three types of religious leaders are commonly found in the Muslim rural areas of South Asia: *mullah*s, *mawlānā*s, and *pīr*s. A *mullah* is a prayer leader and religious functionary who performs various ceremonies for the villagers, usually in association with a particular mosque or sector of the village. His office is hereditary, and he exercises control over secular affairs through discourses on Fridays on nonreligious matters. The *mawlānā* is better educated than the *mullah* in theology and serves as an interpreter of the Qur'ān. The *mullah* ordinarily supports himself entirely through his religious occupation, but the *mawlānā* generally earns his living from a secular occupation. A *pīr* is a holy man who commands a following of both Hindus and Muslims in the South Asian countries.

Religious amalgams

The remnants of Buddhism in South Asia are found in the Himalayan states of Bhutan and Nepal, as well as in the Indian territories of Himachal Pradesh, Kashmir, Sikkim, and northern West Bengal. The Sinhalese of Sri Lanka also practice Buddhism. The Himalayan Buddhists worship Hindu deities and observe certain Hindu ceremonies; sometimes they employ a Brahmin priest. Certain Himalayan tribes such as the Lepchā, the Bhutia, the Limbu, and the Lahaula, who practice Buddhism, combine it with animistic beliefs. The Chakmā of Bangladesh profess to be Buddhists, but their religious practices are mixed with the folk Hinduism of West Bengal. The same fusion of beliefs appears among the Magh of Chittagong, who have added the worship of Śiva and Durgā to the Buddhist observances.

Several other religions, including Jainism, Sikhism, Christianity, and Zoroastrianism, are also found in South Asia. Jainism is the chief religion of the district of Jodhpur and of certain trading and business castes. It may be regarded as a sect of Hinduism, and intercaste marriages are frequent. Sikhism, like Jainism, has a close affinity with Hinduism. Sikhs are disciples of their 10 gurus, some of whose writings are compiled in the sacred book the *Adi Granth*. The Sikhs are concentrated in Punjab, though migrants are found all over India. One of the most remarkable figures in the religious history of India was Kabīr (d. 1518), a mystic poet who established a new religious sect linking Hinduism and Islām. Groups of his followers are scattered through northern India.

Religion has been both the inspiration and the matrix of South Asian art, which is discussed at length in the article SOUTH ASIAN ARTS.

The cultures of the tribes of all India, the Himalayan states, and Sri Lanka are characterized by dances and songs. Most of these reflect the community spirit of the tribes and their patterns of life. The village *akharā* (dancing ground) and the youth dormitory, found in most of the tribes of India, are important in the development, maintenance, and transmission of the tribal dance pattern. The numerous traditional festivals are inseparably linked with singing, dancing, and drumming.

Modern developments. The traditional cultures of South Asia are rural, caste oriented, conservative, and religious in outlook. They have altered somewhat in the last 150 years under the impact of British rule and in response to modern education, technological development, and political change.

The tendency of the lower castes to rise upward accelerated under British rule. This process of upward mobility has been variously named Brahmanization, Sanskritization, and Kṣatriyaization. It may be observed both in tribal and in nontribal communities. Some of the tribes have been greatly influenced by the Kṣatriya *varṇa*, or class. This *varṇa* includes a number of caste groups, headed by the artistocratic Rājput lineages and differing widely in status. Some tribal and lower caste groups have been able to distinguish themselves by using the class name Kṣatriya or claiming Rājput descent. They marry their daughters to men of Rājput lineage. There are also examples of certain tribal groups claiming the status of Brahmins in the Hindu caste system. The Bauri of West Bengal claim to be Brahmins by virtue of their observance of the mourning period of 11 days, wearing of the sacred threads, and worship of Hindu deities.

Attempts to escape caste

Lower caste Hindus have made even more vigorous efforts to raise themselves in the caste hierarchy. Organized violation of caste rules by the so-called untouchable castes developed under the leadership of B.R. Ambedkar, who finally despaired of eliminating untouchability from Hinduism and led his followers into Buddhism. A similar turn to Buddhism took place quietly in Sri Lanka. There are instances in India of lower caste groups seeking to adopt the customs and rights of higher caste groups and being prevented from doing so. Such efforts have led to the partial breakdown of the *jajmānī* system in the villages and have also been a factor in the migration of the numerically weaker castes to the towns.

Some of the tribes in the hilly and forested areas of India were converted to Christianity by European missionaries, and made a conscious effort to abandon their tribal traditions. After India gained its independence, however, some of them foresook their Christianity in order to participate in certain political and economic privileges enjoyed

by the traditional tribal groups. In northeastern India, where Christianity is strong among the tribes, they pressed demands for separate statehood within India, resulting in the establishment of Nāgāland, Meghalaya, and other tribal states.

The process of modernization and Westernization has impinged upon every sector of the South Asian cultures. The rate and direction of change differ from region to region. South Asia has been selective in what it has accepted from the West, mingling its acquisitions with many traditional institutions. Thus the new industrial towns are treated as modern places of pilgrimage; the secularization of society is pursued in terms of religious tolerance; and the parties in democratic elections contend in terms of old values. South Asia is clearly in a period of transition from traditional societies to modern ones, and the course it is following is unique. (L.P.V.)

EAST ASIA

East Asia as a cultural entity is here defined as comprising, first, the Chinese and groups that have been derived from the Chinese ethnically or culturally and, second, those cultures that were greatly influenced by China at the time that they became states. Among the first category, of course, are the Chinese themselves, the Taiwanese, and, with some equivocation, the Miao and Yao. The second category comprises such peoples as the Japanese, Koreans, Manchus, and Min-chia. Other peoples have also been influenced by the Chinese, but, because they have not formed states of their own, this influence is difficult to determine and is often not emphasized. This is the case among, for example, the Nakhi of southwest China and the Ainu of Hokkaido.

Recognition of ties with China is the most characteristic feature of East Asian cultures. It unites peoples as disparate in many aspects of life as the Hui-hui of China's northwest, the Japanese, and the Manchus. The area thus has a special significance for many of the peoples themselves and is not simply a construct of social scientists.

People and languages. Some peoples in Asia more or less form a buffer zone around East as well as South Asia. These ethnic groups are of diverse origins and cultures. The Ainu, situated on the island of Hokkaido, appear to represent in ethnic terms a conservative autochthonous refugee group that cannot easily be connected with any other group. They are linguistically distinct from other groups but culturally akin to the peoples of the Soviet Maritime Province and Eastern Siberia. The Manchus, Xojen, Daghur, and Monguors are small ethnic groups situated along China's northern and northwestern frontier. The first two speak a language of the Tungusic branch of the Altaic linguistic family, while the Daghur and Monguors speak Mongolian languages, also of the Altaic family.

The Islāmic Hui-hui

The Hui-hui (also called Tungan in Chinese Turkistan and Panthay in southwest China), or Chinese Muslims, take their ethnic identity from their religion. Those aspects of life in which they differ from Chinese are related to their practice of Islām, although they also exhibit a greater esprit de corps and competitiveness. There is a natural tendency for members of an ethnic unit who can communicate readily with members of the dominant group to merge with that group, and many Hui-hui have seen themselves as predominantly Chinese. But it is also true that Chinese Muslims have regarded themselves as an alien and superior people to the Chinese.

Extending eastward from the Tibetan ranges and plateau, the Tsinling Mountains form a dividing line between border groups of Ural-Altaic linguistic affiliation to the north and Sino-Tibetan, Tai-Kadai, Austronesian (Malayo-Polynesian), Austro-Asiatic, and perhaps independent linguistic affiliations to the south. Most of the non-Chinese ethnic groups found along the borders of Tibet and China speak a language affiliated to the Tibeto-Burman branch of the Sino-Tibetan linguistic family.

The Lolo (or Yi) and Min-chia have occupied the highland area of southwest China for over 1,000 years. A number of Lolo traits—among them a language that indicates an affinity to Tibeto-Burman, a tall stature with a high-bridged nose, the use of felt, a mixed pastoral and agricultural society, and the use of poisoned arrows—appear to indicate a culture with diverse and distant origins. The Lolo seem to be most alike in culture, language, and physical type to the peoples of southeastern Tibet. They appear to have originated in the same borderland that they now occupy, although perhaps more to the west.

The Min-chia have been a part of a centralized political system since the 7th century, when their principal city, Tali, was the capital of the Nan Chao state. The Yüan dynasty emperor Kublai Khan conquered Nan Chao in 1253, but the area around Tali is to this day primarily inhabited by the approximately 1,130,000 Min-chia. The Min-chia have been rice cultivators for over 1,000 years and now are highly acculturated to Chinese ways of living. Many speak Chinese as well as Min-chia.

The linguistic affiliation of the Miao and Yao to major linguistic groups is still in dispute, but there is no doubt but that the two are linguistically related to each other and have borrowed heavily from Chinese. Miao names for themselves are Hmong, Hmung, or Hmu, followed by a further word indicating subethnic affiliation. The Yao refer to themselves as Kim Mien, Kim Mun, and Yu Mien. The Miao number about 5,000,000 in China and 400,000 in Southeast Asia. The Yao number more than 1,400,000 in China and more than 200,000 to the south. Both derive from the Yangtze Valley region and, in the case of the Yao, probably from the mountains along the east coast of China. They appear to have been recognized by the Chinese as ethnic units for over 2,000 years. Both are distributed for the most part in small enclaves sometimes no larger than a village, although there are also larger settlements. The People's Republic of China has recognized a number of Yao autonomous counties (*hsien*), and an autonomous special administrative district (*chou*) has been set aside for the Miao in Hunan Province, as well as two autonomous regions in Kweichow Province. The sociopolitical fragmentation of the Miao and the Yao has apparently been caused by their countless attempts to escape domination and assimilation by the Chinese. The last independent Miao group disappeared at the end of the last Miao rebellion in 1870. Both Miao and Yao have drifted southward, and now both groups are found as far south as Thailand.

Ethnic and language groups in Taiwan

The original inhabitants of Taiwan (Formosa) were Austronesian (Malayo-Polynesian) speakers, but, within the last 300 years, after the establishment of trading posts on the island by the Dutch, the Austronesian speakers have been gradually pushed back into the mountains, in part by Hakka Chinese from Kwangtung Province but mostly by Minnan (Amoy) Chinese from Fukien Province, directly across the Formosa Strait. There are now about 16,000,000 Taiwanese. The majority speak one of several dialects of the Fukienese languages, a Sinitic tongue. A minority speak Hakka, another Sinitic language. Many mainlanders in Taiwan speak Mandarin Chinese. Within the last 25 years many Chinese have come to identify with the family, associational, and professional ties that they have established on Taiwan. As a result they and especially their children have come to associate more with Taiwan than with China.

Japanese is a composite speech in which Austronesian was the earliest ingredient. A later Altaic influence came to overlay Austronesian forms, and many Chinese words have subsequently been borrowed.

Korean linguistic affiliations seem to parallel those of Japan but with different emphasis. Altaic, specifically Tungusic, linguistic influences are very strong, and cultural influences from the north and east have been more prominent. The Chinese, for example, conquered Korea and established military colonies in the 1st century BC, one such outpost lasting until the 4th century AD.

The dominance of China

By definition the peoples of East Asia turn toward Chinese culture but with varying degrees of ambivalence. Perhaps the Koreans, Manchus, and Min-chia have been the more assiduous students. One can contrast the attitudes of these nationalities with the open defiance and antagonistic acculturation maintained by the independent Lolo (Yi) of the Ta-liang Shan and the belief of the Japanese from the 10th century on that they should be treated as equals

rather than clients by the Chinese. On the other hand, such groups as the Miao, Yao, and some Lolo speakers lost their ability to control their affairs to any large extent beyond the village level, thus tending to accept the Chinese great tradition. In early China may be seen an approximation of the feudal system of Europe. Men who held political power and an authoritative position were overlords and not simply bureaucrats. The political structure was that of a lineage state; that is, it was considered that everyone, or at least everyone of importance, within the state was related. Ideally, therefore, a vassal was not only a subordinate—a client—but a relative as well. The lord should be a more direct descendant, a member of a senior generation, or in some way more closely related to the founder of the line than the vassal. If the kinship relationship between two men who wished to establish a vassal and lord relationship was not close enough, it appears that genealogical charters could be altered to fit social and political needs. The regularized system of interstate relationship, called tribute in the literature, between China and other countries was modelled upon a system of exchange between patron and client that existed in feudal China. According to the world view by which the tribute system operated, there was only one true universal culture—that of the Chinese. The tribute system was the means of emphasizing this fact. It consisted of a number of ceremonial acts, the most famous of which was the full kowtow, in which the ambassador from the foreign court prostrated himself full length in front of the emperor or the latter's representative. He thus expressed not only submission and subservience in military and civil affairs but also obsequious deference in cultural, ceremonial, and ethical matters. The tribute system was a means of carrying on diplomacy between the dominant power—that is, the "Middle Kingdom"—and other less equal powers and civilizations. Tribute was mostly an exchange of gifts, the Chinese often giving more in value than they received. The important element was the bringing of the various peoples together under the common umbrella of customary law and ritual, or attitudes toward virtue. The adoption of the Chinese ideographic system, calendar, Classical literature and art, court ceremonies, methods of government and law, and even dress and music were further aspects of the Chinese cultural hegemony.

The tribute system

The crucial period for the development of China and also East Asia was after the fall of the Han dynasty, about AD 220. Han society was comparable to Rome in its general complexity of organization and in its decline into equally fragmented pieces. Yet a central power was to reappear in the 7th century. The reasons for this revival were several, but the most important was that although the barbarian areas, especially those that threatened China, could fight well and at times conquer China, they never emulated it to the same extent that the Western barbarians emulated Rome.

There is some agreement that the pre-modernization periods in East Asia can be called "traditional" ("classical" has a different connotation and should refer to a period preceding the traditional). The traditional period has lasted a long time, not without change but with essentially the same types of social structures. In China the traditional period began during the T'ang dynasty; that is, during the 7th century AD. In Korea it began with the Yi dynasty in 1392 and in Japan with the Tokugawa shogunate in 1603.

Kinship patterns. The common bases upon which the luxuriant growths of East Asian social structure grew are few in number and relatively simple. One is the tendency to maintain extended patrilocal families; that is, for sons to bring their wives to live within the same household or, if not, at least close enough for all descendants to form a single social, economic, and ceremonial unit during the lifetime of the father and very often the mother. Due to family or sometimes circumstances of wider importance, it may not be practical or even considered desirable for sons to live and work together, but almost always one of the children will be on hand to care for the aged parents. Sometimes, if there are no sons, a man will marry into the family, the husband of a daughter living with his wife's family.

Whether it is a woman or man who marries in, the effect seems to be the same. The spouse, or his or her children, tends to establish an identity for inheritance and descent through residence in the house into which they marry or into which they are born.

Another basic element of East Asian social organization is the ego-centred kinship system. In such a system an individual does not place himself within a kinship group by reference to a group in which he has membership but rather calculates the distance of each relative from himself. He is thus the centre of the kin group, and those too far on the periphery cease to be relatives.

Main characteristics of the kinship system

This ego-centred system has two forms. One is the kindred form, the type of kinship system found in the West, in which relatives on both the mother's and father's side are equally considered as kin. The second form may be regarded as an asymmetrical extension of the kindred form. This is the patrilineal segmentary lineage, which emphasizes the relationship between the parent and child on the father's side of the family. The line of descent from grandson to great-grandfather is thus given prominence.

Characteristic of the segmentary lineage is a tendency for residence to equal kinship affiliation. Thus, most of those who live within the same village or encampment are believed to be related. Members may move out to form colonies, however, and in this way lose their original identity. Other individuals and even families move into the residential unit, and in time they or their descendants are accepted as relatives. Within any residential area, however, there is a core group of old families, so to speak, toward whom the others gravitate and claim relationship of some sort.

The last basic element of East Asian social organization is ancestor worship, especially of one's patrilineal ancestors. Shamanistic religious practices often related to ancestor worship are prominent.

Apparently most of Europe and northern Asia at one time maintained a social organization of the type depicted above. It is also found in northern and eastern Africa. East Asia is exceptional because not only have many of the features of this model been maintained until recently, even down to the present, but because they were also accompanied by the rise of a centralized state.

Sociopolitical organizations. As stated above, Chinese civilization began as a lineage state (one in which political subordinates were ideally relatives of inferior rank in the lineage) and one in which the patrilineal segment of a lineage was of particular importance. Japanese political structure was also a political system tending toward a state based upon the segmentary lineage. It is almost impossible to maintain a strong centralized system of government along with a segmentary lineage social organization because forces for centralization are countered by those for segmentation. In China this "familial feudalism" came to an end with the Ch'in dynasty (221 BC), when a bureaucratic, authoritative system of government was introduced for all China. Although China subsequently became fragmented, indeed for a time became a feudal society, it never reverted to the lineage state as a form of government.

Japan entered into its bureaucratic period under the impact of Chinese influence, which was at its height during the Taika reform era beginning in 645. By the 11th century, however, during the Fujiwara period, local family-centred warrior bands held Japan in de facto control. With the rise to power of Minamoto Yoritomo (died 1199), the welding into a national state of local centres of power based on residence and descent groups reached its climax.

Korean sociopolitical organization managed to combine a number of seemingly conflicting factors as late as the 12th century: a bureaucratic structure, in part oriented around a Chinese-like civil service examination system, combined with a very class-conscious society in which local power rested largely in the hands of aristocratic estate holders. The residents on these estates—slaves, serfs, and nobles—were all united by common genealogical charters. Unlike Shang dynasty China, however, these lineage estates did not integrate to form a lineage state. Linguistic evidence for medieval Korean social organization can be found in the use of place-names along with patronymics.

There are, for example, 84 place-names that qualify the Kim surname.

The traditional social structure in all three nations is similar in one respect: although segmentary lineages continued to exist, they were unable to dominate and determine the organization of the state. Nor can these be called feudal societies.

Significance of the tax system

Taxation and tax reforms and their relation to land tenure were important factors in traditional Chinese society. Reforms were initiated by the Northern Wei dynasty, which controlled North China from AD 386 to 534/535. At first, the reforms consisted of limitations to the amount of land any individual could control and of qualifications on inheritance rights. During the T'ang dynasty (618–907) this system was changed to a direct and, as compared to the past, heavy tax on land. The emphasis shifted from taxing each person equally, as in a poll tax, to a tax on resources. As a result, large estates apparently were broken up into small, independently owned farms and relatively small landlord-owned estates.

A second factor of great importance in shaping Chinese traditional society was the commercialization and urban orientation that developed in China. The percentage of persons living in urban centres in China even today is small, but by at least the Ming dynasty (1368–1644) and probably already by the Sung (906–1279) the influence of city life upon the nation was very strong.

Gentry society. This period in Chinese history is usually referred to as that of a "gentry society," a term of considerable ambiguity. On the one hand, one can speak of the scholar gentry or, more accurately, the degree-holding gentry—those called *shen-shih* in Chinese. Such individuals were granted a special legal as well as social status because of their success in the examination system. Some few members of this group, by continuing up the degree ladder, received bureaucratic appointments. These may be called the bureaucratic scholar gentry. Then there were others who, because of their position as landlords, may be termed landlord gentry.

To understand traditional Chinese society one should translate gentry simply as important and influential persons and then attempt to understand in what manner their pre-eminence was obtained and by what means their influence was exerted. Government service, the examination system, education, landed wealth, wealth in general, tenantry, and social mobility can best be examined as interrelating within a system of government, as well as of society. The summit of the system was the Imperial court supported by a minute elitist bureaucracy. The court and civil service system were organized as though the government was an autocratic, although benevolent, despotism. In a formal sense this was true. There was little an individual could do to counter the will of the central government if he met with its full displeasure. It is not fully understood how the theoretical or formal structure of the government, which can be deduced from examining old statutes, actually operated. It is, however, evident that the government of the various dynasties depended upon a client–patron system of structured relationships and on informal government to maintain stability in the countryside.

The personalization of contractual relationships

By late Ch'ing (1644–1911/12) and Republican times this relationship was called *kan-ch'ing.* To have good *kan-ch'ing* is to have a sense of well-being, a feeling of being at ease, especially in relationships between parties of unequal status who are not kinsmen. Those who have good *kan-ch'ing* are in a position to help each other rather than to compete with each other. In other words, it is a personalization of otherwise contractual relationships.

Landlord–tenant relations. Despite the superficially despotic central government, the landlord was primarily dependent upon the goodwill of the tenant if he was to get his rent. It is true that, should the tenant refuse to pay the rent, the landlord could ask for help from the magistrate, but such aid, in the short run at least, might prove to be very costly, as the landlord would be saddled with all court costs besides having to satisfy those greedy lower officials upon whose goodwill he had made himself dependent. Thus it was better for both parties, tenant and landlord, to keep the central government at a distance—especially military officials. The tenant, of course, normally paid the rent. For him not to do so and present no excuse would be tantamount to rejecting the landlord's right to the land. But the actual amount to be paid was open to negotiation. If drought, flood, too much rain at the wrong time of year, insect plagues, or other factors adversely affected the harvest, it was the landlord's obligation to remit as much of the rent as necessary for the tenant to live. The tenant was in a better position to know the actual growing conditions and the real condition of the harvest. If good *kan-ch'ing* existed, the landlord would not press overly for the rent, and the tenant would be fairly honest about paying it in good years.

The lack of security in rural areas meant that good relations between landlord and villager were necessary to protect the landlord against bandits. In an area in which the gentry were well respected, they were able to maintain an effective militia (mostly composed of villagers) for the defense of the village and their own property. But if the villagers hated the landlord, residents of the rural area where he lived might offer him no protection against bandits coming from a neighbouring area or might simply attack him themselves.

More symbolic contributions made by tenants to the landlord consisted of gifts of food and produce presented at festivals. During rites of passage (at birth, marriage, death, etc.) in the landlord's house, tenants as well as freeholders would contribute labour. The landlord would make monetary contributions to his neighbours when they needed help. Tenant children often worked as domestics in the "big house," and sometimes a landlord would take a tenant girl to be his "little wife" (second, subordinate spouse). The tenant was courteous to the landlord, calling him "master" or "elder."

In addition to forgiving rents at times of distress to the tenant who fulfilled his obligations, the landlord acted as an intermediary between the rural area and the functionaries of the central government. He had the poise, education, and background that made it possible for him to argue the case for an accused villager or attempt to have the tax rate adjusted or obtain a *pai-lou* ("memorial") in honour of a faithful widow or earnest local historian. It was also expected of landlords to obtain financing for bridges, schools, temples, and other semipublic buildings. With the aid of the village headman, the landlord organized the maintenance of public works by means of corvée labour (labour exacted in lieu of taxes). At the village level this was probably more like a series of days of cooperative community effort than unrewarded drudgery. This unofficial body of village headman and landlord was also responsible for morality in the community. They often helped to work out a compromise in a dispute or even acted as judges. During the Ch'ing dynasty they were responsible for bimonthly public readings of the emperor K'ang-hsi's "Sacred Edict" (*Sheng yü*):

The "Sacred Edict" of K'ang-hsi

> Be filial and respect the social relationships, be frugal and diligent, esteem scholarship and eschew unorthodoxy, be law abiding and pay your taxes.

Sometimes local children were taught along with the children of the "big house" by a tutor, or a school was established elsewhere for the neighbourhood, usually at the Classical (Confucian) temple. These illustrations indicate only some of the functions of the client–patron system of government.

The burdens of this system lay initially upon the tenant but tended to drain the resources of the landlord. It is difficult to imagine a landlord maintaining good *kanch'ing* and making a great deal of profit from his landholdings. But, by investing in urban-based enterprises, such as pawnshops, grain shops (in which a surplus could be sold at times of greatest demand), and small industries, the gentry could recoup its losses.

It was difficult to become wealthy through the ownership of land alone and thereby to acquire gentry status because of the rules of equal inheritance by all the male heirs. Wealth was often initially acquired in the cities or, if acquired in the countryside, frequently by such dubious

means as banditry. Later this wealth was transferred to land both for economic security and for social prestige.

Families and lineages. The extended families of the "big house" were complex organizations including often only remotely related individuals seeking patronage. The peasant families, on the other hand, tended to be small, approximating a nuclear family (parents and children), although the large, extended pattern was the ideal. For many the cyclical joint (nuclear-extended) family corresponded closest with reality. This pattern, which is a basic feature of East Asian social organization, assumes the dissolution of the extended family after the death of the parents. To the individual the pattern is cyclical, as he is born into a household composed of grandparents and their married sons, which breaks up into nuclear households upon the death of the grandparents. As sons mature it is recreated, only to dissolve with the father's death.

In South China, especially in the provinces of Kwangtung, Kwangsi, and Fukien, the client–patron relationship was solidified by the continued power of segmentary lineages, the *tsu.* In Taiwan large lineage organizations were rare. Most individuals of Chinese descent resident on the island maintained only shallow lineage organizations and remembrances of ancestors.

The kindred form of kinship organization was an element within Chinese and thus Taiwanese kinship organization, but it was not as important for the Chinese as it was for the Koreans and certainly not as important as it was for the Japanese.

Korean Yi dynasty society developed a gentry similar to that of China, but, while in China the importance of the gentry lay in their function as community leaders in villages where they owned only a small percentage of the land, in Korea the gentry (known in Korea as *yangban*) owned most of the land. Koreans possessed a stronger class consciousness, and land ownership was limited mostly to the bureaucratic class.

In recent times at least, the Koreans have tended to practice primogeniture rather than equal inheritance by all sons. The joint family described for the Chinese has thus not been common for the Koreans, although the eldest son, after receiving his inheritance, is responsible to some extent for the welfare of his younger male siblings. The result is a weakly united extended family, a family that does not live together but still feels responsible for its members. The system of kinship terminology indicated by Korean terms of address is much like that of western Europe. It indicates the importance of the nuclear family and bilateral (paternal and maternal) kindred, while the Chinese terms of address indicate an emphasis on patrilocal residence. Other systems of kinship terminology in Korea show the importance of patrilineal ties, as well as the former presence of segmentary lineages.

Tokugawa Japan (1603–1867) was a highly bureaucratic state working within a feudal framework. During this time there were probably as many civil servants in Japan as there were in all of China at the same period, despite the difference in size and population. Admittance to the bureaucracy was limited to the former warrior class, Samurai or *bushi,* who were placed on stipends in times of peace and whose caste position was protected by law.

Because of the exercise in Japan at this time of tighter political controls, especially vigilance by the Tokugawa and daimyo (hereditary feudal lord) for signs of disloyalty, which might be punished by confiscation of land, there was less need for a client–patron system to emerge, although the Japanese form of the segmentary lineage, the *dozuku,* only gradually declined in importance. A client–patron relationship existed naturally between the daimyo-executive and *bushi*-bureaucrat, but this relation varied from area to area. It tended to be thought of more in terms of formal obligations and efficiency rather than as one based on personalities. While in China there had been a personalization of contractual relationships, in Japan there was a ritualization and formalization, if not to say contractualization, of personal relations.

The Tokugawa period was one of increasing urbanization and commercialization. There was a development of small industries and an improvement of agricultural techniques, based in part upon specialization and the partial commercialization of agriculture. It became more profitable to work the land in small nuclear family groups now that farm management demanded more care and a growing demand for labour existed in the urban centres. As a consequence, the nuclear family came to be the dominant form in rural Japan. The position of the nuclear family in traditional Japanese society was also strengthened by the gradual emergence of a pattern of primogeniture. Primogeniture is relatively less painful in Japan because of the respect given adopted sons-in-law, who often are the younger brothers who did not inherit the estate into which they were born but whose children inherit their wives' estates.

Socio-economic change in Tokugawa Japan

The other groups covered in this section (except the independent Lolo) were dominated by or integrated into the sociopolitical organizations of other East Asian groups or cultures during the traditional period.

The Hui-hui, for example, are very similar in social and familial form to the Chinese, differing only in those aspects in which religion has been influential. One finds in China Chinese-Islāmic communities existing as compact segregated enclaves, focussing on a single mosque. There is more community spirit than among the Chinese, and the Islāmic minister, *chiao-chang,* is also the leader of the community.

The situation of the independent Lolo (Yi) of the Ta-liang Shan is complex because of the interrelation between caste, class, and lineage affiliation. Only about one-tenth of the population of the Ta-liang Shan were Black Lolos (Mosu, or Nakhi)—that is, the upper caste of "pure" Lolos. The sociopolitical organization of the Mosu was the segmentary lineage with confederations, the latter continually rearranging because of feuding over "subjects," household attendants, and slaves. The tripartite grouping into subject or White Lolo, attendant, and slave was the result of contact with Chinese. Slaves were recently captured Chinese who after several generations came to regard themselves as Lolo and became household retainers. Their master then would permit them to become White Lolo with the status of subject. Members of the lower caste were apparently not integrated as kin with the Black Lolo but formed their own patrilineages. The relations between Black Lolo and subjects and retainers were superficially relaxed and egalitarian. They ate the same food, slept in the same house, and observed the same rules of hospitality. One might say that the greatest concern of a Black Lolo was for the welfare of his subject, because, if he acted wisely, kindly, and generously, he could attract followers. This became, of course, a point of discord between himself and other Black Lolos, as the men he might attract already had ties as subjects, attendants, or slaves with other Black Lolo.

Socialization and education. East Asian traditional society was dominated by middle-aged men and women. Within the joint family it was the wife—a former daughter-in-law and later a mother-in-law—whose voice was paramount. In the outside world the middle-aged man directed affairs after years of apprenticeship. The transitions from one stage of life to the next were all gradual, except for retirement. Adulthood was not achieved by passing some initiation rite, taking a head, or getting married—and certainly not by reaching a certain age—but only by acting responsibly. Retirement marked a sharp break: within a short time a powerful and authoritative adult might be converted into a gentle grandparent.

Children were closely integrated into the household. In China, Korea, and Japan especially it was believed that they were never able to repay the debt to their parents, and thus they strove to succeed and by this means win parental approval. This was especially true of brothers who had to cooperate in the joint family but who were also competing individually for parental approval.

Economic life. *Settlement patterns and housing.* There are basically two house types in East Asia. One type is exemplified in its simplest form by the Ainu hut. Uprights support a ridgepole connected by rafters to the corners. Reed matting is used both for walls and roofing, as well as for flooring. The essential point is that the uprights, not the walls, support the roof. The other type may be

Dwelling types

exemplified by the Lolo house, which is constructed of wooden planks that, together with uprights, support the roof. The roof is made of planks held down by stones.

The North Chinese house is fundamentally the Ainu hut with elaborations. Large pillars may replace the simple uprights of the Ainu, fired bricks the mat walls, and tiles the mat roof, but the plan of construction remains the same. It is possible for an entire wall of a Chinese house to fall away without affecting the stability of the remaining sections. This is also the traditional house type of the Manchus, Hui-hui, Min-chia, Koreans, Taiwanese, Miao, and Yao. Significant elaborations include the construction of a raised sleeping platform heated by flues from the stove. The Koreans prefer a heated floor instead. The house may be enclosed within a courtyard among Manchus, Chinese, Min-chia, Hui-hui, and sometimes Miao and Yao. Or a smooth, hardened earth area, a *matang,* may be found in front of the house, as among the Koreans.

The Japanese house may be seen as a highly original synthesis of basic Ainu hut and Lolo house. Uprights are used, not necessarily pillars, so that the walls carry some of the weight. The mat flooring again suggests the Ainu type.

In the rural areas, houses may be grouped in tight clusters or as isolated farmsteads. By and large the Chinese, Manchus, Min-chia, Koreans, Ainu, and Hui-hui live in tightly clustered settlements, while the other peoples have both. On Taiwan the Chinese-derived population tends to live more often in isolated farmsteads reminiscent of the settlement patterns of the United States Middle West.

Agriculture and trade. Every one of these societies is to some extent dependent upon agriculture. The Ainu have perhaps been mostly dependent upon fishing, gathering, capturing falcons for sale, trapping, and hunting—especially to obtain trade goods from the Japanese.

Most Chinese, Min-chia, Koreans, Taiwanese, Hui-hui, and Japanese practiced a labour-intensive/land-scarce type of agriculture during the traditional period in which the primary beast of burden was man.

For South China, Korea, Japan, Taiwan, and among the Min-chia rice is the dominant crop. The traditional method of growing rice requires the use of a water buffalo for preparing the soil, in addition to tremendous amounts of human energy for transplanting, weeding, and harvesting. In order to grow paddy, or wet rice, the farmer must have more control over his water supply than nature generally assures. To satisfy this need, countless small irrigation systems have been constructed throughout East Asia. Only some of the marginally arable land of the Hui-hui and adjacent regions in China's Northwest are totally dependent on irrigation. Here waterwheels, placed along the riverbank and canals, are used.

The Miao, Yao, Manchus, and Lolo made more use of animals and undomesticated plants. The Lolo depended as much on pastoralism as on agriculture. The Manchus definitely depended primarily upon agriculture, but at nearly every point a beast of burden assisted man in working the soil. Although the Manchu today grow the same crops as the Chinese farmers of the North China Plain (corn [maize], kaoliang, wheat, oats, millet, and buckwheat), their fields are worked by oxen or horses. Goods are transported in carts pulled by animals. Animals are fed grain rather than left entirely to scavenge. Only in the kitchen garden does Manchu agriculture resemble the intensive cultivation of the Chinese.

In all of East Asia during the traditional period a commercial and monetary economy was manifest. Farmers produced more than was necessary for subsistence, selling their surplus to buy goods at a market or to pay taxes and rents or repay loans. It is difficult to arrange the traditional economies of East Asia along a scale, but certainly by the beginning of the 19th century Japan was the most commercialized and industrialized. The power of the Chinese gentry and the centralized state, always jealous of their prerogatives, stifled industrial development in China. The same was apparently the case in Korea, whereas Japan's postfeudal society was in this respect more like that of Europe.

Degrees of economic development prior to modernization

Religion and art. The syncretic religions found throughout the Far East developed through the interweaving of several belief systems. Ancient contributions were shamanism—that is, belief in an unseen world of gods, demons, and ancestral spirits responsive only to the shaman, or priest—and a belief in an impersonal supernatural force. In anthropological literature this force is often called *mana,* but in the Orient the term used is *tao,* the "way," or "lode" as its more fundamental and ancient meaning. This force has two aspects, an active and a passive, in Chinese known as *yang* and *yin,* respectively. Perhaps such beliefs derive from the areas to the south, but such a conceptualization of nature could also have derived from the philosophical underpinning of shamanism. A third ancient element is ancestor worship. Important later ingredients have been Buddhism and, in Korea, Christianity, which has been closely associated with Korean nationalism.

Features of East Asian shamanism

Twentieth-century Tungus (including Manchu) shamanism is probably as close to the ancient shamanistic foundation of East Asian beliefs as can still be found. There is a tendency for a shaman to represent his own lineage, although a shaman does not have to limit his services to his kin group. A feature of shamanistic practice is the séance, in which the shaman sends one of his souls out to meet with spirit helpers whose job it is to induce the lost soul, or fraction of a soul, of a patient to return. The séance demands both control and ecstasy. It is a dangerous occupation, psychologically demanding. In one variation, the shaman, instead of sending out one of his souls, becomes "possessed" by the spirit he has contacted. Much of the popular religious Taoism of China uses shamanistic séances of the latter type. Sometimes, a priest—that is, a person primarily concerned with ritual and doctrine rather than with personalized contact with spirits—is prominent, as in Japanese Shintō.

In religious terms *yang* is decidedly better than *yin.* Chinese saints such as Kuang Ti (supposedly a general who lived during the period of the Three Kingdoms, about the 3rd century after Christ) had an abundance of *yang.* Graveyard trees, the ghosts of those who died in childbirth, or those without male heirs have too much *yin.* The latter, called *kuei* in Chinese, supposedly caused much of the misfortune in traditional China. It therefore behooves people to propitiate the *kuei* at the same time that they take care of their own ancestral spirits. If the *kuei* cannot be placated by offerings made at crossroads or by a special festival celebrated at midsummer, then they may hopefully be frightened away by "hot noise," a literal translation of the Chinese word for happiness, with firecrackers, red-coloured paper, and by chanting Classical literature.

The three-part soul of one's own ancestor requires care after death lest it become a *kuei.* Generally, one's own ancestors are remembered by burning incense at the family altar. Ancestor worship is very ancient among the Chinese and probably among some of the other peoples in Asia, but it apparently became important in Japan only after the importation of Chinese culture. Before that time the Japanese worshipped only the deceased founder of the lineage. The reverence bestowed upon the emperor may be seen as deriving from this custom.

The social and intellectual life of the peoples of East Asia has affected their interpretation of the nature of religion. The Chinese learned gentleman has tended to be an agnostic, whereas his Japanese counterpart is generally a Buddhist of the Zen sect. In China and Korea there has been both a Confucian activism and a Taoist passivism. In Japan, on the other hand, Zen encouraged its *bushi* adherents to find their way within the world rather than by withdrawing to some lonely and beautiful spot, as in the Taoist ideal.

Aesthetically the Chinese gentry and their Japanese counterparts expressed themselves along similar lines. Fundamental to their visual art is the skill perfected in practicing calligraphy with brush and ink stone. The novel, a literary form dependent on a "middle class" having leisure time and an interest in details of personality rather than simply in characters of epic proportion, developed much earlier in both China and Japan than it did in the West. Stylized operatic theatrical productions, the *Ching-hsi* of China and the Nō of Japan, were enjoyed by the literati but were in form and content simply the most polished of a series

of musical theatrical productions found throughout the area in the form of shadow plays, puppet shows, and tales of itinerant storytellers. It is in pornography that a difference may be found, the Japanese celebrating an exuberant phallicism, the Chinese being more sensual and playful.

Modern developments. For the peoples of East Asia the 20th century has been a time of quickening change. The Taiwanese have emerged as a distinct ethnic group and nation, whereas the Manchus, once the rulers of China, have become eclipsed. By the time of the fall of the Ch'ing dynasty in 1911/12, most Manchus had become so Sinified that they were simply absorbed into the Chinese population, though some pockets of Manchus (the Bannermen) who had developed a strong sense of national identity and who resisted absorption by the Chinese remained. The establishment and sponsorship in Manchuria (Northeastern Provinces) of Manchukuo by the Japanese in 1932 gave such groups a respite. Now three generations removed from the fall of the Ch'ing dynasty and one from the unification of China under the Communists, there is probably little left of the Manchus as a distinct people.

The Ainu of Hokkaido have in a sense been fighting a losing battle against the better organized Japanese since the 1st millennium of the Christian Era. The Ainu, until Russian penetration of the Far East, were valued by the Japanese as a market. The Russian advance led to closer Japanese control over the Ainu and, after the Meiji Restoration (1868), to much closer supervision of Ainu life. The Ainu were encouraged to become sedentary farmers rather than moving on from plot to plot. This often led to their neglect of fishing and other traditional occupations. Large numbers of Japanese have since settled on Hokkaido, which has led to intermarriage, and for over 100 years now the Ainu have been encouraged to become successful within the framework of modern Japan. Despite discrimination by some Japanese, especially up to the time of World War II, the Ainu have accepted assimilation into Japanese society. To what extent the old ways will continue to be observed by some families cannot be ascertained, but as a distinct people the Ainu may soon disappear except in the ethnographic record.

The fate of the Min-chia was sealed much earlier, in the Yüan dynasty (1206–1368), when Kublai Khan conquered the Nan Chao state. The Min-chia were encouraged to become Chinese literati, and they have since then competed for Chinese honours with even greater fervour than the Chinese themselves. They achieved a high measure of success in Chinese society so that over the centuries they have become very Sinified. At the present time no political, social, or cultural situation of a nature that would slow the Min-chia's rapid assimilation into the Chinese population seems likely to come into being.

Ethnic awareness of the Muslim Hui-hui in China

One might assume that the Hui-hui are also on the way to losing their distinct identity, but in fact the victory of the atheistic Communist Chinese has heightened the ethnic awareness of the Islāmic Hui-hui, who have maintained their religious bonds. During the last quarter of the 19th century they were the victims of extreme religious persecution, in the course of which millions of them were killed. Now only tolerance and a real end of discrimination by the Chinese will lessen the Hui-hui's resistance to being assimilated. They have apparently been allowed to play a part as a nominally autonomous group by the Chinese Communists.

In one sense the Ta-liang Shan (independent) Lolo (called Yi by the Chinese) have created one of the more successful countercultures to the Chinese. They have maintained their independence and identity during 2,000 years of Chinese pressure. During this time they were able to elaborate a social and ceremonial organization of their own and to develop a non-Chinese and non-alphabetic writing system. But also during the years, other Lolo groups, which are closely related to the independent Lolo in speech and culture yet living outside the mountain fastness of the Taliang Shan and under Chinese jurisdiction, have increased in number until there are about 5,450,000 of them, not including the Nakhi, Lisu, Lahu, and Akha. There are, however, far fewer independent Lolo left: Chinese control is obviously gaining.

The so-called acephalous political organization (*i.e.*, lacking a governing head or chief) of the Lolo, Miao, Yao, and other groups in southern and southwestern China has given them certain advantages. The primary advantage lay in the inability of the Chinese to be done with them by one decisive battle or campaign. But it has proved a disadvantage as well, as it has left them unable to deal with the gradual encroachment of the Chinese onto their lands, first as individuals, later as officials. Only by enslaving the Chinese and destroying their settlements were the Lolo along the Szechwan–Yunnan border able to hold their own. Once deprived of the strength to carry out such drastic measures and forced to deal with the powerful government of the People's Republic of China, the Lolo, like the other non-Chinese peoples of southern and southwestern China, will probably find within a generation or two that all that remains of their ethnic uniqueness are some folk-art motifs and a few officially sponsored folk festivals.

Paradoxically, the 50,000,000 non-Chinese of southern and southwestern China have been able to maintain their own culture and language for thousands of years; yet, now that a government of China exists that pays special attention to them and that is sometimes sympathetic to them, they are likely to become totally acculturated. The reason for this is that they live scattered in small enclaves among the Chinese population.

Relations between the Taiwanese and the "mainlanders"

As pointed out already, the Taiwanese control most aspects of their lives and, through their domination of the provincial government, the careers of many "mainlanders" on the island. The latter are attempting to re-Sinify the Taiwanese by teaching Mandarin Chinese in the schools, by the cultural-restorations movement exemplified by the building of a beautiful new national museum, and by other government services and programs. But the fact that the Taiwanese own the land and control the resources, plus their greater numbers, suggests a different direction of development. If Taiwan is allowed to settle its own affairs, it is more likely that the Taiwanese will absorb the "mainlanders" than vice versa.

China and the West. Traditional East Asian culture, based on the tribute system and the respect for Chinese intellectual values, ended when it proved impossible to ignore the West and when the West would not agree to be just a somewhat different type of barbarian to be incorporated into the established order. Had the demands of the West been only those of imperialistic barbarians, they could have been dealt with in the classical manner. As it was, the dominant powers of the Far East had to see themselves as students instead of teachers. To accept this meant the destruction of the mythology underpinning the tribute system. The Westerners refused to kowtow and insisted on recognition at the national level. They defeated the Chinese militarily but did not thereupon attempt to conquer China and set up a new dynasty. Within a short time China lost suzerainty over Korea, over the Tungus on the northern watershed of the Amur, over the Khalkha Mongols, the Tibetans, the Vietnamese, the Ryukyuans, the people of Tannu Tuva, and the majority of Kazakhs and Kirgiz.

The response of the Manchu court to this situation was an attempt at antagonistic acculturation; that is, an attempt at learning the technology of the West without accepting Western values or allowing any changes in Chinese social, political, or economic organization. This response allowed the court to survive during the initial stages of the revolutionary period, which began in China partly because of the weakness of the court and its foreign origin but also because of a growing awareness that the gentry system was inadequate to supply services felt to be essential to a modern state. The use of modern arms at first enabled the court to put down rebellion, but by the 20th century the buildup of foreign mercantile and industrial centres in the major coastal cities and the activity of Western missionaries in the interior had awakened a growing desire for modernization and a reassertion of China's identity. It was only natural that the original leaders in the anti-Ch'ing movement should have come from those areas in closest contact with the West. The government tried to meet their demands by changing from the Classical system

of education to one stressing Western thought, by allowing the development of industry, and even by accepting the idea of a constitutional monarchy—in fact, abandoning the earlier attempt at antagonistic acculturation. But the anti-Manchu sentiment that had been released was too strong to halt the fall of the Ch'ing dynasty in 1911/12.

China from the fall of the Manchus until 1950 found itself bound by a number of severe contradictions. Those who had given the revolution intellectual force stressed individualism, Western intellectualism, science, universal education, democracy, national reconstruction, and an improvement in the peoples' livelihood, as well as other liberal and popular measures. These measures were all suited to the needs of the times. During previous periods of Chinese history, such as the Ch'in (221–206 BC) and the Sui (AD 581–618), the Chinese had been quite able to rework their institutions drastically. The new reformers, however, had no real power base in the countryside. Their strength lay in the Western-influenced treaty ports and was suspect to the majority of Chinese. Those who soon came to have real power, the warlords who from 1912 to 1949 controlled most of China independently of the central government, did not understand the nature of the changes that were needed. Most of the warlords had abandoned Classical ideals, it is true, but they had not replaced them with those of the West. In fact, they were primarily opportunists or chauvinistic nationalists. The head of the Kuomintang, Chiang Kai-shek, reflected the desires of the nation to reconcile the different factions, and he might have been successful in doing so had the Japanese not sought to prevent the emergence of a modern China.

In some areas modernization did occur. There was limited industrialization; a socially conscious literary movement exemplified especially by the *pai-hua* (vernacular-language) movement led by Hu Shih and the bitter essayist Lu Hsün; the building of railroads and motor roads; the organization of one of the more efficient postal services in the world; and a nationwide, although not compulsory, school system. But the basic problem was that the leaders lacked the power to deal with the patron–client relationship that had held the traditional society together. As the warlords of China increased services, as industrialization continued, as classical principles well adapted to the maintenance of good *kan-ch'ing* were abandoned in favour of individualism, and, most importantly, as the old-fashioned gentry lost their ability to intercede for the welfare of the community, the traditional institutions became means of exploiting the farmers. This was the case because, as the power of the government increased, the restraint on the landlord that had made it essential that he keep the respect and goodwill of his neighbours and tenants was removed. The government gave the landlord protection from bandits of whatever derivation and assured the collection of rents. It became no longer necessary for the landlord to maintain a good standing in the community in which he owned land. In the area near major cities in which this process had evolved furthest, landlords, now often urban industrialists, divorced themselves entirely from the problems of the land and appointed an estate manager who collected a set amount of rent and kept whatever else he could squeeze out of the farmers.

Breakdown of traditional relationships

The client–patron system had functioned amazingly well in traditional China. Few such holistic systems, encompassing political, educational, artistic, social, ethical, and economic goals, have lasted so long and with such vigour. Its major weakness—its lack of consistent service (in regard to the provision of regular admittance to schools, for example) and justice—was also a major virtue, as it accompanied a government that lay lightly upon the citizenry. But it became impossible to retain only a part of the system—namely, privileges for the gentry and nepotism in government. These were not destroyed until the Chinese Communist Party had fled to the countryside to lead a revolution in the classical Chinese manner.

The Communists' main thrust was a reorganization of society from the village level upward, with the cooperation of all "progressive" elements in an attempt to do away with "feudalism." This involved the elimination of vestiges of the client–patron system, along with many other associated traditional values, such as the hierarchical position of men in Chinese family life. Emphasis was placed upon the services individuals could offer the community and state regardless of the status of the person and his connections (*kuan-hsi*) or how those of higher rank felt about him (*kan-ch'ing*). In summary, the personalized, traditional society was considered exploitive and inefficient. Thus, the old lines of structural personalization were discarded and new ones established, such as farm cooperatives, women's clubs, literary movements, and anti-Japanese militia and crop improvement committees.

Non-Communist East Asia. Korea became gradually weaker under the Yi dynasty (1392–1910). The Yangban (gentry) took over once-public lands and then did not pay taxes. To make up for the deficit the freeholders were taxed more heavily. They could not afford the taxes and lost the land, which thereupon passed into the hands of the bureaucratic landlord class. When famine occurred the central government had no reserves to alleviate the situation. Meanwhile, the intelligentsia, unaware of the real peril, indulged themselves in factional disputes more serious perhaps than those that had contributed to the fall of the Ming dynasty in China (1368–1644). The West largely bypassed Korea, which remained oriented along traditional lines after China had long been opened up to Western trade, missionizing, and interference and after the Meiji Restoration had set Japan on a path of modernization and industrialization. The Yi dynasty would probably have been swept aside in due time by a Christian- or Tonghak- (a syncretic revitalistic religious response to the West including elements of both Eastern religion and Christianity) led rebellion if Japan had not invaded Korea first and conquered it.

The Japanese conquest increased the Korean sense of national unity and in many ways modernized the country. South Korea is one of the more industrialized states in Asia, and a land-reform program is in effect.

Japanese society at the beginning of the 19th century had the strengths of feudal values interwoven into a bureaucratic system of government. Its people were ready, however, to discard the remnants of the feudal class system. It seemed better to be a prosperous businessman than a penniless samurai.

Recent social changes in Japan

In recent times some novel social forms have emerged in Japan, in the development of which the Japanese have been able to draw upon a number of value systems. One of these has been Bushido, the hierarchical and authoritarian conception of the role and status of the *bushi* service bureaucrat, based on a mixture of classical Chinese, feudal Japanese, and bureaucratic values. With its strong emphasis on loyalty in a vertically ordered system of two-person reciprocity, this way of the samurai is one of the important values that have shaped modern Japan.

Another hierarchically structured model dominant in some parts of Japan has been the *dōzoku,* the combination of kith and kin with landlord and tenant. In other areas, relations between landlord and tenant, although influenced by the *dōzoku* model, tended toward abuse by the landlord after a strong central government had assured his rights. This led to the growth of unrest and militancy among the rural population, finally suppressed in the 1930s.

The paternalistic model of organization in Japanese industry, known as *oyabun-kobun,* is probably inspired by both the Bushido system of values and the *dōzoku* (segmentary lineage). The result has been security for the worker, full employment, and ordered advancement with a minimum of division along class lines and in the professions.

The third organizational model has been drawn from the local kindred kinship group and the cooperating local group, the *buraku* (hamlet). These local units have become especially important since a land reform that occurred after World War II brought an end to landlordism in rural Japan. These two sources have provided the inspiration for egalitarianism and a desire for consensus found among the Japanese.

The populace is also divided into associational frames of reference such as industrial firms and villages. Differences in rank and status are important, but class is not impor-

tant, except for former outcaste groups such as the Eta. Economically, the system probably works as well if not better than that of the West, because it does not tend to cause social alienation.

The interaction of these various concepts in the political arena has been a mixed blessing. Perhaps some unique adjustment—allowing for efficiency in government, the desire for consensus, and homage to rank while furthering egalitarianism—will be achieved in the future.

In the 20th century East Asia as a cultural entity, as defined and described at the beginning of this article, was badly shaken by the collapse of traditional China. At times it has seemed that Japan was destined to take China's place, but Japan's defeat in 1945 changed this. Up to the early 1980s China has directed its attention to its Inner Asian frontiers and to internal social, cultural, and economic change, while Japan, South Korea, and Taiwan have concentrated more on industrialization and on developing their international trade. Given a continuation of present circumstances, one might predict the end of East Asia as a psychological reality within another generation. (F.B.B.)

SOUTHEAST ASIA

Southeast Asia, in its broadest definition, comprises those continental margins and offshore archipelagoes of Asia lying south of China, north of Australia, and east of India. Its continental portion embraces the autonomous nations of Burma, Thailand, Laos, Kampuchea (formerly known as Cambodia), and Vietnam. Its insular portion consists of the island nation of Singapore, at the tip of the Malay Peninsula, and it can be defined to include the two sprawling archipelago nations of Indonesia and the Philippines. It also includes Malaysia, a political amalgam of two northern Borneo states and the Malay states of the peninsula. In addition, there is the independent sultanate of Brunei in northern Borneo. The region extends over 2,000 miles (3,200 kilometres) from north to south and 3,500 miles (5,600 kilometres) from east to west.

Most of Southeast Asia has a stable, homogeneous tropical climate. Its large, shallow archipelagic seas and extensive fringing bays help stabilize the region's average monthly temperatures at around 81° F (27° C).

Four vast, southward-flowing river systems shape continental Southeast Asia's topography and major settlement

Distribution of Southeast Asian peoples and cultures.

patterns. They are the Irrawaddy and Salween (Burma), Chao Phraya (Thailand), and the Mekong (marking the Thailand–Laos frontier and traversing both Kampuchea and Vietnam). The shorter, eastward-flowing Red River (Song Hong) reaches the Gulf of Tonkin farther north, near the Chinese border. All except the Salween flow through broad alluvial plains and fertile deltas, where intensive rice agriculture sustains dense population centres and large cities. No comparably large river systems exist in the islands. Closest in length are the huge meandering rivers of Borneo, the world's third largest island. The other major Indonesian and Philippine islands are, unlike the mainland, volcanic. Their topsoils support an intensive rice agriculture.

Language communities

Ethnic groups. Southeast Asia has one of the world's most ethnically diverse populations. In Burma alone, between 125 and 140 languages are spoken; in the Indonesian archipelago well over 200 distinct languages are in use. This complex ethnolinguistic mosaic, with all its cultural diversity, has been studied only in part, and major problems of descriptive ethnology and linguistics still abound. The political frontiers obviously have little to do with the human social boundaries in the region: the Laos–Thailand border along the Mekong River, for example, divides in two the large Lao ethnic community of the mid-Mekong Basin, and the northern Burma–Thailand border splits the Shan people into only nominally separate "national communities."

Many of the region's languages, though mutually incomprehensible, belong to three widespread language families—Sino-Tibetan, Mon-Khmer, and Austronesian (Malayo-Polynesian). The scattered languages of the Sino-Tibetan and Mon-Khmer families are indigenously restricted to the peoples of the mainland, while the languages of the Austronesian family are indigenous both to portions of the mainland and to the two archipelagoes. Two of the mainland's most important language groups—Tai and Vietnamese—cannot be conclusively placed in any of these families; like many of the mainland's smaller "independent" languages, their origins and ancient historical connections are still in doubt. Independent in another sense are the several important Chinese languages (Hakka, Hokkien, Cantonese, etc.) spoken by the largely urban Chinese of both the mainland and the archipelagoes; while forming a subgroup of the Sino-Tibetan family, these languages are not indigenous to the region, having recently been spread there by Chinese immigrants.

Chinese, Indian, and Islāmic influences

By the early Christian Era, Chinese and Indian merchants had already extended their trading networks well into Southeast Asia. Lured by the area's natural wealth, they had opened both overland and maritime trade routes to tap its minerals, spices, and jungle products. Into the Neolithic villages and port settlements, they had peacefully begun to introduce the skills, social patterns and religions of two major civilizations. From about AD 100 to 1500, Indian, rather than Chinese, civilization became imprinted most explicitly in the region. Chinese influence spread overtly only among the people of Vietnam. Throughout "farther India" (Burma, southern Thailand, Kampuchea, and southern Vietnam), on coastal west Malaya, in eastern Sumatra, and on Java's north coast, pioneer Indian settlements grew up along the trade routes. As they waxed commercially, they expanded their religious and political influence. Indian Sanskrit scholars, monks, and priests settled and helped consolidate these communities into regional, theocratic, and socially stratified "Indianized states," economically based upon irrigated rice agriculture. These Indianized states were variously and at different times either Buddhist or Hindu-Brahmin in their dominant religious orientation. Until the mid-14th century they struggled among themselves for political supremacy and the control of regional trade. In doing so they implanted Indian religions, legal codes, social patterns, cosmologies, syllabic writing systems, classical literature, graphic arts, drama, and music throughout much of Southeast Asia.

A second major historical influence has been that of Islām. Between the 13th and the 15th centuries Arab and Indian Muslim traders began to dominate the maritime trade with the coastal peoples of Sumatra, Malacca, the Malay Peninsula, and many of the islands eastward to Mindanao. Often settling and intermarrying among the local ruling families of these scattered principalities, they imparted a pervasively Islāmic way of life. Islām embodied a monotheistic philosophy of religious brotherhood, revealed and concretely chartered by the Qur'ān. It contrasted with the already widespread polytheistic Hinduized religion that emphasized caste-segmented ritual and a variety of beliefs. By the 17th century, missionaries and converted chieftains (sultans) had widely extended Islām along the trading routes to Indonesia's Spice Islands (the Moluccas), into the southern Philippines, and, on the mainland, even among the Cham population of southern Vietnam. While also helping to undermine Java's Indianized state of Majapahit, Islāmic culture had begun by this time to penetrate deeply—mainly in insular Southeast Asia—into the belief systems, languages, literatures, and domestic law of many indigenous peoples.

Indigenous culture traits

Despite the spread of Indian, Islāmic, and Chinese civilizations into the region, Southeast Asia's interior, less accessible peoples have retained certain widespread, indigenous culture traits from the pre-Christian era. These include slash-and-burn (shifting field) agriculture, the terrace irrigation of wet rice, and the domestic use of chickens, pigs, and water buffalo. Other such traits are a highly diversified use of bamboo (to construct houses, tools, weapons, musical instruments, containers, etc.), separate premarriage dormitories for men and women, megalithic monuments, pile-supported dwellings, and multifamily longhouses. Associated patterns have included trial marriage, the blood feud, headhunting, strong local patterns of etiquette and custom, weak institutions of political leadership, and the practice of making decisions through rituals of ordeal and divination. Most of the technologically simpler peoples of even the remote interior have acquired the use of iron and the blacksmith's skills. Yet, such has been their generally ingenious, careful, and effective use of all available plant and animal resources that the French geographer Pierre Gourou was able to describe Tonkinese peasant life in northern Vietnam before World War II as a "civilization of the vegetable kingdom."

The Burmese, Thai, Khmer, and Laotian peoples. The lowlands of Burma, Thailand, Kampuchea, and Laos are each occupied by one politically predominant ethnic group—respectively, the Burmese, Thai, Khmer, and Lao. They probably total about half of mainland Southeast Asia's population. The Burmese inhabit the valleys of the Irrawaddy, Sittang, and Chindwin rivers, the Arakan Coast, and the Tenasserim panhandle; they extend northward to about 25° N. The Thais live on the alluvial plains of the Mae Nam Chao Phraya (Chao Phraya River) and its tributaries in central and south Thailand. The Khmers inhabit Kampuchea's interior plain drained by the Mekong and Tonle Sap rivers. The Lao occupy both banks of the Middle Mekong River and extend into Thailand. Although separated by language, ethnicity, and nationality, these peoples are alike in their agrarian economy, social organization, and adherence to Theravāda Buddhism.

Settlement patterns

These mainly rural peoples live in settlements that vary from compact house clusters to the more common linear communities extending along rivers, irrigation canals, roads, or paths. The size of a settlement may range from a few families to over 3,000 people. Houses are rectangular, gable-roofed, and usually built on piles two to six feet above the ground; they range in width from 10 to 25 feet and in length from 20 to 40 feet. Most have plaited bamboo walls and floors, with thatched roofs; houses built of planks with roofs of tile or sheet iron usually proclaim wealth and high status. Better houses may contain several rooms and have shuttered windows; poorer houses often consist of single compartments opened only by doors. Kitchens, often essentially wood-framed earthen hearths with stones to support cooking pots, may be separately partitioned, sometimes occupying rear verandas. Roofed front verandas, reached from the ground by short ladders, serve among the Burmese and Thai for other household chores and for sociability. Furnishings are usually simple but may include low eating tables, bed mats, storage bins, baskets, water jars, shelves, Buddha images, household al-

tars, and spirit houses. Almost every settlement includes a Buddhist temple compound and, additionally, among the Burmese, a brick pagoda containing a religious relic. Temple compounds in the larger settlements of all these peoples may also contain monks' quarters, meeting halls, and tomb monuments.

Rice, the major crop and staple food, is grown in many different varieties, usually selected for their productivity and endurance under local conditions. It is generally grown in permanent, diked fields watered by rainfall or—as in Burma's dry zone—by irrigation. Both annual cropping and multicropping are widely utilized. Draught buffalo (water buffalo) and bullocks are commonly used to plow and harrow the fields for rice planting; animal dung, ashes, and paddy stalks are frequently, if erratically, used as fertilizer. Common planting techniques include broadcasting, dibbling, and transplanting from seedling nurseries, depending upon local soil and water conditions. Hand sickles are generally used for rice harvesting. Threshing and winnowing techniques are quite varied and include trampling by buffalo.

Supplementary vegetables, tree crops, and other crops are also widely grown, both in house-plot gardens and in rotation on multicropped rice fields. Vegetables include beans, eggplants, tomatoes, onions, garlic, chillies, cucumbers, yams, sweet potatoes, white potatoes, gourds, cassava, peppers, ginger, mint, turmeric, and other exclusively local plants. Tree crops include bananas, coconuts, mangoes, durians, betel nuts, citrus, jackfruit, papaya, guavas, tamarind, and sapodilla. Other crops, sometimes raised commercially, include rubber, cotton, corn (maize), millet, sesame, sugarcane, and various condiments. No single farming household, however, will normally raise more than a few of these items. Burma's Tenasserim area specializes in tree crops, while in Kampuchea the sugar palm (*Borassus flabellifer*) has become a national symbol because of its local importance as a source of thatching material, fruit, sugar, and juice.

A major animal food is fish—fresh, dried, or salted. Although particularly important in the Burmese diet, it is found everywhere in local trade and, especially in its dried and salted form, readily reaches even communities distant from fishing areas.

Social organization typically is based upon the nuclear-family household—*i.e.,* essentially parents and their unmarried children; there is no tradition of extended-family groups or clans. Traditional society is largely stratified in hereditary ranks according to degree of royal ancestry, aristocratic background, and even religious or military achievement. The variety of such ranking has allowed individuals to move from one rank to another and occasionally even from the bottom of the traditional social ladder—*i.e.,* from among formerly indentured people and slaves.

Religious practices among mainland Buddhists

Religion is a blend of Theravāda Buddhism and local spirit worship. Buddhist theology posits that man undergoes a cycle of separate existences and that all animate life is endowed with individual souls. The moral and behavioral guidelines of his faith enable a devout Buddhist to progress toward his goal of Nirvāṇa by acquiring merit during his lifetime. There are many merit-earning acts. They include becoming a monk, financing construction of a temple, having one's son ordained as a monk, visiting Buddhist shrines, contributing to the repair of a temple, giving daily food to monks, entering the monkhood as a novice, attending the temple on all Buddhist holy days, and generally obeying Buddhist precepts. Conversely, by flouting Buddhist precepts, one can diminish one's stockpile of merit and even risk being reincarnated as a less desirable form of life in the next existence. Devout Buddhists are enjoined from taking life and usually even refrain from killing mosquitoes. Yet, this does not prevent most from eating meat or fish. If another person kills an animal, no merit is lost by eating its meat. The fisherman loses no merit because his catch is thought to die from leaving the water and not from the fisherman's action.

The worship and propitiation of local spirits provides the complementary, non-Buddhist religious dimension. Known as *nat*s in Burma and *phi* in Thailand and among the Lao, these spirits are ubiquitous, are thought to exercise great influence over daily human fortune, and are susceptible to approach and manipulation. The Burmese formally recognize 37 major *nat*s and a horde of lesser ones; the Thai, Khmer, and Lao recognize comparably large numbers. There are spirits of one's house, village, and rice field; there are many others of lakes, rivers, forests and of objects and periods. Equally various are the rituals necessary to keep them placated and amicable. Accidents, sickness, epidemic, drought, floods, and domestic problems are generally blamed upon the malevolence of spirits. Individual households and villages maintain shrines for placating their respective guardian spirits, usually through offerings of food and flowers. Male and female mediums can, when in trance, communicate with certain spirits and ascertain from them the shape of future events.

Because entering the monkhood is a major merit-generating act, most men spend part of their lives as monks. A young man will be initiated at about 14 years of age as a novice monk and remain in the monkhood temporarily, for several months or half a year. His initiation, a ritual re-enactment of Lord Buddha's own renunciation of material wealth and assumption of monastic discipline, is a major festive occasion; the initiate's head is shaved, and he receives a new name, recites the monastic vows, and dons the monk's orange robe. During his monkhood the novice obeys the same rules governing diet, celibacy, and material possessions that discipline the senior monks. He lives in the temple monastery, begs his morning food in the community, and recites the sacred texts. He usually leaves the monastery without taking the examinations for advancement in the monkhood. He may return later in life either for another short period or to enter the monkhood permanently.

The full-time Thai Buddhist monk usually assumes an active pastoral role in the community of his home temple. The role commits him to officiate at the weekly temple services and at the monthly and seasonal rituals. Normally, it also requires that he conduct individual family ceremonies, as invited, for weddings, house blessings, cremations, and ordination of novices. He is a locally influential religious counsellor on important matters such as determining auspicious dates for personal activities. He may even study *sajjaad,* or magical healing, and thus extend his leadership into matters of health.

Since illness is often attributed to hostile spirits, its cure is not an established responsibility of the professional Buddhist monk. There are many sorts of locally recognized healers. Among the Thai, they include the spirit doctor (*maw phii*), who, through therapy such as text chanting, body massage, and the use of herbal medicines, is able to coax out, or extract, the hostile intrusive spirit. A *maw khan* specializes in recalling a patient's wandering personal soul and thereby restoring his health. Mediums can often diagnose illness by singling out the responsible *phi* and even, when in trance, contacting it directly for therapeutic advice. Such healers and diagnosticians may employ explicitly Buddhist symbols and ritual acts, while the pastoral monk, on the other hand, may utilize "magical healing" among his congregation; yet, healers and monks seem seldom to conflict. Using different techniques, they both provide some "mental-health" therapy; in addition, the healers are frequently astute both as physical therapists and as physicians.

The Vietnamese. The Vietnamese are heavily concentrated in the northern Red River Plain of Tongking and in the southern Mekong Delta area. They are settled only thinly along the coast between. In the north, where population density is very high, rice cultivation is supplemented by root crops such as manioc, taro, and sweet potatoes; in the south, more exclusively rice-growing areas predominate. Villages tend to specialize in pursuits such as metalworking, silk production, and coastal fishing; trade between such specialized communities has traditionally been important.

Chinese cultural influence in Vietnam

Chinese influence has profoundly affected Vietnamese society, setting it apart from the mainland societies farther west. Vietnamese use paternal surnames and, for purposes of ritually honouring their paternal ancestors, congregate

into patrilineal clan groups. The oldest male of the clan's senior branch usually conducts the ritual and maintains the ancestral clan shrine, its altars, and its commemorative tablets. Since this vital responsibility descends only among males, the importance of having male children is stressed more than in Thailand or Burma. Vietnamese Buddhism, formally of the Mahāyāna school, is also of Chinese origin. Far fewer men enter the monkhood in Vietnam than in the westerly Theravāda mainland countries. Those who do usually become full-time professionals; they follow primarily scholarly pursuits, do not beg for daily food in their communities, and play little or no pastoral role. Some become divination specialists, making use of Taoist ritual techniques, another Chinese cultural influence.

Vietnamese society has also incorporated traditional Confucian social doctrine binding subject to ruler, son to father, wife to husband, younger to older brother, and friend to friend in ideally respectful, permanent relationships. These ties have closely supported Vietnam's traditional hierarchical systems of civil and religious authority extending from the supreme emperor down to the village-level "council of notables." The intervening bureaucracy, mainly educated Mandarin landholders, has traditionally represented the emperor and is split into a number of ranks, each with its special privileges, powers, and status trappings. One could attain or better one's rank in the Mandarin bureaucracy through education and by passing examinations in Chinese characters and Classics. While this fostered some mobility both in rank and in residential location among the bureaucracy, the peasantry remained closely rooted to its villages. This "rootedness" is religious in nature, exemplified in the villagers' attachment to local clan shrines and also in the Vietnamese *dinh*. The *dinh* is a walled compound containing a sanctuary for the village's patron deity—often a legendary or historical personage—together with sanctuaries for lesser local spirits. While the *dinh* does not contain monk's quarters, it often provides a meeting place for the discussion of village affairs. Above all, it is a focal point for the discharge of the villager's crucial ritual obligations to the locally powerful deities and to the numerous spirits that, in traditional belief, control his world.

Montagnard cultures

The Indochinese hill peoples. In Vietnam, as throughout Southeast Asia, the lowland peoples tend to be culturally distinct from their upland neighbours, even when they belong to the same ethnolinguistic group. Vietnam's own interior hill peoples, the many groups collectively known by the French word Montagnard (Mountaineer), have traditionally been despised by the surrounding Vietnamese, Khmer, and Thai as "savages." Like the other scattered hill and mountain peoples of northern Thailand, Laos, and Burma, most are economically dependent upon shifting field cultivation and upon supplementary trade in the products of forest and of local craftsmanship. Mostly they live in scattered, impermanent settlements often located on steep slopes at high altitudes. They are predominantly and elaborately animistic in their religious beliefs and ritual practices, and their community leaders are usually endowed with some shamanistic ability as curers, diviners, or trance mediums.

Rice is the most desired food and usually also the staple crop among the mainland hill peoples. Some groups acquire it mainly by trading other crops for it, such as tea and opium. In Laos the hill peoples are generally self-sufficient in rice but also produce cane, wax, Spanish peppers, shellac, cardamom, and many other trade items; these often pass through the ethnically Laotian, river-mouth trading villages along the Mekong tributaries to their ultimate lowland buyers. In return, the mountain farmer receives such essential items as cloth, steel tools, and salt. Today, he also receives an increasing flow of Western consumer goods and even cash.

Varieties of Indonesian societies

Indonesia. *Rice farmers of Java and Bali.* The peoples of Indonesia may be divided into several categories. The first includes the irrigation rice farmers of the strongly Hinduized inland areas of Java and Bali. These two peoples comprise about half of Indonesia's total population, and their densely settled homelands reflect Indonesia's severest population pressures. But the Balinese have escaped the Islāmization experienced by the Javanese; their expressively rich religion, Ugama Bali, shows the widespread influence of classical Indian cosmology, ritual organization, and litany. Such influence may also be seen in the ancestral shrines, village temples, and courtyard structures adorned with Hindu art motifs carved into wood and volcanic stone. While both Balinese and Javanese share a common, pervasively Hinduized cultural heritage, the Balinese retain certain old Hindu caste distinctions and stress status differences more formally than the Javanese, especially those between aristocrat and commoner. By his simultaneous membership in a number of groups based on kinship and occupation, the typical Balinese villager also participates in a formally structured local community.

Islāmic peoples of Indonesia. The second category of societies includes the trade-oriented Islāmic peoples scattered along the coastal and riverine portions of the archipelago. Economically, these peoples range from full-time merchants to petty traders who supplement their livelihood by occasional gardening and cottage industry. In religious orientation, they are Muslims and share a fundamental respect for Qur'ānic tradition and law. While linguistically facile in Malay, which serves as their commercial lingua franca, they also speak a variety of native languages. The three largest constituent societies are those of the Malays of lowland eastern Sumatra and western Borneo and the mutually similar Makasarese and Buginese societies composed of peoples who stem from southwestern Celebes but are today scattered widely along the coast of the archipelago. Other small societies include hamlets, villages, and port-town enclaves of mixed Javanese, Arab, Portuguese, Indian, Chinese, Dutch, and other ancestries.

Marginal peoples. A third category of Indonesian societies comprises mainly isolated peoples unaffected by Indian or Islāmic influence. Their economy has consisted mainly of shifting-field rice cultivation or, as in extreme eastern Indonesia, the gardening of sago and various root crops. By the late 19th century, several of these peoples had experienced Christian-missionary influence. Until the 20th century, many retained their traditional customs of sporadic intervillage warfare and headhunting. Their traditional religious beliefs were richly animistic, with conspicuous emphasis upon ancestor-revering ritual. Included in this category are the Toradja of central Celebes, the scattered Dayak peoples of Borneo, a number of interior peoples of Nusa Tenggara (principally the islands of Lombok, Sumbawa, Flores, Timor, and Sumba), several smaller Sumatran groups (Gayo, Rejang, Lampung), and certain peoples of Seram and the Moluccas in extreme eastern Indonesia.

Major Sumatran peoples. Three other major peoples inhabit Sumatra: the Achinese of the island's northern end, the interior Batak somewhat farther south, and the upland Minangkabau of west central Sumatra. None has experienced the extensive Indian cultural influence felt in Java and Bali. Yet, historically, all have adopted foreign religions: the Achinese and Minangkabau have long been Islāmized, while the Batak have been significantly and increasingly influenced by Christian missionaries. All three peoples depend heavily upon rice agriculture (both wet and dry) and share western Indonesian patterns both of language and of material culture.

The matrilineal Minangkabau

The Minangkabau have traditionally occupied handsome, multifamily wooden longhouses (*rumah gadang*). Together with the historically cognate Minangkabau Malays of the Malay Peninsula (Negeri Sembilan state), they probably constitute the world's largest matrilineal society. Each Minangkabau man and woman, even after marriage, maintains permanent membership in his or her maternal, natal longhouse. Hence, Minangkabau fathers often split their residence between their wife's and their own natal longhouses. Their children, growing up in the mother's longhouse, tend to experience their fathers as "visitors," whereas their frequently co-resident uncles (mother's brothers) of the same longhouse often become equally or more familiar. In his wife's longhouse a man holds no property and, at best, only exercises supervisory control over his wife's property affairs. In his own natal longhouse he inherits property through his mother and

exercises influence, control, and even formal leadership both in the property and the ritual affairs of his maternal "corporation." He tends to assume a partial "father role" toward his sister's children, while, with his own children, he partially relinquishes it to his wife's brothers. By Islāmic law he is entitled to four wives simultaneously, but polygyny among the Minangkabau has been relatively rare. So also has been the observance of Islāmic property law, which favours males as heirs over females, for it conflicts sharply with Minangkabau customary laws of inheritance.

Although matrilineal organization is unique among the Minangkabau in Indonesia, it may once have been more widespread. It also occurs in Negeri Sembilan and even among certain Montagnard groups in Vietnam, such as the Mnong. The traditional Minangkabau clans have steadily subdivided into more numerous, locally autonomous subclans and have lost some of their traditional ways. In Negeri Sembilan the introduction of smallholder rubber cultivation in the early 1920s began to divert labour away from the traditional wet-rice cultivation, which had been a major source of economic strength for the matrilineal clan.

The Javanese. Three culturally similar ethnolinguistic groups predominate on Java and the nearby isle of Madura: the Javanese, the Sundanese, and the Madurese. The Javanese, occupying central and eastern Java, are most numerous.

Sedentary farm communities in Java

Most Javanese are lowland sedentary farmers, tilling small irrigated rice fields and household gardens. A large Javanese population also inhabits the mountainous interior, growing cassava as a staple crop. Upland villages consist mostly of dispersed hamlets; in the lowlands relatively nucleated communities predominate, although usually strung along roads or rivers. Rural houses are small, rectangular, and usually built close together on the ground. House frames are of wood, walls of plaited bamboo, roofs of thatch, and floors of tamped earth. Small gardens, rice granaries, and livestock yards (for chickens, goats, and buffalo) frequently augment the rural family homestead. The countryside is interlaced by many hundreds of densely populated, contiguous rural settlements. The average "landed" farmer owns perhaps 1.24 acres (0.5 hectare) of cultivable land; many others own far less, and millions subsist entirely by renting or sharecropping land. Most rural Javanese live at a bare subsistence level.

Javanese society divides into two major strata: a small upper stratum and a large lower stratum of rural villagers and manually employed townspeople. Javanese also recognize a vertical division into two religious groups: the *santri* and the *abangan. Santri* Javanese seriously observe Islāmic principles in their daily life; they conduct the five daily prayers, fast during the *pasa* month (Ramaḍān), refuse to eat pork, attempt to make the Mecca pilgrimage, pay their religious tithes, and obey other Islāmic obligations. *Abangan* Javanese proclaim no such devotion and ignore, or even flout, most of these observances. Most Javanese are *abangan,* but *santri* are found widely throughout Javanese society. In the ancient, princely court areas of central Java and in many towns, there are conspicuous localized *santri* communities of merchants, craftsmen, and entrepreneurs. Scattered *santri* families are widely influential also among the nobility, in urban intellectual circles, and in rural villages.

The Javanese life cycle is strongly influenced by non-Islāmic religious beliefs about cosmic and social order. While one's social position and ultimate fate are foreordained, correct family-focussed ritual helps prevent accidents, illness, and misfortune. The central ritual, or *selamatan,* is basically one of distributing sanctified food; this explicitly generates spiritual awareness and emotional equilibrium within the family, particularly during crises. Major family *selamatans* are performed during pregnancy and at childbirth, circumcision, betrothal, marriage, and death. An elaborate series of protective *selamatans* also follows childbirth until, on the 245th day, the postnatal crisis period ends and the baby ritually "descends to Earth" during a major family *selamatan.* Another *selamatan* series also follows a death; it usually symbolizes the deceased's gradual metamorphosis into an idealized, sacred forebear who will continue, it is believed, supernaturally to assist his living descendants. Participants in such family *selamatans* include one's kinsmen, neighbours, and—to recite the appropriate Qur'ānic verses and prayers—local religious leaders.

Child rearing and marriage ceremonies

Social order and emotional self-control are also dominant values in Javanese child rearing. Whatever his social stratum, a Javanese child begins early to learn the complex language etiquette and other behaviour denoting respect toward his parents, other senior kinsmen, and—more widely—all senior people. Discipline begins at about two years of age and variously assumes the form of scolding, bodily punishment, supernatural punishment (by ghosts, monsters, evil spirits), or invidious comparisons with older siblings or unrelated age peers. The shy and withdrawn personalities of many adult Javanese seem to be partly the result of this conditioning. Among preadolescents, boys tend to expand their outside social contacts more widely than girls; the latter, even when in school, maintain responsibilities at home in cooking, paddy threshing, and care of younger siblings. For boys, circumcision between the ages of 10 and 15 marks the transition to adolescence and, among *abangan,* to the ideally proper "Muslim" status; for girls the transition is observed by a *selamatan* at first menstruation. Many Javanese parents avoid imparting sexual knowledge to their children. Chaperonage of unmarried women is fairly common, especially in upper Javanese society, and premarital pregnancy brings great shame to a girl's family. Abortion is considered sinful.

Marriage celebrations involve the most intricate and important rituals of the Javanese life cycle. Weddings are occasions of great display, rich in Hindu–Buddhist symbolism. While most marriages are probably no longer parentally arranged, parental approval remains an important factor. Young men often send intermediaries to gain the approval of a girl's guardian, who, following Islāmic law, is usually her father or brother. Getting married is a protracted process of betrothal (negotiation, gift exchanges, formal announcement), setting an auspicious wedding date, holding the ceremony, paying the bride price, celebrating the subsequent wedding *selamatan,* and possibly carrying out postwedding familial exchanges. The usual marriage age, especially in rural areas, is 15–18 for girls and 17–20 years for young men, and a newly married couple is usually not expected to be economically or residentially independent. The couple frequently lives for several years with the bride's parents.

During and after middle age, many Javanese become increasingly preoccupied with the relationships between natural and supernatural phenomena. Comprehending them requires sensitivity to *kebatinan,* problems of inner experience, as well as observation and knowledge. These are sought through individual and group meditation (*sudjud*), with the aid of systematic exercises, recitations, prayers, devotional offerings, abstinence, and visits to ancestral graves. The primary devotional symbol tends to be "one god," who may also be identified with a particular angel, ancestor, or spirit. Javanese meditation groups differ in their concepts of life, death, the afterlife, and the spirit world, but they usually claim that their philosophy represents *ilmu kedjawen,* or "Javanese science." While much of the imagery is indigenous, it also conspicuously includes both Hindu–Buddhist and Islāmic symbolism.

The Western tendency to make a sharp dichotomy between the natural and the supernatural is generally alien to most Javanese. Their religious philosophy contemplates, instead, the fundamental continuity of man with nature within the known and sensed universe. It stresses the inexorable dependence of man upon superior forces and teaches the value of constant awareness of—and mystical surrender to—these forces. As such, it evokes the expression of the pervasive Javanese values of harmony, balance, and aesthetic sensitivity.

The Philippines. Some 70 ethnolinguistic groups are found in the Philippine archipelago. The dominant, aggregated society, however, consists of the mainly lowland-dwelling Christians on the few large islands, and the label Filipino usually refers to these people. They include a number of large ethnolinguistic groups, which, while strikingly

similar in overall culture, differ in languages, food habits, art forms, dress, housing, and ritual practices. Roman Catholics constitute most of the national population. The non-Christian minority peoples are either Muslim or pagan. Those professing Islām, derogatorily labelled Moros, constitute a small percentage of the national population.

Family relationships among Filipino Christians

Filipino Christians. Christian Filipino society centres upon the nuclear-family group. The father officially heads the family, but women occupy a high social position and exercise much authority, as suggested by their control of 80 percent of Filipino business firms and their fairly dominant position in the scientific–academic community. Within the nuclear family, respect for elders is inculcated early in life; honorific pronouns and articles are obligatory in speech to parents and elders. Collective responsibility within the family is highly valued; older siblings must care for and, if necessary, make considerable sacrifices for their younger siblings, especially in educational opportunity. Stinginess toward close relatives is a serious breach of fundamental Filipino social values.

Social relationships outside the nuclear family are distinctively patterned. The individual recognizes relatives on both the maternal and paternal sides. By carefully bestowing gifts or services upon individual members of his kindred group, a Tagalog develops enduring ties of reciprocal obligation called *utang na loob,* literally "debt of the inside." Two persons become linked through a long period of alternating indebtedness that leads to a complementary relationship wherein obligations often cease to be calculated. While seldom explicitly discussed, such partnerships can involve deep feelings of mutual gratitude and friendship. Normally, an individual's social network includes many such dyadic ties in different stages of development. Even a child's obligation to care for his parents is thought ultimately to rest upon basic indebtedness to the parents for their gift of life. To renege upon one's *utang na loob* obligations is a grave breach of personal trust; it causes shame (*hiya*) and can even lead to violent revenge by the aggrieved.

Filipino society is stratified according to wealth, occupation, and education. Wealthier upper-class people usually live in small towns or regional capitals, in non-Malay-style houses; they tend to have professional occupations. People of different status levels frequently establish ritual kinship ties with one another through the widespread Spanish Catholic custom of ritual co-parenthood (*compadre*). This can facilitate an even wider extension both of *utang na loob* relationships and of entire patron–client networks, the latter being an essential ingredient of political power. Socially important family alliances may also be consolidated by marriage. While national law and Ilocano custom both prescribe equal property inheritance, Ilocano parents, like other Filipinos, will often bestow all their property on only one heir. While concentrating family resources effectively, this custom also perpetuates parental control over "key" marriages and family linkages among many groups.

Rural settlements among the Christians are made up of Malay-style houses (bamboo, pile-supported, thatch-roofed) with their associated rice fields, gardens, and groves of coconut and bamboo. Domesticated animals are mainly chickens, pigs, and water buffalo. In areas of shifting agriculture, the farmer will often move away seasonally from his home to small guardhouses near the crops in distant fields. Where plantation-scale sugar or copra is grown, as in the Visayan Islands, Filipino worker settlements may be conspicuously large and compact.

Islāmic peoples

Other Philippine societies. The Islāmic peoples of the Philippines fall into several categories. The interior Maranao of Mindanao's Lake Lanao area, while primarily wet-rice farmers, also maintain vigorous cottage industries in mat making, weaving, woodwork, bronzework, and brasswork. Less conspicuous as craftsmen but depending both on fishing and rice farming are the Magindanao, the Philippines' largest group of Islāmic people, who inhabit the Cagayan River Valley inland from Cotabato. The Tau Sug, mainly occupying the northern Sulu Archipelago, depend upon extensive maritime trade, pearl diving, handicrafts, dry- (and some wet-) rice agriculture, and a varied horticulture and arboriculture. The Samal of the southern Sulu islands maintain homes, mosques, and agricultural plots ashore but live much of the time on boats, where they engage in fishing and maritime trade. Only their coastal dwellings and Islāmic community ties separate many of these Samal from the pagan Bajau, impoverished fishermen of the same area who live exclusively aboard small family houseboats. The Yakan, of Mindanao's Zamboanga Peninsula and Basilan Island, are fishermen, craftsmen, and gardeners but only occasionally Islāmic.

Social organization among these groups remains significantly traditional. The larger societies are composed of locally powerful social pyramids usually headed by hereditary aristocratic chiefs, or *datus.* A pyramid includes the *datu* and his close kinsmen (including in-laws) of highest social rank, the usually related nobility of lesser rank, and a large subordinate group of dependent local retainers and commoners linked by ties of kinship, fealty, or debt bondage. A *datu*'s title will often proclaim his allegedly direct descent from the Prophet and symbolize his considerable local authority in both religious and civil matters. In practice he usually shares this power with an Islāmic religious adviser (*kadi*) and a council of ranking noblemen. Both locally and in their external ties to the greater society, such sociopolitical pyramids are sustained by intricate combinations of leadership charisma, kinship solidarity, respect for hereditary rank, family size, alliances by marriage, and control over resources, such as rice land and slave labour. Polygyny, cousin marriage, and hypergamy (female marriage upward) are three enduring customs by which, particularly among the nobility, kinship ties are used to bind groups together and become major channels of alliance between families of equal rank within different local pyramids.

Power of the *datu*

Most small sultanates and principalities among the Maranao and Magindanao have this pyramidal organization. The Maranao are more politically fragmented and more recently Islāmized than the Magindanao. The Tau Sug, ethnically the core population of the traditional sultanate of Sulu, have been Islāmized since the 15th century. Historically vigorous in resisting all foreign political and religious domination (Spanish, U.S., and Christian Filipino), their small *datu*-led principalities maintain a regionally marked tradition of political coordination. Today, the Tau Sug are still widely regarded as conspicuously proud, aggressive, and devotedly Islāmic. For their close neighbours, the less Islāmized Samal, the Tau Sug have constituted an ethnically distinct superior social class. While a Tau Sug man may marry a Samal, rarely if ever does a Tau Sug woman marry "down" with a Samal. The Samal maintains a similar class position toward the Bajau, who, as they have begun to settle ashore and adopt Islām, are increasingly allowing their women to marry "up" among Samal men.

In their social organization, economy, technology, dress, art, and proud religious identity, the Islāmic peoples of the southern Philippines are most immediately similar in culture to the coastal peoples of southern Celebes and of western and northern Borneo, such as the Banjarese, Makasarese, Brunei Malays, and others. The similarities stem largely from their common experience of Islām, their traditional dynastic interrelationships, and their collective antipathy toward Christian colonizers. Today, the Philippines' Islāmic groups constitute an increasingly self-conscious political minority with distinct problems of national assimilation.

The many pagan minority peoples of the Philippines live mostly in the highlands of Luzon, where they are collectively called Igorot ("Mountaineers"), and of Mindanao. They range from the small hunting bands of pygmy Negritos (on Luzon and Palawan) to the physically "Malay" terrace rice farmers (such as the Ifugao) of northern Luzon, the Visayan Islands, and Mindanao.

Modern developments. The traditional customs have changed greatly. Except for Thailand, the nations of the region have all experienced the colonial imposition of western legal and administrative codes. Burma and Malaysia knew the Pax Britannica, and Indonesia experienced prolonged Dutch rule. The Philippines were subjected to

successive Spanish and U.S. administrations. Laos, Kampuchea, and Vietnam underwent French administration.

The persistence of old ways

Localized patterns of customary law remain. Many pagan and Islāmized peoples of the southern Philippines and northern Borneo have intricate conceptions of proper interpersonal behaviour and impose sanctions, especially fines, for violations of standards. These often involve questions of sexual and marital propriety and give rise to constant village-level litigation before local headmen or "native-court" adjudicative bodies. Below the level of litigation, sensitivity to minor local custom, or folkways, remains exceedingly widespread, especially throughout insular Southeast Asia. Few topics are more common in the folklore of the Malay languages area than themes of "other villages having other ways."

Divining is still common. Sarawak peoples such as the Iban (Sea Dayak) predict future events with the aid of a rich lore about the flying formations and habits of particular birds. They and other Borneo peoples also often read the entrails of recently killed animals to determine future events. Trial by ordeal is probably still common among many mainland hill peoples and in some interior regions of the archipelagoes; in the 1960s ordeal by water immersion was in occasional use before certain "native courts" of eastern Sabah (Malaysia). The reading of horoscopes is widespread throughout the region, even among educated urban people. The Burmese and Javanese have rich traditions of horoscopy, drawing judgments of the future from an enormous array of temporal, chromatic, auditory, and physiological cues.

The major religions have been dealt with above. In addition to the creeds introduced from outside, indigenous beliefs in natural and ancestral spirits are exceedingly common. Often they are fused with Buddhist, Islāmic, and Christian elements, but they are found in plain form among the smaller, more isolated, and still essentially pagan peoples. The widespread practice of revering ancestral spirits expresses the generally sacred significance of family continuity. The Vietnamese clan shrine is but one major example. The practice occurs in various forms among the Balinese, Batak, Burmese, Thai, Makasarese, and other peoples.

Ethnic images and regional patterns

Ethnic styles and stereotypes have a subtle but important influence on personal judgments and social relationships in Southeast Asia. Among Filipinos, the Ilocano is stereotyped as industrious, tough, frugal, and without a sense of humour; the Bicolano is supposedly even-tempered and religious. Among Islāmic Indonesians, the Makasarese is thought to be excessively proud, quick to take offense, and implacably vengeful. Such stereotypes are likely to be even cruder among culturally less similar peoples. Among the Burmans (the major ethnic group of Burma), for example, the Shan peoples of northern Burma tend to be regarded as uniformly "untrustworthy." Throughout much of Southeast Asia, immigrant Chinese businessmen are considered unfailingly industrious, penurious, and shrewd to the point of dishonesty. The Chinese often reciprocate by stereotyping others, as in Malaysia, as lazy, untrustworthy, and superstitious.

With all their diversity, Southeast Asia's people have several cultural patterns in common. Women command substantial social and economic authority; only among recently immigrant Arabs and Indians are they distinctly excluded from any social sphere, although on formal occasions there is often a physical separation of the sexes. The prevalent type of family organization is that of the nuclear, monogamous family linked to both maternal and paternal kinsmen; unilineally organized large family groups are found only among the patrilineal Vietnamese, the unilineal peoples of Sumatra and the Malaysian state of Negeri Sembilan, and among several hill groups of the mainland and of eastern Indonesia. Widespread sensitivity to, and preoccupation with, social status is another conspicuous pattern. This is visible in the still-traditional court etiquette of Thailand and central Java, but it is also apparent in the widespread sensitivity to language "levels" and to the implications of making a "proper" marriage. Such sensitivity goes with an equally widespread concern for maintenance of self-esteem, or "face"; there is an elaborate personal etiquette for maintaining outwardly harmonious social relations and thereby avoiding the infliction of shame or indignity upon another person.

Population movements

The growth of population and the expansion of cities are among the most important of recent trends in Southeast Asia. Manila, Ho Chi Minh City (formerly Saigon), Kuala Lumpur, and Bangkok are among the world's fastest growing cities. This urban growth opens up wide opportunities for the intermingling of different groups and cultures.

Some population shifts have resulted from government programs. Vietnam's numerous postwar relocation and reeducation camps and resettlement schemes have forced vast numbers of uprooted Vietnamese civilians and Montagnards to settle among new neighbours and cope with new economic circumstances, often under very adverse conditions. The Indonesian government has resettled substantial numbers of Javanese in new communities in central Sumatra. Similarly, the Philippines government has resettled Christians from the crowded Visayan Islands to the northern and western sectors of Mindanao. Rural-development projects in Malaya have relocated substantial numbers of land-poor Malays to pioneer areas cleared for future rubber plantations.

In the 1960s newly opened rubber and palm-oil plantations in eastern Sabah (Malaysia) drew substantial numbers of Indonesian immigrant labourers from the Makasarese area of southern Celebes and from Indonesian Timor. Timber-cutting operations attracted many Christian Filipino labourers south to interior Mindanao. Among the Lawa hill peoples of northern Thailand, the increased costs of maintaining their trained timbering elephants has forced many to sell their animals and seek wage-labour jobs in the lowlands. Families and whole villages of Meo, Lahu, and Yao hill peoples have moved into northern Thailand from upper Burma and Laos in search of new, high-altitude farming areas for the cultivation of opium poppies. Thousands of Vietnamese families, dislocated since 1965 by the massive destruction of their agricultural resources through saturation bombing and herbicide spraying, have had to leave their home communities in search of new livelihoods.

Rise of national languages

The cities and suburbs of Southeast Asia have become commercial centres for the sale of foreign manufactures; they symbolize a transnational culture of salaried economic prosperity, literacy, white-collar employment, and recreation. As centres of government for new, multi-ethnic nations, one of their most urgent tasks is to develop that basic vehicle of national culture, the national language. Bangkok is energetically fostering early school education in the national language (Thai) and literacy in its Indian-derived writing system. The Indonesian language, developed from the literary Malay language of Sumatra, is universally taught in Indonesian schools and has come to be widely spoken and read (in a Romanized alphabet) by younger Indonesians. Malaysia's new national language, another dialect of literary Malay written in a Romanized alphabet, is being vigorously promoted as a common medium to link the large resident Chinese population with the Malays and other indigenous peoples of Sarawak and Sabah. In Manila a version of Tagalog written in a Roman alphabet has been declared a national language and is gaining acceptance. Burmese and Khmer, both written in Indianized scripts, are routine school subjects in Burma and Kampuchea. Vietnamese, mostly written in the Romanized Quoc-ngu script, is increasingly being taught among southern Vietnam's hill peoples.

New nonlinguistic skills are also spreading. Road building in Thailand, Malaysia, and the Philippines has taught local workers the use of motorized equipment ranging from bulldozers to passenger vehicles. In northern Thailand, Mindanao, and northern Borneo, the chain saw has enormously accelerated local timber-cutting operations. In Borneo this tool, together with growing access to inexpensive outboard motors, is revolutionizing the economy of many communities along the rivers. In Vietnam and Thailand the U.S. military forces trained thousands of Vietnamese and Thai in such skills as helicopter operation, ordnance logistics, aircraft maintenance, and the use of electronic computing and tracking systems.

Other tendencies to cultural "homogenization" include an increase in inter-ethnic marriages. In the cities of Java they even occur on a significant scale between ethnically different Christians and Muslims. Another aspect is the displacement of traditional codes of behaviour among urban immigrants: in Sabah (Malaysia), for example, rural Dusun women coming as nurse trainees to the capital city discover that their "native law and custom" does not apply to social or sexual behaviour in the city.

Movements reacting against cultural uniformity have also developed, usually as efforts to reassert traditional cultural values. Since Indonesia obtained its independence, the Javanese have experienced a great proliferation of meditative sects, or *aliran kebatinan,* each usually led by a local guru, or teacher. Many *aliran* meet regularly to examine the detailed ramifications of "Javanese science" and to repudiate materialistic secular values such as efficiency, individual success, and Western scientific attitudes. Nativistic local leaders have also been conspicuous in Borneo, Sumatra, Burma, the Philippines, and peninsular Malaysia; to rally and hold followers, they often invoke the symbols, episodes, and folk heroes of regional history. In some instances these groups have developed into armed revolutionary movements. (P.R.Go.)

SOUTHWEST ASIA

Southwest Asia—or the so-called Middle East, if Egypt is included—may be defined as the region extending from Egypt to Iran. Countries included in the area are thus Egypt, the Sudan, Saudi Arabia, Yemen (Ṣanʿā'), Yemen (Aden), and Oman; Kuwait and the small Persian Gulf states; and Israel, Jordan, Lebanon, Syria, and Iraq. The total land area is approximately 2,700,000 square miles (7,000,000 square kilometres). The area has, in the 20th century, been given other appellations, including the Levant, the Near East, and the Mashriq (Arabic for "the East"), as well as the Middle East.

From the perspective of its cultural geography, Southwest Asia may be divided into two types of region: the arid, infertile desert areas that are the home of the nomadic Bedouin and the fertile, cultivated river valleys of the settled agriculturalists.

The great plateau is a notable physical feature of the Arabian Peninsula and constitutes most of the desert area of the peninsular landmass. Barren, except for occasional oases and the Najd, a pastoral tableland in the north, the peninsula is fronted to the west by mountains rising in the Hejaz, the holy land of Islām, to some 9,000 feet (3,000 metres) and further south, in the Yemen, to some 14,000 feet. The south central portion of the peninsula, an area of some 40,000 square miles (100,000 square kilometres), descriptively named, is known as ar-Rubʿ al-Khali (the Empty Quarter). Here, the average summer temperatures are in excess of 120° F (49° F).

The Fertile Crescent

The outstanding geographical feature of the remainder of Southwest Asia is the Fertile Crescent, an arc of territory stretching from the Nile Valley of Egypt through present-day Israel, Lebanon, Jordan, and Syria, into Iraq. At each horn of the Fertile Crescent there is a river valley—to the east that of the Tigris and Euphrates rivers, in Iraq, and to the west that of the Nile, in Egypt. These valleys are composed of rich and fertile masses of alluvium deposited year after year on a substratum of sand and rock. In Egypt this deposit is almost 40 feet deep. As they are annually replenished, these valleys are continually refertilized. They also provide irrigation and drinking water.

Ethnic groups. Southwest Asia has the longest cultural history of any region in the world and was in fact the birthplace of human civilization. Thee monotheistic religions—Judaism, Christianity, and Islām—originated there. As a land bridge connecting Asia, Africa, and Europe, it has been traversed by numerous peoples, many of whom left small groups in the region. Its cultural evolution has been such that, until recently, minority groups were permitted to retain separate and distinct entities, so that the most conspicuous fact about the Middle East has been its demographic heterogeneity; its population is a mosaic of peoples.

Among the earliest inhabitants of the region were the Sumerians, believed to have been of an Armenoid physical type—roundheaded, of moderate height, and of heavy build. They spoke a language with certain agglutinative features suggestive of the Mongoloid family of languages. The ancient Egyptians were of the Mediterranean physical type—longheaded, dark-haired, relatively slender, and of moderate stature, speaking a separate language classified as Hamitic.

Additional early peoples in the area were the Akkadian, Babylonian, and Assyrian invaders and conquerors of Mesopotamia, the Amorites of northern Syria, the Aramaeans of inner Syria, the Canaanites of the Levant coast, and the Hebrews of the hill country. All of these peoples are generally classified as Semites—not because they possessed any unique physiological feature but because they all spoke languages assigned to the North Semitic family and because they are generally believed to have originated somewhere in the central Arabian Peninsula. Arabic, the primary contemporary South Semitic language, was apparently originally spoken by a small group of traders, townsfolk, and desert nomads in the district of Mecca and Medina. Arabic was the language of Muḥammad and his early followers, and, with the rise and expansion of Islām in the 7th century, it quickly replaced most other languages of the Mashriq. Within the region, Egyptian, Palestinian, Syrian, Iraqi, and Yemeni dialects of Arabic are spoken today. Some of these differ only in pronunciation, while in other instances the colloquial forms may be quite wide apart. Other languages spoken in the region are Hebrew, which is one of the official languages of Israel (the other is Arabic); Aramaic, which is reputed to be still spoken in a few villages of Syria; Kurdish, an Indo-European language spoken by the approximately 10,000,000 Kurds resident chiefly in Iraq, Turkey, Iran, and Syria; and Fārsī, spoken by the majority of Iranians.

Linguistic basis of the Semitic ethnic classification

Settlement patterns and economic organization. *The fellahin ("villagers").* Agriculture has long been and still continues to be the predominant way of life of the majority of the peoples of the Middle East. Spread along the Fertile Crescent and in the isolated oases of the deserts, the overwhelming majority of the people were—and still are—peasants. Despite widespread urbanization, more than two-thirds of the people may still be classified as fellahin.

Family solidarity and the need for security have always precluded a pattern of isolated farmsteads. Instead, the peasants gather together in villages, ranging from modern and well-off communities in Lebanon (particularly among the Christians) to the miserable mud and kerosine-can huts of seminomadic tribesmen. Despite such disparities, however, a broad cultural pattern can be discerned, especially in the Arabic-speaking regions.

Landownership is complicated by the fact that landed property, or the right to work other people's landed property, is divided among the children, with boys sharing equally but with a girl's share equalling only half that of a boy. Complex fragmentation of agricultural land results, with the dispersed small plots, sometimes termed "dwarf holdings," rarely economically feasible. High-interest loans are often not met, and as a result the accumulation of large tracts of land in the hands of a few wealthy landowners is quite common; many debt-ridden peasants are consequently forced into sharecropping. In virtually all of the newly independent nations of the Middle East, land reform is one of the basic tenets of revolutionary programs. Much, however, still remains to be accomplished.

The traditional village

Throughout the region village layout is strikingly similar. At the centre is the mosque, or church, bordered by a few small shops of the grocer, blacksmith, and cobbler. Some five to 10 twisted alleys, just wide enough for a donkey with its side baskets, wind between the walls of low, flat-roofed houses and then narrow into even smaller lanes that generally end where the fields begin. The village square functions as a marketplace for itinerant peddlers and is the scene of village ceremonial events.

The homes, whether of stone blocks or sunbaked bricks, consist of a few rooms and a courtyard. When a son marries, a new room is added along the side of the house, on the roof, or in the courtyard. Stables are uncommon, and the fellahin share with their animals the same dirt-

and dung-littered courtyard and, in winter, the same room for sleeping.

Furniture among the peasants is limited and strictly utilitarian. Since squatting on the floor is the normal position, whether doing the housework or eating with the fingers or with a piece of bread dipped into a common bowl, there is no need for tables and chairs or forks, knives, and spoons. A chest, a pile of bedding stored away during the day in a recess in the wall, a cradle, a few straw mats, a kerosine lamp, and perhaps one or two cheap carpets constitute the essential furniture. Kitchen needs are met by a few clay jars for keeping the drinking water, a large grain bin coated with clay and sealed at the top but open at the bottom for access to the daily need, a copper kettle, a few handwoven baskets, some locally made earthen jars, and a variety of imported bowls and basins. A few coffee cups on a tray for occasional visitors, a few photographs of the sons (daughters are rarely photographed, and their pictures are certainly not on view), some religious prints or calligraphic verses of the Qur'ān, and a newspaper photograph of the local national leader complete the inventory of the typical village home.

Water is generally a scarce commodity. If the peasants are fortunate, they may have a well in the courtyard. Generally, however, water is obtained from common village wells, springs, or ponds. When these dry up during the long arid summer months, animals and humans share the same distant, often polluted, ponds or streams. Piped water to the courtyards or to the village centre is not uncommon among wealthy villagers or in areas in which the government has embarked on special rural development programs. In some regions of Iraq and Egypt and along the rivers of the Levant, although water may be readily available, it often is a source of malaria and other diseases. Flush toilets are very rare, as are outhouses. Urine is generally disposed of in the courtyards, along the paths, or in the fields. Fecal matter is spread in the fields.

Animal dung, in treeless regions, is the prime source of fuel. Women and children carefully gather the dung, shape it, dry it in the sun, and store it on the roof or in the courtyard. The family oven, in which bread is baked, is generally in the courtyard and is a dome-shaped mud affair with a low opening.

The diet is simple and generally monotonous. Its mainstays consist of unleavened bread, accompanied by rice and a few vegetables, usually onions and garlic, and, depending on the region, olives or dates. In season, small amounts of fresh fruit and green vegetables may be added. Tea and coffee are luxury items paid for out of a limited budget. Meat and fat are eaten, by most, only at special ceremonies such as a wedding, birth of a son, or great holidays or in honour of a distinguished visitor.

Health and education among the fellahin

Standards of health and education well demonstrate the poverty of the peasants. Malnutrition is chronic, and infectious diseases are endemic. It is estimated that perhaps nine-tenths of the fellahin suffer from a variety of dysfunctional or debilitating diseases such as trachoma, typhoid, dysentery, intestinal worms, and tuberculosis. Western-type medical aid is still not widely available among peasants, and their main recourse continues to be the traditional village practitioners. Schooling, despite the fact that most countries of the Middle East have enacted laws requiring compulsory education, is uneven and sporadic. Illiteracy among rural adults, particularly women, is still the rule.

The way of life for the early Zionist farmers working the marginal lands of Palestine often was as difficult as that of their fellow Arabs. It was the attempt to break out of that pattern that led to the development among the Jews of collective forms of agriculture—variants of the kibbutz and the moshav—designed to maximize their financial and labour input, to raise their agricultural returns, and to improve their collective standard of living.

The Bedouin. The Bedouin, as one observer has put it, are more glamorous than numerous. They have rarely constituted more than 15 percent of the total population of the Middle East, and in the late 20th century their numbers were rapidly decreasing, even in the Arabian Peninsula, as they voluntarily migrated to the towns to work for the oil industry or to settle on government-sponsored tracts of land.

The homeland of the classical, traditional Bedouin is an area of the northern Arabian Desert, stretching into Iraq, Syria, and Jordan. The Bedouin are nomads in varying degrees, but the true Bedouin are those who possess only camels and who spend their summer months camped around wells or streams and the rest of the year ranging the desert. In kinship they trace their origin back either to Qaḥṭān, an ancient patriarch who lived before Abraham, or to Ishmael, son of Abraham and Hagar. Collectively they constitute the *aṣīlīn,* a closed circle of numerous tribes or tribal confederations.

The material culture of the Bedouin is limited. The chief possession is the home—a long, low, black tent of woven goat hair. Men and women have separate divisions within the tent. The male side, away from the wind, is left open; it has a carpet, spread before a portable stove, or coffee hearth, with a mortar for grinding the coffee, a coffeepot, and cups. This is the social centre of the household, the meeting place for guests, and the site for the transaction of all tribal affairs.

Clothing is simple: a long robe of thick material, a large headcloth wound around the head and held in place by a black goat-hair cord and rawhide, and heelless sandals.

Water is generally too scarce to be used for washing, and sand or animal urine is substituted for use in daily ablutions. The diet is limited, consisting of a variety of milk products such as curds, buttermilk, and cheese, dried fruit, particularly dates, and, when obtainable from the fellahin, grains such as wheat, barley, or rice. Meat, as among the peasants, is a luxury eaten only when an animal has died a natural death or for a special ceremony. The meals are served first to the older men of the tent, then to the younger men and boys, and finally to the women and the girls. The sexes do not intermingle during mealtime. The inadequate diet and low standard of nutrition result in a people who are small, even stunted, and slightly built. By the age of 40, particularly among the women, old age has begun.

Bedouin raiding

Raiding was the traditional means of supplementing the deficiencies of life in the arid zone. The Bedouin took by force from the peasants what they lacked in foodstuffs, material goods, and even women and children. Successful leadership in raids could be a most effective means of developing reputation and power, a practice that to this day has not been completely curtailed.

Social organization. In certain respects the fellahin and the Bedouin share a similar social structure, and thus the pattern traditionally common to both can be broadly sketched. The model described is that of the classical, idealized, Arab way of life.

The family. The family is the most fundamental and important feature of Arab social structure. The family is extended—that is, it is headed by an elderly man and consists of his wife, or wives, his married sons and their wives and children, his unmarried sons, and his unmarried daughters. Daughters, when they marry, leave their own extended families and become incorporated into the extended families of their husbands, even though their moral conduct continues to be the responsibility of the original family.

The extended family may total a dozen or more persons, all of whom live in one house or in a number of adjoining houses or, as among the Bedouin, in a number of tents pitched next to each other. The extended family functions as one entity in economic, political, and military ventures.

The family is patrilineal—*i.e.,* an individual belongs only to the family of his father—and patrilocal (young couples when they marry take up residence in or near the house of the bridegroom's father). It is also patriarchal: the father is the head of his family, and the elderly male who is head of the entire extended family is the absolute ruler over the entire group, traditionally. Even to this day, in certain respects, he has jurisdiction over life and death.

Pride in descent forms one of the most significant traits in the ethos of the peoples of the Middle East. Emphasis on noble ancestry and lineage is a matter of great importance among the Bedouin and to a lesser extent among the fellahin. Tribal and village genealogists trace an individ-

ual back from his individual extended family to his sub-*ḥamūlah* (a cluster of extended families) to his *ḥamūlah* (a large group of families tied together by an actual or assumed genetic relationship) and to his subtribe (*'ashīrah*) and tribe (*qabīlah*). Beyond his tribal affiliation, a man's lineage will be traced to his supposed progenitor dating back to early biblical sources. This tribal pedigree, even among the villagers, can play a fundamental role in determining and justifying positions of traditional authority and political power.

Marriage and divorce. There is a strong tradition of endogamous marriage (that is, of marriage within a very small social circle), ideally with the father's brother's daughter or, failing that, within the same village or tribe or having the same social status. A man may be married to more than one wife simultaneously (polygyny).

Prevalence of polygyny

The prevalence of polygyny among the Arabs has been greatly exaggerated by Western commentators, and the practice has always been the exception rather than the rule, especially in modern times. The simple biological problem of acquiring a surplus of young females plus the economic cost of paying their bride-prices and then adequately supporting them and their offspring all have prevented any more than 4 to 5 percent of the married men from having more than one spouse.

Traditionally marriages are arranged and consummated when the women are still in their teens. This is considered highly proper and beneficial. An old Arab saying holds that there are only three things in life a man must do quickly: bury the dead, serve a guest, and marry off a marriageable daughter.

Great prestige is attached to the male's procreative ability and to the regular delivery of live, preferably male, children. Status is achieved through the production of large families; a childless couple is regarded with contempt. Only the extended family with many children, preferably boys, can be a strong family, providing economic and political security. The injunction to "be fruitful and multiply" thus provides a constant goal.

Term, or temporary, marriage, usually referred to as *muṭ'ah,* dates back to pre-Islāmic days and still survives in certain parts of the Middle East. Term marriages were contracts made with women by soldiers, traders, and travellers under which the couple were legally married for the day, the length of the caravan journey, or for another defined time period. At the stated end of the period the contract was no longer binding. Children born of *muṭ'ah* marriages held all the rights of the offspring of ordinary marriages, but the term wife could not inherit from her husband nor he from her.

The announcement of the birth of a child to the father is based upon long-standing traditions. If the infant is a boy, the father will be told *bishārah,* meaning "good tidings" or "reward." The father will ordinarily give a modest gift to the individual who first brings him this news. Among those who can afford it, a sacrifice of a sheep or a feast is also common. If the infant is a girl, no reward will be given for the announcement, neither will there be a celebration.

Traditional divorce in Arab Muslim society is extremely simple. The male is the sole initiator of such an action. The wife can neither oppose a divorce nor initiate one on her own behalf. The husband pronounces the traditional formula, "I divorce thee," in the presence of two witnesses, and the divorce is effected. The wife must return to her father's (or brother's) family and can claim only that portion of the bride-price that was stipulated in the original marriage contract to be paid in the event of such an occurrence. If a wife should leave her husband and he later agrees to a divorce, she forfeits any part of the bride-price. After the divorce a man may marry immediately, but the woman must wait three months to make sure that she is not pregnant. If she is pregnant, she cannot remarry until she has given birth to the child and reared it, during which time the father (her former husband) must support her. All children belong to the father and, in the event of a divorce, must be delivered up to him.

Among the Arab Muslims no stigma is attached to divorce, and divorced women as a rule remarry as soon as they are permitted to do so.

Socialization. Shortly after birth, the infant will be rubbed with salt and oil, not only to cleanse him but also to enable him to grow up to be modest and courteous. The infant will then be wrapped in swaddling clothes for a time period ranging from 40 days to six months.

Nursing may last for 18 months to three years. A mother is traditionally prohibited from weaning her child before two years. The extended nursing period postpones another pregnancy (suckling periods are generally connected with an abstinence from intercourse), and it is believed to make the child strong.

To mothers it is said: "pampering a girl disgraces thee; pampering a boy makes thee rich." The boy will therefore be nursed longer than the girl. As soon as the child shows the slightest signs of restlessness, he will be breast fed. As a consequence, the female is seen as sympathetic and the woman's breast as a symbol of compassion.

If for some reason, such as illness, a child is nursed by a woman other than its mother, certain protocol must be observed. A woman may not give her milk to another child or have another woman give her child milk without her husband's permission; for the child belongs to the husband's patrilineage, and that important decision rests with him. Furthermore, a boy and a girl nursed by the same woman are considered to be brother and sister and can never marry. Nursing relationships can also be a method of adoption (especially of an orphan): if a woman wishes to adopt a strange child or even an adult, she does so by offering her breast.

The religious rite of circumcision

One of the most important events in a Muslim and Jewish boy's life, not only for himself but also for his parents, is circumcision. The rite of circumcision is a religious duty, and no male can enter heaven uncircumcised. The age at which circumcision is carried out varies: it may be done shortly after birth or in childhood, but it must be done before marriage. Fathers will ordinarily have their sons circumcised soon after birth, not only because it is less painful then but also because of fear that the boy might die before the father has fulfilled the commandment of circumcising his son.

Among Muslims, the rite of circumcision proceeds in a program similar to that of a wedding. It is preceded by an evening of joy in village festivities, henna (a dye) is put on by the woman, and a new outfit is provided for the child. Festival garments decorated with flowers and leaves are worn, and, in similar fashion to a bride, the boy is led in procession around the village in his new outfit. After the ceremony there is a feast at which presents are given. Several boys may be circumcised at once, or the circumcision may be combined with a wedding to save expenses. There is a further connection between circumcision and marriage, for, as it is the duty of the father to marry his children before his death, he attempts to find a suitable mate for them as soon as possible. A boy thus often acquires his bride at his circumcision ceremony, although he will not marry her until sometime after puberty.

The early socialization of a boy and a girl into the traditional family of the Middle East differs profoundly. The growing boy is trained to become an obedient member of his family, able to subordinate his wishes to those of his father and elder brothers. The fact is impressed upon him that the interests of his family always come first and that he must govern his actions to enhance the collective strength of his family. The girl, on the contrary, is not only weaned earlier than the boy but, by the age of five or six, is already being consciously prepared for moving out of the home of her parents and into the home of her mother-in-law. There, she will fill a subordinate and even a servant role—a role that will be improved only as she bears sons.

Religion and health. A discussion of the predominant religion of the area, Islām, can be found in the article ISLĀM. But some understanding of the function of religion in the traditional Middle East can be grasped from an analysis of its role in the peoples' approach to health, disease, and death.

Philosophy of illness. The essential philosophy underlying the traditional system of medicine in the region is that illnesses and injuries are subjective affairs arising from

one's own acts or omissions or caused by someone or something that is possessed with power. Illnesses or injuries do not just randomly occur—they befall a certain victim, at a given time and in a definite manner, because of specific causal actions.

Evil spirits and the evil eye

Two essential elements of this philosophy are belief in animism and animatism, or, more specifically, the belief in the existence of evil spirits (animism) and of the "evil eye" (animatism), or the power of certain persons or objects to affect and influence the human body—and nature as well, in certain circumstances.

Evil spirits abound in the environment, ready to pounce on the unsuspecting victim. Strong, healthy, mature individuals are the least susceptible to such attacks; the most susceptible are infants and children, the weak, the ill, the aged, and normally healthy individuals in certain circumstances (women during menstruation, pregnancy, or while giving birth, for example).

The presence of strong, healthy, mature individuals near the susceptible person is a strong deterrent to evil spirits. As one cannot rely on such persons to be constantly on duty, however, various inanimate objects with strong power to repel the evil spirits are called into play. Common objects of this nature are the Hand of Fāṭimah (beloved daughter of Muḥammad), which may have inscribed on it holy words in Arabic or Hebrew and which is generally worn around the neck (Cochin Jews may put it around the abdomen); the shield of David (a six-pointed star); and blue beads, pieces of jewelry, or bits of cloth that are worn around the neck or attached to the clothing (blue is particularly repugnant to the evil spirits and the evil eye). Sometimes a concoction of evil-smelling herbs will be placed in a bag and worn close to the body, or various religious phrases will be written on paper and sewed into the clothing or put into a bag and worn on the body.

The Bible also possesses the power to repel evil spirits, and thus some Jewish mothers place a copy of it beneath the pillow. Another practice, but less common, is the preservation of the foreskin that is cut off during the *ber-it mila* (the ceremony of circumcision conducted on every Jewish male child when he is eight days old), by drying the piece of skin and powdering it. It is then sewn into a piece of cloth and kept under the pillow or among the blankets of the child's bed.

Evil spirits fear the name of Allāh, which strikes terror into their hearts and weakens them and forces them to withdraw or repels them completely. Consequently, his name is uttered frequently while a person is engaged in the everyday routine of life. Otherwise healthy individuals must, under certain circumstances, be particularly careful to invoke Allāh's name. When, for example, a Muslim couple is about to engage in sexual intercourse, the male must first say a prayer: "I seek refuge in Allāh, from the accursed Satan, in the name of Allāh, the Beneficent, the Merciful." If this prayer is not spoken, the evil spirit will enter the woman, and the child she conceives will be evil, bad, or a devil, or the woman herself might fall ill. A prayer to Allāh also ensures conception—the mere physical act of intercourse is no guarantee.

Vulnerability of women. From the moment of conception until the last birth pang, the pregnant woman is especially sensitive to evil spirits. Each of her actions is carefully watched by them, and, should she commit a transgression or fail to constantly invoke the power of Allāh, retribution will be certain to follow. The afterbirth provides powerful protection for the newborn child and so must be saved. It may be left attached to the child for a period of some hours or overnight, and it then must be preserved in or near the house.

Restrictions on menstruating women

Women during menstruation are thought to be very dangerous. They are not only considered impure and unclean but also, if not actually possessed by a spirit, likely to be transmitters of the actions of evil spirits. They must therefore be separated from others, particularly from the ill and women in labour. Women during menstruation sometimes must leave the home and live in a menstruation hut or tent for the entire period, returning to their homes only after they have been purified. When a woman is permitted to remain in the home, she is subject to numerous restrictions: She must sleep on the floor or on a low bed, must have no sexual relations with her husband, must not even touch him or his bed, and should not prepare any meals or enter a home in which there is an ill person or a woman in labour. Such restrictions are only practicable within the extended family, and disintegration of the extended family leads to forced abandonment of many such practices. The beliefs themselves, however, may persist, as may anxieties when the taboos are broken.

Safeguards against the evil eye. The prevention of illness to the inner body by the evil eye—as distinct from the prevention of illnesses caused by evil spirits—is based on the principle of misleading, deceiving, and deluding the evil eye. The evil eye is particularly feared, and more than half of all deaths are attributed to it. It is attracted to the healthy, the beautiful, the happy, and to children.

In the Middle East, possessors of the evil eye are often women. Psychologists have argued that the evil eye is in reality an envious eye, and the entire corpus of preventive measures seems to be based upon the principle of not attracting its attention (or envy). The youngest are a particular attraction to the evil eye. Thus children, esteemed the greatest blessings, are kept dirty, ragged, and unkempt, particularly when out in public. The child may be called "Oh, dirty one" or "Oh, evil one" and similar names, in order to disguise the true feelings of the parent. The child may be given a false name, and its true name kept a secret, in order that the real name may not be overheard and utilized for negative purposes. The child will never be praised in public or boasted about; on the contrary, it will constantly be decried and complained about. A male child may be dressed as a girl and referred to in the feminine, since females have less prestige. Such practices against the evil eye are especially likely to be followed if there have been previous infant deaths in the family or if there is only one child.

To arouse disgust in the eye of the beholder is far healthier than to arouse admiration; and praise when given must be denied or deprecated. Inquiries about personal or family health, business, or status should be responded to with shaking heads and gloomy predictions. Boasting is considered the fool's way of courting disaster, as is the disclosure of one's future plans. It is possible, however, to accept praise or note good looks, good health, or good fortune if one is careful to constantly invoke the name of Allāh and to deny the force of the evil eye.

Particularly valuable as a defense against the evil eye are amulets. Blue beads are the most common type, and they may be worn on the person or placed in the house or on a dog, horse, cart, or automobile.

Curative practices

If, despite such precautions, evil spirits do gain access to the body and illness sets in, medicine is brought into play. Curative practices are clearly recognized, however, as being less successful ultimately than preventive measures, and their purpose is partly to provoke emotional comfort and security to the patient and his family.

The local practitioner gives the family his undivided attention, identifies and names the disease, makes a positive prognosis, and initiates certain measures to evict the evil spirits or draw away the evil eye. These include smoking, drinking, chanting, praying, burning, bloodletting, emetics, purgatives, and massages. A burning blue rag may be snuffed and the smoke inhaled to weaken or frighten out the evil spirits, especially during childbirth. Charms and holy phrases written on paper may be soaked in a liquid and then drunk in order to internalize the holy power. The spittle of a holy man may be applied to the disturbed organ of the body. The patient's name may be changed so that the evil spirit may somehow be misled and lose the patient or never find him.

Drastic, painful measures may be taken to force out the spirit. A red-hot nail may be pressed against the abdomen of an infant a number of times to force out the evil causing dysentery; it may be pressed against other parts of the skin to evict the evil spirit causing smallpox or rheumatism, or it may be pressed against a "boil" under the tongue to enable the baby to take the breast. The entire family may be required to chant special prayers, songs, or phrases or to fast or suffer other discomforts. Parents may have to

abstain from sexual relations, and members of the family may be required to travel on a pilgrimage. There may be bargaining on the part of the family, and precious animate or inanimate objects may be sacrificed to appease the evil spirit. The patient, recipient of this rich fund of strength, is as a result emotionally able to endure the physical discomfort during the prescribed course of curative treatment and is mentally prepared for possible death should the treatment not succeed.

If the patient should die it is because he or his family, consciously or unconsciously, committed offenses and attracted the evil eye or permitted evil spirits to enter the body to the extent that no power was able to avert the evil and save the patient.

It is clear that both patient and practitioner operate within a cultural framework of knowledge, beliefs, and values that explain their respective actions. The patient and his family search their thoughts and actions to ascertain how the misfortune could have occurred or by whom it could have been inflicted. The practitioner, on his part, listens to the family's statements and the patient's complaint and then formulates his diagnosis and treatment. The success in such treatment in a certain number of cases inspires further faith in the system. There are few cynics among the patients and few charlatans among the practitioners.

Types of medical practitioner

Within this medical system may be distinguished three or four types of local practitioners specializing in particular areas and methods of treatment. Their sex, role, or status may vary, or they may specialize in cures for external complaints such as sores and wounds; or they may practice preventive and curative medicine for the internal body. The latter is generally a male of senior years and of religious–medical standing. To fulfill his role he must be well versed in the concepts of animism and animatism. Such knowledge alone, however, is not sufficient; he must also have a personality that will inspire confidence and elicit information from the patient and his family. In addition, he must be aware of the significance of symptoms and complaints, certain of which may or may not be expressed. He must possess to a high degree the quality of sensitivity and intuitiveness, for many of his diagnoses will be based upon implicit understanding and tacit agreement. He must have the ability to quickly analyze and evaluate the relations between the patient, his family, and his community.

Modern developments. A process of Westernization, modernization, and development has increasingly come to dominate Southwest Asia. The evolution of the traditional folk culture of the fellahin and the Bedouin is being radically altered, and even rural peasants want to live the supposed good life that is made possible by Western technology. The town in the region is the focal centre of this Westernization process, and from there it is dispersed throughout the countryside and into the desert. It is useful, therefore, to examine the traditional town and the ways in which it is changing.

Classical urban pattern. Urban life began in this area of the world, and it is not uncommon to find towns still extant that have been occupied continuously or intermittently over the past 4,000 years. While the Bedouin and the fellahin have long remained rather constant in their culture, the towns have constantly reflected the effects of political changes, military invasions, and population movements. Thus, whereas the nomads and villagers were comparatively homogeneous in both population and occupational structure, the towns contained separate quarters (*harat*) for various ethnic and religious populations and also contained a range of occupations and social classes.

The tradi-ional Arab town

The typical Arab town of the Middle Ages consisted of a mosque, a palace, a bathhouse, a school, a *khān* (hostelry for foreign merchants), a hospital, and a *maydān* (an open field for the horse and cattle market). Two main thoroughfares ran through the town at right angles to each other, leading from the four gates of the thick and heavily fortified walls. From the centre a network of narrow streets and alleys radiated into the residential quarters. Each of these quarters was also walled, frequently with its own bathhouse and school, as well as a mosque, church, or synagogue. The cemeteries and the *maydān* were outside the town walls.

Such was the typical town during the classical Arab period. With the conquests of the Ottoman Turks in the 16th century came urban poverty, exodus, and decay. Only within the 20th century has there been a redevelopment of the urban centres.

20th-century urbanization. Rapid, unplanned, and uncontrolled urbanization is a marked feature of the contemporary Middle East. The 3 percent annual rate of population growth (the population of the region is apparently growing faster than any other major region of the world, except for Latin America) is causing great pressure on available agricultural land and is pushing the excess population into the urban centres. The growing difficulty in finding additional land for cultivation and the chronic weaknesses in the implementation of agricultural reforms are aggravating the already serious situation of large numbers of a redundant, underemployed rural labour force.

Other factors are also at work in the acceleration of the urbanization process: improved roads and transportation have made the towns increasingly accessible; increased communications, particularly through radio and television, have spread the attraction of the cities as centres of education, health, employment, recreation, and a totally different way of life; and the discovery and exploitation of oil have brought thousands of workers into the cities in search of employment. The flow of capital from oil revenues has revolutionized the cultures of some of the countries of the area, particularly Saudi Arabia and Kuwait, and it has had a direct impact on the economy of cities in nearby countries as well.

Israel holds third place in the world in proportion of urban dwellers to total population. In Kuwait, some half of the total population lives in localities of 100,000 and more inhabitants, and, in Lebanon and Syria, the proportion is one-third. This large-scale urbanization has been primarily a 20th-century movement, particularly since World War II.

Urbanization has resulted in a series of physical changes and problems. The uncontrolled growth of what were for the most part medieval towns has led to their mushrooming over surrounding areas at a rapacious rate. Most cities have doubled in size within the past few decades, and some—Beirut, for example—have incorporated surrounding towns. Greater Baghdad and Kuwait have spilled over their city walls. In Israel, almost the entire coastal plains from Haifa in the north to below Tel Aviv-Yafo in the south is gradually evolving into one continuous metropolitan area. The megalopolis, as well as the metropolis, is becoming a significant term in the Middle East.

Problems accompanying urbanization

As in many other regions of the world, acute urban problems have accompanied this movement. Traffic in urban land, with building for quick, speculative profit, has become a major economic activity and has often had the result of greatly modifying traditional values and behaviour. Slums and shantytowns, a hallmark of metropolitan growth in underdeveloped countries, are extensive. In the Middle East, rural migrants build simple one-room shacks. Lacking sanitary amenities, these are crowded next to each other and quickly deteriorate into unhealthy slums. Sections of greater Baghdad, for example, are ringed by slum dwellings mainly of the *ṣarīfah* type—a one-room house constructed mainly of reed matting. It is estimated that there are more than 44,000 *ṣarīfah*s in greater Baghdad—nearly 45 percent of the total number of houses.

The emergence of a large and rapidly growing unskilled (and therefore underemployed or unemployed), illiterate, and unhealthy peasant population in the towns may create a new version of the lumpenproletariat. With little to lose and much to gain, these people may profoundly and radically alter traditional religious and familial values and behaviour. Juvenile delinquency, petty thievery, prostitution, and mob violence frequently accompany such changes. Violence, of course, may be aggravated by political figures. Acute xenophobia, directed particularly at traditional "imperialist" powers, and the brutal elimination of incumbent leaders are two of the more obvious by-products. During the July 1958 revolution in Iraq, for example, street mobs ran amok in Baghdad, pillaging and burning at will. Scores were slaughtered, including King Faysal II and Prime Minister Nuri as-Said.

In certain respects the general life of the majority of the people has been materially improved. The traditional scourges of the region—disease, poverty, and ignorance—are slowly weakening their grip. Clothing, housing, household effects, kitchen utensils, communication equipment such as radio and television, and transportation facilities are becoming increasingly available from the cities of the coast to the towns and villages of the interior and even to the peoples of the desert.

New social classes have developed, and the traditional cleavage of a small wealthy class supported by a mass of poverty-stricken peasants and nomads has been somewhat modified. The upper classes are frequently educated in the West, and their financial resources, their educational interests, and their way of life all orient them away from their own country's traditions.

The new middle class

A new and increasingly numerous middle class has developed. The traditional class of craftsmen, merchants, artisans, and professionals has been augmented by a rapidly growing white-collar population of educated persons who go into law, politics, journalism, clerical and higher administration, and religious and teaching positions. This class frequently manifests an aversion to rural life and earning a living by one's hands.

As a result, the emerging middle class of the Middle East, it has been argued, is lopsided when judged by Western standards. It has a profusion of white-collar workers and "intellectuals," many of whom are chronically unemployed or underemployed and underpaid. Conversely, this class lacks a sufficient number of doctors, engineers, architects, chemists, and technicians.

Disenchantment with many of their own cultural values and with many aspects of their way of life and disillusionment with much of what the West has to offer have resulted in pronounced dissatisfactions and frustrations. To the extent that such general discontent prevails, one might predict a continuation of the social and political instability characteristic of much of the area for the greater part of the 20th century. (An.S.)

The economy

RESOURCES

Continental immensity and geological diversity explain the mineral wealth of Asia, which includes reserves of almost every important mineral. Abundant reserves of coal, oil, natural gas, and uranium, iron, bauxite, and other ores are either being exploited or await development; much wealth also remains to be surveyed. Difficulty of access, however, sometimes constitutes a barrier to exploitation.

Mineral resources. *Coal.* Asia has enormous reserves of coal, amounting to more than half of the world's total, but they are unevenly distributed. The largest reserves are found in China and especially in the Asian part of the Soviet Union; Taiwan, Japan, North Korea, South Korea, Vietnam, Indonesia, and India have smaller but economically important reserves. Burma, Thailand, Malaysia, and the Philippines have only insignificant amounts of poor coal. In Southwest Asia both Turkey and Afghanistan have small economic reserves.

Chinese coal reserves are chiefly high-grade coals. Every province has at least one coalfield, but the largest reserves are in Shansi and Shensi in the north. Szechwan, Shantung, and the Northeast (Fu-shun, in Liaoning Province) are old coal-producing regions with good reserves, and a coal-mining region with large reserves has been developed in central Anhwei, north of the Yangtze River. Mines in Ningsia and Kansu supply northern industrial plants, but their reserves are not clearly known. The long-known reserves in western Hopeh are being exploited.

Coal reserves in Siberia

In the Soviet Union are found the world's largest proven coal reserves, but the extent and quality of Siberian deposits are not fully known. There are more than 200 fields that are worked, but as new economic developments occur, the regional mining picture shifts somewhat according to the quality of the coal and the cost of transport. The brown coals of the Moscow Basin and the higher quality coals of the Donets Basin of the eastern Ukraine continue to be important in the west, and the Vorkuta field west of the Urals and south of the Arctic coast helps supply the western zone. The Ural Mountains are not rich in coal, but there are some small fields of lower grade coals. The Karaganda fields in Kazakhstan in the southeast have huge deposits, but the coal is high in ash, and mining there is not expanding since newer sources of better coals exist in Western Siberia. The Ekibastuz field, north of the main Karaganda fields, is a producer of high-quality coal.

Most of the known coal supplies of the Soviet Union lie in Siberia. The Kuznetsk Basin in Southwestern Siberia has become a giant producer. The Minusinsk Basin in the central region of Western Siberia, the Kansk region to the north along the Trans-Siberian Railway, the Cheremkhovo area west of Lake Baikal, and the Bureya Basin in the southeast are the major areas of production. Many smaller deposits are worked to supply local regions, such as the small and scattered fields north of Vladivostok, on Sakhalin Island, or in the hilly valleys of southeasternmost Turkistan.

Petroleum and natural gas. At least two-thirds of the world's known oil and gas reserves are found in Asia; the proportion may prove higher with the continued exploration of Siberia and the seas of southeastern Asia. Many of the island chains bordering eastern Asia have geological formations favouring petroleum accumulation, and oil fields are in production in Sumatra, Java, and Borneo. Western Asia has the largest known oil reserves, located in Iran, Iraq, and the Persian Gulf area of Arabia. Other regions in Southwest Asia have only small amounts of oil, and known petroleum reserves on the Indian subcontinent are small.

Malaysia is the only important oil-producing area on the mainland of Southeast Asia, although offshore waters may yield production after further exploration. The Philippines are negligible as a producing region, and the petroleum production of Japan is also small. North and South Korea appear to have virtually no prospects of production, but China has a number of oil-producing fields in Szechwan, Kansu, Sinkiang, and the Northeast. The Tsaidam Basin in northwestern Tsinghai Province is also a producing region. Some oil has been produced regularly from oil shales found in the Northeast, and natural gas is exploited in Szechwan.

The Soviet oil and gas fields

In the Soviet Union, Siberia has overtaken Southwest Asia in the production of oil and natural gas. The older fields lie in the southern Volga Basin and in the margins of the Caucasus Mountains. The flanks of the Ural Mountains have a number of large oil fields and small gas fields. The northern Volga Basin, along the western flank of the Ural Mountains, once contained the leading producing regions for oil. Major gas fields are located in the northeastern Ukraine south of Kharkov and in the Carpathian foothills of the western Ukraine. Uzen, on the Mangyshlak Peninsula on the eastern shore of the Caspian Sea, is a major gas-producing field that also yields oil. Another major field is that of Gazli in the Kyzyl Kum Desert south of the Aral Sea, and the rich gas field in the northern Ob River Basin at Berezovo indicates that the entire Ob Basin may yield natural gas. In the Lena River Basin, north of Yakutsk, there are large proven gas reserves.

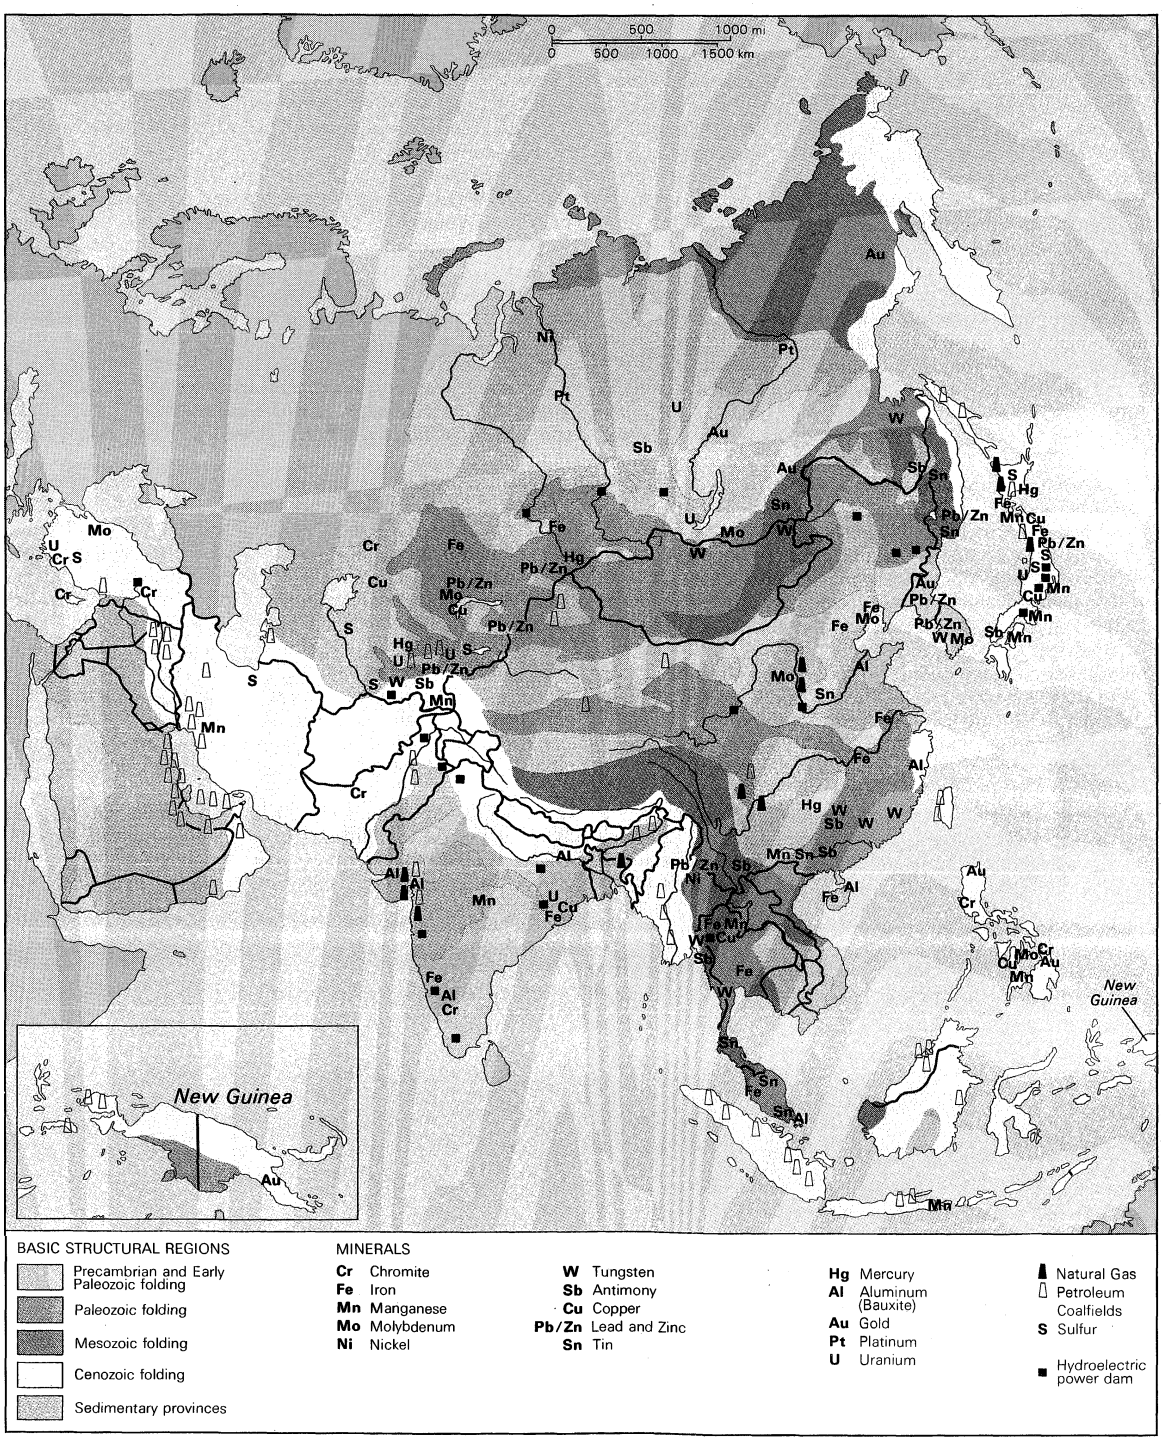
Uranium. Reserves of uranium ore are found in Asia's ancient crystalline rocks. The Soviet Union, China, and India have their own supplies of uranium. The Soviet Union, in particular, has rich ore fields in Kirgizia, between Osh and Tuya Muyun. Chinese uranium resources are probably in northern Sinkiang and southern Hunan.

Iron. All portions of Asia have deposits of iron ore, although not every political state has its own private supply. South Korea, Taiwan, Sri Lanka, and several smaller countries in Southwest Asia appear to have only small iron-ore supplies. Japan has far less than needed by its large iron and steel industry and depends largely on imported supplies. The Philippines has more ore than needed by its modest industrial needs and is an ore exporter. Malaysia produces a considerable volume. Thailand, Burma, and Pakistan have fair amounts of relatively low-grade ores, and Vietnam and Turkey have good ores in substantial volume. Indonesia and India both have large deposits of good iron ores that are reasonably distributed.

Although formerly regarded as deficient in iron ores, China contains huge quantities of varying grades of ores that are widely distributed and often located close to coal supplies. Regional centres of ore mining, smelting, and fabrication are located at An-shan, a southern area of the Northeast; near Peking; in southern Anhwei, west of Shanghai; in central China, east of Wu-han; in southern Inner Mongolia, north of Pao-t'ou; in central western Kansu; and on Hainan Island, off the southern coast. Large iron ore deposits also occur near Chungking in Szechwan. Iron ore in small local volumes is widely located in Kweichow and Yunnan in the Southwest. China ranks among the world's major producers of iron ore.

The Soviet Union formerly depended largely on iron ore from the Krivoy Rog and Kerch basins of the southern Ukraine, but huge deposits of magnetic ore have been found near Belgorod. Iron ore has long been extracted from the Ural Mountains, and further deposits have been found at and near Magnitogorsk in the Southern Urals. There appears to be a virtually unlimited supply of low-grade ore in the Kustanay Basin east of the Southern Urals in southwestern Siberia. A major iron ore range, at Kachkanar, west of the Northern Urals, contains low-grade ores. Large deposits of medium-grade iron ore have been found northwest of Lake Baikal, close to the Cheremkhovo coal deposits. Smaller deposits have been located in the Murmansk Peninsula and at several locations in Eastern Siberia. The Soviet Union has become the world's largest producer of iron ore.

Ferroalloy metals. Asian resources of nickel are not extensive. There is a notable Soviet nickel-ore field at Norilsk (in Northern Siberia); Indonesia also possesses reserves. Japan and the Philippines both produce considerable quantities of nickel.



Basic structural regions and principal mineral and hydroelectric sites of Asia.

Asian countries with reserves of chromium include Turkey, the Philippines, India, Iran, Pakistan, and Cyprus; reserves are also found in Soviet Asia.

Manganese is found in abundance. The Soviet Union has large reserves in Central Asia and in Siberia, and India also possesses large quantities. Chinese reserves are considerable, but those of Japan are limited.

Southern China has exceptionally large reserves of tungsten. Tungsten reserves of Soviet Asia are also important, as are those of molybdenum.

Copper, tin, and zinc

Nonferrous base metals. Asia is not richly endowed with copper ore. In Soviet Asia the principal fields are Almalyk, southeast of Tashkent; Dzhezkazgan, west of Karaganda; Kounrad, Lake Balkhash; and in the Kuznetsk Basin. Japan's widespread copper-ore reserves are of medium importance, and the Philippines have limited reserves. China has deposits in Kansu, Hopei, Anhwei, and Hupeh, but production is insignificant. Turkey, Israel, India, and North and South Korea have small reserves.

Significant reserves of tin exist along a north–south axis running from southwestern China through the Malay Peninsula to Indonesia. Thailand, Burma, Vietnam, Laos, and Yunnan Province in China also have deposits of tin. Soviet Asia has substantial reserves in Transbaikal and also in the Sikhote-Alin Range.

Soviet Asia's lead and zinc reserves—the largest in Asia—are located in the Kuznetsk Basin and in central and eastern Kazakhstan. China also has abundant reserves of zinc and lead ores, and North Korea has important lead resources.

Asia has enormous reserves of bauxite. In Soviet Asia bauxite fields are located in Kazakhstan and in the Sayan Mountains. There are also large reserves in India, Indonesia, the Philippines, and Malaysia, as well as significant reserves in China.

Important quantities of mercury occur in south central China and in the Soviet regions of the Ukraine and Siberia. Magnesite is common in Asia. There are large reserves of antimony in central China; Turkey and Thailand also have substantial reserves.

Gold and silver

Precious metals. Many Asian countries have produced gold from alluvial stream deposits in past centuries, and some continue to do so. Small volumes of alluvial gold are produced in Burma, Kampuchea, and Indonesia, and the headwaters of the Yangtze River in the Tibetan border region yield some gold. India formerly was a large producer of gold from lode mines, but the best ores appear to have been exhausted. Japan, North and South Korea, Taiwan, and the Philippines have significant gold-ore reserves and periodically produce gold from small lode mines.

The Soviet Union has produced gold from lode mines in the Central Ural Mountains for centuries, and in the 19th century there were several gold rushes to work alluvial stream deposits in Siberia on the Lena and Yenisey rivers. In the late 20th century, Soviet gold production was considerable, and lodes were worked in several Siberian locations, centring on the upper reaches of the Kolmya River. The lode at Auezov in eastern Kazakhstan, south of Semipalatinsk, potentially allows the Soviet Union to rival South Africa in rank as a gold producer.

Platinum is mined near Norilsk in the Central Siberian Plateau in Northern Siberia.

Nonmetallic resources. Reserves of asbestos are localized; it is abundant in China, South Korea, and Soviet Asia. Mica is abundant in Soviet Asia and is also found in large quantities in India. Asia has abundant reserves of rock salt, but the hills and "glaciers" of salt in southern Iran have not been exploitable. Reserves of sulfur and gypsum are abundant in Central and West Asia. Japan has large reserves of sulfur. In Vietnam phosphates are obtainable from sedimentary fields and from apatite. The Soviet Union has large deposits of phosphates in the Mangyshlak Peninsula on the eastern shore of the Caspian Sea and other scattered deposits of lesser value. Diamonds are produced in east central Siberia.

Water resources. Asia's water resources constitute a vast potential, both for generating hydroelectricity and for irrigation. In the arid parts of the continent, water is primarily used for irrigation.

Siberian hydroelectric power

Siberian rivers have an excellent hydroelectric potential, for when dammed they provide low falls with an enormous volume of flow. Extreme cold and low winter water levels, however, hinder their exploitation. Thanks to abundant precipitation and great differences in water level, the Soviet Far East has an immense potential for hydroelectricity, although the remoteness of Eastern Siberia discourages industrialization.

Japan, a country of high man-made waterfalls but relatively small volumes of water flow, has already harnessed almost all its rivers that have a hydroelectric potential; this potential, however, is increased by heavy rains, particularly in summer.

The waterpower potential of northern China is extremely limited because the flow of the Huang Ho and other northern rivers is erratic, and all carry heavy volumes of silt. The hydroelectric potential of China south of the Tsinling Mountains, however, is great. The Yangtze River has a considerable waterpower potential, particularly near I-ch'ang, although this site would be expensive to develop.

The hydroelectric potential in the Indian subcontinent is subject to regional variations. The Western Ghāts, which slope down abruptly to the western maritime plains, permit high waterfalls; unfortunately, the rivulets that rise on the summit have an insignificant volume of winter flow. Rivers of the eastern slope of the Deccan, such as the Mahānadi and the Godāvari, lend themselves to the construction of dams with low falls and great volumes of flow, as also do the Himalayan rivers entering the Ganges Plain. The Himalayan ranges offer rich possibilities for the utilization of high waterfalls for generating hydroelectric-

ity, but in winter their waters are very low, and most of the sites would be expensive to develop.

Biological resources. Widely varying climatic conditions, particularly in the distribution of rainfall, have produced terrains in Asia ranging from tundra and desert to forest and alluvial plain, each supporting its appropriate plant cover, on which, in turn, typical animals and birds subsist. The Arctic north of the continent and large areas of the central mountain massif—known as "the roof of the world"—are practically uninhabitable. In addition, even where there is water—and nowhere is water conservation pursued more carefully than in Asia—there are still many areas of undrained swamp. Much else is desert. By far the greater part of Asia remains uncultivated. Prime resources are the extraordinarily intensive agriculture made possible by irrigation of the alluvial soils of the great river deltas and courses; the forests, with commercially valuable species of trees; the flocks of sheep and goats supported by Asia's semiarid deserts and grasslands; and the produce of the intensively fished surrounding seas of South and East Asia.

Timber resources. Much of Northern Siberia, south of the Arctic Circle, is covered by coniferous and mixed forest, which is commercially exploitable. The great deciduous forests of northeast India, Burma, Thailand, and Malaysia contain teak and other important hardwoods, as well as bamboo. Mangrove forests line the waters of the Ganges and Irrawaddy deltas and many small stretches of coast along the Malay Peninsula, Indonesia, and the Philippines. But in the Indian subcontinent lowland, forest has yielded place to cultivated land, as a result of population expansion; agriculture has similarly reduced the natural forest areas of China to insignificance, except in northern Manchuria. Japan, on the other hand, is relatively heavily forested in relation to its area and population, although much of the present cover is planted forest. More than half of the Philippines still carries heavy forest, but good commercial forests cover only one-third of the country. These forests produce valuable hardwoods and the soft "Philippine mahogany."

Crops. In Soviet Asia, the black-earth belt across Southern Siberia is cultivated with grain crops, of which wheat is the most important, as also are areas of the Soviet Central Asian republics. Grain crops, chiefly wheat, are cultivated in North China—where soybeans are also grown—and in Japan. Intensive use of water resources from wells, as well as from irrigated rivers, has enabled grain crops to be raised in Iraq, Iran, Pakistan, and northern India. The great staple of South Asia is rice. It is the chief food crop of Japan, South China, Taiwan, Southeast Asia, the Indonesian islands, the Philippines, Burma, Sri Lanka, and parts of India and Pakistan, and is found in Iran, southwestern Asia, and elsewhere.

Of plantation crops, rubber, from a Brazilian plant imported in the 19th century, is cultivated in Malaysia and Indonesia and also in India and Sri Lanka. Tea is grown on commercial plantations in the uplands of northern India and Sri Lanka for export and in China and Soviet Asia on small holdings for domestic consumption. Sugarcane is harvested in Java, the Philippines, India, and Central Asia; and tobacco is grown widely, notably in Turkey, Soviet Asia, China, and Indonesia. Citrus fruit is produced in the Mediterranean lands, in the Soviet Central Asian republics, and in China and Japan. Date palms are cultivated, particularly in Arabia. Licorice is grown in Turkey. Asia is also a producer of opium from the poppy.

Seminomadic pastoralism

Livestock. The uncultivated steppe lands and deserts of Central Asia and Mongolia support flocks of sheep and goats. Seminomadic pastoralism is the rule there, as it is in parts of Afghanistan, Pakistan, Iran, and Arabia. In Central Asia, the horse and the yak are the riding animal and the beast of burden, respectively; in Arabia, the camel is both. Cattle are raised in agricultural areas. Hides, wool, and other animal products are important economically. Reindeer herds are kept in the northern tundra of Siberia, where they feed on mosses and shrubs. In Siberia, valuable furbearing animals have long been hunted. In India, Burma, and Thailand elephants still work as draft animals in the lumbering industry; particularly in Southeast Asia, the water buffalo is an important draft animal as well as a milk and butter producer. Angora goats are herded in Anatolian Turkey to provide the silky mohair for which they are noted. Silkworms are reared for silk in China, Japan, India, and Soviet Central Asia.

Game birds. North of the Himalayas, such game birds as ptarmigan, grouse, plover, and various kinds of waterfowl are found. South of the Himalayas, pigeons, pheasants, and other game birds are taken. Various kinds of hawk and falcon, trained to hunt, have their habitat in Arabia and other parts of Asia.

Seafood. Fish and other sea creatures and various kinds of crab and shrimp are intensively fished off the coasts of China, Japan, and Southeast Asia. The sturgeon, prized for caviar, is fished commercially, particularly in the Caspian Sea and the rivers of Siberia. (P.Gu.)

Factors in resource development

Resource development. The utilization of Asia's natural resources has depended, to a large extent, not only on the development of technology but also on political circumstances. Thus, until the end of World War II and the beginning of the process of decolonization in Asia, most Asian countries were not free to develop their own natural resources independently and without reference to the economic interest of a metropolitan power. Cultural attitudes also affect the utilization of resources. Cattle, for example, which are a source of immense wealth in many developed countries, are a drain on scarce resources in India, where cultural taboos prohibit the slaughter of cattle either for food or for the conservation of resources when the animals are no longer productive.

The value of natural resources also varies with the prevailing technology. For example, with the application of new technology to the production of cereals, the same area of land can give greatly increased yields. The application of modern technology has also produced improvement in many other areas, such as in Japan for the production of silk or of cultured pearls. Technology may also make it possible to exploit mineral wealth that was previously unusable because of problems of accessibility or of juxtaposition of other minerals.

INDUSTRY

Mining. Asia produces a variety of minerals. Many of these are mineral fuels, such as coal and petroleum. The largest Asian producers of coal are the People's Republic of China and Soviet Asia, followed by India and Japan. Very small quantities of coal are produced in a number of other countries. The Arab countries of Southwest Asia are the principal producers of petroleum in the world. The biggest producer among the Asian countries is Saudi Arabia. Soviet Asia was second, followed by Kuwait, Iran, the United Arab Emirates, and Iraq. The biggest producer of natural gas is Soviet Asia, followed by China, Saudi Arabia, Iran, and Indonesia.

The largest producers of iron ore and ores for ferroalloys are China, Soviet Asia, India, and North Korea. Together these four account for almost all the production of the region. India and China are among the major world producers of manganese ore and between them account for virtually all of Asia's output. Asia's biggest producer of chromite is the Soviet Union, followed by the Philippines, Turkey, India, and Iran. There is also some production of tungsten in China, the Soviet Union and North and South Korea, while nickel is mined in Indonesia, the Soviet Union, and the Philippines. Soviet Asia has become an increasingly important producer of many of the ferroalloys.

Asia is one of the world's main producers of tin-in-concentrates (tin ore that has been partially processed to increase the concentration of tin), providing more than half of the world's total production. Malaysia alone accounts for about half of Asia's production, followed by Indonesia and China. There is also considerable production of copper ore in the Soviet Union, the Philippines, China, and Japan.

The bauxite produced in Asia represents only a small part of total world production, although production in Soviet Asia has increased. Development of the Eastern Siberian gold mines has given Soviet Asia a leading position in the world's production of gold. Asia produces more than

one-tenth of the world's sulfur, principally from Japan and China. Asia also accounts for much of the world's production of graphite, from North and South Korea and from China.

Heavy industry and engineering. Despite the fact that the continent has such a variety of mineral resources, metallurgical industries have not been fully developed, except in Japan and in Soviet Asia. The major producers of steel in the region are Japan and China. Japan, China, and India are the major steel consumers, although the consumption of steel is increasing in Soviet Asia, Pakistan, and the Philippines; Hong Kong is one of the main consumers on a per capita basis. Japan, China, and India are also the region's leading producers of metallurgical coke.

The production of aluminum is concentrated in three countries—Japan, Soviet Asia, and China. India has a relatively well-developed aluminum industry. There is also some production of copper, zinc, lead, and tin in Asia, with Japan and Soviet Asia leading in the production of zinc and lead and Malaysia in the production of tin. Japan, China, and India are leading consumers of tin.

Japan produces every variety of engineering goods, from tankers and locomotives to miniaturized electronic equipment. Since World War II India has also gradually diversified its engineering industries and now produces heavy capital goods (machines and tools used in the production of other goods), various types of industrial machinery, prime movers (engines and other sources of motive power) and boilers, diesel engines, sewing machines, machine tools, agricultural machinery, and all types of electrical equipment. India also produces radio receivers, metal manufactures, railway rolling stock, automobiles, bicycles, and precision instruments. China has also made considerable progress in the field of engineering industries. Other Asian countries have primarily concentrated on the production of durable consumer goods.

Asia's engineering industries

Chemical and petrochemical industries. The consumption of nitrogenous and phosphatic fertilizers has greatly increased in Asia, largely because additional countries have begun to use the advanced techniques and improved seeds that have now become available. The major consumers of fertilizers, on a per acre basis of arable land, have been Japan, South Korea, and Singapore. Because of their vast size and the increased use of fertilizers, India and China are, in absolute terms, among the major consumers. India has greatly increased its production, especially of ammonium sulfate, and has also experimented with fertilizers that have a much higher nitrogen content, such as urea. Production of phosphatic fertilizers has also been increased in Asia.

Asia also produces and consumes basic chemicals, such as caustic soda, soda ash, and sulfuric acid; Japan and China are the leading producers of these, followed by India.

The consumption of pulp and paper throughout the continent has grown steadily, largely because of higher standards of living. The major consumers are Japan and India, and the major producers are China, Japan, Soviet Asia, and India.

Various surveys undertaken under the auspices of the United Nation's Economic and Social Commission for Asia and the Pacific (ESCAP) have shown that there is considerable scope for the manufacture of petrochemical products in Asia.

Manufacturing and textiles. The textile industries, particularly cotton, have expanded greatly in Asia since World War II. Japan and Hong Kong are among the world's largest exporters of cotton textiles, and China, Taiwan, Singapore, Pakistan, and India have also entered the international market. The industry produces cotton yarn, cloth, and finished garments. There is also some processing of wool (both yarn and woven fabrics) in the region. China, India, and Turkey are among the main producers and consumers; China is Asia's chief producer of woollen fabrics. Japan and India have also become major producers of woven rayon and acetate fabrics. Japan has also turned to noncellulose synthetic fibres, especially nylon, acrylic, and polyester fibres.

The expanding textile industry

Industrial development in the region has made relatively significant progress, though in absolute terms progress has been limited; in relation to its size and vast population, the contribution of Asia to total world industrial output has been small. There is, however, a discernible trend toward a transition from light to heavy industry in many countries of the region; the development of Soviet Asia is dramatic, and it is likely that the continent will have an increasing share of world production.

Timber, fisheries, and animal husbandry. Logs are exported from China, Soviet Asia, Malaysia, Indonesia, and the Philippines to industrialized and timber-deficient countries, especially Japan. Thailand and Burma produce special varieties of timber such as teak. Thai teak is also exported to Europe.

Soviet Asia has an enormous forest area. The wood ranges from pine around the Bratsk area to a mixture of pine, larch, aspen, birch, and other species in the region south of Lake Baikal. Logging and transport operations are highly mechanized and have been facilitated by a road-building program.

Bamboos are an important component of wet evergreen, moist deciduous, and dry deciduous forests in the tropical parts of Southeast Asia, principally in Burma, Kampuchea, Sri Lanka, India, Indonesia, Laos, Malaysia, Papua New Guinea, Pakistan, the Philippines, Thailand, and Vietnam. At higher altitudes and in temperate climates in Asia, as in Bhutan, China, Japan, and Nepal, many of the genera found in tropical parts are represented by different species, and other genera are common in China and Japan. Pure bamboo forests are common on slopes where temporary cultivation has been carried on in Burma, Bangladesh, and other parts of Asia.

Asia has a considerable potential for increased development of its fisheries. Japan has shown how far afield a well-organized fishing fleet can go in search of fish. In general, the problems of the fishing industry stem from lack of adequate capital and advanced technology, which tend to restrict fishing to coastal and offshore areas and make it difficult to extend the fishing to the deep seas. Because of a widespread lack of refrigerated transport and storage, there are also the problems of preserving fish after the catch and of transporting the catches to centres of consumption. In some countries freshwater fish are also an important addition to the diet of the local people; the raising of fish in culturally controlled ponds is important in southern China, Indonesia, and the Philippines. While the dairy industry is important in a few countries such as India, Pakistan, Soviet Asia, and Turkey, there is not much large-scale development of beef-cattle farming; Soviet Asia, however, has attempted to develop such patterns. Both China and Japan are discarding their traditional taboos against the use of milk products, and both countries have growing urban dairy industries. China, the world's largest producer of pork, is the only producer in Asia, with Japan as a distant second. The poultry industry has made rapid strides during recent years, and the production of both eggs and broiling chickens has gathered considerable momentum. The availability of feed for poultry is one of the major limiting factors in growth and development of the industry. Straw, obtained from rice crop, is the primary fodder for livestock in southern Asia. Cattle feed is usually supplemented by concentrates, such as oil cake.

The raising of livestock

The raising of sheep and goats for meat and wool is especially important in China, India, Pakistan, and Iran; these animals are also raised in practically all the other countries of Asia. The sheep population of Southeast Asia is small.

In spite of the large number of cattle and sheep in the region, the hides and skins industry has not been fully developed. Technological problems in connection with both the flaying of skins and their curing have not been overcome.

Handicrafts. Traditional cottage industries and handicrafts continue to play an important role in the economies of all Asian countries. They not only constitute an important manufacturing activity in themselves but also are often the only available means of providing additional employment and of raising the level of living for both rural and urban populations. In view of the growing world market for products of traditional Asian cottage industries and for Asian handicrafts, there is room for considerable

expansion, especially in standardizing production and in marketing products in advanced countries.

Other industries. Asian countries are at different stages in developing their pharmaceutical industries. The progress of the industry in Japan is comparable to that achieved in western Europe and the United States. Great progress has also been made in India and, in some respects, in Pakistan, but these two countries have not reached the stage of being self-supporting in technology, raw materials, or equipment. China has begun to develop an industry based on a distinctive blending of Occidental and native pharmaceutical manufacturing. In most of the other countries the pharmaceutical industry is only a processing industry based on basic drugs, imported in bulk, which are then marketed as capsules, tablets, and injectibles. In many Asian countries traditional medicinal products and treatments are still popular, especially in rural areas.

International tourism has developed significantly. The most visited places include Hong Kong, Japan, Thailand, China, Singapore, India, Pakistan, Turkey, Syria, and Israel. Hong Kong and Singapore each have a big entrepôt trade and attract visitors partly because they are duty-free ports. With the gradual lifting of the "bamboo curtain" beginning in the 1970s, the number of tourists visiting China has increased. There is considerable scope for further development of tourism in some Asian countries, for many of them have ancient monuments and natural attractions of great beauty. Unfortunately, many of the places that are most interesting to tourists are not easily accessible.

POWER

The per capita consumption of power in Asia outside the oil-producing countries of the Middle East tends to be very small compared with the world average. Japan is the biggest producer of power in Asia, and its generation capacity amounts to nearly half the region's total. The electricity output by public utilities and similar bodies in the Asian countries includes thermal power, hydroelectric power, and nuclear power. All these types of production have progressed rapidly in Soviet Asia.

Thermal and hydroelectric power

Thermal power has become the most important source of supply among the various types of electric power generated in the region, particularly in the Middle East. There is an increasing tendency to operate thermal power stations for meeting regular demand and to build—or plan—hydroelectric power stations to serve during peak demand periods. In countries such as Afghanistan and Sri Lanka, however, hydroelectric power generation is well developed and is several times greater than the generation of thermal power.

Nuclear power plants have been developed in a number of countries. Japan completed its first atomic power plant in 1967, with a capacity of 160 megawatts, and has constructed more and more such plants. India commissioned its first nuclear power station at Tarapur in early 1969 with a capacity of 200 megawatts, and others were subsequently constructed.

In the construction of steam thermal power stations, there has been a tendency toward a larger unit capacity operating at very high pressure and temperature. The Soviet Union has made extensive use of geothermal power in Asia, with geothermal plants at Makhack Kala, Tashkent, Lake Baikal, and Kamchatka. Japan has two small geothermal plants. The only other Asian country to use geothermal power is the Philippines. Small gas-turbine generating stations have also been installed in many countries. Pakistan uses natural gas from the Sui gas field for both thermal and gas-turbine generation.

AGRICULTURE

The most important modern development in Asian agriculture is the evolution of new high-yielding strains of cereals. This development is being utilized in several Asian countries and has had a marked influence on the yield per acre of cereals since the late 1960s. Rice is the staple food crop among most Asian countries. Asia produces some 90 percent of the world's total supply of rice. Except in the Middle East, India, Pakistan, Afghanistan, Soviet Asia, and Malaysia, rice occupies more land area than any other single crop. In the Middle East, Afghanistan, India, Pakistan, and Siberia wheat is the dominant crop, while in Malaysia rubber occupies the greatest land area, with rice ranking second. The total percentage of land under rice cultivation, as compared to total arable land, is highest in Vietnam, Bangladesh, and Sri Lanka; it varies between 25 and 50 percent in most Asian countries outside the Middle East.

High-yielding cereals

In spite of the fact that the region is the world's largest producer of rice, most countries (among them Sri Lanka and Indonesia) are not self-sufficient in rice. Thailand, the Philippines, China, and Japan are notable exporters of rice. Barley is grown in China and India, among other countries. Corn (maize) is grown in China, Soviet Asia, India, the Philippines, Thailand, and North Korea. India, China, Pakistan, and Soviet Asia also grow sorghum and millet.

Asia produces several plantation crops, of which the most important are tea, rubber, coconuts, sugarcane, and pineapples. The major producers of rubber are Malaysia, Indonesia, Thailand, India, and Sri Lanka. India and Sri Lanka predominate in plantation tea production, and China, Taiwan, and Japan produce several types of tea on small holdings. Coconuts are an important crop in the Philippines, Indonesia, India, and Sri Lanka. India, the world's leader in sugarcane production, produces primarily for domestic use, whereas the Philippines, Indonesia, and Taiwan produce both for domestic consumption and export. The Philippines, Taiwan, and Malaysia produce pineapples, which are canned for export.

The continent produces a variety of tropical and subtropical fruit, mainly for domestic consumption. Transport facilities, where available, can be used only for limited distances. In view of the climatic conditions and the general lack of refrigerated transport, consumption tends to be seasonal and confined to areas close to centres of production. Among the main varieties of fruit produced are bananas, mangoes, apples, oranges and other citrus fruits, pineapples, papayas, and some specialities such as mangosteen (a dark reddish-brown fruit) and durian (a large oval fruit with a prickly rind, a soft pulp, and a peculiar odour). Taiwan, the Philippines, and Malaysia export bananas to Japan.

Except in a few countries, the canning of surplus fruit has been developed only to a limited extent. In view of the tremendous potential for the production of fruit, there is vast scope for increased canning for export, both of fruits and of fruit juices. The fruit canning industry has markedly increased in Taiwan.

The same factors affect the production of vegetables. Vegetables are produced mainly for local consumption, and only tubers can be transported over distances and stored for any period of time. In Taiwan successful efforts have been made in the canning of mushrooms and asparagus, both of which have come to be among the country's leading exports.

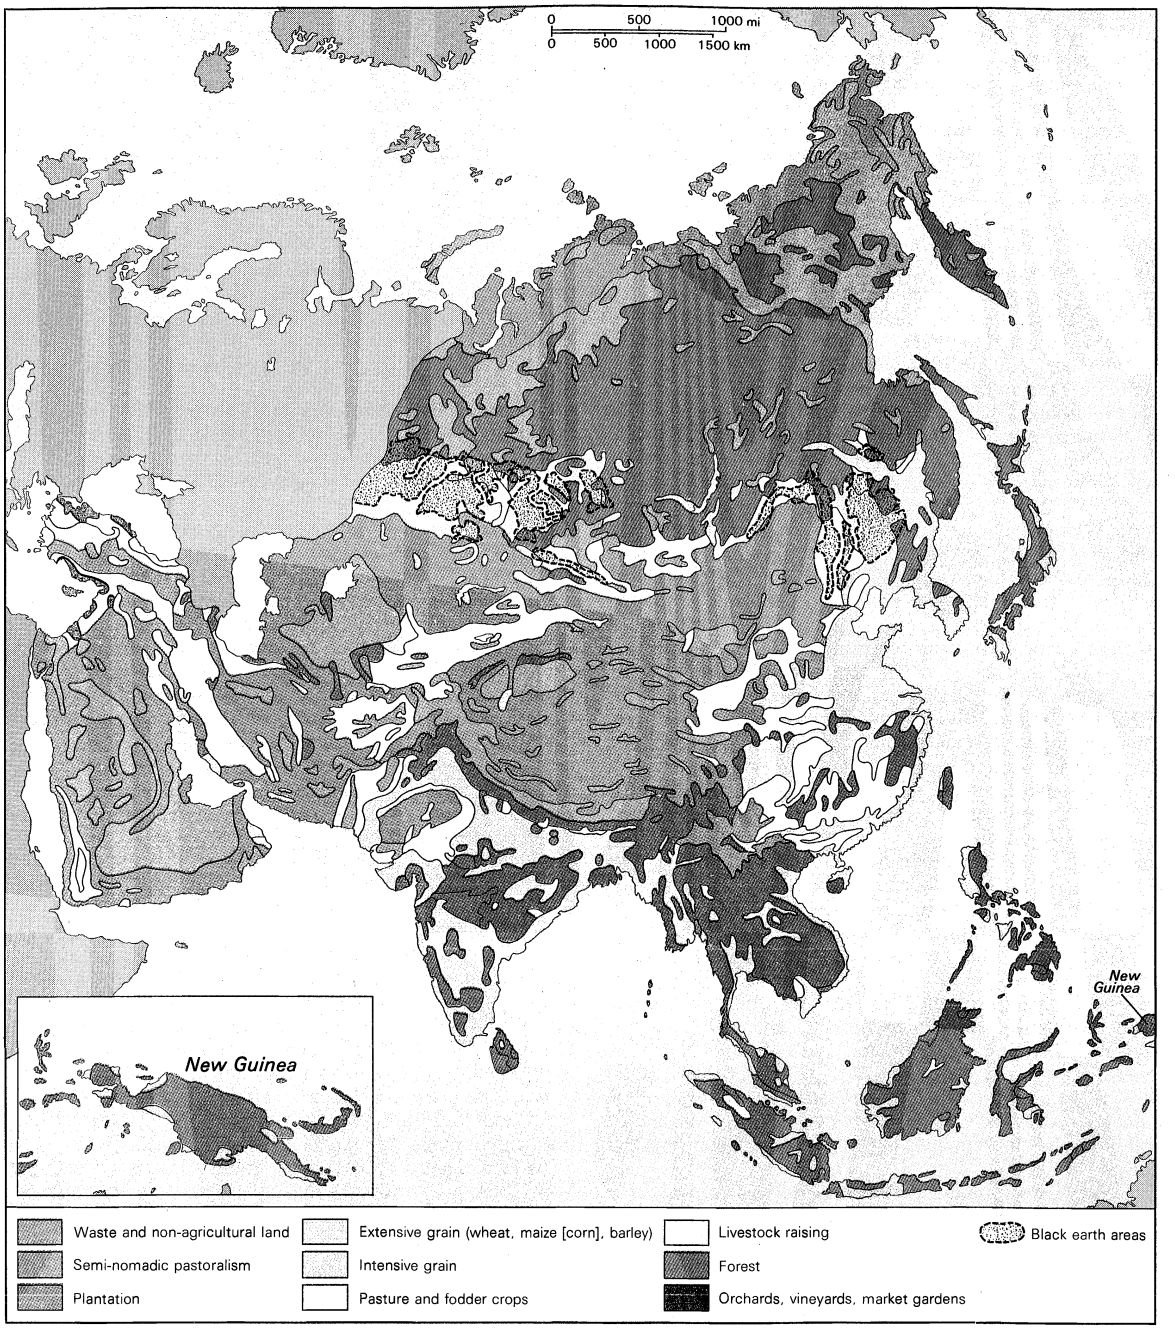
The traditional method of irrigation in Asia is by gravity water flow. The water from upstream storage reservoirs or diversion dams is carried through canals to field distributaries. The fields adjoin one another, and the water is able to flow from one field to the next; it may, however, take some time for the water to move across the terraced fields back to the canal system. The disadvantages of this system include the loss of water by evaporation and seepage and the possibility that the continuously flowing water will carry with it soil nutrients, fertilizers, and pesticides. In Japan and Taiwan water is moved by small electric pumps, which operate continuously during the growing seasons.

Methods of irrigation

By the late 20th century more attention was being given to the use of underground water by lift. The use of ordinary pumps as well as of deep-bore well turbine pumps has become common, especially in India, Pakistan, and Iran. Such irrigation avoids some of the disadvantages of flow irrigation and allows for easier drainage.

Of the crops cultivated in the region, rice, sugarcane, and, in Soviet Asia, sugar beets need the most water. Cereals other than rice, legumes, and root crops can be grown even on rain-fed land.

The availability of an assured source of water supply



Agricultural regions of Asia.

is an important element in the new technology, which also requires the use of fertilizer in conjunction with the improved cereal seeds that have been developed. Huge irrigation projects in Southern Siberia, southwestern Soviet Asia, and Pakistan are rapidly altering traditional agricultural patterns.

TRADE

Several centuries before the Christian Era, Asian countries had commercial relations among themselves as well as with the countries of the West. In the earliest days nomadic tribes carried on this trade over considerable distances, using barter as the medium of exchange. Particularly important in such trade were fine textiles, silk, gold and other metals, various precious and semiprecious stones, and spices and aromatic products. There was a considerable expansion of trade during the Greek era around the 4th century BC, by which time various land routes had been well established connecting Greece, via Asia Minor, with the northwestern part of the Indian subcontinent. Further development of land and sea routes, especially to South India, occurred during Roman times. This East–West trade flourished in the first four centuries AD but was subject to considerable vicissitudes in later centuries. During this period there was also a great expansion of trade to Southeast Asia and to China through what are now Malaysia and Kampuchea.

Ancient trade patterns

After Spain, in the 15th century, became interested in discovering a direct sea route to Asia—an interest that led to the discovery of the Western Hemisphere—the era of the great circumnavigators arrived in the 16th century. Portugal was one of the first countries to dream of establishing a monopoly over the lucrative spice trade with Asia. The Dutch and the British started similar enterprises at the turn of the 17th century, each country establishing its own East India company. The British began by centring their activities on the Indian subcontinent and extended their interest to Burma, Ceylon (now Sri Lanka), and present-day Malaysia. The Dutch first concentrated on Ceylon but later expanded into and concentrated on Southeast Asia. The French were able to establish only minor footholds on the Indian subcontinent, but their 19th-century

penetration of Indochina was more successful. Spain was content with the control it had established over the Philippines. Over the course of time these European trading companies developed into colonial empires.

The export trade of Asia was formed by these historical circumstances. In the days before the East India companies, the products of Asia were those demanding the exploitation of human skills, such as silk and textiles, and such precious commodities as spices and aromatic products, which depend especially upon climatic and soil conditions and careful human labour.

The colonial trading system

With the development of the East India companies and the further assumption of colonial rule, a new pattern of trade emerged. Generally speaking, the colonial countries became the exporters of raw materials and imported the finished products from their metropolitan rulers. During this period tea and tobacco also entered into international trade, and jute became a monopoly product of the Indian subcontinent. Until the end of the 19th century Japan had trading relations mainly with Korea and China and generally remained somewhat aloof from world trade. China was the first country of Asia to have any significant trade relations with the Western Hemisphere; these were chiefly with the United States.

The latter half of the 19th century and the early part of the 20th constituted the heyday of colonial rule. By the first decade of the 20th century, Japan had emerged as a major military and naval power and gradually developed into an important trading partner with the rest of the world. The era that followed was that of the colonies' struggle for political independence, which reached its climax immediately after World War II. Fifteen years after World War II the great British, French, and Dutch empires had virtually ceased to exist in Asia.

As a result of the achievement of independence by the former colonies, the emergence of the People's Republic of China, and the development of Japan into one of the major producing and trading countries of the world, the old established patterns of trade have changed considerably. Most of the newly independent countries have planned their economic and social development and have tried—with varying degrees of success—to diversify their production and to develop new industries, even if they cannot wholly overcome the handicaps of the colonial past.

Internal trade. In view of the division of labour that existed between the colonial countries and the metropolitan powers in colonial days, it is not surprising that the economies of the independent countries of Asia are often more competitive than complementary. In the case of certain countries, such as the Philippines, Sri Lanka, India, Afghanistan, Iran, and Pakistan, their intraregional exports have amounted to only a small fraction of their total exports. Iran, Afghanistan, Taiwan, South Korea, the Philippines, and India imported only about one-tenth of their requirements from other Asian countries by the early 1980s. Japan, the most developed of Asian countries, exported only about one-third of its products to developing ESCAP countries, and Japan received from these countries only about one-fourth of its imports.

Competitive economies

Asia is the biggest producer of rice in the world; rice is indeed one of the most important commodities of intraregional trade, and it is the most important export item of such countries as China, Pakistan, and Thailand.

There has been an effort on the part of Asian countries to improve their trading position by joining in commodity agreements. Malaysia, for example, is a member of the International Tin and Rubber Agreement. Other Asian countries are members of the International Sugar Agreement. The Asian Coconut Community was established in 1968, with Sri Lanka, India, Indonesia, Malaysia, the Philippines, Singapore, and Thailand participating. Bangladesh, India, Indonesia, and Sri Lanka were instrumental in the formation of the International Tea Promotion Association in 1979. Participation in these commodity agreements is not designed so much to promote intraregional trade as to help stabilize the prices of the primary products produced in Asia that then enter into world trade.

China was one of the main trading partners of the Socialist bloc of countries in Europe, especially the Soviet Union, in the early days after the revolution. China has since sought trade contacts with other Asian countries. In many cases trade agreements between China and other Asian countries are in the form of barter agreements. China's most important trading partners in Asia have been countries such as Japan, Burma, Sri Lanka, India, Indonesia, Malaysia, Pakistan, and Singapore.

In 1958 a special effort was made to promote intraregional trade by the establishment, under the auspices of ECAFE, of intraregional trade talks. An important intraregional organization has been the Association of South East Asian Nations (ASEAN), which was established in 1967 to promote the economic and social development of the region. The ASEAN has fostered joint economic ventures among member states (Indonesia, Malaysia, the Philippines, Singapore, Thailand, and Brunei), and has worked to reduce trade barriers.

There has, however, been little effort at trade integration on a regional or subregional basis in Asia. In this respect Asia lags behind Latin America and, to some extent, Africa. Trade between India and Pakistan, which could be of great mutual benefit, is hampered by political relations between the two countries.

Many Asian countries are engaged in diversifying their internal production. Their goal is generally self-sufficiency rather than specialization and division of labour among a number of countries. As Asian countries increasingly become industrialized, however, and as they make greater use of their individual natural advantages, trade among the countries of the region could become more complementary.

External trade. The external trade of Asian countries has been considerably affected by the political ties that existed in colonial times, when important trade connections were established and when a certain trade pattern developed that proved convenient for both trading partners to continue. This convenience extended even to payments arrangements; the former British colonies were part of the sterling area, while the former French colonies found the franc a convenient medium of exchange. In addition, a system of Commonwealth preferences existed within the sterling area in Asia.

Several factors have tended to interfere with this pattern since the 1960s: the European Economic Community (EEC) was formed, with a new system of preferences; Japan became a major producer of both consumer and capital goods and a major market for the commodities exported from other Asian countries; and China began to take increasing interest in trade with countries outside the Socialist bloc.

Major export items

The main items exported from the developing countries of Asia are rubber, tea, crude petroleum and petroleum products, rice, sugar, copra, coconut oil and palm oil, cotton and cotton fabrics, jute and jute fabrics, tin-in-concentrates, tobacco, wood products, iron ore, wool, and hides and skins. Spices, which were such an important part of the trade with Western countries in earlier centuries, now form a very small part of the total exports of Asia.

Since the major exports of the developing countries of Asia are primary products, both their volume and price depend upon external demand, which fluctuates according to the level of industrial activity in developed countries. As a result there are great fluctuations both in the volume and price of exports. Further, there has been a tendency on the part of developed countries to replace some of these primary products with synthetic products, such as synthetic rubber and nylon and polyester fabrics. The developing countries are faced, therefore, with the problem that, even when they are able to increase their volume of exports, there is no corresponding increase in the value of their exports. In addition, the price of the consumer and capital goods exported by the advanced countries to the developing countries has been steadily rising since the end of World War II.

The main imports

The main imports of the developing countries have been machinery and transport equipment (including trucks, automobiles, and tractors); other manufactured goods; chemicals, including fertilizers; food, beverages, and tobacco, especially cigarettes; mineral fuels; and oils and fats. There

has been a decline in British exports to the sterling bloc countries of Asia in the postwar period. The major trading partners of France in Asia have been the countries of Indochina and the Middle East, while The Netherlands trades extensively with Indonesia. West Germany has developed considerable trade with Asia in the postwar period.

Since 1959 the Soviet Union has increased its trade with Asian countries, especially Burma, Sri Lanka, India, and Indonesia, which have been pursuing a neutralist foreign policy and have accepted military and economic aid from the Soviet Union as well.

The United States has been the biggest provider of economic aid to many Asian countries in the postwar period; there has also been a concurrent increase in trade between the United States and Asian countries. The dominant Asian trading partner of the United States is Japan; others include Saudi Arabia, Taiwan, South Korea, Hong Kong, Indonesia, Singapore, Malaysia, and the Philippines.

In its efforts to trade with countries outside the Socialist bloc, China has increased its trade with such countries as the United States, the United Kingdom, Australia, Canada, and France; it has also entered into a series of trade agreements with Japan. Trade between China and the United States came to a virtual standstill in 1950, when the United States imposed an embargo on hundreds of commodities; while the ban continues to apply to traffic in certain strategic goods, in 1971 it was lifted for other commodities. As a result, in the late 20th century the United States became one of the largest exporters to China. China has also been working to extend its trade relations with the newly independent countries in Africa.

During the 20th century petroleum has become an important part of the trade of West Asian countries of West Asia with the rest of the world. Iran and the Arab countries are among the chief beneficiaries of this trade. Originally, the Western powers had considerable economic superiority, which they used to negotiate terms that were less advantageous to the producing countries. The producing countries, in their turn, began to work closely together to protect their common interest; negotiations have resulted in much better terms for the producing countries, as shown in the strength of the Organization of Petroleum Exporting Countries (OPEC) formed in 1960.

TRANSPORTATION

Reference has already been made to the main transport systems that linked Asia and the Western world. Until the 19th century the land, or caravan, routes, supplemented by oceangoing vessels, were predominant. In the latter half of the 19th century there was a major shift to seagoing vessels. Rail transport has begun to play a progressively more important role, mainly in the internal movement of passengers within individual states and in the transport of heavier goods over longer distances. Concurrently, there has been considerable development of ports and harbours, linked to their hinterlands by rail and road. Air transport has proved to be not only the speediest but also often the cheapest means of transport, especially for costly items of relatively small weight and bulk. Air transport plays a particularly important role in landlocked countries—such as Afghanistan, Nepal, and Laos—and in the opening up of relatively inaccessible areas.

Within Asian countries animal transport remains the main means for the local transport of goods from one village to another or from the villages to a central marketplace. The animals, used for plowing during the cropping season, are also used for transport of goods at other times. The diesel truck, however, is rapidly replacing draft animals for internal traffic, and there is a simultaneous development of roads and highways in most countries.

Inland navigation is important in certain countries; a good river and canal system is capable of carrying goods and passengers at small cost over considerable distances. Among the countries having a well-developed inland water transport system are Bangladesh, Burma, Thailand, the former Indochina countries, and China. There are also great riverine ports such as Calcutta, Rangoon, Bangkok, and Ho Chi Minh City; oceangoing ships can navigate the Mekong River to inland ports such as Phnom Penh (Kampuchea) and can sail up the Yangtze River to Wu-han (China). Ultimately, it may be possible to connect even Laos with the sea by an extension of inland navigation facilities on the Mekong. The Yangtze, Sungari, and Hsi rivers of China provide a wide network of routes for motorized barges, supplementing traditional water transport.

Means of internal transport

For the movement of petroleum products there has been some development of pipelines, especially in West Asia and western and southwestern Soviet Asia. Pipelines have considerable advantages, such as economy and speed, but they also have the disadvantage of being subject to political vicissitudes when they cross international boundaries. Meanwhile, there has been considerable development of large oil tankers, which, through economies of scale, can compete with the most efficient pipelines and can also effect point-to-point delivery. (C.V.N.)

Administrative and social conditions

HISTORICAL DEVELOPMENT

The Pre-European era. The first sophisticated organization of space, people, and cultural system is customarily attributed to ancient Southwest Asia. In the earliest times there emerged the concept of a normal political state ruled by a god-king to whom all resources belonged and who held total power over the human population. Whereas some early states were city-states, the long-term trend was toward the spatial state that included rural hinterlands. States rose and fell in the ancient Orient as the conceptual system spread both westward into the Mediterranean Basin, as well as into the peninsula of Europe, and eastward into India and China. Historically, Indian political systems dominated South and Southeast Asia, Chinese systems controlled East Asia, and variations on the original model continued in Southwest Asia, while steadily changing variations developed new patterns in the Mediterranean Basin and the European peninsula.

Ancient state systems

At the end of the 15th century, at the time of Vasco da Gama's voyage to India (which signalled the dawn of European influence in Asia), the situation on the continent was approximately as follows: East Asian systems were relatively stable; the political situation in Southeast Asia was in a state of flux, as several states were in decay, and Islāmic political missionaries from Arabia had not yet succeeded in consolidating their influence; South Asia was similarly in a state of flux as the Mughal Empire struggled to achieve spatial hegemony over the Indian subcontinent; Southwest Asian political systems were experiencing a period of readjustment as the Turkic peoples penetrated the region and began to assume control; Central Asia was experiencing the last phase of the expansion of the Mongols, as well as the spread of Islām; no formal political states had so far evolved in the Siberian zone.

The evolution of European contact. The evolution of Europe's political relationship with Asia may be conveniently divided into two phases. The earlier phase that characterized the modern political geography of Asia was one in which some of the states of the European peninsula were able to introduce political controls into the unstable parts of the remainder of the Eurasian continent. The second, and more recent, phase has been characterized by the withdrawal of these controls from the whole of the southern zone, despite the fact that varying economic and political links remain operative. In the northern zone, however, where at an earlier stage no political states were in existence, the current phase is marked by the integration of the territory into the Soviet Union, a state centred on the eastern part of the European peninsula.

South and East Asia. The earliest European contacts with parts of southern and eastern Asia aimed at trade in the exotic products of the East; Europeans used their seapower to establish control over the trade routes. The European countries fought each other for the monopoly of the Eastern trade and established trading posts ("factories") at various points extending from Persia to South China and to the East Indies. The Portuguese, who were the first to arrive in India (1498), Malaya (1511), and southern China (1514), began to trade with these areas and established the first European trading posts there. The Dutch and the

Trade and politics

British followed not long after and the French and the Danes a little later. By 1700 the coasts of southern and southeastern Asia were dotted with European-controlled trade ports. Gradually these ports became points of territorial expansion, as Europeans increasingly intervened in the hinterlands so as to extend their control over production and trade. Some areas, such as Burma, Thailand, and Vietnam, were of little trading interest to the Europeans, and others, such as China, Korea, and Japan, declined to deal with the Europeans freely. By 1700 Portuguese power was in decline and the primary division of trading territories resulted from wars between the Dutch, English, and French, the Eastern conflicts often mirroring those in Europe itself. As a result, the Indies became a Dutch preserve, India became a British zone, and Spain held the Philippines. Only in the latter had the Christianizing of Asians as well as the acquisition of territory been an initial objective.

Political settlements in Europe after the conclusion of the Napoleonic Wars (1815) affected Southeast Asia. The Indies became totally Dutch, Britain acquired control over Malaya, and France gave up its claims to large territories in India in favour of Britain. The trading companies of The Netherlands and Great Britain ceased to operate in 1798 and 1858, respectively, and territorial political administration was assumed by the two governments. France returned to Southeast Asia somewhat later, taking over weak political states unable to resist encroachment, in order to establish power in Indochina. During the 19th century the United Kingdom took over Burma by stages, finally annexing it to India, and eventually assuming political control over a portion of western Borneo never effectively occupied by The Netherlands. The United States took over the Philippines from the Spanish in 1898. The German effort to gain control over the Chinese Shantung Peninsula was thwarted by other European powers, so that Germany had to be content with a long-term lease on the territory of the city of Tsingtao in southern Shantung, and a railroad-building concession. Germany did, however, become a political power in the Pacific islands in the late 19th century. During the last half of the 19th century, European countries pressured China into granting small holdings, called treaty ports, which were guaranteed by treaties, and these dotted the China coast and extended up the Yangtze Valley as far inland as Chungking in West China.

Thailand (then called Siam) remained free from political encroachment, and both Korea and Japan spurned all European effort to establish trade or to obtain political privilege. Late in the 19th century, however, Japan began its own political expansion, first in the form of establishing a sphere of influence, and then by conquest, taking over the Kuril Islands to the north and the Ryukyu Islands to the south, in 1875, and gained Korea and Taiwan in 1895. In 1905 Japan obtained southern Sakhalin and then gradually gained control of Manchuria, finally establishing the puppet state of Manchoukuo there in 1932. The expansion of the Turkish Ottoman Empire in Asia Minor left much of Arabia outside organized political control, and numerous small sheikhdoms continued to exist independently around oases in southern Arabia and along the Persian Gulf.

Japanese expansion

Central Asia. In AD 1400 the pastoral empire of the Golden Horde ruled all of Central Asia and much of eastern European Russia. During the 15th and 16th centuries Russian agricultural colonization spread eastward, and the exploitation of furs and forest timber products began; by the end of the 16th century, Russian explorers had crossed the Urals. In 1639 the first Russian explorer reached the Pacific Ocean at the Sea of Okhotsk, and in 1650 the Russians and the Chinese reached their first impasse over the control of trade and territory in the Amur River Valley. As in Siberia there were only small and fragmented ethnic territories lacking formal political organization, Russian political control was rapidly and easily achieved there. Expansion east of the Caspian Sea, however, proceeded more slowly, and it took until the end of the 19th century to bring the many Islâmic pastoral societies under control and to extend Russia's boundaries to the frontiers of Persia and Afghanistan in the south and to China in the Central Asian zone.

THE CONTEMPORARY PATTERN

The end of colonialism. During the late 19th and early 20th centuries the European powers were educating Asian peoples in methods of modern political administration and economic development. Political and cultural nationalisms gained in strength after 1900, focussing on traditional culture systems in the various regions. Political independence came to parts of southwestern Asia between 1920 and 1926, after the collapse of the Ottoman Empire, as a result of a deliberately planned separation of various ethnic groups. Conflicts and changes continued in Southwest Asia as the century progressed, heightened by the setting up of the State of Israel in 1948.

The Japanese wartime confrontation with and subsequent defeat of Western military power in Southeast Asia in 1942 gave an enormous psychological stimulus to nationalistic movements for political independence even during the Japanese occupation, and each colonial ruler was faced with demands for the end of colonial status as World War II came to an end with the defeat of the Japanese.

The United States in 1935 had promised the Philippines independence in 1945; this promise was fulfilled in 1946, after World War II, and this first release from externally administered status in the East was the forerunner of other moves. Political independence came to India and Pakistan in 1947; Ceylon (now Sri Lanka) and Burma in 1948; Indonesia in 1949; Cambodia (now Kampuchea) in 1954; nominally to both Vietnam and Laos in 1954; and to Malaya in 1957, with the Borneo colonies being added in 1963 to form the Federation of Malaysia. Singapore withdrew from Malaysia to become an independent state in 1965. After Indonesia annexed Portuguese Timor in 1976, British Hong Kong and Portuguese Macau remained the only European colonial holdings in Asia. The Soviet Union has largely avoided charges of imperialism in Central Asia and Siberia because territories there have been given the status of autonomous republics within the federal union.

Independence of colonial states

Problems of Asian nationalism. Three major conflicts occurred after World War II in which Western powers and their allies, Asian or other, were drawn into wars with Communist-supported Asian forces. The first of these was the French war in Indochina (1946 to 1954), which ended with the withdrawal of the French and the nominal independence of the territories of the region. The second was the Korean War (1950 to 1953), in which North Korean troops, later supported by the Communist Chinese, invaded South Korea, whose government was supported by United Nations forces; the result was a perpetuation of the division of the country into North and South by a cease-fire agreement. The third conflict was the war in Vietnam in which the United States supported the South Vietnamese government against Communist North Vietnam; fighting later spread to Laos and Cambodia. The government in South Vietnam collapsed in 1975, and on July 2, 1976, the two Vietnams were formally united as the Socialist Republic of Vietnam.

By the beginning of the 1970s Asian nationalism had recovered internal political and cultural control from the Western powers in all the larger countries of Asia, except in the Asian part of the Soviet Union. Within the Soviet Union, Russian strength has been sufficient to prevent outright rebellion, although the flight of some pastoral ethnic groups has continued back and forth across the boundary between the Soviet Union and China. Political independence has been much more completely achieved than has economic independence or social and economic advancement. Internal stability has also sometimes been threatened by regional or ethnic imbalances, as in East Pakistan (now Bangladesh). Japan has emerged as the most ethnically unified nation-state in Asia, and its great economic development from 1945 has resulted in relative internal stability. Elsewhere in Asia, political and cultural conditions have been in flux, as nationalistic groups, ethnic minorities, and political parties strive for the attainment of different objectives and as different nation-states attempt

Problems after independence

to pursue their national interests. Contrasts between traditional rural societies and modern urban industrial populations raise new kinds of problems. The establishment of the People's Republic of China in 1949 represented one of the major political developments of the century in Asia and is fraught with long-term consequences for South and Southeast Asia. In Southwest Asia the Arab–Israeli conflict threatens to create worldwide repercussions if the conflicting interests cannot be reconciled.

Continuing European linguistic influences. Europe has imprinted many permanent marks upon Asian cultures. Perhaps this is most noticeable in the continued use of European languages. Russian, English, and French are the dominant languages used, but German, Spanish, Dutch, and Portuguese are also employed in particular regions. Thus, German ethnic minorities in Soviet Central Asia continue to use German; older Filipinos speak Spanish; Indonesians use Dutch; and Portuguese is employed in Macau, Timor, and former Portuguese India. Vietnam, Kampuchea, and Laos continue to use French as a lingua franca, and French is taught in many schools. Dutch is the lingua franca of the educated class in Indonesia and is still taught in some schools. Pilipino is the official language of the Philippines, while English serves as a lingua franca and is taught throughout the schools. In Malaysia, India, and Hong Kong, English has an official status, is taught in schools, is spoken widely among the educated classes, and is the language of parliamentary debate. In parts of Southwest Asia, French and English are commonly spoken and are often taught in schools. Within Soviet Central Asia and Siberia, Russian is becoming more widely used and is the only common language. English, the most widely used non-Asian language, is a lingua franca throughout East, South, and Southwest Asia. (Jo.E.S.)

HISTORY

Prehistory

The traditional picture of Asia as the cradle of mankind provided the impetus for Western scholars to search this part of the world for the vestiges of man's biological and cultural beginnings. The romanticism of this notion has been tempered by scientific discoveries indicating that man had inhabited Europe and Africa as long as Asia, but Asia was nonetheless important in its broad spectrum of climatic zones, from Arctic to temperate and tropical, its mountain ranges and grassland steppes, its inland seas and Arctic tundra, plus other ecological settings to which prehistoric and modern man had to adapt both biologically and culturally. Since the formation of the present geological features of Asia during the period of mountain-building activity in the Middle Tertiary (about 35,000,000 BP [Before Present]) the continent gave rise to major taxa of primates that included the dryopithecine apes of the Miocene–Pliocene age (21,000,000 BP) and the earliest known hominid, *Ramapithecus punjabicus*. With the onset of the Pleistocene (about 2,000,000 BP), Asia was one of the habitats of the australopithecines, who, by middle Pleistocene times (500,000–200,000 BP), were replaced by *Homo erectus* forms. Evidence of Neanderthal man and later *Homo sapiens* (modern man) appeared during the upper Pleistocene, which began about 150,000 years ago. Thus, the major events of human evolution are represented in the paleontological and archaeological record of Asia.

THE FOSSIL RECORD OF PREHISTORIC MAN IN ASIA

Areas of human occupation. Human occupation in Asia from 100,000 years ago until about 35,000 years ago, a period that includes the geological-climatic events of the third interglacial and the initial glaciation of the Würm (Last) Glacial Period, was restricted to a considerable degree by the extension of ice sheets that covered portions of eastern Europe, the Tibetan plateau, and the diagonal mountain chains of Central Asia during periods of peak glaciation. These conditions blocked passage between Europe and eastern Asia save for narrow corridors not covered by ice. For this reason, high-altitude glaciated regions in western Asia and in the Himalayas are poor in prehistoric sites. The Bosporus remained dry land during much of the Pleistocene and formed the main avenue of communication between the Near East and the Black Sea. During periods of maximum glaciation, the Caspian Sea rose 250 to 300 feet (76 to 91 metres), and in this condition of flooding by waters fed by glacial melt it formed with the Volga River a spillway into the Black Sea. The Aral Sea enlarged in rhythm with the Caspian, and to the south and the east of the Ural Mountains a vast swamp marked the limits of glacial ice. With the onset of interglacials, of which the third is the one relevant to the period of time under consideration, these landlocked bodies of water became lowered while the Black Sea was elevated, since it was fed by oceans expanding in size from water liberated by melting marine glaciers. During these peak glaciation periods, portions of Asia were isolated from Europe.

Effects of glaciation

Thus, with the onset of the Würm glaciation some 70,000 years ago, climatic conditions effectively separated the Neanderthal populations of western Europe from those Neanderthals of western Asia whose occupation sites are recognized today in the Zagros Mountains of Iran and just north of the Elburz Mountains and Hindu Kush in Iran, Soviet Central Asia, and Afghanistan. With the onset of the second phase of glaciation (Würm II Stadial) 40,000 years ago and during a short period of milder climates in Europe and western Asia, the Neanderthal occupations were replaced by the sites of early modern hominids.

The Bering Strait formed an effective land bridge between northeastern Asia and the New World during the glacial epochs but ceased to serve as such with the elevation of sea levels during the Third Interglacial and again after the Würm glaciation. The former continental landmasses of the Sunda Shelf and Sahul Shelf in Southeast Asia were separated at the close of the Pleistocene as sea levels rose. These areas were dry during the Riss and Würm glaciations and provided a passageway for populations moving from Southeast Asia to Australia. The geographical boundary of Wallace's Line, running between Bali and Lombok, Borneo and the Celebes, Mindanao and Sangi, isolated the Australian fauna, including man, from Southeast Asia during the upper Pleistocene. South Asia was affected by glacial activity in the Himalayan region but in the south that area retained a tropical ecological setting throughout most of the Pleistocene. The upper Pleistocene of China is characterized by deposits of yellow earth, or loess, upon which man settled. The climate remained cold and dry for much of this period in China.

Remains of Neanderthal man. More than a dozen sites with fossils of Neanderthal man have been located in the Near East. Prehistoric research began there in 1864, when Louis Lartet (who later discovered Cro-Magnon man) rediscovered in Syria an ancient settlement observed some 30 years earlier. In 1878 an inventory of Stone Age artifact discoveries was compiled, but the first fossil find of early man in western Asia was made in 1900 at Grotte d'Antelias, in Lebanon. The remains of a seven-year-old child were recovered in 1938 in Lebanon at Ksar 'Akil, a rock-shelter near Beirut dated to 43,750 years BP. Discovery of an adult Neanderthal skull was made in 1925 at el-Zuttiyeh (Robbers' Cave) at Lake Tiberias in Israel—the "Galilee Skull" now datable to 70,000 years BP. In its vicinity is the cave of Har Qedumim (Jebel Qafzeh), where Neanderthal bones of comparable antiquity were recovered in 1933–35. The cave at Amud, also in this region, yielded in 1961 bones dated to the period of the Würm I Stadial of the last Ice Age (70,000–50,000 BP).

Neanderthaloids from western Asia

Near Jerusalem the Shuqbā (Shukbah) Cave contained human remains that had been deposited at the end of Neanderthal occupation of this part of Asia—*i.e.*, at about 35,000 years BP. The most critical discoveries in Israel are from two caves adjacent to one another in the Mt. Carmel range—Maghārat at-Tabūn, excavated in 1929–

Political divisions of Asia.

34, and Maghārat as-Skhūl, excavated in 1931–32. The age of occupation deposits at at-Tabūn ranges from 70,000 to 37,750 years BP. The occupation of as-Skhūl may have been slightly later, but both caves have yielded Neanderthal fossils with many physical features characteristic of later *Homo sapiens* hominids.

The original designation *Palaeoanthropus palestinus* assigned to the Mt. Carmel hominids was later dropped from use. The Turkish sites of Karain near Adala, excavated in 1949, and Musa Dağı have yielded teeth that may belong to the Würm I hominids, but the dating of these sites remains uncertain. Shanidar Cave in Iraq was excavated from 1953 to 1960. Its deposits range in age from 60,000 to 44,950 years BP and include the bones of a child and several adults. The two sites of Würm I date in Iran are the Kermanshah Cave, near Bisitun, and the Tamtama Cave, near Orūmīyeh (Urmia). Excavation of these fossil-bearing deposits began in 1949.

Fossils of Neanderthals were found in the Soviet Union in 1924 at the cave of Kiik-Koba, in the Crimea. Two skeletons, both missing skulls, appear to have been purposeful burials. The deposit dated to the early part of Würm I, while at another Crimean site, called Staroselye, excavated in 1952, the fossil remains date to 35,000 years BP. Teshik-Tash cave, in Uzbekistan, yielded in 1938–39 a child burial of the Würm I–II Interstadial, but the skeletal remains unquestionably belonged to a Neanderthal population. Less certain is the dating of an alluvial deposit containing some prehistoric human remains found in 1925 along the lower Volga River at Undory. Aman-Kutan Cave, in Samarkand, has the earliest dated fossil Neanderthal in Central Asia.

In eastern and Southeast Asia, hominid fossils resembling the western Asiatic Neanderthal hominids have been recovered from sites that date from the early part of the upper Pleistocene and even into the beginning of post-Pleistocene, or Recent, times (10,000 BP). The taxonomic status of these hominids is uncertain, but they have been given the colloquial appellation of Neanderthaloids, even though some populations of this hominid group were contemporaries of *Homo sapiens sapiens,* who emerged in western Asia, Europe, and Africa by the beginning of the Würm II Stadial of the last Ice Age, about 40,000 years BP.

Neanderthaloids from Southeast Asia and eastern Asia

Since the excavation in 1922 at Sjara-osso-gol River in Ordos, China has provided numerous loci with human remains. This site may have been inhabited contemporaneously with the occupation of the other Ordos site, Ti-shao-kou-wan, which was investigated in 1957. Both appear to be of upper Pleistocene date (*c.* 150,000–10,000 BP).

Earlier than these is the Ting-ts'un site, in Shansi, excavated in 1954 and dated to the Third Interglacial (100,000–70,000 BP). Still more ancient is the human skull from the cave at Ma-pa, in Kwangtung, which may be late middle Pleistocene; *i.e., c.* 125,000 years BP. Other series of Neanderthaloids appear in the fossil record of Java at the upper Pleistocene site of Ngandong, on the Solo River.

At the time of the excavation of 11 skulls from Ngandong in 1931–32, the specimens were named *Homo (Javanthropus) soloensis,* but modern systematists regard these fossils as similar to the Chinese Neanderthaloids and to the Neanderthals of western Asia. Two skulls from a limestone terrace overhanging an ancient lake near the village of Wadjak, in Java, were discovered in 1890, and these constitute the earliest discovered fossil hominids from Asia, although they were not reported until 1921. They have been dated to the very end of the Pleistocene or possibly to the beginning of post-Pleistocene times (*c.* 10,000 BP), but

Major sites of Upper Pleistocene hominid remains in Asia.

they resemble the Ngandong Neanderthaloid specimens in a number of striking ways. Fossil evidence of Neanderthal man has not been reported from southern Asia, although this region contains artifactual materials made by hominids of the period of time under consideration.

A few bone fragments from a late middle Pleistocene deposit (*c.* 125,000 BP) at Ushikawa, on the Japanese island of Honshū, were reported in 1957, but the bones are too incomplete to make possible a reliable identification of their taxonomic status.

Homo sapiens remains. In western Asia the first appearance of modern *Homo sapiens* coincides with the onset of the Würm II Stadial of the last Ice Age, about 40,000 years BP, approximately the same period of time that *sapiens* hominids replace Neanderthals in Europe and Africa. As noted above, Neanderthaloid hominids persisted in eastern and southeastern Asia until the close of the Pleistocene, but they appear to have constituted isolated populations in this part of the world, where modern-type *sapiens* had also appeared by late upper Pleistocene times (*c.* 30,000 BP).

The earliest date for *Homo sapiens* in Southeast Asia is 37,650 years BP, assigned to a skull specimen discovered in 1959 at Niah Cave, in Borneo. Late upper Pleistocene is also the date for the Chinese fossils found in 1930 at the Upper Cave of Chou-k'ou-tien, near Peking, in 1951 at Tzuyang (formerly Tzeyang), in Szechwan, in 1956 at Kai-t'o-tung in Laipin, Kwangsi, and at Ch'i-lin Shan, in the same province. Fossils were also found in 1958 at Chaisha (formerly Liukiang), also in Kwangsi; this site may have lower deposits dating to a period contemporary with the Würm I Stadial (70,000–50,000 BP), as is certainly the case at the site of Ch'ang-yang (Lungtung), in Hupeh Province, investigated in 1957.

Japan has yielded a *sapiens* specimen in the fossil record taken from Aichiken, in Honshū, in 1958, but the date can only be specified as upper Pleistocene. In 1921 a skull with Negrito or Pygmy features was reported from an alluvial deposit of the Río Pasig near Manila, but the dating of this specimen from the Philippines is uncertain.

Southeast Asia's record of *sapiens* fossils does not commence until the beginning of the geological Recent period (*i.e.*, after 10,000 BP), save for a single hominid lower molar found in northern Indochina in a deposit of uncertain antiquity. Similarly, southern Asia does not provide a *sapiens* fossil series for this period; the earliest skeletal remains, coming from Sai-Nahar-Rai near Allahabad in north-central India, date to 10,345 to 10,311 years BP.

Near Eastern *sapiens* fossils

The Late Stone Age (Mesolithic) site of Bellanbandi Palassa in Sri Lanka (Ceylon) has yielded a dozen skeletal specimens of *H. sapiens* from a deposit dated about 5000 years BC.

In the Near East, Lebanon offers two Pleistocene sites with *sapiens* fossils: a cave at Abri Bergy, near Antilas, which was excavated in 1948, and the previously mentioned site of Ksar 'Akil, which has a middle Würm deposit (*c.* 40,000 BP) superimposing the portion of the shelter from which the Neanderthal specimens had been removed in 1938. Similar hominids came from an upper level of the Har Qedumim cave, in Israel, as well as from the Mugharet el-Kebareh and Wādī Maghārah (Mugharet el-Wad) caves of the Mt. Carmel Range, where excavations in 1931 provided data on late upper Pleistocene occupations. At Malta, in Siberia, a late Würm (*c.* 15,000 BC) *sapiens* specimen was recovered in 1929, but other sites in the Soviet Union have provided few skeletal remains from this period.

MORPHOLOGY OF ASIAN FOSSIL REMAINS

Features of the skull

Neanderthal morphology in western Asia. The classification of upper Pleistocene Asian hominids as Neanderthal, Neanderthaloid, and sapient forms becomes meaningful when the physical anthropologist compares the osteological and dental anatomy of the fossils from the sites just discussed. Some Neanderthal specimens of western Asia closely resemble the Würm I Neanderthals of Europe with regard to the possession of a massive supraorbital torus (browridges), a low-lying forehead, large face with large eye sockets (orbits), large nose, dolichocranic or mesocranic cranial form, chinned or chinless mandible, bulging of the occipital bone (at the back of the skull) into a "chignon," taurodont molars, a cranial capacity with a mean of about 95 cubic inches (1,550 cubic centimetres), and a range from 78 to 104 cubic inches (1,270 to 1,700 cubic centi-

metres), inclusive, of both sexes, a modern-like dentition (apart from taurodonty), and a body conformation that was burly and muscularly well developed. The misconception that Neanderthals walked with slightly flexed knees and a hunched posture was based upon the examination of a Neanderthal skeleton from La Chapelle-aux-Saints, in France, an arthritic and aged male. The retroversion of the head of the tibia (large bone of the lower leg) was also considered to be indicative of a slumped posture and plodding gait.

Recent reinvestigation of the La Chapelle specimen and other Neanderthal skeletons does not indicate that this hominid's locomotor pattern was significantly different from that of later and modern hominids. Stature ranged from about 61 inches (154 centimetres) for females to 68 inches (173 centimetres) for males.

The Asiatic specimens that show the most striking physical resemblances to European specimens of Neanderthal man (such as those from La Chapelle-aux-Saints and La Ferrassie, in France, Spy, in Belgium, and the Neander Valley specimen, in West Germany) are from Amud and Shuqbā, in Israel, as well as some of the skeletons from the series of the Mt. Carmel caves, from Shanidar, in Iraq, and from Kiik-Koba, Aman-Kutan, and Teshik-Tash in the Soviet Union.

Other Neanderthal fossils of western Asia, however, bear closer phenotypic similarity to the Third Interglacial Neanderthals of Europe as represented in the sites of Ehringsdorf, East Germany, and Steinheim, in West Germany, and Fontéchevade, in France, where the specimens exhibit less morphological specialization than do the Würm I inhabitants of Europe. These Third Interglacial Neanderthals are more like modern hominids in their possession of lower mean cranial capacity, with a range of 67–89 cubic inches (1,100–1,450 cubic centimetres) for both sexes, the absence of an occipital "chignon," less muscular marking of the cranial vault, longer faces, and a tendency toward linearity of body build. The postcranial long bones are not bowed, as is the case with many Neanderthal specimens of Europe and western Asia of Würm I times. With these more modern-looking Neanderthals may be associated the western Asiatic fossils from Ksar 'Akil, in Lebanon, Har Qedumim, el-Zuttiyeh, and the majority of specimens from the Mt. Carmel series in Israel and those from the Soviet site of Staroselye. The specimens from Maghār-at at-Tabūn and Maghārat as-Skhūl have been studied in greatest detail and are recognized by most physical anthropologists as representative Neanderthal populations evolving into the sapient type of humanity that has dominated this part of the world for the past 40,000 years. For the other sites of western Asia noted earlier, either the fossil evidence is too fragmentary or the comparative anatomical studies are not sufficiently complete to permit classification beyond the statement that a Neanderthal phenotypic pattern seems to be represented.

Neanderthal morphology in eastern Asia. For the Neanderthaloids of eastern Asia, the fossil record is less complete. Incisor teeth from Sjara-osso-gol and Ting-ts'un are "shovelled," a feature found in high frequency among living peoples of modern Asia and not unknown among *Homo erectus* specimens at the middle Pleistocene site of Chou-k'ou-tien. Cranial bones from Ti-shao-kou-wan and Ma-pa are thick, the skull from the southern China locality having a capacity of about 75 cubic inches (1,225 cubic centimetres) as well as robust features similar to the skull vaults from Ngandong. Yet the Javanese skulls, which are 11 in number and the only case of a population series for this period of time, have a mean cranial capacity well under this value, the means for males and females being 71 cubic inches (1,158 cubic centimetres) and 64 cubic inches (1,042 cubic centimetres), respectively. The range of cranial capacity for the series is 63–77 cubic inches (1,035–1,255 cubic centimetres). In this feature the Chinese and Javanese Neanderthaloids do not resemble the Neanderthaloids of Broken Hill and Saldanha Bay, in Africa, but are more like the middle Pleistocene *Homo erectus* specimens from Asia, from which phylogenetic line they most likely evolved. Similarities with *Homo erectus* are also obvious in the pronounced angularity of the occipital bone (at the back of the skull), platyrrhinic nasal indices (indicating wide nasal openings in the skull), the thickness of the parietal bones (at the sides of the skull), and the location of the maximum width of the skull at points just below the parietal area. Yet the frontal torus (browridge) is of the divided pattern, as it is in Neanderthals, rather than forming a continuous bar. It is with the Wadjak specimens that cranial capacities increase to 94 cubic inches (1,550 cubic centimetres) for the female and 100 cubic inches (1,650 cubic centimetres) for the male. Specific features of large and chinned mandibles, broad and flat faces with broad noses and massive browridges, alveolar prognathism (forward projection of the tooth-bearing portion of the upper and lower jaws), and deep palates have led physical anthropologists to note the close similarity of the Wadjak specimens to modern aboriginal Australian and Melanesian populations rather than to modern Asians. Even less is known of the postcranial anatomy of these Neanderthaloids, but stature estimates based on two modern-looking tibial bones (from the lower leg) directly associated with the Ngandong crania suggest a height of about 70 inches (178 centimetres) for the male. The stature of the Ti-shao-kou-wan specimen is estimated for a thick-walled femoral (thigh bone) fragment as 66 inches (167 centimetres) if the specimen was male and 63 inches (160 centimetres) if female. The humerus (upper arm bone) from Ushikawa is thought to belong to a female less than 55 inches (140 centimetres) in height, and it differs from the humeri of modern Japanese by its narrowing of the proximal (shoulder) end and the pronounced thickening of the cortical area of the bone. The short stature and stocky body build of the greater number of Neanderthals and Neanderthaloids is considered by some anthropologists to have been an adaptive mechanism for surviving cold climatic conditions, where increased body bulk helps conserve body heat. Certain features of the Neanderthal-Neanderthaloid face have been explained as thermal adaptations to cold stress. The taller and more linear body conformation of the Solo specimens is especially interesting in view of the fact that this particular population lived in the tropical belt, where cold adaptation was not a factor of survival.

Skull morphology

Body build of Asian Neanderthals

The Asian sapiens fossils. The *Homo sapiens* fossil specimens are not unlike contemporary Asiatic populations, with the exception of the skull from Niah Cave, which resembles more closely the skulls of Australians than Borneans in structural features. Three of the seven specimens from the Upper Cave site at Chouk'outien have been compared to contemporary populations of Ainus, Melanesians, and Eskimos, and a broad range of phenotypic and polymorphic features may have been common in this part of Asia during later Pleistocene times (30,000–10,000 BP). Very similar to the skeletal anatomy of present occupants of eastern Asia are the specimens from Tzu-yang, Kai-t'o-tung, Ch'ang-yang, and Chai-sha, Kwangsi, save that the male postcranial skeleton from the latter site suggests a low height of 150 centimetres, which is just on the upper border of Pygmy stature. The skull fragments from Aichi-ken in Japan are sapient, as are the other fossil remains from upper Pleistocene sites in western Asia noted above.

LIFE-STYLES OF PREHISTORIC MAN IN ASIA

Stone-tool industries. The life of Asiatic hominids of this period can be reconstructed in large part from archaeological data of preserved stone tools and weapons. Two technological traditions are represented in deposits dated to the middle Pleistocene (*c.* 125,000 BP)—the bifacial-hand-ax and cleaver-tool industries of western and central Asia and the chopper–chopping-tool traditions of eastern and southeastern Asia. The transitional zone of these two traditions occurs in India, where it has been defined as the "Movius Line," after H.L. Movius, an American prehistorian who has conducted research in Asia. The bifacial-hand-ax and cleaver-tool tradition is called Acheulian in Europe, Africa, and western Asia, where it appears stratigraphically earlier than the flake-tool industry called Levalloisian, although flakes and bifaces occur together in some sites in this area.

Acheulian and Levalloisian tool traditions

Acheulian hand axes have been found in deposits in the caves of Mt. Carmel, in Israel, in Jordan and Syria, Turkey, Arabia, Iran, Iraq, Afghanistan, and eastward to Armenia, the Crimea, and the Caucasus Mountains. The Narmada Valley of India is particularly rich in hand axes, the first discovery of a paleolithic tool in South Asia having been made in the Madras area of India as early as 1863. Levallois flakes made by a prepared core technique occur in increasing frequency with the dawn of the upper Pleistocene in India, where they are a final phase (dating from *c.* 150,000 years ago) of another flake-tool tradition, called Soan. Apart from a few isolated cases of hand axes in China, the only place in Southeast Asia where these tools appear is in Java, where they are associated with the Patjitanian tool industry, which also has certain Levalloisian features. Chopper–chopping tools also appear in Java during this period, as do tool industries called the Sangiran flake industry and the Ngandongian industry. These are marked by the presence of antler picks, stingray barbs, and bola stones as well as small stone flake tools.

With the advent of colder climatic conditions and the onset of the Würm I Stadial (70,000 BP) in western Asia, the bifacial-hand-ax industries were replaced by flake-tool traditions; one of these was an evolved Levalloisian and another the Mousterian tool industry, in which stone flakes were retouched to make tools but not specifically manufactured from prepared stone cores. The Mousterian tradition is intimately associated with Neanderthal man in western Asia, as is seen at Ksar 'Akil, the caves of Mt. Carmel, a number of sites in Jordan and Syria, Kiik-Koba in the Crimea, Shanidar in Iraq, Teshik-Tash in central Asia, Molodova in the western Ukraine, and far eastward in the Ordos region near the Great Wall of China. In southern Asia, the later phase of the Soan tool tradition resembles the Mousterian. Elsewhere in eastern and southern Asia, the chopper–chopping-tool tradition persisted until the close of the Pleistocene (*c.* 10,000 BP). In Burma, in the vicinity of the Irrawaddy River, a silicified wood or tuff was manufactured into choppers and retouched flakes. These tools represent the Anyathian industry. The Tampanian industry of Malaysia is another local variation of the chopper–chopping-tool tradition. On the shores of the Sea of Azov in the southern U.S.S.R. this tradition merged with the limits of diffusion of the Mousterian tradition. At the upper Pleistocene localities of Chou-k'ou-tien, quartz flakes with working at both ends occurred with choppers, chopping tools, and small scrapers. A tool tradition of flaked stone balls and bifacial choppers but no bipolar flaking is called the Fenho industry, and its Third Interglacial date marks the transition to the upper Pleistocene traditions that have features of the Asiatic Mousterian in combination with older styles. In eastern and southeastern Asia many elements of this culture persist into terminal Pleistocene times, when Mesolithic cultures, characterized by small-blade microliths, replaced the older traditions.

Mousterian tool industries

Fire, shelter, and cultural data. Human occupation during the upper Pleistocene included the areas inhabited by *Homo erectus* of the middle Pleistocene as well as extensions into areas that earlier hominids had not entered. Biological and cultural adaptation to cold climatic conditions permitted settlement of higher altitude regions of Asia, and with the retreat of the ice sheets man followed game fauna into the newly opened country. Cold climates were made more tolerable by the use of caves and rock-shelters, some of which served as places of burial as well as hearths and industry sites. Open-air encampments continued to be used in some regions, however. Fire, which has been reported in Asia as early as 360,000 years ago from evidence of charcoal and charred bone at the *Homo erectus* deposits of Chou-k'ou-tien, in China, was controlled by the hominids of the upper Pleistocene, thus enabling them to move into wider areas of settlement and survive under a wide range of ecological settings. The control of fire by man, along with cave dwelling and the wearing of skins sewn together with bone awls, enabled prehistoric man to survive the cold conditions of the later upper Pleistocene. Traces of fire are found in most of the open-air, cave, and rock-shelter sites where skeletal and artifactual remains have been preserved, but the traces of charcoal and calcined bones do not appear in disturbed deposits, as at Ngandong. Among the undisturbed sites are the caves at Mt. Carmel, Aman-Kutan, Molodova, and Ch'i-lin Shan. Neanderthal man practiced burial of the dead at the Mt. Carmel caves, Kiik-Koba, Teshik-Tash, in the Upper Cave of Chou-k'ou-tien, Ksar 'Akil and Malta. At Molodova, the remains of a hut can be identified by the oval of mammoth bones and tusks enclosing some 15 separate hearths. This is evidence of open-air housing during a warm phase of the upper Pleistocene, although caves and rock-shelters continued to be the most common form of habitation in areas where they were naturally present. Evidence of cannibalism occurs at Solo, as it does in several Neanderthal sites of Europe. The presence of diseased and aged individuals in the Neanderthal community at Shanidar speaks of a more humane aspect of upper Pleistocene life. Pictorial or plastic art does not appear in the archaeological record for Neanderthal man and emerges only with the presence of *Homo sapiens.*

Fire and shelter

Throughout a broad geographical range of habitation in the Asiatic landmass, upper Pleistocene hominids were successful hunters of large game animals. For the western and central Asiatic Neanderthals these were Paleoarctic fauna, which can be identified as cold adapted or warm adapted according to their occurrence in periods of high glaciation or interglacial–interstadial recessions of the ice. In Israel, the warm-climate fauna are marked by remains of hippopotamus and rhinoceros, cold-climate fauna by deer and antelope. In central Asia the cold-adapted woolly rhinoceros, mammoth, and reindeer were abundant. South and Southeast Asian fauna were distributed also in southern China and merged with the Paleoarctic fauna of northern China. In India, some of the fauna of the middle Pleistocene survived until well into the late upper Pleistocene, as suggested by the presence of certain species of bovids. The persistence of tropical conditions throughout much of the Pleistocene in southern and Southeast Asia gives a very different faunal picture from that of western and Central Asia.

PHYLOGENETIC AFFINITIES OF ASIAN FOSSILS TO MODERN MAN

Physical anthropologists are cautious in assuming phylogenetic affinities of living human populations to specific hominid fossil specimens of the Pleistocene, although some scholars have asserted that the living races of man can be recognized in the ancestral hominid record as far back as the middle Pleistocene. Beyond a few thousand years, however, physical resemblances of particular osteological or dental features between living and extinct populations become fewer in number and more tenuous as reliable data for establishing phylogenetic lines and classifications, and it is no longer a common practice in physical anthropology to attempt a "racial phylogeny" for a population beyond the limits of a few millennia. The traditional racial categories of Veddoid, Caucasoid, Mongoloid, Australoid, and the like are no longer regarded as particularly meaningful in relation to knowledge of prehistoric man.

In western Asia, the Natufian people of the Mesolithic of Israel do not resemble the present populations of the Near East; hence, it is not surprising that still earlier hominids, such as the Neanderthals of western Europe, fail to reflect obvious connections with contemporary Israelis, Lebanese, Syrians, etc. In Southeast Asia, the Neanderthaloid specimens from the sites of Solo and Wadjak in Java and Niah Cave in Borneo do not resemble the present inhabitants of mainland and island Southeast Asia, although some features of Neanderthaloid crania appear in the contemporary native populations of Australia and Melanesia. With the coming of Mesolithic (Middle Stone Age) post-Pleistocene cultures (after 12,000 BP) in Southeast Asia, the populations bearing these new traditions are represented in the osteological record by only a few specimens that are similar in anatomically significant ways to modern Southeast Asians. The earliest known fossil specimen of a Pygmy or Negrito population in Asia has come from Indochina, but it is only as ancient as the Neolithic Period of culture (*c.* 8000 BP). The antiquity of Pygmy populations in Malaysia, the Philippines, Anda-

Affinities of pygmy peoples

man Islands, and New Guinea remains unknown, but it no longer seems reasonable to conceive of a "Pygmy race" binding these dwarfed Asiatic groups to Pygmies of Africa. Pygmy populations of Asia bear many more resemblances of physical characters to the macropopulations surrounding them than to more distant Pygmy populations.

Skeletons that can be reasonably identified as Chinese first appear in the Far East around 3000 BC, although some phenotypic variables, such as shovel-shaped incisors, which appear in high frequency in populations of Asiatic descent, occur as well in *Homo erectus* fossils from Chouk'ou-tien. The high frequency of Chinese characters in the indigenous populations of Southeast Asia is explained by historic movements of Chinese into regions to the south of their ancient cultural area. In southern Asia, the hominid skeletal record has been recognized as useful in drawing some phylogenetic affinities between living Indians and their ancestors of a few thousand years ago, but the evidence for Pleistocene man in India was established upon the discovery of stone industries rather than upon a rich fossil record. It is with the food-producing Neolithic (New Stone Age) cultures of Asia that biological similarities between extinct and contemporary human populations become apparent, but this represents an antiquity of only four or five millennia. It was from Asia that man moved last to the uninhabited vastness of Oceania, Australia, and the Western Hemisphere. Movements of Asian people into Europe has continued to the present day in eastern Europe and the Aegean. (K.A.R.K.)

The ancient world

The history of Asia in the past 2,500 years is primarily the result of the interaction of five main influences: (1) Chinese, (2) Indian, (3) Islāmic, (4) European, including Russian, (5) Central Asian. Of these, the first four represent different kinds of civilization. The fifth has little originality but has been of significance in affecting the distribution of peoples and of political power.

China has molded the civilization of eastern Asia including Japan, Korea, and Annam and has been a primary influence on Mongolia, Tibet, Thailand, Kampuchea, and Burma. Wherever Chinese influence exerted itself, it introduced Confucianism, a distinctive style of art and, above all, the Chinese script.

Hindu and Buddhist influences

Indian influence has mainly expressed itself through Hinduism and Buddhism. These are not merely religious in nature but have carried with them Indian art and literature and often an Indian alphabet, as in Tibet, Java, and Kampuchea. Indian influences have affected the peoples of Central Asia and Southeast Asia, including the Malay Archipelago (the East Indies) and Indochina. Buddhism spread into China and Japan, but Indian culture on the whole has itself been little affected by Chinese art, literature, or ethics.

Islām spread widely in all directions from its original home in Arabia. It subjugated Southwest Asia, in which it is still the principal religion, and also eastern and northern Africa. It spread for a time into eastern Europe and Spain. In the other direction it got a firm hold in the northwest and northeast of the Indian subcontinent, and the states of Pakistan and Bangladesh now cover these two areas. Beyond India it reached the Malay Archipelago (the East Indies), where it submerged earlier Hindu influences. Through Central Asia it reached and affected China, but it gained no foothold in Japan and Indochina. Islām, like Buddhism, took with it everywhere a special style of art and culture. It was usually accompanied by the use of the Arabic alphabet, and the vocabulary of this language forms a large part of the languages of the Muslim peoples.

Central Asia has been the region into and through which these various powerful influences have been projected. Archaeological excavations have shown that early in the Christian Era there flourished in the Tarim basin small states, such as Khotan and Kucha, which possessed a mixed culture comprising Chinese, Indian, Iranian, and even Greek elements. Buddhist, Christian, and Manichaean edifices have been found as well as libraries in many languages, two of which were previously unknown. Through Central Asia, Greek influences and later Islām penetrated India, and Buddhism passed from India into the Far East and into parts of Southeast Asia.

The various tribes or peoples of the area have no common name. Linguistically they fall into several groups, such as Turks, Mongols, and Huns; and, in the face of difficult communications and terrain, only occasionally did several of the groups come together in one state. In history, Central Asia has acted rather like a sponge, absorbing pressures and sooner or later transmitting them. Time and again these pressures have produced invasions of the peripheral regions, and in the Christian Era the following may be mentioned: the early invasion of Europe by the Avars, Huns, and Bulgarians; the conquest of northern India by the White Huns; the conquest of Russia by the Mongols; the conquests of Timur; the conquest of Asia Minor and eastern Europe by the Turks; the invasion of India by the Mughals; the conquest of China first by the Mongols under Kublai Khan and later in the 17th century by the Manchus.

THE MIDDLE EAST

The ancient Middle East, or Near East, is a historical concept denoting the extent, in space and time, of the earliest civilized societies. Through archaeology, it is known that in this area the change from food gathering to food production first began and that the diffusion of agriculture, not only in the knowledge of grains but also in the technique of harvesting, took place. Toward the 3rd millennium BC the emergence of river-valley civilization in Mesopotamia and Egypt set this area apart from the peasant cultures of the rest of Asia and Europe. The cradle of Mesopotamian civilization was the southernmost part of the Tigris–Euphrates valley, and there the first cities arose. As is known from the remains of their pottery, the earliest settlers of this marshy plain had descended from the highlands of southwestern Persia. These people were probably Sumerians, speaking a very remarkable language, which has not been brought into relation with any known tongue. Physically they belonged to the Mediterranean group of peoples. The high civilization of the Sumerian south penetrated the Semitic-speaking peoples of the middle regions of the valleys, whence arose the Akkadian dynasty under the ruler Sargon. The Akkadians finally absorbed the Sumerians, and out of this mixture emerged the state of Babylon under Hammurabi, the lawgiver, in the 18th century BC. But the epics and books of wisdom of the Sumerians remained the classical texts of both Babylonians and, later, Assyrians. The Sumerian civilization had invented writing, at first as a practical requirement of the organization of their temples. They used pictograms, later supplementing them with phonetic signs. The form of the society that built the earliest cities has been called theocratic socialism. Its basis was a well-balanced mixed economy in which agriculture, stock breeding, and hunting existed side by side. Through the export of rugs and textiles, weapons and jewelry, the influence of Sumerian civilization permeated the whole of the ancient Middle East.

Tigris–Euphrates valley

The Babylonian state collapsed before invaders, the Kassites, from Elam, who controlled Babylon for five centuries. They adopted the civilization and Semitic language of their subjects. The Hittites, who first invaded Babylonia about 1595 BC, created a considerable empire covering northern Syria and the greater part of Asia Minor in the 14th century BC. In the archives found at their capital, eight languages are represented, including Sumerian and Akkadian. Subsequently the Assyrians, who seem to have been an offshoot of the Babylonians using almost the same language, asserted themselves and in the 11th century BC became the chief power. Their empire gradually broke up, finally succumbing before the Medo-Persian power at the close of the 7th century BC. Babylon itself was taken by the conqueror Cyrus the Great of Persia in 539 BC, but its culture and religion continued to exercise great influence long after the Persian conquest.

In Egypt the cultural continuity was even stronger than in Mesopotamia, and there was never any change corresponding with the displacement of Sumerian by Akkadian in Mesopotamia. Whereas that land was dotted with au-

Egyptian civilization

tonomous cities, Egypt began in the upper reaches of the Nile Valley as a royal domain, which extended to cover the whole valley and to found a 1st dynasty about 3100 BC. The administration and major activities of society were centralized to an extreme degree; and it was accepted that in the person of pharaoh, the living king, a god had taken charge of the people. With relatively minor breaks the established order continued for many centuries, Egyptian influence at times reaching eastward to the upper Euphrates. Up to about 1200 BC the history of the ancient Middle East had passed through two main phases, the emergence of the first great civilization in Mesopotamia and Egypt and subsequently the gradual spread of that civilization to the periphery. About 1200 BC new waves of invaders broke into Asia Minor and the Levant, destroying the Hittite Empire and disrupting Egypt, and after this the creative power of the Middle East waned. Its main achievement was in the consolidation of acquired knowledge. From this period the centres of power move both to the west and to the east of Egypt and Mesopotamia.

As has been seen, Persian power in the 6th century BC destroyed the Assyrian Empire and in 539 BC captured Babylon and created the Achaemenid Empire. The Persians, with whom the Medes are often coupled, appear to be Aryan in origin, their language and religion offering remarkable analogies to those of the early Hindus in India. These two peoples appear to have had a common origin in central Asia. The Achaemenid power at its greatest extended from the Oxus and Indus in the east to Thrace in the west and Egypt in the south, but it fell before Greece after lasting for more than 200 years. Darius and Xerxes were repulsed in their efforts to subjugate the Greek peninsula; and Alexander the Great of Macedonia conquered their successor, Darius III, in 331 BC. But the greater part of the empire continued to exist under new masters, the Seleucids, as a Hellenistic power that was of great importance for the dissemination of Greek culture in the east. About the same period (227 BC–AD 226) the Parthian Empire arose under the Arsacids in Khurasan. The Parthians were probably a Turanian tribe who had adopted Persian customs. At one time their power stretched from India to Syria. They withstood the Romans but succumbed to the Persian dynasty of Sassanids, who ruled for about four centuries, establishing the Zoroastrian faith as their state religion and maintaining an equal conflict with the eastern Roman Empire. But in the 7th century AD their power was overwhelmed in the first rush of the Muslim conquest that established Islām in Persia and in the neighbouring lands.

INDIA AND INDIANIZED ASIA

The subcontinent of India is divided from the rest of Asia by the Himalayan mountain ranges. This has by no means kept India in isolation, but it has resulted in the growth over a period of two to three millenniums of a Hindu civilization that in many of its aspects is unique. Archaeologists have unearthed the remains of a city civilization on the upper Indus valley that appears to have flourished in the 3rd millennium and to have had affinities with Sumerian civilization.

'he
.ryans

Hindu civilization came about in the 1st millennium BC as a result of the intermingling of Aryan and pre-Aryan cultures. Entering India sometime between 1800 and 1500 BC, the nomadic Aryans settled in the northwest, thence gradually during the 1st millennium BC encroaching eastward on the pre-Aryan peoples in the Ganges valley and producing a multiplicity of settled states and a fusion of cultures. Society came to be dominated by a hereditary priestly class of Brahmans. Political multiplicity is a characteristic of India's history, and the occasions on which most of the subcontinent was united under one rule were few and relatively brief. Such periods occurred during the Mauryan rule of Aśoka in the 3rd century BC, the Delhi sultanate in the 13th and 14th centuries AD, the Mughal Empire of the 17th century, and British rule in the 19th century.

India lacked a common political consciousness probably because its social consciousness had developed so strongly. The Indo-Aryan culture of the northern plains spread across the southern part of the peninsula during the second half of the 1st millennium BC, and the Dravidian peoples of the south (Tamils, Kanarese, etc.) were at one with the north in accepting Hinduism and the caste system, a division of the population into groups, based partly on race, partly on occupation. In Hinduism, India cradled the oldest surviving world religion. India's greatest achievements lie in the intellectual and cultural field, and its religious and philosophical systems and Sanskrit literature stand among the finest achievements of the human mind. From the 4th century BC two scripts were in use—Kharosthi in the northwest and the more important Brahmi elsewhere. From the latter, regional modifications developed not only for India but also for Central and Southeast Asia. Indian grammar, law, architecture, sculpture, painting, music, arts, and such crafts as metal casting, enamel work, jewelry, and ivory and wood carving were highly developed. In India the invention of calculation on a system of nine digits and zero took place. Indian art and science grew directly from its religions and philosophies.

In the main this was a Brahmanical achievement, but in the 6th and 5th centuries BC various reactions to Brahmanism began, the most important being the doctrines of Gautama Buddha, which in the form of Buddhism grew into one of the greatest religions in the world. For many centuries the intellectual development of the Hindus depended mainly on the interaction of Buddhism and Hinduism, but Buddhism was finally absorbed and disappeared in India. But it proved acceptable on the frontiers and spread far and wide. Ceylon was converted. In the northwest it crossed the passes into Afghanistan and moved along the trade routes through Turkistan into China, bearing with it in literature, sculpture, and painting various material forms of Indian culture. It passed into Korea and Japan, gradually adapting itself to its new environments. In the 7th century AD Buddhism was imposed on Tibet, and the country remains a stronghold of the faith. To the south, in the early centuries of the Christian Era, Buddhism followed the trade routes across the seas to Southeast Asia; and, as a result, mixed cultures sprang up in which Indian influences are discernible. In this direction, unlike the movements to the north, Hinduism also followed Buddhism; and petty Indianized kingdoms in Burma, Thailand, Malaya, Indonesia, and Indochina were set up, and a movement of traders, scholars, and travellers took place. Some of the greatest surviving architectural creations in the Indian world—for example, Borobuḍur and Lara Jonggrang in Java and Angkor Wat in Kampuchea—were conceived and built in Southeast Asia. The kingdom of Champa in Indochina marked the farthest reach of Indian culture. There it came directly into contact with Chinese civilization, which had molded the adjacent empire of Annam. Champa was overrun by Annamite armies in the 15th century AD.

Spread of Indian influences

In general, the contacts between India and the west took place on the material plane. Trade, for example, between the Roman Empire and Southeast Asia via southern India was considerable even in the early centuries of the Christian Era. On the whole, western Europe was little affected by India until the end of the 18th century.

SOUTHEAST ASIA

The peoples of this extensive region belong to many races, of whom the first with a determinable history were the speakers of the Mon-Khmer languages still used in Pegu Division of Burma and Kampuchea (historical Cambodia). Early in the Christian Era, Indianized kingdoms were established in Cambodia and in Champa.

Cambodia. The earliest Cambodian, or Khmer, kingdom, founded in the 1st century AD, is known only by its Chinese name, Fu-nan. Many of the features that distinguished later Khmer kingdoms made their first appearance in Fu-nan between the 1st and 6th centuries. Based upon the Mekong delta and a well-developed irrigation system, Fu-nan was prosperous and carried on a flourishing trade with China and India. As a kingdom it was organized in the Indian fashion, with a god-king reigning from a holy mountain in the capital at Vyadhapura (Ba Phnom) over surrounding vassal kingdom that extended from southern Vietnam in the east to the Malay Peninsula in the west

and northward over the Korat plateau. Continuous contact with India gave Fu-nan a cultured bureaucratic elite, accomplished in the arts and sciences and techniques of statecraft and artistic expression, while the social structure, manner of life, and beliefs of the Khmer peasant remained fundamentally unchanged.

Internal dynastic struggles brought about the fall of Funan in the latter half of the 6th century and of its successor state, Chen-la, founded on Phum Basac in the middle Mekong valley, in the 9th century. It was Jayavarman II (reigned *c.* 790–850) who established the capital in the region of Angkor, where he and his successors constructed grand monuments. The power of the Khmer Empire reached its height under Suryavarman II (reigned *c.* 113–*c.* 1150), who built the famous Angkor Wat, the ruins of which still stand. His armies ranged as far as North Siam in the west, the Bay of Ban Don in the south, and as far north as the fringe of the Red River delta of Tongking.

Zenith of Khmer empire

Domestic instability caused by the accession of weak rulers to the monarchy left the Khmers open to the attacks of their neighbours, and their difficulties were compounded when Buddhism began to undermine the Brahmanical hierarchy of the state; yet Jayavarman VII (reigned 1181–*c.* 1215/19) was able to extend the empire farther afield than any of his predecessors. The empire quickly crumbled in the 13th and 14th centuries; first as the Thai in the west seized power from their Khmer overlords and the Chams expelled an occupying army, and then as the Mongols extended their support to the Thai and Chams, invading Cambodia from Champa in 1283.

Champa. Champa was an ancient kingdom of Indochina extending over the southeastern coastal region of modern Vietnam from Tourane (Da Nang) in the north to Cape Varella in the south. It was occupied by the Chams, a people of Indonesian stock who had come in contact with the higher civilizations of the Chinese then ruling Tongking and of Indian merchants from overseas. This latter Indian influence prevailed, and Champa became a powerful state, second only to the Khmer Empire of Cambodia.

Appearing during the 2nd century AD under the name of Lin-yi in Chinese histories, Champa first comprised four small states named after Indian regions: Amaravati (Quang-nam), Vijaya (Binh-dinh), Kauthara (Nha-trang), and Panduranga (Phan-rang). Unified later under strong dynasties, these states disappeared one by one in the same order (from north to south) in the course of 14 centuries during which the Chams retreated under the pressure of the Vietnamese. Eventually the race was almost completely annihilated.

The Burmese

Other peoples. Meanwhile, the Burmese, who are linguistically allied to the Tibetans, entered Burma from the northwest. By the 16th century, Burma had become a united kingdom. The Thais, or Siamese, who speak a language of the Chinese type but use an Indian alphabet, infiltrated from southern China and took power in Thailand in the 13th century. The Annamites and Malays are discussed above. All these peoples have been closed about by the cultures of India and of China, and the higher elements of their civilization have been taken from these two primary sources.

EAST ASIA

China and Sinicized Asia. Chinese civilization appeared in northern China in the latter half of the 2nd millennium BC. The discovery at An-yang in Honan province in 1899 of thousands of bone fragments, many of them inscribed, has confirmed the existence of the Shang dynasty (18th–12th century BC), which previously had been thought to be legendary. Early Chinese civilization grew in the Huang Ho plain extending southward toward the Yangtze and westward and northward along the Wei and Fen valleys in Shensi and Shansi provinces. During the Chou dynasty (1111–255 BC), the great formative age of Chinese civilization, the intervening areas populated by groups of a lower culture were conquered and absorbed.

In Han times (206 BC–AD 220) the centre of Chinese culture was still in the north, but by the Sung dynasty (960–1279) the Yangtze valley began to outweigh the north in population and importance. Chinese expansion to the north, which reached the steppelands during the Chou dynasty, was much slower, and it came to a halt on the steppe, among the nomadic herdsmen, where the Chinese system of settled agriculture could not be applied. This conflict between two ways of life resulted in the building by the Chinese of a series of defensive walls, finally linked together by the Ch'in dynasty into the Great Wall.

Korea and Annam came under Chinese dominance in the Ch'in-Han period, but the former broke free again in the 4th century AD and the latter in the 10th century. Both absorbed Chinese culture. On the other hand, Japan, which was a united power by the 4th century AD, never came under Chinese rule. Japan, however, received the first elements of higher culture from China through Korea, and in later times Japan set itself with determination and success to absorb Chinese culture.

In early historical times in China, society was dominated by a hereditary ruling class whose religion, involving the cult of heaven and of the family and clan, was not shared by the masses. The rulers were the custodians of the written language and of the traditions, and the scholars among them gradually formed during a period of political troubles a system of ethics and political theory that the philosophers Confucius and Mencius preserved and transmitted to posterity. These thinkers, moreover, had evolved the rational, ethical ideal of the ruler, the "son of heaven," holding the mandate of heaven but not himself divine, and capable of being replaced if his conduct betrayed his position. Theirs, too, was the ideal of the supremacy of learning and of the scholar-ruler that became the accepted standard of the mandarin (higher civil-service) administrator of Imperial China.

Many centuries passed, however, before the ideal of government through bureaucracy, selected on the basis of learning, reached its fulfillment. Not until the T'ang dynasty (AD 618–907) was the examination system, through which the mandarins were selected, functioning fully. This administrative system undoubtedly provided the backbone of the remarkable political continuity of the Chinese Empire and helped to strengthen the ideal of political unity, "all under heaven," which was throughout a feature of Chinese political theory. The actual achievement of unity under the Ch'in dynasty (221–206 BC) set the standard for the following 2,000 years, a unity that persisted through about 20 successive dynasties. Different as was the empire of the 19th century from that of the Ch'in, it had in fact undergone no major political revolution in the interim. Rebellions might take place, provinces might break away, rulers might change or be changed, but the system persisted.

The Ch'in dynasty

China's artistic achievement, like its ethical and political system, was greatly influenced by the scholar bureaucracy. This is especially true of those arts that were based on the written character, whether in the form of literature or calligraphy or a great deal of Chinese painting. But the mainstream of Chinese culture was also affected from the outside. New ideas, especially in the early centuries of the Christian Era, entered freely from India and the Iranian world. Of these, Buddhism was much the most important, competing with Confucianism for the allegiance of the upper classes, deeply penetrating the later Taoist religion, and providing a pattern for the organization of the Taoist Church. With Buddhism, too, came a deep influence on all Chinese art.

An outstanding characteristic of Chinese civilization was its inventiveness, which produced, among other things, paper, printing, gunpowder, the mariner's compass, the sternpost rudder, and the wheelbarrow. Chinese silks, ceramics, jades, and bronzes early found a market in other parts of Asia and in Europe. The expansion of the Western (Former, or Earlier) Han dynasty (206 BC–AD 25) into Central Asia opened up a major caravan route through Turkistan that for centuries provided a link with the Roman world. China's relations with the nomad peoples affected the movements of peoples throughout Central Asia, from time to time creating repercussions in the Middle East, in Europe, in northern India, and in Iran. By the 2nd and 3rd centuries, Chinese influence was felt in Korea in

the north, and a southern sea route was opened from India and the west around Malaya to Annam and southern China; and by these land and sea routes trade and travellers passed freely. After the rise of Islām in Southwest Asia, trade by sea flourished, and Arab ships were to be seen at Canton and Chinese junks in the Persian Gulf.

In the 8th century the caliphate and the T'ang empires came into direct land contact and conflict (AD 751). Overland contact, interrupted from time to time by the pressures of the steppe peoples, was maintained from this time until the 13th century. Then a sudden major outburst of the Mongols created for a short period a single empire reaching from southern Russia to the Pacific, allowing Europeans for the first time to visit and write about China. The Mongol Empire soon dissolved, but the legend of Cathay that was born in European minds lived on and, in the 16th century, played its part in inducing the Portuguese to venture around the Cape of Good Hope and the Spaniards to cross the Pacific. Thus there came to the West a more detailed knowledge of Chinese civilization, which in the 18th century created in Europe a craze for things Chinese. But by this time the Chinese Manchu Empire was decaying, its administration corrupt and its inspiration dead.

The Mongol empire

Japan. Japan had early begun to assimilate Chinese culture introduced both directly and via Korea, and in AD 645 a deliberate and wholesale introduction of Chinese forms of government took place. But the Imperial administration remained subordinate to a number of great landed-warrior families who fought among themselves for control of the country. The Fujiwara, the Taira, and the Minamoto bore the brunt of the struggle, the Minamoto emerging victorious and in 1192 establishing a dual system under which an emperor ruled in name while the real power rested in the hands of a hereditary military chief called the shogun. This system was carried on by the Ashikaga family (1338–1573) and the Tokugawa family (1603–1868). In the 16th century the Portuguese reached Japan and attempted to introduce Christianity. In the resulting ferment, ideas of conquest developed among a remarkable group of leaders, one of whom, Hideyoshi, organized the invasion of Korea. Death interrupted his plans, and a reaction set in under his successor, Ieyasu, who decided on a policy of isolation. Christianity was forbidden, and Japan was closed to foreigners, and it so remained until after 1854. The early history of Japan was chiefly remarkable for the single-minded way in which its people were able to close ranks and follow a set line of policy such as deliberately setting out to copy Chinese culture, adapting Chinese forms of government, or shutting out the foreigner.

Islām

The term Islām covers the peoples and states that accepted the faith and law of Islām and professed to live by them. Islām begins with the life and teaching of the prophet Muhammad in Arabia in the early 7th century AD. The first Muslim state in Medina erupted in successive waves of conquest over Arabia into the Fertile Crescent and across Persia into Central Asia. Its influence reached into China and northern Asia; at the same time, it had also pushed westward across northern Africa to the Atlantic. Fresh impulses of conquest took Islām into southern Europe and through Spain into France. By sea first and then by land, Islām was also carried into India, thence by sea again southeastward to Malaya and the East Indies. The heart of the Islāmic world, however, was and is the Middle East. The caliphate under the Umayyads of Damascus (661–750) and then the 'Abbāsids of Baghdad (750–1258) became the principal power.

Early conquests

Wherever Islām was accepted it carried with it a sense of unity based on its strictly formulated faith and on its holy law, which, despite much variation of custom over so vast a zone of conquest, remains a common ideal and pattern of belief and conduct for the whole Muslim world. Wherever it has gone it has taken its language, Arabic, which is the holy tongue of Islām, the language of the Qur'ān and of the traditions of the Prophet. Almost all the languages of the Muslim world have borrowed heavily from Arabic and are written in its script. The art and architectural forms of Islām, too, are distinctive, proclaiming the unity of the Islām cultural pattern. Through their military and political power, reinforced by their culture, the Muslims brought together two formerly conflicting worlds, the diversified Mediterranean tradition of the ancient Middle East, Greece, and Rome and the rich civilization of Persia, a fusion which produced great scientific and philosophic developments. Islāmic scholars preserved something of the heritage of Greek antiquity, which was later handed on to Christian Europe. Through the Arabs the Chinese art of papermaking and the Indian system of numerals reached Europe.

Arab power was explosive and quickly burned itself out, and by the 11th century fissiparous tendencies produced a singularly complete collapse of the empire of which the European crusaders and traders in the 12th and 13th centuries took advantage by invading the Middle East. But the peoples on the periphery carried Islām with them. The khanate of the Golden Horde, which between 1241 and 1395 ruled from the Danube to the Urals, was a Muslim state, as also were its successors in the Crimea, the Caucasus, and the Volga. In the 14th century the Islāmized Ottoman Turks brought large areas of Europe under Muslim rule and created an Ottoman Empire that lasted until 1922. Muslim dynasties ruled in Persia, and Islām was carried through Central Asia in two main waves into northern India by the Turks (1000–1526) and the Mughals (1526–1707). The Muslims never fully subjugated southern India, but their rule in the north under such rulers as Akbar and Shāh Jahān was brilliant, both politically and culturally. But Hindu powers, especially in western India, struck back at the Muslims in the 17th century, creating disorder and disrupting the empire. In these disturbed conditions, European trading companies already established on the Indian coasts, especially the English and the French, were drawn in to compete for political supremacy.

Through trade Islāmic influence had reached out in the 16th century from India to Malaya and Indonesia, peacefully overlaying Hindu culture in the main centres, though not in Bali.

The influence of Asia on Africa was until the 19th century greater than that of Europe. The ancient Middle East drew on the resources both in men and material of the regions beyond the Upper Nile Valley. The ancient Abyssinian kingdom was founded by Semites from southern Arabia, and Islām penetrated both north and south of the Sahara across to western Africa. There was a continuous Arab migration to eastern Africa, resulting in the founding of a series of cities on the coast. There was also an ancient connection between India and eastern Africa, which was reinforced in the 19th century by Indian immigration.

Asian influences in Africa

The great civilizations of Asia spread out over immense areas. Although they were separated one from the other by distance and slow communication, their contacts were numerous and between them the cross-fertilization of ideas and material culture was extensive. They were slow growing and slow changing, based in the main on subsistence economies. Their upper classes, however, created an active trade in ideas and luxury goods and in each civilization developed a way of life, whether Indian, Chinese, or Islāmic, that was chiefly remarkable for its inner harmony. Each religion or ethical code formed a way of life for its peoples, and all aspects of life served to express this. Nevertheless, that their ways of life were very different one from the other is to be seen, for example, in their respective attitudes toward history. The Chinese regarded the writing of their own history as an important state function and a significant branch of literature. Official historians were regularly at work producing official histories of each dynasty. In this way the doctrines of Confucianism were perpetuated, and the official record of the times was made to conform to the accepted doctrines. What man did in life was taken to be supremely important. The civilizations of the ancient Middle East and of Islām produced histories and chronicles justifying the ways of God to man and, in the case of Islām, seeking to show that a good Muslim would be a good ruler or a good subject. What

a Muslim did was necessarily important. In contrast, the Brahmans of India disregarded their own history. They did not regard the recording of man's practical activities as of any significance compared with spiritual issues. These differences illustrated the fact that Oriental civilizations did not find uniform solutions to their problems.

The modern era

ASIA AND WESTERN DOMINANCE

At the close of the 15th century—that is, about a quarter of a century before the Mughals began to conquer northern India and a half-century before the last great dynasty of China (the Manchu) established itself—a Portuguese fleet under Vasco da Gama found its way around the Cape of Good Hope into Indian waters. While the Mughals went on to conquer the Indian mainland, the Portuguese made themselves masters not only of Indian waters but of all the eastern seas. Where they led, the Spanish, Dutch, French, and English followed. Above all, trade was sought, especially in silks and spices; but various attempts were also made to spread Christianity, especially by the Portuguese and Spanish, who had themselves felt the proselytizing impact of Islām in Europe and North Africa and were not reluctant to carry the fight to the East.

European contact

During the 15th to the 19th centuries Europe itself was changing rapidly. Nation-states were growing up. The foundations of a scientific, industrial, and technological revolution were laid. Europe learned how to navigate the oceans, apply sea power, wield artillery, organize representative government, cultivate religious toleration, and use money and credit in trade. Thus, it was a supremely confident Europe that began to feel its way along the coasts of the traditional, slow-changing societies of Asia.

The Portuguese quickly established themselves in Goa (India) and Macau (Macao) off the Chinese mainland; the Spanish took the Philippines in 1565. The rivalries of Europe were extended to Asian waters, and the Dutch evicted the Portuguese and consolidated a spice empire in Java and Sumatra, centring on Batavia (Jakarta). Between 1740 and 1805 the French and British on the coasts of India struggled with each other for supremacy, which the British won, in the process being drawn into the vacuum that the collapse of the Mughal Empire had created. During the 19th century British power easily spread across India to the Himalayas, and the whole subcontinent and its people became a major field of British investment. To protect this, new British bastions of power were erected in Aden, Persia, Arabia, Burma, and Singapore.

Meanwhile the French, pushed out of India and forestalled in Burma, established control over Cochin China, Annam, Tongking, Laos, and Cambodia. The independence of Siam (Thailand) was preserved because of its buffer position between the British in Burma and the French in Indochina.

In the Middle East, the Ottoman Empire was crumbling under internal stresses and external pressures. In 1882 the British took control of Egypt in order to safeguard the new route to India through the Suez Canal (1869), and the French, who had already crossed the Mediterranean into northern Africa, later found a foothold in Syria. The Far East was to some extent protected by distance and the rivalries of the European states elsewhere, but in 1842 and thereafter China was forced to open some of its ports to foreign trade and residence and to accept treaty provisions giving a special position to foreigners, an "Open Door" status that was substantially maintained until the 1930s. Beginning in 1854, the United States opened Japan, under arrangements similar to those forced on China, and, in turn, Japan opened Korea (1876).

The opening of China and Japan

Meanwhile, across central and northern Asia, Russia was advancing by military force, political manipulation, and colonization. By 1900 Russia was established on the Pacific coast, and both China and Korea were being threatened from land and sea.

THE RECOVERY OF ASIA

By the late 19th century the peoples and governments of Asia had begun to react to the impact of Europe. Japan, a tightly organized, compact island state, moved first by again making a deliberate decision to acquire the material power and organization of the apparently superior power, this time the European. By 1894 the legal and judicial order had been modernized; a new school system had been created; the foundations for a modern economy had been laid; the military system had been modernized; and a constitutional system had been established (1889). These changes enabled Japan to negotiate revision of its "unequal" treaties with the Western states. Its new power also enabled Japan to defeat China in 1894–95 and Russia in 1904–05. These two wars enlarged Japan to include Formosa (1895) and Korea (1910) and gave it a position in Manchuria from which to move in empire building on the Asian mainland.

European domination in Asia, together with the introduction of "Western learning" into Asian countries, gave rise to nationalist movements. Capitalist enterprise and higher-education policies in the Islāmic world, China, Southeast Asia, and India had brought into existence new intellectual and middle classes, which sought to introduce into their several countries the political and economic institutions of the West but, at the same time, to reject Western political and economic supremacy. Everywhere in Asia nationalism and anticolonialism formed the coordinates of these movements. Although nationalism itself tended to isolate the Asian countries into self-contained units, the individual nationalist movements interacted on one another. The victory of Japan over Russia and the early successes of the Chinese reform and revolutionary movements stimulated action elsewhere in Asia. The United States, after displacing Spain in the Philippines (1898), committed itself to Philippine autonomy. The rise of the freedom movement in India encouraged similar developments in Ceylon, Burma, and Indonesia. The revival of Islām in the Middle East after World War I stimulated Muslim consciousness in India and Southeast Asia.

In China the first reaction to the Western impact was anti-Manchu as well as antiforeign. The failure of the Boxer Rebellion (1900) inaugurated a period of Manchu reform designed to avoid revolutionary change. Revolutionaries were, however, successful in replacing the dynasty with a parliamentary republic in 1911–12. The traditional provincialism, however, soon made ineffective the national parliamentary republic, although China as a state retained its identity. National political unity began to be reestablished when the Kuomintang, or Nationalist Party, took over the government of China (1928). At the same time, however, Marxist–Leninist ideas were introduced into China with the organization of the Chinese Communist Party, affiliated with the Communist International. In the ensuing struggle the Nationalist government maintained its ascendancy until 1949. The establishment of the People's Republic by the Chinese Communist Party not only inaugurated the Communist phase of the Chinese revolution but also enabled Chinese and Russian influence to replace Western in a number of peripheral areas. Japan's defeat in World War II resulted in the loss of its empire. Korea became independent but was divided. But following the occupation entailed by defeat, Japan again quickly reestablished itself economically and resumed its position among the important states.

Chinese civil struggle

In the Indo-British empire an effort was made by the British to establish forms of representative and responsible government. But the attempt to hand over power roused the self-consciousness of the Muslim and Hindu communities so that the subcontinent, when freed in 1947, was also partitioned into two independent countries—Pakistan and India. Nationalism had been sufficiently strengthened in Burma and Ceylon during World War II so that Britain was obliged to concede independence by 1947. A new relationsip with Malaya was similarly established a decade later. With British imperial responsibilities being thus largely liquidated, other European powers began to yield their positions. The United States granted independence to the Philippines in 1946. The Dutch gave way to the Indonesian nationalists (1949); and the French, by 1954, had been compelled to withdraw from Indochina. The U.S. occupation of Japan was officially terminated

by the peace treaty that became effective in 1952. Thus the tide of the West in Asia was reversed after World War II. Internal political and economic stability, however, had not always been fully established following independence. In the background the U.S.S.R., on the landward side, strengthened its grip on central and northern Asia, and the United States, on the seaward side, sought to fill the power vacuum left by the Japanese defeat in the Pacific, with the U.S.S.R. supporting Communist Vietnam against the United States and its anti-Communist allies. In the Middle East the Arab and Muslim states had regained or reasserted their independence, but they were small, weak, and divided. Continuing hostility to the new Jewish state, Israel, after its proclamation (1948), as well as fear of European domination, served at least as a symbolic bond of union for the Arabs. Turkey, which had become a republic in 1923, deliberately, abandoned Islām as the state religion and under Kemal Atatürk began to turn itself into a modern Westernized nation-state.

Economic and social developments in Asia had not kept pace with the rate of political change. An enormous increase in population, especially in India, China, and Japan, had occurred; and, except in Japan, the masses were probably poorer at the close of the period of European dominance than they had been at the beginning. The disparity between the masses and their new, mainly middle-class rulers had become more glaring than ever; and the new nations of Asia, though free, were neither secure nor stable. In short, the influence of the West had created revolution in Asia and had complicated, not simplified or clarified, the problems facing Asians.

ASIAN GEOGRAPHICAL FEATURES OF SPECIAL INTEREST

Mountain ranges

ALTAI MOUNTAINS

A great topographic spine of Inner Asia, the Altai straddle parts of China, Mongolia, and the Soviet Union, stretching more than 1,000 miles (1,600 kilometres) southeast to northwest, from the Gobi (desert) to the West Siberian Plain. The jagged mountain ridges, whose name derives from the Turkish–Mongolian *altan,* meaning "golden," separate the waters of such great rivers as the Ob (flowing north to the Arctic Ocean) and its major tributary, the Irtysh, from the rivers draining into the vast Central Asian basin. There are three main prongs of the system—the Soviet, Mongol, and Gobi Altai; and the Soviet peak, Belukha, at 14,783 feet (4,506 metres) is the highest point. Although historically these mountains have been something of a remote barrier, the Altai are now famous for their mining and hydroelectric potential, while the ancient ways of life of their peoples are being rapidly transformed.

Physical features. *Physiography.* The Soviet Altai lies in eastern Kazakhstan and the Gorno-Altai sector of the Russian Soviet Federated Socialist Republic. A belt of northern foothills separates it from the rolling West Siberian Plain, while in the northeast it borders the Zapadny (Western) Sayan uplands and the mountains of the Lebed River Basin. The Mongol Altai (rising to Hüyten Orgil, over 14,000 feet) thrusts away to the southeast, then eastward. The Gobi Altai begins some 300 miles southwest of Ulaanbaatar, the Mongolian capital, and occupies the country's southern portions, towering over the Gobi expanses.

Geology. The Altai were originally formed in the great geological upthrusts of the Hercynian orogeny, about 300,000,000 years ago, and were worn down, over the long periods of geological time, into a peneplain, a plateau with generally accordant summit heights. At the beginning of the Quaternary Period, about 2,500,000 years ago, new upheavals thrust up magnificent peaks of considerable size along a zone of weakness in the Earth's surface. Quaternary glaciation scoured the mountains, carving them into rugged shapes, and deepened valleys from a V- to a U-shaped cross section; river action was also intensive and left its marks on the landscape. As a result of these differential geological forces, the highest ridges in the contemporary Altai—notably the Katun, Severo- (North) Chu, and the Yuzhno- (South) Chu—tower more than 13,000 feet, running latitudinally in the central and eastern portions of the Soviet sector of the system. The Tabyn-Bogdo-Ola (Tavan Bogd Uul in Mongolian), the Mönh Hayrhan Uul, and other western ridges of the Mongol Altai are somewhat lower. The highest peaks are much steeper and rockier than their Alpine equivalents, but the ranges and massifs of the middle Altai, to the north and west, have ridges of about 8,200 feet, whose softer outlines betray their origins in presenting ancient, smoothed surfaces. Valleys are nevertheless jagged and gorgelike. The ridges are separated by steppelike structural hollows (notably the Chu, Kuray, Uymen, and Kansk), which are filled with crumbly deposits up to 50,000,000 years old. Heights range from 1,600 to 6,600 feet above sea level.

The extreme dislocations suffered by the Altai over the course of geological time have occasioned a variety of rock types, many of them altered by volcanic activity when great former geosynclines, sediment-filled structural downwarps, were thrust upward in mountain-building epochs. There are considerable accumulations in the various structural depressions. The layers of nonferrous and rare metal-bearing rocks contain exploitable deposits of iron, mercury, gold, manganese, and tungsten that have a very high commercial value.

Climate. The regional climate is severely continental: because of the influence of the great Asiatic anticyclone, or high-pressure complex, the winter is long and bitterly cold. January temperatures range from 7° F (−14° C) in the foothills to −26° F (−32° C) in the sheltered hollows of the east, while in the Chu steppes temperatures can plunge to a bitter −76° F (−60° C). There are occasional tracts of the permanently frozen soil (or permafrost) that coats great stretches of the Soviet Far North. July temperatures are warm (often to 75° F [24° C], sometimes up to 104° F [40° C]) on the lower slopes, but summers are short and cool in the higher portions. In the exposed west, particularly at heights of between 5,000 and 6,500 feet, precipitation is high: as much as about 80 inches (2,030 millimetres) may fall quite evenly throughout the year. The amount decreases by a third farther east, and some areas have no snow at all. Glaciers coat the flanks of the highest peaks: some 1,200 in number, they cover an area approaching 600 square miles.

Temperature ranges

Drainage. The Soviet and Mongol portions of the Altai are criss-crossed by a network of turbulent, youthful rivers, fed mainly by melted snow and summer rains, occasioning spring and summer floods. The Katun, Bukhtarma, and Biya are among the biggest. Rivers of the Gobi Altai are shorter, shallower, and often frozen in winter and dry in summer. There are more than 3,500 lakes, most of structural or glacial origin. Those of the Gobi Altai are often bitterly salty.

Plant life. There are four fairly distinct vegetation zones: mountain subdesert, mountain steppe, mountain forest, and the Alpine regions. The first, found on lower slopes and in hollows of the Mongol and Gobi Altai, reflects the high summer temperatures and low rainfall: the sparse life includes wormwood and halophytic plants (those growing in salty soils). The mountain steppe zone rises to about 2,000 feet in the north and to 6,600 feet in the south and east. Meadows and mixed grass steppes characterize the former, and grassy herbs of the wormwood-fescue type the latter: only in the higher areas are mountain vines and bush steppes found. The mountain forest zone is most characteristic of the Soviet Altai, where it covers about 70 percent of the territory, mostly in the low and medium

mountain regions. Forests reach up to 6,500 feet but climb to 8,500 feet on less exposed slopes of the central and eastern Altai. Trees include coniferous growths, birches, aspens, and larches, and there are many huge clearings. A forest belt is practically nonexistent in the Mongol and Gobi Altai, but isolated clumps of Siberian trees grow in sheltered spots. Alpine vegetation—sub-Alpine shrubs giving way to meadows widely used for summer pasture and then mosses and bare rock and ice—is found only on the highest ridges.

Animal life. Animal life follows vegetation patterns. Various small rodents populate the mountainous semideserts and steppes, while bird life includes eagles, hawks, and kestrels. Most birds and animals are of Mongolian origin: marmot, jerboa (a jumping rodent), and antelope. Siberian animals (bear, lynx, musk deer) and birds (grouse, woodpecker, and crossbill) frequent the moist coniferous forests. Alpine animal life includes the mountain goat, snow leopard, and mountain ram.

The people. The Soviet Altai is peopled by groups of Altaic, Russian, and Kazakh origin. Only in the 1960s did the formerly tribal Altaic peoples—distinguished on the basis of dialect—cohere into a unified group. Their principal occupation is the breeding of cattle or sheep. The Russians are mainly agriculturalists or, significantly, miners. The Kazakhs mostly raise sheep, cattle, and wild horses, utilizing the summer alpine pastures (and erecting temporary dwellings), while keeping their stock under shelter in winter. The Mongol Altai is the home of groups of Kazakhs, Khalkhas, and the nomadic Oyrat. Sheep, goats, and camels are raised in the drier south, with large horned cattle becoming prominent in the north. Horse breeding is widespread. The shortages of water in the south necessitate migratory movements of up to 120 miles on the part of the nomads, who erect temporary villages. The development of agriculture, however, is producing more settled ways of life.

Peoples and their ways of life

Study and exploration. Scientific research into the Altai dates only from the 18th century but was stimulated when gold was discovered in 1828. Russian geologists and engineers pioneered the collection of data. Soviet expeditions from the U.S.S.R. Ministry of Geology and Tomsk V.V. Kuibyshev State University and expeditions from the Academy of Sciences of the Mongolian People's Republic have uncovered a wealth of geological and topographical data, and many peaks have been scaled. (N.I.M.)

HIMALAYAS

The Himalayas of Asia include the highest mountains in the world, with more than 30 peaks rising to heights of 24,000 feet (7,300 metres) above sea level. One of these peaks is Mt. Everest, the world's highest, which reaches a height of 29,028 feet (8,848 metres). The great heights of the mountains rise above the line of perpetual snow. The vast permanent snowfields attracted the attention of the pilgrim mountaineers of ancient India, who coined the Sanskrit name Himalaya—from *hima,* "snow," and *ālaya,* "abode"—for this great mountain system. In modern times, the Himalayas have constituted the greatest attraction and the greatest challenge to mountaineers throughout the world.

Forming the northern border of the Indian subcontinent and an almost impassable barrier between it and the lands to the north, the ranges form part of the great mountain belt stretching halfway around the world from northern Africa to the east coast of Asia. The Himalayas themselves stretch uninterruptedly for about 1,550 miles (2,500 kilometres) from west to east between Nānga Parbat (26,660 feet), in the disputed state of Jammu and Kashmir, and Namcha Barwa (25,445 feet), in Tibet. Between these eastern and western extremities lie the three Himalayan kingdoms of Nepal, Sikkim, and Bhutan. The Himalayas are bordered to the northwest by the mountain ranges of the Hindu Kush and Karakoram and to the north by the high Plateau of Tibet. The width of the Himalayas from south to north varies between 125 and 250 miles. Their total area amounts to about 229,500 square miles (594,400 square kilometres).

Though India has sovereignty over most of the Himalayas, Pakistan and China occupy parts of them. In the state of Jammu and Kashmir, Pakistan has administrative control of 32,362 square miles "line of control" of the range lying north and west of a cease-fire line established between India and Pakistan in 1972. China's occupation of 14,000 square miles in the Ladākh district of Kashmir, as well as Chinese incursions to the south of the McMahon Line (a 1914 boundary line limiting Tibetan sovereignty in the Assam Himalayas of northeast India) in the North East Frontier Agency (now Arunachal Pradesh) in 1962, have accentuated further the boundary problems faced by India in the Himalayan region.

Physical features. The Himalayas' most characteristic features are their soaring heights, snowcapped and steep-sided jagged peaks, valley glaciers often of stupendous size, topography deeply cut by erosion, seemingly unfathomable river gorges, complex geological structure, and a rich temperate and alpine vegetation. Viewed from the south, the Himalayas appear as a gigantic crescent, with its main axis rising above the snow line, where snowfields feed the valley glaciers and constitute the sources of most of the Himalayan rivers. The greater part of the Himalayas, however, lies below the snow line. The mountain-building process that created the range is still active and is accompanied by erosion by rivers and landslides of great dimension.

From south to north, the Himalayan ranges can be grouped into four parallel, longitudinal mountain belts of varying width, each having distinct physiographic features and its own geological history. They are designated as the Outer, or Sub-Himalayas; the Lesser, or Lower Himalayas; the Great, or Higher, Himalayas; and the Tethys, or Tibetan Himalayas. Farther north lie the Trans-Himalayas in Tibet proper, eastward continuations of some of the most northerly Himalayan ranges. From west to east the

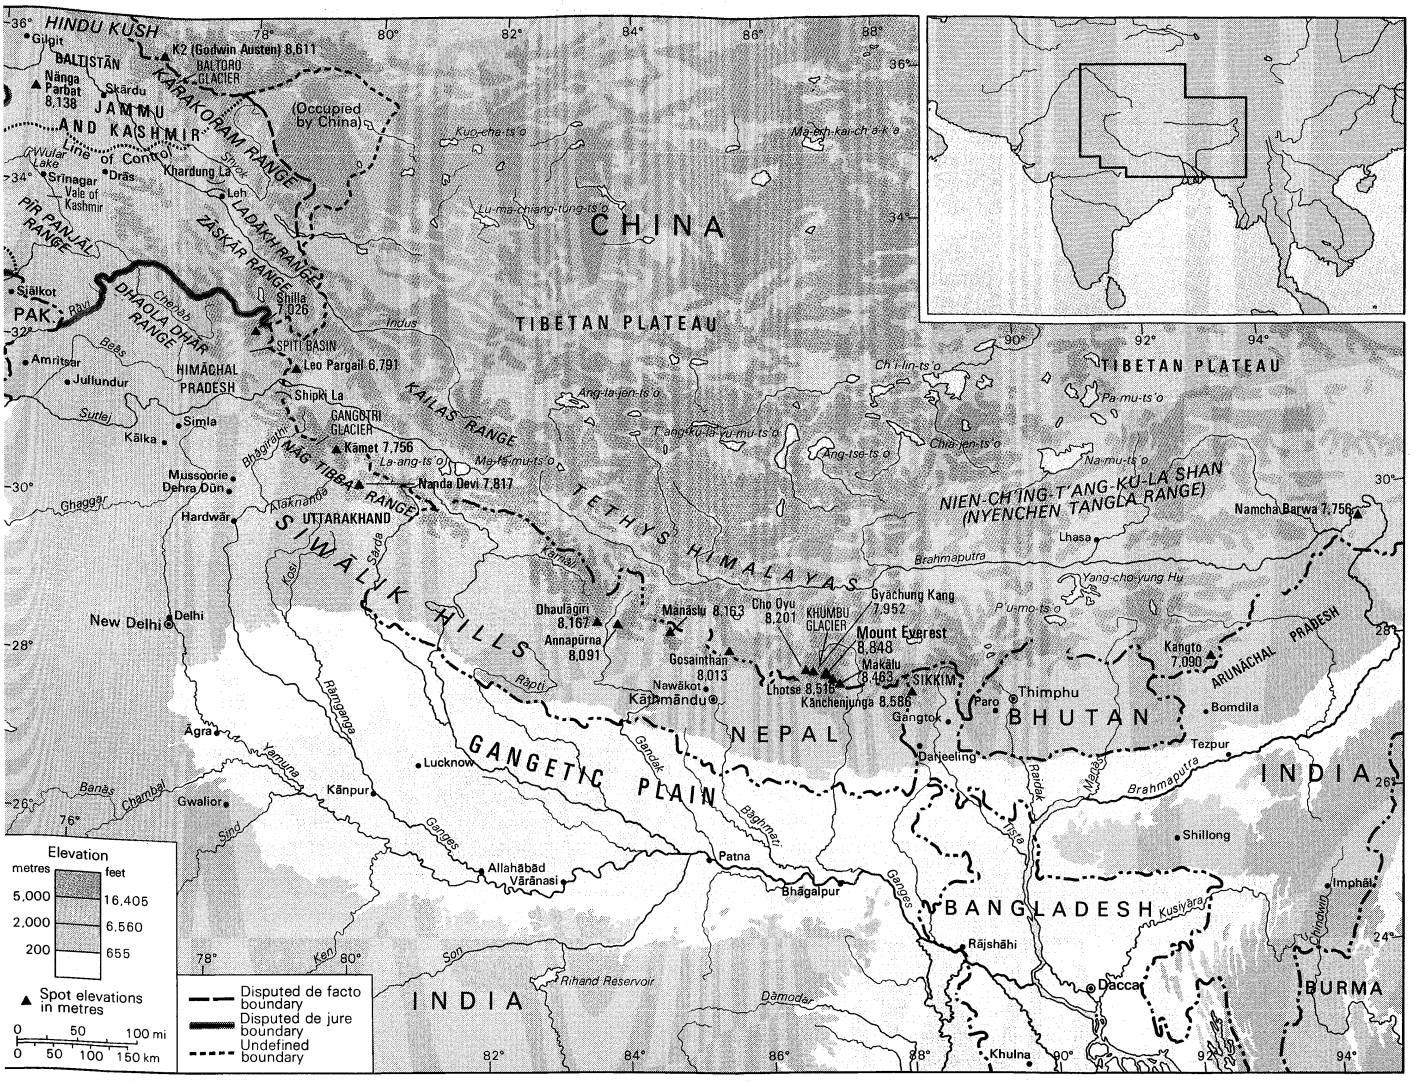
Horses grazing on the steppe grass in the southern region of the Gobi. The Altai Mountains in the background form the southwestern boundary for the desert.



The Himalayan region of the Indian subcontinent.

Himalayas are divided broadly into three mountainous regions: Western, Central, and Eastern.

Physiography. The Outer Himalayas comprise flat-floored structural valleys and the Siwalik Hills, which border the Himalayan mountain system to the south. Except for small gaps in the east, the Siwalik run for the entire length of the Himalayas with a maximum width of 62 miles in the Indian state of Himachal Pradesh. In general, the 900-foot contour line marks their southern boundary; they rise to another 2,500 feet to the north. The main Siwalik range has steeper southern slopes facing the Indian plains and descends gently northward to flat-floored basins, called *dūns*. The best known of these is the Dehra Dūn, in Uttarakhand, which is in the mountainous parts of Uttar Pradesh.

Northward, the Siwalik Range abuts against a 50-mile-wide massive mountainous tract, the Lesser Himalayas, where mountains rising to 15,000 feet and valleys with altitudes of 3,000 feet run in different directions. There is a general conformity of altitude among neighbouring summits, which creates the appearance of a highly dissected plateau. The three principal ranges of the Lesser Himalayas, the Nāg Tibba, the Dhaola Dhār, and the Pīr Panjāl, have branched off from the Great Himalayan Range lying farther north. The Nāg Tibba, the most easterly of the three ranges, is 26,795 feet high near its eastern end, in Nepal, and forms the watershed between the Ganges and the Yamuna, in the Uttarakhand.

To the west, the picturesque Vale of Kashmir, a structural basin (*i.e.*, an elliptical basin in which the rock strata are inclined toward a central point), forms an important section of the Lesser Himalayas. It extends from southeast to northwest for 100 miles, with an average elevation of 5,100 feet, having a width of 50 miles; it is traversed by the meandering Jhelum River, which runs through the Wular Lake, the largest freshwater lake in India.

The backbone of the system is the Great Himalayas, a range rising above the line of perpetual snow.

Highest peaks of Himalayas

The Great Himalayan Range rises to its maximum height in Nepal, having in that section nine of the 14 highest peaks of the world. From west to east they are: Dhaulāgiri 1 (26,810 feet; 8,172 metres), Annapūrna 1 (26,504 feet; 8,078 metres), Manāslu 1 (26,760 feet; 8,156 metres), Cho Oyu (26,750 feet; 8,153 metres), Gyāchung Kang 1 (25,991 feet; 7,922 metres), Mt. Everest (29,028 feet; 8,848 metres), Lhotse 1 (27,923 feet; 8,511 metres), Makālu 1 (27,824 feet; 8,481 metres), and Kānchenjunga 1 (28,208 feet; 8,598 metres).

Farther east the range changes from a southeasterly to an easterly direction as it enters Sikkim. After this, it runs eastward for another 260 miles through Bhutan and the eastern part of Arunachal Pradesh as far as the peak of Kangto (23,260 feet) and finally turns northeast, terminating in Namcha Barwa.

There is no sharp boundary between the Great Himalayas and the ranges, plateaus, and basins lying to the north of the Great Himalayan Range, generally grouped together under the name of the Tethys Himalayas and extending far northward into Tibet. In Kashmir the Tethys are at their widest, forming the Spiti Basin and the Zāskār Mountains, the highest peaks of which, to the southeast, are Leo Pargail (22,280 feet; 6,791 metres), rising north of the Sutlej River opposite Shipki La (pass), and Shilla (23,050 feet; 7,026 metres).

Geology. A study of the geological history of the Himalayas reveals that marine sediments of Paleozoic and Mesozoic eras (between about 65,000,000 and 570,000,000 years ago) deposited on the floor of the ancient Tethys Sea; the frontal part of the crystalline massif (mountain mass) of peninsular India; estuarine deposits along the flanks of the embryonic mountains; and finally products of surface erosion of the rising mountains—all contributed to the formation of the present-day range. The uplift of the Himalayas took place in at least three distinct and widely separated phases. The first phase of the major mountain-building movement took place at the close of the Eocene Epoch (about 38,000,000 years ago), although the beginning of the main Himalayan uplift started in Middle and Upper Cretaceous times (from about 100,000,000 to 65,000,000 years ago), with the advancement of the crystalline massif of peninsular India toward the Plateau of Tibet. This movement caused the rise of the Tethys Himalayas, along with the greater part of the Great Himalayas. In the second phase of upheaval, which occurred in the Miocene Epoch (7,000,000 to 26,000,000 years ago), the estuarine deposits and the Indian Massif formed the ranges of the Lesser Himalayas. The final mountain-building phase started at the end of the Tertiary Period (about 7,000,000 years ago), lifting the detrital deposits accumulating at the base of the Himalayas to form the Siwalik Range, the foothills of the Outer Himalayas. Since the middle Pleistocene Epoch (about 1,500,000 years ago), the Himalayas have risen at least 4,500 feet, an occurrence witnessed by early man. That the Himalayas still continue to rise is evidenced by the upheaval of the younger river terraces.

Formation of the ranges

Precambrian metamorphic rocks (rocks formed by heat and pressure from 570,000,000 to 4,600,000,000 years ago) form the bulk of the Himalayas. These rocks represent the frontal part of the Indian Shield, which, according to the theory of continental drift, pushed northward, uplifting the Himalayas as it pressed against the Asian landmass. Only in the Spiti Basin and in a few other localities can large outcrops of marine sediments from Paleozoic and Mesozoic times be seen.

Plutonic rocks (formed deep down from a molten state), such as granites and granodiorites of pre-Miocene age (*i.e.,* more than 26,000,000 years old), outcrop in extensive areas in north Kashmir, forming the whole of the Ladākh Range and the greater part of the area of Baltistān to the west of the Drās River and to the south of the Karakoram Range. The intrusion during post-Miocene times (*i.e.,* within the last 7,000,000 years) of tourmaline granite into an older series of gneisses (rocks formed by heat and pressure and made of bands that differ in colour and composition) and schists (crystalline rocks, the constituent minerals of which are usually arranged in a foliated or parallel pattern), aided by upthrusts in many areas, has given rise to many of the high peaks of the Himalayas, such as Makālu, Manāslu, and Nānga Parbat, which are typical examples. Mt. Everest and its two associated peaks, Lhotse and Cho Oyu, are, however, formed of limestones and pelitic (clay and mudstone) rocks, the latter dipping toward the north. It is possible that the entire formation of Mt. Everest is thrust up over a foundation of gneiss, as nappes or overturned folds.

The nappe structure of the Himalayas can also be seen elsewhere in the ranges. The Krol Nappes of the Simla region, in Himachal Pradesh, and the Garhwal Nappes, of Uttarakhand, are typical. These nappes are also evident in Nepal in the Nawākot and Kāthmāndu areas, which were formed along the line of the main central thrusts. This thrust zone borders the Great Himalayas to the south, rising abruptly in height and showing changes in the sequence of geological beds. The Pīr Panjāl Range, for example, owes its origin to thrust faulting; in the Simla region Krol limestones of Carboniferous Period (*i.e.,* from 280,000,000 to 345,000,000 years old) are overthrust onto much younger deposits of Pliocene Epoch (from 7,000,000 to 2,500,000 years old).

The geological structure is much simpler in the Outer Himalayas, where the foothills are mainly composed of Tertiary formations (from 2,500,000 to 65,000,000 years old), grouped under the Lower, Middle, and Upper Siwaliks. These consist mostly of freshwater deposits, such as sandstones, shales, and conglomerates. The Lower Siwaliks are from 1,800 to 6,000 feet thick, the Middle Siwaliks from 3,000 to 4,500 feet thick, and the Upper Siwaliks from 4,500 to 6,000 feet thick. At the same time that the Siwalik deposits were occurring, lacustrine (lake) deposits known as Karewas (flat-topped terraces) were being formed in the Vale of Kashmir. Both the Karewas and Siwaliks show evidence of glaciation during Pleistocene times (from 10,000 to 2,500,000 years ago).

Drainage. The Himalayas are drained by 19 major rivers, of which the Indus and the Brahmaputra are the largest, each having catchment basins about 100,000 square miles in extent in the mountains. Of the other 17 rivers, five belong to the Indus system—the Jhelum, Chenāb, Rāvi, Beās, and Sutlej, with a total catchment area of 50,958 square miles; nine belong to the Ganges system—the Ganges, Yamuna, Rāmganga, Kāli (Sarda), Karnāli, Rāpti, Gandak, Bāghmati, and Kosi, draining another 84,098 square miles; and three belong to the Brahmaputra system—the Tista, Raidak, and Manās, draining another 70,769 square miles.

Major Tibetan rivers

Most of the Himalayan rivers flow in troughs, the trends of which are generally determined by the branching ranges of the Great Himalayas. The rivers of the Indus system as a rule follow northwesterly courses, whereas most of the rivers of the Ganges–Brahmaputra systems take easterly courses while in the mountain region.

To the north of India, the Karakoram Range, with the Hindu Kush (Mountains) on the right and the Ladākh Range on the left, forms the great water divide, shutting off the Indus system from the rivers of Central Asia. The counterpart of this divide on the east is formed by the Kailas Range and its eastward continuation, the Nienchʼing-tʼang-ku-la Shan (Nyenchen Tangla Range), which prevent the Brahmaputra from flowing northward. South of this divide, the Brahmaputra flows eastward for about 900 miles before cutting across the Great Himalayan Range in a transverse gorge, although many of its Tibetan tributaries flow in an opposite direction, as the Brahmaputra may once have done.

The Great Himalayan Range, which normally would form the main water divide throughout its entire length, functions as such only in limited areas. This situation exists because the major Himalayan rivers, such as the Indus, Brahmaputra, Sutlej, and at least two headwaters of the Ganges—the Alaknanda and Bhāgirathi—are older than the mountains they traverse. It is believed that the Himalayas were uplifted so slowly that the old rivers had no difficulty in continuing to flow through their channels and, with the rise of the Himalayas, even acquired a greater momentum, which enabled them to deepen their valleys more rapidly. The elevation of the Himalayas and the deepening of the valleys thus proceeded simultaneously, with the result that the mountain ranges emerged with a completely developed river system cut into deep transverse gorges, ranging in depth from 5,000 feet to 16,000 feet and in width from six to 30 miles. The earlier origin of the drainage system explains the peculiarity that the major rivers drain not only the southern slopes of the Great Himalayan Range but to a large extent its northern slopes as well, the water divide being north of the crest line.

The role of the Great Himalayan Range as a watershed can, nevertheless, be seen between the Sutlej and Indus valleys for 360 miles; the drainage of the northern slopes is carried by the north-flowing Zāskār and Drās rivers, which drain into the Indus. Glaciers also play an important role in draining the higher altitudes and in feeding the Himalayan rivers. Several glaciers occur in Uttarakhand, of which the largest, Gangotri, is 20 miles long. The Mahalangur *himāl* ("snowfield"), with its Khumbu Glacier, drains the Everest region in Nepal. The rate of movement of the Himalayan region glaciers varies considerably; in the neighbouring Karakoram ranges, for example, the Baltoro Glacier moves about six feet a day, while others, such as the Khumbu, move only about a foot daily. Most of the Himalayan glaciers are in retreat.

Glaciers

Soils. Not much is known about the Himalayan soils. The north-facing slopes generally have a fairly thick soil

cover, supporting dense forests at lower altitudes and grasses higher up. The forest soils are dark brown in colour and silt loam in texture and occur mainly in Uttarakhand; they are ideally suited for growing fruit trees. The mountain-meadow soils are well-developed but vary in thickness and in their chemical properties. Some of the wet, deep, upland soils of this type in the Eastern Himalayas—for example in the Darjeeling Hills and in the Assam Valley—have a high humus content that is good for growing tea. Podzolic soils (infertile, acidic forest soils) occur in a 400-mile-long belt along the valley of the Indus and of its tributary the Shyok, to the north of the Great Himalayan Range, and are also found in patches in Himachal Pradesh. Farther east, saline soils occur in the dry Ladākh Plateau. Of the soils that are not restricted to any particular area, alluvial soils (deposited by running water) are the most productive, though they occur in limited areas, such as the Vale of Kashmir, the Dehra Dūn and on the high terraces flanking the Himalayan valleys. Lithosols consisting of imperfectly weathered rock fragments deficient in humus content cover many large areas at high altitudes and are the least productive soils.

Climate. The Himalayas, as a great climatic divide affecting air- and water-circulation systems, exercise a dominating influence upon meteorological conditions in the Indian subcontinent, to the south, and in the Central Asian highland, to the north. By its situation and stupendous height, the Great Himalayan Range obstructs the passage of cold continental air from the north into India in winter and also forces the southwest monsoonal (rain-bearing) winds to give up most of their moisture before crossing the range northward, thus causing a heavy precipitation of rain and snow on the Indian side but arid conditions in Tibet. The average annual rainfall on the south varies between 60 inches (1,525 millimetres) at Simla and Mussoorie in the Western Himalayas and 120 inches at Darjeeling in the Eastern Himalayas. At places such as Skārdu, Gilgit, and Leh, in the Indus Valley, to the north of the Great Himalayan Range, only three to six inches of rainfall occur.

The precipitation pattern

Local relief and situation determine the meteorological variations experienced not only in different parts of the Himalayas but even on different slopes of the same range. Because of its favourable location on top of the Mussoorie Range facing the Dehra Dūn, the town of Mussoorie, at a height of about 6,100 feet, receives 92 inches of rainfall annually, as against 62 inches recorded in the town of Simla, which lies behind a series of ridges at a height of 6,600 feet. The Eastern Himalayas, being at a lower latitude than the Western Himalayas, are relatively warmer; the lowest minimum temperature so far recorded was at Simla, in the Western Himalaya, −13° F (−25° C). The average minimum temperature for the month of May, recorded in Darjeeling at 6,380 feet elevation, is 52° F (11° C). In the same month, at an altitude of 16,500 feet in the neighbourhood of Mt. Everest, the minimum temperature is about 17° F (−8° C); at 19,500 feet it falls to −8° F (−22° C), the lowest minimum being −21° F (−29° C). At this time during the day, in areas sheltered from strong winds that blow at more than 100 miles an hour, the sun is often pleasantly warm, even at that altitude.

There are two periods of wet weather—the winter rains and the rains brought by the southwest monsoon winds. Winter precipitation is due to the depressions advancing into India from the west, causing heavy falls of snow. Within the regions where western disturbances are felt, condensation takes place in upper air levels at a height of 10,000 feet from the surface; as a result, precipitation is much greater over the high mountains. It is at this season that snow accumulates around the Himalayan high peaks and that the Western Himalayas receive more rain than the Eastern Himalayas. In January, for example, Mussoorie in the west receives almost three inches, while Darjeeling to the east receives less than an inch. By the end of May, meteorological conditions are reversed. Southwest monsoon currents passing over the Eastern Himalayas reach heights of 18,000 feet; in June, therefore, Darjeeling receives about 24 inches, and Mussoorie less than eight inches. The rains cease in September, after which the finest weather in the Himalayas prevails until the beginning of winter in December.

Plant life. Himalayan vegetation can be broadly classified into four groups: tropical, subtropical, temperate, and alpine. This division is based mainly on altitude and rainfall. Local variations in relief and climate, as well as exposure to sun and winds, cause considerable variation in the composition of the vegetation within each group. Tropical evergreen rain forest is confined to the humid foothills of the Eastern and Central Himalayas. The evergreen dipterocarps—a group of timber- and resin-producing trees—are common; their different species grow on different soils and on hill slopes of varying steepness. *Mesua ferrea* (rose chestnut) occurs on porous soils at altitudes between 600 and 2,400 feet (185–730 metres); bamboos grow on very steep slopes; oaks and chestnuts grow on the lithosol, covering sandstones from Arunachal Pradesh westward to central Nepal at altitudes of from 3,600 to 5,700 feet. Alder trees grow along the watercourses on the steeper slopes. At higher elevations they are succeeded by mountain forests in which the typical evergreen is *Pandanus furcatus,* a type of screw pine. Besides these trees, some 4,000 species of flowering plants, of which 20 are palm, are estimated to occur in the Eastern Himalayas.

Types of vegetation

With the decrease of rainfall and the increase of altitude westward, the rain forests give place to tropical deciduous forests, where the timber tree, sal, is the dominant species, thriving best on high plateaus at 3,000 feet (wet sal), as well as higher up, at 4,500 feet (dry sal). Westward, steppe forest (*i.e.,* forest on an extensive plain), steppe, subtropical thorn steppe, and subtropical, semidesert vegetation occur successively. Temperate forests extend from about 4,500 to about 11,000 feet and contain conifers and broad-leaved temperate trees. Evergreen forests of oaks and conifers have their westernmost outpost on the hills above Murree, some 30 miles northwest of Rāwalpindi, in Pakistan; these are typical of the Lesser Himalayas, being conspicuous on the outer slopes of the Pīr Panjāl, in Kashmir, India. *Pinus roxburghi* (chir pine) is the dominant species at altitudes of from 2,700 to 5,400 feet. In the inner valleys this species may occur even at an altitude of 6,300 feet. Deodar cedar, a highly valued timber tree, is another species particular to the Himalayas, occurring mainly in the western part of the range. Stands of this species occur between 6,300 and 9,000 feet and also tend to grow at still higher altitudes in the upper valleys of the Sutlej and the Ganges. Of the other conifers, blue pine and spruce make their appearance between about 7,300 and 10,000 feet.

The alpine zone begins above the tree line between 10,500 and 11,700 feet and extends as far as 13,700 feet in the Western Himalayas and 14,600 feet in the Eastern Himalayas. In this zone all the wet and moist alpine vegetation is to be found. Juniper is widely distributed, preferring sunny sites, steep and rocky slopes, and drier areas; on Nānga Parbat they are found even at an altitude of 12,750 feet. Rhododendron occurs everywhere but more abundantly in the wetter parts of the Eastern Himalayas, where it grows in all sizes from trees to low scrub. Mosses and lichens grow in shaded areas at lower levels where the humidity is high; flowering plants occur at high altitudes, especially on Nānga Parbat and Mt. Everest.

Alpine plants

Animal life. The animal life of the Eastern Himalayas is derived mainly from that of the South Chinese and Indo-Chinese region. It is primarily the type of animal life found in the tropical forest and is only secondarily adapted to the subtropical, mountain, and temperate conditions prevailing at higher altitudes and in the drier western areas. The animal life of the Western Himalayas, however, has more affinities with that of the Mediterranean, Ethiopian, and Turkmenian regions. The past presence in the region of some African animals, such as the giraffe and the hippopotamus, can be inferred from fossil remains in the Siwalik deposits of the Outer Himalayas. The animal life at higher altitudes above the tree line consists almost exclusively of species, adapted to the cold, that have originated in the area, having evolved from the wild life of the steppes (extensive plains) after the Himalayan uplift. Elephants, bison, and rhinoceroses are restricted to certain

areas of the forested *terai* (moist or marshy lands, now largely drained) at the base of the low hills in the Outer Himalayas. The Indian rhinoceros was once abundant all over the foothill zone of the Himalayas but is now becoming extinct; the musk deer and the Kashmir stag, or hangul, are also on the point of extinction. The Himalayan black bear, the clouded leopard, the langur monkey (a long-tailed Asian monkey), and the cat are some of the other denizens of the Himalayan forests. Himalayan goat antelopes are also found.

Exotic game animals

In higher altitudes above the tree line, the snow leopard, the brown bear, the red panda, and the Tibetan yak can occasionally be seen. The yak has been domesticated and is used as a beast of burden in Ladākh. The typical inhabitants of higher altitudes above the tree line are, however, diverse types of insects, spiders, and mites, which form the only animal life that can live as high up as 20,700 feet.

Catfish of the genus *Glyptothorax* live in most of the Himalayan streams, on the banks of which is found the Himalayan water shrew. Lizards of the genus *Japalura* are widely distributed. *Typhlops,* a genus of blind snake, is common in the Eastern Himalayas. The butterflies of the Himalayas are extremely varied and beautiful, especially the genus *Troides.*

The bird life is equally rich but is more in evidence in the east than in the west. Among some of the common Himalayan birds are different species of magpie—the black-rumped, the blue, and the racket-tailed; titmouse; chough (related to the jackdaw); whistling thrush; and redstart. A few strong fliers, such as the lammergeier (bearded vulture), the black-eared kite, and the Himalayan griffon (an Old World vulture), can also be seen in Sikkim. The snow partridge and the Cornish chough are found at elevations of 18,600 feet.

The people. Of the three principal ethnic types in the Indian subcontinent—the Indo-Aryan, the Mongolian, and the Dravidian—the first two are well represented in the Himalayas, although mixed in varying proportions in different areas. Waves of immigration into the mountains have occurred from all directions in the past and have caused intermingling of peoples. Generally speaking, the Great Himalayas and the Tethys Himalayas are inhabited by Tibetan and other Mongoloid people; the Lesser Himalayas are the home of the tall, fair Indo-Aryans. In the Outer Himalayan region of Jammu and Kashmir the Indo-Aryans are called Dogras and are divided into two main castes, Brahmins and Rājputs. In the Kashmir Valley the same type is represented by the Kashmīrī people. The Gaddis and Gūjars, who live in the hilly areas of the Lesser Himalayas, also belong to the Aryan type. The Gaddis are essentially a hill people; they possess large flocks of sheep and herds of goats and come down with them from their snowy abode in the Outer Himalayas only in winter, returning again to the highest pastures in June. The Gūjars are a migrating, pastoral people living from their herds of sheep, goats, and a few cattle, for which they seek pasture at various altitudes.

The Champa, Ladākhī, Balti, and Dard peoples live to the north of the Great Himalayan Range in the Kashmir Himalayas; the Dard are Aryan, the others Mongoloid. The Champa lead a nomadic pastoral life in the Upper Indus Valley. The Ladākhī have settled on terraces and alluvial fans flanking the Indus in Kashmir. The Balti have spread farther down the Indus Valley and have adopted Islām.

The Aryan racial type is represented by the Kanets in Himachal Pradesh and the Khāsas in Utturakhand. In Himachal Pradesh the majority of the inhabitants of Kinnaur and Lāhul-Spiti districts are Mongoloid, having immigrated from Tibet.

In Nepal, the Tibeto-Nepalese and Indo-Nepalese form the two main ethnic divisions, which are further subdivided into a large number of ethnic groups, including the Newārs, the Tamangs, the Gurungs, the Magars, the Sherpas, and the Kirāts. The Kirāts were the earliest inhabitants of the Nepal Valley. The Newārs are also one of the earliest Nepalese groups. The Tamangs inhabit the high valleys of Ganesh Himal (Nepal, southwest of Himachal Pradesh). The Gurungs live on the southern slopes of the Annapūrna Massif (mountain mass), pasturing their cattle as high as 12,000 feet. The Magars inhabit western Nepal but migrate seasonally to other parts of the country. The Sherpas, who live to the south of Mt. Everest, are famed mountaineers.

The people of Sikkim belong to three distinct ethnic groups—the Lepchās, the Bhutias, and the Nepalese. Generally speaking, Nepalese and Lepchās live in western Bhutan and Bhutias of Tibetan origin in eastern Bhutan. Arunachal Pradesh is the homeland of several groups—the Abors or Adis, Akas, Apa Tanis, Daflas, Khamptis, Khowas, Mishmis, Mombas, Miris, and Singpho. Ethnically, all these groups are Indo-Mongoloid; linguistically, they are Tibeto-Burman. Each group lives in a distinct river valley, practicing shifting cultivation (*i.e.,* constantly changing the land on which they raise crops).

The economy. *Resources.* The Himalayas abound in economic resources. These include rich arable land, extensive grassland and forest, workable mineral deposits, and easily harnessable waterpower. The most productive arable lands in the Western Himalayas are in the Vale of Kashmir, the Kāngra Valley, the Sutlej Basin, and the terraces flanking the Ganges and Yamuna in Utterakhand; these produce rice, corn (maize), wheat, and millet. In the Central Himalayas in Nepal most of the arable land is in the foothills and on the adjacent plains; this land produces four-fifths of the total rice production of the country, amounting to 1 percent of world production. The region also produces large crops of corn and wheat. In addition to cereals, most of the cash crops of the country—jute, sugarcane, and oilseeds—are grown in this region.

Arable lands, minerals, and water resources

Most of the fruit orchards of the Himalayas lie in the Vale of Kashmir and in the Kulu Valley of Himachal Pradesh. Such fruit as apples, peaches, pears, and cherries, for which there is a great demand in the cities of India, are grown extensively. There are rich vineyards on the shores of Dal Lake in Kashmir, which produce grapes of good quality from which wine and brandy are made. On the hills surrounding the Vale of Kashmir grow walnut and almond trees, the nuts of which are exported to India where oil is extracted from them. Bhutan also has fruit orchards and exports oranges to India.

Of the plantation crops, tea is grown mainly on the hills and on the plain at the foot of the mountains in the Darjeeling district. Tea in limited quantity is also grown in the Kāngra Valley. Plantations of cardamom, a spice used in curry, are to be found in Sikkim, Bhutan, and the Darjeeling Hills. Medicinal herbs are grown in plantations in the Uttarkāshi and Pithorāgarh districts of Uttarakhand.

Transhumance (the seasonal migration of livestock) is widely practiced during the summer months in the Himalayas pastures, called *margs,* in Kashmir. Sheep, goats, and yak are raised on the rough grazing lands available.

Woodlands occupy at least one-third of the Himalayas, covering more than two-thirds of the total area of Bhutan and Sikkim. They constitute the greatest asset of the mountains, although their fuller use is hampered because of inaccessibility. Logs of timber are floated down the Himalayan streams to sawmills located at the foot of the mountains. Forest-based industries, to manufacture matches, rayon, and paper pulp, are being established in Bhutan.

The Himalayas are rich in minerals, although their exploitation is restricted to the more accessible areas. Jammu and Kashmir state is the most mineralized region. Sapphires are found in the Zāskār Mountains, and alluvial gold in the nearby bed of the Indus. There are deposits of copper ore in Baltistān, and iron ores are found in the Vale of Kashmir. Ladākh contains borax and sulfur deposits.

Mineral resources

Coal deposits exist in the Jammu Hills. Bauxite occurs in Jammu and Kashmir. Nepal, Bhutan, and Sikkim have extensive deposits of coal, mica, gypsum, and graphite and ores of iron, copper, lead, and zinc.

The Himalayan rivers have a tremendous hydroelectric potential, which has been harnessed more intensively since the five-year plans were introduced in the 1950s in India. A giant multipurpose river-valley project is located at Bhākra-Nāngal on the Sutlej River in the Outer Himalayas; completed in 1963, it has a storage capacity of

348,218,000,000 cubic feet (9,860,000,000 cubic metres) of water and a total installed capacity of 1,050 megawatts. Three other Himalayan rivers, the Kosi, Gandak, and Jaldhāka, have been harnessed by India, which then supplies the power to Nepal and Bhutan.

Transportation. The difficulty of transport in the Himalayas has always constituted a barrier to economic growth. Only in recent years have new highways been built, making the Himalayan region accessible from both the north and the south. Of these, the 75-mile, all-weather Tribhuvan Rajpath road connecting Kāthmāndu, capital of Nepal, with India and the 65-mile road connecting Kāthmāndu with Kodari, on the Tibetan border, deserve special mention. The Hindustān–Tibet road—Indian National Highway No. 22—which passes through Himachal Pradesh has also been considerably improved by the government of India; this 300-mile highway, which runs through Simla, once the summer capital of India, connects the Punjab plains with the Indo-Tibetan border near the Shipki La (pass). There are only two main railroads, both of narrow gauge, penetrating into the Lesser Himalayas from the plains of India—one in the Western Himalayas, between Kālka and Simla, and the other in the Eastern Himalayas, between Siliguri and Darjeeling. There is another narrow-gauge line in Nepal, running 29 miles from Raxaul to Amlekhganj and connected with Kāthmāndu by an electrically operated aerial cableway, which transports cargo in baskets. Two other short railroads run to the Outer Himalayas—one, the railroad of the Kulu Valley, from Pathānkot to Jogindarnagar; the other from Hardwār to Dehra Dūn. A short railway, formerly running between Wazīrābād and Jammu through Siālkot, is now permanently closed.

There are two major airstrips in the Himalayas—one at Gaucher, Kāthmāndu, capital of Nepal, and the other in Srīnagar, capital of Kashmir—which are served by national and (except Srīnagar) international airways. Besides these, there are also many airstrips of local importance in the hills and in the *terai* district of Nepal.

From the Punjab plains the only direct approach to the Vale of Kashmir is by the National Highway No. 1A from Jullundur to Uri through Jammu, Banihāl, Srīnagar, and Bāramūla. It crosses the Pīr Panjāl Mountains through a tunnel at Banihāl. The old road from Rāwalpindi to Srīnagar through Pakistan has lost much of its former importance. Within the Kashmir Himalayas, the Srīnagar to Leh road connects Leh in Ladākh with the Nubra Valley, passing over the 17,730-foot-high Khardung La—the first of the high passes on the historic caravan trail to Central Asia from India. Many other new roads have been built in recent years.

Sikkim commands the historic Kālimpong to Lhasa caravan trade route, which passes through Gangtok. Before 1956, there was only one (30-mile) motorable highway running between Gangtok and Rongphu, on the Tista River near the Sikkim–West Bengal border, which then continued southward to Silīguri for another 70 miles. Since then, several roads passable by jeep have been built in the southern part of Sikkim, and a highway in northern Sikkim connects Gangtok with Lachen (Lachung).

Arunachal Pradesh is connected with the Brahmaputra Valley by roads running from Namsai to Chowkham, Sadiya to Roing, Pāsighāt to Dibrugarh, Along to Sonarighat, North Lakhimpur to Hapoli, and Tezpur to Bomdila.

Study and exploration. The first Himalayan sketch map of some accuracy was drawn up by Father Antonio Monserrate, a Spanish missionary to Akbar's court in 1590. In 1733 a French geographer, Jean-Baptiste Bourguignon d'Arville, compiled the first map of Tibet and the Himalayan range based on systematic exploration. In the middle of the 19th century, the Survey of India organized a systematic program to measure correctly the heights of the Himalayan peaks. The Nepal and Uttarakhand peaks were observed and mapped between 1849 and 1855. Nānga Parbat, as well as the peaks of the Karakoram to the north, were surveyed between 1855 and 1859. The surveyors did not allot individual names to the innumerable peaks observed but designated them by figures and roman numerals. Thus, at first Mt. Everest was simply labelled as "h", this was later changed to Peak XV in 1849–50. In 1865, Peak XV was renamed for Sir George Everest, surveyor-general of India from 1823–1843. Not until 1856 were the computations sufficiently advanced for it to be realized that Peak XV was higher than any other peak in the world. By 1862 more than 40 peaks of 18,288 feet and above had been climbed for surveying purposes.

Early explorations

The Survey of India has prepared some large-scale maps of the Himalayas from aerial photographs. Parts of the Himalayas have also been mapped by German geographers and cartographers with the help of ground photogrammetry. (S.P.C.)

HINDU KUSH

The Hindu Kush is one of the great watersheds of Central Asia, forming part of the vast alpine zone that stretches across the continent from east to west. Broadly defined, it is a mountain system nearly 1,000 miles (1,600 kilometres) long and possibly 200 miles (320 kilometres) wide, running northeast to southwest, and dividing the valley of the Amu Darya (the ancient Oxus River) to the north from the Indus River Valley to the south. There is no agreement among geographers as to its precise boundaries. To the east, the Hindu Kush buttresses the Pamir Plateau near the Chinese border, after which it runs southwest through Pakistan and into Afghanistan, finally merging into minor ranges in western Afghanistan. The highest peak is Tirich Mīr, which rises on the Pakistan–Afghanistan border to 25,263 feet (7,700 metres).

Historically, the passes across the Hindu Kush have been of great military significance, providing access to the northern plains of India. Alexander the Great, king of Macedonia, who passed over the Hindu Kush in the 4th century BC, was among those who invaded India by this route. During the period of British rule in India, the Indian government was keenly concerned with the security of these passes, and more especially with their own control of an associated physical feature to the south, the Khyber Pass. The Hindu Kush range has rarely constituted the frontier between major powers, but has usually formed part of an intermediate buffer zone.

The name Hindu Kush first appears in 1333 in the writings of Ibn Baṭṭūṭah, the medieval Berber traveller, who said that the name meant "Hindu killer," a meaning still given by Afghan mountain dwellers, who are traditional enemies of Indian plainsmen. More likely the name is a corruption of the classical term Hindu-Caucasus, or else Hindu-Koh, meaning "Indian Mountains."

Physical features. The eastern limit of the Hindu Kush is difficult to determine because of a locally complex topography, although the Karambar Pass (14,225 feet, or 4,345 metres) between the valleys of Chitrāl, Pakistan, and Gilgit, Jammu and Kashmir, may be tentatively accepted as marking the boundary. The western limit is still more uncertain, as the mountains lose height and fan out into minor ranges. The Kermū Pass (10,879 feet, or 3,316 metres) to the west of Kābul may, nevertheless, be regarded as indicating the approximate boundary of the range. Geologists, however, consider the Hindu Kush range to extend much further west not only into Afghanistan but also into Iran.

Physiography. Three main sections of the Hindu Kush may be defined. These are the eastern Hindu Kush, which runs from the Karambar Pass in the east to the Dorāh Pass (14,940 feet, or 4,554 metres) not far from Tirich Mīr; the central Hindu Kush, which then continues to the Khāvāk Pass (11,640 feet, or 3,548 metres) to the north of Kābul; and the western Hindu Kush, also known as the Kūh-e-Bābā, which gradually descends to the Kermū Pass.

Three main regions

In its extreme eastern section, between the passes of Karambar and Baroghil (12,480 feet, or 3,804 metres), the eastern Hindu Kush region is not very high and has mountains that often take the form of rounded domes. Further to the west the main ridge rises rapidly to Baba Tangi (21,368 feet, or 6,513 metres) and becomes rugged, after which, within the space of about 100 miles, are concentrated the highest mountains of the entire region—about two dozen summits of more than 23,000 feet, or 7,000 metres, in height. A first cluster of high peaks around

Ūrgand, Afghanistan (23,094 feet, or 7,039 metres) is followed further south by the massif (principal mountain mass) of Saraghrar (24,111 feet, or 7,349 metres). Another line of imposing mountains, which includes Koh-i-Langar (23,162 feet, or 7,060 metres), Shachaur (23,346 feet, or 7,116 metres), Udrem Zom (23,376 feet, or 7,125 metres), and Nāder Shāh (23,376 feet, or 7,125 metres), leads to the three giant mountains of the Hindu Kush, which are Noshaq (24,580 feet), Istro Nal (24,242 feet), and Tirich Mīr (25,263 feet). Most major glaciers of the Hindu Kush—among them Kotgāz, Ushko, Niroghi, Atrak, and Tirich—are in the valleys of this section.

Watershed of the Central Hindu Kush

The central region lies almost entirely within Afghanistan. According to the report of a British expedition in 1967, this region "has no nice, easily definable east–west ridge but rather a tortuous twisting watershed with massive off-shoots running north towards the Soviet Union and south into Nuristan (a region of Afghanistan)." Maximum heights, which are lower than those in the eastern section, include Koh-i-Bandakor (22,451 feet, or 6,843 metres), Koh-i-Mondi (20,498 feet, or 6,248 metres), and Mīr Samīr (19,878 feet, or 6,059 metres). These peaks are surrounded by a host of lesser mountains. Glaciers are poorly developed, but the mountain passes—which include Putsigram (13,450 feet, or 4,100 metres), Verān (15,400 feet, or 4,700 metres), Ram Gol (15,400 feet, or 4,700 metres), and Anjoman (13,850 feet, or 4,225 metres)—are high, thus making transmontane communications difficult.

The mountains of the western region fan out gradually toward the Afghan town of Herāt, near the Iranian border, declining into hills of lesser importance. Communication is easier in this region, as the passes, such as the Shebar Pass (9,800 feet, or 2,987 metres), have long since been crossed by roads.

A wider definition of the limits of the Hindu Kush would lead to the inclusion of a fourth region known as Hindu Rāj in Pakistan. This is formed by a long, winding chain of mountains—with some lofty peaks, such as Darkot (22,447 feet, or 6,842 metres), and Būni Zom (21,499 feet, or 6,553 metres)—which strikes southward from the Lupsuk Peak (18,853 feet, or 5,746 metres) in the eastern region, then continues to the Lawarai Pass (12,100 feet, or 3,700 metres) and beyond to the Kābul River. If this chain were to be considered as part of the Hindu Kush, then the outlying mountains of the Swāt Kohistān region of Pakistan to the south would also form part of the complex. For most purposes of this article, however, the Hindu Rāj and its associated ranges are excluded from consideration.

International boundaries running through the Hindu Kush are primarily those of Pakistan and Afghanistan. The Karambar Pass lies about 40 miles west of the Chinese borders, while to the west the Hindu Kush, strictly considered, approaches the border between Afghanistan and Iran without extending into Iranian territory. Between these extremes the Pakistan–Afghanistan border follows the main watershed of the Hindu Kush throughout its eastern region, from Lupsuk Peak just north of the Karambar Pass to the Dorah Pass just south of Tirich Mīr. Not far from the Dorah Pass the boundary leaves the main watershed and follows minor spurs until it crosses the Kābul River, continuing along the crest of the Spīn Ghar Range toward the south. The Khyber Pass constitutes an important strategic gateway because it cuts through the Spīn Ghar instead of through the Hindu Kush thus offering a comparatively easy route between the valley of the Kābul and the plains of Punjab.

The Khyber Pass

The erratic boundary line is the result of a series of compromises reached at the end of the 19th century between the British and the ruler of Afghanistan; called the Durand Line, after the British negotiator, it has been inherited by the modern states of Pakistan and Afghanistan. Another curious configuration established about the same time and as yet unchanged is the Vākhān region (Wakhan Corridor), a panhandle of Afghan territory designed to act as a buffer between British India and tsarist Russia.

Geology. In many of its features the Hindu Kush resembles its eastern neighbour, the Karakoram Range that extends from Tibet into Pakistan. The Hindu Kush, which some authorities consider to be a continuation of the Karakoram, has the same core of igneous metamorphic rock (*i.e.,* rock formed by heat and pressure that has solidified from a molten state) flanked, especially toward the north, by sedimentary material. In the Hindu Kush, however, there appears to be a greater prevalence of sedimentary rocks—a fact that may explain the softer and more rounded forms of many of the mountains. In the Afghan section the core of the chain is formed by a complex sequence of metamorphic rocks containing marble, together with intrusions of granodiorites (rocks formed deep down by heat and pressure, and containing a certain admixture of both dark-coloured and light-coloured minerals). In Nūrestān, Afghanistan, the hills consist mainly of schists (medium- or coarse-grained metamorphic rocks), gneiss (a coarse-grained rock in which bands containing granular materials alternate with bands of schistose materials), and intrusions of granite with zones of migmatite (rock consisting of alternate layers of granite and schist). The Hindu Kush differs markedly from the Karakoram, however, in the winding direction of its strike (*i.e.,* its course, or bearing).

Drainage. The Eastern Hindu Kush appears to be formed of two parallel chains, consisting of a lower one to the north, which acts as a watershed, and a higher southern one that carries the main peaks. Drainage is comparatively simple on the northern side but highly complex on the southern one, where valleys follow two contrasting directions—northeast to southwest and roughly east to west. Most of the rivers, such as the Panjsher, the Alīngar, the Konar, and the Pānjkora, follow the northeast to southwest direction and are then suddenly deflected toward the east–west axis by the Kābul River, into which they flow. The Karambar and Ghizar valleys also take the same east to west direction. The Indus River, however, swerves in its course from one direction to another as it makes its roundabout descent toward the lower plains.

Climate. Since the range separates one important zone of Asia from another, the climate shows great variations. The mountains of Swāt Kohistān are virtually within the area of the rain-bearing monsoon winds, and most of the Eastern Hindu Kush, as well as the Hindu Rāj, rises up at the extreme limit of monsoonal Asia. The Central and Western Hindu Kush, however, border the Mediterranean climatic zone. Thus, moving from the southeast to the northwest and west, one moves from a region of rainy or snowy summer (from July to September) and of dry winters into a region of hot dry summer and cold and rainy or snowy winter (from December to early March). Climatic variations between these opposites also occur, producing often striking local contrasts.

Climatic contrasts

A graphic image of climatic conditions is presented by the glaciers. The mantle of snow and ice is heaviest at the extreme eastern end of the Hindu Kush in Pakistan, where the Chiāntar Glacier is situated, and is also heavy in the higher section around Tirich Mīr and Saraghara and in parts of the Hindu Rāj. Toward the west, however, glaciation is more sporadic. In the Central Hindu Kush, mountains 12,000 feet high are often bare almost to the summit. Most of the glaciers of the Hindu Kush appear to be retreating. A striking feature of some glacial regions are the so-called nieves penitentes, which are protruding spikes of frozen snow forming the illusion of kneeling human figures, sometimes two or three feet high, which are especially noticeable in the early morning; they are caused by the alternation of fierce sun and rapid evaporation during the day and of severe cold at night.

Plant life. Differences in latitude and the variety of climates make it difficult to generalize about vegetation. Compared to the Himalayas of Nepal, and still more to those of Sikkim and Bhutan, the mountains of the Hindu Kush appear bare, stony, and poor in vegetation, although there are local exceptions. Some rich forests and pastures are found in the extreme southeast of the extended Hindu Kush region, as well as in the hills of Swāt Kohistān and in the Pānjkora Valley of the Dīr District, Pakistan. Parts of the valleys of the Gupis and Yāsīn rivers in the Gilgit area enjoy sufficient summer precipitation to be partially covered with vegetation. In the valleys of the Swāt and Dīr districts, as well as in some parts of the Chitrāl area, rice is cultivated.

The highlands of the eastern extremity of the Hindu Kush, with their rolling pastures, bear some resemblance to the plateau landscape of Tibet, but further south the valleys become arid and stony. A typical view in parts of Chitrāl, for example, would include snowy peaks in the distance, dry, barren, brick-red or ochre-coloured mountains all around, and bright emerald-green islands of vegetation near the villages where springs and irrigation furnish abundant water. In such oases, poplar trees are a distinct feature, often being accompanied by old and gigantic plane trees.

Much moisture carried by the monsoon winds penetrates the lower part of Chitrāl across the Lawarai Pass, so that stands of coniferous trees occur in the surrounding districts. The valleys of Nūrestān receive sufficient precipitation to have some pastureland and forests.

To the west of Afghanistan, and to the north of the Hindu Kush, extremely dry summers prevail; much of the country is stony, or sparsely covered with thorny and spiny plants, or with poor grass.

Animal life. The meagre vegetation of most parts of the Hindu Kush does not favour an abundance of wild animal life. The snow leopard manages barely to survive in the most remote valleys. Bears formerly roamed Nūrestān, but few remain today. The markhor (a kind of wild goat) was once abundant, but hunters have now thinned the stock. Birdlife is rich, however, and eagles are occasionally to be seen.

The people. A long and tormented history, together with fragmented topography, has produced a veritable mosaic of ethnic units in the region. Kirgiz nomads, about 30,000 in number, graze their herds on the Vākhān uplands. The lower parts of the Vākhān and the higher parts of the Sang Lēch and Anjoman valleys, all on the northwest slopes of the Hindu Kush, are sparsely inhabited by the so-called Pamir Tadzhiks, most of whom are Shī'ah Muslims. Other Tadzhiks (who are Sunnī Muslims), Uzbeks, and some Ḥazāra (Persian-speaking Mongols) live in the valleys of the central and western parts of the Hindu Kush. Afghans are found in the major towns, in Kābul, and in many districts to the south of the Hindu Kush, with the exception of Nūrestān.

On the southeast (Pakistan) side of the Hindu Kush, most people are Chitrāli, a racially mixed ethnic group that shows a marked cultural unity.

The Kafirs of Nūrestān

The Kafirs of Nūrestān and of Chitrāl are an exceptionally interesting people. Their name means "infidel" or "non-Muslim" and seems to have been used since the 11th century. Traditionally, they are divided into two groups—the *kalash* ("black") Kafirs of Chitrāl, and the *kati* ("red") Kafirs of Nūrestān. In the remote past, the Kafirs possibly inhabited a much larger area. The Kafirs of Nūrestān were forcibly converted to Islām in 1896.

Physically, the Kafirs do not seem to differ much from their neighbours; they speak a language classed by some as Dardic. It is in their religion and culture that their ethnic individuality is most strikingly expressed. In religion they practise a form of polytheism; worship consists mainly in the sacrifice of animals. Dancing is important, and divination through shamans is practiced. The dead are disposed of, unburied, in heavy wooden coffins. Large wooden statues of ancestors, often on horseback, stand near graveyards; many are works of vigorous and elemental beauty. Kafir homes are strong rectangular wooden buildings. Their economy is based on agriculture, hunting, and the raising of goats and oxen.

The economy. *Resources.* The economic resources of the region remain virtually undeveloped. It is thought that the northern slopes may contain coal and perhaps petroleum or natural gas; the presence of gold, silver, copper, zinc, and lead also is suspected. Quantities of salt are known to exist, and lapis lazuli (a deep blue mineral, used as a gem), rubies, and beryl (a mineral, usually green, one variety of which is emerald) have been reported. There is some antimony (a white metallic element used in alloys of medicine) in Chitrāl. There is a hydroelectric potential, especially in the Daryā-ye Qondūz and Kowkcheh river basins on the northern side. Forests are still partially standing, but much merciless lumbering is rapidly reducing this resource. While many local peoples, especially the Chitrāli, make ingenious use of springs and rivers by building small aqueducts, agriculture would benefit greatly from more modern methods of irrigation. The local economy is at the bare subsistence level. Some dried fruit, a little lumber, mineral salt, charcoal, fodder grass, mats, and ropes are exported, mainly from Chitrāl. Sheep and goats are also raised.

Transportation. The Hindu Kush offers a formidable barrier to communication. There are, however, some important passes. The Baroghil Pass (12,480 feet, or 3,804 metres high), at the head of the Chitrāl Valley, is one of the lowest and easiest openings in the 1,500 miles of forbidding mountains that border the north of India and Pakistan. Further west the highest section of the Hindu Kush offers, for about 100 miles, a wall quite unpassable by normal means of communication. In the Central Hindu Kush the passes are also high; only in the western section do more accessible passes occur. In 1964 a tunnel was completed under the Sālang Pass (12,008 feet, or 3,660 metres) north of Kābul; consequently, for the first time in history, the great mountain wall has been pierced, making the north of Afghanistan accessible to the south at all seasons.

The Kakal Tunnel

The Hindu Kush can now be approached by motor transport from many directions. Chitrāl in the south is accessible, via the Lawarai Pass from Peshāwar, while the Kakal Tunnel has made Khānābād in the north accessible from Kābul. Lesser roads lead on to Feyzābād and, from there, to the Vākhān corridor, or to Zībāk, both situated in the heart of the mountain ranges. Many major peaks are now barely three or four days march from the last village accessible to motor transport.

Study and exploration. The West took note of the Hindu Kush when Alexander and his armies crossed the mountains, which according to some authorities, he did twice. The Hindu Kush was well known to Arab geographers, as well as to the Chinese, who occupied Chitrāl in the 8th century AD. Marco Polo, the Venetian traveller, and his group passed along the Hindu Kush through the Vākhān region. The mountains were also traversed by Timur (Tamerlane), the Mongol conqueror, in the 14th century and by Bābur, the Turkish conqueror who founded the Mughal empire, in the 15th century, in their expeditions against India. A number of explorers visited the region in the 19th century, and much knowledge was gained by the British during the two wars that they waged against Afghanistan from 1838 to 1842 and from 1878 to 1879. Further detailed knowledge of the area has been gained in the 20th century. In the second half of the 20th century hundreds of mountaineering and exploring expeditions have visited the Hindu Kush. (F.M.)

KARAKORAM RANGE

A mountain system of Central Asia, the Karakoram Range extends some 300 miles from the easternmost part of Afghanistan to the southeast. The borders of the Soviet Union, China, Pakistan, Afghanistan, and India all converge within the system.

Physical features. *Physiography.* The Karakorams consist of a group of parallel ranges with several spurs. Only the central part is a monolithic range. The width of the system is about 150 miles; the length is increased from 300 to 500 miles, if the easternmost extension—the Ch'iang-ch'en-mo Shan (called Chāng Chenmo in Jammu and Kashmir) and Pantong ranges of the Tibetan Highlands—is included. The Karakoram Range is one of the highest mountain systems in the world; its average height is around 20,000 feet (6,100 metres), and four peaks exceed 26,000 feet, the highest being K2 (Godwin Austen, Chogori, Dapsang) at 28,250 feet (8,611 metres). K2, the second highest peak in the world, was first climbed by an Italian expedition in 1954; the remaining high peaks were climbed in 1956–58.

Glaciation

The topography is characterized by craggy peaks and steep slopes. The southern slope is long and very steep, the northern slope steep and short. Cliffs and taluses (great accumulations of large, fallen rocks) occupy a vast area. In the intermontane valleys, rocky inclines occur widely. Transverse valleys usually have the appearance of

narrow, deep, steep ravines. Because of their great height, the Karakorams are characterized by heavy glaciation, the total glaciated area amounting to 6,900 square miles (17,800 square kilometres). Glaciers occur on both slopes, but glaciation is more developed on the southern, more humid slope. The snow line on the southern slope of the Karakorams begins at an altitude of 15,400 feet; glaciers begin at 9,440 feet. On the northern slope the figures are 19,400 feet and 11,580 feet, respectively. Often, glaciers combine to form complex glacial systems occupying not only valleys but also the watersheds. Seasonal thawing of the glaciers give rise to serious floods on the southern slopes. Traces of ancient glaciation are evident at altitudes of 8,500 to 9,500 feet.

The Karakorams serve as a watershed for the basins of the Indus and Tarim rivers. The formation of river channels, for the most part, occurs in the high-altitude zone, the melted waters of seasonal and perpetual snows and glaciers being principal feeders of the rivers. Groundwaters accumulate in the rocky taluses and contribute to a more even flow throughout the year. During winter, huge layers of ice are formed.

Geology. Structurally, the Karakorams originated from folding in the Cenozoic Era (up to 65,000,000 years ago). Granites, gneisses, crystallized slates, and phyllites dominate the geological composition. To the south and north, the crystal centre of the Karakorams is edged by a region of limestones and micaceous slates of the Paleozoic and partly of the Mesozoic eras (from 190,000,000 to 570,000,000 years old). To the south the sedimentary rock is sometimes cut by intrusions of granite. Certain areas expose slate at the surface, which yields more rapidly to weathering.

At the end of the Mesozoic Era (65,000,000 years ago), the region of Karakorams was characterized by great structural changes, and the Karakorams emerged as the result of intensive, geologically recent upheavals. Today there is still frequent seismic activity in the region, some events being of great violence. Hot springs are found in several areas.

There is also evidence of stannic tungsten on the northern slopes of the Karakorams and of alluvial gold on the southern slopes.

Climate. The climate of the Karakoram Range is for the most part semi-arid and sharply continental. The southern slopes are exposed to the humidifying influence of the monsoons coming in from the Indian Ocean, but the northern slopes are extremely dry. In the lower and central part of the slopes, rain and snow is precipitated in small quantities; average annual precipitation does not exceed four inches. At altitudes of more than 16,000 feet precipitation always takes a solid form, but, even lower down, in June, snow is not infrequent. At altitudes of around 18,700 feet, the average temperature during the warmest month is lower than 32° F (0° C), and, at altitudes between 12,800 and 18,700 feet, the temperature is lower than 50° F (10° C). Rarified air, intensive solar radiation, strong winds, and great ranges of temperature are characteristic climatic features of the region.

High-altitude vegetation patterns

Plant and animal life. The high-altitude vegetation of the northern and southern slopes of the Karakorams is varied. On the northern slope, at altitudes of 7,900 to 9,200 feet on the rocky desert soil, a complex of plant combinations of such species as flowering plants of the genus *Kalidium,* and horsetail (genus *Equisetum*) has developed. In this area it is not uncommon to encounter vast expanses completely devoid of vegetation. Only at the source of the Yarkand River (Tarim Basin) and its tributaries up to altitudes of 10,000 feet is there enough moisture to support individual thickets of brushwood (mainly barberry) and poplars. In the central part of the northern slope, at altitudes of 8,500–10,200 feet, a desert-steppe landscape is developed, with vegetation consisting of sparse thickets of coarse grasses and wintergreen. At altitudes of 10,500–11,500 feet, a mountain steppe predominates, and, in places that are most humid and well sheltered from winds, there are prairie steppes. Still higher up are found high-altitude expanses of wintergreen, wormwood, and meadows of desert-like plants. Sparse combinations of wintergreen and prickly herbs of the genus *Acanthus* are located on the coarse soils near the arable-land zone. On the moister southern slopes, more extensive and varied vegetation is found. Valleys up to 10,000–11,500 feet support forests of pine, Himalayan cedar, and, near streams, willows and poplars. Higher up, high-altitude steppes rather like typical alpine meadows predominate.

Notable animals of the region include the snow leopard, wild yak, and Tibetan antelope; in the southern foothills wild asses are also found. There are a great number of pikas and marmots. Among birds, the Pallas sand grouse, Tibetan capercaillie, partridge, ibis white dove, and red brambling are characteristic.

The people and economy. Being centred in an area of very high ranges covered with immense glaciers, the Karakorams are extremely inaccessible. Mountain passes are situated at altitudes of about 16,000 feet and are open only five or six months of the year. Sections along the banks of rivers and lakes are utilized as pasture, and in places, on the southern slopes, agriculture is developed, with two harvests in years when water is plentiful. Apricot orchards are extensive.

Exceptionally severe natural conditions in the Karakorams make life hard for man. An area of almost 80,000 square miles supports a population of only a few tens of thousands of people, mainly Tibetans, who live in villages at altitudes of up to 14,800 feet. Most of the Tibetans are farmers who grow barley, oats, and millet and who breed cattle. Individual groups of Tibetans lead a nomadic or seminomadic way of life and are occupied with the breeding of yaks, *dso* (a hybrid of the yak and common cow), sheep, and goats; they also do some hunting. Other peoples include the Baltis, who are Muslim, and the Ladākhis, who, like the Tibetans, are Tibetan Buddhist. Also there are the Burishki people, who speak a language that occupies a singular place in linguistic classification. The Burishki are Muslims and are settled on farms. (G.D.B.)

KUNLUN MOUNTAINS

The Kunlun Mountains (K'un-lun Shan), which extend approximately 1,675 miles (2,680 kilometres) from the Pamirs in the Soviet Union on the west to the Sino-Tibetan ranges on the east, constitute the longest mountain system in Asia, uniting dozens of ranges that are among the highest on Earth. Located in the People's Republic of China, within the autonomous regions of Sinkiang Uighur and Tibet and the province of Tsinghai, the Kunlun Mountains form the northern wing of the geologically uplifted region known as High Asia—the highest such region in the world.

The position of the Kunlun Mountains, between Tibet and the northern plains of Central Asia, determines the sharply asymmetrical structure of the system. Although the average elevation of the watershed ridges in the southern ranges is about 21,325 feet (6,500 metres), when viewed from the south the ranges rise only from about 3,300 to 4,900 feet above the Plateau of Tibet, which itself has an average height of between about 14,500 and 16,500 feet. As seen from the Tarim and Ala Shan plains to the north, however, which have an average altitude of only about 2,600 to 3,900 feet, the watershed ridges of the northern ranges (the average elevation of which is about 19,650 feet) create the impression of gigantic mountains that tower up to 14,765 feet over the surrounding plains.

General alignment of the mountains

Physical features. *Physiography.* General alignment is nearly latitudinal (from east to west), but individual segments change direction significantly, following the outlines of the Tarim Basin, the Ala Shan Desert, and the Tibetan massifs (mountainous masses). The most significant such deviations occur in the Khotan–Keriya (Ho-t'ien–Yü-t'ien) sector (about 81° E), which faces the Lop Nor plain (about 90° E). Here, the strike of the mountains shifts abruptly from northwest–southeast to southwest–northeast, before again resuming its northwest–southeast alignment.

Almost the full length of the Kunlun Mountains consists of parallel chains of ranges, the tallest of which are those closest to Tibet, separated by vast depressions and narrow

valleys. Because they are higher in relation to the surrounding plains, the northern slopes (the Tarim and Ala Shan) are steeper and more complexly dissected, while the southern slopes (those facing Tibet) are shorter, sometimes taking the form of ledges that are only weakly dissected. Whereas the heights of the major Kunlun peaks are several thousand feet shorter than the famous Himalayan peaks, the average height of the Kunlun and Himalayan ridges are almost equal. The elevations of the Kunlun mountain passes (from 18,700 to 20,340 feet), however, surpass those of the deeply eroded Himalayas.

The Kunlun system is not uniform in structure, being subdivided into two unequal sections—the smaller western and the principal eastern part. The western Kunluns (between the Pamirs and the alignment change in the Khotan–Keriya region) form three parallel chains of ranges crowded closely together. The Sha-li-k'o-erh, T'a-shih-k'u-erh-kan (Tashkurgantag), Agyl, and Sugettag ranges form the southern chain, which adjoins the Karakoram Range; the inner and highest chain is formed by the Mu-ssu-t'a-ko-a-t'e, Tokhtakoram, and Karangutag ranges; the Tiznaf and Sandzhutag ranges make up the northern chain. Because the mountain chains of the western Kunluns are divided only by narrow intermontane depressions, the width of this part of the system usually does not exceed about 60 miles.

The highest groups of peaks in the western Kunluns are found on its flanks—in the Gissar sector, the 24,865-foot (7,579-metre) Kung-ko-erh and the 24,757-foot (7,546-metre) Mu-ssu-t'a-ko-a-t'e massifs; in the Khotan sector, the 23,008-foot (7,013-metre) Karangutag and the 23,891-foot (7,282-metre) Mu-ssu massifs. In the intervening So-ch'e–Yarkand sector, however, all the ranges are lower; even the main peaks rarely reach 19,650 feet. Where the alignment changes in the Khotan–Kariya region, the northern chain of the Kunluns is interrupted, and ranges of the high inner chain border the Tarim Basin, on the side of which they are abruptly bounded by a gigantic ledge.

The eastern Kunluns are characterized by a complex branching of mountain chains that pass around broad intermontane valleys. The unitary direction characteristic of the western Kunlun ranges is lost here; individual ridges are often situated at an angle to one another. Moreover, the width of the mountain system increases sharply, reaching about 375 miles in places.

The Russian, the A-erh-chin Shan-mo (Astin Tagh), and the group of Nan Shan ranges form the northern chain of the eastern Kunluns, which many consider an independent mountain system. Near the Lop Nor plain these ranges describe an arclike curve in which their alignment changes from southwest–northeast to northwest–southeast. The western branch of the arc (with northeastern alignment) is made up of two ranges with a width of from 19 to 25 miles. The Russian Range, whose crest rises to 21,738 feet (6,626 metres), is the only one of noteworthy height within this branch; A-erh-chin Shan-mo (Astin Tagh) is as much as 11,500 to 13,000 feet lower, especially in the segment contiguous with the Tsaidam Basin.

The Nan Shan ranges

The eastern branch of the arc, which is formed by the system of Nan Shan ranges,is separated from the principal mountain chains of the eastern Kunluns by the vast Tsaidam depression. The five to seven ranges that constitute the Nan Shan system, which has an overall width of up to 186 miles, include Ch'i-lien Shan-mo (Richthofen), T'o-lai Shan (Khrebet Tkholo-shan'), Su-lo Shan (Suess), Wu-lan-ta-pan Shan (Humboldt), Ta-k'en-ta-fan Shan (Ritter), and southern Koko Nor. While the height of their crests varies from about 16,700 to 20,700 feet, the elevation of the longitudinal (north–south) intermontane valley floors between them varies from 10,500 to 11,800 feet. The Su-lo Shan, which rises to 20,820 feet (6,346 metres), is the highest of these ranges; but the most developed, as a mountain range, is the Ch'i-lien Shan-mo.

The principal chains of the eastern Kunluns are located between the Tsaidam Basin and the Tibetan uplands. The northernmost of these, the Ch'i-man–Burkhanbudda chain, is the lowest; the level of its series of summits is from about 17,400 to 18,000 feet. It rises massively above the Tsaidam Basin but stands out in only mild relief when seen from the Tibetan side. Forming an extension of the inner chain of the western Kunlun ranges is the Przhevalsky Range (Arkatag), the highest and longest in the eastern Kunluns and the principal structural pivot of this part of the mountain system. It contains the tallest peaks of the entire Kunlun Mountains, the 25,341-foot (7,724-metre) Wu-lu-k'o-mu-shih Ling and the 25,328-foot (7,720-metre) T'ieh-k'o-li-k'o Shan (also called the Chong-Karlyk-Tag [Great Snow Range] or Shapka Monomakha [Hat of Monomakh]). The crest of the range is snow covered and steep walled, rising vertically almost 3,300 feet; its mountain passes (K'a-la-mu-lun Shan-k'ou, Rekviem, and others) have elevations of close to 18,000 feet. The southern chain, formed by the K'u-k'u-shih-li (K'o-k'o-hsi-li) and Pa-yen-k'a-la Shan (Bayan' Karashan') ranges, is about 3,300 feet lower than the Arkatag.

The high plains separating the inner mountain chains of the eastern Kunluns from those to the north and south lie at the same elevation as the plateaus in the foothills of the Tibetan uplands and have a similar landscape. The most extensive of these is the Kul'tala Plain, which lies between the Przhevalsky Range and the Ch'i-man chain and which is up to 59 miles wide. Covering its surface next to the mountains are fields of broken stone; in areas of lower elevation there are salt marshes, as well as the A-ya-ko-k'u-mu Hu (Aiag Kum Kul') and A-tz'u-k'o Hu (Achchik Köl) lakes.

Geology. The principal folded structures and granitic rocks of the Kunluns are of Hercynian age, a period that lasted from about 230,000,000 to 250,000,000 years ago, during which there was much mountain building in the Eastern Hemisphere. The inner depressions of the Kunluns, however, are relatively recent structures in their entirety, being formed by deposits that are no more than 26,000,000 years old; only the largest of them, the Tsaidam depression, contains a thick sedimentary cover of which Jurassic deposits (136,000,000 to 190,000,000 years of age) represent the oldest strata. The Kunluns also represent a region of very recent movements of the Earth's crust, and great seismic (earthquake) activity.

Drainage. The Kunluns form a part of that region in Central Asia in which there is only internal drainage, associated mainly with the Tarim, Ala Shan, Tsaidam, and Kul'talin basins. Only the most easterly spurs of the mountain system, where the sources of the Huang (Yellow) and Yangtze rivers are located, have drainage systems that empty into the ocean.

Two groups of rivers compose the river network of the Kunluns: the large streams that rise in the Karakoram Range and in northern Tibet, cutting through the entire chain of Kunlun ranges by way of gorges, and the small streams that drain the slopes of the peripheral ranges.

Major rivers

The major rivers—the Gez, Yarkand, K'a-la-k'a-shih (Kara Kash), Yü-lung-k'a-shih (Yurang Kash), K'o-li-ya (Keriya), Ha-la-mu-lan (Kara Muran), and Ch'e-erh-ch'en (Cherchen)—form lengthy, zigzag valleys. In the broad and open longitudinal valleys between mountain ranges, the rivers flow quietly and calmly for long distances; in the ravines that bisect the ranges, however, short sections of the rivers flow through narrow gorges in violent torrents.

Although they receive some rainwaters, the Kunlun rivers are fed mainly by snows and glaciers. Therefore, the volume of flow varies with the seasons; 60 to 80 percent of it occurs in the summer months, when intensive thawing of snow and ice in the mountains is combined with maximum precipitation. In winter, the discharge of the rivers is extremely insignificant; in spring and autumn it is somewhat greater.

Glaciation. In spite of the great elevation, there is little glaciation in the Kunluns because of the extreme dryness of the climate; external snows persist only along the deep crevices of the highest peaks.

The main centres of glaciation, in which are found dozens of glaciers that are usually not more than six miles long, are the Kung-ko-erh, Mu-ssu-t'a-ko-a-t'e, Wu-lu-k'o-mu-shih, and Tyumenlik massifs, where elevations approximate about 23,000 feet. All the glaciers are notable for their unusual steepness, dropping 20 to 30 feet in every 100 feet of length.

Soils. Because the surface layer of the Kunluns does not receive moisture during a large part of the year, soil formation proceeds at a very slow rate. In general, the soils have little productive capacity, contain many coarse skeletal soil elements, and are almost devoid of humus. Brown soils appear only in the vicinity of the Pamirs and in the eastern Kunluns, where the moisture levels are better and vegetation richer.

Aridity and extremes of temperature

Climate. Located within the arid region of Central Asia, the Kunluns are almost totally isolated from the climatic influence of the Indian and Pacific Ocean monsoons. Instead, they are under the constant influence of the continental air mass, which causes great annual and daily temperature fluctuations. Desert yields to mountain steppes only near the Pamirs (King Ata Tagh) and the Tibetan mountains (Pa-yen-k'a-la Shan [Bayan' Karashan'] and the eastern Nan Shans), where the amount of annual precipitation increases to about 18 inches (455 millimetres). In these areas, up to 80 percent of the precipitation falls in summer—an indication of its relationship with the monsoons.

In the high-altitude zone, with its extremely sharp daily fluctuations of temperature, weathering from heat and frost reaches great intensity, accounting for the presence of an enormous quantity of loose material. Wind erosion and accumulations of loose debris are very apparent on the Gobi slope of the peripheral ranges. Maximum aridity occurs in the middle segment of the mountain system, between 78° and 93° E; to the west and east, however, the climate is somewhat moderated. Characteristic of the Kunluns as well as of the entire arid region of Central Asia are the winds; the strongest of which occur in autumn, when they often reach gale intensity.

Scanty cloud cover and prolonged sunshine are also characteristic of the Kunluns. Naturally, the amount of warmth in the Kunluns varies with the altitude: in the lower tier of mountains, (those bordering the northern plains), the average temperature in June is 77° to 82° F (25° to 28° C) and not lower than 16° F (−9° C) in January; in the upper tier of mountains and on the border of Tibet, however, the average temperature in July is less than 50° F (10° C) and often falls to −31° F (−35° C) in winter. Summers in the lower belt are long and hot; in the upper belt, they are short and cold.

In the most arid part of the Kunluns, precipitation is less than two inches annually in the foothills and about four to five inches in the high altitudes. The climate of the lower tier is that of the hot, Gobi-type desert; of the upper belt, it is that of the cold, Tibetan-type desert. Associated with these, in turn, are accumulations of loess—fine, wind-blown material—that forms a cover on the dissected mountain relief and is found at altitudes up to about 13,000 feet.

Soil characteristics

Plant life. Because of the primitiveness of the soil cover, the extreme deficiency of moisture, and, in the high altitudes, the insufficient warmth, the natural conditions of the Kunluns are not very favourable for plant growth. Plants have a stunted appearance and possess a number of distinctive physiological peculiarities. Most often they are perennial, dwarfish semi-shrubs with stiff leaves and deeply penetrating root systems. The number of species of plants is very limited, and the plant cover itself extremely thin.

In the most arid part of the Kunluns, desert-like conditions prevail at high altitudes. Only two types of landscape are to be seen—the hot desert of the lower part of the mountains and the cold desert of the Alpine region. In both zones, completely barren spaces predominate, alternating with small areas that support a thin plant cover.

In the western and eastern extremities of the mountain system, however, the higher moisture levels and richer vegetation are more conducive to the formation of more fertile soil. In these areas, the vertical zonality of the plant cover is more complex and includes zones that do not occur in those parts of the Kunluns that consist entirely of desert. In the middle-altitude region there is a zone of desert-like steppe (a grassy and almost treeless plain) in which there is a somewhat thicker plant cover as one proceeds upwards. Mountain steppes then emerge, as well as scattered forests, small at first but then larger. A well-developed forest zone, interspersed with mountain steppes and meadow sections, appears in the extreme west and the extreme east of the Kunluns.

Animal life. In the totally arid part of the Kunluns, animal life is meagre and has little variety; it becomes somewhat richer and more varied in the approaches to the Pamirs and in the eastern spurs of the system, where mountain steppe and forest vegetation appears. The predominant animal life in these areas consists of hoofed animals and rodents. Especially characteristic of hoofed animals are the mountain sheep (in the west the *arkhar* and in the east the *kukuyaman* type); the mountain goat; the wild ass; and the wild yak. The rodents are represented by mouse hare, field vole, and, on the meadowland slopes, marmot. Beasts of prey commonly found include wolf, fox, bear, and, in the west, snow leopard.

The people and economy. Most of the Kunluns is unpopulated; only the large river valleys, up to an altitude of about 10,000 feet, contain any inhabitants. Settlements become fewer deep in the mountains and nonexistent in the high-altitude zone and on the Tibetan slope. The Uighurs, the most numerous population group, are concentrated in large settlements in the foothills bordering the Tarim Basin; Tadzhiks live in the western and Mongols in the eastern mountains. Agriculture and small-scale, nomadic animal husbandry are the basic occupations of the mountain population. The main agricultural crops are wheat and barley; domestic animals that are bred include sheep, goats, and yaks.

Throughout their extent the Kunluns are almost impassable, because of their deep and narrow ravines, steep slopes, mountain passes of great height, and torrential streams. In addition there is an absence of fuel facilities for vehicles and of forage for pack animals. Even the caravan trails are rare and difficult, especially in the highly eroded middle belt of the mountains.

Of the three automobile roads through the Kunluns, one proceeds along the southern edge of the Tarim Basin, partially using the ancient Silk Road that until the 16th century connected China with Central and western Asia. The other two roads, both of which lead into Tibet, cut across the Kunluns: the western road passes along the T'i-shih-yuëh-fu (Tiznaf), Yarkand (Raskem), and K'a-la-k'a-shih (Kara Kash) river valleys and the eastern road reaches Tibet by a route that extends from Ko-erh-mu (Golmo; in the Tsaidam Basin) to the upper reaches of the Yangtze River and then runs through the Ch'i-man Shan, the eastern spur of the Przhevalsky (Marco Polo Range) and the K'o-k'o-hsi-li (Kukushili).

Because the interior of the Kunluns has not been studied extensively, information about the mineral resources of this vast and geologically heterogeneous territory is extremely scant. Evidences of gold-bearing deposits have been found in various parts of the mountain system, and gold was extracted until the beginning of the 20th century, principally along the upper course of the Yu-lung-k'a-shih Ho (Yurung Kash). Nephrite (a type of jade) is widely distributed and has been extracted from rock deposits and river alluvium. There are well-known rock deposits of this mineral in the Karangutag Range, while alluvial deposits are found in the river valleys of the K'a-la-k'a-shih and Yulung-k'a-shih Ho (Yurung Kash). Small deposits of lead and zinc have been discovered at a number of points in the northern chain of the western Kunluns, while in the K'a-la-k'a-shih Ho Valley, above Sai-t'un-la (Shakhidulla), indications of tin-bearing deposits have been found. Deposits of iron and chromitic ores and evidence of copper mineralization have been located in the Nan Shan and A-erh-chin Shan-mo (Astin Tagh) ranges. Oil is recovered in the Tsaidam Basin, and there are extensive coal-bearing deposits in the intermontane depressions of the western and eastern Kunluns. Although coal is mined in many of these areas, it is on a small scale and solely for local needs.

The exploitation of the mineral resources of the Kunluns is hampered by the harsh natural environment, the great height of the mountains, difficulties of access, lack of water supplies, and scarcity of population.

(V.M.S.)

PAMIRS

The Pamir mountain area belongs mainly to the Gorno-Badakhshan *avtonomnaya oblast* (autonomous region) of the Tadzhik Soviet Socialist Republic of the U.S.S.R. It is surrounded by the Central Asian mountain systems of the Hindu Kush, Kunlun, Gissar-Alai, and Tien Shan.

The territory of the Pamir mountain area is bounded on the north by the Trans Alai Range (Zaalaysky Khrebet); on the east by the Sarykol Range, which forms the border between China and the U.S.S.R.; on the south by Lake Zorkul, the Pamir River, and the source of the Pyandzh River bordering Afghanistan; and on the west by the north–south segment of the Pyandzh Valley. The eastern parts of the Peter I and Darvaz ranges on the northwest are included within the Pamirs, since their glaciers comprise a single system with the glaciers of the northwestern Pamirs. The derivation of the word Pamir has not been definitely established.

Physical features. *Physiography.* The Pamirs are a combination of east–west and north–south ranges, with the former predominating. The east–west Trans Alai Range, which forms the northern frame of the Pamirs, falls steeply to the intermontane Alai Valley. The high central part of the range, between the Tersagar Pass on the west and Kyzylart on the east, averages between 19,000 and 20,000 feet (5,790–6,095 metres), reaching its highest point at Lenin Peak, 23,400 feet (7,134 metres). South from the Trans Alai extend three north–south ranges. Of these, the western, the Academy of Sciences Range, and the central, Zulumart, are relatively short; and the eastern, Sarykol Range, forms the eastern border of the Pamirs. The area east of the Sarykol Range is sometimes called the Chinese Pamirs.

Principal mountain ranges

The north–south Academy of Sciences Range enters into the northwestern Pamir system, where it rises into a huge barrier, reaching 24,584 feet (7,495 metres) in Communism Peak (the highest point in the U.S.S.R.). The eastern slope of the Academy of Sciences Range is covered on the south face by the Fedchenko Glacier. The western slope intersects other ranges that lie still farther to the west: the Peter I Range, with Moscow Peak (22,300 feet); the Darvaz Range, with Arnavad Peak (20,000 feet); and the Vanchsky and Yazgulemsk ranges, with Revolution Peak (22,900 feet). The ranges are separated by deep ravines. To the east of the Yazgulemsk Range, in the central portion of the Pamirs, is the east–west Muzkol Range, reaching 20,400 feet (6,980 metres) in the Soviet Officers Peak. South of it stretches one of the largest ranges of the Pamirs, called Rushan on the west and Bazar-Dara or Northern Alichur on the east. Still farther south are the Southern Alichur Range and, to the west of the latter, the Shugnan Range. The extreme southwestern Pamirs are occupied by the Shakhdarin Range, composed of north–south (Ishkashim Range) and east-west elements, rising to the Mayakovsky Peak (20,000 feet) and Karl Marx Peak (22,100 feet). In the extreme southeast, to the south of Lake Zorkul, lies the east–west Vakhan Range.

Eastern and western Pamirs

It is customary to divide the Pamirs into a western area and an eastern area, distinguished by their forms of relief. In the eastern Pamirs a medium-mountain relief predominates on a high raised foundation. While the heights above sea level average 20,000 feet or more, the relative heights of the peaks above their foundation do not in most cases exceed 3,300–5,900 feet. The ranges and massifs have mainly rounded contours, and the wide and flat-bottomed valleys and troughs between them, situated at heights of 12,100–13,800 feet, are occupied either by quietly running, meandering rivers or by dry channels. The valleys and slopes of the ranges are covered by layers of loose material.

In the western Pamirs the relief is high mountain and sharply disjointed, alternating between low ranges and alpine ridges capped by snows and glaciers; and there are deep, narrow ravines with high, rapid rivers. The valleys and depressions are filled with debris, so that almost the only suitable places for human settlement are the alluvial fans in the valleys of tributaries of the Pyandzh River. The transition from the eastern-Pamirs type of relief to the western-Pamirs type occurs gradually. The conventional boundary is a line joining the ridge of the Zulumart Range with Kara-Bulak Pass in the Muzkol Range; from Pshart Pass, it follows the ridge of the Northern Alichur Range to Lake Zortashkol, where it turns south to the valley of the Pamir River.

Geology. Geologists divide the Pamirs into three zones according to the characteristics of their rock formations: the northern, central, and southern Pamirs. The southern zone consists of metamorphic rocks (gneiss, quartzite, marble, and others) to which a majority of researchers attribute a Precambrian age (more than 570,000,000 years ago). The zone on the whole represents a huge anticlinorium, or series of stratified arches. The central zone of the Pamirs contains limestone, sandstone, and shale rocks of the Jurassic, Triassic, and Permian periods (136,000,000 to 280,000,000 years ago) and also red-coloured terrestrial rocks of the Lower Cretaceous Period (136,000,000 years ago). There are some marine rocks of the Lower and Middle Paleozoic Era (345,000,000 to 570,000,000 years ago) and lava and tufaceous rocks of the Paleocene (54,000,000 to 65,000,000 years ago). The structure of the central Pamirs is that of a huge synclinorium (an inverted arch caused by fracturing); it is separated from the northern Pamirs by a deep fracture.

In the structure of the northern Pamirs, two subzones can be discerned: a Paleozoic zone, which stretches to the ridge of the Trans Alai Range, and a zone beyond, which is composed of more recent deposits. The Paleozoic subzone of the northern Pamirs is a huge anticlinorium with a complex internal structure. It is separated from the Trans Alai subzone by the Karakul fracture. The Trans Alai subzone is very complex. Its western part is a fan-shaped anticlinorium, in the centre of which emerge Jurassic deposits; radiating outward are more recent, dislocated rocks of the Lower Cretaceous Period. The eastern part has Cretaceous and Paleocene deposits in a system of conflicting folds. Because of the numerous overthrusts, or horizontal faults, in some places the layers overlap each other. On the north the Trans Alai subzone is bounded by the deep Gissaro-Trans Alai fracture, separating the Pamirs from the Gissaro-Alai system.

Severity of climate

Climate. The climate of the Pamirs is arid and continental. These features are more pronounced in the eastern part, where there are broad, closed basins in which cold air is retained and a barrier of high ranges intercepting moist air currents. There is a mixed circulation of air—western (cyclonic) and southern (monsoonal). In the valleys of the western Pamirs the amount of annual precipitation is four to 10 inches (100 to 254 millimetres), and in the eastern Pamirs two to five inches. In the high altitudes and on slopes of mountains, the amount of precipitation increases, reaching 32 to 40 inches on the Fedchenko Glacier. The thickness of the snow blanket in the western Pamirs reaches 20 to 28 inches, and in the eastern it reaches 1.5 to four inches. The average January temperature in the eastern Pamirs at heights around 11,500 feet is 0° F (−17.8° C). Winter here is long (October through April) and severe, and extremes of temperature have been recorded at below −58° F (−50° C)—in Bulunkul in 1953, −64.9° F (−53.3° C). In the short summer, temperatures do not rise above 68° F (20° C). The climate of the valleys of the western Pamirs is more moderate. The average temperature in January at heights of about 6,900 feet is 18.7° F (−7.4° C), and in July it is 72.5° F (22.5° C), but temperatures vary greatly. The period of vegetation (with temperatures of 41° F [5° C]) is 223 days in Khorog and 140 days in Murgab.

Glaciation. The Pamirs have 1,085 glaciers, covering an area of 3,105 square miles (8,040 square kilometres). The largest centres of glaciation occur in the Academy of Sciences, Trans Alai, Rushan Northern Alichur, Yazgulems, Darvaz, Peter I, and Zulumart ranges. The largest valley glacier, Fedchenko (length 44.3 miles; 72 kilometres), starts in the Academy of Sciences Range; other glaciers in this range include the Grumm-Grzhemaylo (23 miles), Garmo (17 miles), Sagran (15 miles), and Geographic Society (13 miles). The main glaciers of the Trans Alai Range are the Sauk-Dara (16 miles), Korzhenevsky (around 13 miles), October (10.9 miles), and Lenin (5.9 miles). In

the eastern Pamirs shallow bog glaciers and snow fields predominate.

Drainage. The rivers belong mainly to the basin of the Amu Darya (the ancient Oxus), which forms the frontier between the U.S.S.R. and Afghanistan and flows into the Aral Sea. Its upstream extensions are the Pyandzh and the Pamir. The area also contributes to the basin of the Tarim, which flows eastward into China. Lakes include Karakul (a salt lake), Rangkul, Shorkul, Zorkul, Yashilkul, and Sarez.

Plant life. Vegetation in the Pamirs, especially in the eastern Pamirs, is poorly developed. Bare cliffs or a cover of surface rubble predominate. At high altitudes the vegetation changes with increasing altitude from mountain desert flora to mountain drought-resisting plants, then to mountain steppe vegetation, and finally to cold-resistant plants. Native forms predominate, but some forms from Central and Southwest Asia are found. The eastern Pamirs are a cold, high-mountain desert, with woody vegetation completely absent and with low-growing plants that are adapted to the severe conditions. On the dry mountain slopes there are low shrubs of winter fat, the only form of vegetable fuel in the area, and plant cover, such as the Pamir tansy, oxytropis, astragalus, local species of wormwood, the bulbous iris, and meadow grass. On the bottoms of the moist valleys, sedge and cobresia meadows are abundant.

Mountain flora

The vegetation of the western Pamirs is richer, although on the mountain slopes and bottoms of valleys there is a prevalence of wormwood and haloxylon. At heights over 8,500 feet, spiny pillow-form plants (*e.g.,* acanthus, spiny astragalus) are widespread. At heights over 10,500 feet, yugan, kamol, fescue, and feather grass are found. At 12,500 to 14,100 feet are alpine cobresia meadows; above 14,500 feet vegetation is sparse. Along the rivers of the western Pamirs are dense growths of willow, sea buckthorn, birch, poplar, and hawthorn. A thinner wood–shrub vegetation reaches heights of 12,500 feet, including Juneberry, almond, birch, and juniper. On irrigated lands there are cultivated plantings of grape, apricot, apple, pear, walnut, and mulberry trees.

Animal life. The fauna of the Pamirs are not numerous. In the eastern Pamirs are found the *arkhar* (a mountain sheep), the long-tailed marmot, and the large-eared Tibetan wolf. Birds include the Tibetan mountain turkey, the Tibetan raven, the horned lark, and the snow vulture. The western Pamirs have the mountain goat (*kiik*), brown bear, wolf, fox, snow panther, lynx, weasel, marten, *zayatstolay* (a hare), dormouse, and flying mouse. Birds include the Indian oriole, bluebird, dark-breasted pheasant, stone partridge, and paradise flycatcher. The Pamirs have few fishes; only the carp and the Tibetan loach are known.

The people and economy. More than 90 percent of the population are Tadzhiks living in the western Pamirs. Their languages belong to the Iranian group, and those who are religious are Shī'ite Muslims. The inhabitants of the eastern Pamirs are Kirgiz, who speak a Turkic language and are Sunnite Muslims.

Nearly all are peasants whose chief occupation is farming and livestock breeding. The small amount of arable land is planted with grain, beans, gourds, and potatoes, and there are orchards of apples, pears, apricots, and mulberry trees. Sheep and goats are the predominant livestock.

Agriculture

Industry in the Pamirs includes several small hydroelectric power stations and a few mines. In the eastern Pamirs, brown coal and common salt are mined. There is evidence of industrial deposits of gold, gems, jasper, lazulite, mica, asbestos, and talc. Thermal and mineral springs are common. There are auto routes across the Pamirs from Dushanbe in the west to Khorog in the south and from there to Osh in the east. Another route runs from Khorog south through the once impassable ravine of the Pyandzh–Pamir rivers. Buses go from Khorog to several regional centres. Many other routes are accessible only to pedestrians and pack animals.

Study and exploration. Modern exploration began with the Russian A.P. Fedchenko, who in 1871 succeeded in reaching the northern foot of the Pamirs from the Alai Valley. In 1877 the Russian geologist I.V. Mushketov visited the valley of the Muksu River and the vicinity of Lake Karakul. In 1877–78 the Russian zoogeographer N.A. Severtsov, penetrating into the depth of the mountain country, made a chart of its structure. In 1878 an expedition under the Russian naturalist V.F. Oshanin discovered the large valley glacier subsequently named A.P. Fedchenko. From 1884 through 1887, the Pamirs were explored by the zoologist G.Y. Grum-Grzhimaylo, who provided valuable data on glaciers of the northwestern and northeastern Pamirs.

Under the Soviets, explorations in the Pamirs have become systematic. In 1928 an expedition of the Academy of Sciences of the U.S.S.R. explored the region of the Fedchenko Glacier, making possible the first accurate topographical maps of the northwestern Pamirs. In 1933 the first high-mountain glaciological observatory in the world was constructed on the Fedchenko Glacier, at a height of about 14,800 feet. The Tadzhik–Pamir Expedition of 1932 resulted in important monographs on the geology, geomorphology, and hydrogeology of the Pamirs. Soviet alpinists have contributed much to the investigation of the Pamir region—a part of the world not easily accessible.

(T.K.Z.)

TIEN SHAN

The Tien Shan (Pinyin Dian Shan), Chinese for "Celestial Mountains," forms one of the great mountain systems of Central Asia. Straddling the border between the U.S.S.R. and China, it stretches for about 1,800 miles (3,000 kilometres) from west-southwest to east-northeast. It is about 300 miles wide in places at its eastern and western extremities but narrows to about 220 miles in width at the centre.

The Tien Shan are bounded to the north by the Dzhungarian and southern Kazakhstan plains and to the southeast by the Tarim Basin; to the southwest, the Gissar-Alai Mountains form part of the Tien Shan, making the Alai (Alayskaya), Surkhandarya (Surkhobskaya), and Gissar (Gissarskaya) valleys the boundaries of the system with the Pamir mountain ranges. The Tien Shan also include the Chu-Ili Mountains (Chu-Iliyskiye Gory) and the Karatau Range (Khrebet), which extend far to the northwest into the Kazakhstan lowlands. Within these limits the total area of the Tien Shan is about 386,000 square miles (1,000,000 square kilometres).

The highest peaks are a central cluster of mountains forming a knot, from which ridges extend along the boundary between China and the Soviet Union; these peaks are the Pobeda Peak (Pik Pobedy, or Victory Peak), which is 24,406 feet (7,439 metres) high, and the Khan-Tengri Peak, which is 22,949 feet (6,995 metres) high.

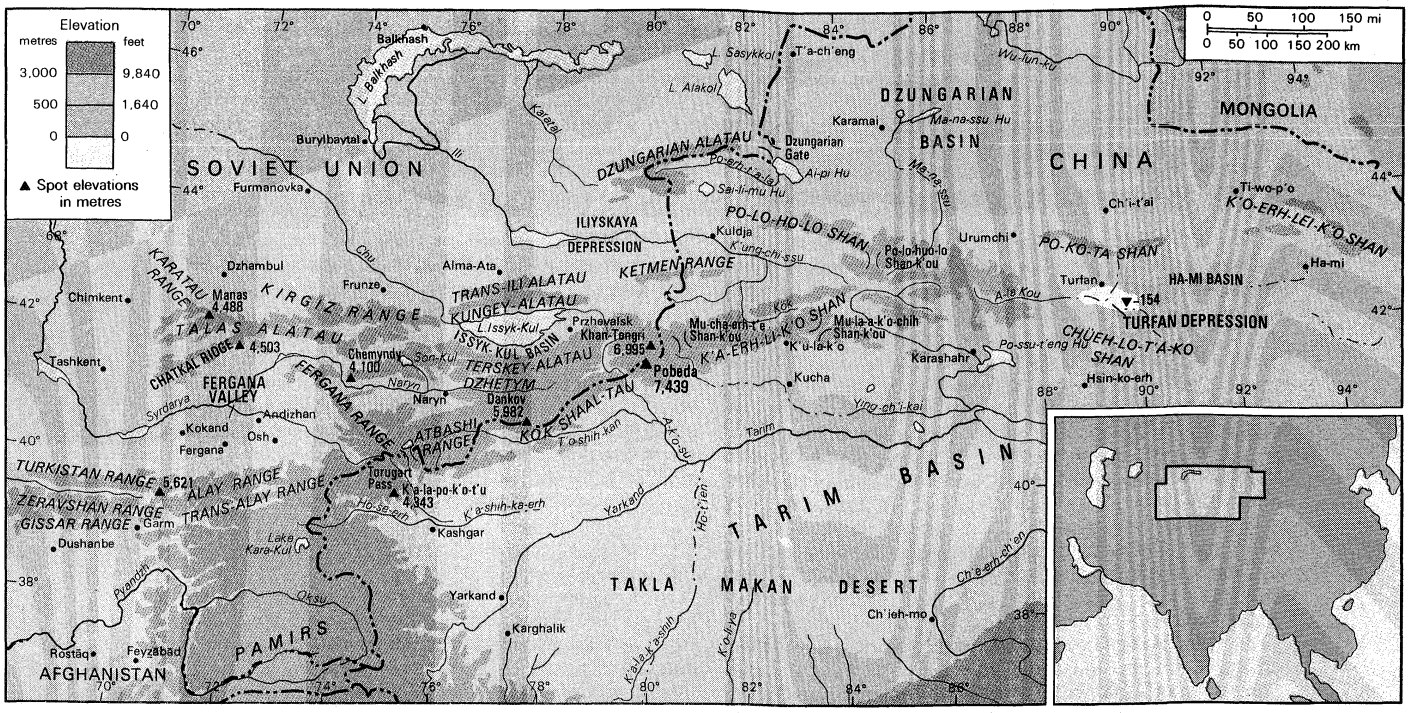
The highest peaks

Physical features. *Physiography.* The relief is characterized by a combination of mountain ranges and intervening valleys and basins, trending generally from east to west. The deepest depression in the eastern Tien Shan is the Turfan Depression, within which is the lowest point in Central Asia—505 feet (154 metres) below sea level. Thus, the differences in elevation in the Tien Shan are extreme, exceeding four and a half miles. The eastern extension of the Turfan Depression is the Ha-mi Basin; both basins are bounded on the north by the Poko-to Shan, with elevations of up to 17,864 feet (5,445 metres), and by the eastern extremity of the Tien Shan, the K'o-erh-lei-k'o Shan, which reaches heights up to 16,158 feet (4,925 metres).

The ranges are of the alpine type, with steep slopes; glaciers occur along their crests. The basins are bounded on the south by the low rising Chiao-lo Shan. West of the Turfan Depression is one of the greatest mountain knots of the eastern Tien Shan: the O-ha-pu-t'e Shan, which reaches. elevations of up to 18,208 feet (5,550 metres). The ridge has considerable glacial development, as well as numerous forms of relief that indicate the area was the site of ancient glaciation.

West of 84° east, the eastern Tien Shan ridges fork, trending in southwestern and northwestern directions, and enclose the vast Ili Depression (Iliyskaya Vpadina), which gradually widens and loses height as it proceeds westward. It is bounded on the north by the Po-lo-ho-lo Shan, which

The Ili Depression



The Tien Shan.

has glaciers in the eastern part and is characterized by steeply sloping ridges. This range also gradually descends westward, where, at a height of 6,801 feet (2,073 metres), lies the great undrained lake of Sai-li-mu Hu. The Ili Depression is bounded on the south by the highest mountains in the eastern Tien Shan—the K'a-erh-li-k'o Shan, reaching heights up to 22,346 feet (6,811 metres), and the isolated Ketmen Range (Khrebet Ketmen), which rises to an elevation of 11,936 feet (3,638 metres) in the central part of the depression.

The northern extremity of the Soviet part of the Tien Shan forms the Dzhungarian Alatau Range (14,645 feet [4,464 metres]), which is subject to considerable glacial action. To the south, the Trans-Ili Alatau Range rises abruptly above the Ili Depression to a height of 16,315 feet (4,973 metres). The successive transition of climatic zones, determined by altitude, from arid and dry steppe at lower levels to glacial at the summit is evident on the northern slopes of this range. The Kirgiz (Kirgizsky) and Talas (Talassky) Alatau ranges, rising above 13,000 feet and located farther west, also belong to the outer chain of the northern Tien Shan. There is a great difference in elevation between these outer mountain ridges and the plains at their base. Streams, therefore, usually plunge down the mountainsides through deep gorges and, as they flow out onto the plains, form vast fan-shaped deposits of silt and mud. On the fertile land formed by this process are located many oases and population centres, including the cities of Alma-Ata and Frunze in the Kazakh and Kirgiz Soviet Socialist republics. The Kungey-Alatau and Terskey-Alatau ranges also belong to the northern Tien Shan. They rise to a height of 17,100 feet (5,212 metres) and border the vast Issyk-Kul Basin, the centre of which is filled by the lake Issyk-Kul.

The Aksay River (T'o-shih-kan Ho in Chinese) Basin and most of the Naryn River Basin are situated within the inner Tien Shan. This region is characterized by the alternation of comparatively short mountain ranges and valleys, both extending east and west. The predominant elevations of the mountains vary from about 10,000 to 15,000 feet, while the elevations of the depressions that separate them vary from between about 6,000 to 10,500 feet. The most important ranges are Borkoldoy (16,565 feet [5,049 metres]), Dzhetym (16,178 feet [4,931 metres]), Atbashi (15,702 feet [4,786 metres]), and the Kok Shaal-Tau Range, in which Dankov Peak reaches a height of 19,626 feet (5,982 metres).

The elevation of the mountains increases in the Saryd-zhaz River (called K'un-a-li-k'o Ho in Chinese) Basin area in the central Tien Shan, which lies to the east of the Akshiyrak Range. The separate ranges gradually converge, forming the high-altitude mountain knot already mentioned, which includes the Khan-Tengri crests and Pobeda (Victory) Peak.

The Fergana Range

In contrast to most of the Tien Shan ranges, which run approximately east–west, the Fergana Range (Fergansky Khrebet), separating the inner region from the western and southern Tien Shan, extends from southeast to northwest. Its maximum elevation is 15,354 feet (4,680 metres). The southwestern slopes display a variety of climatic zones in the course of their gradual descent.

The western Tien Shan ranges lie north of the Fergana Valley (Ferganskaya Dolina). Several short but high and steep ranges running southwest–northeast here meet the southern sides of ranges running westward and northwestward. The highest peak is the Chatkal Ridge (14,773 feet, or 4,503 metres), and the predominant elevations vary from about 7,500 to 10,500 feet.

The southern Tien Shan ranges (including Turkistan, Zeravshan, and Alai, among others) border the Fergana Valley on the south and extend chiefly east and west. The maximum elevation is 18,441 feet (5,621 metres), with several peaks above 15,000 feet. To the south, the Tien Shan meets the Pamirs. Foothills approach the northern slopes of the ranges; there are oases on the plains below the mountains.

Geology. The mountains of Tien Shan are composed in the main of crystalline and sedimentary rocks of the Paleozoic Era (from 570,000,000 to 225,000,000 years ago). The basins that lie between the mountains are filled with sediments from the Mesozoic (225,000,000 to 65,000,000 years ago) and Cenozoic (65,000,000 years ago to the present) eras. These sediments were chiefly formed by the erosive action of the area's rivers. Granite-like rocks crop out over much of the area in the north and east of the Tien Shan.

The north and east portions of the region underwent folding during the mountain-building period that occurred during the Early Paleozoic Era; it has been uplifted dry land since, and its original sedimentary cover has been almost completely obliterated by erosion. The southern and western parts of the Tien Shan, however, consist principally of sedimentary metamorphosed (structurally changed by heat and pressure) rock and, to a lesser degree,

of intrusive and volcanic rock. These regions experienced folding during the Late Paleozoic Era.

A new stage of development began in the middle of the Tertiary Period (about 26,000,000 years ago) and has continued to the present time. It has been characterized by sudden movements of the Earth's crust. Loose fragments of rock have slid into the valleys and formed accumulations; those in the Fergana Valley are almost five miles thick. Shallow lakes were formed in many valleys and later evaporated, leaving behind salty deposits.

Subsequently, glaciers deposited boulder moraines (accumulations of earth and stones) in the mountains, while gravel and loess (wind-borne deposits) strata accumulated in the valleys. Zones of deep faulting occur, usually along the boundaries between the ridges and the valleys. Large-scale horizontal movements have occurred along the great Talas Fergana fault, which traverses nearly the entire Tien Shan system along the northeastern slopes of the Fergana Range and its northwestern extension. The deep faults are associated with catastrophic earthquakes that occurred at Verny (1887), at Kashgar (1902), in the northern Tien Shan chains (1911), and at Chatkal (1946), and Khait (1948).

Largest glacial areas

Glaciation. The total area of the Tien Shan glaciers exceeds 3,800 square miles, of which more than four-fifths is in the Soviet Union. Largest among the several glacier areas are the Khan-Tengri-Pobeda region and the O-ha-put'e Shan. There are also many glaciers in the Kok Shaal-Tau Range, the Akshiyrak Range, the Trans-Ili Alatau Range, and the southern Tien Shan. The largest glacier in the Tien Shan is Inylchek Glacier (Lednik), which is approximately 37 miles long; it descends from the western slopes of the Khan-Tengri massif and branches into numerous tributaries. Other large glaciers in this area include North (Severny) Inylchek (24 miles) and Mu-cha-erh-t'e Shan-k'ou (21 miles). The length of the largest Tien Shan glaciers elsewhere is usually between six and 12 miles; the most usual size is that of the relatively small valley glaciers, from about one and a half to three miles long.

The glaciers are usually fed by snowfall upon the glaciers themselves or by snow avalanches from the surrounding slopes. Glacial action in the Tien Shan is apparently decreasing; most glaciers are either receding or standing still. During recent decades, however, large glaciers in the inner Tien Shan region have made short-term advances. The glaciers of Tien Shan feed many large rivers, including the Naryn, Sarydzhaz, Ili, and Zeravshan.

Drainage. The rivers of the Tien Shan flow into major inland depressions, such as the Azalskaya and Tarim. The largest rivers are the Ili and Chu in the northern Tien Shan, Naryn in inner Tien Shan, Sarydzhaz in central Tien Shan, and Zeravshan in southern Tien Shan. Their maximum flows occur at the end of spring and in summer. Freshets sometimes cause catastrophic flows of mud and stone. Much water is diverted for irrigation. Hydroelectric power plants have been constructed on the Naryn, the largest river of the Tien Shan; the largest is Toktogul, completed in 1979.

The largest lake is the undrained Issyk-Kul, situated at 5,279 feet (1,609 metres). The lake, which has an area of 2,425 square miles, is saline and does not freeze in the winter; it is used for navigation and is a popular resort and tourist attraction. Po-ssu-t'eng Hu (533 square miles in area) is situated in the eastern Tien Shan.

Climate. The position of Tien Shan in the centre of Eurasia governs its sharply continental climate, characterized by great extremes of temperature in summer and winter. The characteristic aridity of the region is manifest in the surrounding deserts and dry regions. The area absorbs much solar heat, and there are about 2,500 hours of sun each year. The climate becomes progressively cooler and more humid as the elevation of the mountains increases. Permafrost (perennially frozen subsoil) is extensive above 9,000 feet. The prevalent air masses are transported over the Tien Shan by moisture-bearing westerly winds from the Atlantic Ocean. Most of the precipitation falls on the windward western and northwestern slopes at altitudes of between about 7,500 and 9,000 feet; it varies from between about 28 and 31 inches at one extreme and 59 and 79 inches at the other. To the east and in the interior regions of the Tien Shan, the total precipitation decreases to between eight and 12 inches, and it amounts to less than four inches in places. Maximum precipitation falls on the southern Tien Shan in March and April, and the summer is dry. In western and northern Tien Shan most of the rain falls during the warm period of the year, with a maximum in April or May. Most of the rain in the inner and eastern Tien Shan regions falls during the summer months. Many mountain valleys here are used as winter pastures because of the small amount of snow that falls in wintertime.

Precipitation

Temperatures vary in the Tien Shan, mostly depending on height. Summer is hot in the foothills: the mean temperature in July in Fergana Valley may reach 81° F (27° C); in the Ili Depression it may reach 73° F (23° C); and up to 93° F(34° C) to the east, in the Turfan Depression, where the climate is even more continental. The temperature in July at a height of about 10,500 feet in inner Tien Shan drops to 41° F (5° C), and frost is possible throughout summer. The mean temperature in January in Fergana Valley is 25° F (−4° C); in the Ili Depression it is 14° F (−10° C); and it drops to −9° F (−23° C) in the Alpine regions of inner Tien Shan, while in places (in particular, Aksay Valley) temperatures of −58° F (−50° C) have been recorded.

Plant life. The characteristics of the living world of the Tien Shan are largely determined by the region's distinct zones of elevation, which provide a diverse distribution of soils and vegetation. In the foothills and plains at the base of the mountains semidesert and desert areas have usually developed; these zones continue to heights of between 5,250 and 5,800 feet. In the Tien Shan they are characterized by ephemeral vegetation growths that die out at the beginning of summer; xerophyte (adapted to a scant supply of water) grasses, wormwood, and the desert shrub ephedra are generally distributed. The most common landscape in the Tien Shan is steppe, which occurs at elevations of between about 3,500 and 11,000 feet.

The forests of the Tien Shan alternate with steppes and meadows. They are principally on the northern slopes and extend to an elevation of 9,000 to 9,800 feet. On the lower slopes of the outer ranges the forests are principally deciduous, consisting of maple and aspen, with extensive admixtures of wild fruit trees (apples and apricots). Vast areas of the southwestern slopes of the Fergana Range are occupied by very ancient nut-bearing forests. Stands of pistachio, walnut, and juniper are found up to 7,500 feet on the shaded slopes of several western and southern Tien Shan ranges. North and east of the Fergana Valley, coniferous forests predominate. At the upper boundary they are often replaced by sparse juniper forests. The water meadow forests in the river valley bottoms, in which aspen, birch, poplar, and various brushwoods ordinarily grow, lie far outside the forest zone. The forest glades and areas adjacent to the upper tree line are usually covered with meadow vegetation. Sub-Alpine meadows of mixed grasses and cereals extend up to almost 10,000 feet on the moist northern slopes but on southern slopes are usually replaced by mountain steppes. There are short-grass Alpine meadows up to 11,500 feet. In the inner and eastern Tien Shan regions, at elevations between 11,500 and 12,000 feet and sometimes higher, the level areas and gentle slopes are "cold deserts," with sparse and short vegetation. Mosses and lichens are found in the areas of the glacial zone that are free of snow and ice.

Animal life. Animals in the Tien Shan include the wolf, fox, and ermine. There are also many typical Central Asian species, inhabiting chiefly the high mountains; these include snow leopard, mountain goat, Manchurian roe, and mountain sheep. The forest–meadow–steppe zone is inhabited by bear, wild boar, badger, field vole, members of the jerboa family (nocturnal jumping rodents), and members of the Ochotonidae family (short-eared mammals related to the rabbits). The many birds include the mountain partridge, pigeon, Alpine chough, crow, mountain wagtail, redstart, Himalayan snow cock, and other species. The lower zones—desert and semiarid regions—are visited by animals from the neighbouring plains, such

as antelope, gazelles, Tolai hares, and gray hamsters. Lizards and snakes are also found. (Y.Y.R.)

The people and economy. Several million people live in the Tien Shan. The Fergana Valley is the most densely populated, with more than 500 persons per square mile (195 per square kilometre) in places. Most of the Tien Shan is occupied by the Kirgiz and Uighur ethnic groups. Tadzhiks, Uzbeks, Kazakhs, and Mongolians reside along the periphery of the region. Substantial Russian and Ukrainian populations have been established in the Soviet part of the Tien Shan in recent decades; Chinese populations live in the eastern Tien Shan. Agriculture has developed in the valleys and on the mountain slopes with the aid of irrigation, and livestock herding is practiced in the mountains.

After the Russian Revolution of 1917, the nomadic Kirgiz and Kazakhs adopted a settled way of life. Their principal occupation is the herding of livestock; in the summer herds of horses, sheep, and cattle are driven to the mountain pastures. Where conditions permit, agriculture is developed. The Uighurs live principally by irrigated agriculture, supplemented by handicraft production. Except for the Mongolians, the other peoples of the Tien Shan also engage in agriculture. (S.I.B.)

Study and exploration. The Russian Geographical Society played a major role in the scientific exploration of the Tien Shan. From 1856 to 1857 the Russian geographer P.P. Semyonov-Tyan-Shansky gave the first scientific description of many regions of northern and inner Tien Shan, while the expeditions of another Russian geographer, G.Y. Grum-Grzhimaylo, in the 1880s, contributed greatly to the exploration of the eastern Tien Shan. The peak of Khan-Tengri was ascended for the first time in 1931 by a Soviet expedition led by M.T. Pogrebetsky. Pobeda Peak, the highest point, was conquered in 1956 by another Soviet expedition led by V.M. Abalakov. (Y.Y.R.)

Deserts

ARABIAN DESERT

One of the great desert regions of the world, the Arabian Desert occupies almost the entire Arabian Peninsula. Covering an area of about 900,000 square miles (2,331,000 square kilometres), it is bordered on the west by the Red Sea, on the north by the Syrian Desert, on the south by the Arabian Sea and the Gulf of Aden, and on the east and northeast by the Persian Gulf, the Gulf of Oman, and the Arabian Sea.

A large part of the Arabian Desert lies within the modern kingdom of Saudi Arabia. Yemen (Ṣan'ā'), on the coast of the Red Sea, and Yemen (Aden), on the coast of the Gulf of Aden, border the desert to the southwest. Oman, bulging out into the Gulf of Oman, borders the desert at its eastern extremity. The sheikhdoms of the United Arab Emirates (former Trucial States) and Qatar rim the region to the north, stretching along the southern coast of the Persian Gulf. The sheikhdom of Kuwait abuts the northern Persian Gulf between Saudi Arabia and Iraq; a Neutral Zone—diamond shaped—lying to the west of Kuwait is shared by Saudi Arabia and Iraq. In the northwest the desert extends into Jordan.

Seen from the air the Arabian Desert appears as a vast expanse of light sand-coloured terrain, with an occasional indistinct line of escarpments or mountain ranges, black lava flows, or reddish systems of desert dunes stretching to the horizon. Camel trails crisscross the surface between watering places. On the ground, features become distinctly individual and the relief seems more prominent. Vegetation at first seems nonexistent, but to the discerning eye can be seen as a minor fuzz on the surface, or as bits of green where shrubs strive to survive. There is almost always a breeze, which changes seasonally to winds of gale force. Cold or hot, these air currents chill the body or roast it. The sun and moon are bright in clear skies, although dust and humidity may cut visibility with little warning. Contrary to ideas commonly held in more northern climes, the desert is often a lovely place.

Physical features. Western Arabia formed part of the African landmass before a rift occurred in the earth's crust, as a result of which the Red Sea was formed and Africa and the Arabian Peninsula became separated. The southern half of the peninsula consequently has a greater affinity with the Somalia and Ethiopia regions of Africa than with northern Arabia or the rest of Asia. The northern Arabian Desert merges imperceptibly into Arab Asia through the Syrian steppe (treeless plain). The bulge of Oman contains a mountain range similar to ranges in Iran.

African affinities

The greatest length of the peninsula from northwest to southeast is about 1,600 miles (2,600 kilometres), from north to south not quite 1,400 miles (2,300 kilometres), while from east to west the maximum width is about 1,300 miles (2,100 kilometres). It is narrowest from Rābigh on the Red Sea to Manama on the Persian Gulf—a distance of about 700 miles.

Three corners are high: the southwest corner in Yemen, where Ḥaḍūr Shu'ayb reaches a height of 12,336 feet (3,760 metres); the northwest corner in Hejaz (a part of Saudi Arabia), where Jabal al-Lawz reaches a height of 8,562 feet (2,580 metres); and the southeast corner in Oman, where al-Jabal al-Akhḍar attains an altitude of 9,774 feet (2,980 metres). Much of the Yemen Plateau is over 9,840 feet (2,999 metres) high. To the north and east elevations decrease. Steep cliffs and steep canyons descend from highlands into adjacent seas south and west. Northeast slopes in Oman are short and steep, but on the southwest flanks the slopes grade gently to the Rub' al-Khali desert basin. The southern plateau is cut by great steep-walled canyons into rugged limestone masses that have held the peoples of that region in isolation for hundreds of years. On lower surfaces eastward in Dhofar grow shrubs that yield the fragrant frankincense and myrrh.

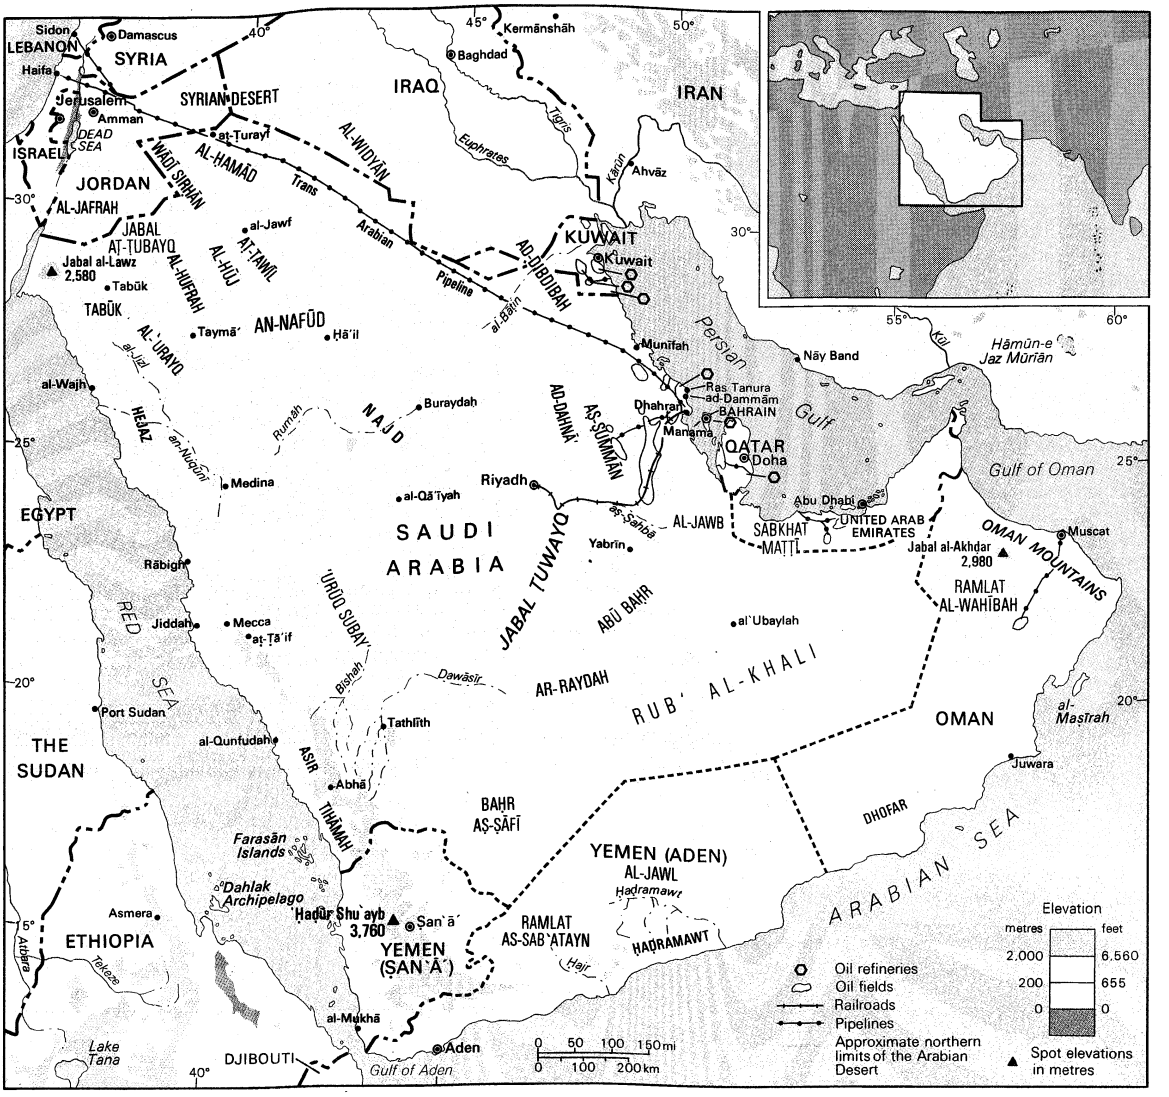
The rest of the peninsula displays a moderate relief characterized by broad plains or steppes. At least a third is covered by sand. The Red Sea escarpment, however, stands in sharp contrast to the moderate relief of the interior plateaus. South of aṭ-Ṭā'if, east of Mecca, the scarp is young, rugged, and dissected into short, steep canyons and ridges. At the foot of the scarp the Tihāmah coastal plain slopes to the sea; at Jabal as-Sawdā', near Abhā in Asir, the drop is about 9,000 feet in six miles. North of aṭ-Ṭā'if the Hejaz and Najd plateaus seldom rise above 3,600 feet (1,100 metres), except where volcanic fields occur or where remnants of the crystalline rocks that underlie the region rise to the surface. The slope to the Persian Gulf averages eight feet per mile.

Geology. The Arabian Desert consists of two major regions: the first, the ancient Afro-Arabian Shield of rocks that are igneous (solidified from a molten state) and metamorphic (transformed by heat and pressure) in the west; and the second, younger sedimentary rocks that pitch gently away from the Shield toward the Persian Gulf basin. Floods of volcanic lava in the west disturbed drainage patterns and created new divides. The highlands of the Hejaz, Yemen, the Ḥaḍramawt, and Oman display structural complexes of the whole rock spectrum. Volcanic activity in Yemen and Oman dates from the Mesozoic Era (from 65,000,000 to 225,000,000 years ago), while more recent volcanic eruptions occurred in Aden, Asir, Hejaz, and Jordan between the Oligocene Epoch, which began 38,000,000 years ago, and the Recent Epoch, which began about 10,000 years ago.

The two major structural regions

Physiography. Mountainous highlands rise in northwest Hejaz, in the Asir region, in Yemen, and in Oman. Lesser ranges have been uncovered by erosion in the interior. Eighteen volcanic fields are scattered through the west, mainly in Hejaz, several of them being more than 10,000 square miles in area.

Plateaus are a common desert feature. Jordan east of the Dead Sea forms a moderately elevated plateau. To the southeast, Jabal Tubaiq rises higher, standing as a mass of sandstone deeply cut into by numerous seasonal watercourses (wadis). Farther southeast the plateaus of Tabūk, Taymā', Ṭawīl, al-Hufrah, and al-Hūj reach to the west edge of an-Nafūd (Great Nafud), a sand desert in the north. Through central Najd, a highland region southeast of an-Nafūd, a series of west-facing scarps mark cuestas (low ridges with steep faces on one side and gentle slopes



The Arabian Peninsula.

on the other) of limestone reaching to highlands of the Ḥaḍramawt in the south, where the plateau of al-Jawl (Jol) is located.

Below the plateaus spread broad plains, stony, cherty (composed of compact microcrystalline quartz), or gravelled, their surfaces well preserved under the arid climate; some plains are duricrusted (covered with a crust of soil formed by salts), having smooth, firm surfaces formed by the cementation of sandy debris at groundwater level. Typical of the stony plains is al-Ḥamād, which stretches from an-Nafūd northward into the Syrian Desert. Chert plains were formed on the post-Eocene to pre-Miocene surface (*i.e.*, between 26,000,000 and 38,000,000 years old) in al-Ḥamad, and in al-Malsūnīyah region east of the Khurayṣ oil field. The gravel plains resulted from deposits left from 10,000 to 2,500,000 years ago by ancient river systems now represented by such wadis as ar-Rummah–Bāṭin, Sahbā, and Dawāsir–Jawb, which carried vast loads of sediment from the interior toward the Persian Gulf. Ad-Dibdibah was the delta of Wādī ar-Rummah–Bāṭin, and al-Ḥadabah was the delta of Wādī aṣ-Ṣahbā. The gravel plains of ar-Raydah and Abū Baḥr, and adjacent areas covered by sand, formed the delta of the Dawāsir–Jawb system. Several of the deltas that were formed by these ancient rivers are as large in area as the delta of the Nile. The plateau of the northern Ṣummān is smooth where it has been uncovered from under ad-Dibdibah gravels. Farther south, the surface is cut by erosion into many closed basins.

When the Arabian Peninsula was shifted away from Africa during the continent-building process, the Afro-Arabian Shield was greatly elevated, thus disturbing prior drainage patterns. The uplifting of the peninsula and the appearance of cracks or faults were accompanied by large upwellings of lavas that filled valleys and covered ridges and mountains. The Arabian platform was tilted northeastward, creating a prominent regional divide along its western rim from Yemen to Jordan. In the south another regional divide separates the coastal drainage of the Ḥaḍramawt from the Wādī Ḥaḍramawt system inland, and a third system, also in the south, divides the al-Jawl region from the system draining into the Rub' al-Khali. The Oman Mountains divide short, steeply graded northeast-flowing wadis from the less steep wadis flowing southwest into the eastern Rub' al-Khali.

The effects of geological uplift

Lesser divides enclose basins in Hejaz, Najd, and Jordan. Four adjacent interior basins are to be found in the shield between latitude 21° and 26° N. Others occur in the Tabūk area, in the Wādī as-Sirḥān, at al-Jafrah in south Jordan, and in the Jordan–Dead Sea depressions. Hundreds of smaller basins, seldom larger than four to eight miles in diameter, are found in volcanic fields, in the shield, and in many poorly drained areas of sedimentary rocks. A few of these small basins are saline, but the vast majority are floored by silts deposited in thin layers.

Most drainage channels in the Arabian Desert are either dry or else are intermittent, flowing only when rains are heavy. Two systems flow perennially in the region—the Tigris–Euphrates rivers and Wādī Ḥajar in the southern Ḥaḍramawt.

The main drainage systems of al-Widyān, ar-Rummah–Bāṭin, Sahbā', and the Dawāsir–Jawb were the scenes of

great floods in the Quaternary Period, which began 2,500,000 years ago. Today floods are infrequent but no less destructive; they seldom, however, reach the desert sands where the channels have been dammed up. The directions taken by several large systems have been altered by stronger streams that have intercepted them; examples are such wadis as the Jizl-Ḥamd in northern Hejaz and the Ḥaḍramawt in the south.

Where they enter large expanses of sand, wadis lose their identities. The alluvium carried in flood time is added to the sand body and redistributed by the wind. About two-thirds of the Arabian Desert is drained by complete wadi systems. The intermittent action of running water is more effective than the erosive action of the winds in shaping the landscape. Most of the exceptions are provided by the formation of sand dunes and the grooving of rocks by wind-borne sand.

The *sabkhah* (saline flat) of Eastern Arabia is usually a gently sloping sandy plain with concentrated salt brine at or just below the surface, located on a coastal plain. It has formed by the filling of embayments with sand—a process that continued as the sea level retreated—while the high rate of evaporation concentrated the trapped seawater to strong brine. Scouring of the sandy surface by *shamāl* (north to northwest) winds exposes the salty crust, which may then be dissolved into brine by winter rains. High tides may spread the saline surface waters inland. The salt crust does not usually attain a thickness of more than three feet. It may be interbedded with sand, silt, mud, or other deposits formed by evaporation, such as gypsum. The surface of Sabkhat Maṭṭī, the largest single exposed *sabkhah,* is sometimes composed of soft, wet, muddy, and salty slush, with a hard crust less than three feet deep. It is very treacherous to the unwary traveller, be he on foot, camelback, or in a motor vehicle. The *sabkhah* surface has no direct analogy with quicksand, but its danger lies in the inability of the traveller to recognize its nature in time to avoid sinking into a morass. Northwest of the oil refinery on Ras Tanura, *sabkhah*s carry a thin crust of salt and sand, underlain by soft calcareous (chalky) mud that is formed in shallow tidal flats by algae and eventually is covered by sand or salt. This calcareous mud has the consistency of custard.

The eastern Rub' al-Khali has a broad *sabkhah* floor that rises to less than 330 feet in elevation, which seems to be the highest altitude that *sabkhah*s attain.

There are saline basins, akin to playas (the sandy, salty, or mud-caked floors of desert basins) in the Americas, which develop in enclosed valleys, either from the evaporation of flood waters bearing dissolved minerals, or—more usually—from the evaporation of saline waters nurtured by nearby outcrops of salt. The Arabic name for this kind of salt flat is *mamlaḥah.* Arabs have quarried crude salt from both *sabkhah* and *mamlaḥah* for hundreds of years.

Sand covers at least a third of the Arabian Desert, occurring as dunes of varying size and complexity or as a thin film on surfaces of lower relief. With few exceptions, sand does not accumulate in flat sheets but in dunes, ridges, or giant complexes. The variety of dune shapes and sizes in the Arabian Desert is legion. Many forms have not been described in print. Contrary to statements by early western explorers that there is nothing but a shapeless sea of sand, the sand desert develops along systematic lines with distinct and characteristic patterns. There are also clear-cut genetic relationships between dunes in adjacent areas. In such huge sand areas as the Rub' al-Khali, the evolution of dune forms can be traced from simple dunes into the more complex types.

Sand-dune formations

The two largest sand bodies in Arabia are an-Nafūd in the northwest, and the Rub' al-Khali (ar-Ramlah) in the southeast. An-Nafūd has an area of 26,000 square miles; the Rub' al-Khali has an area of 229,000 square miles. Between them are two almost parallel arcs of more or less continuous dunes. The outer arc, convex to the east, is ad-Dahnā', about 750 miles long and from six to 50 miles wide. The inner arc is shorter and less continuous and includes six elongated *nafūd*s situated in low areas between the west-facing limestone escarpments of the central Najd. The two major arcs are separated by the great Jabal Ṭuwayq cuesta. Ad-Dahnā' connects with an-Nafūd in the northwest and with the Rub' al-Khali in the southwest. The inner belt grows more disconnected south of 24° N and dies out before reaching Wādī ad-Dawāsir.

An-Nafūd fills an irregular basin surrounded by hills, ridges, and buttes (isolated hills rising abruptly from the surrounding land) or mesas (land formations having relatively flat tops and steep rock walls). Its sand was eroded and carried by winds from outcrops of sandstone that lie west and northwest. An-Nafūd is characterized by a unique dune form, a giant crescent slipface (the slope on the leeside of the dune that approximates the angle of rest of loose sand, usually about 32°) moving through a thick mass of loose sand. The lee hollow in front of the slipface is floored by bedrock, barren of sand. The impression obtained from an aerial view is of hooflike hollows, that extend from the southwest edge, well across the Nafūd. Along other margins of the desert and through the centre are linear and pyramidal dunes. The Nafūd has been a barrier to travel for ages, only rarely attempted by Western travellers. A caravan route runs from northwest to southeast connecting the oases of al-Jawf with those of Ḥā'il. The topographic relief of dunes in the Nafūd may exceed 300 feet.

With an area of about 230,000 square miles—larger than France—Rub' al-Khali displays a variety of dune forms that appears to be unique, although parts of the Sahara show many similar dunes as well as a few that are different. The name Rub' al-Khali (the Empty Quarter) is not usually used by the Bedouins who travel over it, who refer to it instead as ar-Ramlah (the Sand). The Rub' al-Khali has five general types of sand terrains: (1) crescentic or transverse; (2) linear; (3) giant dune complexes, or "sand mountains," that take the shapes of domes, pyramids, huge crescents, and sigmoidal (S-shaped) ridges; (4) hook-shaped dunes; and (5) dunes with vegetation and moisture. The eastern Rub' al-Khali fills a broad shallow basin, floored mainly by *sabkhah*s that slope toward the southern shores of the Persian Gulf. The floor west of the 51st meridian rises to the southwest to nearly 3,600 feet (1,100 metres) and is composed largely of gravel plains. Highlands surround this sand desert on the northeast, south, and west.

"The Empty Quarter"

The greatest volumes of sand lie in the eastern basin and—as has been discovered through the use of aerial photography—are arranged in belts. These belts appear to have accumulated during the Pleistocene Epoch (from 10,000 to 2,500,000 years ago) at several successive stages that were related to the advance and retreat of sea levels.

Ramlat as-Sab'atayn in eastern Yemen, in the lowland south of the western border of the Rub' al-Khali, has an area of about 60 by 150 miles, or about 10,000 square miles. It is composed mainly of transverse and linear dunes.

Ramlat Ahl Wahībah is located near the extreme eastern cape of the peninsula; it is an oblong dune field 60 by 100 miles wide, made up of linear ridges and interdune valleys oriented almost north and south.

An elongated sand body named al-'Urayq lies in the southern part of the Wādī ar-Rummah basin. 'Irq as-Subbay' (*'irq* is an Arab word for linear sand dune) dams the middle Wādī al-Jarab drainage system. A small cluster of broad transverse dunes has formed on the south coast east of the port of Aden.

Climate. The Arabian Desert spreads across 22° of latitude from the 12th to the 34th parallel north; it may thus be considered as a tropical desert. Summer heat is intense, reaching a maximum 124° F (51° C). In the interior the heat is dry and tolerable. Coastal regions and some highlands, however, attain high summer humidity with dews and fogs at night or early morning. Rainfall averages less than four inches (100 millimetres) a year but can range from zero to 20 inches. Interior skies are usually clear except for intermittent winter rains, spring hazes, or dust storms. Torrential rains flood the main drainage basins infrequently. Winters are invigoratingly cool, with the coldest weather occurring at high altitudes and in the far north. A minimum recorded at aṭ-Ṭurayf on Tapline (the Trans-Arabian Pipeline) in 1950 was 10° F (−12° C),

and was accompanied by several inches of snow and an inch of ice on ponds. Summer rains in the Rub' al-Khali accompany the monsoon winds from the Indian Ocean. Winter rains may occur in the northern Rub' al-Khali. The most arid part of the Arabian Desert appears to be on the western margin of the Rub' al-Khali, north of Wādī ad-Dawāsir.

Dominant winds blow from the Mediterranean, swinging to the east, southeast, south, and southwest in a great arc. Two semiannual windy seasons occur from December to January and from May to June. These are called *shamāl*s (from the Arabic: "north"), and last from 30 to 50 days with wind velocities averaging 30 miles per hour. *Shamāl*s, which try the patience of man and beast, are dry, transport huge loads of sand and dust, and alter the shapes of sand dunes. Millions of tons of sand are carried by each storm into the Rub' al-Khali. Blown sand does not rise more than a few feet, except when picked up by whirlwinds, dust devils, or regional sandstorms. Winds box the compass in central Najd and in the southeastern Rub' al-Khali. Strong southeast gales sweep the big sand desert for several days at a time, reversing the effect of *shamāl*s on dunes.

The power of desert winds to excavate basins is much exaggerated. The wind is important as an agent of erosion but, as mentioned above, is never as effective as running water.

"Brown rollers"

The sudden appearance on the horizon of the "brown roller" in spring or fall can be frightening. This is a frontal storm up to 60 miles wide, carrying sand, dust, and debris high in the air; it is followed by a sharp drop in temperature and often by rain. Wind velocities reach gale force for half an hour or so. Hot days produce myriads of dust devils (*jinn*) and the ill-famed mirage.

Soils. Desert soils differ from humid soils in that they undergo less chemical weathering. Mechanical weathering breaks down coarse particles into finer grains. Quartz sand abounds, covering more than a third of the desert surface. Granular debris from the crystalline basement of the Precambrian shield forms pebbly fans about the bases of hills. Sands and silts are washed down to lower levels and are then winnowed out by winds. Fine materials grade down to silt. Smaller particles, such as clays, rarely form. Limestone, when pulverized, forms silt-sized dusts. Waterborne silts eventually are deposited in *khabari,* or silt flats. Irrigated silt flats are farmed, the soils having proved to be fertile. Najd villages that once depended on November rains to raise their winter wheat, now irrigate and farm all year. Highlands of Asir and Yemen are terraced for crops. Salt flats in the desert, though too salty for many crops, if irrigated and drained properly, can be cultivated. Many of the plants that grow in saline soils, and which are called halophytes, are succulents that are suitable as camel fodder. The date palm thrives on salty soils if properly irrigated and drained.

Desert dune sands are generally dry but can hold rainfall to depths of three feet or more, thus nourishing xerophytes (plants adapted to survive under arid conditions). Shrubs unique to the area, called *'abl* and *ghaḍā,* send out long, shallow roots to catch the slightest bit of moisture. The roots make good firewood.

The highlands of Yemen and Asir produce forests of juniper trees. Valleys and lower slopes are extensively terraced for soil and water conservation and produce many crops, of which coffee is important in local markets. The soils are derived from crystalline rocks of high mineral content.

Plant life. There is a great variety of desert flora and fauna. Plants are primarily xerophytic or halophytic. After spring rains long-buried seeds germinate and bloom in a few hours. The normally barren gravel plains turn green. Even chert plains produce late winter and early spring grazing for camel and sheep. The plains were once the home of the famed Arab horse, but grazing was always too poor to support a large horse population. Certainly all the grazing areas were overgrazed, thus contributing to the formation of the present widespread barren tracts. Halophytes grow on the saline flats and include many succulents and fibrous plants that can be eaten by camels. The sedge, which grows in sandy areas, is a tough plant with deep roots that help to hold down the soil. The tamarisk tree is often found on the borders of oases, where it helps to prevent the encroachment of sand.

The rare shrub *rāk,* or *arāk,* is known as the "toothbrush bush," its twigs being used by Arabs to polish their teeth. Many herbs grow throughout the desert and are well known to the Bedouins, who use them for seasoning, preserving food, perfuming clothing, and washing hair. The eastern Rub' al-Khali, generally thought to be dry and barren, supports much plant life on flanks of giant dunes, including a sweet grass called naṣī that provides the main forage for the now-rare oryx (a species of African antelope). There are no cacti in the Old World, except for those imported from the Americas. One of these imports, the prickly pear, thrives and is fed to livestock, the fruit being eaten by people. Spiny and thorny plants are common. The euphorbia, a plant with milky juice and flowers with no petals, grows in Hejaz, and the camelthorn is everywhere. Acacia trees were once abundant in Jibal Tuwayq, but the demand for charcoal decimated them. The few growing in wadis and gardens provide welcome shade. A single clump of four stands in daring isolation on the edge of al-Mijann overlooking the southern Persian Gulf and the feared Sabkhat Maṭṭī (the treacherous saline flat already mentioned). Junipers reach a great size in high Asir and Yemen. The trunks are cut into the beams and pillars that characterize the region's architecture. The milkweed tree (*ishar*) grows to a height of 20 feet in Wādī al-Bāṭin and is common in the wadis of Najd and in Wīdī Bīshah.

The ubiquitous date palm

The date palm is grown in many oases, the dates themselves providing food for humans, camels, donkeys, and horses. There are many varieties. The palm supplies wood for building and for making water well frames and pulley shafts of ancient type; its fronds are used for handicrafts and for thatching roofs. The oases also produce many fruits and vegetables such as rice, alfalfa, henna (a shrub which yields a reddish-orange dye), citrus, melons, onions, tomatoes, barley, wheat, and—in higher regions—peaches, grapes, and prickly pears.

Animal life. The animal life is varied and unique. Desert insects include the fly, the malaria-carrying *Anopheles* mosquito, fleas, lice, ticks, roaches, ants, termites, beetles, and mantids (predatory insects), which camouflage themselves as leaves, twigs, or pebbles. Also found are the scavenging dung beetle, myriads of butterflies, moths, and caterpillars, and the pestiferous locust that periodically plagues the landscape and populace in great swarms.

Arachnida (a class of segmented invertebrates) include large sapulgids (scorpion-killers), scorpions, and spiders. Sapulgids grow to eight inches (20 centimetres) in length. Scorpions also range up to eight inches and are coloured black, green, yellow, red, and off-white. The scorpion's painful sting is deadly to small children.

Pools in oases contain small fish. There are a few amphibious animals, such as newts, salamanders, toads, and frogs. Reptiles include lizards, snakes, and turtles. The *ḍabb,* a fat-tailed lizard, lives on the plains and reaches a length of up to three and a half feet. It is a vegetarian with toothless jaws; its fat tail, roasted, is a Bedouin delicacy. The monitor lizard reaches lengths up to three feet; it feeds on locusts and other insects. Many lizards, including skinks, geckos, agamids, and collared lizards, are found in the sands. A salmon-coloured lizard, the *dammūsa,* is lively and pretty, seeking the black beetle for food, and literally diving and swimming in the slipfaces of the sand dunes. An agamid lizard (*ṭuḥayḥī*) scurries across the sand with its tail coiled like a watch spring, uncoiling when it stops.

Among the snakes, all of which are feared by Arabs, the sand cobra—relative of the sea snake—is slim, sand-coloured, and venomous. Vipers abound in sand and rocks but, being nocturnal, are seldom seen in the heat of day.

Birds of the Arabian Desert include local species as well as migrant groups. The migrants are from northern Europe, Africa, and India. The local birds breed from late winter to early spring. Many of the young display excellent camouflage. The bifasciated (striped) lark, the sand grouse, the Arabian courser, and the lesser bustard live in the desert all year, as also do several falcons, eagles,

and vultures. The peregrine falcon is seen in Asir; saker and lanner falcons (a brown falcon with a golden cap) are found in Najd and the Eastern Province; and the kestrel is everywhere. The saker falcon (an aggressive light-brown falcon) is often captured young and trained by Bedouin falconers to hunt the bustard and sand grouse. Ravens in pairs or flocks may appear anywhere. Three eagles are known—the white-tailed, golden, and tawny eagles. Vultures were more numerous when camels were in greater use. The largest, a black species with a wing spread of up to 12 feet, has nearly disappeared. The Egyptian vulture (*ar-rakhamah*), a medium-sized bird coloured white and black with yellow, is widely distributed. The lammergeier vulture lives in Asir and Yemen. There are several owls, a burrowing species being common.

Migrant birds follow several flyways, one through the central Najd and others on each coast. Water and shore birds migrate in fall and spring between northern Europe and the tropics. Bee-eaters, warblers, babblers, carrion kites, swallows, martins, swifts, wheatears, shrikes, larks, flycatchers, hoopoes, and some exotic species may be seen alone, in pairs, or in flocks. Cranes, heron, flamingoes, ducks, and small wading birds feed on shores and in the lakes which intermittently appear. The ostrich, once abundant in the sand deserts, has been extinct since 1940.

Desert game

Mammals were probably numerous before the Arabs hunted them with rifles, shotguns, and submachine guns from motor vehicles. Gazelles, which roamed the plains in herds of hundreds before World War II, are almost extinct. The oryx had disappeared from the Rub' al-Khali by 1960. The ibex (a species of wild goat), which dwells on cliffs in Jibal Tuwayq, has been decimated. In desert plains, the ratel (a badger-like carnivore), the fox, and the civet cat live in territorial isolation. Wolves are much feared but, although widespread, are not numerous. The hyena lives wherever sheep are herded, preferring escarpments that provide cover. Jackals are to be seen, especially at dusk when they appear for water. There are hares, as well as golden sand rabbits. Small rodents include the jerboa (a mouselike rodent), mice, rats, and porcupines, while small hedgehogs are often found among rocks. Troops of baboons run in Asir.

The people. Man has inhabited the Arabian Desert since early Pleistocene times. His artifacts have been found widely spread throughout the desert but are most abundant in the southwestern Rub' al-Khali, where game was prolific until about 30 years ago. Archaeological research was not encouraged by the government until recently, so little is known about mankind in Arabia in earlier epochs. Remains of cultures from the last 3,000 years occur in Hejaz, Asir, Yemen, and the Ḥaḍramawt. More recent remains—perhaps 1,000 to 2,000 years old—are being examined in the Eastern Province; most of them date from the early years of the Islāmic period.

The Bedouin know little of their history beyond the dawn of Islām. They adapted to nomadic desert life by breeding camels, Arab horses, and sheep, but also conceded to necessity by growing date palms and other crops. The Bedouin seldom abandoned the nomadic life for the oasis longer than was essential to gather crops, generally hiring others for agricultural labour; finding grazing and water were their main concern, in addition to conducting raids to seize horses and camels. Grouped in hereditary tribes, the Bedouin claimed certain lands as their *dirah* (tribal territory), where their flocks could graze and water. After 1925 King Ibn Sa'ūd of Saudi Arabia, who encouraged the Bedouin to settle in oases, was able to use his influence to prevent intertribal raiding, and to make the tribal *dirah* of less importance. Tribal loyalties remain strong and no Bedouin of a noble tribe will marry into a lesser tribe. Islām is their way of life, but modernization has brought much change and has lessened religious influence. Townsmen have kept their identity distinct from that of the Bedouin; each group regards the other with contempt. This feeling has lessened somewhat, however, since more Bedouins have settled in towns.

Western cultural influences

Western cultural influence began with the discovery of petroleum in 1936 and led to the introduction of the motor vehicle, airplanes, telephone, radios, telegraphs, and, recently, television. The cinema has also become popular, despite disapproval by religious leaders.

Schools were few and were only for boys until 1960; since then, however, girls are also taught. The veil is still worn by women, and, though the lot of women has improved, their place remains in the home.

The economy. *Transportation.* Travel today in the Arabian Desert is easy and rapid. Instead of the slow, laborious camel caravan, motor vehicles now roar across desert terrains. Jet planes fly overhead, and the railroad from ad-Dammām on the Persian Gulf to Riyadh, the political capital of Saudi Arabia, covers the distance in a few hours. Arab countries have planned rebuilding the railroad from Medina to Damascus, destroyed in World War I, but conflict with Israel appears to have halted construction. Paved roads cross the desert from the Persian Gulf to Jidda and also follow the Trans-Arabian Pipeline from Dhahran to Sidon in Lebanon. Semi-maintained dirt roads connect many Arab communities. New roads have been built into Asir, making that province and its fine agricultural produce accessible to the markets of Riyadh, aṭ-Ṭā'if, Mecca, Jidda, and Medina. A Saudi Arabian government airline schedules flights between towns in different regions of the desert.

About 80 percent of the Arabian Desert is accessible to motor vehicles, with or without roads. Essential equipment consists of vehicles equipped with sand tires and two-way radios, and having the capacity to carry fuel, food, and water, as well as repair parts and camping equipment.

Resources. The greatest natural resource of the Arabian Desert is its underground water supply, which, as it remains virtually unreplenished because of low rainfall, in effect consists of Pleistocene waters that are now being tapped. Modern techniques are being used by the governments of Arab countries to develop water sources and to irrigate soils for farming.

The oil boom

Petroleum was found in 1936 in the Eastern Province at Dammām Dome, on which the oil-company town of Dhahran is built, but commercial production was not achieved before 1938. Since World War II many new oil fields have been brought into operation, with production exceeding 3,000,000 barrels daily; reserves are enormous and the end is not yet in sight. Prospecting for other minerals has been in progress since 1950.

Building materials in use before the mid-20th century were stone, adobe, a crude cement made from impure calcareous (chalky) rock taken from the floor of the Persian Gulf, the wood of the date palm, the wood of the juniper in the Asir region, and thatches of cane, palm fronds, or other vegetation. Modern construction utilizes steel, concrete, light alloys, imported lumber, local stone—especially granites from Asir and limestone from the Najd—and slates from Hejaz. Salt and gypsum are produced from saline flats.

Study and exploration. Before the 18th century few travellers or would-be conquerors had succeeded in penetrating the Arabian Desert; fewer still had written about it. Scientific exploration began in 1762 with a Danish expedition led by the German surveyor Carsten Niebuhr. In the 19th century, British officers of the Indian government undertook surveys of the surrounding seas and coasts.

The first classical work on the geography of Arabia, *Travels in Arabia Deserta* (1888), was written by the English traveller C.M. Doughty. At the turn of the 20th century, the Czech explorer Alois Musil travelled through northern Hejaz and Najd, mapping topography as he went. In 1917 H. St. John Philby, an official of the British Foreign Office, paid a visit to the Sultan of Najd (later King Ibn Sa'ūd of Saudi Arabia); Philby later became a Muslim, settled in Riyadh as a councillor to Ibn Sa'ūd, and explored the Arabian Desert by camel and motor car, writing detailed and accurate accounts of his travels. Another British official, T.E. Lawrence, who worked with the Sultan of Hejaz against the Turks in World War I, gained fame for his romantic writings about his exploits in the region. Many individuals travelled in limited parts of the desert; the most notable among them is the British traveller Wilfred Thesiger, who crisscrossed the Rub' al-Khali after World War II.

The discovery of oil in 1932 on Bahrain and the subsequent American exploration of the Arab mainland that began in 1933 led, as already mentioned to the opening of the Arabian Desert to Western influence. After World War II, geographical and geological exploration intensified and was accompanied by vast aerial photographic surveys as a result of which the first accurate maps of the peninsula were prepared and published between 1956 and 1965. Since 1950, the U.S. State Department and the U.S. Geological Survey have co-operated with the Kingdom of Saudi Arabia in conducting surveys of mineral resources.

(D.A.H.)

GOBI

One of the great desert and semidesert regions of the globe, the Gobi (from Mongolian *gobi,* meaning "waterless place") stretches across the vastness of Inner Asia over huge stretches of both the Mongolian and Chinese People's republics. Contrary to the perhaps romantic image long associated with what—at least to the European mind—was a remote and unexplored region, much of the Gobi is not sandy desert but bare rock. One may drive over this surface by car for long distances in any direction; northward, say, toward the mountains of the Altai and Hangayn ranges or eastward toward the city of T'ien-shan or southward toward the Pei Shan-mo. To the west, 1,000 miles (1,600 kilometres) from the Gobi's eastern limits, lies the Sinkiang region, a great basin enclosed by the Plateau of Tibet to the south and the Tien Shan ranges to the north. The desert as a whole occupies a vast arc of land 1,000 miles long and 300 to 600 miles wide. The region first became known to Europeans through the remarkable 13th-century descriptions of Marco Polo. Modern geographical study of the Gobi has mainly been undertaken by Russian scholars, though a series of works has appeared in Mongolian and Chinese since the 1960s. For the purposes of the present article, the Gobi is defined as lying between the Altai Mountains and Hangayn Nuruu (Hangayn Mountains) in the north; the eastern Tien Shan in the west; and the A-erh-chin Shan-mo, Pei Shan-mo, and Yin-shan Shan-mo in the south.

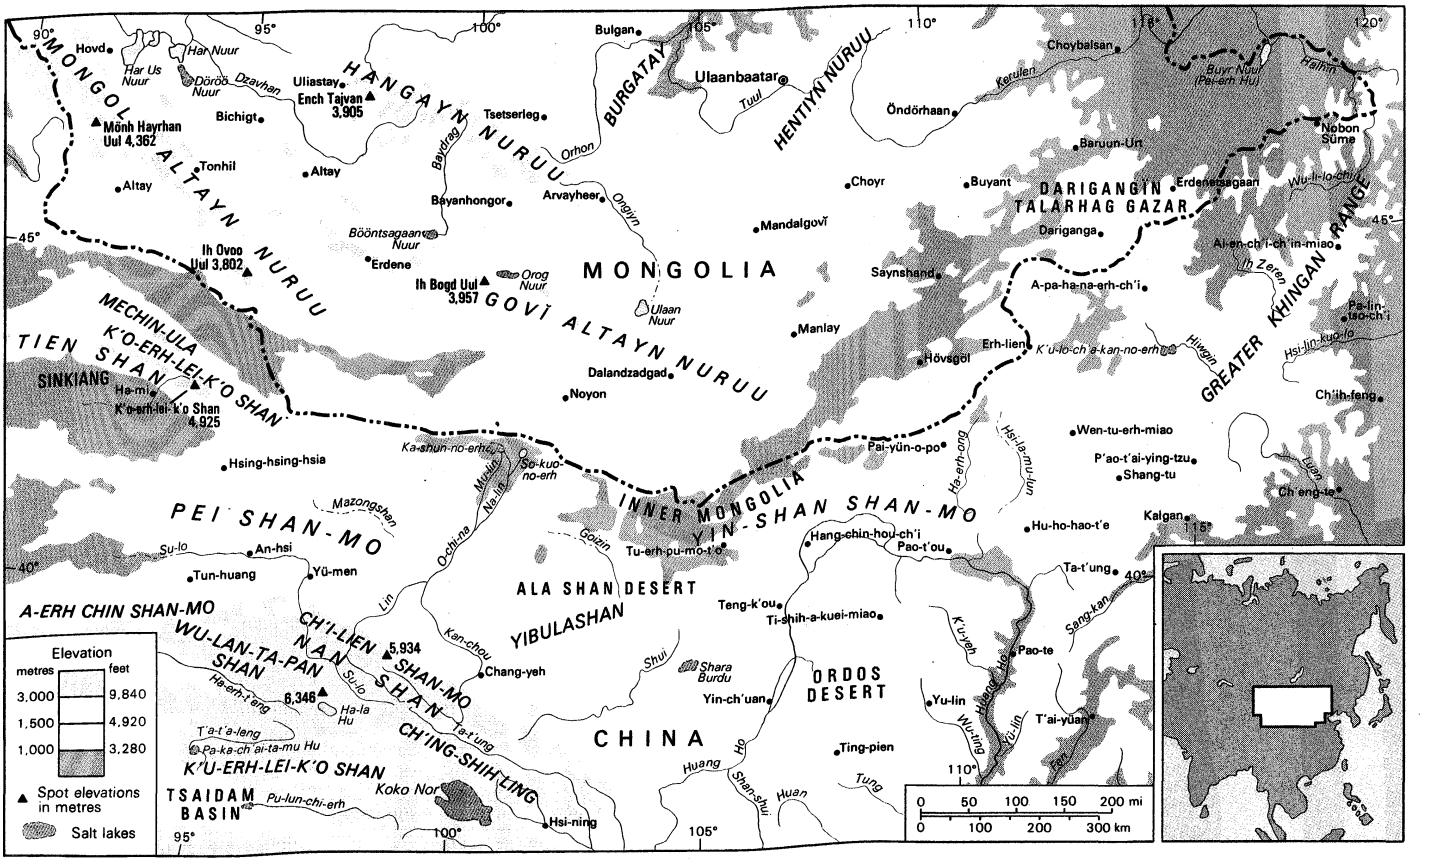
Physical features. *Physiography.* The Gobi consists of the Ka-shun, Dzungarian, and Trans-Altai Gobi (south of the Mongolian Altai Mountains) in the west and the Eastern, or Mongolian, Gobi in the centre and east.

Regional subdivisions

The Ka-shun is bounded by the spurs of the Tien Shan to the west and the Pei Shan-mo in the south and rises as high as 5,000 feet (1,525 metres). It is gently corrugated, with a complex labyrinth of wide hollows separated by flat hills and rocky crests sometimes rising more than 300 feet above the plain. The desert is stony and waterless, though salt marshes lie in the secluded depressions. The soil is grayish brown and contains gypsum. Vegetation is very rare, though richer in the riverbeds, where there are individual shrubs of tamarisk, zaysansky haloxylon and nitre bush (both saltworts), and annual halophytes (plants growing naturally in soils containing certain salts).

The Trans-Altai Gobi is situated between the eastern spurs of the Mongol Altayn Nuruu (Mongolian Altai), the Govĭ Altayn Nuruu (Gobi Altai) in the north and east, and Pei Shan-mo in the south. The plain is elevated, sharp, and rugged. Alongside the plains and the isolated group of low, rounded hills is a fairly extensive mountain area, extending over six miles out into the plain. The mountains are very barren and broken up by dry ravines. The western section of the Trans-Altai Gobi is basically a plain, too, but interspersed with small raised areas and furrowed by dry riverbeds and, again, with extensive salt marshes. In the central portion this fragmentation increases, and mesas (flat-topped, steep-sided hills) appear along with dry gullies ending in flat depressions, occupied by *takyr* (clayey tracts). The Trans-Altai Gobi is quite parched, with annual precipitation of less than four inches, though there is always water underground. There are virtually no wells and springs, however, and vegetation is very sparse and almost useless for livestock.

The Dzungarian Gobi is situated north of the Ka-shun Gobi, between the eastern spurs of the Mongol Altayn Nuruu and the eastern extremity of the eastern Tien Shan (the K'o-erh-lei-k'o Shan). It is like the Trans-Altai Gobi, and its edges are fractured by ravines, alternating with residual hills and low mountain ridges.



The Gobi.

The Eastern Gobi is of similar character, with altitudes varying from 2,300 to 5,000 feet, but enjoys rather more precipitation—up to eight inches (200 millimetres) a year—though with virtually no rivers. The underground waters are relatively abundant and only partly mineralized. They are also near the surface, feeding small lakes and springs. The vegetation, however, is sparse: herb wormwood in coarse, grayish-brown soil. In the moister depressions there are the usual salt marshes and grassy swamps. In the northern and eastern outlying regions, where more precipitation occurs, the landscape of the desert gradually mellows, sometimes even becoming steppes.

Geology. The Gobi's various chalky plains are chiefly Paleocene to Recent (up to 65,000,000 years old), though some of the low, isolated hills are older. The terrain contains small masses of shifting sands. In the central Gobi, Mesozoic remains of dinosaurs (65,000,000 to 225,000,000 years old) and Paleogenic and Neogenic fossils of mammals have been found. The desert also contains Paleolithic and Neolithic sites occupied by ancient man.

Fossils

Climate. The climate is acutely continental and dry, ranging from January's −40° F (−40° C) to 113° F (45° C) in July. Winter is severe; spring is dry and cold; and summer is warm. The annual total precipitation varies from 2.7 inches (69 millimetres) in the west to more than eight inches in the northeast (the maximum falls in summer), and in the eastern regions the impact is quite monsoonal. North and northwestern winds prevail over the Gobi.

Drainage and soils. Aridity in the Gobi depends on the relative chalkiness of the soil and has been aggravated by the strong mountain structure to the west. The lakes have correspondingly shrunk, leaving a series of terraces considerably farther from and higher than the present shorelines. Indeed, Wu-lan Hu (east of the Pei Chan-mo), Orog Nuur, and Böontsagaan Nuur (in the easternmost Mongolian Altai) are but shadows of their former selves.

The drainage of the desert is largely underground; surface rivers have very little constant flow. Mountain streams are confined to the Gobi's fringes and even then quickly dry up, as they disappear into the loose soil or the salty, enclosed depressions. Many rivers flow only in summer. On the other hand, subterranean water is widespread and of sufficient quality to allow cattle raising.

The soil is chiefly grayish-brown and brown carbonaceous (rich in carbon), gypseous (containing gypsum), coarse gravel, often combined with sandy salt marshes and *takyr.*

Plant life. Vegetation is sparse and rare. On the plateau, and on the plains beneath the mountains, small bushlike vegetation occurs: echinochloa (a type of succulent grass found in warm regions), yellowwood bean caper, winterfat (a shrub covered with densely matted hairs), Dzungarian reaumur, nitre bush, and bushlike halophytic vegetation. In the salt marshes, too, halophilous groups prevail: potash bush, Siberian nitre bush, tamarisk, and annual halophytes; in the sands grow zaysansky haloxylon, the sandy wormwood, and sparse perennial and annual herbs such as the Gobi kumarchik and timuriya. In semidesert tracts vegetation is richer, belonging to the herbaceous-wormwood groups: Gobi feather grass; the annual Gobi kumarchik (*Agriophylum gobicum*); the perennials timuriya (*Timouria villosa*) and snakeweed (*Cleistogenes* sp.); and cold wormwood. There are herb meadows with rhizome Mongolian onions and herb salt marshes with sparse beds of bushlike *Caragana.* In the Gobi Altai and other high mountains, desert-grass steppes completely cover the lower slopes, and, on the upper parts, mountain versions of the feather-grass steppes appear.

Areas with fairly rich vegetation

Animal life. Animal life is varied, with such large mammals as the wild camel, the ass kulan (*Equus asinus ferus*), the dzheiran gazelle, and the dzeren (an antelope). Przewalski's horse, which once ranged in the western region of the desert, is probably extinct in the wild. Rodents include marmots and gophers, and there are reptiles.

The people and economy. The population density is small—fewer than three persons per square mile—mostly Mongols with Chinese in Inner Mongolia. The Chinese have increased greatly in recent years. The main occupation of the inhabitants is nomadic cattle raising, though, in regions where the Chinese are concentrated, agriculture is predominant. The living quarters of the Mongol nomads are felt yurts (types of tent), while the Chinese farmers live in *fanzy,* clay homes built from crude brick.

The province of the Gobi and its semidesert sections is mainly a livestock region, sheep and goats constituting more than half of the total herds. Next come the large-horned cattle. Horses make up only a small percentage of the total and, together with the large-horned cattle, are concentrated in the lusher semidesert of the southeastern region. A fair number of the livestock still consists of two-humped camels, still used for transportation in some areas. Pasturage for cattle is available all year round because of underground waters. Livestock raising is nomadic, and herds move ten times a year, migrating as much as 120 miles between extreme points.

Useful mineral deposits are scant, but there are pockets of petroleum around the city of Saynshand (about 250 miles southeast of Ulaanbaatar), and, in the Mongolias as a whole, salt and light metal ores are mined. Agriculture is developed only along the river valleys.

Natural resources

The Gobi is intersected by railroads in the east and west. There are several highways: from the town of An-hsi to the town of Ha-mi across Pei Shan-mo and the Ka-shun Gobi, from the town of Kalgan (northwest of Peking) to Ulaanbaatar, and from Ulaanbaatar to Dalandzadgad (some 300 miles south-southwest of Ulaanbaatar). In addition, various ancient caravan tracks crisscross the Gobi in all directions. (M.P.Pe.)

KARA-KUM

Kara-Kum (Peski Karakumy in Russian, in the transliteration system of the Akademiya Nauk; Russianized Turkmen *karakumy,* "black sand"; *i.e.,* with vegetation) is the name given to a great sandy desert comprising about 60 percent of the area of the Turkmen Soviet Socialist Republic of the U.S.S.R. Another, smaller desert in the Kazakh S.S.R. near the Aral Sea is called the Aral Kara-Kum.

Physical features. *Physiography.* The Turkmen Kara-Kum is approximately 115,000 square miles (300,000 square kilometres) in area. It is bordered on the north by the Sary-Kamysh Depression, on the northeast and east by the Amu Darya Valley, and on the southeast by the Karabil Highlands and Badkhyz semidesert. In the south and southwest the desert runs along the foot of the Kopet-Dag Mountains, and in the west and northwest it borders the course of the ancient valley of the Uzboy River. It is divided into three parts: the elevated northern Unguz Kara-Kum; the central, low-lying Tsentralny Kara-Kum; and the southeastern Kara-Kum, through which runs a chain of salt marshes. Across the border of the Unguz and Tsentralny Kara-Kum there runs the Unguz chain of saline, isolated, wind-eroded hollows.

The relief of the Turkmen Kara-Kum is quite sharp and clear-cut and reflects its origin and historical development. The surface of the Unguz Kara-Kum has been eroded by violent winds. The plain of the Central Kara-Kum runs from the Amu Darya to the Caspian Sea along the same incline as the river. The height of wind-accumulated, half-overgrown, sand ridges ranges from five to 100 feet (1.5–30 metres), depending on age and wind velocity. Somewhat less than 10 percent of the area consists of crescent-shaped dunes (*barkhany*), some of them 250 feet or more in height. There are numerous hollows of clay deposits, called *takyr,* and saline land formed by the evaporation of subsoil waters.

Climate. The climate of the Turkmen Kara-Kum is continental, with long, hot summers and unpredictable but warm winters. The average temperature in July in the north and along the shore of the Caspian Sea ranges from 79° to 82° F (26° to 28° C), and in the central part of the Central Kara-Kum from 86° to 90° F (30° to 34° C). In January, average temperatures are 25° F (−4° C) in the north and 39° F (4° C) in the south, but temperatures may fluctuate from as low as −4° F (−20° C) to 97° F (36° C) within a 24-hour period. The average annual rainfall varies from 2.75 inches (70 millimetres) in the north to six inches (150 millimetres) in the south. Precipitation occurs mainly in autumn and early spring, more than half of it

Climate of the Kara-Kum

between November and April. There is little snow. The prevailing northeasterly and northwesterly winds are mild.

Plant and animal life. The vegetation is quite varied, consisting mainly of grass, small shrubs, bushes, and trees. The humid early spring permits the widespread growth of ephemeral plants—the main animal fodder—while in the barchan dune areas the typical vegetation consists of cereals, the wormwood shrub, and trees of the species *Ammodendron conollyi.* The most common bushes are species of *Astragalus, Calligonum,* and the salt-tree (*Salsola richteri*). In regions of deep underground water, the white haloxylon is the most typical plant, but in regions where water is nearer to the surface, the black haloxylon occurs. The vegetation of the Turkmen Kara-Kum can be used as hay in winter by camels, sheep, and goats.

Animals are not numerous, but they are of many kinds. The insects include ants, termites, ticks, beetles, darkling beetles, dung beetles, and spiders. Various species of lizards, snakes, and turtles also occur. The most common birds are skylarks, haloxylon (sacksal) jays, wagtails, and desert sparrows. Among the rodents are gophers and jerboas. The tolai hare, the hedgehog, barchan cat, and corsac fox and also the dzheran (a gazelle) usually live near *takyr* soils.

The people and economy. The population is composed of Turkmen, among whom some tribal distinctions have been preserved. Formerly nomadic, they settled into agricultural pursuits or fishing on the shores of the Caspian. Collective and state farms have developed permanent settlements, with gas and electricity. Cattle-raising brigades care for the socialized livestock. The development of oil, gas, and other industries has brought new settlements, populated by diverse nationalities.

Irrigation and economic development

Irrigation has made the desert suitable for the raising of livestock on a large scale, especially astrakhan sheep. The Karakum Canal has brought water to Southeastern Kara-Kum, the southern border of the Tsentralny Kara-Kum, and along the foot of the Kopet-Dag Mountains, where fine-fibred cotton is now grown in the oasis areas. The proposed extension of the canal to the shore of the Caspian Sea will permit the cultivation of the subtropical arid regions.

Intensive economic development after World War II brought an industrial revolution to the Kara-Kum. Factories, gas lines, railroads, and highways have changed the face of the region. Hydroelectric stations are under construction at Takhiyatas and Tyuyamuyun. (B.A.F.)

TAKLA MAKAN

A desert of Central Asia and one of the largest sandy deserts in the world, the Takla Makan (Takolamagan in Chinese Pinyin) occupies the central part of the Tarim Basin in China. The desert area extends about 600 miles (960 kilometres) from west to east, and it has a maximum width of 260 miles and a total area of about 105,000 square miles (272,000 square kilometres). The desert reaches altitudes of 3,900 to 4,900 feet (1,200 to 1,500 metres) in the west and south and from 2,600 to 3,300 feet in the east and north.

Physical features. The Takla Makan is flanked by high mountain ranges: the Kunlun in the south, the Tien Shan in the north, and the Pamirs in the west. There is a gradual transition to the marshy Lop Nor (Lop Lake) Basin in the east, and, in the south and west, between the sandy desert and the mountains, lies a band of sloping desert lowland composed of pebble-detritus deposits.

Physiography. Several small mountain ranges and chains, composed of sandstones and clays from the Paleogene and Neogene periods (10,000 to 65,000,000 years ago), rise in the western part of the desert. The arc-shaped Mazar Tagh (Mazar Mountains), located between the Ho-t'ien Ho (Ho-t'ien River) or Khotan Darya (Khotan River) and the Yarkand River valleys, arch toward the southwest. Ninety miles long and from two to three miles wide, with a maximum height of 5,363 feet, they rise an average of only 1,000 to 1,150 feet above the surface of the sandy plain. The Chiao-lo Shan (Chöl Tagh) is also an insular range, surrounded on all sides by massifs of moving sands. Rosstagh, also known as Tokhtakaz Mountain, its highest peak, is 5,117 feet (1,560 metres), and the range rises from 600 to 800 feet above the plain. Both ranges are covered by a shallow mantle of eluvium and rock debris and have sparse, desert-type vegetation. In the north, the sands of the Takla Makan form a clear boundary with the vegetated Tarim River Valley.

The general slope of the plain is from south to north, and thus the rivers running off from the Kunlun Mountains flow in this direction. The Ho-t'ien and K'o-li-ya (Keriya) river valleys have survived up to the present, but a majority of the shallower rivers have been lost in the sands, after which their empty valleys fill up with windborne sand.

Wind-formed surface features

The surface of the Takla Makan is composed of friable alluvial deposits several hundred feet thick. This alluvial stratum has been affected by the wind, and its wind-borne sand cover is as much as 1,000 feet thick. There is a variety of eolian (wind-formed) topographic features, and sand dunes of various shapes and sizes are encountered. These eolian sand dunes were formed through the weathering of the alluvial and colluvial deposits of the basin and of the foothill plains of the Kunlun and eastern Tien Shan. The size of the larger sand-dune chains is considerable: they range from 100 to 500 feet high and 800 to 1,650 feet wide, with a distance between the chains of from one-half to three miles. The highest eolian topographic forms are the pyramidal dunes, rising 650 to 1,000 feet. In the eastern and central parts of the desert, networks of hollow dunes and large, complex sand-dune chains predominate. They are also common in the western portion of the desert (east of the Ho-t'ien Ho Valley), where transverse and longitudinal (with respect to the wind) topographic forms coexist. On the edge of the desert, semipermanent, clustered sand dunes with tamarisk and niter-bushes, as well as clayey regions with disconnected sand dunes, predominate. Such a diversity in wind-formed features is a result of the complex wind conditions of the basin.

Climate. The Takla Makan's climate is moderately warm and markedly continental, with a maximum annual temperature range of 70° F (21° C). Precipitation is very low, ranging from 1.5 inches (38 millimetres) in the west to 0.4 inch in the east. The air temperature in the summer is high, rising as high as 100° F (38° C) on the eastern edge of the desert. In July the average air temperature reaches 77° F (25° C) in the eastern regions. Winters are cold: in January the average air temperature is 16° to 14° F (−9 to −10° C), and the low in winter is generally below −4° F (−20° C). Northerly and northwesterly winds predominate in the summer in the western region. These two air currents, on meeting near the desert's centre at the end of the K'o-li-ya Ho, create a complex circulation system that is clearly reflected in the topography of the sand dunes. In the spring, when the surface sand becomes warm, ascending currents develop, and northeasterly winds become particularly strong. During this period hurricane-force dust storms, filling the atmosphere with dust to altitudes of from 11,500 to 13,000 feet, often occur. Winds from other directions also raise clouds of dust into the air, covering the Takla Makan with a shroud for almost the entire year.

Hydrography. Since the Tarim depression is an internal-drainage basin, the entire runoff from the surrounding mountains collects in the basin itself, feeding the rivers and the groundwater strata. In all probability, the groundwater table under the sands has an unbroken course, flowing west to east to Lop Nor. The importance of rainfall in moistening the sands and feeding the groundwaters is slight, due to its small quantity and high rate of evaporation. The rivers draining the Kunlun Mountains penetrate from 60 to 120 miles into the desert, gradually drying up in the sands. Only the Ho-t'ien Ho crosses the desert and, in July and August, occasionally carries its waters to the Tarim River.

The groundwater table

Plant and animal life. Vegetation is very sparse in the Takla Makan—almost the entire territory is devoid of plant cover. In depressions among the sand dunes, where the groundwaters lie no deeper than 10 to 16 feet from the surface, thin thickets of tamarisk, niter-bushes, and reeds may be found. The thick strata of moving sands, however, prevent the wider spread of this vegetation. Along the edges of the desert, in the area where the sand dunes meet

The Takla Makan Desert.

the river valleys and deltas and where the groundwaters lie comparatively close to the surface, the vegetation is richer. Here, in addition to the plants mentioned above, a number of species characteristic of river valleys are found: Turanga poplar, oleaster, camel thorn, Zygophyllaceae (caltrop family), and saltworts. Sand dunes in hummocks frequently form around the scrub.

The animal life of the Takla Makan is sparse. Only in peripheral regions of the desert, in ancient and modern river valleys and deltas where water and vegetation appear, are the fauna more diverse. Herds of gazelles are found in open spaces, and there are wild boars in river valley thickets. Wolves and foxes are among the carnivores. As late as the beginning of the 20th century, tigers could be found, but they have since been exterminated. Rare animals include the Siberian deer, which inhabits the Tarim River Valley, and the wild camel, which at the end of the 19th century roamed over a considerable portion of the Takla Makan as far as the Ho-t'ien Ho but now appears only occasionally, in the eastern desert region.

There are a large number of rabbits, gerbils, field mice, and jerboas in the sand dunes, and, among insectivores, the long-eared hedgehog and bats are common. Small, tufted larks and the Tarim jay are the commonest birds.

The people and economy. There is no fixed population in the Takla Makan. Hunters make periodic visits, but the area territory is not used by stock breeders because of the almost complete absence of vegetation.

Indications of the presence of petroleum have recently been found in the two regions—Kashgar–Khargalik at the western part of the Tarim Basin and Aksu Kucha at the northern edge of the basin. (M.P.Pe.)

Drainage systems and waterways

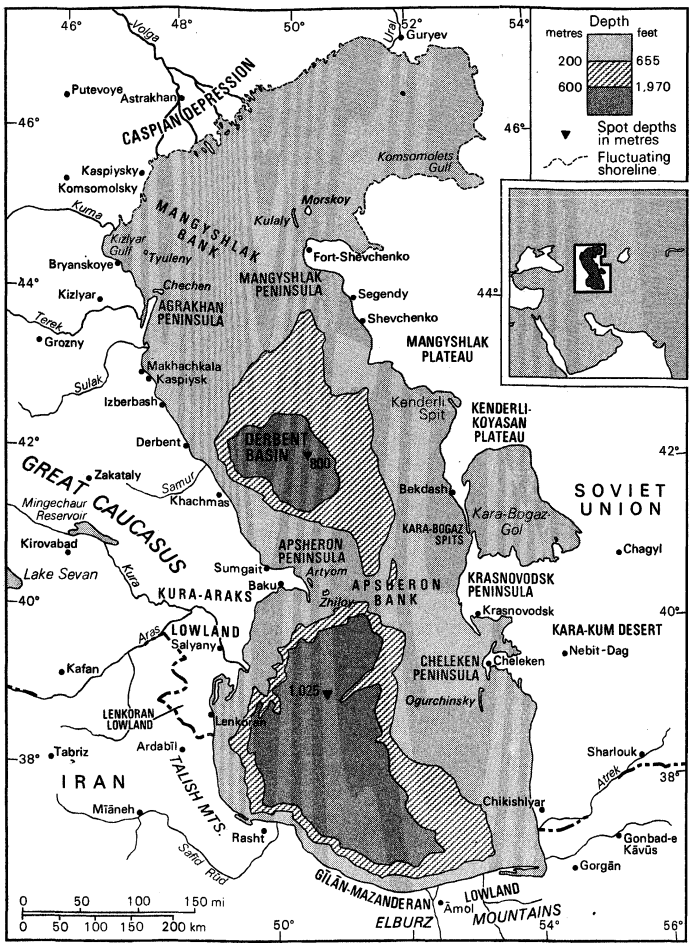
The subsequent sections on the various drainage systems and waterways to be found in Asia are arranged in the following order: Southwest Asia, South Asia, East and Southeast Asia, and Siberia.

CASPIAN SEA

The Caspian Sea lies beyond the Caucasian mountain peaks and dominates the huge, flat expanses of western Central Asia. Its name derives from the ancient Kaspi peoples, who once lived in Transcaucasia to the west; among its other historical names, Khazarsk and Khvalynsk derive from former peoples of the region, while Girkansk stems from Girkanos, "the country of the wolves." Its elongated shape sprawls for nearly 750 miles (1,200 kilometres) from north to south, although its average width is only 200 miles (320 kilometres). It currently covers an area of 143,000 square miles (370,000 square kilometres)—larger than Japan—while its surface lies some 93.5 feet (28.5 metres) below ocean level. The maximum depth, toward the south, is 3,360 feet. Except for its southern shores, which lie at the foot of the giant Elburz Mountains of Iran six-sevenths of the Caspian coast runs through Soviet territory.

It is often stated that the Caspian is the greatest salt lake in the world. But this is not absolutely correct, as scientific studies have shown that, until geologically quite recent times, it was linked, via the Sea of Azov, the Black Sea, and the Mediterranean, to the world ocean. This factor has molded strongly all aspects of its physical geography. The Caspian is of exceptional scientific interest, because its history, particularly in respect to former fluctuations in both area and depth, offers clues to the complex geological and climatic evolution of the region. Man-made changes, notably those resulting from the construction of dams, reservoirs, and canals on the immense Volga River system (which drains into the Caspian from the north), have had their own effect on the contemporary hydrological balance. The Caspian is also of great importance in the transportation networks of the region and in the

Importance of sea-level fluctuations



The Caspian Sea.

production of petroleum and gas. It is anticipated that the use of its splendid sandy beaches for health and recreation resorts will increase considerably in the future.

Physical features. The Caspian possesses as many as 50 islands, mostly small. Chechen, in the northwest, is the largest, followed by Artyom, Zhiloy, Tyuleny, Morskoy, Kulaly, and Ogurchinsky. The basin, as a whole, is usually divided into the North, Middle, and South Caspian, using relief and, in part, hydrological characteristics as the basis.

Shoreline features. The shores of the North Caspian are low and reflect the great accumulation of alluvial material washed down by the Ural, Terek, Sulak, and, above all, the Volga rivers, the deltas of which are extensively developed. The western shore of the Middle Caspian is hilly. The foothills of the Great Caucasus loom close but are separated from the coast by a narrow marine plain. The Apsheron Peninsula, on which the city of Baku is sited, thrusts out into the sea here, while, just to its south, the floodplain of the Kura and Araks rivers forms the Kura-Araks Lowland. The southwestern and South Caspian shores are formed of the sediments of the Lenkoran and Gīlān-Mazanderan lowlands, with the high peaks of the Talish and Elburz mountains rearing up close inland. The eastern shore of the South Caspian is also low and is formed by sediments resulting from wave action; it is broken sharply by the low, hilly Cheleken and Krasnovodsk peninsulas. For the most part, the eastern shore of the Middle Caspian is precipitous, with the sea destroying the margin of the limestone plateau of Mangyshlak and Kenderli-Koyasan. A most important feature of this area is the Kara-Bogaz-Gol, the Caspian's largest, split off from the main body of water by the Kara-Bogaz barrier spits; the Krasnovodsk and Kenderli spits are similar in type.

The major rivers—the Volga, Ural, and Terek—empty into the North Caspian, with their combined annual flow accounting for 88 percent of all river water entering the sea. The Sulak, Samur, Kura, and a number of smaller rivers flow in on the western littoral, contributing about 7 percent of the flow, and the remainder comes in from the rivers of the Iranian shore. The eastern littoral is notable for a complete lack of permanent streams.

Submarine features. The North Caspian, with an area of 30,000 square miles, is the shallowest portion of the sea, with an average depth of 13 to 20 feet, reaching a maximum of 66 along the boundary with the Middle Caspian. The bottom is formed of a monotonously rippling sedimentary plain, broken only by a line of southern bars and shoals—some of which provide foundations for Tyuleny, Kulaly, and Zhemchuzhny islands—reflecting underlying structural rises. Beyond this belt, known as the Mangyshlak Bank, the Middle Caspian, 53,000 square miles in area, forms an irregular depression with an abrupt western slope and a gentler eastern gradient. The shallowest portion—a shelf with depths up to 330–460 feet—extends along both shores, with the westernmost slope furrowed by submerged landslips and canyons. The remains of ancient river valleys have been discovered on the gentler northern slope; the bottom of the depression is formed of a plain that deepens to the west. The Apsheron Bank, a belt of shoals and islands rising from submerged elevations of older rocks, marks the transition to the South Caspian, a depression covering about one-third of the sea. This is fringed by a shelf that is narrow to the west and south but widening to the east. A series of submerged ridges breaks up the relief to the north, but otherwise the bottom of the depression is a flat plain, with the maximum depth of 3,360 feet.

The three main topographic divisions

Geology. The relief of the Caspian Sea reflects its complex geological structure. The northern portion forms a peripheral section of the North Caspian tectonic depression, a vast downwarp in the Earth's surface that is itself part of the great ancient structural block known as the Russian Platform. The Mangyshlak Bank links the mountainous peninsula of the same name to the east with underlying western shore structures; all the rocks concerned reflect an outlying structural uplift of the Hercynian mountain-building movement, which occurred some 290,000,000 years ago. The bottom of the Middle Caspian is very complex. To the west, the submarine shelf is part of the sagging edge of the Great Caucasus Geosyncline, while the submerged Turan Platform on the east swells up in the feature known as the Kara-Bogaz swell. The Apsheron Peninsula regions bear the impress of the Alpine mountain-building and folding period (dating from some 10,000,000–26,000,000 years ago), which created the Caucasian ranges, as do the folded structures of the western South Caspian depression. The entire South Caspian, in fact, has as its base a suboceanic-type basalt crustal structure, although this is overlain in the south by huge accumulations of sedimentary layers many miles thick. The great age thus indicated for the area has led geologists to postulate that this is the remnant of the geologically ancient Tethys Sea. Similarly, the North Caspian Sea bottom is also very old, dating back to Precambrian times, or at least 570,000,000 years ago. The bottom of the North and Middle Caspian has a continental-type crustal structure. It has been suggested that the Middle Caspian depression results from a sagging at the edge of these ancient structures that occurred in Late Paleozoic times, about 250,000,000 years ago; the border between the Middle and South Caspian is, in fact, still experiencing folding activity.

Until the upper Miocene, about 12,000,000 years ago, the sea basin of the Caspian was connected to the Black Sea, through the structural depression known as the Manych Trench. After an upper-Miocene elevation, the Caspian became an enclosed body, with oceanic submarine characteristics preserved today only in the South Caspian. The ocean connection was reestablished in the upper Pliocene, about 2,500,000 years ago, and it is possible that there was also a link northward across the Russian plain to the Barents Sea of the Arctic.

Pre-Miocene link with the Black Sea

In the ensuing Quaternary times, great glaciers advanced and retreated across the Russian plain, and the Caspian Sea itself—in successive phases known as Bakin, Khazar, and Khvalyn—alternately shrank and swelled out. This process left a legacy in the form of peripheral terraces,

marking old shorelines, and can also be traced in the recent underlying sedimentary layers.

The Caspian Sea bottom is now coated with young sediments, finely grained in the shallow north but with shell deposits and oolitic sand—reflecting the high lime content of the Caspian waters—widespread in other coastal areas. Lime also affects the composition of the much deeper bottom layers.

Climate. The North Caspian lies in a moderately continental climatic zone, while all the Middle (and most of the South) Caspian lies in the moderately hot belt. The southwest is touched by subtropical influences, and this remarkable variety is completed by the desert climate prevailing on the eastern shores. Atmospheric circulation is dominated in winter by the cold, clear air of the Asiatic anticyclone, while in summer spurs of the Azores high-pressure and the South Asian low-pressure centres are influential. Complicating factors are the cyclonic disturbances rippling in from the west and the effect of the Great Caucasian ranges. As a result of these factors, northwesterlies (32 percent of occurrences) and southeasterlies (36 percent) dominate circulation patterns. Savage storms are associated with northerly and southeasterly winds.

Summer air temperatures are quite evenly distributed (average July–August figures: 75°–79° F [24°–26° C], with an absolute maximum of 111° F [44° C] on the sunbaked eastern shore), but winter temperatures range from 14° F (−10° C) in the north to 50° F (10° C) in the south. Average annual rainfall varies from 67 inches to eight inches (1,700 to 200 millimetres) over the sea. Most falls in winter and spring. Evaporation from the sea surface is very high, reaching 40 inches a year. Ice formation afflicts the North Caspian, which usually freezes completely by January, and in very cold years floating ice comes as far south as the Apsheron Peninsula region.

Hydrography. Short-term wind-induced fluctuations in the sea level can rise to up to seven feet, though such rises average about two feet. Seiches (rises induced by barometric pressure changes) can cause similar fluctuations. Tidal changes are but a few inches, and seasonal rises induced by high spring water in the rivers are not much more.

One of the more fascinating aspects of the study of the Caspian, however, is the reconstruction of long-term fluctuations over the centuries from archaeological, geographical, and historical evidence. It seems the Caspian reached a level of 72 feet below sea level about 4,000 to 6,000 years ago and again early in the 19th century AD. A still lower level held from the 7th to the 11th centuries, while the lowering that took place between 1929 and 1957 stemmed from the effects of climatic change resulting in lesser river influx and increased evaporation amplified by reservoir construction on the Volga, and from river water consumption for irrigation and industry. The flow of water into the Kara-Bogaz-Gol, now about 12 feet lower than the Caspian, has also had an effect. By the late 20th century, the water level was very close to the −93.5 feet level, reflecting a balance between input (rainfall, river inflow, subterranean upwelling) and consumption (evaporation, flow into the Kara-Bogaz-Gol, human usage) that gave the latter a slight edge and hence a projected annual lowering of the level by three inches (7.5 centimetres). If, however, the north-flowing Vychegda and Pechora were diverted into the Volga, it would seem that the present level could at least be maintained (and possibly even increased, under favourable climatic conditions) until the year 2000. Soviet planners have given serious attention to the requirements and implications of such an ambitious project.

Recent attempts to preserve the sea level

In summer, the average seawater temperature is 75°–79° F (24°–26° C), with the south a little warmer. There are, however, significant winter contrasts, from 37°–45° F (3°–7° C) in the north to 46°–52° F (8°–11° C) in the south. Upwellings of deep water at the eastern littoral—a result of prevailing-wind activity—can also bring a marked drop in summer temperature. Salinity in the Caspian is about 1.27 percent on average, but this conceals a variation from a mere 0.1 percent near the Volga outlet to a high of 32 percent in the Kara-Bogaz-Gol, where intense evaporation occurs. Caspian waters differ from those of the ocean in their high sulphate, calcium, and magnesium carbonate content and—as a result of river inflow—low chloride content.

Water mass circulation occurs, basically, in a north to south movement along the western shore, with a complex pattern developing further south, where there are several subsidiary movements. Currents can be speeded up where they coincide with strong winds, and the sea surface is often ruffled by wave action, with the maximum storm waves being observed near the Apsheron Peninsula.

Marine life. There are about 850 animal and more than 500 plant species represented in the Caspian—a relatively low figure for a body of water of this size. Animal life has been affected greatly by changes in salinity. It includes, among the fish, sturgeons, herring, pike, perch, and sprat; several species of mollusks; and a variety of other organisms including sponges. Some 15 species of Arctic (*e.g.*, the Caspian seal) and Mediterranean types complement the basic fauna. Perch are important among freshwater fish varieties. Some organisms have migrated to the Caspian quite recently: barnacles, crabs, and clams, for example, have been transported by sea vessels; grey mullets have been deliberately introduced by man.

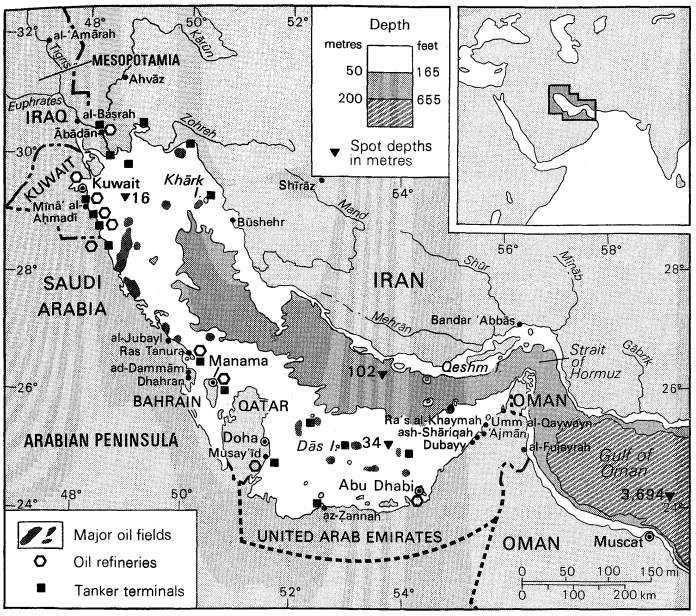
The economy. The Caspian was long famous for its sturgeon catch, but this has been reduced greatly in recent years, as a result of the decline in sea level, and the connected drying up of the most favourable places for spawning. The seal industry is, however, being developed in northern regions. Oil and gas have now become the region's most important resources, following extensive geological surveys in the 1940s and 1950s. Seabed oil is extracted from derricks and artificial islands, most of which are concentrated off the shores of the Azerbaijan S.S.R., supplying half that republic's total oil extraction volume. The extraction of such minerals as sodium sulphate from the Kara-Bogaz-Gol is also of considerable economic importance. Finally, the Caspian is of major importance for transportation in the region: petroleum, wood, grain, cotton, rice, and sulphate are the basic goods carried, while Astrakhan, Baku, Makhachkala, Krasnovodsk, and Shevchenko are the most important ports. They are also connected by regular passenger runs, while railway stock is transported direct, without unloading, on the Baku–Krasnovdsk run. (A.N.K./O.K.L.)

PERSIAN GULF

The Persian Gulf (known to the Arabs as the Arabian Gulf) is the shallow marginal sea of the Indian Ocean that lies between the Arabian Peninsula and southwest Iran. The sea has an area of 92,500 square miles (240,000 square kilometres). Its length is 615 miles (985 kilometres), and its width varies from a maximum of 210 miles to a minimum of 35 miles in the Strait of Hormuz. It is bordered on the north, northeast, and east by Iran, on the northwest by Iraq and Kuwait, on the west and southwest by Saudi Arabia, Bahrain, and Qatar, and on the south and southeast by the United Arab Emirates and part of Oman. The term Persian Gulf is often used to refer not only to the Persian Gulf proper but also to its outlets, the Strait of Hormuz and the Gulf of Oman, which open into the Arabian Sea. The discussion here deals with the Persian Gulf alone.

Physical features. *Physiography.* The Iranian shore is mountainous, and there are often cliffs; elsewhere a narrow coastal plain with beaches, intertidal flats, and small estuaries borders the gulf. The coastal plain widens north of Būshehr on the eastern shore of the gulf and passes into the broad deltaic plain of the Tigris, Euphrates, and Kārūn rivers. Cliffs are rare on the Arabian shore of the gulf, except around the base of the Qatar Peninsula and in the extreme southeast around the Strait of Hormuz. Most of the Arabian shore is bordered by sandy beaches, with many small islands enclosing small lagoons.

The gulf is very shallow, rarely deeper than 300 feet (90 metres), although depths exceeding 360 feet are found at its entrance and at isolated localities in its southeastern part. It is noticeably asymmetrical in profile, with the deepest water occurring along the Iranian coast and a broad shallow area, which is usually less than 120 feet deep, along the Arabian coast. There are numerous is-



The Persian Gulf.

lands, some of which are salt plugs or domes and others merely accumulations of coral and skeletal debris.

The Persian Gulf receives very small amounts of river-borne sediment except in the northwest, where the Tigris, Euphrates, and Kārūn, together with other small streams, empty into the gulf. The rivers reach their peak flow in spring and early summer, when the snow melts in the mountains; disastrous floods sometimes result. There are some ephemeral streams on the Iranian coast south of Būshehr, but virtually no fresh water flows into the gulf on its southwest side. Large quantities of fine dust are, however, blown into the sea by predominant northwest winds from the desert areas of the surrounding lands. Biological, biochemical, and chemical processes lead to the production of considerable calcium carbonate in the form of skeletal debris and fine mud. The deeper parts of the Persian Gulf adjacent to the Iranian coast and the area around the Tigris–Euphrates Delta are mainly floored with gray-green muds rich in calcium carbonate. The shallower areas to the southwest are covered with whitish-gray or speckled skeletal sands and fine carbonate muds. Often the sea floor has been hardened and turned to rock by the deposition of calcium carbonate from the warm, salty waters. Chemical precipitation is abundant in the coastal waters, and sands and muds are produced that mix with the skeletal debris of the local sea life. These sediments are thrown up by the waves to form coastal islands that enclose lagoons. The high salinities and temperatures result in the precipitation of calcium sulfate and sodium chloride to form extensive coastal salt flats.

Seafloor

Geology. The present-day Persian Gulf, together with its northwestern continuation now infilled by the deposits of the Mesopotamian rivers, is thought by some to be the remains of a once much larger basin of deposition aligned northwest to southeast that existed throughout a large part of geological history. In this basin many thousands of feet of sediments accumulated, consisting mostly of limestone and marls (loose, crumbling earthy deposits containing calcium carbonate), together with evaporites and organic matter, which ultimately produced the area's vast oil resources.

Climate. The gulf has a notoriously unpleasant climate. Temperatures are high, though winters may be quite cool at the northwestern extremities. The sparse rainfall occurs mainly as sharp downpours between November and April and is higher in the northeast. Humidity is high. The little cloud cover is more prevalent in winter than in summer. Thunderstorms and fog are rare, but dust storms and haze occur frequently in summer. The wind that blows predominantly from a north–northwest direction—the so-called *shamāl* (Arabic: "north wind")—is seldom strong and rarely reaches gale force. Squalls and waterspouts are common in autumn, when winds sometimes reach speeds of 95 miles per hour in as little as five minutes. Intense heating of the land adjacent to the coasts leads to gentle offshore winds in the mornings and strong onshore winds in the afternoons and evenings.

Hydrography. The small freshwater inflow into the gulf is mostly from the Tigris–Euphrates–Kārūn rivers. The water temperatures range from 75° to 90° F (24° to 32° C) in the Strait of Hormuz to 60° to 90° F (16° to 32° C) in the extreme northwest. These high water temperatures and a low influx of fresh water result in evaporation in excess of freshwater inflow; high salinities result, ranging from 37 to 38 parts per 1,000 in the entrance to 38 to 41 parts per 1,000 in the extreme northwest. Even greater salinities and temperatures are found in the waters of the lagoons on the Arabian shore. The tidal range varies from about four to five feet around Qatar and increases to 10 to 11 feet in the northwest and nine to 10 feet in the extreme southeast. When onshore winds are strong, the level of the coastal waters, particularly in the southern gulf, may rise by as much as eight feet, causing extensive flooding of the low coastal plains. Tidal currents are strong (five miles per hour) in the entrance of the gulf but elsewhere—except between islands or in estuaries and lagoon entrances—rarely exceed one to two miles per hour. The wind affects local currents and sometimes reverses them.

Tides

Waves rarely exceed 10 feet in height and are largest in the southern gulf. The swell from the Indian Ocean affects only the water at the entrance of the gulf; when it is opposed by wind, very turbulent conditions result. The general circulation pattern appears to be caused by water entering from the Indian Ocean, evaporating, becoming denser, and sinking to flow out into the Indian Ocean beneath the inflowing open ocean water.

The waters of the area support many plants and animals, but the high temperatures and salinities lead to a diminution in the variety of forms; many Indian Ocean forms penetrate only a small way into the gulf.

The economy. Until the discovery of oil in Iran in 1908, the Persian Gulf area was important mainly for fishing, pearling, the building of dhows (Arab lateen-rigged boats), sailcloth making, camel breeding, reedmat making, date growing, and the production of other minor products, such as red ochre from the islands in the south. The arid lands surrounding the gulf produced little else and, except for the rich alluvial lands of the Mesopotamian plain, supported only a small population of fishermen, date growers, and nomads. Today these traditional industries have declined, and the economy of the region is dominated by the production of oil. The Persian Gulf and the surrounding countries account for about one-third of the world's total oil production and have more than one-half of the world's proved reserves. The area has been explored only in a preliminary way, and there are still far fewer drill holes in the area than are put down in a single year in the United States. Offshore exploration below the shallow waters of the gulf has revealed the presence of large reserves of oil and gas. These discoveries have led to numerous legal wrangles between states about exact territorial limits. Large quantities of oil are refined locally in Iran, in Bahrain, and elsewhere, but most of it is exported to northwestern Europe and other parts of the world as crude oil.

Oil

Other exploitable mineral deposits appear to be rare, but only cursory surveys have been made. Exploration is actively being pursued in the area.

Fishing is becoming highly commercialized. The traditional pearl-fishing industry has declined since the introduction of the Japanese cultivated pearls in the 1930s. Large fishing industries have been set up in Kuwait, Qatar, and Bahrain, and some countries have become exporters of fish.

There has always been a considerable sea trade carried on by local craft between the Persian Gulf and Africa and India; this is now completely dominated by an incessant flow of large tankers that carry oil from the large marine terminals at Khārk Island, Kuwait, az-Ẓahrān (Dhahran), Bahrain, Musay'īd, az-Zannah, Dās Island, and other locations to all parts of the world. The heavy traffic and

the offshore oil installations have produced many hazards, despite the use of a system of radio-navigational stations. (G.Ev.)

RED SEA

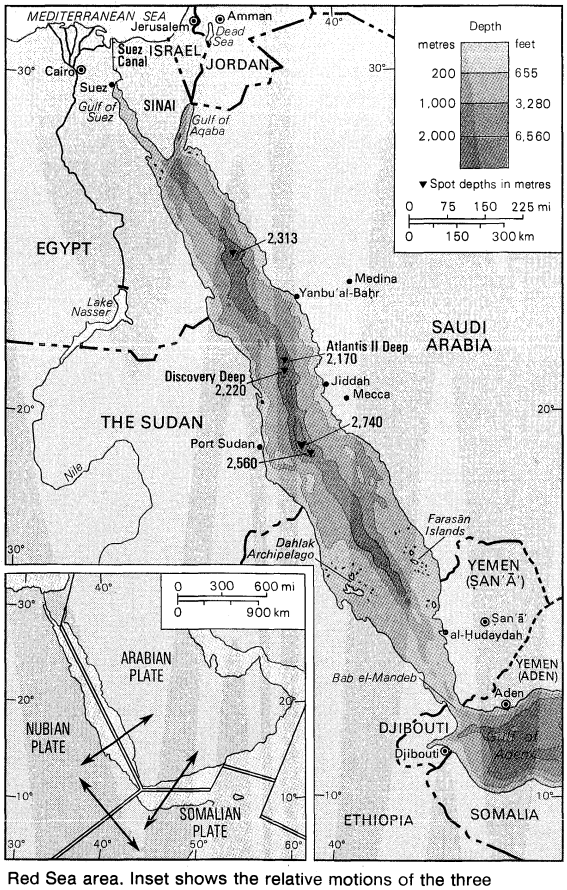
The Red Sea is a narrow strip of water extending southeastward from Suez for about 1,300 miles (2,100 kilometres) to the Straits of Bab el-Mandeb, which connects with the Gulf of Aden and thence with the Indian Ocean. The sea separates the coasts of Egypt, The Sudan, and Ethiopia to the west from those of Saudi Arabia and Yemen (Ṣan'a') to the east. Its maximum width is 190 miles; its greatest depth 9,580 feet (2,920 metres); and its area approximately 169,000 square miles (438,000 square kilometres). The Red Sea contains some of the world's hottest and saltiest seawater. When the Suez Canal is open, it is one of the most heavily travelled waterways in the world, carrying maritime traffic between Europe and Asia. Its name derived from the colour changes observed in its waters. Normally the Red Sea is an intense blue green; occasionally, however, it is populated by extensive blooms of the algae *Trichodesmium erythraeum,* which, upon dying off, turn the sea a reddish-brown colour.

Physiography and submarine morphology. The Red Sea lies in a fault depression that separates two great blocks of the Earth's crust—Arabia and North Africa. The land on either side, inland from the coastal plains, reaches heights of more than 6,560 feet above sea level, with the highest land in the south.

The Gulfs of Suez and Aqaba

At its northern end the Red Sea splits into two parts, the Gulf of Suez to the northwest and the Gulf of Aqaba to the northeast. The Gulf of Suez is shallow—approximately 180 to 210 feet deep—and it is bordered by a broad coastal plain. The Gulf of Aqaba, on the other hand, is bordered by a narrow plain, and it reaches a depth of 5,500 feet. From approximately 28° N, where the Gulfs of Suez and Aqaba divide, south to a latitude near 25° N, the Red Sea's coasts parallel each other at a distance of about 110 miles apart. Here the sea floor consists of a main trough, with a maximum depth of some 4,100 feet, running parallel to the shorelines.

Inset adapted from D.P. McKenzie, D. Davies, and P. Molnar, "Plate Tectonics of the Red Sea and East Africa," *Nature,* vol. 226, p. 244 (April 18, 1970)



Red Sea area. Inset shows the relative motions of the three plates that make up the Red Sea area.

South of this point, and continuing southeast to latitude 16° N, the main trough becomes sinuous, following the irregularities of the shoreline. About halfway down this section, roughly between 20° and 21° N, the topography of the trough becomes more rugged, and several sharp clefts appear in the sea floor. Because of an extensive growth of coral banks, south of 16° N only a shallow narrow channel remains. The sill separating the Red Sea and the Gulf of Aden at Bab el-Mandeb is raised by this growth; therefore, the depth of the water is only about 380 feet, and the main channel becomes very narrow.

The clefts within the deeper part of the trough are unusual sea floor areas in which hot brine concentrates are found. These patches apparently form distinct and separated deeps within the trough having a north-south trend, whereas the general trend of the trough is from northwest to southeast. At the bottom of these areas are unique sediments, containing deposits of heavy metal oxides from 30 to 60 feet thick.

Most of the islands of the Red Sea are merely exposed reefs. There is, however, a group of active volcanoes just south of the Dahlak Archipelago (16° N), as well as a recently extinct volcano on Jebel Tier.

Geology. The Red Sea occupies part of a large rift valley in the continental crust of Africa and Arabia. This break in the crust is part of a complex rift system that includes the East African Rift valley, which extends southward through Ethiopia, Kenya, and Tanzania for almost 2,200 miles, and northward for over 280 miles from the Gulf of Aqaba to form the great Wadi Aqaba–Dead Sea–Jordan Rift, also extending eastward for 600 miles from the southern end of the Red Sea to form the Gulf of Aden.

Relationship to the Great Rift System

The Red Sea Valley cuts through the Arabian-Nubian Massif, a central mass of Precambrian igneous and metamorphic rocks (*i.e.,* formed deep in the earth under heat and pressure from 570,000,000 to 4,600,000,000 years ago), whose outcrops form the rugged mountains of the adjoining region. The massif is surrounded by Paleozoic marine sediments (from 225,000,000 to 570,000,000 years old). These sediments were affected by the folding and faulting that began in the Late Paleozoic Era; the laying down of deposits, however, continued to take place during this time and apparently continued into the Mesozoic Era (from 65,000,000 to 225,000,000 years ago). The Mesozoic sediments appear to surround and overlap those of the Paleozoic and are in turn surrounded by Early Tertiary sediments (from about 54,000,000 to 65,000,000 years old). In many places large remnants of Mesozoic sediments are found overlying the Precambrian rocks, suggesting that at one time a fairly continuous cover of deposits existed above the older massif.

The Red Sea is considered a relatively new sea whose development probably resembles the Atlantic Ocean in its early stages. The Red Sea's trough apparently formed in at least two complex phases of land motion. The movement of Africa away from Arabia began during the lower Eocene Epoch (50,000,000 years ago). The Gulf of Suez opened up during the lower Oligocene Epoch (about 35,000,000 years ago), and the northern part of the Red Sea in early Miocene time (25,000,000 years ago). The second phase began about 3,000,000 to 4,000,000 years ago, creating the trough in the Gulf of Aqaba and also in the southern half of the Red Sea Valley. This motion, estimated as amounting to 0.59 to 0.62 inches (15–15.7 millimetres) a year, is still proceeding, as indicated by the extensive volcanism of the past 10,000 years, by earthquake activity, and by the flow of hot brines in the trough.

Climate. The Red Sea region has very little precipitation in any form, although prehistoric artifacts seem to indicate that there were greater amounts of rainfall in times gone by. In general, the year-round climate makes an active life difficult, for the average temperature varies between 77° and 82° F (25° and 28° C), and there is a very high degree of relative humidity in summer. In the northern part of the Red Sea area, extending down to 19° N, the prevailing winds are north to northwest. Best known are the occasional westerly, or "Egyptian," winds,

which blow with some violence during the winter months and are generally accompanied by fog and blowing sand. From latitudes 14° to 16° N the winds are variable, but during the months of June through August strong northwest winds move down from the north, sometimes extending as far south as the Straits of Bab el-Mandeb; by September, however, this wind pattern retreats to a position north of 16° N. South of 14° N the prevailing winds are south to southeast.

Hydrography. No water enters the Red Sea from rivers, and rainfall is scant; but the evaporation loss, in excess of 80 inches a year, is made up by an inflow through the eastern channel of the Straits of Bab el-Mandeb from the Gulf of Aden. This inflow is driven toward the north by prevailing winds and generates a circulation pattern in which these low salinity waters (the average salinity is about 36 parts of salt per thousand) move northward. Water from the Gulf of Suez has a salinity of about 40 parts per thousand due to evaporation, and consequently a high density. This dense water moves toward the south and sinks below the less dense inflowing waters from the Red Sea. Below a transition zone, which extends from depths of about 300 to 1,300 feet, the water conditions are stabilized at about 72° F (22° C), with a salinity of almost 41 parts per thousand. This south-flowing bottom water, displaced from the north, spills over the sill at Bab el-Mandeb, mostly through the eastern channel. It is estimated that there is a complete renewal of water in the Red Sea every 20 years.

Salinity and temperature

Below this southward-flowing water, in the deepest portions of the trough, there is another transition layer, only 80 feet thick, below which, at some 6,400 feet, lie a number of pools of hot brine. The brine in the Atlantis II Deep has an average temperature of almost 140° F (60° C), a salinity of 256 parts per thousand, and contains no oxygen. There are similar pools of water in the Discovery Deep, and in the Chain Deep (at about 21°18′ N). Heating from below renders these pools unstable so that their contents mix with the overlying waters; they thus become part of the general circulation system of the sea.

The economy. *Resources.* Three major types of mineral resources are found in the Red Sea region: petroleum deposits, evaporite deposits (sediments laid down as a result of evaporation, such as salt, gypsum, and dolomite), and the newly discovered heavy metal deposits in the bottom oozes of the Atlantis II and Discovery deeps, which lie between 21°15′ and 21°30′ N. The oil and gas deposits are being exploited to varying degrees by the nations adjoining the sea. The evaporites are utilized only very slightly, primarily on a local basis. Of the heavy metal deposits, none of which had been touched, those contained in the sediments of the Atlantis II Deep alone were estimated as having a $25,000,000,000 value. The sediment of the Discovery Deep also has a significant metalliferous content but at a lower concentration than that in the Atlantis II Deep. These deposits are in the form of fairly fluid oozes, with an average of about 85 percent brine. The average analysis of the Atlantis II Deep deposit reveals an iron content of 29 percent; zinc 3.4 percent; copper 1.3 percent; lead 0.1 percent; silver 54 parts per million; and gold 0.5 parts per million. The total brine-free sediment estimated to be present in the upper 30 feet of the Atlantis II Deep is about 50,000,000 tons. These deposits appear to extend to a depth of 60 feet below the sediment surface, but the quality of the deposits below 30 feet is unknown.

Mineral deposits

The recovery of sediment located beneath 5,700 to 6,400 feet of water poses problems. But since most of these metalliferous deposits are fluid oozes, it is anticipated that it may be possible to pump them to the surface much the same way as oil. There are also numerous proposals for drying and beneficiating (treating for smelting) these deposits after recovery. It would indeed seem that exploitation is now feasible, provided international agreements can resolve legal difficulties.

Navigation. Navigation in the Red Sea is difficult. The unindented shorelines of the northern half provide few natural harbours; in the southern half the growth of coral reefs has restricted the navigable channel and blocked some harbour facilities. At Bab el-Mandeb the channel is kept open by blasting and dredging. Atmospheric distortion (heat shimmer), sandstorms, and highly irregular water currents add to the navigational hazards.
