In the uplands above 3,300 feet, stands of single species become more common, and trees such as oak, beech, red cedar, and pine become increasingly dominant. Above 6,500 feet, cloud or moss forest characterized by conifers, tree ferns, and a wealth of fungi and epiphytes (such as mosses and orchids) appears.

Papua New Guinea possesses a rich variety of reptiles, marsupials (animals that carry their young in pouches), native freshwater fish, and birds but is almost devoid of large mammals. Since the Tertiary Period (which occurred from 66,400,000 to 1,600,000 years ago), the island has been isolated from Southeast Asia by the sea, and its animals thereafter evolved in isolation. This appears not to have been true for plant life, for New Guinea has been a centre of dispersal for many plants to all neighbouring regions. The extraordinary profusion in Papua New Guinea of such plants as orchids, figs (*Ficus*), and false beech (*Nothofagus*) and of such animals as cassowaries (large, flightless birds), birds of paradise, parrots, butterflies, and marsupials—including the tree kangaroo and phalanger—gives the island an unparalleled biogeography.

Papua New Guinea's unique biological species have long been sought by collectors all over the world. The government has introduced several conservation and protection measures; the export of birds of paradise is now banned, and hunters thereof are restricted to the use of traditional weapons. Similarly, the export of many other birds and butterflies and of crocodile skins is strictly regulated. Other policies encourage the controlled expansion of selected exports of "farmed" orchids and crocodiles and of "cultivated" butterflies and other insects.

Settlement patterns. More than 80 percent of the country's population lives in rural areas. Rural settlement patterns are extremely varied. In isolated areas of the southern interior there still remains a handful of the previously common giant communal structures that house the whole male population, with a circling cluster of women's huts. In many coastal areas, villages stretch between the beach and an inland swamp in long lines, broken into clan or family segments. In the Highlands numerous village forms exist: in the Eastern Highlands and Chimbu provinces, villages previously clustered along ridgetops for defensive purposes are dispersing increasingly downslope; in the Western Highlands and Enga provinces, the traditional form is of scattered households each surrounded by its own land, with separate houses for men and women; in the Telefomin area, clustered villages are supplemented by scattered garden houses at a distance from the central settlement. Housing styles originally reflected environmental circumstances, ranging from houses built over the sea in sheltered coastal areas, which avoided mosquitoes and simplified sanitary disposal problems, to houses dug into the ground to retain heat in the colder parts of the Highlands. Such adjustments are disappearing as Western-style housing becomes more common.

The 14 percent of the population that is urban lives in towns whose original location was determined either by access to a good harbour for early colonial planters or, in the interior, by the sufficient availability of level land for an airstrip. Despite the greatly diminished importance of plantations and the removal out of town of most of the

Lowland
rain forest

Wildlife
conservation

Rainfall
patterns

airstrips, these origins help determine the existing urban layout. Within the towns, of which Port Moresby and Lae are the largest, there are great contrasts in housing. Port Moresby has, for example, grand modern apartment blocks overlooking the sea, but nearly half its population lives in squatter settlements. Rapid urban growth, at about 6 percent annually, and considerable income inequalities mean that public or low-cost housing cannot be built in sufficient quantities to accommodate much more than a relatively small portion of the urban population.

More than
700 ethnic
groups

The people. *Ethnic composition.* Papua New Guinea's ethnic composition is extremely complex. There are more than 700 ethnic groups; these are often separated into two major divisions, Papuan (constituting more than four-fifths of the total population) and Melanesian (constituting all but about 1 percent of the rest of the population). Very small minorities of chiefly Micronesian and chiefly Polynesian ethnic groups can be found on some of the outlying islands. Within the larger divisions, characteristics vary widely; the Melanesians, for example, who generally inhabit the coastal regions and offshore islands, range from the relatively tall, light-skinned Trobriand Islanders to the black-skinned people of Buka. Ethnic Papuans, who live mainly in the interior, are often physically characterized by other citizens as stocky and muscular.

While at independence in 1975 the expatriate community of 40,000 was predominantly of Australian and Chinese origin, a decade later the slightly smaller foreign community was more mixed, with the largest non-Western group being from the Philippines.

Linguistic composition. There are two radically different indigenous language types—Austronesian, or Melanesian, and non-Austronesian, or Papuan—and the language areas generally reflect ethnic divisions. Some 200 related Austronesian languages occur, mainly in the islands and along the New Guinea coast. The approximately 550 non-Austronesian languages have small speech communities, the largest being the Enga, in the Wabag area. Because of the multiplicity of tongues, Tok Pisin has developed as an effective lingua franca.

Religious composition. About three-fifths of the populace consider themselves Protestant, and the largest portion of these are Lutheran. Nearly a third are Roman Catholic. The remainder include Anglicans and Bahā'īs. Despite the numbers enrolled in introduced religions, traditional religious beliefs persist, and rituals of magic, spells, and sorcery are still widely practiced.

Demographic trends. Population growth is high, about 2.7 percent annually, and two-fifths of the population is under 15 years of age. Since employment in the commercial sector has grown much more slowly (it declined in the 1980s), the government has attempted to concentrate its policies on rural, village-based development in an attempt to reduce urban migration and demands for formal employment. In the early 1980s the birth rate, though falling, was 50 percent higher than the world average, while the death rate was only 25 percent higher and falling much faster. Consequently, full employment is likely to remain a problem.

The economy. *Resources.* From 1970 onward, major mineral discoveries have transformed the Papua New Guinean economy from one dependent on tropical crops (coffee, copra, cacao) to one that depends for much of its exports on minerals. Large gold and copper deposits have led to major development at Panguna on Bougainville, Ok Tedi in the Star Mountains, Misima Island in Milne Bay, Porgera in the Western Highlands, and Lihir Island near New Ireland. After 70 years of exploration, major natural gas and oil finds were made in the late 1980s; at the end of the decade plans for their exploitation were being prepared.

Dispute
over
mineral
revenues

Such resource exploitation has caused local groups to contest, principally with the national government, the distribution of mineral revenues. Open warfare broke out on Bougainville, and the island's gold and copper mine was closed in 1989. Despite this, revenues from mining provided one-fifth of government revenue during the 1980s.

Forestry exploitation, extensive particularly around Madang, in the northeast, and on New Britain and New

Ireland islands, accounted for some 10 percent of exports. While fisheries have great potential, this industry has been especially erratic.

Agriculture. Most agricultural production is for subsistence, and production remains difficult to estimate. Almost all commercial crop production is exported. High-quality Arabica coffee is grown throughout the Highlands, while cacao is grown in the islands, oil palms in western New Britain and the southeastern mainland, and robusta coffee on the north coast; copra is produced in all lowland areas, together with some rubber. Production of all crops has been stagnant since 1985. However, after 1975, smallholder growers increasingly took over the bulk of production, replacing plantations.

Industry. Industrial output is of little significance, accounting for only one-tenth of gross domestic product despite the government's attempts to promote its expansion. Processing and manufacturing are centred chiefly in Lae and Port Moresby; products include food, beverages, tobacco goods, wood products, textiles, and metal goods.

Finance. The kina, Papua New Guinea's currency, remained stable and very strong following independence, although problems on Bougainville in 1989 resulted in its devaluation. Responsible financial management remains a strong feature of the Papua New Guinean economy. Foreign investment and taxes thereon have dominated the economy and government receipts since independence.

Trade. Papua New Guinea's trade is roughly in balance. Its exports, principally gold and copper, go primarily to Japan and Europe. Australia has consistently supplied just under half of the country's imports since independence. After machinery and transport equipment, foodstuffs are a major import; the basic diet of most urban dwellers consists of rice and canned fish or meat, very little of which is produced within the country.

Transportation. Despite the construction of the Okuk Highway, which links Lae to all major Highland towns, air transport remains the most important and, from Port Moresby, essentially the only form of interurban transportation. Papua New Guinea has more regularly operative airstrips per 1,000 population than almost any other country in the world. International air access is via Jackson's Airport, Port Moresby.

Administration and social conditions. Papua New Guinea is a member of the Commonwealth, with the British monarch as its head of state. The government follows a unicameral parliamentary system. The head of state appoints the prime minister, who presides over the National Executive Council; the governor-general, who is nominated by the council and represents the crown; and the chief justice, who presides over the six- to eight-member Supreme Court. Political parties are extraordinarily divisive and numerous and have weak local organization. A feature of parliamentary politics in Papua New Guinea during the 1980s was the frequency of motions of no confidence in the government (allowed every six months under the 1975 constitution). Despite the frequent changes of government, policies have remained notably stable. Papua New Guinea's major foreign policy concerns are its bridging role between Southeast Asia and the rest of the Pacific and its relations with Indonesia, which have been occasionally strained as a result of events in neighbouring Irian Jaya. A feature of Papua New Guinea's political life has been its active and free press staffed almost exclusively by national journalists.

Education. Despite Papua New Guinea's impressive progress in education, three-fifths of all adults are illiterate. Only about two-thirds of all children attend primary school, only half of those attending finish primary school, and only one in six primary-school students receives any secondary schooling. The rapid growth and extreme youthfulness of the population (42 percent are under 15 years of age) mean that educational demand outstrips supply even though education is a major item of government expenditure. Families opt to educate sons rather than daughters: for every 10 boys in primary schools, there are 8 girls; at secondary school the figure is 6 girls, and at university 2 girls.

Health and welfare. The village and the family in Papua

New Guinea provide largely those welfare services which, in more developed countries, are assumed by the state. Health expenditure in Papua New Guinea as a proportion of total government spending is relatively high for a developing country. Pneumonia and malaria are among the leading causes of mortality. Emphasis on primary health care at the village level has reduced maternal and infant mortality and led to a rapid increase in life expectancy.

Cultural life. Despite incorporation into the modern world, Papua New Guinea retains a rich variety of village cultures, expressed in its human-molded landscapes and its sculpture, painting, storytelling, dance, and body decoration. The Papua New Guinea National Museum and Art Gallery at Waigani has a significant collection of ethnographic artifacts, and the government encourages the continuation and, in some cases, the revival of activities associated with traditional cultures.

For statistical data on the land and people of Papua New Guinea, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

The peopling of New Guinea. Relatively little archaeological work has been carried out in New Guinea. On the basis of current evidence, it has been postulated that parts of New Guinea were occupied as early as 50,000 years ago. Remains of swamp-drainage channels and other water-management works indicate the existence of intensive agriculture on the island around 7000 bc. The intensity and length of time of human occupation of the Highlands are evidenced by the extent of man-made landscapes in the region. These discoveries are made even more interesting by the fact that the sweet potato, the present staple crop of the region, does not seem to have arrived in the area from the Americas until 300 or 400 years ago. It is presumed that taro was the earlier staple, as it still is in some isolated Highlands basins such as that at Telefomin.

The colonial period. Malay and possibly Chinese traders took spoils and slaves from New Guinea for hundreds of years. The first European visitor may have been Jorge de Meneses, who possibly landed on the island in 1526–27 while en route to the Moluccas. The first European attempt at colonization was made in 1793 by Lieutenant John Hayes, a British naval officer, near Manokwari, now in Irian Jaya. The Dutch, however, claimed the western half of the island as part of the Dutch East Indies in 1828; their control remained nominal until 1898, when their first permanent administrative posts were set up at Fakfak and Manokwari. Captain John Moresby of Great Britain surveyed the southeastern coast in the 1870s, and European planters had moved onto New Britain and New Ireland by the 1880s. By 1884 the southeastern quadrant of New Guinea had been established as a British protectorate, and in the same year the German New Guinea Company began its administration of the northeastern quadrant. Despite early gold finds in British New Guinea (after 1906 administered by Australia as Papua), it was in German New Guinea, administered by the German imperial government after 1899, that most early economic activity took place. Plantations were widely established in the islands and around Madang; labourers were brought from the Sepik River, the Markham Valley, and Buka Island.

German New Guinea was taken over by Australia as a mandated territory of the League of Nations in 1921, after World War I. It remained administratively separate from Papua, where the protectionist policies of Sir Hubert Murray (lieutenant governor of Papua, 1908–40) did little to encourage colonial investment. The discovery in the 1920s of massive gold deposits at the Bulolo River and Edie Creek in the mandated territory increased the disparity of colonial impact in the different regions. In the early 1930s an even greater discovery was made—nearly 1,000,000 people previously unknown to Europeans were contacted in the Highlands basins of the Australian mandate. At first, the Highlanders were utilized as a massive new source of labour for the coastal plantations, a role they continue to play. At the end of World War II, however, the growing of Arabica coffee by small landholders

spread rapidly throughout much of the Highlands. Cacao also was rapidly adopted as a plantation and smallholder crop in the islands and around Madang.

In 1945 Australia combined its administration of Papua and that of the mandate into the Territory of Papua and New Guinea, with the common capital at Port Moresby, on the south coast of Papua. From 1946 Australia administered the mandate of New Guinea as a United Nations trust territory. Despite the general lack of economic development in Papua, its one large town of Port Moresby grew rapidly and attracted large numbers of migrants, particularly from the poorer areas.

Independence. Self-government was achieved on Dec. 1, 1973, and full independence from Australia on Sept. 16, 1975. At independence there were attempts in both Bougainville and Papua to secede from the new state. The crisis on Bougainville was subdued as a result of the introduction of provincial government and a devolution of some national powers to such governments. The Papuan movement was also pacified by this action, but it, too, lacked cohesive support. In late 1988 secessionism was rekindled on Bougainville as a result of disputes over the distribution of mineral revenues, and in 1990 Bougainville declared independence, though its independence was not recognized by any country. (R.T.J.)

For later developments in the history of Papua New Guinea, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

Solomon Islands

Solomon Islands, an independent country in the southwestern Pacific Ocean, consists of a double chain of volcanic islands and coral atolls in Melanesia, occupying a total land area of 10,954 square miles (28,370 square kilometres). Buka and Bougainville islands, at the northwestern end of the Solomons chain, form the North Solomons province of Papua New Guinea. Honiara, on Guadalcanal Island, is Solomon Islands' capital and largest city.

PHYSICAL AND HUMAN GEOGRAPHY

The land. The main islands of the group are large and rugged, rising to 8,028 feet (2,447 metres) at Mount Makarakomburu (Makarakombou) on Guadalcanal. They lie in two parallel chains: the western includes Vella Lavella, Kolombangara, New Georgia, and Guadalcanal; the eastern, Choiseul Island, Santa Isabel, and Malaita. The chains converge on Makira (San Cristóbal) Island. Geologically, they are part of the volcanic arc extending from New Ireland, in Papua New Guinea, to Vanuatu.

The climate is tropical oceanic; that is, hot and humid, but relieved by cool winds and abundant, year-round rainfall. Temperatures seldom exceed 90° F (32° C) and rainfall generally averages 120–140 inches (3,000–3,500 millimetres) a year. Heavily wooded, mountainous terrain is characteristic and, although there are extensive plains, only those on the northern side of Guadalcanal have been developed for large-scale agriculture. As in most island groups, animal life is limited. There are hot springs on Savo, where a volcano last erupted in the 1840s. Solomon Islands has a number of other volcanoes. Tinakula in the Santa Cruz group and Kavachi, a submarine volcano near New Georgia, for example, have erupted regularly every few years, and Simbo Island has a solfatara (a volcanic area or vent that yields only hot vapours and sulfurous gases). Earthquakes and destructive cyclones also occur regularly.

The people. Most of the population is Melanesian. Polynesians, forming a small minority, live mainly on outlying atolls, principally Ontong Java, Rennell and Bellona, the Reef Islands, Sikaiana, Tikopia, and Anuta. There are also Gilbertese from Micronesia, who were resettled there between 1955 and 1971, and small numbers of Chinese and Europeans. Anglican, Roman Catholic, South Sea Evangelical, United (a union of Methodists and Congregationalists), and Seventh-day Adventist denominations exist in Solomon Islands, and almost all of the islanders are Christian. More than 60 languages and dialects are spoken. English is the official language, but Pijin, an English-based pidgin, is the one most widely used and understood.

Early
agriculture

Principal
islands

Discovery
of gold

Most of the people live in small rural villages. They engage mainly in subsistence gardening, pig raising, and fishing but are also involved in the cash economy.

The economy. Solomon Islands' main resources, fish and timber, have been exploited excessively, with little regard for their depletion. Its other export products are derived from plantation crops: palm oil from oil palms, copra from coconuts, and cocoa from the cacao plant. Japan, Thailand, and Australia are the major customers. The chief imports are machinery, fuels, manufactured goods, and food, and Australia is the main supplier. A government plan to reduce food imports by growing rice locally was scuttled in 1986 when a cyclone destroyed the rice cultivations on Guadalcanal.

Traditional
handicrafts

The islands have significant reserves of bauxite (on Rennell Island) and phosphates (on Bellona Island), and some gold has been extracted on Guadalcanal. Manufacturing includes fibreglass products, boat building, batteries, and clothing, in addition to fish freezing and canning. Traditional handicrafts, including woodwork, shell inlay, mats, baskets, and shell jewelry, are made both for the tourist market and for export. Indigenous currencies such as shell money (from Malaita) and red-feather money (from Santa Cruz) are also made for use in customary transactions. Henderson Field, near Honiara, is the principal international airport, although airfields at Munda, Nusatupe (at Gizo), and Graciosa Bay (at Santa Cruz) may also serve as international points of entry. Solomon Islands Airlines, which is owned by the government, provides domestic air service. Ports handling overseas cargoes include Honiara, Tulagi (the prewar capital), and Gizo. Aola Bay, Viru, and Graciosa Bay are used mainly for log exports. Interisland shipping is operated both privately and by the government.

Administration and social conditions. Solomon Islands is an independent parliamentary state and a member of the Commonwealth. As established by the constitution of 1978, the British monarch is the head of state and is represented by a governor-general who is appointed by the monarch upon recommendation by Parliament. The governor-general must be a citizen of Solomon Islands. Parliament, which is elected every four years by universal adult suffrage, is composed of 38 members. Executive power is exercised by a prime minister chosen by and from Parliament and a cabinet of 12 ministers (also members of Parliament). Although political parties exist in name, their organization and discipline tend to be loose. Political loyalties are based on personal and local factors rather than on broad class interests or ideology. As a result, the prime minister rarely commands a clear majority in Parliament, and so he owes his position to the sometimes shaky support of a coalition of parties or factions. In 1981 considerable decentralization occurred with the establishment of seven provincial bodies that assumed control of matters regarding transportation, economic development, health, and education.

Before World War II, schooling was solely the concern of the missions. Since then the government has become involved. Primary education was provided mostly by subsidized mission schools until 1974, when local authorities assumed responsibility. There are several secondary schools, a multi-faculty college of higher education, and a branch (1971) of the University of the South Pacific. Some students study overseas, especially in Fiji and Papua New Guinea. There is a hospital at Honiara.

Much of traditional culture endures. Crafts are promoted by the Solomon Islands National Museum, established in 1969 in Honiara, and dances and music are regularly performed. Panpipes and percussive "bamboo bands" (assemblages of drums made of bamboo) are popular. Since the 1970s an indigenous literary movement has developed. The writing is in English and mostly published in Solomon Islands.

For statistical data on the land and people of Solomon Islands, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

The Solomon Islands were initially settled by at least 2000 BC—well before the archaeological record begins—prob-

ably by people of the Austronesian language group. Lapita pottery was in use in Santa Cruz and the Reef Islands about 1500 BC. Material radiocarbon dated to about 1000 BC has also been excavated at Vatulumu Cave (Guadalcanal), Anuta, Santa Ana, and Tikopia.

The first European to reach the islands was the Spanish explorer Álvaro de Mendaña de Neira, in 1568. Subsequently, unjustified rumours led to the belief that he had not only found gold there but had discovered where the biblical King Solomon obtained the gold for his temple in Jerusalem. The islands thus acquired the name *Islas de Solomón*. Later Spanish expeditions to the southwest Pacific, in 1595 and 1606, were unable to confirm the discoveries reported by Mendaña. Geographers came to doubt the existence of the group, and it was not until the late 18th century, after further sightings by French and English navigators, that the Solomons were accurately charted. After the settlement by the English of Sydney in 1788, naval and commercial shipping began increasingly to pass through the Solomons' waters.

Roman Catholic missionaries in the 1840s failed to establish a settlement but did so in 1898. Anglican missionaries, who had been taking islanders to New Zealand for training since the 1850s, began to settle in the Solomons in the 1870s. Other missions arrived later.

By the late 19th century the islands were being exploited for labour to work the plantations of Fiji and other islands and of Queensland, Australia. About 30,000 labourers were recruited between 1870 and 1910. To protect their own interests Germany and Britain divided the Solomons between them in 1886; but in 1899 Germany transferred the northern islands, except for Buka and Bougainville, to Britain (which already claimed the southern islands) in return for recognition of German claims in Western Samoa and parts of Africa. The British Solomon Islands Protectorate was declared in 1893, partly in response to abuses associated with labour recruitment and partly to regulate contacts between islanders and European settlers, but mainly to forestall a threat of annexation by France. Colonial rule began in 1896. Although generally humane, administrators were more concerned with promoting the interests of European traders and planters than with those of the islanders, and islanders were punished harshly for offenses against colonial law and order. The murder of government tax collectors on Malaita in 1927 was answered with a savage punitive expedition, backed by an Australian warship. Together with some of his associates, Basiana, the leader of the assassins, was later hanged, and his young sons were forced to witness the execution.

With the outbreak of World War II in the Pacific, the Japanese began occupying the protectorate early in 1942, but their advance farther southward was stopped by U.S. forces, who invaded on August 7. Fighting in the Solomons over the next 15 months was some of the most bitter in the Pacific; the long struggle on Guadalcanal was the crucial battle of the Pacific war. Throughout the campaign the U.S. forces and their allies were strongly supported by the islanders. At the end of the war, because of the proximity of an airfield and the availability of flat land and of the military's buildings, Honiara on Guadalcanal became the new capital, replacing Tulagi.

Another result of the war was to stimulate political consciousness among the islanders and so inspire a nationalist movement known as Maasina Rule, which lasted from 1944 to 1952. Subsequently, in response to the worldwide movement for decolonization, the Solomons set out on the path of constitutional development. The nation was formally renamed Solomon Islands in 1975, and independence was attained on July 7, 1978. (H.M.La.)

For later developments in the history of Solomon Islands, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

Vanuatu

Vanuatu is a republic consisting of a chain of 13 principal and many smaller islands in the southwestern Pacific Ocean, 500 miles (800 kilometres) west of Fiji and 1,100 miles east of Australia. The islands extend from north to

The
naming
of the
Solomons

south for 400 miles in an irregular Y shape and have a total area of 4,707 square miles (12,190 square kilometres); they include Vanua Lava and Gaua (Santa Maria) in the Banks and Torres groups; and Espiritu Santo, Aoba, Maéwo, Pentecôte (Pentecost), Malakula, Ambrym, Épi, Éfaté, Erromango, Tanna, and Anatom. Formerly the jointly administered Anglo-French condominium of the New Hebrides, Vanuatu achieved independence in 1980. The capital, largest city, and commercial centre of the republic is Vila, on Éfaté Island.

PHYSICAL AND HUMAN GEOGRAPHY

The land. A diverse relief—ranging from rugged mountains and high plateaus to rolling hills and low plateaus, with coastal terraces and offshore coral reefs—characterizes the islands. Sedimentary and coral limestones and volcanic rock predominate; frequent earthquakes indicate structural instability. Active volcanoes are found on several islands, including Mount Séré'ama on Vanua Lava, Mount Gareit on Gaua, Mount Benbow and Mount Marum on Ambrym, and Mount Yasur on Tanna. There are also several submarine volcanoes in the group, and some islands have solfataras or fumaroles. The highest point is Mount Tabwémasana, 6,165 feet (1,879 metres), on Espiritu Santo, the largest island. The climate divides into two seasons—hot and wet from November to April and cooler and drier from May to October. The southeast trades are the prevailing winds, although northerlies during the hot season provide most of the heavy rainfall. Rainfall varies from 80 inches (2,000 millimetres) in the south to 160 inches in the northern islands. Much of the group is covered by dense rain forest, but drier regions have patches of savanna grassland. Abundant bird and insect life contrasts with the sparse fauna. Of the 11 types of bats found in Vanuatu, three are found only there.

The people. The indigenous population, called ni-Vanuatu, is overwhelmingly Melanesian, though some of the outlying islands have Polynesian populations. More than 100 local Melanesian languages and dialects are spoken; Bislama, an English-based pidgin, is the national language and, along with English and French, is one of three official languages. Religions include Christianity, traditional ancestor worship, and cargo cults.

The economy. Subsistence agriculture has traditionally been the economic base of Vanuatu, together with an elaborate exchange network within and between islands. Economic changes occurred with the development of European plantations in the island group after 1867: cotton was the initial crop, followed by corn (maize), coffee, cocoa beans, and coconuts (for copra). Cattle ranching was instituted later. By the 1880s French planters had reversed the initial British domination of the plantation sector, though they, too, found it increasingly difficult to compete with ni-Vanuatu producers, who could fall back on subsistence agriculture in times of economic downturn. French hopes of economic hegemony, based on high world prices for copra and the importation of Vietnamese labour in the 1920s, were dashed by the worldwide depression of the 1930s. By 1948 most of the copra in the island group was being produced by the ni-Vanuatu themselves, though it was not until the development of cooperatives in the 1970s that they were finally able to assume control of the trade.

Copra, cocoa, fish, and beef remain the most important exports. Imports, of food and manufactured goods, come principally from Australia. Though Vanuatu looks toward large-scale agricultural development for its long-term economic growth, since independence tourism has emerged as the largest earner of foreign income.

On most of Vanuatu's islands, roads link coastal settlements; there are few interior roads. Interisland transportation is by boat or airplane. Bauerfield airport, near Vila, and Pêkoa airport, near Luganville on Espiritu Santo, are international airports, and many smaller airfields are scattered throughout the islands.

Administration and social conditions. The constitution of 1980 provides for a president, elected to a five-year term by an electoral college comprising the parliament and the presidents of the Regional Councils. Members of the parliament are elected to four-year terms on the

basis of universal franchise. The parliament elects the prime minister from among its members, and the prime minister then appoints the Council of Ministers from among members of the parliament. The constitution also provides for a National Council of Chiefs, composed of "custom chiefs," which is concerned with matters relating to custom and tradition. Island government councils have taken the place of the Regional Councils proposed in the constitution. The Supreme Court hears and determines civil and criminal proceedings.

Although attempts have been made since independence to institute a single, and English-speaking, education system, much French economic aid has been channeled into the maintenance of the Francophone school system, and thus French aid has ensured that the 25 percent of ni-Vanuatu children who are French-speaking attend French-language schools. Only a small proportion of ni-Vanuatu children undertake post-primary education, but with more than 300 primary schools, the nation's elementary school attendance is one of the highest in the Pacific.

Health care in Vanuatu consists of two hospitals in Vila supplemented by smaller hospitals, clinics, and dispensaries on the other islands. Malaria, tuberculosis, hookworm, and gastroenteritis are the most common diseases.

Cultural life. The overwhelming majority of ni-Vanuatu are subsistence agriculturalists, living in small rural villages where activities revolve around the land. The constitution has guaranteed that land cannot be alienated from its "indigenous custom owners," or traditional owners, and their descendants. More than an economic resource, land is the physical embodiment of the metaphysical link with the past, and identification with a particular tract of land (expressed by the Bislama phrase *man ples*) remains one of the fundamental concepts governing ni-Vanuatu culture. On many islands the men of a clan still gather nightly at their local *nakamal* to drink kava and communicate with the spirits of their ancestors, whose bones typically are buried nearby. Through magic stones they will contact and try to control the all-pervasive spiritual realm. Among the vast majority of rural dwellers *kastom* (custom), along with Christianity, continues to guide daily life.

For statistical data on the land and people of Vanuatu, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

Archaeological evidence indicates that by 1300 BC islands in northern Vanuatu were settled by the makers of the distinctive Lapita pottery from Melanesian islands to the west. Since then, there have been successive waves of migrants, including people of Polynesian origin on the southern islands of Futuna and Aniwa. Around AD 1200, a highly stratified society developed in central Vanuatu with the arrival (from the south, according to tradition) of the great chief Roy Mata (or Roymata). His death was marked by an elaborate ritual that included the burying alive of one man and one woman from each of the clans under his influence. European contact began with the Portuguese explorer Pedro Fernández de Quirós (1606), followed by the French navigator Louis-Antoine de Bougainville (1768) and the British captain James Cook (1774). Cook mapped the group and named it the New Hebrides. European missionaries and sandalwood traders settled on the fringes of islands from the 1840s, but their impact on the indigenous people was minimal. Significant cultural change occurred only after the 1860s, as thousands of ni-Vanuatu men and women who had been indentured to work on plantations in Fiji and New Caledonia, and in Queensland, Australia, began to return to their homes. Many established new forms of political influence within the network of Protestant (mainly Presbyterian) missions or successfully competed against European traders and planters in the group. To protect the interests of the mainly British missionaries and mainly French planters, the British and French governments established rudimentary political control with a Joint Naval Commission in 1887. This was succeeded in 1906 by an Anglo-French condominium, under which resident commissioners in the capital, Vila, retained responsibility over their own nationals and jointly ruled the

The education system

The return of indentured workers

Volcanoes

indigenous people. This clumsy administrative arrangement had only a slight impact, however, on most of Vanuatu, whose chief European contact continued to be with either missionary or planter. The islands became a major Allied base during World War II, when the spectacle of free-spending black American troops inspired the development of the John Frum cargo cult on Tanna into an important anti-European political movement. After the war, local political initiatives originated in concern over land ownership, more than one-third of the New Hebrides then being owned by foreigners.

Independence was agreed upon at a 1977 conference

in Paris attended by British, French, and New Hebrides representatives. Elections were held and a constitution was drawn up in 1979. Despite an unsuccessful attempt in mid-1980 by Jimmy Stevens, the Na-Griamel Party leader, to establish Espiritu Santo Island as independent from the rest of the group, the New Hebrides became independent within the Commonwealth under the name of the Republic of Vanuatu ("Our Land Forever") on July 30, 1980. (R.Ad.)

For later developments in the history of Vanuatu, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

MAJOR POLITICAL UNITS OF MICRONESIA

Guam

Guam, the largest, most populous, and southernmost island of the Mariana Islands and an unincorporated territory of the United States, lies in the Pacific Ocean about 5,800 miles (9,300 kilometres) west of San Francisco and 1,600 miles east of Manila. The total land area is 209 square miles (541 square kilometres). Agaña is the capital. The most populous settlements are Tamuning, Apra Harbor, and Mangilao.

PHYSICAL AND HUMAN GEOGRAPHY

The land. The island is sharply divided into a northern limestone plateau with a general elevation of about 500 feet (150 metres) and an area of higher, volcanic hills to the south. The plateau is covered with a thick growth of jungle; the volcanic hills support mainly sword grass. The hills rise more than 1,000 feet above sea level, and their lower slopes to the east (and also in part to the west) are covered with younger limestones, generally similar to those of the northern limestone plateau. The higher hills are Mount Lamlam, which rises to an elevation of 1,332 feet (406 metres); Mount Bolanos (1,220 feet); and Mount Sasalaguan (1,109 feet).

Guam has a pleasant tropical climate. Temperatures range from 70° to 90° F (21° to 32° C) and are fairly even throughout the year. Average annual rainfall is about 95 inches (2,400 millimetres), three-fourths of which falls during the wet season, generally starting in May or June and lasting through November. The even climate is punctuated by destructive typhoons that occur at irregular intervals.

The people. The native Guamanians, ethnically called Chamorros, are basically of Malayo-Indonesian descent with a considerable admixture of Spanish, Filipino, Mexican, and other European and Asian influences. Their vernacular, called the Chamorro language, is a distinct language with its own vocabulary and grammar mixed with many Spanish words. The word Chamorro is derived from Chamorri, or Chanioli, the ancient name for chief. English and Chamorro are the official languages; although Chamorro is still used in many homes, English is the language of education and commerce. The predominant religion is Roman Catholicism.

Before World War II the villages were the main social and economic units, preserving customs and traditions similar to those of 19th-century Spain. The fiesta held in memory of a patron saint was the great social and religious event of the year for each village, and it brought together people from other villages. Fiesta customs are still observed in modern Guam. Changes in the social life and institutions of Guamanians, however, have come about with economic improvement and increasingly international contacts.

The economy. The development of Guam into an important U.S. military base brought about profound changes in the island's agricultural patterns after World War II. Foodstuffs were imported in increasing amounts, discouraging the cultivation of many formerly important truck crops. Guam now imports most of its food.

All branches of the U.S. armed forces are represented at military facilities on Guam. Andersen Air Force Base, at the northern end of Guam, is a part of the U.S. Strategic Air Command; the armed forces also operate a naval sta-

tion with a ship repair yard, a naval air station, a communications station, and a hospital. The availability of work at the military facilities has drawn many islanders from their former lives of subsistence agriculture and fishing.

Tourism is the most prominent component of the economy after the military, with more than half a million tourists visiting from Japan alone in 1987. There are several luxury hotels along Tumon Bay, which has been highly developed as a tourist area. A modern international airport links Guam with Japan, Hawaii, the U.S. West Coast, the Philippines, Australia, and other parts of Asia. Guam is a duty-free port, and this status has attracted a number of small manufacturing companies from countries in Asia and has also prompted some immigration. In the 1970s poultry farming, garment-finishing plants, and an oil refinery were established. Major imports are petroleum products, machinery, automobiles and transport vehicles, manufactures, and food.

Administration and social conditions. Guam is an unincorporated territory of the United States governed under the Organic Act of Guam, passed by the U.S. Congress and approved by the president on Aug. 1, 1950. The Organic Act made all Chamorros U.S. citizens, but they were not given the right to vote in national elections.

The act was amended in 1968 to provide for the popular election of a governor and lieutenant governor for four-year terms. All persons 18 years of age or older are permitted to vote. The legislature is a unicameral body with 21 senators directly elected at large for a term of two years. Guam has no constitution. The people of Guam, in seeking to improve their political relationship with the United States, voted in 1982 in favour of pursuing a commonwealth relationship similar to that established in the Northern Marianas. A draft Commonwealth Act was approved by the people in 1987, and negotiations with the U.S. Congress were initiated.

The judiciary consists of the Federal District Court of Guam, whose judge is appointed by the U.S. president for a term of eight years. There are two levels of local trial courts: the Superior Court of Guam, for criminal and civil cases, and the traffic, juvenile, and small-claims courts. Judges are appointed by the governor with consent of the legislature and are reconfirmed by majority public vote every four years. Appeals may be made to the U.S. Court of Appeals for the Ninth Circuit and to the U.S. Supreme Court.

Each of the island's villages is headed by a popularly elected commissioner. A chief commissioner, elected by the commissioners, acts as liaison between the governor and the districts.

Education is compulsory between the ages of six and 16. The University of Guam, opened in 1952, is a four-year institution with colleges of agriculture, business and public administration, arts and sciences, and education. Graduate programs at the master's level are also available. Health facilities include public, private, and military hospitals and local clinics.

Cultural life. Guam is culturally diverse, with Chinese, Japanese, Filipino, Korean, and other Asian communities of significant size in addition to its indigenous and mainland U.S. populations. As a centre of transportation and communication for the island region it also has sizable

Fiesta
tradition

Village
commis-
sioners

numbers of islanders from various parts of Micronesia, such as Palau, Yap, Truk, Pohnpei, Kosrae, and the Marshall Islands. The extended family is the main social unit for most groups on Guam, although many of the younger members travel and live in the United States. Folk arts and handicrafts of Guam have enjoyed a revival in recent years with the advent of various public and private groups that have promoted music, dance, and other traditional cultural arts for the benefit of both the local community and tourists.

U.S. national holidays are celebrated on the island, as are several significant local dates such as Discovery Day, March 6, which commemorates the arrival of Ferdinand Magellan in 1521. The museum and library on Guam have active programs for the community, and the university is also a promoter of regional arts and culture. There are daily and semiweekly newspapers and quarterly and monthly magazines published on Guam, and several radio and television stations broadcast local and international news and features daily.

For statistical data on the land and people of Guam, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

Guam, like the other Mariana Islands, was settled before the second quarter of the 2nd millennium BC by an Indonesian-Filipino people. Archaeological research shows that by AD 800 they had developed a complex society that erected elaborate stone pillars (*halege*), which served as supports for communal houses (*latte*).

Ferdinand Magellan probably landed on Guam in 1521. The island was officially claimed by Spain in 1565, and there was no attempt to conquer it until the latter part of the 17th century. After an uprising in 1670 and 25 years of intermittent warfare, the Spanish subdued the population with considerable bloodshed. Disease, particularly smallpox and influenza, also played an important role in the decimation of the population. Typhoons in 1671 and 1693 caused further destruction and loss of life. Guam remained a Spanish possession until 1898, when, in the course of the Spanish-American War, the U.S. warship *Charleston* steamed into the harbour of Apra and shelled the old fort. Guam was ceded to the United States, and the other islands of the Marianas were sold by Spain to Germany in 1899. From that time until 1950 (except for the period of its occupation by the Japanese during World War II) the governor of the island was a naval officer appointed by the president of the United States.

During World War I Japan occupied Germany's island possessions north of the Equator, and after the war Japan received the Marianas (except Guam) and the Caroline and Marshall groups as a mandate under the League of Nations. Japan retained possession of the islands even after it withdrew from the League in 1933.

In World War II the Japanese landed on Guam just after the attack on Pearl Harbor and occupied the island by Dec. 12, 1941. U.S. forces retook Guam by Aug. 10, 1944. It was a major air and naval base for the squadrons of bombers that attacked Japan near the end of the war. Under the jurisdiction of the U.S. Navy, it was made a territory (1950) that was administered by the U.S. Department of the Interior (from 1973, by the Office of Territorial Affairs, within that department). Guam remains the site of major U.S. naval and air bases; about one-third of the land in Guam is owned by the U.S. armed forces.

In the 1970s Guam gradually began to move toward representative self-government. The first popularly elected governor ran for office in 1970, and in 1972 Guam was given the right to send one nonvoting delegate (entitled to vote in committees, however) to the U.S. House of Representatives. In 1978 the U.S. Senate accorded Guam the right to adopt a territorial constitution. In 1982, in a referendum offering six options, the option of commonwealth status won a plurality (48 percent) of votes.

(D.A.B.)

For later developments in the history of Guam, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

Kiribati

Kiribati is a republic of low-lying coral islands in the central Pacific Ocean. Of its 33 islands, only 20 are inhabited. The population is concentrated in the 16 Gilbert Islands, which straddle the Equator. From the Gilbert Islands, Kiribati extends 250 miles (400 kilometres) to the west to Banaba (formerly Ocean Island) and 1,800 miles to the east, to the Line Islands, three of which are inhabited. In between lie the islands of the Phoenix group, which have no permanent population. The capital is at Bairiki on Tarawa atoll in the northern Gilberts. Kiribati and Tuvalu were formerly joined as the Gilbert and Ellice Islands Colony.

PHYSICAL AND HUMAN GEOGRAPHY

The land. A few of the islands are compact with fringing reefs, but most are atolls. The largest atoll (and one of the largest in the world) is Kiritimati (Christmas Island) in the Line group, which has a land area of 150 square miles (388 square kilometres) and accounts for about one-half of the country's total. Kiritimati was used for U.S. and British nuclear testing in the 1960s; it now has a large coconut plantation and fish farms. Banaba rises to 265 feet; its rich layer of phosphate was exhausted by mining from 1900 to 1979. It is sparsely inhabited. Average rainfall in the Gilbert group ranges from 120 inches (3,000 millimetres) in the north to 20 inches in the south. Most rain falls in the season of westerly winds, from November through March; from April to October, northeast trade winds prevail. Temperatures are usually in the range of 75° to 85° F (24° to 30° C).

Coconut palms dominate the landscape on each island. With the products of the reef and the ocean, coconuts are the major contributors to village diet—not only the nuts themselves but also sap tapped from the fruit-bearing spathes. The resulting “toddy” is used in cooking and as a sweet beverage; fermented, it becomes a powerful intoxicant. Breadfruit and pandanus also are grown. *Cyrtosperma chamissonis*, a coarse tarolike plant, can be cultivated in pits, but plants such as taro, bananas, and sweet potatoes are scarce. Pigs and chickens are raised.

The people. The people are Micronesian and speak a single language, which has 13 sounds; “ti” is pronounced as “s” or “see”; thus Kiribati, pronounced “Kiri-bas,” is the local rendition of “Gilberts.” English is widely spoken, especially on Tarawa. Half of the population is Roman Catholic, and most of the rest is Congregational Protestant.

For many years the population of most islands has remained static because of migration to the rapidly growing urban centres of South Tarawa, where one-third of the population now lives. Betio, the port and commercial centre, has a population density of 13,000 per square mile (5,000 per square kilometre), most living in single-story accommodations. The rural population lives in villages dominated by Western-style churches and large open-sided thatched meetinghouses. Houses of Western-style construction are seen on outer islands and are common on Tarawa.

The economy. Until 1979, when Banaba's phosphate deposit was exhausted, Kiribati's economy depended heavily on the export of phosphate. Before the cessation of mining a large reserve fund was accumulated; the interest now contributes to government revenue. Other revenue earners are copra, mostly produced in the village economy, and license fees from foreign fishing fleets. An Exclusive Economic Zone of 1,350,000 square miles is claimed. Kiribati depends on foreign aid for most capital and development expenditure. Food accounts for one-third of all imports. The main shipping links are with Australia and Fiji. While South Tarawa has an extensive wage economy, most of the people living on outer islands are subsistence farmers with small incomes from copra, fishing, or handicrafts. These are supplemented by remittances from relatives working elsewhere. Interisland shipping is provided by the government, and most islands are linked by a domestic air service. Tarawa and Kiritimati have major airports.

Administration and social conditions. Kiribati is a member of the Commonwealth. It has a president chosen by national election from among four candidates chosen by

The importance of coconuts

and from members of the legislature (who are also popularly elected, for a four-year term). The president chooses his ministers from the legislature, and they remain responsible to it. One seat is reserved for the people of Banaba, who have been resettled in Fiji. Local government is through elected island councils.

Primary education is compulsory, and selected pupils attend government- or church-run secondary schools. Kiribati conducts its own technical and teacher training, but other higher education is by overseas scholarship. Tarawa has two hospitals, and there are clinics on all of the inhabited islands.

Cultural life. Kiribati society remains conservative and resistant to change; ties to family and traditional land remain strong, and conspicuous displays of individual achievement or wealth are discouraged. The building and racing of sailing canoes is a popular pastime. Musical composition and dancing in customary styles are regarded as art forms and are the basis of widespread competition. Volleyball and soccer are now widely played.

For statistical data on the land and people of Kiribati, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

The first settlers in the Gilbert Islands and Banaba came from Southeast Asia, by way of Micronesia, some 4,000–5,000 years ago. About the 14th century AD the southern islands received an influx of Samoans, and soon thereafter the islanders adopted a gerontocratic style of government (based on rule by elders). The Line and Phoenix islands had no prehistoric population.

Spanish explorers sighted some of the islands in the 16th century, but most did not appear on charts until the early 19th century, when first whalers and then coconut-oil traders reached the islands. From the mid-19th century, labour was recruited in the Gilberts for plantations elsewhere in the region.

The Gilbert Islands became a British protectorate in 1892, and Banaba was annexed in 1900 after the discovery of its rich phosphate deposits. Both were linked with the Ellice Islands as the Gilbert and Ellice Islands Colony from 1916; the colony subsequently was extended to include most of the Phoenix and Line groups and, for a time, Tokelau. Administration was through island governments, which sometimes became enmeshed in sectarian rivalries between Roman Catholics and Protestants. As a response to drought and perceived overpopulation in the 1930s, a resettlement scheme was initiated for the Phoenix Islands; a later scheme saw other Gilbertese resettled in the Solomons.

During World War II the Gilberts were occupied by the Japanese and later liberated by American forces. The colony had few services until aid-funded development programs were introduced after the war. An elected House of Representatives was established in 1967. The subsequent emergence of racial tensions led to the division of the colony in 1975–76. In 1976 the British High Court rejected Banaban claims for massive compensation over mining issues. The Gilbert Islands achieved independence as Kiribati in 1979.

After independence a high priority was given to economic development, especially the exploitation of marine resources. Kiribati belongs to the South Pacific Forum and the Commonwealth. (B.K.M.)

For later developments in the history of Kiribati, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

Marshall Islands

The Republic of the Marshall Islands, a self-governing republic, consists of some of the easternmost islands of Micronesia. The Marshalls are composed of two parallel chains of coral atolls, the Ratak, or Sunrise, to the east and the Ralik, or Sunset, to the west. The chains lie about 125 miles (200 kilometres) apart and extend some 800 miles northwest to southeast. The islands and islets number more than 1,200 and have a total land area of 70

square miles (181 square kilometres). Majuro Atoll is the capital of the republic.

The Marshalls were administered by the United States as part of the U.S. Trust Territory of the Pacific Islands from 1947 to 1986, when the Trust Territory was dissolved by the U.S. government.

PHYSICAL AND HUMAN GEOGRAPHY

The land. None of the 29 low-lying coral atolls and the five coral islands in the Marshall group rises to more than 20 feet (six metres) above high tide. The islands are coral caps set on the rims of submerged volcanoes rising from the ocean floor. The island units of the Marshalls are scattered over about 180,000 square miles of the Pacific. The largest atoll in the group and in the world is Kwajalein, which has a land area of only six square miles but surrounds a 655-square-mile lagoon. The Marshall Islands' nearest neighbours are Wake Island (north), Kiribati and Nauru (south), and the Federated States of Micronesia (west).

The climate is tropical, with a mean annual temperature for the entire group of 82° F (28° C). Annual rainfall varies from 20 to 30 inches (500 to 800 millimetres) in the north to 160 inches in the southern atolls. The wettest months are October and November. Several of the northern atolls are uninhabited due to insufficient rainfall. Most of the Marshall Islands are true atolls, consisting of an irregular, oval-shaped coral reef surrounding a lagoon; the islets lie along the coral reef. The islands and islets of the Ratak chain tend to be more heavily wooded than those of the Ralik. Coconut and pandanus palms and breadfruit trees are the principal vegetation. Soils are generally sandy and low in fertility.

The people. The native people of the Marshalls are Micronesians. The most populous atolls are Majuro and Kwajalein, which offers employment at the U.S. missile testing range; together they have more than two-thirds of the country's total population. The remaining one-third of the population lives in traditional villages on the outer islands away from the two urban centres. The American missionary effort began in the Marshalls in the 1850s and was very successful. The Marshallese today are predominantly Christian. The Marshallese and English languages are spoken, but only a minority are fluent in the latter.

The economy. Substantial U.S. subsidies to the Republic of the Marshall Islands under the Compact of Free Association (see below) and the leasing of land for the U.S. missile testing range on Kwajalein are the main sources of revenue for the nation. Employment and modern amenities at both Majuro and Kwajalein serve as magnets that draw people to the two urban centres.

On the outer islands, subsistence farming, fishing, and the raising of pigs and poultry are the principal economic activities. Coconut, pandanus, breadfruit, and taro are the major food crops. The production of copra is the main source of income for the outer islands. The chief import is processed foods. Other major imports include machinery and transport equipment, manufactured goods, and fuels, mainly from the United States, Japan, and Australia.

Transportation among the atolls and islands is by boat or air. Government-owned ships make scheduled trips among the islands. Several commercial cargo lines also serve the islands. Majuro has a commercial dock complex, and many of the atolls have good anchorage within their lagoons. Majuro and Kwajalein have international airports, and domestic and regional flights link some of the other atolls and islands.

Administration and social conditions. Under the constitution adopted in 1979, the government consists of a president elected by a unicameral, 33-member parliament known as the Nitijela. The Council of Iroji (Chiefs) has mainly a consultative function, concerned with traditional laws and customs.

A hospital on Majuro, a small sub-hospital on Ebeye (part of Kwajalein Atoll), and dispensaries on other islands provide health care. There are primary schools, both public and church-run, on the inhabited islands and islets. Majuro and Jaluit atolls each have a public secondary school. Majuro is also the site of a centre for continuing

Scattered island group

Rule by elders

Education

education operated by the Federated States of Micronesia's College of Micronesia.

HISTORY

The Marshall Islands were settled initially around the beginning of the Christian Era by Micronesians who may have been influenced by early Polynesian (Lapita) culture. Radiocarbon dates from earth-oven charcoal samples that were excavated in Laura village on Majuro yielded dates of about 30 BC and AD 50. The early Marshall Islanders were skilled navigators and made long canoe voyages among the atolls.

Sighted in 1529 by the Spanish navigator Álvaro Saavedra, the Marshalls lacked the wealth to encourage exploitation or mapping. The British captain Samuel Wallis chanced upon Rongerik and Rongelap atolls while sailing from Tahiti to Tinian. The British naval captains John Marshall and Thomas Gilbert partially explored the Marshalls in 1788, but much of the mapping was done by Russian expeditions under Adam Johann Krusenstern (1803) and Otto von Kotzebue (1815 and 1823). U.S. whalers frequented the islands from the 1820s, and U.S. and Hawaiian Protestant missionaries began efforts to convert the islanders in the 1850s. Germany established a coaling station on Jaluit Atoll by treaty with island chiefs and in 1886, by agreement with Great Britain, established a protectorate over the Marshalls. Japan seized the islands in 1914 and later (after 1919) administered them as a League of Nations mandate. Occupied by the United States in World War II, following heavy fighting at Kwajalein and Eniwetok, the Marshall Islands were made part of the United Nations Trust Territory of the Pacific Islands under jurisdiction of the United States in 1947. After their populations were removed to other atolls, Bikini and Eniwetok served as an official testing ground for U.S. nuclear bombs (1946–58). The tests stopped in 1958 and cleanup efforts began in the late 1960s. During the trial resettlement of the Bikinians, however, their atoll was found to be too contaminated for permanent habitation, and by the late 1970s the people had to be evacuated once again. The Eniwetok people were returned to their homeland, and a program to monitor Bikini was put in place.

After voting to separate from the other entities of the Trust Territory of the Pacific Islands, in 1978, the Marshall Islands drew up a constitution that was approved by the voters in 1979. It formed the republic and brought internal self-government. In 1982 the government signed the Compact of Free Association with the United States. This agreement was subsequently approved by the voters in 1983. The compact requires that the United States remain responsible for defense and external security and that it provide financial assistance for the republic. The compact entitles the United States to use the missile testing range on Kwajalein Atoll. The compact's articles provide for the republic to become fully independent and to alter its status with the United States at any time, subject to approval of the residents through plebiscites. In 1983 the islanders reopened negotiations on the compact's provision regarding compensation for the people of the four atolls affected by the U.S. nuclear tests. The United States agreed to set up a separate fund for the people of the four atolls and established an open-ended fund to cover personal injury claims among the islanders; it also agreed to set up a joint U.S.-Marshallese claims tribunal. A further agreement set up a fund to improve living conditions on Ebeye atoll, where all Micronesians working on the Kwajalein missile range and base resided. The Trust Territory was dissolved in 1986 by the U.S. government with the approval of the UN Trusteeship Council. (R.C.Ki.)

Micronesia

The Federated States of Micronesia is an internally self-governing country in the western Pacific Ocean. It is composed of more than 600 islands and islets in the Caroline Islands archipelago and is divided, roughly along cultural and linguistic lines, into the states of Yap, Truk, Pohnpei, and Kosrae. The total land area is about 270 square miles (435 square kilometres). The capital is Kolonia,

on the island of Pohnpei. To the west of the Federated States of Micronesia lies the Republic of Palau, also in the Caroline archipelago, and to the east is the Republic of the Marshall Islands. These two nations, together with the Commonwealth of the Northern Marianas and the Federated States of Micronesia, were administered by the United States as the Trust Territory of the Pacific Islands from 1947 to 1986.

PHYSICAL AND HUMAN GEOGRAPHY

The land. The islands are of two general types: high volcanic islands that support a large variety of plant forms and low-lying coral atolls with poorer soil. The main landmass in Yap is distinctive in that it was formed by folds in the Earth's crust and is continental in geologic composition. Each of the four states has as its population centre an elevated landmass of fairly large extent. These range in size from Pohnpei, with an area of 129 square miles, to Yap and Truk, each with 39 square miles. The volcanic islands of Truk are an anomaly in the Pacific since they are encircled by a reef but have not yet subsided beneath sea level to become a classic atoll. Yap Island and six islands in the Truk group rise to more than 500 feet (150 metres), and Kosrae and Pohnpei islands have peaks of 2,061 feet and 2,593 feet, respectively. The coral atolls consist of groups of small islands, formed atop a coral reef enclosing a lagoon.

The climate is tropical, with high humidity and a mean annual temperature of 81° F (27° C). There is little seasonal variation in temperature. Rainfall averages 120 inches (3,000 millimetres) per year throughout the area, although Pohnpei receives more than 200 inches yearly. There are distinct rainy and dry seasons, the latter occurring during the height of the northeasterly trade-wind season between December and April. Yap, which alone is situated in the monsoon area, has westerly winds for part of the year. Numerous typhoons originate in the east each year, usually spinning off to the northwest toward Yap and the Mariana Islands and seldom striking any of the other islands.

On the high islands, mangrove swamps grow along the shore, and grassland or scrub ascends to tropical rain forests in the interior mountain areas. Settlements are almost without exception located near the coast. Volcanic islands, with their richer soil, support many different species of plant life. On coral atolls the predominant forms of vegetation are the coconut palm and pandanus and breadfruit trees. Atoll dwellers typically locate their houses on the lagoon side of the island.

The people. The native people of the Federated States, while generally classified as Micronesian, are very diverse in physical types, cultures, and languages. The people of Yap Island have Melanesian-like features and speak a language only distantly related to the other languages of the area. Inhabitants of the coral atolls in Yap state are similar in language and culture to the people of Truk, although their languages are not mutually intelligible. Both Truk and Pohnpei contain several dialects, and the inhabitants of Kapingamarangi and Nukuoro, two atolls in the southwestern portion of Pohnpei state, are Polynesians and speak languages unrelated to Pohnpeian. Only Kosrae has complete ethnic and linguistic unity. Altogether eight local languages are recognized as distinct, and dialectal differences in the outlying atolls add further variety.

Almost half of the total population lives in Truk. Pohnpei has about 30 percent, and Yap and Kosrae have about 10 percent and 7 percent, respectively. In recent years there has been some migration to the towns for employment and education, and the four main towns—the capitals of each state—now contain about one-quarter of the total population. The birth rate remains high, and mortality rates have been sharply reduced. The population is growing by about 3 percent yearly. Almost the entire population is Christian. English is spoken widely in commerce and government throughout the nation.

The economy. Subsistence farming and fishing are the principal economic activities. The main staples are breadfruit, taro, coconuts, and bananas, but yams, cassava, and sweet potatoes also are grown on some of the high islands.

Compact
of Free
Association

Coastal
settlements

Poultry, pigs, and dogs are sometimes also raised for food. The main source of revenue is U.S. government grant aid, which continues under the Compact of Free Association signed in 1982 and which accounts for an estimated 70 percent of the gross national product. Government employment is by far the major source of income, and this in turn supports the service industries that make up the private sector. Exports, which account for less than 5 percent of the gross national product, include copra, a few marine products, black pepper, and handicrafts. Additional income is derived from the sale of fishing rights and from a slowly expanding tourist industry. Local commercial fishing is developed only on a small scale, and large-scale agriculture has repeatedly proved a failure. Much of the Federated States' food, including rice, fruits, vegetables, meat, and fish, and almost all manufactured goods and fuel oil must be imported.

Interisland and international transportation are by air or ocean freighter. The major commercial ports are at Takatiki near Pohnpei, Kosrae, Colonia on Yap, and Moen. International airports are located on Yap, Pohnpei, and Moen. Smaller ships operated by the government provide service to the outlying atolls in each state. Some of the atolls are also linked by weekly flights on smaller planes. On major islands all villages are connected by a road system, and main roads in the commercial centres are paved.

Administration and social conditions. Under the 1979 constitution, the government of the Federated States of Micronesia consists of a president and vice president elected by the unicameral National Congress, made up of one at-large senator from each state, with four-year terms, and single-district senators (elected on the basis of population), with two-year terms, including one each from Yap and Kosrae, three from Pohnpei, and five from Truk. Each of the four local state governments has a popularly elected governor and a unicameral legislature. There are no political parties. The judicial system consists of the Supreme Court of the Federated States of Micronesia, state courts in each of the four states, and municipal courts in each political subdivision of each state. Recognized customary law is in force wherever it does not conflict with constitutional law.

There are elementary schools on every island, and each state has at least one public high school. The Community College of Micronesia, with its main campus on Pohnpei and extension programs in other states, is the only institution for higher education in the Federated States of Micronesia, but several U.S. universities offer extension programs for teacher training. A hospital is maintained in each of the state capitals, and dispensaries have been built on all major islands. Local healers continue to practice massage and other traditional medical skills.

Cultural life. Although only the people of Yap and a few of the outlying atolls in Truk still wear traditional dress (loincloths for men and grass skirts or lavalavas for women), most villagers live much as their ancestors did. They support themselves by subsistence farming and fishing, use traditional food-preparation techniques, and gather in community meetinghouses for ceremonies and leisure activities. Islanders from some of the remote atolls have maintained their skills in the construction and navigation of large single outrigger canoes. The seamanship of the islanders is probably their most remarkable achievement and has astonished Westerners since initial contact. Wood carving, which was originally practiced for religious purposes, has become a commercial enterprise. Women in some of the islands still weave lavalavas on traditional belt looms, and nearly everywhere large sleeping mats are plaited of pandanus leaves. Tattooing, once used widely to indicate social status, is seldom practiced today, but the traditional dances remain a favourite form of entertainment.

For statistical data on the land and people of Micronesia, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

The eastern Caroline Islands, like the Marshall and Gilbert islands, were probably first settled from the New Hebr-

ides-Fiji area in the millennium before the Christian Era. Archaeological and linguistic evidence suggests that the earliest migrants worked their way up the chain of islands to the east and gradually spread westward from the Marshalls. Pottery dating to the beginning of the Christian Era has been found in Truk, and artifacts of similar antiquity have been unearthed in other islands in the east. The languages of the area, with the exception of the two Polynesian outliers and Yap, are closely related to one another and show striking similarities to Vanuatuan tongues. The high island of Yap appears to have been settled from the west, probably from the Philippines or Indonesia. Pottery and shell adzes found there date from the 2nd century AD and show a resemblance to types discovered in the Marianas. Yap's caste system and other features of its social organization are unparalleled elsewhere in the area. The renowned Yapese stone money was quarried in nearby Palau and the Marianas. In later centuries a reciprocal tribute and trade system was evolved with the surrounding coral atolls, sometimes termed the Yap Empire or Yapese Empire. In the eastern islands of Pohnpei and Kosrae, some seven centuries ago, a major social upheaval occurred, possibly under the impact of invasion from the south. Fortified settlements were built of huge basaltic logs, their ruins still visible today, and political authority over each island was centralized even as the society became more stratified.

The islands were visited occasionally during the 16th century by Spanish navigators and were later named for the Spanish king Charles II. During the 19th century European naval ships followed whalers and traders to the islands, and the inhabitants experienced their first intensive contact with foreigners and their wares. In 1886 Spain finally colonized the Carolines, but its short rule was ended in 1899 when the islands were sold to Germany at the conclusion of the Spanish-American War. Germany, in turn, yielded the islands at the outbreak of World War I to Japan, which gained formal title to them in 1920 as a League of Nations mandate. At first Japan attempted to develop a solid economy; later it used the islands as an outlet for surplus population; and finally it fortified them just before World War II. In July 1947 the Carolines, together with the Marshalls and northern Marianas, became a United Nations trust territory under U.S. administration. They were designated as a strategic area to allow the United States to set up military bases as deemed necessary; consequently, ultimate responsibility for the Trust Territory of the Pacific Islands rested in the UN Security Council rather than in the UN General Assembly, as was the case with other trust territories.

Micronesian leaders began negotiations with the United States for full self-government in 1969. The constitution that was drafted in 1975 became the basis for the federated government that went into effect in 1979. By that time, however, the Marianas, the Marshalls, and Palau had voted to separate from the proposed federation; this left only the "inner states" of Yap, Truk, Kosrae, and Pohnpei to compose the new political entity. In a 1983 plebiscite, voters approved a Compact of Free Association with the United States. The compact provides for internal self-government for the Federated States of Micronesia, while requiring that the United States remain responsible for defense and external security and that it provide financial assistance. The articles of the compact provide for the Federated States of Micronesia to become fully independent and alter its status with the United States at any time, providing this change of status is approved in plebiscites. The compact has a 15-year duration but is renewable by mutual consent. (F.X.H.)

For later developments in the history of Micronesia, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

Nauru

Nauru is an independent nation consisting of a solitary raised coral island located in southeastern Micronesia, 25 miles (41 kilometres) south of the Equator. It is about 2,480 miles northeast of Sydney, Australia, and a slightly

Yap's atypical social organization

Absence of political parties

greater distance southwest of Honolulu. Nauru has a total land area of about 8 square miles (21 square kilometres) and a circumference of 12 miles. The capital is Yaren administrative centre.

PHYSICAL AND HUMAN GEOGRAPHY

The land. Most of Nauru rises somewhat abruptly from the ocean, and there are no harbours or protected anchorages. A fairly fertile but relatively narrow belt encircles the island and surrounds the shallow inland Buada Lagoon. Farther inland, coral cliffs rise to a plateau 100 feet (30 metres) above sea level, with the highest point at about 213 feet. The plateau is largely composed of rock phosphate, leached from guano, or bird droppings. The mineral deposit covers 70 percent of the island, and its extraction has left irregular, pinnacle-shaped outcrops of limestone that give the landscape a forbidding, otherworldly appearance.

Other-worldly appearance of the landscape

© L. Zann/Australasian Nature Transparencies

Coral pinnacles harbouring phosphate, Nauru.

Nauru's climate is tropical, with daytime temperatures around 82° F (28° C), tempered by ocean breezes. Rainfall, averaging 81 inches (2,060 millimetres) annually, is extremely variable, and prolonged droughts occur. The only locally available water is collected from roof catchment systems, and water is imported as ballast on ships returning to Nauru for loads of phosphate. There are no rivers or streams.

Soils are generally poor and highly porous, and the irregular rainfall limits cultivation to the coastal belt and the lagoon's fringe. Subsistence crops, consisting mainly of coconut palms, pandanus, bananas, pineapple, and some vegetables, are not adequate to support the population. Varieties of plants and trees, however, number about 200. Nauru is a favourite stopover point for migratory birds, and chickens have been introduced. There was an absence of mammals until rats, mice, cats, dogs, and pigs were also imported.

The settlement pattern is dispersed. People are scattered along the coastal zone, and there is one small village, Buada, inland near the lagoon.

The people. Of the fewer than 10,000 residents of Nauru, about three-fifths are reported to be indigenous Nauruans. Other residents are employees of the government of Nauru or the Nauru Phosphate Corporation. A

number of Europeans serve as administrators and technicians for the phosphate industry and some government agencies. There are a number of Chinese shopkeepers.

Nauruan is the national language. No adequate written grammar of the language has been compiled, and its relationships to other Micronesian languages are not well understood. English is widely spoken.

Missionization came later to Nauru than to many other Pacific islands. The first Protestant evangelist arrived in 1899 and was followed three years later by the first Roman Catholic missionary. Today, the Nauru Congregational church claims about 60 percent of the population, with the remainder belonging to the Roman Catholic church.

The economy. The quality of Nauru's phosphate is the highest in the world. The mineral rock is Nauru's main resource and sole export, totally dominating the island's economy. The phosphate industry and government services together provide almost all of the island's salaried employment, with the exception of that along the coastal and lagoon perimeters, fishing, manufacturing, and tourism are of minor value to the overall economy.

Phosphate has been mined on Nauru since 1907. For most of the 20th century, the phosphate industry was owned and operated by a British corporation. The government of independent Nauru gained control in 1970, and the Nauru Phosphate Company, an agency of the government, now manages the industry. The phosphate rock is crushed on the island and is transported by truck and narrow-gauge railway to a cantilever system that loads the product on ships moored to buoys in the open ocean.

On a per capita basis, Nauru is one of the wealthiest countries in the world. Landowners receive royalties from the phosphate earnings, and, by choice, many Nauruans are unemployed. Australia and New Zealand are the main customers for Nauru's phosphate. Australia supplies more than 90 percent of Nauru's imports. Most food, water, and manufactured goods are imported. With the exception of those levied on alcohol and tobacco, there are no import duties, and there is no income tax. By any standard, consumption levels are high, and much of the island's manual labour is done by outsiders.

Because it is projected that Nauru's phosphate deposits will be exhausted by about the year 2000, a major portion of the earnings are invested abroad. The future economic well-being of Nauruans depends on the success of the investment program, which includes a shipping line, an international airline, and extensive real-estate holdings in more than a half-dozen countries.

Nauru has its own banking system; the Bank of Nauru is wholly owned and operated by the government. As one consequence of its colonial history, Nauru is within the Australian monetary system, and Australian currency is the nation's legal tender.

Transportation on the island is good. A paved road system links all villages, and, reflecting the nation's high level of income, there is an abundance of motor vehicles of most varieties. Surface transportation to other destinations is difficult. Because there are no wharves or natural harbours, passengers and cargo are shuttled by barge between oceangoing vessels and a small artificial anchorage. Most regional and international travel is by air. The country launched its national airline, Air Nauru, in 1970, and in the mid-1980s the international airport with modern terminal facilities was expanded. Air Nauru has a fleet of Boeing jets.

Administration and social conditions. Nauru's constitution, implemented with independence in 1968, calls for broadly phrased fundamental rights and freedoms for individuals and a government that combines parliamentary and presidential systems. The parliament has 18 members. Unless dissolved by a vote of no confidence, it has a tenure of three years and elects the president, who is both head of state and head of government. The president appoints a cabinet of four or five members from the parliament. Nauru is a special member of the British Commonwealth, having all benefits of membership except the right to attend meetings of the Commonwealth heads of government.

The tripartite judicial system comprises a Supreme Court,

Importance of phosphate mining

Tripartite
judicial
system

a District Court, and a Family Court. The Supreme Court, presided over by a chief justice, has both original and appellate jurisdiction. At Nauru's request, final appeals may be taken to the High Court of Australia.

Basic services in education and health are provided free to all citizens. Education is compulsory between the ages of 6 and 16. The government provides several kindergartens and elementary and secondary schools. The Roman Catholic mission has its own school system at the same three levels. Students go abroad, mainly to Australia, for higher education.

Nauru's wealth is a mixed blessing. The predominance of sedentary life-styles and high levels of consumption of food, alcohol, and tobacco have resulted in widespread personal health problems: The rates of obesity, high blood pressure, and diabetes are among the highest in the world, and, while vital statistics are not readily available, life expectancy for Nauruans is known to be lower than that for most other Pacific islanders.

HISTORY

When and from where the first inhabitants of Nauru reached the island remain unknown. A long period of relative isolation is believed to account for the distinctiveness of the indigenous language. By the time of the arrival of Europeans in the early 18th century, Nauruan society consisted of 12 matrilineal kinship groups, each having a chief.

An English sailing vessel sighted the island in 1798, but extensive contact with Europeans did not begin until the 1830s, when the whaling industry penetrated eastern Micronesia, and Nauru became a port of call for vessels in search of food and water supplies. Shortly thereafter, a small number of European beachcombers settled on the island, bringing with them alcohol, firearms, and foreign diseases. Intraisland warfare among competing districts escalated, becoming particularly intense in the 1880s. Encouraged by a few German traders concerned about their own interests on the island, Germany incorporated Nauru into its Marshall Islands protectorate in late 1888. The German administration and the arrival of the missionaries shortly thereafter brought an end to armed hostilities. In 1906 the Pacific Phosphate Company, a British concern, negotiated an agreement with the German administration to begin the mining of Nauru's phosphate deposits, and the operation began the following year.

With the onset of World War I, a small Australian force occupied Nauru and removed most German nationals. In 1920 Nauru became a mandated territory within the framework of the League of Nations. Australia, Britain, and New Zealand were named as the responsible authorities, but in actual practice the administration remained in Australian hands. The phosphate industry was taken over by the newly formed British Phosphate Commission, a joint Australian, British, and New Zealand enterprise.

World War II brought another occupier when Japanese forces arrived in August 1942. In the following year, 1,200 Nauruans were taken to Truk (now Chuuk) to serve as forced labourers on Japanese military installations there. A Japanese airstrip on Nauru became the target of American bombers, and the island suffered air attacks for the next two years. In September 1945, Australian troops again took possession of Nauru. On Jan. 31, 1946, with their numbers depleted by almost 500, 737 Nauruans were returned home.

In November 1947, Nauru became a United Nations trust, an arrangement paralleling the former League of Nations mandate. The same three metropolitan powers were the responsible authorities, but Australia continued to provide the actual administration.

A series of developments in the 1950s and particularly in the early 1960s led to self-government and eventually political independence and ownership of the phosphate industry. In October 1967 an agreement granting Nauruan independence was concluded. Jan. 31, 1968, the 22nd anniversary of the return of Nauruans from Truk, was chosen as Independence Day for the Republic of Nauru. Political parties are of lesser importance than personalities in Nauruan politics. One man, Hammer DeRoburt,

has dominated the political scene, serving as president for most of the period since independence. (R.C.Ki.)

For later developments in the history of Nauru, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

Northern Mariana Islands

The Northern Mariana Islands, a self-governing commonwealth in political union with the United States, is composed of 22 islands and islets in the western Pacific. It is a part of the Mariana Islands, a chain of volcanic mountain peaks and uplifted coral reefs extending from latitude 12° to 21° N and longitude 144° to 146° E. (The Marianas chain also includes the politically separate island of Guam.) The Northern Marianas has a land area of 184 square miles (477 square kilometres). Saipan (47 square miles), Tinian (39 square miles), and Rota (33 square miles) are the principal islands and, together with Alamagan and Agrihan, are inhabited. Another island, Pagan, was evacuated in 1981 after a severe volcanic eruption.

PHYSICAL AND HUMAN GEOGRAPHY

The land. Rota, the southernmost island, consists of a volcanic base capped with coral limestone, giving it a terraced appearance. Four southern islands (Farallon de Medinilla, Saipan, Tinian, and Aguijan) are composed of limestone and have gently rolling elevations and few mountains. The islands farther north are volcanic peaks. Mount Pagan erupted in 1922 and again in 1981, 1983, and 1988; Farallon de Pajaros (also called Urucas), the northernmost of the Marianas, and Asuncion are also active volcanoes. Agrihan volcano, the highest of the Northern Mariana group, rises to 3,165 feet (965 metres). Besides Guam, the nearest neighbours are the Bonin Islands (north) and the Federated States of Micronesia (southeast).

The climate is tropical, with average yearly temperatures on Saipan ranging between 79° F (26° C) and 82° F (28° C) and annual rainfall averaging about 70 inches (1,800 millimetres). Typhoons strike the islands periodically. Rainfall is significantly less on the northernmost islands. The four limestone islands have tropical or scrub forests at higher elevations and coconut palms and casuarina trees along the coast, with the exception of Farallon de Medinilla, which is barren. Where level or gently sloping areas occur, cattle are grazed. The steep slopes of the volcanic islands from Guguan northward are mostly barren. Their soils are generally shallow and low in fertility.

The people. The native people of the Northern Mariana Islands are Micronesians. Three-fifths of the population are Chamorros, descendants of the original inhabitants, who intermingled with Spaniards, Mexicans, Filipinos, and various other Europeans and Asians. About 14 percent of the population are Filipino. About 12 percent of the population are Carolinians, descendants of people who migrated from the central Carolines during the 19th century. There are small numbers of Europeans and Asians (other than Filipinos) as well.

Having lost most of their original Pacific Islands culture, the people of the Northern Mariana Islands have a mode of life that is Spanish Roman Catholic but is influenced by American culture. Saipan has more than 85 percent of the commonwealth's total population. Chamorro, related to Indonesian, is the principal language; English is the official language, and Japanese is widely used.

The economy. Tourism is the principal economic activity. Saipan and Rota are the main tourist centres and offer luxury hotels. The tourists are mainly Japanese and Americans. Subsistence farming, including the cultivation of taro, cassava, yams, breadfruit, vegetables, and bananas, is practiced extensively by many islanders to supplement their cash income. Copra production, fishing, pig and cattle raising, truck farming, and handicrafts have dwindled in recent years. Small manufacturing industries were introduced from Korea, China, and the Philippines, and such economic activity, with the continuing rise in tourism, has encouraged much immigration from Asia.

Saipan, Tinian, and Rota have paved roads. Transportation between the islands is largely by air, with some boat

Tropical
climate

United
Nations
Trust

traffic primarily for cargo. Saipan is the largest port, followed by Tinian and Rota. Saipan has an international airport.

Administration and social conditions. Part of the Trust Territory of the Pacific Islands granted to the United States by the United Nations in 1947, the Northern Marianas voted in plebiscite for status as a U.S. commonwealth in 1975. Some aspects of the commonwealth status were implemented in 1976, and the full commonwealth became effective upon the dissolution of the Trust Territory for the Marianas by the U.S. government in 1986. Eligible residents of the commonwealth became U.S. citizens at that time.

According to the constitution of 1978, residents elect a governor, a lieutenant governor, and a bicameral legislature made up of nine senators and 14 representatives. The administrative headquarters of the commonwealth are at Chalan Kanoa on Saipan.

All inhabited islands have primary schools and hospitals. There are public and church-run secondary schools on Saipan. The College of the Northern Marianas, a public junior college, was established in 1976.

Cultural life. In recent years there has been an increase in the cultural diversity of the Northern Marianas. There are growing Filipino, Chinese, and Korean communities, although none of these has political representation. The Carolinian community, which has lived at Saipan for more than 100 years, is represented in the legislature. The local Chamorro population, with its tradition of extended families, is dominant. A local arts council has promoted folk arts and cultural events in the community, and a small museum and library have been established. Public beach parks and preserves as well as two large golf courses provide recreation. American national holidays and several local holidays are celebrated. Two local weekly newspapers are supplemented by the Guam daily newspaper, which provides some local coverage; all are published in English. There are several radio and television stations.

HISTORY

Archaeological evidence at Chalan Piao on Saipan indicates that the Northern Marianas were settled by an insular people originating in Southeast Asia. They made a distinctive red-slipped ware, sometimes incised with lime-filled decoration, closely related to Philippine wares. By AD 800 a plain, unslipped ware was in use, and stone architecture had developed. Parallel rows of upright pillars topped with hemispheric capstones (*halege*) were erected. According to early Spanish accounts, the pillars were supports for structures called *latte* (after which term the culture is named), which may have served as men's houses or as canoe sheds. Each village had from one to several *latte* structures. Stone and shell tools were used and the betel nut was chewed, as shown by extended burials most often located between the rows of *latte*.

Ferdinand Magellan was the first to open the Marianas to the West when he stopped there briefly during his first circumnavigation in 1521. There is some historical question as to which island he actually visited, but Magellan named the islands the Ladrões (Spanish: "Thieves") because while he was there some of the islanders took a small skiff that he had trailing behind one of his ships.

In 1565 Miguel López de Legazpi landed at Umatac, Guam, and proclaimed Spanish sovereignty over the Ladrões; some priests went ashore to say the mass. No colonies were started at that time, however, because the Spanish were more interested in conquests in the Americas, the Philippines, and the Moluccas. The British adventurer Thomas Cavendish was the next to visit the Marianas, in 1588 aboard the *Desire*. He traded briefly, and as he left he ordered his men to open fire from the rear of the ship to discourage the islanders from following.

The effects of the early explorers and those who followed them to the islands were not unmixed. On the one hand the Europeans provided ironware and cloth, which was traded for fresh produce. On the other hand they introduced infectious diseases, including influenza, smallpox, leprosy, venereal diseases, and tuberculosis, which severely depleted the indigenous population.

The permanent colonization of the islands began with the arrival of Father Diego Luis de Sanvitores in 1668. With him were priests, laymen, women, and some Filipino soldiers. Mariana of Austria, the regent of Spain, financed his mission, and he renamed the islands the Marianas in her honour. Sanvitores and his colonists established churches and religious schools. A series of revolts attended these efforts, since the islanders resisted conversion to a religion that did not fit traditional beliefs. The Spanish during this time, in order to control the islanders more effectively, moved the population of the Marianas into enclaves and segregated the people into villages. Many islanders were killed in the process of relocation. Others died during their adjustment to new social environments, and the population was further decreased.

In 1680 the Spanish sent reinforcements led by Don José Quiroga, who was interim governor of the Marianas from 1680 to 1696. He subdued the islanders after a series of revolts, sieges, murders of missionaries, and burnings of churches that was known as the "Chamorro wars" and that resulted in many islanders fleeing to the hills. In reprisal, the entire native population was relocated from Saipan and Rota in the northern Marianas to the island of Guam. Finally, the Chamorro people took the oath of allegiance to the king of Spain, accepted Spanish customs, and began to wear Western-style clothes, cultivate corn, and learn to eat meat. Artisans were sent to the villages to teach sewing, spinning, weaving, tanning, iron forging, stone masonry, and other crafts. By 1698 the subjugation of the Marianas was complete.

The Spanish branched out from the Marianas into the rest of Micronesia, meeting only mild resistance. Guam became a regular stop for the Spanish galleons traveling between the Philippines and Mexico. By the 19th century the Marianas had become involved in European colonial rivalries. The Germans as well as the British began to encroach on the Spanish claims in Micronesia, and difficulties were averted in 1886 by the mediation of Pope Leo XIII, whose efforts in this regard prevented war between Germany and Spain. But Spain's empire was weakening, and by 1898 war with the United States was at hand. After American naval forces under the command of Commodore George Dewey defeated the Spanish fleet in the Philippines and took Guam, Spain made the decision in 1899 to withdraw entirely from the Pacific and sold its possessions—including all of the Marianas except Guam, which the Americans still held—to Germany.

The Germans promptly established an administrative centre at Saipan, which had served as the seat of the Spanish administration after the Americans captured Guam in 1898. This period marked the permanent division between Guam and the northern Marianas. Schools, a hospital, and other public buildings were erected in the northern Marianas, and colonists were encouraged to emigrate from Germany. Large coconut plantations were started, as were other agricultural projects. Copra production was the main German agricultural interest.

German control in the northern Marianas ended abruptly with the outbreak of World War I. In October 1914 the Japanese navy took possession of the northern Marianas and the rest of Micronesia. Japan's authority for this seizure was based upon several secret agreements with the British designed to keep the peace in Asia in the event of war. After World War I Japan received the northern Marianas by the terms of the Treaty of Versailles on June 28, 1919, and then later as a mandate under the League of Nations on Dec. 17, 1920. The United States, which continued to hold Guam, recognized this mandate on Feb. 11, 1922.

Japanese rule in the northern Marianas was direct and allowed the islanders little part in local government. The basic laws of Japan were extended to the islands with only such modifications as were needed to meet local conditions. Formal educational facilities were restricted, emphasis being placed upon learning the Japanese language. Public health conditions, however, were improved, and hospitals were established. Economic development was Japan's main interest, and large sugar plantations and refineries were started at Saipan and Rota. Large amounts

U.S.
citizenship

Effects
of early
explorers

German
adminis-
tration

of labour and capital were made available. There was full employment, and the islanders were made more productive than they had been before.

When World War II began the Japanese immediately took Guam from the United States and made their domination of the Marianas complete. The larger islands of Saipan, Tinian, Rota, Pagan, and Agrihan, along with Guam, became bases for Japanese expansion to the south and east. In 1943, U.S. forces began to reduce Japanese strength in Micronesia, and in June–July 1944 the Marianas were neutralized with the recapture of Saipan, Tinian, and Guam. The three islands then became Allied bases for the bombing of the Japanese home islands; the atomic bombs dropped on Hiroshima and Nagasaki were flown from a base at Tinian. Most of the individual islands of the Marianas were bypassed, and with most of these communication was not reestablished until the war was over.

U.S.
invasion

The U.S. invasion of the Marianas during World War II completely destroyed the Japanese-created economy in the islands. The United States began the task of rebuilding. President Harry S. Truman signed a Trusteeship Agreement with the United Nations for the administration of the northern Marianas as a district within the Trust Territory of the Pacific Islands in Micronesia on July 18, 1947, and delegated responsibility for the civil administration to the U.S. Navy. Then, on July 1, 1951, following the signing of the peace treaty with Japan and the renouncing of all Japanese claims to the northern Marianas, U.S. administrative responsibility under the UN Trusteeship was transferred to the secretary of the interior. A special designation of "strategic" trusteeship was made, which placed the ultimate jurisdiction of the Marianas under the United Nations Security Council. The other Micronesian island groups of the Marshalls and the Carolines were also covered under this Trusteeship Agreement.

The United States pledged to "promote development . . . towards self-government or independence as may be appropriate." In 1969 political status talks began between the Micronesians from the entire Trust Territory and U.S. representatives. In 1973 the northern Marianas began separate negotiations with the United States that led to a plebiscite in 1975 in which the people approved a commonwealth status in association with the United States. The new government began operations under its own constitution and an elected governor, who was installed in January 1978. Eligible residents of the Northern Marianas became U.S. citizens. The United States declared the trusteeship officially ended on Nov. 4, 1986.

(D.A.B.)

Palau

The Republic of Palau (Palauan: Beluu era Belau) is an internally self-governing republic. It consists of about 340 coral and volcanic islands perched on the Kyushu-Palau Ridge in the western Pacific. The Palau archipelago lies in the southwest corner of Micronesia with the Philippines 550 miles (885 kilometres) to the west, New Guinea 400 miles to the south, and Guam 830 miles to the northeast. It reaches from latitude 2°55' to 8°12' N and from longitude 131°05' to 134°44' E. A huge barrier-reef system, continuous on the west and broken on the east, encircles most of the archipelago's 188 square miles (488 square kilometres) of land: its major populated islands are Babelthup (Babeldaob), Koror, Malakal, Arakabesan, and Peleliu. The sparsely populated Kayangel Islands to the north of Babelthup and the raised coral islands of Angaur, Sonsorol, Pulo Anna, and Tobi south of Peleliu lie outside the barrier-reef system. Koror Island, rising to 2,061 feet (628 metres) just south of Babelthup, is the provisional capital and largest population centre.

Palau was a member of the UN Trust Territory of the Pacific Islands established in 1947 and administered by the United States. The U.S. government dissolved the trusteeship in 1986, but repeated measures to win the required 75 percent support for a compact of free association between Palau and the United States were unsuccessful, and the United States retained responsibility as the administering authority.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and drainage.* All but six of Palau's islands lie within an expansive lagoon, enclosed by the barrier reef, that stretches northeast to southwest for almost 70 miles. Babelthup, the largest island (153 square miles), is volcanic, mainly andesite, and is bounded by thick mangrove forests broken occasionally by sandy beaches on the east coast. Its highest point, Rois Ngerekelehuus, in the northwest, is 794 feet high. Babelthup is essentially a rolling upland, part grassland and part jungle, that has been incised by stream action to form a well-developed drainage system of three rivers. With 150 inches (3,800 millimetres) of rain annually, considerable erosion has taken place on Babelthup in spite of the stability provided by laterite soils, clays, and vegetation. The Palauan practice of burning the grassy upland areas during the dry season has contributed to erosion.

Mangrove
forests

Since 1977 Babelthup has been connected by a concrete bridge to the 3.6-square-mile Koror, which, in turn, is linked by causeway to Malakal island, the site of Palau's deepwater port, and Arakabesan island. The combined area of the three smaller linked islands is seven square miles. All are of volcanic origin. Beginning adjacent to southern Babelthup and eastern Koror, however, and filling the huge lagoon for 28 miles south to Peleliu are 320 green velvet "rock" islands. These are uplifted reef structures of coralline limestone, each deeply undercut at sea level. Some of the islands are large, towering 600 feet, and have interior brackish lakes, containing unique organisms, that are connected to the lagoon by subterranean channels. Plant growth is thick on the rock islands and, together with the chemical action of heavy rains, has sculpted and broken the surfaces, producing razor-sharp edges and points and broken rubble. The limestone islands have rich deposits of phosphate, and the more accessible ones have been mined.

The inhabited coral islands outside of Palau's reef-lagoon-island system sit on volcanic substructures and consist of Kayangel Islands, 25 miles north of Babelthup, and Angaur, six miles south of Peleliu, which was heavily mined for its phosphate first by the Germans and later by the Japanese. Sonsorol, Pulo Anna, and Tobi, all with areas of less than one square mile, are 180 miles southwest of the Palau archipelago. All are flat platform structures with fringing reefs.

Climate. Palau's climate is tropical. Rainfall varies from 120 to 160 inches per year. Humidity is fairly constant, ranging from 77 to 84 percent, and temperatures vary not more than 10° F (5.5° C) diurnally, monthly, or annually, from a mean of 81° F (27° C). Northeast trade winds prevail from December to March and southwest monsoons from June to October. Prevailing oceanic currents offshore are the North Equatorial Current and the Equatorial Countercurrent.

Geologically, Palau sits on the Philippine Sea Plate only 30 miles west of the 26,200-foot-deep Palau Trench, the western boundary of the upthrusting Pacific Plate. Despite its close proximity to this subduction zone, Palau rarely experiences earthquake activity.

Palau's marine environment exhibits a rich fauna balanced by an abundant terrestrial flora. This richness derives from Palau's close proximity to Indonesia, New Guinea, and the Philippines. Palau has more species of marine life than any other area of similar size in the world; corals, fish, snails, clams, sea cucumbers, starfish, sea urchins, sea anemones, jellyfish, squid, and feather worms exist in profusion and variety. Common flora are the beach morning glory, Polynesian ironwood tree, pandanus, and various species of palm and fern. The birds of Palau are abundant and colourful, and many migrate to or through Palau twice annually. A few species of reptile and amphibian live in Palau, including a unique frog that gives birth to live young. Insects are also abundant. The accidentally introduced coconut rhinoceros beetle did enormous damage to coconut palms until it was brought under control by the parasitic scolia wasp.

Unique
frog species

The people. Palau's people are generally of medium height with diverse skin tones and facial types. The islands were inhabited from 2,000 to 3,000 years ago by

Emperor angelfish (*Pomacanthus imperator*) swimming among the corals in the barrier-reef channel of Aulong Island, Palau.

© Douglas Faulkner/Sally Faulkner Collection

successive waves of Malays from Indonesia, Melanesians from New Guinea, Philippine natives, and some Polynesians from outlying Polynesian islands in Micronesia, who formed the basic genetic stock.

During the past two centuries Europeans, Japanese, and Americans have made genetic contributions. The southwest islanders, who are culturally and linguistically distinct from the Palauans, are the only minority group; they trace their origin to a group of ancestral survivors of one or more canoes that drifted to Sonsorol from Ulithi Atoll, northeast of Yap. Palauan is a Western Austronesian language and is very complex in that it has many irregularities that make formulation of grammatical and lexical rules difficult.

The indigenous Palauan religion of powerful ancestral and nature spirits was supplanted by Christianity. The only remnant of past belief systems is the Modekngel religion, which developed as a syncretic movement in response to colonial pressure. In addition to the well-established Roman Catholic, Lutheran, and Seventh-day Adventist churches, missionaries of the Jehovah's Witness, Mormon, Bahá'í, and Assemblies of God faiths have carried their message to Palau.

Palauans are atypical Micronesians in their desire to migrate overseas. There are a number of substantial Palauan communities on Guam, in Hawaii, and on the U.S. West Coast. This continued migration and the apparent decline in birth rates have resulted in a small negative population growth rate.

The economy. Since the end of World War II, the major employer in Palau has been government—first the U.S. Navy, then the Trust Territory of the Pacific Islands, and finally the government of Palau. Nevertheless, in the rural areas outside Koror the subsistence economy is active. Women typically gather and cultivate wet taro, sweet potato, and cassava, and men fish and tend pigs, which are used at customary feasts. Tourism has grown considerably during the late 20th century and has also made some contribution to the republic's economic growth.

With the majority of Palau's population in Koror, that island has a good system of paved roads. There are stretches of paved road on Babelthup, and the roads built in 1944–46 by U.S. military forces on Peleliu and Angaur are still usable. Transportation between islands is by boat or airplane. There is regular commuter service from Koror to Peleliu and Angaur, and trips by speedboat to coastal villages on Babelthup usually can be completed in a few hours. There is an international airport located on Babelthup.

Near-shore reef fishing is carried out on a subsistence and small-venture basis, but it does not generate signifi-

cant government revenue. Offshore tuna fishing by foreign vessels provides a small amount of government revenue through the sale of licenses.

Administration and social conditions. The constitution of the Republic of Palau established a presidential form of government, which was installed in 1981. The executive consists of separately elected offices of president and vice president, a Council of Chiefs to advise the president on traditional laws and customs, and a Cabinet. The National Congress consists of a Senate and a House of Delegates. Both executive and legislative branches are elected for four-year terms. The Palau judiciary consists of a Supreme Court and a National Court of Common Pleas with both trial and appellate divisions. At the local level, each of the 16 traditional settlement areas comprises a state with an elected governor and legislature. Palau has no armed forces.

Each of the rural states has an elementary school. Three church-run high schools and a public high school take most of those who complete the eighth grade. The Micronesian Occupational College on Koror was established in 1969 and was reaccredited in 1987.

Health care is provided by the hospital on Koror and dispensaries in each rural state. The incidences of mental illness, suicide, and alcoholism in Palau are higher than in most countries.

Cultural life. Pragmatic adaptation, persistence of wealth-exchange customs, and competition characterize Palauan society. Palauans adapted to a century of colonial intrusion—Spanish, German, Japanese, and American—by viewing reality as something imposed from the outside to which one must adjust quickly if it is to be manipulated. Reciprocity and redistribution customs carried out between clans exchange food and services for money and gifts at births, house completions, and funerals. Women are the strength of society and control land, money, and titles. Men, previously occupied as fishermen and warriors, continue their traditional tasks in the rural areas and, as an adaptation to modern society, compete for elected office, in business, and in baseball. Traditional art forms persist in chants and storyboards, which are now made for sale to tourists rather than for decoration of men's clubhouses. The Palau National Museum in Koror has a small but instructive collection of artifacts.

Adaptation
to
occupation

HISTORY

Large hillside terraces, numerous stone ruins, and megaliths on Babelthup give evidence of a vital culture before contact with European explorers. The first extensive contact of Palauans with Westerners took place after the shipwreck of the East India Company's packet *Antelope* in 1783. George Keate's *An Account of the Pelew Islands* (1788), which recounted the friendship and high adventure found in Palau, served to fuel the European myths of the noble savage and island paradise. The first 70 years of the 19th century were punctuated by the occasional visits of whalers and traders, who left beachcombers and firearms behind. Diseases communicated by contact with Europeans led to the deaths of many islanders, and firearms were prized for intervillage warfare, which was ended in 1883 through the peaceful intervention of Captain Cyprian Bridge of HMS *Espiègle*. Spanish and German colonial influence was expressed through Roman Catholic missionaries. The Japanese navy expelled the Germans at the beginning of World War I, and, although the Japanese period is locally remembered as one of economic development and order, the Palauans were a marginal minority by 1936. Japan lost Palau in World War II in a struggle that was socially destabilizing and confusing to the Palauans.

After a short period of administration by the U.S. Navy, Palau became part of the United Nations Trust Territory of the Pacific Islands under U.S. administration in 1947. A constitution was adopted in 1981 (following two prior referendums), and elections were held in the same year. The country became internally self-governing in 1981. Palau signed a Compact of Free Association with the United States in 1982, but the required number of voters failed to pass the referendum in 1983. The compact required that the United States remain responsible for external security

Nuclear
weapons
controversy

and defense and that it provide financial assistance for Palau, but conflict arose over Palau's constitutional prohibition on the operation of U.S. nuclear-powered or nuclear-armed vessels and aircraft within the jurisdiction of Palau. According to the terms of the compact, the United States reserved this right as well as the right to neither confirm nor deny the presence or absence of such weapons in Palau. Several attempts were made to revise the constitution, revise the compact agreement, and secure Palauan approval, and the United States dissolved the trusteeship in 1986. The issue remained unresolved, however.

In 1985 volatile internal politics resulted in the assassination of the first president, Haruo I. Remeliik. In August 1985 Lazarus E. Salii was elected to serve out the four-year term begun by Remeliik in January 1985, but Salii himself met a violent death in August 1988. (D.R.Sh.)

Tuvalu

Tuvalu, an independent nation composed of nine small coral islands, lies south of the Equator in the central Pacific Ocean. The islands are scattered in a chain lying approximately northwest to southeast over a distance of some 420 miles (676 kilometres). The islands are small; Tuvalu has a land area of less than 10 square miles (26 square kilometres). The capital is Fongafale, on Funafuti Atoll. Tuvalu was formerly called Ellice Islands and with colonial Kiribati formed the unit known as Gilbert and Ellice Islands Colony.

PHYSICAL AND HUMAN GEOGRAPHY

The land. The group includes both atolls and reef islands. The atolls—Nanumea, Nui, Nukufetau, Funafuti, and Nukulaelae—have islets encircling a shallow lagoon; the reef islands—Nanumanga, Niutao, Vaitupu, and Niulakita—are compact with a fringing reef. The islands are low-lying, most being 13 to 16 feet (4 to 5 metres) above sea level. There are no rivers; rain catchment and wells provide the only fresh water. Rainfall averages 100 inches (2,500 millimetres) in the north and 125 inches in the south. The prevailing winds are southeast trades; westerly storms occur from November to February, but hurricanes are rare. Daytime temperatures range from 80° to 85° F (27° to 29° C).

Because the soils are porous, agriculture is limited. Coconut palms thrive, and breadfruit trees and pandanus are grown. Taro and bananas can be grown in pits. Pigs and chickens are raised, and seabirds, fish, and shellfish are caught for food. The islands are increasingly dependent on imported food.

The people. The Tuvaluans are Polynesian, and their language, called Tuvaluan, is closely related to Samoan. The major exception is Nui, which was heavily settled in prehistoric times by Micronesians from the Gilbert Islands (now Kiribati). English is taught in the schools and widely used. Almost all of the population belongs to the Church of Tuvalu (the former Ellice Islands Protestant Church).

Although most people live on the outer islands in extended family households clustered into villages, about one-third of the population lives on Funafuti, the centre of government and commerce. Population growth has been slowed by family planning; life expectancy at birth is about 60 years. About 10 percent of the population lives overseas, either pursuing education, working in the Nauru phosphate industry, or working on merchant ships.

The economy. Most Tuvaluans are subsistence farmers and are aided by remittances from relatives working overseas. A small quantity of copra is produced for export, the sale of stamps accounts for modest earnings, and fees are collected from foreign fishing fleets, but the country depends heavily on foreign aid. It imports most of its food, fuel, and manufactured goods. Retailing is handled by community-based cooperative societies. Tuvalu uses Australian currency but also issues its own coinage. There is a single bank, a joint government-commercial venture.

Tuvalu has air links with Kiribati and Fiji; for international shipping, it depends on irregular regional services. Seaplanes have been used for interisland travel, but generally the outer islands depend on a single government

vessel. Motorcycles are common on Funafuti, but there are few automobiles.

Administration and social conditions. Tuvalu is a constitutional monarchy within the Commonwealth, with the British sovereign (through a governor-general) as head of state. The government is a parliamentary democracy with a unicameral legislature elected by universal adult suffrage. There are no political parties: the prime minister is chosen by and from the legislature. Tuvalu is a member of the South Pacific Forum.

The government provides universal primary education and, under a joint arrangement with the Church of Tuvalu, secondary education to school certificate level for selected pupils. A few are sent overseas for further education and training. Medical facilities are centralized on Funafuti, but all other islands have clinics with trained medical staff.

Cultural life. The Tuvaluan life-style has been Westernized to an extent, but Western-style amenities are few. Only Funafuti has a regular electricity supply; the government publishes a brief news sheet, but there is no newspaper; a few motion pictures are shown, but there is no television; and there is only a single radio station. Most Tuvaluans live in villages of a few hundred people, tend their gardens, and fish from handcrafted canoes. Traditional music and dancing still enjoy a strong following, along with Western forms. Volleyball, soccer, and cricket are popular. Tuvaluan life, despite urbanization and modernization, still rests on a firm traditional base that emphasizes the importance of community consensus and identity.

For statistical data on the land and people of Tuvalu, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

The first settlers were from Samoa and probably arrived in the 14th century AD. Smaller numbers subsequently arrived from Tonga, the northern Cook Islands, Rotuma, and the Gilbert Islands. Niulakita, the smallest and southernmost island, was uninhabited before European contact; the other islands were settled by the 18th century, giving rise to the name Tuvalu, or "Cluster of Eight."

Europeans first discovered the islands in the 16th century through the voyages of Álvaro de Mendaña de Neira, but it was only from the 1820s, with visits by whalers and traders, that they were reliably placed on European charts. In 1863 labour recruiters from Peru kidnapped some 400 people, mostly from Nukulaelae and Funafuti, reducing the population of the group to less than 2,500. A few were later recruited for plantations in Queensland, Australia, as well as in Fiji, Samoa, and Hawaii. Concern over labour recruiting and a desire for protection helps to explain the enthusiastic response to Samoan pastors of the London Missionary Society who arrived in the 1860s. By 1900, Protestant Christianity was firmly established.

With imperial expansion the group, then known as the Ellice Islands, became a British protectorate in 1892 and part of the Gilbert and Ellice Islands Colony in 1916. There was a gradual expansion of government services, but most administration was through island governments supervised by a single district officer based in Funafuti. Ellice Islanders sought education and employment at the colonial capital in the Gilbert group or in the phosphate industry at Banaba or Nauru. During World War II, U.S. forces were based on Nanumea, Nukufetau, and Funafuti, but hostilities did not reach the group.

From the 1960s, racial tension and rivalries over employment emerged between Gilbertese and Ellice Islanders. Ellice Islanders' demands for secession resulted in a referendum in 1974, transition to separate colonial status between October 1975 and January 1976, and independence as Tuvalu in 1978. After independence the main priorities were to establish the infrastructure for a separate, if small, nation, and to seek foreign assistance to match political independence with economic viability. (B.K.M.)

For later developments in the history of Tuvalu, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

MAJOR POLITICAL UNITS OF POLYNESIA

American Samoa

American Samoa, a territory of the United States, consists of the eastern part of the Samoan archipelago. It is situated in the central Pacific Ocean about 1,600 miles (2,600 kilometres) northeast of New Zealand and 2,200 miles southwest of the Hawaiian Islands. The territory includes the six Samoan islands east of the 171° W meridian and is part of Polynesia. Western Samoa, its closest neighbour and a self-governing nation, consists of the nine Samoan islands west of that meridian.

American Samoa, with a total land area of 77 square miles (199 square kilometres), includes the inhabited islands of Tutuila, Tau, Olosega, Ofu, and Aunuu and an uninhabited coral atoll named Rose Island. Swains Island (inhabited), a coral atoll 280 miles northwest of Tutuila and geographically not a part of the archipelago, was made a part of American Samoa in 1925. The capital of American Samoa is Pago Pago, on Tutuila.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Except for the coral atolls, the islands of American Samoa were formed within the past 7,000,000 years by volcanic activity; their interiors are high and rugged. The main island of Tutuila, with an area of 53 square miles, rises steeply above deep inlets. The most notable of these inlets is Pago Pago Harbor, which almost divides the island in two. Tutuila's highest peak is Mount Matafao (2,141 feet [653 metres]). The Manua island group (Tau, Olosega, and Ofu islands), situated about 60 miles east of Tutuila, constitutes the second largest island area. Coral reefs are common to the extremities of the islands, particularly Tutuila; some of the reefs form barriers that enclose lagoons.

Climate. The climate is tropical and rainfall is ample. Pago Pago receives about 200 inches (5,000 millimetres) annually. Most streams carry greater volumes of water in the highlands than near the sea and do not reach the ocean; rather, they filter into the porous basalt rocks. Hence, coastal wells provide much of the water supply. Temperatures are unusually constant; average temperatures range from 68° to 90° F (21° to 32° C). Average humidity is 80 percent. The moderate southeast trade winds prevail, but severe storms can occur during the wet season, from November to March.

Plant and animal life. Rain forests with tall ferns and trees cover the mountainous interiors of the islands. Plantations of taro, coconut, and other food crops are located on the coasts. Although the islands are not rich in animal life, some of their bird species—such as the rare tooth-billed pigeon—are unique. Wildlife includes the flying fox, lizards, rats, harmless snakes, and pigs. The islands also have a rich insect life.

Settlement patterns. Most people live in coastal villages. Pago Pago, the only town, is the main port and administrative and commercial centre. Since the mid-20th century many American Samoans have migrated to the United States, with the result that there are more American Samoans abroad than on the islands.

The people. The Samoans are a Polynesian people closely related to the native peoples of New Zealand, Tahiti, Hawaii, and Tonga. The Samoan way of life, or *fa'a Samoa*, is communal. The basic unit of social organization is the extended family (*aiga*). These extended families are arranged in villages, which are grouped into districts. The extended families are headed by chiefs (*matai*), who are selected by their extended families on the basis of consensus. Most chiefs' titles are very old. The village chiefs together make up a village council (*fono*), which controls and runs village affairs. Even after decades of foreign influence, most Samoans still live according to *fa'a Samoa*, and nearly all of them are fluent in the Samoan language. Most of the American Samoans, nonetheless, also speak English. The Congregational Christian Church has the largest following among religious institutions; most

of the remaining population is either Roman Catholic or Methodist.

The economy. *Industry and agriculture.* The U.S. administration is the main employer. Tuna canning (by American-owned canneries) and tourism are major industries. Agriculture is organized on a semicommercial basis for the production of taro, bananas, tropical fruits, and vegetables. Traditional family gardens produce coconuts, breadfruit, and yams. Production nearly meets domestic needs, and the U.S. government has implemented programs to increase production to self-sufficiency levels.

Social legislation ties American Samoa more closely to U.S. costs of living than its South Pacific neighbours.

Transportation. A major public works program on American Samoa has increased the number of miles of paved roads. Most of the program has been carried out on the island of Tutuila. Pago Pago is the only port of note. An international airport is located on Tutuila, and smaller airstrips operate from the islands of Tau and Ofu.

Administration and social conditions. *Government.* American Samoa is an unincorporated, unorganized territory, the people of which are U.S. nationals but not citizens. The territory's chief executive, according to the constitution of 1967, is the governor. Until 1977 the governor was appointed by the U.S. Department of the Interior; in response to a referendum of 1976, however, the offices of governor and lieutenant governor are filled by popular election. Elections are to be held every four years. The minimum voting age is 18. The Fono (bicameral legislature) is autonomous in its disposition of local revenues and is the sole lawmaking body, subject to the governor's approval. The 21 members of the House of Representatives are elected by universal suffrage; one is a nonvoting delegate elected from Swains Island. The 18 senators are chosen by councils of chiefs, in accordance with Samoan custom. In 1981 the first official delegate from American Samoa to the Congress of the United States was elected. Apart from Swains Island, the islands are divided into three administrative districts (each with an appointed district governor), which are subdivided into a total of 14 counties. Chiefs representing each family form village and district councils. This autonomous village control is linked with the central government through three district governors appointed by the governor. Each village has a village court with authority to adjudicate on minor misdemeanours.

Education. Education is compulsory between the ages of six and 18 in American Samoa. Televised instruction, given mainly in English and mostly by teachers and technicians from the United States, is available to local schools. The American Samoan Community College offers vocational training and nursing programs, with university education available from universities in Hawaii or on the U.S. mainland. (P.R.C./A.We.)

HISTORY

The Samoan islands were settled by Polynesians (probably from Tonga) in about 1000 BC. By about AD 200 Samoa had become the centre of much of the settlement of Eastern Polynesia.

The Dutch navigator Jacob Roggeveen sighted Samoa in 1722, and other European explorers, beachcombers, and traders followed. The London Missionary Society sent its first missionaries to the islands in the 1830s. More missionaries traveled to the islands as missionary influence spread to Tutuila and later the Manua Islands. In 1878 the United States signed a treaty for the establishment of a naval station in Pago Pago Harbor, and in 1899 eastern Samoa was annexed by the United States.

By 1904 the eastern islands had all been ceded to the United States, but the U.S. Congress did not formally accept the deeds of cession until Feb. 20, 1929. Under the administration of the U.S. Navy (1900–51) American Samoa became a strategic naval base, but the Samoan leaders had little administrative power. In 1951 control of the

Presence of
coral reefs

Fa'a
Samoa

Village
courts

territory was transferred to the Department of the Interior. The U.S. government appointed a governor who had full powers to administer the territory. He appointed political advisers and senior civil servants from the United States to help him. The Samoans agitated for control of their country's affairs, and in 1977 Peter Coleman, a Samoan, became the territory's first elected governor. Since then, all members of the territory's House of Representatives have been elected by the citizens. Except for defense, the governor and the Fono run American Samoa's affairs. American Samoans are U.S. nationals and can move freely between their country and the United States. (A.We.)

Cook Islands

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief and drainage.* The Cook Islands is an internally self-governing island state in free association with New Zealand in the south Pacific Islands. The 15 tiny islands have a total land area of 91 square miles (236 square kilometres) but are spread over 770,000 square miles of sea. The capital is Avarua on Rarotonga. Each island is the top of one or more volcanoes, but only on the largest islands do the plugs and craters of now-extinct volcanoes still dominate the skyline; these rise to 2,139 feet (652 metres) on Rarotonga, an island only four miles (six kilometres) wide. Most other islands of the southern group (such as Atiu, Mangaia, Mitiaro, and Aitutaki) show various combinations of atoll and high-island formation. The northern group islands (including Penrhyn, Manihiki, Rakahanga, and Nassau) are atolls, narrow and low-lying sandbanks resting on circular reefs around lagoons rich in marine life.

The land areas being so small, there are no rivers, and only the largest islands have even small streams. There are small freshwater lakes on the high islands of Mangaia, Atiu, and Mitiaro; saltwater lagoons inside all the atolls; and fringing lagoons between most islands and their outer reefs. The rain that falls on the atolls permeates the island coral and is naturally stored in a lens-shaped layer above the heavier salt water. The islanders must rely on wells and rainwater storage tanks to conserve their limited sources of water.

Soils. Soils on the low-lying atolls are very limited in depth and quality. Most of the high island of Rarotonga is ruggedly mountainous, with narrow valleys having small but fertile pockets of soil. The coast consists of makatea, or upraised coral reef, of limited fertility. Between the mountains and the coast, however, is a ring of fertile volcanic soil. On the other high islands much of the area is likewise taken up by eroded central slopes encircled by makatea, but again there are areas of fertile soil between. The problem of erosion has been greatly accentuated by the planting of pineapples and other export crops on soils that, in the long term, are too fragile for plantation farming.

Climate. All the islands lie within the tropics, but the southernmost just barely. Because the Cook Islands are small, mid-ocean islands swept by the southeast trade winds, temperatures are generally moderate. The mean annual temperature on the southern island of Rarotonga is 75° F (24° C), but on the northernmost island of Penrhyn it is 82° F (28° C).

Seasons are not clearly marked. The English terms summer, winter, spring, and autumn are used, but Cook Islanders also recognize the traditional local patterns of prevailing winds, rainfall, and temperature. Rainfall, though erratic over the years, tends to be uniform across the various islands. It averages 80 inches (2,000 millimetres) on Rarotonga, though with considerable difference between the windward and lee sides of the central mountains, and is slightly lower on Aitutaki and slightly higher on Penrhyn.

The spectacular climatic hazard is hurricanes, which strike with destructive force between December and March about once or twice every 10 years. Less spectacular, but at times equally destructive of agriculture, are droughts, to which the northern group is more vulnerable than the southern.

Plant and animal life. Only a limited range of plant life

thrives in the north, the coconut and the pandanus being predominant. On the fertile areas of the southern islands, a wide range of tropical fruits and vegetables flourishes. Indigenous species include taro, yams, bananas, breadfruit, and sweet potatoes. Introduced species—in many cases grown for export—include citrus fruits, tomatoes, pineapples, papayas, beans, and zucchini.

The original Polynesian settlers brought with them pigs, dogs, chickens, and a type of small rat. These are still the main fauna, though a few goats, horses, and other animals have been introduced. Some native birds became extinct in the 19th century after Europeans introduced cats. The *kakirori*, or Rarotongan flycatcher, an attractive tiny bird unique to Rarotonga, had been reduced by the early 1990s to about 30 breeding pairs, which were protected by the government conservation service.

Settlement patterns. Most Cook Islanders live in villages, the largest of which is Avarua on Rarotonga, though some people (in Rarotonga particularly) live on their farming lands. The former indigenous houses of thatch and timber have been almost totally replaced by homes of cement and timber with iron roofs.

The people. With the exception of the inhabitants of isolated Pukapuka, who are of predominantly Samoan and Tongan descent, almost all Cook Islanders have mixed Polynesian ancestry. Inter-marriage with European, Chinese, and African settlers was common in the early 19th century. The Christian denominations, particularly the Cook Islands Christian Church, account for nearly all religious affiliation.

There are two main indigenous Polynesian languages, one for the island of Pukapuka and the other (with dialectal variations) for all other islands. English is spoken by most Cook Islanders, and the literacy rate is more than 90 percent.

The population is static at about 17,000 and has been so for many years. Natural increase is high but is offset by emigration to New Zealand and Australia. Today more than twice as many persons of Cook Islands ancestry live in New Zealand than in the Cook Islands. The main nonindigenous population is of European origin by way of New Zealand. There is considerable internal migration from the smaller islands to Rarotonga, the most populous island, where there is generally full employment.

The economy. The largest industry by far is tourism, mainly from New Zealand, Australia, Canada, the United States, and Europe. The second largest industry is international finance, as the Cook Islands are a major tax haven. Government plays a significant part in the economy and is the largest employer, mainly for the provision of services; production and commerce is almost all private. Taxes are moderate, foreign investment is encouraged, and foreign aid—largely from New Zealand—makes a significant contribution to the economy. The banking system comprises two Australian retail banks, a New Zealand merchant bank, a government development bank, and a number of offshore banks dealing with international finance.

No mineral resources are exploited, though phosphate exists on the floor of the Manihiki lagoon, and there are vast deposits of manganese and cobalt and some other metals on the seabed near Manihiki. Agricultural production at present consists mainly of small farming, either for home consumption or for airfreight to New Zealand in its off-season. Commercial fishing for export is done mainly by Taiwanese vessels operating out of American Samoa, but there is widespread fishing for home consumption. A new cultured-pearl industry promises to generate more income than all agriculture, fishing, and industry combined.

The small industrial sector entails clothing and shoe manufacturing and food processing, mainly for export to New Zealand. The major imports are from New Zealand, Japan, and the United States. Energy is mainly produced from imported fuels, though there is some use of solar and wind power.

Each island has a network of roads; a paved road encircles Rarotonga. Regular service by small aircraft connects all the main islands, but shipping is erratic. Externally there are direct air services to New Zealand, Australia, Hawaii, Tahiti, Fiji, and Western Samoa from the international

High
literacy
rate

Ring of
fertile
volcanic
soil

airport on Rarotonga. External shipping is mainly with New Zealand and the United States.

Administration and social conditions. The Cook Islands is a self-governing state. Its government is democratic, with general elections, by universal suffrage, held every five years. The two main parties are the Cook Islands Party and the Democratic Party. The constitution, adopted in 1965, has been amended several times. Local government, including the Parliament of the Cook Islands, is mainly elected, but a council of hereditary leaders, the House of Ariki (High Chiefs), advises the government on traditional matters of land ownership, custom, and the like.

Education is universal and compulsory from the ages of 5 to 16, with some church schools operating in addition to those run by the government. Higher education is available at such schools as the national Teachers College and Nurses College, through apprenticeship schemes, and through an extension centre of the University of the South Pacific at Avarua; many overseas scholarships are provided by the government and by overseas donors.

Free medical services are available from a government-owned hospital or dispensary on each island. Dental treatment is also free for schoolchildren. Filariasis is common, and the diseases more commonly found in developed countries—diabetes, cardiovascular disorders, cirrhosis of the liver—are becoming more widespread. Automobile accidents are a major problem.

Cultural life. Culturally the islands are relatively homogeneous, with the culture of Pukapuka—which was settled from western, rather than eastern, Polynesia—showing most variation from the general pattern. The government plays an active role in cultural life, particularly in the sponsorship of song and dance festivals for which the islands are renowned. A small library and museum in Avarua provide additional cultural attractions. Owing to tourism and intensive interaction with neighbouring industrialized nations, much international (generally Western) culture has been incorporated into the native lifeways. Nevertheless, traditional ceremonies, such as that celebrating the first haircut of the favourite son in a family, are as vibrant as ever. A distinctive style of food preparation draws on the traditions of Europe, China, Fiji, and Tahiti. Christian tradition, some of it from the English Victorian era, is strongly manifest, with modern American-derived evangelistic services and rituals becoming more common. The major national holiday is Constitution Day, which usually gives rise to a 10-day celebration. A Tiare ("Gardenia") Festival, a float parade, and a series of song and dance competitions fill the annual calendar of festivities.

There is a national (government-owned) radio station serving all islands, a government-owned television service to Rarotonga and Aitutaki, and a private FM radio station. The only daily newspaper, formerly government-owned, was privatized in 1989.

HISTORY

Polynesians, mainly from the area now known as French Polynesia, were the only inhabitants of the Cook Islands until the 19th century. With only minor exceptions, each island was autonomous, and within each of the larger islands there were several competing tribal communities. Spanish explorers visited several islands in the northern group in the late 1500s and early 1600s but did not stay. Captain James Cook was the first European to call at most of the southern group, in 1773, 1774, and 1777.

English and Tahitian missionaries of the London Missionary Society began arriving in 1821 and were the first foreigners to settle. They established a theological college on Rarotonga and exerted a strong influence on the form of government that evolved in each of the islands over the next half century.

Fear of a French takeover, such as that which had occurred in nearby Tahiti and other islands of the Society Group, prompted some chiefs to petition the United Kingdom to declare a protectorate over the Cook Islands. The British government eventually complied in 1888. A single federal parliament was established, the first time that these scattered islands had come under a united government.

New Zealand was keen to annex the Cook Islands, but

the United Kingdom would not agree to this except on certain conditions, one of which was that the request for annexation must come from the Cook Islands. With some New Zealand persuasion, chiefs of the largest islands petitioned for annexation, which was undertaken in 1901. After 1912 the federal parliament was allowed to lapse, and no direct representation at the national level occurred until 1946, when a Legislative Council was organized. In 1957 its powers were extended and its name changed to Legislative Assembly.

In 1965 the Cook Islands moved to self-government but retained an associated-state relationship with New Zealand. Under this arrangement, the Cook Islands is a sovereign state, but New Zealand is responsible for defense, after consultation with the prime minister of the Cook Islands. (R.G.C./M.T.C.)

For later developments in the history of Cook Islands, see the *Britannica Book of the Year* section of BRITANNICA WORLD DATA ANNUAL.

Easter Island

Easter Island (Isla de Pascua), a Chilean dependency in the eastern Pacific Ocean famous for its giant stone statues, represents the easternmost outpost of the Polynesian island world. It stands in isolation 1,200 miles (1,900 kilometres) east of lonely Pitcairn Island and 2,200 miles west of Chile. Forming a triangle 14 miles long by seven miles wide, the island has an area of 63 square miles (163 square kilometres); its highest point, Mount Terevaka, is 1,969 feet (600 metres) above sea level. To its original inhabitants the island is known as Rapa Nui ("Great Rapa") or Te Pito te Henua ("Navel of the World"); its first European visitors, the Dutch, named it Paaseiland ("Easter Island") in memory of their own day of arrival. Its mixed population is predominantly of Polynesian descent; almost all live in the village of Hanga Roa on the sheltered west coast. The island is a province that is administratively part of the region of Valparaíso, Chile.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The small and hilly island is not part of a sunken landmass but is a typical oceanic high island formed by volcanoes rising from the seafloor. Geologic and oceanographic evidence shows that no perceptible emergence or submergence of the island's coastline has taken place since the last fall in sea level, which occurred less than 10,000 years ago. Three extinct volcanoes chiefly composed of tuff (a rock formed of compacted volcanic fragments) and joined by their own lava flows give the island its characteristic triangular shape. Parasitic tuff craters and cones (*i.e.*, craters and cones formed on the side of, or near, volcanoes after the original vent has become plugged up) are interspersed in the landscape, which is otherwise dominated by eroded lava fields. Most of these fields are thickly packed with both large and small lumps of cellular and tuffaceous lava that is either black or rusty in colour. Stoneless surface soil is sparse; it is suitable for extensive cultivation mainly in the Hanga Roa and Mataverí area in the southwest, at Vaihu and on the plain southwest of the volcano Rano Raraku, and on the prehistorically cleared Poike peninsula in the eastern corner of the island. Rain collects in the partly bog-covered crater lakes of the volcanoes Rano Kao, Rano Raraku, and Rano Aroi. One intermittent stream, fed by the Rano Aroi crater lake, flows down Mount Terevaka's slopes before disappearing into the porous soil. Water from the extremely deep crater of Rano Kao, which is about 3,000 feet wide, is piped to Hanga Roa. The coast is formed by soft, eroded, ashy cliffs, with a vertical drop of about 500 to 1,000 feet; the cliffs are intercepted by long stretches of low, hard, and rugged lava formations. There is no natural harbour, but anchorage is found off Hanga Roa on the west coast; off Vinapu and Hotu-Iti on the south coast; and off Anakena and in the Bahía la Perouse on the north coast. Notable among the few small offshore islets are Motu-Nui, Motu-Iti, and Motu-Kaokao (which figured in a local bird cult) near the southwest cape. The only true sand beach is at Anakena; most other beaches are of gravel. Caves abound,

Formed by three extinct volcanoes

Council of hereditary leaders

Petition for protectorate status

many consisting of subterranean rooms joined by narrow tunnels extending far into the lava beds.

Climate. The climate is subtropical. The warmest months are January through March, when the average temperature is 73° F (23° C), and the coolest months are June through August, when the average temperature is 64° F (18° C). Average annual precipitation is about 49 inches (1,250 millimetres) but with considerable annual variation. September is the driest month, and the heaviest rainfall occurs in June and July. Winds in June and August are irregular; during the rest of the year trade winds from the east and southeast are dominant. From September through March the Peru (or Humboldt) Current, which has an average temperature of about 70° F (21° C), flows against the island.

Plant and animal life. Indigenous plants and animals are few. At the time of European arrival the toromiro tree, endemic to the island, was the only wild tree and the Carolina wolfberry the only wild shrub, the vegetation being predominantly herbaceous. The toromiro tree was overexploited by the island wood carvers, and the last local specimen died in the 1950s. The species was saved from extinction, however; the Norwegian Archaeological Expedition collected seeds and planted them in the Gothenburg Botanical Garden, and saplings from the garden were reintroduced to Easter Island in 1988. Analysis of pollen deposits has revealed that other trees and shrubs, among them the giant Chile palm, were formerly present on the island until exterminated by extensive fires occurring at the time of aboriginal human settlement. Today only 31 wild flowering plants, 14 ferns, and 14 mosses are reported. Grass and small ferns dominate the barren landscape, whereas the boggy crater lakes are thickly covered by two imported American species, the totora reed (an important building material) and *Polygonum acuminatum* (a medicinal plant). A number of cultivated species of plants were also introduced partly from America and partly from Polynesia before the arrival of Europeans; of these the principal species was the sweet potato, which was cultivated in extensive plantations and formed the staple diet. Bottle gourds, sugarcane, bananas, taro, yams, and two useful trees (*i.e.*, the Asiatic paper mulberry, with bark used for cloth manufacture, and the American *Triumfetta semitriloba*, with bark used for rope making) were of aboriginal importation, as also probably were the husk-tomato, a small variety of pineapple, and the coconut.

Before the arrival of human beings, the only vertebrates were either fish or seabirds capable of long flights. The animal life on land was otherwise restricted to a very few species of isopods (an order of crustaceans), spiders, insects, worms, a snail, and a centipede. Vast quantities of flies, large cockroaches, and a small scorpion were introduced recently. A small, long-legged chicken reported to have laid blue eggs was introduced in pre-European times but later interbred with European varieties. The aboriginal edible Polynesian rat was subsequently replaced by larger European species. Sheep, horses, cattle, and pigs were introduced by the missionaries who established themselves ashore in 1864. Sheep were especially numerous for almost a century after foreign ranchers began commercial ranching in 1870; sheep ranching came to an end in the mid-1980s, but cattle ranching was enhanced. A large wild cat, living in caves, is of unknown introduction. A Chilean partridge, a quail, and a small hawk have been added to the wildlife since 1880. Sea turtles and seals are now rare curiosities, but crayfish and various coastal and deep-sea fishes abound around the coast.

The people. The island's population represents the easternmost settlement of a basically Polynesian subgroup that probably derived from the Marquesas group. The original Rapa Nui vocabulary has been lost except for some mixed Polynesian and non-Polynesian words recorded before the Tahitian dialect was introduced to the decimated population by missionaries in 1864. Today Spanish is generally spoken. In their traditions, the islanders consistently divide themselves into descendants of two distinct ethnic groups, the "Long-Ears" and the "Short-Ears" (see below). Inter-marriage is common, and an influx of foreign blood has become increasingly dominant in recent years.

The economy. Whereas the aboriginal economy was based on the cultivation of sweet potato, chicken raising, and coastal fishing, the island has shifted to a cash economy based on tourism. The opening of an airport near Hanga Roa has permitted an increasing influx of tourists since the 1960s, and a few small hotels have been built in the village area, where many islanders and settlers from continental Chile also have accommodations in their homes. The ties to continental Chile are strengthened through twice-weekly flights from Santiago and the building of schools, hospitals, and a large community hall for sports and performances. A well-organized Chilean national park system provides guided tours and security for the unique archaeological monuments. Reforestation projects have been successfully initiated, including eucalyptus plantations at Vaitea and coconut groves in Anakena Bay.

HISTORY

The first European to land on Easter Island was the Dutch admiral Jacob Roggeveen, who paid it a single day's visit in 1722. He and his crew found a population that they described as being of mixed physical types who worshiped huge standing statues with fires while they prostrated themselves to the rising sun. Some of them, said to be "white men," had their earlobes slit and hanging to their shoulders, a distinctly non-Polynesian custom.

An expedition dispatched by the Spanish viceroy of Peru rediscovered the island in 1770. The Spanish spent four days ashore and were the first to report that the aborigines had their own local form of script. They estimated a population of some 3,000 persons.

A civil war seems to have raged on the island before the arrival of the British navigator Captain James Cook in 1774; a decimated, poverty-stricken Polynesian population of only about 600 or 700 men and fewer than 30 women was found by the Englishmen, who also observed that the large statues were no longer venerated, most of them having been deliberately overthrown. In 1786 the French navigator Jean-François de Galaup, comte de La Pérouse, arrived and found some 2,000 people on the island; he tried in vain to introduce domestic animals. A number of sailing vessels, including whalers, visited the island from 1792 onward. By 1860 the population was about 3,000, but a major slave raid launched from Peru in 1862, followed by smallpox epidemics, reduced the population to 111 in 1877. At the end of the 19th century it began to increase once more. In 1864 Brother Eugène Eyraud, a French Catholic missionary, became the first foreigner to settle on the island; as a result, the population became converted to Christianity by 1868. Settlers from Tahiti began to raise sheep in 1870. In 1888 the island was annexed by Chile, which leased nearly all its territory for sheep raising; in 1954 the Chilean navy administration took over the sheep range. In 1965 a civilian governor was appointed by the Chilean government, and the islanders became full Chilean citizens. Within a single generation the Easter Islanders successfully responded to a complete acculturation to continental standards without losing their pride in their own ancestors and their skills and customs. Annually in February old and young of both sexes meet in contests to revive the arts and practices of the island's past, including carving, tattooing, reed-boat building, and traditional singing and dancing.

Archaeology. The island is famous for its gigantic stone statues, of which there are more than 600, and for the ruins of giant stone platforms (*ahus*) with open courtyards on their landward sides, some of which show masterly construction. Archaeological surveys were carried out in 1886, 1914, and 1934; archaeological excavations were initiated in 1955. The excavations revealed that three distinct cultural periods are identifiable on the island. The early period is characterized by *ahus* at Tahai, Vinapu, and Anakena, carbon dated to *c.* AD 700–850. The first two were admired and described by Captain Cook; the wall in Anakena remained hidden below ground until it was excavated archaeologically in 1987. The excavations in Anakena have revealed that a variety of statues were carved in the early period, among them a smaller prototype of the middle-period busts, which mainly differ from the

latter by their rounded heads and stubby bodies. Another type was a realistic sculpture in full figure of a kneeling man with his buttocks resting on his heels and his hands on his knees, in one case with his ribs exposed, all features characteristic of pre-Inca monuments at Tiahuanaco in South America. In the middle period, c. 1050–1680, statues were deliberately destroyed and discarded, and all *ahus* were rebuilt with no regard for solar orientation or masonry fitting. The sole desire seems to have been to obtain strong platforms capable of supporting ever taller and heavier busts, the classical *moai* of the middle period.

Burial chambers also were constructed within the *ahus* in the middle period. The sizes of the statues made were increased until they reached stupendous dimensions; the slim and lofty busts also had huge cylindrical *pukao* (top-knots) of red tuff placed on top of their slender heads. Most middle-period statues range from about 10 to 20 feet in height, but the biggest among those formerly standing on top of an *ahu* was about 32 feet tall, consisted of a single block weighing about 82 tons (74,500 kilograms), and had a *pukao* of about 11 tons balanced on its apex. The largest statue still standing partly buried in the deep silt below the quarries is about 37 feet tall, and the largest unfinished one with its back attached to the rock is about 68 feet tall. Traditions, supported by archaeology, suggest that the images represented important personalities who were deified after death.

Statues of the middle period were all quarried from the special yellow-gray tuff found in the crater walls of Rano Raraku. Inside and outside the crater bowl numerous unfinished statues and thousands of crude stone picks are scattered about, bearing witness to a sudden interruption of the sculptors' work. The unfinished images show that each statue had its front and sides completed to a polish before the back was detached from the bedrock. The image was then slid away to be raised at random in the rubble below the quarries to have the back finished before being moved to some distant *ahu*. Eye cavities and topknots were added only after the monument was erected; recent discoveries have revealed that these concavities had inlaid eyes of white coral with a dark stone disk as pupil. From one to a dozen completed statues would stand in a row on a single *ahu*, always facing inland.

Experiments based on island traditions in 1955–56 showed that the numerous basalt picks left in the quarries were perfectly suitable for carving the hard tuff. Reenactments showed that 12 islanders were able to lift a 25-ton

statue about 10 feet off the ground and to tilt it on end on top of an *ahu*; this work took 18 days with no tools other than two wooden logs that were used as levers. Stones of all sizes were wedged under the statue one by one to form a slowly rising cairn in order to lift the giant monoliths upright. Tradition claimed that the statues had “walked” across the terrain to their distant destinations, but in the experiment 180 islanders were able to pull a medium statue over the ground. A renewed experiment in 1986 revived the tradition and discovered that 15 men sufficed to move a medium-sized statue over the ground in upright position by jerking it ahead with a system of ropes.

The middle-period busts clearly evolved from a local prototype and have no counterpart elsewhere. Also peculiar to the middle period was a bird cult with attendant birdman rites that survived into the third, or late, period. Its ceremonial centre was the village of Orongo, on top of Rano Kao, which consisted of stone houses with roof vaults built as false arches. These houses and contiguous circular masonry dwellings with roof entrances are characteristic of the early and middle periods on the island; while unknown elsewhere in Polynesia they are common in the adjacent area of South America.

Traditional culture. The late-period Easter Islanders dwelt in boat-shaped pole-and-thatch houses or in caves. This period was marked by internal wars, general destruction, and cultural decadence. The *mataa*, or obsidian spearpoint, which was mass-produced, is the characteristic artifact of this period. Wood carving and small crude stone figurines replaced monumental art. Written wooden tablets covered with incised signs (called *rongo-rongo*) placed in boustrophedon (a method of writing in which the lines run alternately from right to left and from left to right) were copied from earlier specimens merely for ritual purposes; their proper reading was forgotten, and—despite many claims—modern attempts at deciphering them have failed. During this period art treasures were hidden in secret family caves, while the upright *ahu* images were successively overthrown. Silt from the abandoned quarries descended to the chests of the blind and unfinished busts standing at the foot of the volcano, rendering their overthrow impossible and thus securing for posterity the eyesless heads that have given the island its fame.

Tradition maintains that destruction began after a period of peaceful coexistence between two people of different culture and language—the Long-Ears and the Short-Ears. The latter, tired of toiling for the former, all but exterminated them in a pyre along an ancient ditch at Poike on the far northeastern coast. Carbon dating and genealogies concur in placing this event and the beginning of the late period at about AD 1680. The original construction of the artificial Poike ditch, according to carbon dating, took place in about AD 380.

The First International Science Congress convening on Easter Island in 1984 agreed on a resolution defining the island as the site of a pre-European civilization. The recent excavations, which reveal that the earliest settlers arrived with previously developed architectural concepts and a highly specialized megalithic masonry technique, support island traditions, which claim that the first ancestors arrived in an organized party of emigrants and not merely as casually wind-driven fishermen. (Th.H.)

French Polynesia

French Polynesia (French: Polynésie Française) comprises about 130 islands with a total land area of some 1,550 square miles (4,000 square kilometres) scattered over an area of the south-central Pacific between latitudes 7° to 27° S and longitudes 134° to 155° W. The islands are administered as an overseas territory of France.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* There are five distinct groups of islands, all protrusions of parallel submarine ridges trending from the northwest to the southeast.

The Society Islands are the most westerly of the group and the most important in terms of land area (40 percent) and population (85 percent). Except for a few small atolls,

Unfinished
carvings

the Society Islands are of the high-island type, their formation having resulted from the emergence of underwater volcanoes. The volcanic cones are highly eroded and cut up into high crests and deep, radiating valleys. The often lushly vegetated mountains drop abruptly to narrow coastal strips or directly into lagoons or the sea. The islands are protected from the force of the sea by almost completely encircling barrier reefs.

Tahiti and
Moorea

The most highly populated of the Society Islands are Tahiti and its neighbour, Moorea, both situated in the eastern Windward Group, or Îles du Vent. Tahiti, formed of two ancient volcanic cones, is particularly striking because of its dramatic silhouette, which rises 7,352 feet (2,241 metres) above sea level. The mountains are empty of all human settlement, habitation and planting being entirely limited to the coastal strip and valley outlets of the island. Moorea, separated from Tahiti by a channel 8.5 miles (14 kilometres) wide, is also a high island and is encircled with very white coral sand beaches. It is well-connected to Tahiti by boat and taxi planes—a consequence of the booming tourist industry.

Some 75 miles to the west of Tahiti are the Leeward Islands, or Îles sous le Vent, made up of five high islands and four atolls. They closely resemble the Windward Islands in appearance. Raiatea, a double island group, is the largest and most densely populated of the Leeward Group. Separated by a channel that is about two miles wide, Raiatea and its northern neighbour, Vaitoare, are located on the same mountain mass and lie within a single barrier reef. Both have coastal plains suitable for growing coconut palms and raising stock. The growing of vanilla, once an important crop, declined in the 1970s. The Leeward Group's port is Uturoa, located on Raiatea. To the east of Raiatea is the picturesque island of Huahine, a volcanic structure bisected by a shallow arm of the sea.

The
decline of
vanilla
growing

Finally, to the west of Raiatea lies the beautiful little island named Bora-Bora. It is formed from two volcanic peaks rising to 2,385 feet and 2,169 feet and dropping abruptly to the lagoon. Bora-Bora is one of the centres of the tourist trade in French Polynesia.

The Tuamotu Archipelago, lying to the east of the Society Islands, has an area of 280 square miles and consists of some 80 islands. These are low, flat islands or atolls of coral origin, surrounding a lagoon. Their size varies greatly: the largest ones, such as Rangiroa, reach 29 square miles; the smallest are made up of a few acres of land barely protruding above the surface of the sea. With only porous, coral-based soils and with no permanent streams, they have no agricultural potential aside from the ever-present coconut trees. The lagoons, however, are a source of fish, pearls, and mother-of-pearl shell. Only Rangiroa, with its airport, is in close contact with Tahiti. Elsewhere, living conditions are difficult, and many people emigrate to Tahiti. French nuclear installations are situated in the Tuamotus; test sites are on Mururoa and Fangataufa, both ceded to France in 1964.

Morphologically different, the Îles Gambier (Mangareva) lie at the southern extremity of the Tuamotu Archipelago and include four large, high islands and a few islets (14 square miles). The main island is Mangareva.

The 14 islands of the Marquesas group lie 900 miles to the northeast of Tahiti. They have a land area of 405 square miles. Some of them are high islands (over 4,000 feet), with sharp and twisting contours. Unlike the Society Islands, they are not protected from the sea by a barrier reef, with the result that they lack a coastal plain. Approaching the islands from the sea is difficult. People live exclusively in the valleys, where they engage in farming.

The Austral Islands, or Îles Tubuai, situated 450 miles south of Tahiti, make up the southernmost part of the territory. This chain of four islands, with the addition of the isolated island of Rapa in the southeast and the uninhabited Marotiri and Maria islands, covers 57 square miles. All of the islands are of volcanic origin but are relatively low (270 to 1,440 feet) and have unpronounced contours. Income is derived from agriculture (taro, arrowroot, copra, market vegetables) and pandanus plaiting.

Like the Marquesas and the Gambier-Tuamotus, the Austral Islands have poor connections with Tahiti. As

elsewhere, the hard living conditions cause many people to migrate to Tahiti and Papeete.

Climate. The climate is tropical—warm and humid. A warm rainy season lasts from November to April, and a relatively cool dry season from May to October. The dispersion of the islands through 20° of latitude, however, results in regional climatic variation. Except in the Marquesas and the northern Tuamotus, rainfall is abundant, falling in violent showers. As much as 120 inches (3,050 millimetres) falls on the coastal areas. There are local variations due to differing exposures; on average, the windward coasts receive more precipitation.

Abundant
rainfall

The temperature varies only slightly throughout the year. At Papeete the average annual temperature is 79° F (26° C); the high average is 91° F (33° C) in March and the low average 70° F (21° C) in August. The Austral Islands, farther south, enjoy a cooler climate; the low average can go down to 64° F (18° C) in September. The relative humidity is always high—80 to 90 percent on the average. The high areas are continually enveloped in a heavy cloud formation.

The territory is in the trade-wind zone. The dominant winds thus blow from the north and northeast, but they tend toward the southeast between May and October. There are long periods of calm (April, May, June) but with occasional typhoons. During occurrences of El Niño Current the territory is frequently in danger of typhoons.

Plant and animal life. Because of the recent origin and the isolation of the islands, there is little variety in terrestrial flora and fauna. Most of the plant species were introduced by the first Polynesians, and others were introduced by Europeans.

The vegetation's appearance varies with the ecological conditions. On the limestone soils of the atolls, it has a pronounced xerophilous (desert-plant-type) character. On the high volcanic islands it is more diversified; ferns have often conquered the hills and plateaus, whereas rain forests are established in the upper valley areas. On coastal plains coconut, breadfruit, and various fruit trees flourish.

The land fauna is especially limited, and most of the species have been introduced. No mammals are indigenous to the islands; there are feral goats, pigs, horses, cattle, and rats. A fish, called *nato*, and a variety of shrimp are found in the islands' freshwater streams. The marine life in the lagoons and surrounding seas is rich.

Patterns of settlement. On the high islands, homes are scattered through the coconut groves along the coastal roads. Villages are spaced two to three miles apart and typically have a church, government house, school, shop, pastor's home, and a few residences. The contemporary rural house is of concrete construction in a yard shaded by fruit trees, with a separate kitchen made from traditional materials (palm, bamboo) where food is prepared and eaten. On the atolls, the population is usually grouped together in villages located close to the passes through the surrounding reefs. Population and business activity tend to concentrate in the Papeete area. The town consists of the old colonial city (still the business centre), residential areas (often on the heights), and an excellent harbour.

The people. Most of the people throughout the islands may be classed as Polynesian, speaking eastern Polynesian languages (although intermixture has left few pure Polynesians). There are minorities of Chinese, Europeans, and Americans. About 95 percent of the population is Christian. More than one-half is Protestant, about 40 percent is Roman Catholic, and the remainder belongs to various other Christian denominations. The Evangelical Church of French Polynesia is the dominant church.

The economy. Many resources are used for local subsistence, including fruits, products from fishing and planting, and materials for the construction of traditional types of houses and canoes. Pigs, cattle, and chickens are raised for food. The traditional exports—copra and vanilla—have greatly declined, but this loss of revenue has been partially compensated for by the development of fishing, especially with the extension of territorial waters to 200 miles offshore in 1978. Shrimp and oysters are farmed; and the cultured-pearl industry is important, especially on the Tuamotu and Gambier island groups.

The
development of
fishing

Manufactured products include coconut oil, processed foods, printed textiles, construction materials, copper wares, beer and soft drinks, and sandals; traditional handicrafts and boats are made on some of the outer islands. Hydroelectric power plants on Tahiti began service in the early 1980s.

Revenue has been greatly increased by tourism and by an influx of French military personnel to support the nuclear testing facilities in the Tuamotus. Logistical support activities on Tahiti and Hao Atoll have created additional employment.

There have been considerable developments in transportation facilities since the early 1960s, including the construction of a modern port in Papeete, construction of an international airport at Faaa, and development of air services with some of the outlying islands: Moorea, the Leewards, the western Tuamotus, the Marquesas, and the Australs. There is scheduled shipping to other regions in the Pacific, but interisland shipping remains largely dependent on local unscheduled schooner sailings. The road network has been increased to several hundred miles of paved or stone-surfaced roadway.

Administration and social conditions. Represented in the French parliament by two deputies and a senator and placed under French law, the territory is administered locally under the statutes of 1977 and 1984. These provide for a popularly elected territorial assembly, a high commissioner appointed by the French government, and a president and Cabinet selected from the assembly.

Schooling is compulsory to the end of primary school and is conducted largely in government schools, supplemented by mission schools.

Cultural life. Polynesia's cultural and artistic traditions have been misrepresented and to an extent have been reduced to a sort of folklore by the romantic image that Europeans adopted. A local ethnographic museum and a local learned society have contributed to efforts to preserve the territory's cultural heritage. The absence of newspapers in Polynesian languages, the small amount of broadcasting in the Tahitian language, and the nonrecognition of vernacular languages as official languages all threaten what survives of Polynesian culture.

For statistical data on the land and people of French Polynesia, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

Archaeological evidence suggests that the Marquesas Islands may have been settled in about 200 BC from western Polynesia. In subsequent dispersions, Polynesians from the Marquesas migrated to the Hawaiian Islands in about AD 300 and reached the Society Islands by about the 9th century AD. Large chieftainships were formed on Tahiti, Bora-Bora, and Raiatea. Teriaroa, north of Tahiti, was a royal retreat, and Taputapuata, on Raiatea, was the most sacred shrine in the islands.

European contact with the islands of French Polynesia was gradual. The Portuguese navigator Ferdinand Magellan sighted Pukapuka in the Tuamotu group in 1521. The southern Marquesas Islands were discovered in 1595. The Dutch explorer Jacob Roggeveen in 1722 discovered Makatea, Bora-Bora, and Maupiti. Captain Samuel Wallis in 1767 discovered Tahiti, Moorea, and Maiao Iti. The Society Islands were named after the Royal Society, which sponsored the expedition under Captain James Cook that observed from Tahiti the 1769 transit of the planet Venus. Tubuai was discovered on Cook's last voyage, in 1777.

The history of the Society Island groups is virtually that of Tahiti, which was made a French protectorate in 1842 and a colony in 1880. French missionaries went to the Gambier group in 1834, and in 1844 a French protectorate was proclaimed, followed by annexation in 1881. The Austral Islands were also evangelized from Tahiti, and as late as 1888 Rimatara and Rurutu sought British protection, which was refused. They were placed under the French protectorate in 1889 and annexed in 1900. The Tuamotus were part of the kingdom of the Pomare family of Tahiti, which came originally from Fakarava. These islands were claimed as dependencies of Tahiti within the protectorate

by France in 1847 and became part of the colony in 1880. In the Marquesas, Nuku Hiva was annexed to the United States in 1813 by Captain David Porter of the frigate *Essex*, but the annexation was never ratified. French occupation of the group followed the landing of forces from a French warship, requested by the chief of Tahuata (near Hiva Oa). Soon after there was a quarrel with the French; in 1842 the chiefs ceded sovereignty to France.

The islands were administered as the French Colony of Oceania. The colony was ruled by a naval government until 1885, when an organic decree provided for a French governor and Privy Council and for a General Council, representing the islands, that had some control over fiscal policies. The powers of the General Council, however, were cut back in 1899, and in 1903 it was replaced by an advisory council, the function of which was purely administrative. In 1940 the voters on the islands chose to side with the Free French Government of Charles de Gaulle, and many islanders fought alongside Allied armies during World War II. French Polynesia was made an overseas territory of France in 1946. It was provided with a territorial assembly and was allowed to elect one representative to the French National Assembly and one to the French Senate.

In 1957 the French government extended the powers of the local Territorial Assembly. In 1958 Pouvanaa a Oopa, vice president of the Council of Government, announced a plan to secede from France and form an independent Tahitian republic. He was subsequently arrested; the movement collapsed, and local powers were again curtailed. France issued new statutes granting more local autonomy in 1977, but the pro-independence and pro-autonomy parties continued to call for popular election of the president and either more autonomy or outright independence.

In 1963 the French government began the nuclear testing program on Mururoa atoll. Mururoa and neighbouring Fangataufa were ceded to France by the territorial assembly in 1964. In response to worldwide pressure the tests were moved underground on Fangataufa in 1975. In the mid-1980s political parties and environmental-protection and human rights groups united to protest France's continued nuclear testing. In 1985 world attention focused on the area when the French secret service blew up a yacht owned by the Greenpeace environmental group as it was preparing to lead a protest near Mururoa atoll. (F.J.W.)

For later developments in the history of French Polynesia, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

Tonga

Tonga is a constitutional monarchy and a member of the Commonwealth. Its official name is Pule'anga Fakatu'i 'o Tonga, or Kingdom of Tonga. Situated in the south-western Pacific, it consists of 169 islands divided into three main island groups: Tongatapu in the south, Ha'apai in the centre, and Vava'u in the north. Isolated islands include Niuafo'ou, Niuaotoputapu, and Tafahi in the far north and 'Ata in the far south. Tonga's total land area of 290 square miles (750 square kilometres) is dispersed between latitudes 15° to 23° S and longitudes 173° to 177° W. The capital, Nuku'alofa, on the island of Tongatapu, is approximately 1,245 miles (2,000 kilometres) northeast of Auckland, N.Z.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The summit of volcanic undersea mountains forms the two roughly parallel chains of the Tongan islands. Most of the islands of the western chain are classified as high islands because they have been raised well above sea level by repeated volcanic activity. Four of them are still active volcanoes. Some of the islands composed of lava formed by shield volcanoes, such as Late and Kao, have a cone-shaped, hard surface that is not easily eroded. Others, such as Fonuafo'ou (Falcon Island), were formed by more explosive volcanoes, and their surfaces, composed of ash and pumice, have eroded readily.

The low islands of the eastern chain have been capped

Erosion
and coral
growth

by coral polyps and foraminifera (marine organisms that have calcareous shells), which build coral rock and limestone reefs. The continuing growth of coral counteracts the sea's erosion of the reefs and the islands enclosed by them. A protective reef surrounds Tongatapu Island; many islands in the Vava'u group lack such protection and are shrinking.

Tongatapu Island, a raised atoll in the Tongatapu group, is the largest island in Tonga, with an area of 99 square miles, and is the most densely populated. The highest point in Tonga, 3,380 feet (1,030 metres), is on Kao Island in the Ha'apai group. 'Eua Island (Tongatapu group) has an old volcanic ridge rising to 1,078 feet above sea level. The Vava'u group has hills ranging from 500 to 1,000 feet, and Vava'u Island has a fine, large landlocked harbour. The effects of natural erosion are particularly vivid in Vava'u. Rainwater reacting with the carbon dioxide in vegetation acquires acidic properties and dissolves coral and limestone rock, thereby forming caves. The sheer cliffs and sandspits of Vava'u and Nuku'alofa have been caused by the constant action of the waves. There are no rivers in Tonga. There are creeks, however, on 'Eua and on Niuatoputapu, one of the far northern islands. The geologic subsidence of Vava'u, followed by two phases of uplift, resulted in the formation of the Ano Lagoon.

Climate. Tonga has a semitropical climate except in the northernmost islands, where a truly tropical climate prevails. Temperatures range from 60° to 70° F (16° to 21° C) in June and July to 80° F (27° C) in December and January. The mean annual humidity is 77 percent. The mean annual rainfall varies from 63 inches (1,600 millimetres) in Tongatapu to 87 inches in Vava'u; on Niuatoputapu the annual rainfall averages 101 inches. Humidity is higher as the distance from the Equator lessens. The northern islands, which are closest to the Equator, are particularly vulnerable to typhoons, which generally occur between December and April.

Plant and animal life. The well-drained, fertile soils of 'Eua, Kao, Tofua, Late, and the slopes and hilltops of Vava'u support original forests. 'Eua has the greatest number and variety of trees, and the ridge on the eastern side is a forest reserve. Some of the more significant are the hiapo, or paper mulberry, the fau (*Hibiscus tiliaceus*), the coconut, the ngatata, and the toi and tavahi, which constitute a majority of the trees on 'Eua. The sandy, rocky, dry soils of the coasts and the direct exposure to strong winds and salty spray create unfavourable conditions for coastal vegetation. To conserve moisture, plants near the shore have small, waxy, or hairy leaves. Tidal sand and mud flats have swampy areas that support mangroves. Behind the mud flats, trees with buttress roots, such as the *lekileki*, sometimes grow.

Tonga's land birds include doves, rails, starlings, kingfishers, owls, cuckoos, shrikes, bulbuls, purple swamp hens, and swiftlets. The red-breasted musk parrot and the blue-crowned lory, considered by some to be the most beautiful birds in the Pacific, inhabit 'Eua. Island cliffs serve as homes for red-tailed and white-tailed tropic birds. Among the native birds of Niuafu'ou Island is the incubator bird. The common reef heron is a native shore bird. Transient species include the golden plover, wandering tattler, long-billed curlew, and bar-tailed godwit. Tongan waters attract several varieties of seabirds such as noddies, terns, frigate birds, and mutton birds. The village of Kolovai on Tongatapu Island is the home of the fruit bat (often called "flying fox" because of its appearance). The fruit bat clings to large trees by day and flies at night to forage for food.

Human settlement. About three-quarters of the Tongan population live in the three major island groups, and nearly two-thirds live on Tongatapu Island. The urban population has been steadily growing and now accounts for more than a third of the total population. Many Tongans migrate overseas, to the United States and New Zealand in particular.

The majority of the population live in villages. Traditional structures are called *fale*; they are rectangular in shape and have thatched or corrugated tin roofs and sides made of woven coconut leaves, reeds, or timber. Some Tongans reside in South Seas colonial-style wooden homes

with gingerbread trim and outside walls in pastel shades.

Nuku'alofa, the name of which signifies "Abode of Love," has all the amenities of a capital city. It is also a major port of entry and has several wharves and piers. Much of Nuku'alofa's economic activity revolves around coconuts and coconut products. Other ports and commercial centres are Neiafu in the Vava'u group and Pangai in the Ha'apai group.

The people. Tongans are closely related to Samoans and other Polynesians in culture, language, and racial makeup. More than 90 percent of the population claims an original Polynesian ancestry. Contact with Fiji has resulted in the transference of some Melanesian physical characteristics. Inter-marriage with Europeans has become more common, especially as a result of the increasing out-migration of Tongans since the 1970s. Religion is an important aspect of Tongan society, and most Tongan families are members of a church. About 47 percent belong to the Free Wesleyan Church; 16 percent are Roman Catholics; 14 percent belong to the Free Church of Tonga; 9 percent are Mormon; and the remainder belong to smaller denominations. The Tongan language is taught in primary schools and is the official language, in addition to English, which is studied as a second language.

The economy. Agriculture is the mainstay of the Tongan economy. Coconuts, bananas, and vanilla beans constitute the main cash crops, and other important crops include yams, taro, cassava, corn (maize), watermelons, pineapples, and tomatoes. All land is essentially owned by the Crown, but large estates have been divided among the nobles of Tonga. Land is parceled out to peasant proprietors: every male aged 16 or over is entitled to an allotment of 7.5 acres (three hectares) of land for cultivation. Timber production, livestock raising, and fishing also contribute to Tonga's economy.

Manufacturing industries include a plant that produces plastic pipe; several charcoal-producing plants, which export charcoal to New Zealand; canning and corrugated-iron-rolling factories; small handicraft enterprises; and other manufacturing concerns established by local and foreign investors. Crop processing has been undertaken by cooperative societies; the Tonga Feeds Manufacturing Society procures stock feed, and vanilla is processed by the Leimatu'a Vanilla Society located in the Vava'u group. Remittances from Tongans working overseas—especially in New Zealand, the United States, and Australia—and tourism have both contributed significantly to the growth of the Tongan economy.

More than half of Tonga's road network is all-weather roads, almost all of which are located on the two largest islands. Tonga has no railroad. Nuku'alofa and Neiafu

Coconuts germinating on a copra plantation on Lifuka in the Ha'apai Group, Tonga.

(Vava'u) are ports used for external shipping. Copra and bananas are exported from Pangai (Ha'apai group). Regular international air service to New Zealand, Fiji, Western and American Samoa, and Niue is available from Fua'amotu Airport on Tongatapu. Domestic flights are serviced by airports on 'Eua, Ha'apai, Vava'u, Niuafu'ou, and Niuatoputapu.

Administration and social conditions. Tonga's constitution, granted in 1875 by King George Tupou I and amended only slightly since, establishes a constitutional monarchy. The chief executive is the monarch, who appoints a Privy Council. The council consists of the monarch and the Cabinet. The Cabinet has a prime minister, deputy prime minister, six other ministers, and the governors of Ha'apai and Vava'u. The unicameral legislature consists of a speaker, the members of the Cabinet, nine nobles selected by the 33 nobles of Tonga, and nine representatives elected for three-year terms by literate taxpaying males and literate females aged 21 and over. Popularly elected town and district officials are the only form of local government; town officials represent villages, and district officials have authority over groups of villages. The most important administrative divisions are the three island groups.

Education is free for all Tongans, and attendance is compulsory between the ages of six and 14. The government runs primary, secondary, and vocational training schools, including a teacher-training college. Some primary and secondary schools as well as vocational institutions are run by churches. Tongans receive free dental and medical treatment. Although the general health of the population is adequate, several communicable diseases, such as influenza, typhoid, filariasis, and tuberculosis, exist. Family planning aids are disseminated with the help of the United Nations and New Zealand.

Cultural life. Although Western influence has somewhat altered traditions and culture in Tonga, certain Tongan rituals and art forms survive. For example, Tonga shares with Fiji, Samoa, and parts of French Polynesia the elaborate ritual surrounding the drinking of kava. The drink, prepared from the root of a pepper plant, has the properties of a mild narcotic.

Carving was traditionally done by men, but the craftsmanship was inferior to that of other Polynesians, such as the Maori. Carving and other traditional crafts of higher quality have been produced, however, in response to the demands of the tourist market. Women manufacture tapa cloth from bark and weave mats and baskets from several varieties of pandanus leaves. Traditional dancing is an important part of national ceremonies and local village festivities. In the popular paddle dance, called *me'etu'upaki*, dancers carry paddle-shaped boards painted or carved with abstractions of the human body. Other popular dances include the *kailao*, a war dance; the *lakalaka*, a group action song performed while standing; the *ma'ulu'ulu*, an action song performed while seated; and the *tau'olunga*, an individual dance accompanied by singing. An oral tradition persists in Tongan villages in the form of proverbs, religious epics, genealogies, poetry, fables, and myths.

For statistical data on the land and people of Tonga, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

Tonga was first inhabited about 3,000 years ago by Austronesian-speaking people, who made elaborately decorated Lapita ware. From at least the 10th century AD Tonga was ruled by a line of sacred kings and queens, the Tu'i Tonga. About 1470 the reigning Tu'i Tonga transferred his temporal powers to his brother under the title of Tu'i Ha'a Takalaua. A similar transfer of power about 1600 resulted in the creation of a third line of monarchs, the Tu'i Kanokupolu, who eventually became the rulers.

Although some islands were visited by the Dutch navigators Jakob Le Maire and Abel Janszoon Tasman in 1616 and 1643, respectively, effective European contact dates from Captain James Cook's visits between 1773 and 1777. Cook called the Tonga islands the Friendly Islands because the native inhabitants had provided him with necessary

supplies and had given him a warm welcome. The London Missionary Society and a mission of Methodists made unsuccessful attempts to introduce Christianity to Tonga in 1797 and 1822, respectively. A renewed attempt by the Methodist mission in 1826 was successful, and a Roman Catholic mission was established by the Marists in 1842. Between 1799 and 1852 Tonga went through a period of war and disorder. This was finally ended by Taufa'ahau, who had been converted to Christianity in 1831 by the Methodist missionaries. He became Tu'i Kanokupolu and subsequently took the title King George Tupou I in 1845. During the king's long reign (1845-93), Tonga became a unified and independent nation with a modern constitution (1875), legal code, and administrative structure. With Taufa'ahau as its most important convert, Christianity spread rapidly. In separate treaties, Germany (1876), Great Britain (1879), and the United States (1888) recognized Tonga's independence. George I was succeeded by his great-grandson George II, who died in 1918. During his reign the kingdom became a British protectorate (1900) to discourage German advances. Under the treaty with Great Britain (amended in 1905), Tonga agreed to conduct all foreign affairs through a British consul, who had veto power over Tonga's foreign policy and finances. George II was followed by Queen Salote Tupou III, who ruled from 1918 to 1965. She was succeeded by her son Prince Tungi, as Taufa'ahau Tupou IV. In 1970 Tonga regained full control of domestic and foreign affairs and became a fully independent nation within the Commonwealth. (S.L.)

For later developments in the history of Tonga, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

Wallis and Futuna

Wallis and Futuna is a small overseas territory of France consisting of two Pacific island groups separated by an expanse of open ocean. The territory is in western Polynesia and is located south of Tuvalu, west of Western Samoa, and northeast of Fiji. The islands of Melanesia are to the west. The capital is Mata Utu, on Uvea (Wallis).

The island of Wallis takes its European name from its 18th-century British discoverer, Captain Samuel Wallis, but the indigenous name, Uvea, has a much greater antiquity. Neither Uvea nor Futuna should be confused with islands of the same or similar names elsewhere. Uvea is sometimes confused with Ouvéa in the Loyalty Islands near New Caledonia. Futuna has a namesake among the islands of the nation of Vanuatu (formerly the New Hebrides), and, indeed, folklore suggests that both the namesake and Sikaiana Island in the Solomon Islands were settled from Futuna in the pre-European era.

PHYSICAL AND HUMAN GEOGRAPHY

The land. Uvea is a volcanic island, but it is relatively low, with a maximum height of only 476 feet (145 metres). Its total land area is 23 square miles (60 square kilometres). Uvea is surrounded by a barrier reef with 22 uninhabited islets; they have a collective land area of about one square mile, and the highest elevation is 200 feet. The reef is broken by passes that give boats access to the main island, and the area between the reef and the island is a sheltered fishing ground.

Futuna lies a little over 125 miles (200 kilometres) to the southwest, and it has a smaller neighbour, Alofi. Both are volcanic islands. Futuna has an area of about 25 square miles, and volcanic peaks reach a height of 2,493 feet. Alofi's land area is only 11 square miles, and its highest elevation is about 1,198 feet. Futuna and Alofi are separated by a channel of about two miles in width, and both islands are partially sheltered by fringing reefs.

Both Uvea and Futuna islands have good water supplies, as there are numerous streams and wells. Alofi is without fresh water and has no permanent settlements.

The soils of Uvea and Futuna islands are volcanic but of limited fertility, and a number of factors restrict agricultural production. Only about one-fourth of the available land is suitable for cultivation. The system of land tenure has resulted in a fragmentation of land parcels. Tradi-

tional agricultural practices alternate two or three years of cropping with long fallow periods, and there has been a cumulative deterioration of the soil.

The territory's climate is tropical with high humidity. Two seasons are fairly well delineated—a hot, rainy period from November to April during which tropical storms may occur, and a dry, cooler season with trade winds from the southeast during the rest of the year.

Basic subsistence crops have been introduced: coconuts, breadfruit, bananas, taro, cassava, yams, mangoes, and pineapples. The coconut groves on Uvea were destroyed by the rhinoceros beetle in the 1930s, but the pest did not reach Futuna and Alofi. Substantial stands of undisturbed natural forest remain only on Alofi and a small section of Uvea. Otherwise, forests have virtually disappeared, and erosion is a problem on Futuna. Reforestation schemes have been implemented since the early 1960s.

All of the territory's land mammals have been introduced. Pigs are of ceremonial importance and very highly valued. The Roman Catholic mission keeps a small herd of cattle, but the small islands lack suitable pasture land. Chickens constitute a minor part of the diet, and dogs and cats are kept as pets. Fish and other marine fauna provide the bulk of dietary protein.

Villages are dispersed on the islands, mainly on the coast. There are no real urban areas. The international airport is located at Hihifo on northern Uvea.

The people. The indigenous people are Polynesians, but there are significant differences between the languages and peoples of Uvea and of Futuna islands. It appears that Uvea was settled about 3,000 years ago, and the people were subsequently conquered by Tongans. As a consequence, cultural, historical, and linguistic ties link Uvea and the Tongan archipelago. In contrast, local folklore suggests that Futunans had their origins in Samoa; their language is related to that of Samoa, and the Futunans share many cultural traits with Samoa. While the people of the islands have long been governed by a French administration and all profess the Roman Catholic faith, they do not share a common identity. Futuna is reluctantly tied to Uvea, and its people have expressed a desire to have separate territorial status.

The population of Uvea comprises two-thirds of the territory's total, and the rest live on Futuna. The Uvean and Futunan population in Nouméa, New Caledonia, numbers slightly more than those who live on the home islands. The majority in New Caledonia are Uveans. Opportunities for employment abroad and limited options combined with population pressures at home have caused the exodus. The expatriates are an asset as long as they remain abroad, but they would place an intolerable burden on local resources if they were to return home.

The number of French expatriates in Wallis and Futuna has always been small. Of the total resident population in the islands, only a few hundred are of European descent. Nonetheless, French is the official language of administration.

The economy. Most of the people of Wallis and Futuna are subsistence agriculturalists, and primary production is restricted to the basic subsistence crops. The notion of selling produce from the land is contrary to traditional custom, wherein items are bartered and not sold. Similarly, fish are caught for the immediate needs of family, near kin, and neighbours. Most are taken in sheltered areas within the fringing reef, and little fishing is done in the open sea.

Wallis and Futuna is truly resource-poor, and very little revenue is earned from exports. A small amount of trochus shell is exported to New Caledonia.

Differences between Uvea and Futuna islands give advantage to the Uveans. The French administration is located on Uvea, and that island has the better infrastructure. Roads and public services are superior, most households have running water and electricity, and videotapes are available from Nouméa, New Caledonia. The administration is the island's largest employer. In contrast, Futuna is somewhat isolated, without roads or cars, and administrative positions are scarce.

The international airport on Uvea is linked by jet service

to Fiji and New Caledonia, and a small plane operates between Uvea and Futuna islands. A cargo vessel travels between the islands and Nouméa about a dozen times a year.

Administration and social conditions. In late 1959, by an overwhelming majority, the people of Wallis and Futuna voted to change their political status from that of a protectorate to that of an overseas territory of the French Republic. Legislation passed two years later incorporated traditional powers into the new administrative arrangement.

The territory is divided into three districts that correspond to three traditional political divisions, or kingdoms (more accurately, paramount chieftaincies)—one that includes all of Uvea and two on Futuna. A French-appointed high administrator (*administrateur supérieur*) is the chief executive officer of the territory and serves as the president of the Territorial Council. The council includes the three kings and three others appointed by the president with the approval of the Territorial Assembly. The council decides on matters of general policy.

The Territorial Assembly has legislative power and consists of 20 members (13 from Uvea and seven from Futuna) elected for five-year terms by universal suffrage. The high administrator has fairly broad veto powers over actions of the Assembly. As an integral part of France, the territory is represented in and elects a deputy and a senator to the French national parliament.

Before the islands became an overseas territory, schools in Wallis and Futuna were operated tuition-free by the Roman Catholic mission. In 1961 the education system came under the French Ministry of National Education. Today, elementary and lower-secondary schools remain free and available in the territory; higher levels of education must be pursued in New Caledonia and metropolitan France. Free health services are also available at dispensaries on both Uvea and Futuna islands and at a hospital on Uvea.

HISTORY

The Dutch explorers Jakob Le Maire and Willem Corneliszoon Schouten sighted Futuna in 1616 during the early voyages of exploration in the Pacific. A lapse of 151 years occurred before Captain Samuel Wallis discovered Uvea in 1767. There was another lapse of more than 50 years before the whaling industry reached the area, in the 1820s, and Europeans began to make regular calls at both islands.

French Marist priests arrived as missionaries in the 1830s. They achieved considerable success within a decade and have remained an important force in the politics of the island group. Protestants never mounted a serious challenge, and the inhabitants of the islands were spared the religious conflicts that were common elsewhere in the Pacific.

As early as the 1840s, the islanders petitioned for French protection, but France was slow to respond; Wallis became a French protectorate in 1887, and Futuna in the following year. Over the next five decades, the French administration became well-entrenched and ruled the colony with a relatively firm hand.

In 1942, in its preparations for the Japanese invasion of the American central Pacific, the United States based 6,000 troops on Uvea, and within a short time they built a system of roads, two landing strips, and anchoring facilities in the lagoon. These developments still form the basis of the island's infrastructure.

A permanent change in the colony's status occurred in 1959 when the islanders elected to become an overseas territory of France. In subsequent elections, the people of Wallis and Futuna have demonstrated conservatism, opposing Socialist governments in France and any proposal for a change in their dependent status. (R.C.Ki.)

Western Samoa

Western Samoa, a former United Nations trust territory and a self-governing nation since 1962, consists of the western part of the Samoan archipelago. Its islands, situated in the south-central Pacific Ocean about 2,700 miles (4,300 kilometres) east of Australia and 2,200 miles southwest of

the Hawaiian Islands, are among the westernmost islands of Polynesia. Western Samoa consists of nine islands west of the 171° W meridian. American Samoa, its closest neighbour and an unincorporated territory of the United States, consists of the six Samoan islands east of that meridian in addition to Swains Island, a coral atoll 280 miles to the north.

Western Samoa has a total land area of 1,093 square miles (2,830 square kilometres). It includes the inhabited islands of Upolu, Savai'i, Manono, and Apolima and the uninhabited islands of Fanuatapu, Namu'a, Nu'utele, Nu'ulua, and Nu'usafee. The capital of Western Samoa is Apia, on Upolu.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The islands of Western Samoa are rocky and were formed by volcanic activity that progressed from east to west within the past 7,000,000 years. The largest island of Western Samoa is Savai'i (659 square miles); its highest peak is Silisili (6,099 feet [1,859 metres]). There have been two eruptions from Savai'i volcanoes in historic times, the more recent in 1911. The other large island is Upolu (432 square miles), which has five uninhabited, offshore islets. Manono and Apolima are smaller islands that lie between the two main islands.

Except where the shorelines are marked by cliffs formed by recent lava flows, all of the islands are ringed by coral reefs and shallow lagoons. The volcanic soils are easily exhausted by farming but support lush vegetation, which varies from plantations of taro, coconuts, and other food crops on the coast to rain forest and mountain rain (or mist) forest farther inland.

Climate. The climate is tropical. Rainfall varies from more than 100 inches (2,540 millimetres) on the northern and western coasts to 300 inches inland, but porous soils and rocks make water supplies unreliable. Hence, coastal wells are the only water source for much of the rural population. Temperatures are unusually constant, the monthly mean varying only 1.2° F (0.7° C) from an average of 79° F (26° C). The southeast trade winds prevail, varying occasionally to northerlies during the wet season, from November to March, when severe storms are liable to occur.

Animal life. The islands are not rich in animal life. Nevertheless, of the 53 species of birds, at least 16 are unique, including a rare tooth-billed pigeon. The only native mammals are the flying fox and smaller bats. There are several species of lizards and two harmless snakes of the boa family. Rats, wild cattle, and pigs have been introduced. There are centipedes and millipedes, scorpions, spiders, and a rich insect life.

Settlement patterns. Most people live in coastal villages. Apia, on the northern coast of Upolu Island, is the nation's only town. It is the main port and administrative and commercial centre and has grown rapidly because it offers employment opportunities. Since World War II many Western Samoans have migrated to the United States and New Zealand.

A typical village features *fale*—traditional oval-shaped houses with thatched or corrugated tin roofs and open sides—clustered around the village green, or *malae*, but these are giving way to rectangular timber or concrete-block houses with walls and windows.

The people. The Samoans are of eastern Polynesian stock. Their language, believed to be the oldest of the Polynesian tongues, is closely related to the Maori, Tahitian, Hawaiian, and Tongan languages. English is also widely spoken. Within the villages, close kinship ties have traditionally bound individuals into a sternly collectivist society. Elected family leaders called matai form village or district councils to administer group affairs. Extended blood ties traditionally have linked family or village groups; beyond the social framework of well-regulated village life a network of allegiances arose, with the major families striving for supremacy and regularly plunging the islands into warfare. The material culture was utilitarian, and most artifacts are unadorned. There appears to have been no dominant priestly class; family elders performed the rituals of a pantheistic religion.

While European contact and a cash economy have produced some changes in values and traditional authority, preservation of the culture has become an important goal among Western Samoan leaders; many outward features of rural life have thus remained virtually unchanged. The Christian churches were easily absorbed into the village social structure; some of the remotest villages have churches of cathedral proportions. The Congregational Christian Church in Samoa (formerly the London Missionary Society) is predominant, followed by the Roman Catholic and Methodist faiths and smaller groups of the Church of Jesus Christ of Latter-day Saints and Seventh-day Adventists.

The economy. *Agriculture and industry.* Copra and cacao account for a majority of the exports, followed by bananas, taro, coffee, and other fruits. Growing fishery and lumber industries have made increasingly large economic contributions. In the manufacturing sector Western Samoa has diversified beyond the traditional coconut and handicrafts to produce clothing and footwear, animal feed, tropical beverages, beer, and coconut by-products. Electrical energy production has shifted away from thermal generation, which requires imported fuels, and toward hydroelectric generation.

Transportation. About one-fifth of all roadways in Western Samoa are paved. Regular shipping services link the main islands with ports abroad; international airlines operate flights to and from American Samoa, Fiji, New Zealand, and Australia. The principal trade and transport links are with Hawaii and California to the north and Fiji, New Zealand, and Australia to the south.

Administration and social conditions. *Government.* In 1962 Western Samoa became the first independent Polynesian state, and in 1970 it joined the Commonwealth. The constitution provides for parliamentary government but blends Samoan and English traditions. There were originally two heads of state, with the provision that when one died (which happened in 1963) the other would continue as sole head of state for life, after which the head of state would be elected by Parliament for a five-year term from among the four "royal son" titleholders. The prime minister is elected by Parliament and appoints a Cabinet of eight other ministers from elected members.

The Parliament has 47 members. Two represent the Indi-

Volcanic eruptions

Cluster of traditional *fale* and a present-day rectangular house with walls and windows in the village of Papa, Savai'i, Western Samoa.

vidual Voters, the population of mixed-blood citizens, who vote by universal suffrage. The remaining 45 are Samoan matai, who alone are eligible as candidates or voters; but they in their turn have been chosen by consensus of their entire family. In each village, matai form a council to run their own affairs.

Education. Education in Western Samoa is optional, but most children attend school. Selected pupils receive higher education at government- or mission-run secondary, vocational, or teacher-training institutions. The University of the South Pacific has its School of Agriculture at Alafua. Western Samoa has established its own university, the National University of Samoa, but most high school graduates go overseas for their university education.

(P.R.C./A.We.)

For statistical data on the land and people of Western Samoa, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

Polynesians settled in the Samoan islands in about 1000 BC, as indicated by shards of decorated Lapita ware found in Mulifanua Lagoon on Upolu. Characteristics of the Samoan language indicate that the settlers probably came from Tonga. Pottery manufacture ceased by about AD 200, by which time Samoa had become the centre of much of the settlement of eastern Polynesia. Contact between Samoans, Tongans, and Fijians continued and is recorded in hundreds of legends and genealogies.

Europeans began to arrive in the first half of the 18th century, and the Samoans welcomed them at first for the technology and goods they brought. John Williams, a member of the London Missionary Society, arrived to establish a Christian mission in 1830. He converted Malietoa Vainu'upo, who had just conquered all of Samoa, and the entire population soon converted. By the 1850s a foreign settlement had sprung up around Apia Harbour. As more settlers arrived from the United States, Great Britain, and Germany and tried to persuade their respective governments to annex Samoa, the Samoans began to resist. Rival Samoan leaders played the foreign powers against each other in pursuit of their factional wars. Urged on by their nationals in Samoa, the three powers became more embroiled in Samoa's affairs. They frustrated attempts by the Samoans to establish a national government. In 1878 the United States signed a treaty for the establishment of a naval station in Pago Pago Harbor. Great Britain and Germany signed similar agreements the following year. War between the three powers in 1889 was prevented only by a great hurricane, which sank six of their warships. They signed the Berlin Act to provide for the neutrality of the islands and to avoid further conflict. Finally, in 1899, eastern Samoa was annexed by the United States and the western region, by Germany. The Samoan people were not consulted, and many resented it deeply.

In Western Samoa the drive for political independence began in 1908 with the Mau a Pule, a movement led by the orator chief, Lauaki Namulau'ulu, during the German administration. The Samoan leaders were dissatisfied with the German governor's attempts to change the *fa'a Samoa* (the Samoan way of life) and centralize all authority in his hands. The governor called in warships, and Lauaki and nine of his leading supporters surrendered. They were tried and exiled to Saipan in the Mariana Islands.

On Aug. 30, 1914, New Zealand troops occupied Western Samoa and met no resistance from the Germans. For the next few years the Samoans did not resist New Zealand rule. The influenza epidemic of 1918, however, which killed more than 20 percent of the population, prompted accusations of official negligence and united most of the people against the New Zealand administration. In 1920 the League of Nations granted New Zealand a mandate over Western Samoa. When the New Zealand-appointed governor tried to further undermine the power of the matai leadership and that of the local business community, an organized political movement emerged. The movement, called the Mau ("Strongly Held View"), was led by O.F. Nelson, whose mother was Samoan. New Zealand claimed that part-Europeans such as Nelson were

misleading the Samoans, and the Mau was outlawed. New Zealand troops were sent in, and Nelson was exiled to New Zealand. On Dec. 28, 1929, during a peaceful Mau demonstration in Apia, Tupua Tamasese Lealofi III, one of the Mau leaders, and other Mau supporters were shot by New Zealand troops. This only strengthened the Mau's determination to win their struggle.

In 1935 the first Labour government came to power in New Zealand, and it recognized the Mau as a legal political organization. The Samoan independence movement continued until 1962, when Western Samoa regained its political independence.

(A.We.)

For later developments in the history of Western Samoa, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

BIBLIOGRAPHY

Physical and human geography. RON CROCOMBE, *The South Pacific* (1983); and FREDERICA M. BUNGE and MELINDA W. COOKE (eds.), *Oceania, a Regional Study*, 2nd ed. (1985), provide comprehensive information. Large-scale maps are found in *Atlas of the South Pacific*, 2nd ed. (1986), published by the New Zealand government. HEROLD J. WIENS, *Atoll Environment and Ecology* (1962), explores the physical characteristics of Pacific Islands environments. The classic demographic study is NORMA MCARTHUR, *Island Populations of the Pacific* (1967, reprinted 1983); see also VERN CARROLL (ed.), *Pacific Atoll Populations* (1975). On physical anthropology, see WILLIAM HOWELLS, *The Pacific Islanders* (1973). F.R. FOSBERG (ed.), *Man's Place in the Island Ecosystem* (1963), and DOUGLAS L. OLIVER, *Oceania: The Native Cultures of Australia and the Pacific Islands*, 2 vol. (1989), survey aspects of Pacific Islands societies. UNIVERSITY OF THE SOUTH PACIFIC, INSTITUTE OF PACIFIC STUDIES, *Pacific Tourism, as Islanders See It* (1980), analyzes the impact of tourism. Current writings about the area are found in *Pacific Islands Business* (monthly, Fiji); *Pacific Magazine* (bimonthly, Hawaii); and *Pacific Islands Monthly* (Australia). JOHN CARTER (ed.), *Pacific Islands Yearbook*, 15th ed. (1984), is a detailed reference work on contemporary conditions and events. For further research, see C.R.H. TAYLOR, *A Pacific Bibliography: Printed Matter Relating to the Native Peoples of Polynesia, Melanesia, and Micronesia*, 2nd ed. (1965); and *Bibliographie de l'Océanie*, published irregularly by the Société des Océanistes in Paris.

History. The best general history of the precolonial Pacific is K.R. HOWE, *Where the Waves Fall: A New South Sea Island History from First Settlement to Colonial Rule* (1984). For early periods, see JOHN TERRELL, *Prehistory in the Pacific Islands: A Study of Variation in Language, Customs, and Human Biology* (1986); PATRICK VINTON KIRCH (ed.), *Island Societies: Archaeological Approaches to Evolution and Transformation* (1986); PETER BELLWOOD, *Man's Conquest of the Pacific: The Prehistory of Southeast Asia and Oceania* (1978) and *The Polynesians: Prehistory of an Island People*, rev. ed. (1987); JANET DAVIDSON, *The Prehistory of New Zealand* (1984); and M.P.K. SORRENSON, *Maori Origins and Migrations: The Genesis of Some Pakeha Myths and Legends* (1979). ROBERT D. CRAIG and FRANK P. KING (eds.), *Historical Dictionary of Oceania* (1981), is a comprehensive reference source. For current writings, see *Journal of Pacific History* (semiannual, Australia).

The following histories focus on special topics: FRANCIS X. HEZEL, *The First Taint of Civilization: A History of the Caroline and Marshall Islands in Pre-Colonial Days, 1521-1885* (1983); JOHN GARRETT, *To Live Among the Stars: Christian Origins in Oceania* (1982); and F.J. WEST, *Political Advancement in the South Pacific: A Comparative Study of Colonial Practice in Fiji, Tahiti, and American Samoa* (1961, reprinted 1984). Biographies that date from European contact can be found in J.W. DAVIDSON and DERYCK SCARR (eds.), *Pacific Islands Portraits* (1970); and DERYCK SCARR (ed.), *More Pacific Islands Portraits* (1978).

The development of Pacific trade and the establishment of exploitative industries are discussed in DOROTHY SHINEBERG, *They Came for Sandalwood* (1967), the first full-length study of trade in the Pacific; H.E. MAUDE, *Of Islands and Men: Studies in Pacific History* (1968); O.H.K. SPATE, *The Spanish Lake* (1979), *Monopolists and Freebooters* (1983), and *Paradise Found and Lost* (1989); MASLYN WILLIAMS and BARRIE MACDONALD, *The Phosphateers: A History of the British Phosphate Commissioners and the Christmas Island Phosphate Commission* (1985); K. BUCKLEY and K. KLUGMAN, *The History of Burns Philp: The Australian Company in the South Pacific* (1981); PETER CORRIIS, *Passage, Port, and Plantation: A History of Solomon Islands Labour Migration, 1870-1914* (1973); and MICHAEL MOYNAGH, *Brown or White?: A History of the Fiji Sugar Industry, 1873-1973* (1981).

Politics is studied in PETER LARMOUR and ROPATE QALO

Settlers in
Western
Samoa

(eds.), *Decentralization in the South Pacific: Local, Provincial, and State Government in Twenty Countries* (1985); UENTABO FAKAOFU NEEMIA, *Cooperation and Conflict: Costs, Benefits, and National Interests in Pacific Regional Cooperation* (1986), discussing national self-realization; LEONARD MASON and PATRICIA HERENIKO (eds.), *In Search of a Home* (1987), reports by island authors on problems of immigrants in urban centres; HARUHIRO FUKUI (ed.), *Political Parties of Asia and the Pacific*, 2 vol. (1985), an encyclopaedic source; FRANK P. KING (ed.), *Oceania and Beyond: Essays on the Pacific Since 1945* (1976); and DIRK ANTHONY BALLENDORF and FRANK P. KING (eds.), *Oceania Today: Towards New Directions and Political Self-Actualization* (1980). See also STEWART FIRTH, *Nuclear Playground* (1987).

Traditional cultures. ANDREW P. VAYDA (ed.), *Peoples and Cultures of the Pacific: An Anthropological Reader* (1968); ROBERT KIRK and EMÖKE SZATHMARI (eds.), *Out of Asia: Peopling the Americas and the Pacific* (1985), which explores the demography and language; and LYNDALL RYAN, *The Aboriginal Tasmanians* (1981). Cultural life, beliefs, and customs are examined in LENORE MANDERSON (ed.), *Shared Wealth and Symbol: Food, Culture, and Society in Oceania and Southeast Asia* (1986). Other works include WILLIAM A. FOLEY, *The Papuan Languages of New Guinea* (1986), a treatment of the most complex linguistic area of the world; EMILIANA AFEAKI, RON CROCOMBE, and JOHN MCCLAREN (eds.), *Religious Cooperation in the Pacific Islands* (1983); A.C. HADDON and JAMES HORNELL, *Canoes of Oceania* (1975); and BEN R. FINNEY (comp.), *Pacific Navigation and Voyaging* (1976). The arts are surveyed in SIDNEY M. MEAD (ed.), *Exploring the Visual Art of Oceania: Australia, Melanesia, Micronesia, and Polynesia* (1979); ADRIENNE L. KAEPLER, *Artificial Curiosities: Being an Exposition of Native Manufactures Collected on the Three Pacific Voyages of Captain James Cook, R.N.* (1978); and ROLAND W. FORCE and MARYANNE FORCE, *The Fuller Collection of Pacific Artifacts* (1971). MILES M. JACKSON (ed.), *Pacific Island Studies: A Survey of the Literature* (1986).

Melanesian cultures. H.C. BROOKFIELD, *Melanesia: A Geographical Interpretation of an Island World* (1971), is a comparative survey of geography. R.J. MAY and HANK NELSON (eds.), *Melanesia, Beyond Diversity*, 2 vol. (1982), presents general information. An excellent summary is ANN CHOWNING, *An Introduction to the Peoples and Cultures of Melanesia*, 2nd ed. (1977). On material culture, B.A.L. CRANSTONE, *Melanesia: A Short Ethnography* (1961), remains useful. A fine study of a particular people is MARIE REAY, *The Kuma: Freedom and Conformity in the New Guinea Highlands* (1959). Syntheses and collections of papers on aspects of society and culture in New Guinea include PAULA BROWN, *Highland Peoples of New Guinea* (1978); PAULA BROWN and GEORGEDA BUCHBINDER (eds.), *Man and Woman in the New Guinea Highlands* (1976); ANDREW STRATHERN (ed.), *Inequality in New Guinea Highland Societies* (1982); JERRY W. LEACH and EDMUND LEACH (eds.), *The Kula: New Perspectives on Massim Exchange* (1983); R.M. GLASSE and M.J. MEGGITT (eds.), *Pigs, Pearls, and Women: Marriage in the New Guinea Highlands* (1969); GILBERT H. HERDT (ed.), *Rituals of Manhood: Male Initiation in Papua New Guinea* (1982), and *Ritualized Homosexuality in Melanesia* (1984); DAN JORGENSEN (ed.), *Concepts of Conception: Procreation Ideologies in Papua New Guinea* (1983); PAULA G. RUBEL and ABRAHAM ROSMAN, *Your Own Pigs You May Not Eat: A Comparative Study of New Guinea Societies* (1978); and C.A. GREGORY, *Gifts and Commodities* (1982). Other works include MICHELE STEPHEN (ed.), *Sorcerer and Witch in Melanesia* (1987); L.L. LANGNESS and JOHN C. WESCHLER (eds.), *Melanesia: Readings on a Culture Area* (1971); MARILYN STRATHERN (ed.), *Dealing with Inequality: Analysing Gender Relations in Melanesia and Beyond* (1987); P. LAWRENCE and M.J. MEGGITT (eds.), *Gods, Ghosts, and Men in Melanesia: Some Religions of Australian New Guinea and the New Hebrides* (1965); and PETER WORSLEY, *The Trumpet Shall Sound: A Study of "Cargo" Cults in Melanesia*, 2nd ed. (1968).

Micronesian cultures. A general overview is offered in WILLIAM H. ALKIRE, *An Introduction to the Peoples and Cultures of Micronesia*, 2nd ed. (1977). JOHN L. FISCHER, *The Eastern Carolines* (1957, reprinted 1966), is a regional study. Special topics are discussed in MARK R. PEATTIE, *Man'yo: The Rise and Fall of the Japanese in Micronesia, 1885-1945* (1988); DONALD F. MCHENRY, *Micronesia, Trust Betrayed: Altruism vs. Self Interest in American Foreign Policy* (1975); and DAVID NEVIN, *The American Touch in Micronesia* (1977). A good island history is DAVID HANLON, *Upon a Stone Altar: A History of the Island of Pohnpei to 1890* (1988). For further study, see MAC MARSHALL and JAMES D. NASON, *Micronesia, 1944-1974: A Bibliography of Anthropological and Related Source Materials* (1975).

Polynesian cultures. The following works treat the development of Polynesian cultures: IRVING GOLDMAN, *Ancient Poly-*

nesian Society (1970); JESSE D. JENNINGS (ed.), *The Prehistory of Polynesia* (1979); ROBERT BOROFKY, *Making History: Pukapukan and Anthropological Construction of Knowledge* (1987); PATRICK VINTON KIRCH, *The Evolution of the Polynesian Chiefdoms* (1984); and ANTHONY HOOPER and JUDITH HUNTSMAN (eds.), *Transformations of Polynesian Culture* (1985).

Major political units of Melanesia. *Fiji:* On geography and demography, see R. GERARD WARD, *Land Use and Population in Fiji* (1965). Socioeconomic aspects are studied in CYRIL S. BELSHAW, *Under the Ivi Tree: Society and Economic Growth in Rural Fiji* (1964); H.C. BROOKFIELD, F. ELLIS, and R.G. WARD, *Land, Cane, and Coconuts* (1985); and R.F. WATTERS, *Koro: Economic Development and Social Change in Fiji* (1969). Traditional Fijian society and 20th-century change are discussed in R.R. NAYACAKALOU, *Leadership in Fiji* (1975); JOHN NATION, *Customs of Respect: The Traditional Basis of Fijian Communal Politics* (1978); and G.K. ROTH, *Fijian Way of Life*, 2nd ed. (1973). R.A. DERRICK, *History of Fiji* (1946), is a pioneering study and an excellent introduction. DERYCK SCARR, *Fiji, a Short History* (1984), gives a general account. PETER FRANCE, *The Charter of the Land: Custom and Colonization in Fiji* (1969), deals with the foundations of colonial policy. BRUCE KNAPMAN, *Fiji's Economic History, 1874-1939: Studies of Capitalist Colonial Development* (1987), examines the colonial economy. On the history of Indians in Fiji, see K.L. GILLION, *Fiji's Indian Migrants: A History to the End of Indenture in 1920* (1962), and *The Fiji Indians: Challenge to European Dominance, 1920-1946* (1977). See also ADRIAN C. MAYER, *Peasants in the Pacific: A Study of Fiji Indian Rural Society*, 2nd ed. (1973). The political situation is outlined in BRIJ V. LAL (ed.), *Politics in Fiji: Studies in Contemporary History* (1986); and the coup is discussed in BRIJ LAL, *Power and Prejudice: The Making of the Fiji Crisis* (1988).

New Caledonia: OFFICE DE LA RECHERCHE SCIENTIFIQUE ET TECHNIQUE OUTRE-MER, *Atlas de la Nouvelle-Calédonie et dépendances* (1981), gives an account of the territory's development, with detailed maps. *Comptes économiques* (annual), and INSTITUT NATIONAL DE LA STATISTIQUE ET DES ÉTUDES ÉCONOMIQUES, FRANCE, *Résultats du recensement de la population de la Nouvelle Calédonie* (1984), are useful official publications. Political and social affairs are the subject of VIRGINIA THOMPSON and RICHARD ADLOFF, *The French Pacific Islands: French Polynesia and New Caledonia* (1971); MYRIAM DORNOY, *Politics in New Caledonia* (1984); and ALAN WARD, *Land and Politics in New Caledonia* (1982). Sociological studies include J.M. KOHLER, *Colonie ou Démocratie* (1987); J.M. KOHLER and P. PILLO, *Impact de l'opération café en milieu mélanésien* (1982); J.M. KOHLER and LOÏC J.D. WACQUANT, *L'École inégale: éléments pour un de sociologie de l'école en Nouvelle-Calédonie* (1985); and K.R. HOWE, *The Loyalty Islands: A History of Culture Contacts, 1840-1900* (1977). ALAIN SAUSSOL, *L'Héritage: essai sur le problème foncier mélanésien en Nouvelle-Calédonie* (1979); and PIERRE GASCHER, *La Belle au bois dormant: regards sur l'administration coloniale en Nouvelle-Calédonie de 1874 à 1894* (1974), provide accounts of French settlement. The most comprehensive history is JOHN CONNELL, *New Caledonia or Kanaky? The Political History of a French Colony* (1987).

Papua New Guinea: The best general work is still the book by H.C. Brookfield, cited at the beginning of the *Melanesian cultures* section. Many aspects of European exploration are included in JAMES SINCLAIR, *Kiap: Australia's Patrol Officers in Papua New Guinea* (1981). Essential historical coverage is provided in J.L. WHITTAKER et al. (eds.), *Documents and Readings in New Guinea History: Pre-History to 1889* (1975). J.A. BALLARD (ed.), *Policy-Making in a New State: Papua New Guinea, 1972-1977* (1981), examines political decision making; and the Melanesians' view of change is discussed in GERNOT FUGMANN (ed.), *Ethics and Development in Papua New Guinea* (1986). Among the best anthropological works are LAWRENCE S. GROSSMAN, *Peasants, Subsistence Ecology, and Development of the Highlands of Papua New Guinea* (1984); ROY A. RAPAPORT, *Pigs for the Ancestors: Ritual in the Ecology of a New Guinea People*, new ed. (1984); and MARILYN STRATHERN, *Women in Between: Female Roles in a Male World: Mount Hagen, New Guinea* (1972). FRAISER MCCONNELL, *Papua New Guinea* (1988), is an informative bibliography.

Solomon Islands: PATRICK VINTON KIRCH and D.E. YEN, *Tikopia: The Prehistory and Ecology of a Polynesian Outlier* (1982); JUDITH A. BENNETT, *Wealth of the Solomons: A History of a Pacific Archipelago, 1800-1978* (1987); DAVID HILLIARD, *God's Gentlemen: A History of the Melanesian Mission, 1849-1942* (1978); ROGER M. KEESING and PETER CORRISS, *Lightning Meets the West Wind: The Malaita Massacre* (1980); HUGH LARACY, *Marists and Melanesians: A History of Catholic Missions in the Solomon Islands* (1976); HUGH LARACY (ed.), *Pacific Protest: The Maasina Rule Movement, Solomon Islands, 1944-1952* (1983); and DEBORAH WAITE, *Art of the Solomon Islands:*

From the Collection of the Barbier-Müller Museum (1983). For further study, see SALLY EDRIDGE (comp.), *Solomon Islands Bibliography to 1980* (1985).

Vanuatu: The standard bibliography is PATRICK O'REILLY, *Bibliographie méthodique, analytique et critique des Nouvelles-Hébrides* (1958); his *Hébridais: répertoire bio-bibliographique des Nouvelles-Hébrides* (1957), provides short sketches of some of the persons (principally European) in Vanuatu's colonial past. See also JOSÉ GARANGER, *Archaeology of the New Hebrides: Contribution to the Knowledge of the Central Islands* (1982; originally published in French, 1972), an account of the excavation of Roy Mata's burial site; MICHAEL ALLEN (ed.), *Vanuatu: Politics, Economics, and Ritual in Island Melanesia* (1981), comparative ethnographic studies; UNIVERSITY OF THE SOUTH PACIFIC. INSTITUTE OF PACIFIC STUDIES, *Vanuatu* (1980), with contributions by leading ni-Vanuatu figures; JEREMY MACCLANCY, *To Kill a Bird with Two Stones: A Short History of Vanuatu* (1981), a survey; RON ADAMS, *In the Land of Strangers: A Century of European Contact with Tanna, 1774-1874* (1984), an account of the first hundred years of European contact; and JEAN GUIART, *Un Siècle et demi de contacts culturels à Tanna, Nouvelles-Hébrides* (1956), on the origins and development of the John Frum cargo cult.

Major political units of Micronesia. *Guam:* LAURA THOMPSON, *Guam and Its People*, 3rd rev. ed. (1947, reprinted 1969), remains a valuable source. An overview of economics, politics, and industry is given in WILLIAM LUTZ, *Guam* (1987). For history, see PAUL CARANO and PEDRO C. SANCHEZ, *A Complete History of Guam* (1964); TIMOTHY P. MAGA, *Defending Paradise: The United States and Guam, 1898-1950* (1988); and ROBERT F. ROGERS, *Guam's Commonwealth Effort 1987-1988* (1988). Guam in World War II is discussed in TONY PALOMO, *An Island in Agony* (1984).

Kiribati: TONY WHINCUP, *Nareau's Nation: A Portrait of the Gilbert Islands* (1979), offers insights into modern life. ROSEMARY GRIMBLE (ed.), *Migrations, Myth, and Magic from the Gilbert Islands: Early Writings of Sir Arthur Grimble* (1972), gives an account of myth, legends, and traditions. See also GERD KOCH, *The Material Culture of Kiribati* (1986; originally published in German, 1965); ALAIMA TALU et al., *Kiribati: Aspects of History* (1979); ALBERT F. ELLIS, *Ocean Island and Nauru: Their Story* (1935); and BARRIE MACDONALD, *Cinderellas of the Empire: Towards a History of Kiribati and Tuvalu* (1982), is comprehensive.

Marshall Islands: ALEXANDER SPOEHR, *Majuro: A Village in the Marshall Islands* (1949, reprinted 1973); and ROBERT C. KISTE, *The Bikinians: A Study in Forced Migration* (1974), describe the ethnology, anthropology, and social conditions.

Micronesia: For a geographic survey, see KENNETH BROWER, *Micronesia, the Land, the People, and the Sea* (1981); and WILLIAM H. STEWART, *Explorer's Atlas of Tourist Maps for the Federated States of Micronesia, Pacific Ocean: Kosrae, Ponape, Truk, and Yap* (1982). Other sources include STEVEN C. SMITH, *The Federated States of Micronesia: An Emerging Nation: An Overview for Peace Corps Volunteers* (1986); and AUSTIN RANNEY and HOWARD R. PENNIMAN, *Democracy in the Islands: The Micronesian Plebiscites of 1983* (1985).

Nauru: General surveys are found in the titles cited in the beginning section of this bibliography. See also RON CROCOMBE and AHMED ALI (eds.), *Politics in Micronesia* (1983); BARRIE MACDONALD, *In Pursuit of the Sacred Trust: Trusteeship and Independence in Nauru* (1988); and the work by M. Williams and B. Macdonald cited in the *History* section.

Northern Mariana Islands: For information on the Northern Mariana Islands, see the works by Francis X. Hezel, Frank P. King, and Dirk Anthony Ballendorf, cited above under *History*, and the works by Mark R. Peattie, Donald F. McHenry, and David Nevin, under *Micronesian cultures*.

Palau: DOUGLAS FAULKNER, *This Living Reef* (1974), is an illustrated survey of the marine environment. See also DOUGLAS OSBORNE, *The Archeology of the Palau Islands: An Intensive Survey* (1966); and GEORGE J. GUMERMAN, DAVID SNYDER, and W. BRUCE MASSE, *An Archaeological Reconnaissance in the Palau Archipelago, Western Caroline Islands, Micronesia* (1981). R.E. JOHANNES, *Words of the Lagoon: Fishing and Marine Lore in the Palau District of Micronesia* (1981); ROLAND W. FORCE and MARYANNE FORCE, *Just One House: A Description and Analysis of Kinship in the Palau Islands* (1972); and H.G. BARNETT, *Being a Palauan* (1959, reissued 1979), are anthropological accounts. DANIEL J. PEACOCK, *Lee Boo of Belau: A Prince in London* (1987), is the story of the first Palauan to visit the West. EDWARD C. BARNARD, *Naked and a Prisoner: Captain Edward C. Barnard's Narrative of Shipwreck in Palau, 1832-1833*, ed. by KENNETH R. MARTIN (1980), is a personal account of a stay in Palau.

Tuvalu: AUSTRALIAN MUSEUM. SYDNEY, *The Atoll of Funafuti, Ellice Group: Its Zoology, Botany, Ethnology, and General*

Structure Based on Collections Made by Mr. Charles Hedley, 10 pt. (1896-1900), is a broad scientific survey. See also ANNE CHAMBERS, *Nanumea Report: A Socio-Economic Study of Nanumea Atoll, Tuvalu* (1975, reissued as *Nanumea*, 1984); and DONALD GILBERT KENNEDY, *Field Notes on the Culture of Vaitupu, Ellice Islands* (1931). HUGH LARACY (ed.), *Tuvalu: A History* (1983), provides an introduction. See also the work by Barrie Macdonald cited above under *Kiribati*.

Major political units of Polynesia. *American Samoa and Western Samoa:* LOWELL D. HOLMES, *Samoan Village* (1974); MARGARET MEAD, *Coming of Age in Samoa: A Psychological Study of Primitive Youth for Western Civilization* (1928), available also in later editions; and DEREK FREEMAN, *Margaret Mead and Samoa: The Making and Unmaking of an Anthropological Myth* (1983), explore the traditional heritage and its interpretations. See also PAUL T. BAKER, JOEL M. HANNA, and THELMA S. BAKER (eds.), *The Changing Samoans: Behavior and Health in Transition* (1986); GEORGE TURNER, *Samoa, a Hundred Years Ago and Long Before* (1884, reprinted 1984); J.W. DAVIDSON, *Samoa mo Samoa: The Emergence of the Independent State of Western Samoa* (1967); and R.P. GILSON, *Samoa 1830 to 1900: The Politics of a Multi-Cultural Community* (1970). A modern survey is offered in FRED HENRY, *Samoa, an Early History* (1980). For further research, see LOWELL D. HOLMES (comp.), *Samoan Islands Bibliography* (1984). The best sources for a discussion of the political development of Western Samoa include MALAMA MELEISEA and PENELOPE SCHOFFEL MELEISEA (ed.), *Lagaga: A Short History of Western Samoa* (1987); and MALAMA MELEISEA, *The Making of Modern Samoa* (1987).

Cook Islands: NORMAN DOUGLAS and NGAIRE DOUGLAS, *Cook Islands, a Guide* (1987), provides a general survey of the whole country; NGATUPUNA KAUTAI et al., *Ati'u: An Island Community* (1984), describes a particular island in greater depth. RICHARD GILSON, *The Cook Islands, 1820-1950* (1980), is a historical survey; and RON CROCOMBE (ed.), *Cook Islands Politics: The Inside Story* (1979), discusses political trends.

Easter Island: A comprehensive introduction is provided in NORWEGIAN ARCHAEOLOGICAL EXPEDITION TO EASTER ISLAND AND THE EAST PACIFIC. 1955-1956, *Reports*, 2 vol. (1961-65). History and culture are outlined in GRANT MCCALL, *Rapanui: Tradition and Survival on Easter Island* (1981). See also THOR HEYERDAHL, *Aku-Aku: The Secret of Easter Island*, trans. from Norwegian (1958, reprinted 1988), *Sea Routes to Polynesia* (1968), *Art of Easter Island* (1975), a survey of art in collections throughout the world, with more than 300 plates of photographs, and *Easter Island—a Mystery Solved* (1989).

French Polynesia: BENGT DANIELSSON, *Work and Life on Raroia: An Acculturation Study from the Tuamotu Group, French Oceania* (1956); and F. ALLAN HANSON, *Rapan Lifeways: Society and History on a Polynesian Island* (1970, reprinted 1983), study society and culture. See also DOUGLAS L. OLIVER, *Ancient Tahitian Society*, 3 vol. (1974), a classic treatment. For history, see ROBERT LANGDON, *Tahiti, Island of Love*, 5th ed. (1979); COLIN NEWBURY, *Tahiti Nui: Change and Survival in French Polynesia, 1767-1945* (1980); and PIERRE-YVES TOULLELAN, *Tahiti Colonial* (1984). Other studies include WILLIAM TAGUPA, *Politics in French Polynesia, 1945-1975* (1976); VIRGINIA THOMPSON and RICHARD ADLOFF, *The French Pacific Islands* (1971); and PAUL HODÉE, *Tahiti, 1834-1984: 150 ans de vie chrétienne en eglise* (1983).

Tonga: JOHN CONNELL, *Migration, Employment, and Development in the South Pacific: Country Report* (1983), vol. 18, *Tonga*, studies the effects of internal and external migration. ELIZABETH BOTT, *Tongan Society at the Time of Captain Cook's Visits: Discussions with Her Majesty Queen Sālote Tupou* (1982), is a standard historical reference. SIONE LĀTŪKEFU, *Church and State in Tonga: The Wesleyan Methodist Missionaries and Political Development, 1822-1875* (1974), is a detailed history. A.H. WOOD, *A History and Geography of Tonga* (1943), is a brief but excellent introduction; and NOEL RUTHERFORD, *Friendly Islands: A History of Tonga* (1977), provides comprehensive coverage of life in Tonga.

Wallis and Futuna: Information on various topics can be found in general sources cited in the beginning section of this bibliography, as well as in such periodicals as *The Pacific Guide* (annual), published in England, mostly for business travelers in the area; and *The Contemporary Pacific* (semiannual), which began publication in 1989, from the University of Hawaii Press; as well as in relevant chapters of such surveys as OTIS W. FREEMAN, *Geography of the Pacific* (1951); and EMILIANA AFEAKI et al., *Politics in Polynesia* (1983).

Western Samoa: For books on the geography and history of Western Samoa, see *American Samoa and Western Samoa* above.

The Pacific Ocean

Of the three oceans that extend northward from the Antarctic continent, the Pacific, occupying about a third of the surface of the terrestrial globe, is by far the largest. Its area, excluding adjacent seas, encompasses about 63,800,000 square miles (165,250,000 square kilometres). It has double the area and more than double the water volume of the Atlantic—the next largest division of the hydrosphere—and its area more than exceeds that of the whole land surface of the globe. The Pacific Ocean stretches from the shores of Antarctica to the Bering Strait through 135° of latitude, or for 9,600 miles (15,500 kilometres). Its greatest longitudinal extent measures some 12,000 miles along the parallel of 5° N, between the coasts of Colombia in South America and the Malay Peninsula in Asia. The mean depth of the Pacific (excluding adjacent seas) is 14,040 feet (4,280 metres), and its greatest known depth is 36,201 feet (11,034 metres)—in the Mariana Trench—also the greatest depth found in any ocean.

The Pacific and Arctic systems mingle their waters in the Northern Hemisphere at the shallow Bering Strait, and in the Southern Hemisphere the Pacific and Atlantic mix in the relatively narrow Drake Passage between Tierra del Fuego in South America and Graham Land in Antarctica. The separation between the Pacific and Indian oceans is less distinct, but generally it is considered to lie along the line of islands extending eastward from Sumatra, through Java to Timor, thence across the Timor Sea to Cape Londonderry in Australia. To the south of Australia the boundary extends across the Bass Strait and thence from Tasmania to Antarctica.

Because of the pattern of major mountain systems of the globe, a relatively small proportion (one-seventh) of the total continental drainage enters the Pacific—i.e., a total

drainage area of less than about three times the total area of Australia. Of the rivers that drain into the Pacific, those of China and Southeast Asia are of the greatest importance; the basins of these rivers support more than one-quarter of the world's population.

The eastern boundary of the Pacific is associated with the American Cordilleran mountain system, which stretches from Alaska in the north to Tierra del Fuego in the south. Except for its extreme northern and southern sections, which are characterized by fjords and their numerous off-lying islands, and except for the deeply indented Gulf of California, the coastal boundary is relatively regular and the continental shelf narrow. The western, or Asiatic, coastal boundary, in contrast, is irregular. Although the mountain systems there lie roughly parallel to the coast, as they do on the eastern Pacific coastlands, the western Pacific is noted for its many marginal seas. From north to south they include the Bering Sea, the Sea of Okhotsk, the Sea of Japan, the Yellow Sea, the East China Sea, and the South China Sea. Their eastern boundaries are formed by southward-jutting peninsulas or island arcs or both. It is of oceanographic significance that the great rivers of eastern Asia—including the Amur, the Huang Ho (Yellow River), the Yangtze, the Hsi and Pearl, and the Mekong—enter the Pacific indirectly by way of the marginal seas.

This article treats the physical and human geography of the Pacific Ocean, followed by discussion of the six major marginal seas of the Pacific. For discussion of the physical and chemical oceanography and marine geology of the Pacific, see OCEANS; for discussion of Pacific peoples and cultures, see PACIFIC ISLANDS. PHYSIOGRAPHY

Relief. The Pacific basin may conveniently be divided into three major physiographic regions: the eastern, western, and central Pacific regions.

Eastern region. The eastern region, which extends southward from Alaska to Tierra del Fuego, is relatively narrow and is associated with the American cordilleran system of almost unbroken mountain chains, the coastal ranges of which rise steeply from the western shores of North and South America. The continental shelf, which runs parallel to it, is steep and comparatively narrow. Significant oceanic trenches in this region are the Middle America Trench in the North Pacific and the Peru-Chile Trench in the South Pacific.

Western region. The seaward boundary of the western region is marked by a broken line of oceanic trenches, extending from the Aleutian Trench in the north through the Kuril and Japan trenches and southward to the Tonga and Kermadec trenches, terminating close to the northeast of North Island, New Zealand. Its structure is more complex than that of the eastern region. Characteristically associated with the ocean trenches of the western region are festoons of either peninsulas or islands or both. The islands, which include those of Japan as well as numerous smaller islands, represent the upper parts of mountain systems that rise abruptly from the deep ocean floor. The island clusters of the western Pacific form the boundaries of the several wide and deep continental seas of the region.

Central Pacific region. The central Pacific region lies between the boundaries of the eastern and western re-

gions. The largest and the most geologically stable of the structural provinces of the Earth's crust, it is characterized by expansive areas of low relief, lying at a general depth of about 15,000 feet below the surface.

Principal ridges and basins. To the east of 150° W the relief of the ocean floor is considerably less pronounced than it is to the west. In the eastern Pacific the Cocos Ridge extends southwestward from the Central American isthmus to the Galápagos Islands. To the south of the Galápagos lies the Peru Basin, which is separated by the extensive Sala y Gomez Ridge from the Southeast Pacific Basin, which, in turn, is separated from the Southwest Pacific Basin by the East Pacific Rise and indeterminate Pacific-Antarctic Ridge, which runs from the Sala y Gomez Ridge to Antarctica in the vicinity of 150° W.

Extending southward from the Tasman Basin (between New Zealand and eastern Australia) is the Macquarie Ridge, which forms a major boundary between the deep waters of the Pacific and Indian oceans. The Hawaiian Ridge extends westward from Hawaii to the 180° meridian.

The submerged parts of the series of ridges that are capped by the island archipelagoes of the western Pacific are continuous and are to be found at depths of less than about 2,000 feet. These ridges include the Aleutian ridge in the northwestern Pacific; the series of ridges extending southward through the Kurils, Bonin, the Marianas, Yap, and Palau; those extending eastward from New Guinea, including the Bismarck Archipelago, the Solomons, and Santa Cruz; and finally the ridges extending southward from which rise the Samoan islands, Tonga, Kermadec, Chatham, and Macquarie.

Bottom deposits. Apart from the narrow coastal zone of the eastern region and the broad continental seas of the western region, the Pacific is floored with pelagic (*i.e.*, oceanic) material derived from the remains of marine plants and animals that once inhabited the waters lying above. Red or brown radiolarian ooze is found along the zone of the Pacific North Equatorial Current, east of 170° W, and on the floors of some deep Indonesian basins. A belt of diatom ooze occurs between 45° and 60° S latitude and across the northern Pacific, between Japan and Alaska. Calcareous globigerina ooze occurs in the shallower parts of the South Pacific, the dissolving power of the seawater at great depths being sufficient to dissolve calcareous material to such an extent that these oozes are not generally found at depths in excess of about 15,000 feet. Silica-containing material, such as radiolarian and diatom ooze, is found at greater depths, but even these siliceous remains are dissolved at very great depths, where the characteristic deposit is red clay. Red clay, which covers no less than half the Pacific floor, is believed to

be formed of colloidal (very finely divided) clays derived essentially from the land.

On the abyssal plains, where sediments accumulate slowly, chemical and biological processes lead to the formation of metal-bearing coatings around objects such as the earbones of fishes. The nodules so formed contain manganese, iron, nickel, copper, cobalt, and traces of other metals such as platinum. They cover large areas of the ocean floor in the Pacific. Similar processes form coatings, called manganese crusts, on the rock surfaces of seamounts.

Among the many different forms of land-derived muds (formed by the erosive action of rivers, tides, and currents) that floor the continental shelves and slopes of the Pacific, the yellow mud of the Yellow Sea is of particular interest. The mud is conveyed to the seabed by the Huang Ho, which drains a vast area of North China blanketed with loess, a fine-grained soil.

Islands. The islands of the western region—including the Aleutians, the Kurils, the Ryukyus, Taiwan, the Philippines, Indonesia, New Guinea, and New Zealand—are continental in character. Geologically they consist, in part, of sedimentary rocks, and their structures are similar to those of the coastal mountain ranges of the adjacent continent.

A geologically important boundary between the continental, or "high," islands and the numerous truly oceanic, or "low," islands of the Pacific is the Andesite Line. In the north and west Pacific the Andesite Line follows close to seaward the trend of the island arcs from the Aleutians southward to the Yap and Palau arcs, thence eastward through the Bismarcks, the Solomons, and Santa Cruz, and thence southward through Samoa, Tonga, Chatham, and Macquarie to Antarctica. Within that boundary, islands are essentially of basalt.

The numerous oceanic islands of the Pacific are unevenly distributed. They lie, in the main, between the tropics of Cancer and Capricorn and occur in great numbers in the western Pacific. The northernmost chain of oceanic islands is associated with the Hawaiian Ridge. The Hawaiian archipelago consists of about 2,000 islands, although the term Hawaiian Islands is usually applied to the small group that lies at the eastern end of the archipelago.

The numerous small islands of Micronesia lie mainly north of the equator and to the west of the 180th meridian. Nearly all are coralline; the principal groups are the Marianas, the Marshalls, the Carolines, Kiribati (Gilbert Islands), and Tuvalu (Ellice Islands).

To the south of Micronesia lies Melanesia, which consists mostly of small coral islands. The region's physiography is dominated by a group of large continental islands, how-

The Pacific Ocean, with depth contours and submarine features.

ever, including New Guinea. The principal Melanesian island groups are the Bismarck Archipelago, the Solomons, Vanuatu (New Hebrides), New Caledonia, and Fiji.

The immense area of Polynesia includes the Hawaiian Islands, the Phoenix Islands, Samoa, Tonga, the Cook Islands, the Society Islands, Tuamotu, and the Marquesas.

GEOLOGY

Evidence drawn from various geophysical fields—seismology, volcanology, gravimetry and paleomagnetism—points to the general validity of the theory of plate tectonics (see PLATE TECTONICS).

Formation
of island
arcs

The Pacific island arcs are believed to have originated in the lateral thrusting of the Eurasian and Australian plates toward and over the Pacific floor, the shapes of the island arcs corresponding to the intersections of the thrust planes with the spherical Earth's surface. The intense folding and faulting along the volcanic zone of the western Pacific provide unmistakable evidence of orogenic (mountain-building) forces at work. The deep basins that lie between the Asian continent and the island arcs were evidently caused by the local downfolding of the Earth's crust; the island arcs themselves, along the line of which volcanic and seismic activity are pronounced, are the result of crustal strata weakened by strong upfolding. On the oceanic side of the island arcs, intense downfolding has resulted in the formation of the deep trenches that fringe the line of the island arcs.

The character of the eastern marginal physiographic region of the Pacific suggests a lateral movement of the North American and South American plates westward over the Pacific floor. This movement causes downfolding of the ocean floor and gives rise to major fault lines (e.g., the San Andreas Fault in California, U.S.) and volcanism in the coastal cordilleran mountains of North, Central, and South America. The floor of the northeastern Pacific is remarkable for its several major fracture zones, which extend east and west and which, in some instances, are identifiable over distances of thousands of miles.

Of great geologic interest are the seamounts (submerged volcanoes), guyots (flat-topped seamounts), and oceanic islands of the Pacific. The numerous tropical islands of the Pacific are mainly coralline. The three principal types of coral reef—fringing, barrier, and atoll, as well as the guyots, which rise within the Pacific from the ocean floor in latitudes north and south of the tropics—are explained partially by the slow subsidence theory advanced by the English naturalist Charles Darwin during the 19th century and partially by the theory of plate tectonics.

CLIMATE

The wind and pressure systems of the Pacific conform closely with the so-called planetary system—i.e., the patterns of air pressure and the consequent wind patterns that develop in the atmosphere of the Earth as a result of its rotation (Coriolis force) and the inclination of its axis (ecliptic) toward the Sun. They are, in essence, a three-celled latitudinal arrangement of the atmospheric circulation in each hemisphere, one arrangement generally representing a mirror image of the other. The vast extent of open water in the Pacific influences wind and pressure patterns over it, and climatic conditions in the South and East Pacific—where the steadiness of the trade winds and the westerlies is remarkable—are the most uniform on the globe. In the North Pacific, however, conditions are not so uniform, particularly the considerable climatic differences between the eastern and western regions in the same latitude. The rigour of the winters off the east coast of the Soviet Union, for instance, contrasts sharply with the relative mildness of winters in the region of British Columbia.

The trade winds. The trade winds of the Pacific represent the eastern and equatorial parts of the air-circulation system; they originate in the subtropical high-pressure zones that are most pronounced, respectively, over the northeast and southeast Pacific between the 30th and 40th parallels N and S. The obliquity of the ecliptic (an angle of approximately $23\frac{1}{2}^\circ$ that is the difference between the planes of the Earth's rotation on its axis and its revolution around the Sun) limits the seasonal shifting of the Pacific

trade-wind belts to about 5° of latitude. The easterly winds along the equator between the two subtropical zones form the intertropical airflow and tend to be strongest in the eastern Pacific. The equatorial region, in which the trade winds of the Northern and Southern hemispheres converge, is the region of calms or light variable breezes and is known as the doldrums.

The trade winds, especially in the eastern Pacific, convey relatively cool air toward the equator; in moving, the air comes in contact with the sea and thus becomes increasingly humid and warm, and high lapse rates (the term used to denote the rate of change of air temperature with increasing height above sea or land surface) result. The average wind speed of the Pacific trade winds is about 13 knots (15 miles per hour). The weather in the trade-wind belts is normally fine, with relatively little cloud cover; such clouds as there are characteristically take the form of broken cumulus (small piles of clouds with flat bases) at about 2,000 feet above sea level. Precipitation, usually in the form of light showers, is slight.

Off the west coasts of the American continent in the trade-wind belts, upwelling of cold, subsurface water causes the overlying air to be cooled below its dew point (the air temperature below which water vapour condenses as dew), with the consequent widespread formation of low, thick clouds. Fog in these regions is not uncommon.

Tropical storms. Although, in general, the climatic conditions of the trade-wind belts are characteristically regular and uniform, storms of great violence do originate there. In such storms, winds of exceptionally great force spiral inward toward a centre of exceedingly low atmospheric pressure. These are the tropical storms known in the western Pacific as typhoons. While the mechanism that triggers typhoons and other tropical storms is not completely understood, ideal conditions for their development occur in the western Pacific between the parallels of 5° and 25° N during late summer and early autumn, when the temperature of surface waters is at least 81° F (27° C). The regions to the east of the Philippines and in the South and East China seas are notorious for these storms, which imperil shipping and often cause severe coastal flooding, accompanied by loss of life and property.

The westerlies. Within the belts of the westerly winds, cold easterly winds from polar regions meet the warm westerly winds of the middle latitudes, causing the formation of the traveling depressions characteristic of middle latitudes. The zone of convergence, or polar front, is most strongly developed in winter when the contrast in temperature and humidity of the air between the converging flows is greatest.

The westerlies in the Southern Hemisphere are steady and strong, and their popular name, "brave west winds," is apt. The gales that accompany the depressions have given rise to the term "roaring forties," named for the latitudinal zone in which the storm winds are of greatest frequency.

The monsoon regime. The western Pacific is subject to a seasonal climatic regime that replaces the planetary system. This is the regime of the monsoon (rain-bearing winds), which is associated with the heating of the Asian landmass in summer and its intense cooling in winter. The heating of air masses over tropical Asia in summer initiates a low-pressure system, which becomes the focal point of the trade winds of both hemispheres. The doldrums, therefore, do not exist in the western Pacific during northern summer because of the immense flow of maritime air into the Asian low-pressure zone. The cooling of the continent in winter results in the development of the Asian high-pressure system, which leads to a strengthening of the trade winds of the Northern Hemisphere.

As a result of seasonal changes in pressure and wind circulation, marked seasonal contrast between continental and maritime influences—the first associated with drought and cold and the second with moisture and heat—is to be found in the whole of the western Pacific from the Sea of Japan southward.

TEMPERATURE AND SALINITY

Temperature. The oceans tend to be stratified, the principal factor being temperature; the bottom waters of

Typhoons
of the
western
Pacific

Uniformity
of climate

the deep parts are intensely cold, with temperatures only slightly above freezing.

The surface zone, where temperature variations are perceptible, is between 300 and 1,000 feet thick. It is more compressed in the temperate Eastern Pacific, along the coasts of North and Central America, where cold water appears at a shallower depth compared to the central and western Pacific.

Ocean temperatures in the North Pacific tend to be higher than those in the South Pacific because the ratio of land to sea areas is larger in the Northern Hemisphere and because Antarctica also influences water temperature.

The mean position of the thermal equator (the line on the Earth on which the highest average air temperatures are found; the line migrates latitudinally with the changing angular distance from the equator of the Sun) in the Pacific, although it lies in the Northern Hemisphere, is nearer to the geographic equator than in the Atlantic and Indian oceans.

There is a pronounced difference in temperature and salinity between the surface and deep zones of the Pacific. The deep zone, which contains about 80 percent of the ocean's volume, has relatively stable temperature and salinity patterns; its average temperature is 38.3° F (3.5° C).

Salinity. The salinity patterns of the surface waters of the Pacific are influenced largely by wind and by rainfall and evaporation patterns. The waters within the belt of calms and variable winds near the equator have lower salinities than those in the trade-wind belts. In the equatorial belt, relatively large amounts of rain fall and little evaporation occurs both because of low wind speeds and because of the generally cloudy skies; salinity in the equatorial belt runs as low as 34 parts per thousand.

The highest surface salinities in the open Pacific occur in the southeastern area, where they reach 37 parts per thousand; in the corresponding trade-wind belt in the North Pacific the maximum salinity seldom reaches 36 parts per thousand. Pacific waters near Antarctica have salinities of less than about 34 parts; the lowest salinities—less than about 32 parts—occur in the extreme northern zone of the Pacific.

The heavy rainfall of the western Pacific, associated with the monsoons of the region, gives rise to relatively low salinities. Seasonal variations there, as well as in the eastern Pacific, where seasonal changes in surface currents occur, are significant.

HYDROLOGY

Surface currents. Pacific trade winds drive surface waters toward the west to form the North and South Equatorial currents, the axes of which coincide, respectively, with the parallel of 15° N and the equator. Squeezed between the Equatorial currents is a well-defined countercurrent, the axis of which is always north of the equator and which extends from the Philippines to the shores of Ecuador.

The major part of the North Equatorial Current swings northward in the vicinity of the Philippines to form the warm Kuroshio (also called the Japan Current). To the east of Japan the Kuroshio swings eastward to form the Kuroshio Extension. The branching of this current in the region of 160° E results in the movement known as the North Pacific Current. The surface waters of the Bering Sea circulate in a counterclockwise direction. The southward extension of the Kamchatka Current forms the cold Oya Current, which flows to the east of the Japanese island of Honshu to meet the warm Kuroshio waters in the vicinity of 36° N. The cold, southeast-flowing California Current forms the eastern segment of the returning branch of the North Equatorial Current system.

The main part of the South Equatorial Current divides into three large branches as it flows westward. The two westernmost branches, on reaching the east coast of Australia, swing south to form the East Australian Current, which, becoming the Tasman Current, turns back to the northeast and dissipates west of New Zealand. The easternmost branch flows first to the south, roughly along the 180° meridian, before turning back to the east in the vicinity of 50° S as the warm South Pacific Current;

between 80° and 90° W this flow turns northward and then westward as the Mentor Current, the waters eventually returning to the South Equatorial Current. Flowing between Antarctica and the South Pacific Current is the cold Antarctic Circumpolar Current, which constitutes the other portion of the South Pacific circulation system; as it reaches the South American coast in the region of 45° S, one branch flows northward along the coast to form the Peru (Humboldt) Current, and a second branch flows southward to pass through the Drake Passage.

Periodically—usually at intervals of three to four years—an anomaly of ocean currents and climatology called El Niño occurs in the South Pacific. This event is associated with the appearance of unusually warm ocean conditions off the tropical coast of South America and with changes in tropical atmospheric patterns (called the Southern Oscillation) that can adversely affect fishing, agriculture, and rainfall patterns along the west coast of South America. During particularly strong events, El Niño can cause weather anomalies in the equatorial and southern Pacific and in northeastern South America, Asia, and North America.

Deepwater circulation. Observations of temperature and salinity at different levels in the ocean reveal well-defined layers, each forming a water mass distinguished by its own temperature and salinity characteristics.

It appears that the most important influence on the vertical circulation of the Pacific is the cold water generated around the Antarctic continent. This dense circumpolar water sinks and then spreads northward to form the bottom layer of the greater part of the Pacific. It is thought that cold, deep water flows northward in the western Pacific in a relatively well-defined current from the vicinity of Antarctica to Japan. Branches from this deep main stream convey cold water eastward and then poleward in both hemispheres.

Deepwater circulation is influenced by the descent of surface water at zones of convergence of neighbouring water flows. In the Pacific Tropical Convergence, which coincides with the Equatorial Countercurrent, water sinks to a depth of about 300 feet before it spreads laterally. The Pacific Subtropical Convergences are located between the parallels of 35° and 40° N and S. Water that sinks at the convergences spreads laterally at increasing depths as the distance from the equator increases. The Antarctic Convergence lies in the zone of the southern westerly winds. A corresponding Arctic Convergence is prominent in the northeastern Pacific.

To compensate for downward-moving water, some water rises at zones of divergence, particularly along the so-called cold-water coasts of both North and South America, where upwelling of cold water is a well-marked phenomenon.

Tides. In contrast to the tides of the Atlantic—which are almost always semi-diurnal (*i.e.*, twice-daily) occurrences—those of the Pacific include many instances of diurnal (daily) and mixed tides. In the diurnal type of tidal oscillation, only a single high water and a single low water occur each tidal day (which lasts for about 24 hours and 50 minutes). Tides of this type occur in the Gulfs of Tonkin and Thailand in Southeast Asia, the Java Sea in Indonesia, and Bismarck and Solomon seas north and east of the island of New Guinea. Mixed tides, in which both diurnal and semidiurnal oscillations appear, are characterized by large inequalities in successive high (or low) water heights. This type of tide is prevalent along much of the Pacific coast.

At certain places in the South Pacific the natural period of oscillation of the sea accentuates the solar tidal oscillation. At these locations the time of the AM (or PM) high (or low) water, instead of getting later each day by about 50 minutes (as is generally the case), occurs at approximately the same time for several days in succession. The tide at Tahiti, for example, follows the Sun and not the Moon—the time of high water occurring, day after day, at about midnight and noon, and that of low water at about 6 AM and 6 PM.

In general, tidal ranges within the Pacific are small. That at Tahiti is about one foot; at Honolulu it is about two feet; at Yokohama, it seldom exceeds five feet; and at Cape

El Niño

Variation

Tidal ranges

Horn it is never more than about six feet. In the upper reaches of the Gulf of California and Korea Bay, however, large tidal ranges of more than 40 feet are common.

ECONOMIC ASPECTS

Biological resources. The Pacific has the most varied complement of plants (*i.e.*, algae) and animals of the world's oceans. The circumglobal mixing of water in the southern and, to a much more limited extent, northern polar reaches of the Pacific permit the intermingling of flora and fauna from other oceanic regions, while temperate and tropical surface waters of the Pacific are more likely to have indigenous biotas. On the rocky, cold-water coasts of North and South America, for example, are found vast forestlike kelp beds made up of brown algae of the genus *Laminaria*, with individual plants often reaching heights of 100 feet or more. They harbour a rich animal complement of invertebrates and fishes approaching a faunal variety that vies with that of tropical rain forests. Where upwelling and other current conditions add nutrients to the offshore surface waters of these same reaches of the Pacific, dense concentrations of plankton-feeding fishes thrive, predominantly those of the herring family and its relatives. Examples include the Japanese sardine and the Peruvian anchovy, both of which are among the largest single-species fishing catches in the world.

Robert Harding Picture Library Ltd.

Fishing for anchovies off the coast of Peru.

In the North Pacific the circulation patterns and runoff from the land create conditions in which demersal, or bottom-living, species abound. The North Pacific hake and the Alaska pollack are prominent examples. Salmon, likewise, thrive in the North Pacific, proliferating there in five species of the genus *Oncorhynchus*, as compared to the single species, *Salmo salar*, of the Atlantic.

In the warm, tropical region—roughly between the North and South Equatorial Current systems—the wealth of marine animals, especially, increases dramatically. The variety of animal life is greater in the western Pacific, where the warm monsoonal climate and variegated land-forms have promoted evolution of the unique Indo-Pacific marine forms. The western Pacific also has the richest and most extensive coral reefs of any ocean, with some six times more species of fish associated with them than with the coral reefs of the Caribbean Sea in the Atlantic. The tropical sea passages between the Pacific and the Indian oceans have also given the latter ocean a rich reef fauna; and Indo-Pacific mollusks have reached copious

evolutionary diversification, with the giant clam, *Tridacna gigas*, as a spectacular example. Another example of the Pacific's richness in species is found among the tunas: six species (one of them endemic) roam the tropical reaches of the Pacific, furnishing more than half of the world's tuna catch.

Whales are a prominent and spectacular component of the Pacific marine biota. The habits of many species include regular, long-distance migrations from cold-water feeding to warm-water breeding and calving grounds, thus predisposing them to global distribution.

Fisheries. Because of the biological richness of certain reaches of the Pacific and because of the large human populations in many of the nations bordering it, the catches there are substantially larger than those in the other oceans and comprise three-fifths of the total world catch. Among Pacific nations Japan and the Soviet Union have the largest fisheries in the world as measured by tonnage caught, but China, the United States, Peru, Chile, South Korea, and Indonesia are also among the world's major fishing nations. The fishing industries in all of these countries are enormous, and all are based at least in part on fisheries in the Pacific. A number of species—including sardines, herring, anchovies, hake, pollack, and shrimp—have been fished in some cases up to, if not beyond, the limits of their sustainable yields.

Salmon fisheries are important in the United States, Japan, the Soviet Union, and Canada, while the fishing quests for tuna have particular significance for the small island nations of the Pacific. The fishing for these species is done mostly by the technologically advanced vessels of Japan, the United States, South Korea, and Taiwan. Many of the tuna are found within the 200-mile exclusive economic zones of the island nations, giving them the opportunity to extract fees for fishing rights and to develop tuna fisheries and processing facilities.

Increasing population pressure and economic and often industrial development in several coastal regions of the Pacific have led to overfishing and impairment of habitat for a number of coastal species. Aquaculture is increasingly supplementing the natural supply. Shrimp, edible and pearl oysters, salmon, sea bream, mullet, and groupers are among the Pacific fauna that have been raised successfully.

In the tropical Pacific prized corals have long been harvested from great depths: pink coral species come mainly from the western Hawaiian atolls, while black coral is extracted from the western islands and shallow seamounts and from Malaysian and Indonesian waters.

Mineral resources. Minerals are extracted from the seawater itself, from offshore alluvial deposits, or from within the continental shelf and may be metallic or nonmetallic, with hydrocarbon fuels being the most valuable among the latter. Prominent in the Pacific also are deepwater metallic mineral deposits of potential economic significance. Fresh water itself is also obtained from the ocean by various methods of desalination, as is done in Japan and Hong Kong.

Minerals from seawater and alluvial deposits. Common salt (sodium chloride) is the most important mineral obtained directly from seawater. Mexico leads the Pacific nations in salt extraction from the sea, mostly by solar evaporation. Bromine extracted from seawater is used in the food, dye, pharmaceutical, and photo industries. The United States and Japan lead in its production among Pacific riparian nations. Magnesium, recovered by an electrolytic process, is used in industrial metal alloys, especially with aluminum; Japan and California are the main sites for its extraction.

Also of importance are the sand and gravel that are extracted from the shallow sea bottom. Japan is the major Pacific producer, but Alaska, Hawaii, and other American Pacific-coast states also rely heavily on offshore sand and gravel. Sand and gravel mining from the seabed is important in nearly all other Pacific countries.

Large submarine deposits of phosphate rock are found in the Pacific off the coasts of Peru, eastern Australia, and California and on the Chatham Rise east of New Zealand. Smaller deposits also occur in lagoons of some of the Pacific Islands.

Whales

Sand and gravel

Deep-sea minerals. Metal-bearing deposits on the deep-sea floor, consisting of nodules, crusts, and accumulations of metallic sulfides from deep vents, are of potential economic interest. In the 1970s and '80s it was hoped that mining the nodules—which contain quantities of manganese, iron, copper, nickel, titanium, and cobalt, as well as small traces of other metals—might be a way to contribute to the wealth of developing nations. Economic considerations and concern over management of mining operations, however, led to cessation of the costly exploration and development of underwater mining technology.

Marine sulfide ores, containing iron, copper, cobalt, zinc, and traces of other metallic elements, are deposited in large amounts by the actions of deepwater hydrothermal vents, such as occur in the Pacific off the Galápagos Islands and on the Juan de Fuca and Gorda ridges.

Submarine hydrocarbons. Deposits of oil and gas under the seafloor are the most valuable and sought-after fuels of the modern world economy. Shallow seas and small ocean basins, such as the South and East China seas, are thought to have a high potential for large reserves. Among the countries bordering the Pacific Ocean and its marginal seas, the proportion of production from submarine reserves varies widely, from less than half in Indonesia and Japan to nearly all in Australia and Malaysia.

Main
sites for
exploration

The principal areas in the southwestern Pacific for offshore oil and gas exploration are in the South China Sea—the waters off Vietnam and off Hai-nan island in China and on the continental shelf northwest of Palawan island in the Philippines—but they also include the area off Natuna Island and some areas off the Sumatran coast in Indonesia. In the northwestern Pacific the main areas lie to the northwest of the island of Kyushu in Japan, in the southern portion of the Yellow Sea and in the Po Hai (Gulf of Chihli), and in regions off Sakhalin Island and the Kamchatka Peninsula. Oil and gas wells have been drilled in the Bering Sea in the north and areas off the southern coast of California in the eastern Pacific. In the southern Pacific, hydrocarbon production and exploration is taking place in the Gippsland Basin off the southeastern coast of Australia; in New Zealand's Cook Strait, its area in the Tasman Sea, and off South Island; and in areas off Fiji.

Trade and transportation. Since the end of World War II there has been remarkable growth in trade between countries on the western Pacific rim—most notably Japan, South Korea, and Taiwan—and North America, particularly the United States. Trade has also expanded between North America and Hong Kong and such Southeast Asian countries as Singapore, Thailand, Malaysia, and, to a lesser degree, Indonesia and the Philippines and in the western Pacific in the north between Japan and South Korea and Australia and Southeast Asia in the south. In addition, trade patterns in the United States have shifted, with Pacific nations now accounting for some two-fifths of overall trade. Los Angeles has surpassed New York City as the port with the country's largest trade volume, in terms of value, and the nearby port of Long Beach has also become one of the nation's largest.

Thus, the Pacific Ocean now contains some of the world's most important trade routes. Most of the exports moving from west to east and from north to south are high value-added manufactured goods. Conversely, most of the exports moving from east to west and from south to north are raw materials.

Outside of the United States, Japan is the largest Pacific trading nation, and the most important commodity flows in the Pacific are to and from Japan. Japanese imports, mostly raw materials, far exceed its exports in tonnage, but in monetary terms Japanese exports give the country an overall positive trade balance. Japan's imports include iron ore and coal from Australia and from India via the Indian Ocean, grain from the American Gulf Coast via the Panama Canal, and crude petroleum from the Persian Gulf via the Indian Ocean and from Indonesia. Its exports—principally motor vehicles, machinery, and precision and electronic equipment—are distributed virtually worldwide, although the largest quantities go to the United States.

Among other Pacific trading nations, Australia and New

Zealand are principally exporters of raw materials, while South Korea, Taiwan, and Hong Kong are highly dependent on trade and are also large importers of raw materials. The small nations of the Pacific Islands contribute only a small fraction to overall Pacific trade, but most of them are heavily dependent on trade, particularly of imports of such basic materials as foodstuffs and petroleum. Generally, the small islands are net importers rather than net exporters, with only Papua New Guinea exporting more than it imports.

With the increased importance of the Pacific in worldwide trade has come a corresponding growth in the size of its transportation infrastructure. Japan, South Korea, China, and the Philippines rank high in ship ownership, and Japan, South Korea, and Taiwan are among the world's major shipbuilding nations. In addition to the ports of Los Angeles and Long Beach, the other major ports in the eastern Pacific are those in San Francisco Bay and in the Puget Sound region. In the western Pacific, Japan's ports on Tokyo and Ōsaka bays dominate trade; other major ports include Pusan in South Korea, Shanghai in China, Kao-hsiung in Taiwan, Hong Kong, and Sydney in Australia. Singapore, though on the fringe of the Pacific Ocean, dominates traffic to and from Southeast Asia and is the principal link between the Pacific and Indian oceans.

Major
ports

Environmental impact of human activity. The Pacific Ocean is able to absorb, dilute, and disperse large quantities of human-generated wastes, but the increasing pace of economic activity—particularly the transport of crude oil and other hazardous substances—has led to measurable levels of pollution in some nearshore waters, especially close to ports and large coastal cities. At the same time, the loads of pollutants in waters close to land have increased—primarily raw sewage, industrial waste products such as heavy metals, and river-borne fertilizers and pesticides. Thus, although the large expanse of open ocean in the Pacific has not been seriously affected, serious problems have arisen in some more confined bodies of water. In a number of instances, populations of commercially important fish and crustaceans have been depleted or made unfit for use by the pollution of confined waters.

STUDY AND EXPLORATION

Early exploration and settlement. The Pacific Islands are thought to have been peopled by influxes from both mainland and archipelagic Southeast Asia. The earliest migrations were to what is now generally referred to as Melanesia. From there generations of voyagers ranged northward into eastern Micronesia and eastward into Polynesia. The peopling of Polynesia, by means of long-range seagoing voyages carried out in larger, seaworthy sailing canoes, constitutes a remarkable feat of navigational skill. These appear to have begun between 3,000 and 4,000 years ago and to have lasted until about 1,000 years ago, when the Maori (a Polynesian people) settled New Zealand. The longest voyages of the Polynesians involved the settlement of Hawaii, first from the Marquesas Islands and later from Tahiti.

European exploration. Pacific islanders had long inhabited their homelands before the European "discovery" of the Pacific in the 16th century. European exploration can be divided into three phases: Spanish and Portuguese, Dutch, and English and French. The Spanish and Portuguese period began with the voyages in the 1520s of Ferdinand Magellan and, after his death, of his crew members. Later discoveries included the Solomon Islands, the Marquesas, and possibly New Guinea, all by the Spaniard Álvaro de Mendaña de Neira; Vanuatu by the Portuguese Pedro Fernandes de Quirós; and the Torres Strait by the Spaniard Luis Váez de Torres.

During the Dutch period—roughly the 17th century—Jakob Le Maire and Willem Corneliszoon Schouten discovered inhabited islands in the northern Tuamotus, islands in the Tonga group, and Alofi and Futuna islands. The best-known of the Dutch explorers, Abel Janszoon Tasman, discovered New Zealand, islands in the Tonga group, the northeastern sector of the Fiji group, and islands in the Bismarck Archipelago.

Exploration and discovery in the Pacific reached its

Voyages
of James
Cook

zenith with the British and French in the 18th century. Four Englishmen—John Byron, Samuel Wallis, Philip Carteret, and James Cook—and the Frenchman Louis Antoine de Bougainville were preeminent. Byron explored the northern Marianas and discovered islands in the Tuamotuan, Cook, and Tokelauan archipelagos. Wallis discovered islands in the Tahiti group, while Carteret sighted Pitcairn Island and explored vast areas of the southern Pacific. Bougainville sailed to Tahiti, Samoa, Vanuatu, New Guinea, and the Solomons.

European Pacific exploration and discovery culminated in the three voyages of Captain James Cook (1768–79). On his first voyage to Tahiti he discovered Raiatea, Vaitoare (Tahaa), Huahine, and Bora-Bora and surveyed the coasts of New Zealand and the east coast of Australia. On his second voyage he sailed south of 70° S, charted Tonga and Easter Island, and discovered New Caledonia. His third voyage included exploration of the North Pacific and Bering Strait, but he was killed in 1779 in the Hawaiian Islands, discovered earlier in the voyage. Cook's voyages left little land to be discovered in the Pacific, and his maps and charts were so accurate that many have not been substantially revised. The remaining island groups and larger landmasses were mapped in the 19th century.

In 1831–36 the English naturalist Charles Darwin sailed on the British naval vessel *Beagle*, collecting the information that he later would use in his writings. Growing interest in the physical and biological properties of the ocean paved the way for the great oceanographic voyages made later in the century. The best-known of these took place in the 1870s, initiated by the British Challenger Expedition, followed by the voyage of the USS *Tuscarora* in the northern Pacific and that of the German research vessel *Gazelle*.

Exploration in the 20th century. Among the most important 20th-century expeditions to the Pacific were those of the American ship *Carnegie* (1928–29), the Danish vessel *Dana II* (1928–1930), the Swedish ship *Albatross* (1947–48), and the Danish ship *Galathea* (1950–52). In the late 1950s the Soviet vessel *Vityaz* carried out detailed soundings of the deep trenches of the western Pacific, and in 1960 the American bathyscaphe *Trieste* descended to the bottom of the Mariana Trench.

Since 1960, numerous shorter cruises have been undertaken; they have been highly effective because of advances in instrumentation and knowledge of the basic characteristics of the ocean. In addition, satellites carrying remote sensing equipment have made it possible to determine with great accuracy the surface characteristics of the Pacific. These two factors have made lengthy cruises unnecessary. Exploration and research of the ocean bottom in the Pacific has likewise benefited from technological advances and has yielded the discovery of manganese nodules and other potentially valuable bottom resources. In addition, knowledge of marine life near active vents associated with centres of tectonic activity and of undersea volcanism has been greatly expanded.

Much of 20th-century oceanographic exploration in the Pacific and elsewhere has been for economic reasons, particularly for the recovery of offshore hydrocarbons in relatively shallow waters; but technology has made possible exploration and exploitation in increasingly deeper waters. Deepwater oil-drilling technology has also been employed to shed much light on the nature of the Earth's crust and the underlying mantle. (C.H.C./Jo.E.B./J.R.Mo.)

The major marginal seas of the Pacific Ocean

BERING SEA AND STRAIT

The Bering Sea (Russian: Beringovo More) is the northernmost part of the Pacific Ocean, separating the continents of Asia and North America at their closest point. To the north it connects with the Arctic Ocean through the Bering Strait (Proliv Beringa), at the narrowest point of which the two continents are about 53 miles (85 kilometres) apart. The boundary between the United States and the Soviet Union passes through the sea and the strait.

The Bering Sea roughly resembles a triangle with its

apex to the north and its base formed by the 1,100-mile-long arc of the Alaska Peninsula in the east; the Aleutian Islands, which constitute part of the U.S. state of Alaska, in the south; and the Komandor (Commander) Islands in the west. Its area is about 890,000 square miles (2,304,000 square kilometres), including its islands. The maximum width from east to west is about 1,490 miles and from north to south about 990 miles.

The Bering Strait is a relatively shallow passage averaging 100 to 165 feet (30 to 50 metres) in depth. During the Ice Age the sea level fell by several hundred feet, making the strait into a land bridge between the continents of Asia and North America, over which a considerable migration of plants and animals occurred.

In addition to the Aleutian and Komandor groups, there are several other large islands in both the sea and strait. These include Nunivak, St. Lawrence, and Nelson islands in Alaskan waters and Karagin Island in Soviet waters.

Physical features. *Physiography.* The Bering Sea may be divided into two nearly equal parts: a relatively shallow area along the continental and insular shelves in the north and east and a much deeper area in the southwest. In the shelf area, which is an enormous underwater plain, the depths are, in most cases, less than 500 feet. The deep part in the southwestern portion of the sea is also a plain, lying at depths of 12,000 to 13,000 feet and divided by separate ridges into three basins: the larger Aleutian Basin to the north and east, the Bowers Basin to the south, and the Komandor Basin to the west. The sea's deepest point, 13,442 feet (4,097 metres), is in the Bowers Basin.

The continental crust is more than 12 miles thick along the shallow shelves and in the Aleutian Islands. The thickness decreases in the slope areas, and in the deep part of the sea the crust is 6 to 9 miles thick.

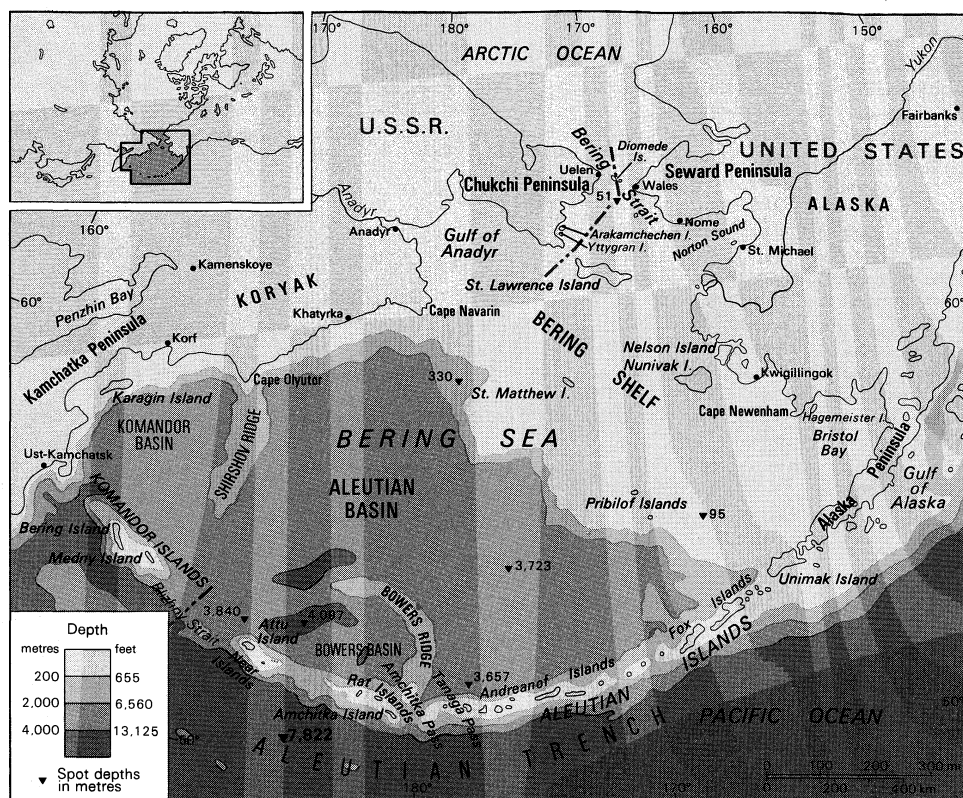

Enormous quantities of sedimentary material enter the sea annually from the land as a result of erosion of the shore. Plant and animal life at the surface also produce sedimentary material, but very little reaches the bottom, and consequently most of the sediment on the floor of the sea is from the land. Along with a great deal of silica, the bottom ooze holds a large quantity of boulders, pebbles, and gravel torn from the shores by ice and carried out to sea. In the southern part, the sediments are rich in material of volcanic origin.

Climate. Although the Bering Sea is situated in the same latitude as Great Britain, its climate is much more severe. The southern and western parts are characterized by cool, rainy summers with frequent fogs, and comparatively warm, snowy winters. Winters are extreme in the northern and eastern portions, with temperatures of –31° to –49° F (–35° to –45° C) and high winds. The summers in the north and east are cool, with comparatively low precipitation. Snow persists on the Koryak coast for as long as 8 months, and on the Chukchi Peninsula for nearly 10 months, with a snow cover one to two feet thick. The annual precipitation in the southern part of the sea is more than 40 inches (1,000 millimetres), mainly in the form of rainfall, while in the northern part the precipitation is less than half as much and is mainly snow.

Mean annual air temperatures range from –14° F (–10° C) in the northern areas to about 39° F (4° C) in the southern parts. Water temperatures on the surface average from 34° F (1° C) in the north to 41° F (5° C) in the south. The period without frosts lasts for about 80 days in the northern part of the sea, where snow is common even in the summer and maximum temperatures are only 68° F (20° C). In the southern area there are nearly 150 days without frost, and the temperature seldom falls much below freezing. January and February are the coldest months, July and August the warmest. Severe storms caused by strong centres of low atmospheric pressure occasionally penetrate the southern part of the sea.

Hydrology. Practically all of the Bering Sea water comes from the Pacific Ocean. The salinity of the surface water is relatively low, 31 to 33 parts per thousand; in the deeper parts of the sea the salinity increases to 35 parts per thousand near the bottom. In winter the northern portion of the sea is covered with ice, and even in summer the water below the surface retains a subfreezing temperature.

The strait
as a bridge

The Bering Sea and the Bering Strait.

The structure of the Bering Sea waters in general is sub-arctic, characterized by the presence in summer of a cold intermediate layer with warmer waters above and below. During the summer the surface water is heated, but a considerable layer of water that was cooled during the winter remains cold and is known as the cold intermediate layer. The maximum thickness of this intermediate layer is about 475 feet in the northern part of the sea and as much as 280 feet in the south. Underneath this layer is one that is slightly warmer, below which lie the colder bottom waters. In the northern and eastern shallow regions of the sea, only two upper layers develop: surface water and a cooler intermediate layer.

Warm oceanic waters from the south enter the Bering Sea through the numerous straits of the Fox Islands, through the Amchitka and Tanaga passes, and to a great extent through the Blizhny Strait between Attu and Medny islands. The Attu, Tanaga, and Transverse currents carry the warm water to the northwest. The Transverse Current, proceeding along the Asian continental slope in the direction of Cape Navarin, branches in two: one branch forms the Lawrence Current moving northward and the other joins the Anadyr Current, which in turn gives birth to a powerful Kamchatka Current that governs the southward movement of the Bering Sea waters along the Asian coasts. Near the Alaska coast the general direction of the water is to the north, a factor responsible for the less severe ice conditions in that part of the sea as compared to the western part. Some of the Bering Sea water passes through the Bering Strait into the Arctic Ocean, but the bulk of it returns to the Pacific. The deep Bering Sea waters rise gradually to the surface and return to the Pacific as surface waters. Thus, the Bering Sea is an important factor in the general circulation of the northern part of the Pacific Ocean waters. The rise to the surface of oceanic waters rich in nutrient salts gives the sea a high biological productivity.

Economic aspects. Biological and mineral resources. The existence in the Bering Sea of the cold intermediate layer separating the deep waters, which are rich in nutrient salts, from the upper photic layer (*i.e.*, the layer exposed to sunlight) results in two growths of floating plant life during the year. The first growth occurs in the spring after

the mixing of waters in winter, and the second during the autumnal mixing, when the cold surface waters descend and the deeper waters come to the surface while there is still sufficient sunlight for plant growth.

This floating plant life consists of some 160 species, of which the most common are diatom algae. The largest concentration of diatoms have been found in the shallow part of the sea. Diatoms are the principal producers of organic matter, and they are consumed by small copepods (microscopic crustaceans), which in turn become the food of fish and mammals. On the continental shelf there are vast quantities of mollusks, echinoderms (particularly sea urchins and starfish), and barnacles. Also abundant on the shelves are sponges, marine worms, and crustaceans. In the southern regions, down to depths of 100 or 130 feet, populations of giant brown algae grow like forests on the rocky bottom. There are about 200 species of algae, some reaching lengths of 200 to 300 feet.

The Bering Sea has more than 300 species of fish, including 50 deep-sea species, of which 25 are caught commercially. The most important among them are salmon, herring, cod, flounder, halibut, and pollack. The islands are breeding grounds for the fur seal and the sea otter. The northern areas are inhabited by the walrus, seal, and sea lion. Several whale species, notably gray whales, migrate to Bering waters to feed during the summer. Intensive fishing in the last half of the 20th century has drastically reduced some of the most valuable fish species, and this has led to greater exploitation of less commercially valuable species.

Oil and gas deposits are believed to exist under the Bering Shelf and along the margin of the Kamchatka Peninsula. The extent of potential reserves, however, is unknown.

Navigation. The Bering Sea is considered to be one of the most difficult bodies of water to navigate. Winter storms are frequent and severe, often coating the superstructures of ships with ice. Wave heights may exceed 40 feet. Added to these hazards are powerful tidal currents in many parts of the sea and fog, rain, and floating ice in the north. In winter the northern area is covered by ice fields about 4 or 5 feet thick, with hummocks in some places more than 100 feet high. At its maximum extent in April, the ice reaches as far south as Bristol Bay and the Kamchatka coasts. Melting begins in May, and by July there is

Vitus
Bering

no ice in the sea except for drift ice in the Bering Strait. Nonetheless, the sea contains important shipping routes for the Soviet Far East, including the eastern terminus at Provideniya on the Chukchi Peninsula for the northern sea route to Arkhangelsk in the west.

Study and exploration. The Bering Strait and the Bering Sea were first explored by Russian ships under Semyon Dezhnyov, in 1648. They are named for Vitus Bering, a Danish captain who was taken into Russian service by Peter the Great, in 1724. He sailed into the strait four years later but did not see the Alaskan coast, although he discovered the islands of St. Lawrence and Diomedes. In 1730 the strait was charted for the first time by Mikhail Gvozdev and Ivan Fyodorov. Bering sailed again in 1733, leading a large expedition from St. Petersburg along the northern coast of Siberia, and he reached the Gulf of Alaska in the summer of 1741. He reconnoitred the southwestern coast of mainland Alaska, the Alaska Peninsula, and the Aleutians, but misfortune befell him, and he perished in that year along with many of his men. In 1780, Russian merchants founded a private company to trade in fur-bearing animals in northwestern America. A geographic study of the Bering Sea was made at the end of the 18th century and was supplemented later by hydrographic studies.

Deep-sea studies were begun in 1827 by British explorers. Extensive work was also done by a U.S. group aboard the American research vessel *Albatross* in 1893–1906. Since then the sea has been systematically studied by Soviet, American, and Japanese investigators. Some of the most detailed study was undertaken by the Soviet vessel *Vityaz* in a series of expeditions undertaken in the 1950s and '60s.

(A.P.L./A.V.A./K.T.B.)

EAST CHINA SEA

The East China Sea, or Eastern Sea, of the western Pacific Ocean—known in Chinese as the Tung Hai (Pinyin: Dong Hai)—borders the East Asian mainland and extends northeastward from the South China Sea, to which it is connected by the shallow Taiwan Strait between Taiwan and mainland China. The sea extends to the east to the chain of the Ryukyu Islands; north to Kyushu, which is the southernmost of Japan's main islands; northwest to Cheju Island off South Korea; and hence west to China. This northern boundary separates the East China Sea from the Yellow Sea.

Physical features. *Physiography.* The East China Sea, which has an area of 290,000 square miles (752,000 square kilometres), is largely shallow, with almost three-fourths of the area less than 650 feet (200 metres) and an average depth of only 1,145 feet. The deeper part is the Okinawa Trough, extending alongside the Ryukyu Islands, with a large area more than 3,300 feet deep and a maximum depth of 8,912 feet (2,717 metres). The western edge of the sea is a continuation of the shelf that extends between the South China Sea and the Yellow Sea. A large number of islands and shoals dot the eastern boundary as well as the area near the Chinese mainland.

The shallow shelf areas are covered with sediments from the bordering landmasses deposited mainly by the Yangtze and other rivers near the northern part of the sea. Coarser sediments of sand occur farther out, and rocks, muds, and oozes are also found in scattered areas. Seismic profiling indicates that the geologic structure beneath the ocean floor consists of nearly parallel folds, with rock ridges near the northern limits of the East China Sea, near the edge of the continental shelf, and along the Ryukyus. These have afforded barriers for sediment brought down by the great Huang Ho (Yellow River) and also the Yangtze. Between the ridges the sediment is up to one mile thick.

Most of the shelf belongs to the stable Neo-Cathaysian Geosyncline (or Cathaysian Platform), dating back at least 300 million years or longer. The Okinawa Trough appears to be perhaps 10 million years old. The Ryukyus are a double-island chain, with several volcanic islands on the East China Sea side. Many of the volcanoes are still active. Epicentres of earthquakes are found along the axis of the Okinawa Trough and the Ryukyu Island arc.

Climate. Weather is dominated by the monsoon wind

The East China, South China, and Yellow seas.

system, the result of differential heating between land and water. In summer the Asian landmass is much warmer than the sea; in the winter it is much colder, particularly in the Plateau of Tibet. Summer heating of air masses over Asia builds areas of low pressure and creates the monsoonal winds, which in this season blow predominantly from the southeast. This brings in warm, moist air from the western Pacific, producing a rainy summer season that is accompanied by typhoons. In winter the situation is reversed: winds blow predominantly from the north, bringing with them cold, dry air from the continent.

Hydrology. Winds also influence water circulation of the Kuroshio (Japan Current), the north-flowing western extension of the warm North Equatorial Current. Some of the Kuroshio enters the eastern part of the East China Sea to form the Tsushima Current, which flows north into the Sea of Japan, while the main part of the current diverts eastward back out into the Pacific south of Kyushu and flows east of Japan. Strengthened by monsoon winds, the Kuroshio is at its widest and fastest in summer, and the axis is displaced well into the East China Sea. This warmed surface water varies from 86° F (30° C) in the south to 77° F (25° C) in the north. In winter, northerly monsoon winds modify the circulation, and the north-flowing Kuroshio, though still important, is reduced in strength, while southerly flowing coastal currents are strengthened. This brings in colder water, with temperatures of 41° F (5° C) in the north to 73° F (23° C) in the south. Some warm water also enters the sea via the Luzon and Taiwan straits.

Because of the constricting nature of the adjoining Yellow Sea and the funnel shape of some of the inlets on the mainland, tidal ranges are especially high along the coast of China. For example, the spring tide range, which

Sea
currents
and tides

is highest in summer and winter, is as much as 23 feet at San-sha Bay and 30 feet at Hang-chou Bay.

Economic aspects. The East China Sea is a region of high marine-life productivity, and China, Japan, and North and South Korea actively fish in the area. Most of the fishing is done by small local boats, although larger trawlers are also used. Tuna, mackerel, shrimps, sardines, milkfish, sea breams, croakers, shellfish, and seaweeds are the main resources harvested.

Oil and natural gas deposits have been discovered under the sea's continental shelf. These discoveries have led to disputes among the bordering countries over the control of areas with potential hydrocarbon reserves, particularly the regions around deep trenches, straits, rocks, and uninhabited islands. A small amount of China's oil production comes from offshore wells in the East China Sea.

In addition to the local shipping traffic in and out of Chinese and Korean ports, the East China Sea serves as the main shipping route from the South China Sea to Japanese and other North Pacific ports. The main ports of the East China Sea are Shanghai in China, Nagasaki in Japan, and Chi-lung in Taiwan.

Study and exploration. Although the East China Sea has been known and traveled for centuries, the major oceanographic research on it has been done since 1950. Most of the research has been carried out by the Chinese, sometimes in cooperation with the Japanese. In addition to gaining a broader scientific knowledge of the sea, these efforts have resulted in the discovery of the warm current coming from the South China Sea and of nearby offshore oil and natural gas reserves. (E.C.La.F.)

SEA OF JAPAN

The Sea of Japan (Japanese: Nihon-kai; Korean: Il Bon Hyae Hyup; Russian: Yaponskoye More) is a marginal sea of the western Pacific Ocean, bounded by Japan and the Soviet island of Sakhalin to the east and by the Soviet Union and Korea on the Asian mainland to the west. Its area is 377,600 square miles (978,000 square kilometres). It has a mean depth of 5,748 feet (1,752 metres) and a maximum depth of 12,276 feet (3,742 metres).

Physical features. *Physiography.* The sea is almost elliptical, having its major axis from southwest to northeast. To the north it is approximately bounded by latitude 51°45' N, while to the south it is bounded by a line drawn from the Japanese island of Kyushu westward through the Gotō Islands of Japan to the South Korean island of Cheju and then northward to the Korean Peninsula.

The sea itself lies in a deep basin, separated from the East China Sea to the south by the Tsushima and Korea straits and from the Sea of Okhotsk to the north by the La Perouse (or Sōya) and Tatar straits. To the east it is also connected with the Inland Sea of Japan by the Kanmon Strait and to the Pacific by the Tsugaru Strait.

The Sea of Japan is a classic semienclosed sea, since its connections with adjacent bodies of water are greatly restricted by the narrow straits. Inflow of water takes place primarily through the eastern and western channels of the Korea Strait; the inflow of water into the Sea of Japan through the narrow and shallow Tatar Strait is negligible, while through the Tsugaru and La Perouse straits the water flows out of the Sea of Japan.

Component basins Underwater, the sea is separated into the Japan Basin to the north, the Yamato Basin to the southeast, and the Tsushima Basin to the southwest. While a narrow continental shelf fringes Siberia and the Korean Peninsula, on the Japanese side of the sea there are wider continental shelves, as well as groups of banks, troughs, and basins lying offshore. The banks lying off the coasts of Japan are divided into groups, which include Okujiri Ridge, Sado Ridge, Hakusan Banks, Wakasa Ridge, and Oki Ridge.

Geology. Yamato Ridge consists of granite, rhyolite, andesite, and basalt, with boulders of volcanic rock scattered on the seabed. Geophysical investigation has revealed that, while the ridge is of continental origin, the Japan Basin and the Yamato Basin are of oceanic origin.

Bottom deposits in the Sea of Japan indicate that sediments of continental origin, such as mud, sand, gravel, and fragments of rock, exist down to depths of 650 to

1,000 feet; hemipelagic sediments (*i.e.*, half of oceanic origin), mainly consisting of blue mud rich in organic matter, are found down to depths of about 1,000 to 2,600 feet; and deeper pelagic sediments, consisting of red mud, are found down to the sea's greatest depths.

The four straits connecting the sea either to the Pacific Ocean or to marginal seas were formed in recent geologic periods. The oldest of these are the Tsugaru and Tsushima straits, the formation of which interrupted the migration of elephants into the Japanese islands at the end of the Tertiary Period (about 1.6 million years ago); the most recent is La Perouse Strait, which was formed about 60,000 to 11,000 years ago and which closed the route used by the mammoths whose fossils have been found in Hokkaido.

Climate. The Sea of Japan influences the climate of Japan because of its relatively warm waters; evaporation is especially noticeable in winter, when an enormous quantity of water vapour rises in the region between the cold, dry polar air mass and the warm, moist tropical air mass. From December to March the prevailing northwest monsoon wind carries cold and dry continental polar air masses over the warmer waters of the sea, resulting in snow along the mountainous western coasts of Japan. In summer the southerly tropical monsoon blows from the North Pacific onto the Asian mainland, causing dense fog when its warm and moist winds blow over the cold currents that prevail over the northern part of the sea at that season. The winter monsoon brings rough seas and causes coastal erosion along the western coasts of Japan. In summer and fall typhoons occasionally occur.

The northern part of the sea, especially off the Siberian coast as well as in the Tatar Strait, freezes in winter; as a result of convection, melted ice feeds the cold currents in that part of the sea in spring and summer.

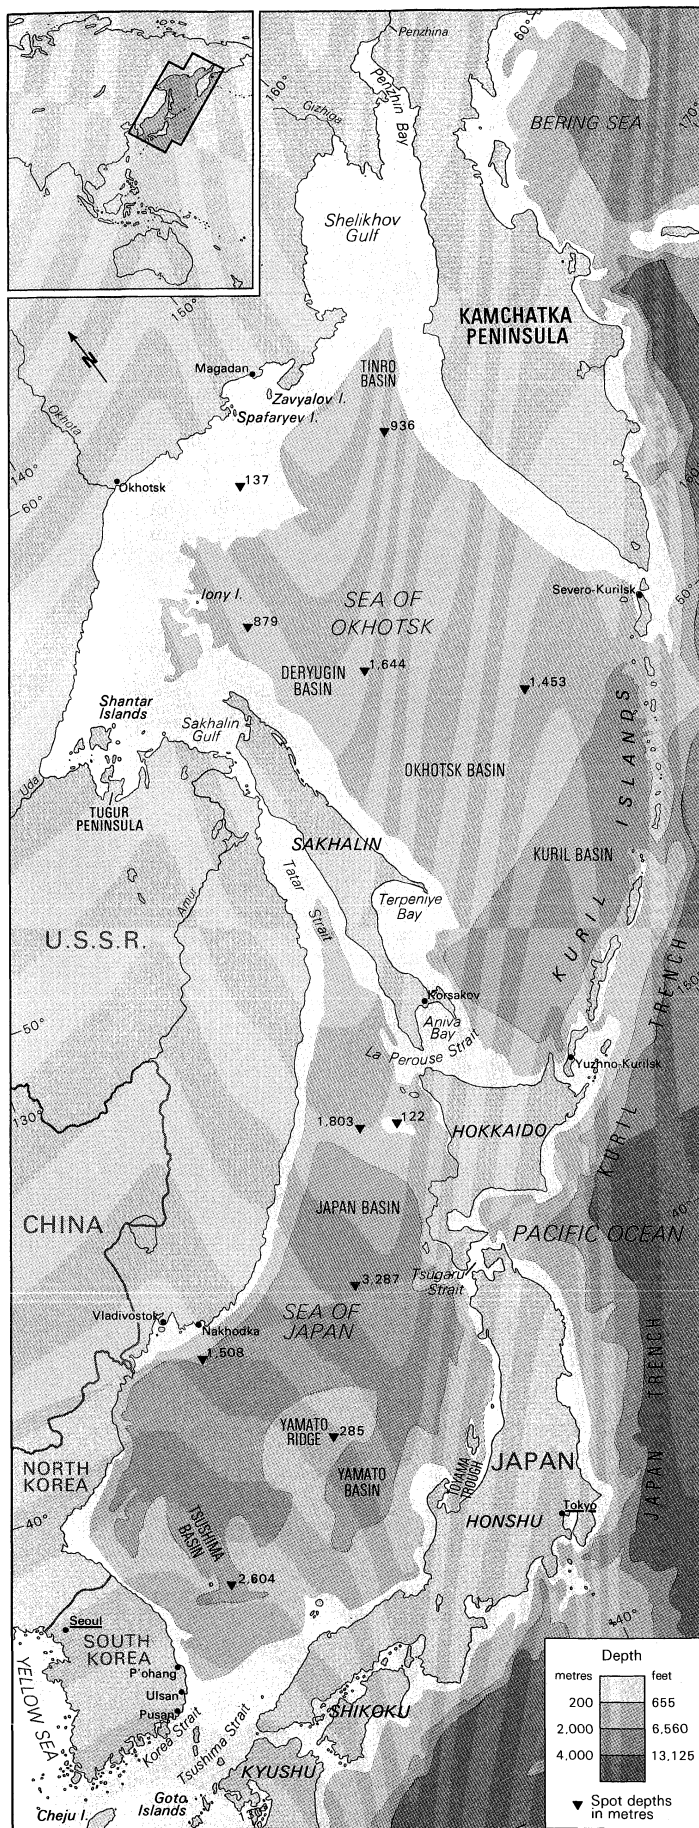

Hydrology. The waters of the sea generally circulate in a counterclockwise pattern. A branch of the Kuroshio (Japan Current), the Tsushima Current, together with its northern branch, the East Korea Warm Current, flows north, bringing warmer and more saline water before flowing into the Pacific through the Tsugaru Strait as the Tsugaru Current, as well as into the Sea of Okhotsk through the La Perouse Strait as the Sōya Current. Along the coast of the Asian mainland three cold currents—the Liman, North Korea, and Central (or Mid-) Japan Sea cold currents—bring cooler, relatively fresh water southward.

The enclosed nature of the Sea of Japan and its three deep basins facilitate the formation of distinct water masses. In the summer months, when the surface is heated by higher air temperatures, a distinct thermocline separates the surface water from the middle water, which is characterized by relatively high temperatures and salinities. The middle water's origin is in the intermediate water layers of the Kuroshio off the coast of Kyushu that enter the Sea of Japan via the Tsushima Current during the winter and spring. A third water mass, the deep water, forms in February and March by the cooling of the water surface in the northern part of the sea; it is of very uniform character, with temperatures ranging narrowly between 32° and 33° F (0° and 0.5° C). The formation of these water masses, particularly the middle water, influences the concentration of dissolved oxygen, which is generally very high; and this contributes to the productive fisheries of the sea.

Economic aspects. Fisheries and mineral deposits form the main economic resources of the Sea of Japan. Pelagic (oceanic) fishes include mackerel, horse mackerel, sardines, anchovies, herring, fishes of the salmon and trout family, sea bream, and squid; the demersal (sea-bottom) category includes cod, Alaskan pollack (bluefish), and Atka mackerel. Seals and whales are also to be found, as well as such crustaceans as shrimps and crabs. The fishing grounds are for the most part on the continental shelves and their adjacent waters.

Herring, sardines, and bluefin tuna have traditionally been caught, but since World War II the fisheries have gradually been depleted. Squid fishing is carried on in the central part of the sea, salmon fishing in the shoal areas of the north and southwest, and crustacean trapping in the deeper parts. The sea is heavily fished by fleets from Japan, the Soviet Union, and North and South Korea.

Prevailing
currents

The Seas of Japan and Okhotsk.

Mineral resources on or in the sea bottom include magnetite sands as well as natural gas and petroleum deposits off Japan and Sakhalin Island.

Trade across the Sea of Japan is only moderate, since most of Japan's trade is with countries outside the sea. Consequently, the most important Japanese ports are located on its Pacific coast. Important ports of South Korea are Pusan, Ulsan, and P'ohang, located on the southeast coast of the country, but most of the shipping in and out of these ports is also destined for countries outside of the sea. Primary Soviet ports are Vladivostok, Nakhodka, and Vostochny. Vladivostok's traffic is primarily with other Soviet ports, while Nakhodka and Vostochny are international ports. Trade between countries around the sea, however, has increased, spurred by the growth of the South Korean economy and by the development of trade agreements with the Soviet Union.

Study and exploration. The waters of the Sea of Japan have been traveled for centuries, and historically they have served to protect Japan from foreign invasions. European exploration in the region began in the 18th century. In the 1780s the Frenchman Jean-François de Galaup, Count de La Pérouse, traveled northward through the Sea of Japan and the strait that was named for him in one of the first voyages both to search for new trade opportunities and to collect scientific data. Robert Broughton, in 1796, also combined exploration with science on his track through the Tatar Strait and then south along the coast of the Russian Far East and around the Korean Peninsula.

Other Russian voyages include those of Adam Johann Krusenstern in the *Nadezhda*, who explored the sea (1803–06) during his circumnavigation of the globe; the *Pallada* (1853–54), which monitored surface temperatures and made tidal observations; and the *Vityaz* (1886–89), which added to oceanographic knowledge of the sea. Also of note are the American North Pacific Exploring (1853–54) and British Challenger (1872–76) expeditions.

Major research cruises by Japan began in 1928 and continued until the start of the Sino-Japanese War in 1937. After World War II the American *Challenger* seismic study of the sea (1951) and the work of the *Baird* added to scientific knowledge and stimulated Japan to reinstitute exploration and research. Most of the current oceanographic work in the sea is characterized by the use of advanced technology, by international cooperation, and by a variety of research projects. (M.U./J.R.Mo.)

European exploration

SEA OF OKHOTSK

The Sea of Okhotsk (Russian: Okhotskoye More), which borders the northwestern Pacific Ocean, is bounded on the west and north by the east coast of Asia from Cape Lazarev to the mouth of the Penzhina River, on the east and southeast by the Kamchatka Peninsula and the Kuril Islands, on the south by the northern coast of the Japanese island of Hokkaido, and on the southwest by Sakhalin Island. Except for the small area touching Hokkaido, the sea is completely enclosed by Soviet territory. Its area covers 611,000 square miles (1,583,000 square kilometres), and it has a mean depth of about 2,818 feet (859 metres). The sea's maximum depth is 11,063 feet (3,372 metres).

Physical features. *Physiography.* For the most part, the continental shore is high and rocky and interspersed with the mouths of large, regional rivers that flow into the sea—the Amur, Tugur, Uda, Okhota, Gizhiga, and Penzhina. The shores of Hokkaido and northern Sakhalin Island are predominantly lower. The Gulfs of Aniva and Terpeniya are found on the southeastern coast of Sakhalin. Nearly all of the other main islands—Shantar, Zavvalov, Spafaryev, Yam, and Tyuleny—are situated close to the shore; only Ion Island is in the open sea.

The formations of the Okhotsk basin have evolved in the Quaternary Period (the last 1.6 million years). The geologic history of the sea shows that the forming of the present hollow was accompanied by repeated glacial transgressions and regressions. The sea bottom has a slope from north to south and southwest. The northern and northwestern parts constitute a continental shallow up to 650 feet in depth, while the remaining area (about 70 percent of the total) is a continental slope from 650 to

Geologic history

5,000 feet deep, on which isolated underwater heights, depressions, and troughs stand out. The deepest part of the sea, the Kuril Basin west of the Kuril Islands, reaches 8,200 feet and deeper.

Large quantities of continental sediment flow into the sea, primarily from the Amur River. Other sources of sediment include that generated by coastal abrasion and volcanic activity. Bottom deposits in the Kuril Basin are a clay-diatom silt, whereas approaching the shore there are fine, silt-covered sands, coarse sands, and pebbles mixed with mussel shells.

Climate. The Sea of Okhotsk is the coldest sea of East Asia; in winter the climate and thermal regime over much of the region differ only slightly from those found in the Arctic. The northeastern, northern, and western regions of the sea experience severe weather during the winter, because of the influence of the Asian continent; from October through April these areas experience very cold air temperatures, are constantly covered with ice, and have very little precipitation. In short, a continental climate pervades these parts of the sea. To the south and southeast the proximity of the Pacific results in a milder marine climate. The coldest months in the sea are January and February; the warmest are July and August. In the northeastern part the average monthly air temperature during February is -4°F (-20°C), while in August the average is 54°F (12°C). To the north and west of the sea, average monthly air temperature is -11°F (-24°C) in February and 57°F (14°C) in August. In the southern and southeastern parts, the average monthly air temperature is 19°F (-7°C) in February and 64°F (18°C) in August. The yearly precipitation averages 16 inches (400 millimetres) in the north, 28 inches in the west, and about 41 inches in the south and southeast.

Hydrology. The water of the Sea of Okhotsk consists of continental drainage, precipitation, and waters flowing from the Pacific Ocean through the straits of the Kuril Islands and from the Sea of Japan through the La Pérouse (Sōya) Strait. During the summer months the sea is warmed to a depth of 100–165 feet. The water temperature on the surface rises to 46° to 54°F (8° to 12°C), and the salinity drops to 32.5 parts per thousand and lower. Deeper water has an average temperature of 29° to 30°F (-1.8° to -1°C) and salinity of up to 34 parts per thousand. The thickness of the cold-water layer fluctuates from a few feet in the southeastern part of the sea to 245–525 feet in the northwest.

The general movement of water in the sea is counter-clockwise. Water flows from the Sea of Japan into the Sea of Okhotsk, accounting for the comparative warmth of its southwestern part. Warm water is also carried into the sea by Pacific currents. Because of the influence of these currents, the waters of the eastern half of the sea are warmer than those of the western part. For the most part, the currents flow clockwise around the Kuril Islands; in the northern half of the straits they flow into the sea, but in the southern half they return into the Pacific. Penzhin Bay has the strongest tides (42.3 feet), while the weakest tides occur at southeastern Sakhalin (2.6 feet). Ice cover appears at the end of October and reaches its greatest extent in March. In the coastal areas it extends to the shore, but in the open sea there is floating ice. The ice vanishes in June, with the exception of the Sakhalin gulfs and the region around Shantar Island, where ice floes are not uncommon in July and sometimes even in August.

Economic aspects. *Biological and mineral resources.* The Sea of Okhotsk is one of most biologically productive of the world's seas. The river drainage, the intense intermingling of waters by straits and wind, and the upwelling of deep, nutrient-laden ocean waters are all favourable to marine life. In those months when it is warm enough, there occurs an extraordinarily rapid spread of life. The flora is represented by algae and seaweed and the fauna by crayfish, sea mussels, crabs, sea urchins, polyps, and various types of fish. Salmon, herring, pollack, flounder, cod, capelin, and smelts (or frostfish), as well as crab and shrimp, are all commercially important. The sea is also inhabited by marine mammals—whales, seals, sea lions, and fur seals.

Almost the entire sea fell under Soviet supervision in 1977 when a 200-mile exclusive economic zone was established. This produced favourable conditions for the development of fisheries and of mineral exploitation. The sea now supplies a large portion of the catches in the Soviet Far East. In addition, deposits of oil and natural gas have been discovered on the sea's northern shelf.

Navigation. Regular navigation connecting the ports of the Soviet Far East is conducted through the sea. On the continental coast the most important of these ports are Magadan in Nagayeva Bay and Okhotsk. Korsakov on Sakhalin Island and Severo-Kurilsk and Yuzhno-Kurilsk on the Kuril Islands are also important. During the winter, ice floes are an impediment to sea navigation, and dense fog is a hindrance during the summer. Strong currents and submerged rocks are other perils of the area. The Sea of Okhotsk region plays an important role in the economic development of the Soviet Far East.

Study and exploration. The Sea of Okhotsk was the first Pacific body of water in which Russian explorers ventured. In 1787 the French navigator Jean-François de Galaup, Count de La Pérouse, sailed northward through the strait named for him and crossed the sea to the Kamchatka Peninsula. The Russian explorer Adam Johann Krusenstern also sailed through the sea to the peninsula in the early 19th century. The expedition of the Soviet research vessel *Vityaz* in 1949 marked the beginning of the modern stage of oceanographic research in the sea. Continuing studies have been carried out by institutes of the Soviet Academy of Sciences. (T.Y.S./A.V.A./K.T.B.)

Russian
exploration

SOUTH CHINA SEA

The South China Sea—known in Chinese (Wade-Giles and Pinyin) as Nan Hai, or the South Sea—is that part of the western Pacific Ocean that borders the Southeast Asian mainland. It is bounded on the northeast by the Taiwan Strait (by which it is connected to the East China Sea), on the east by Taiwan and the Philippines, on the southeast and south by Borneo, the southern limit of the Gulf of Thailand, and the east coast of Malay Peninsula, and on the west and north by the Asian mainland. The southern boundary of the sea is a rise in the seabed between Sumatra and Borneo, and the northern boundary stretches from the northernmost point of Taiwan to the coast of Fukien province, China, in the Taiwan Strait. It embraces an area of about 1,423,000 square miles (3,685,000 square kilometres), with a mean depth of 3,478 feet (1,060 metres).

For map coverage of the South China Sea, see above *East China Sea*.

Physical features. *Physiography.* The major feature is a deep, rhombus-shaped basin on the eastern part, with reef-studded shoals rising up steeply within the basin to the south (Reed and Tizard banks and the Nanshan Island area) and northwest (Paracel Islands and Macclesfield banks). The deep portion, called the China Sea Basin, has a maximum depth of 16,452 feet (5,042 metres), and an abyssal plain with a mean depth of 14,100 feet.

Along the eastern side of the basin the continental shelf falls off sharply near the Philippine islands of Luzon and Palawan and forms the Palawan Trough near the latter island. Along the northwest side of the basin to the mainland is a broad, shallow shelf as wide as 150 miles (240 kilometres). It includes the Gulf of Tonkin and the Taiwan Strait and the large islands of Hai-nan and Taiwan.

To the south, off Vietnam, the shelf narrows and connects with the Sunda Shelf, one of the largest in the world, which covers the area between Borneo, Sumatra and the Malay Peninsula, and includes the southern part of the South China Sea, the Gulf of Thailand, and the Java Sea. This broad trough is about 130 feet deep at its periphery and up to 330 feet in its central part. On the bottom of the shelf is a network of submerged river valleys that converge into the Sunda Depression and then into the China Sea Basin.

The Sunda Shelf is covered with littoral sediments contributed by submerged valleys. The inner zone of mud is characteristic of the continental shelf near the Mekong and Red river deltas, while the sediment of the deeper

Water
currents

parts of the South China Sea is mainly composed of clay. A characteristic part of the sediments in both deep and shallow water is volcanic ash. This is found in layers, derived from large volcanic eruptions in the East Indies, notably the enormous eruption of Krakatoa in 1883, when ash was transported through the entire area by both wind and currents.

Connecting
channels

The South China Sea has connecting channels. The Taiwan Strait on the north is about 100 miles wide, with a depth of about 230 feet. The main deep channel connecting the South China Sea with the Pacific Ocean, the Luzon Strait, lies between Taiwan and the Philippines and has a depth of about 8,500 feet. Shallow channels are found on the east along the Philippine island chain and on the south between Borneo and Sumatra. The western connection to the Indian Ocean is the long Strait of Malacca. At its narrowest part it is 19 miles wide and about 100 feet deep.

The South China Sea is the largest marginal sea of the western Pacific. Some 1 to 60 million years ago, it was rifted and collapsed as a result of seafloor spreading. The China Sea Basin is believed to have dropped 2.5 miles, leaving residual plateaus studded with numerous coral reefs, islets, and banks, some of which are drowned atolls.

Climate. Weather in the sea is tropical and largely controlled by monsoons. In summer, monsoonal winds blow predominantly from the southwest; in winter, winds blow from the northeast. Annual rainfall varies from about 80 inches (2,000 millimetres) to more than 120 inches around the southern basin. Summer typhoons are frequent.

Hydrology. Monsoons control the sea-surface currents as well as the exchange of water between the South China Sea and adjacent bodies of water. In August the surface flow into the South China Sea is from the south through the Karimata and Gelasa (Gasper) straits. Near the mainland the general flow is northeasterly, passing out through the Taiwan and Luzon straits. There is a weak countercurrent on the eastern side of the sea. In February the flow is generally to the southwest; the strongest flow occurs in summer along the bulging part of Vietnam, with speeds of up to three knots (nautical miles per hour) generated by the strong southwestern monsoon.

The near-surface waters are relatively warm (about 84° F [29° C] in the summer) because of the low latitude and a tendency for the equatorial current to feed warm water into the area. In early summer, wind from the southwest not only moves the surface water to the northeast but causes it to be displaced off the coast. As a result, upwelling areas having colder surface temperatures and higher nutrient content are found off central Vietnam. In winter the general surface temperature is cooler, ranging from about 70° F (21° C) in the north to 81° F (27° C) in the south.

The major rivers draining into the South China Sea are the tributaries of the Pearl River delta south of Canton, including the Hsi River; the Red River at Haiphong, Vietnam; and the Mekong River, near Ho Chi Minh City (Saigon), Vietnam. The wet summer season causes the Mekong to triple its annual average flow, and it causes an even greater relative change in the flow of the Red.

Economic aspects. The South China Sea is rich in marine life. Contributing to this abundance are the extensive runoff of nutrient-laden waters from land and the upwellings of water in certain areas of the sea. The sea is heavily fished, however, and is the main source of animal protein for the densely populated Southeast Asian area. Most abundant are the various species of tuna, mackerel, croaker, anchovy, shrimp, and shellfish. Nearly the entire catch is consumed locally, either fresh or preserved.

Large reserves of oil and natural gas have been discovered under the floor of the South China Sea. The main locations for hydrocarbon production are located north of Borneo, east of the Malay Peninsula, and northwest of Palawan.

The South China Sea contains some of the world's most important shipping lanes. The main route to and from Pacific and Indian ocean ports is through the Strait of Malacca and the South China Sea. Generally, oil and minerals move north, and food and manufactured goods move south. Some areas in the central South China Sea

Fishing

are not well sounded, and nautical charts bear the notation "dangerous ground."

Study and exploration. The South China Sea has long been known and traveled. For centuries, however, pirates prowling its waters made passage through the sea hazardous. The sea has been fairly thoroughly studied in the 20th century. A number of cooperative programs have been conducted since World War II, including an expedition by Thailand, the United States, and South Vietnam in 1959–61 that investigated marine life, water structures, and circulation. Satellite photography has been particularly useful. One such study of currents showed that Taiwan acts as a ship's prow, deflecting the north moving currents around the island. Further study demonstrated that these points of deflection are upwell areas, which led to the establishment of commercial fishing there. (E.C.LaF.)

YELLOW SEA

The Yellow Sea (Chinese: Huang Hai) is a large inlet of the western Pacific Ocean lying between the Chinese mainland on the west and north and the Korean Peninsula on the east. It is situated to the north of the East China Sea, which it bounds on a line running from the mouth of the Yangtze River to Cheju Island off South Korea. It measures about 600 miles (960 kilometres) from north to south and about 435 miles from east to west. In the northwest part of the sea, northwest of a line between the Liaotung Peninsula to the north and the Shantung Peninsula to the south, is the Po Hai (Gulf of Chihli). The area of the Yellow Sea proper (excluding the Po Hai) is about 161,000 square miles (417,000 square kilometres), its mean depth is 131 feet (40 metres), and its maximum depth is 338 feet (103 metres).

For map coverage of the Yellow Sea, see above *East China Sea*.

Physical features. *Physiography and geology.* The Yellow Sea, including the Po Hai and Korea Bay, forms a partly enclosed, flat, and shallow marine embayment. Most of the sea, which is deeper than the Po Hai, consists of an oval-shaped basin with depths of about 200 to 260 feet.

The floor of the Yellow Sea is a geologically unique, shallow portion of the continental shelf that was submerged only after the last Ice Age (*i.e.*, within the past 10,000 years). The seafloor slopes gently from the Chinese mainland and more rapidly from the Korean Peninsula to a north-south-trending seafloor valley with its axis close to the Korean Peninsula. This axis represents the path of the meandering Huang Ho (Yellow River) when it flowed across the exposed shelf during times of lowered sea levels and emptied sediments into the Okinawa Trough. The Yellow Sea derives its name from the colour of the silt-laden water discharged from the major Chinese rivers emptying into it. The sea annually receives an immense quantity of sediments, mostly from the Huang Ho and Yangtze River, both of which have formed large deltas. Relict sandy sediments occupy the northern part of the Yellow Sea, the nearshore northern Po Hai, the offshore old Huang Ho delta, and the central part of the south Yellow Sea. The sandy layer is covered with silty and muddy sediments derived from the large rivers of China and Korea since the last glacial period. The dividing line between silt derived from China and sand derived from Korea nearly coincides with the seafloor valley.

Climate. Generally, the climate is characterized by very cold, dry winters and wet, warm summers. From late November to March, a strong northerly monsoon prevails, which in the Po Hai is sometimes accompanied by severe blizzards. Typhoons occur in summer, and in the colder season there are occasional storms. Air temperatures range from 50° to 82° F (10° to 28° C) and precipitation from about 20 inches (500 millimetres) in the north to 40 inches in the south. Sea fog is frequent along the coasts, especially in the upwelling cold-water areas.

Hydrology. The warm current of the Yellow Sea is a part of the Tsushima Current, which diverges near the western part of the Japanese island of Kyushu and flows at less than 0.5 knot (nautical mile per hour) northward into the middle of the sea. Along the continental coasts south-

Floor of
the sea

ward-flowing currents prevail, which strengthen markedly in the winter monsoon period when the water is cold, turbid, and of low salinity.

The tidal range is considerable (13 to 26 feet) along the shallower west coast of the Korean Peninsula, with a maximum spring tide of almost 27 feet. Along the coasts of China it amounts to about 3 to 10 feet (except the Po Hai, where it exceeds 10 feet). In the Yellow Sea the tides are semi-diurnal (*i.e.*, they rise twice daily). The tidal system rotates in a counterclockwise direction. The speed of the tidal current is less than one knot in the middle of the sea, but near the coasts and in the straits and channels stronger currents of more than two or three knots are recorded.

Temperature and salinity

The innermost coastal sections of the Po Hai freeze in winter, and drift ice and ice fields hinder navigation in parts of the Yellow Sea. Surface temperature ranges from freezing level in winter in the Po Hai to summer temperatures of from 72° to 82° F (22° to 28° C) in the shallower parts. Thus, the annual range is very large—from 40° to 50° F (4° to 10° C). In winter the temperature and salinity in the sea are homogeneous from surface to bottom. In spring and summer the upper layer is warmed and diluted by the fresh water from rivers, while the deeper water remains cold and saline. This deep layer of cold water stagnates and moves slowly south in summer. Around this mass of water, especially at its southern tip, concentrations of commercial bottom fishes are found. The dominant salinity in the region is relatively low: in the Po Hai it is 30 to 31 parts per thousand, while in the Yellow Sea proper it is 31 to 33 parts per thousand. In the southwest monsoon season (June to August) the increased rainfall and runoff cause a further reduction in salinity in the upper layer in summer.

Economic aspects. The Yellow Sea, like the East China Sea, is famous for its fishing grounds. The rich demersal (bottom-dwelling) fish resources have been exploited by Chinese, South and North Korean, and Japanese trawlers for years. Although the overall annual catch has grown, the catch by the Japanese has decreased, while those of the Chinese and South Koreans have increased. The main species caught are sea bream, croakers, lizard fish, prawns, cutlass fish, horse mackerel, squids, and flounders; all species, however, are overfished, and the catch of particularly valuable species has declined.

Oil exploration has been successful in the Chinese and North Korean portions of the Yellow Sea. In addition, the sea has become more important with the growth in trade among its bordering nations. The main Chinese ports are Shanghai, Lü-ta, Tientsin, Tsingtao, and Ch'in-huang-tao; the main South Korean port is Inch'on, the outport for Seoul; and that for North Korea is Namp'o, the outport for P'yongyang.

Study and exploration. The Yellow Sea has been studied fairly extensively in the 20th century, but its geologic, physical, and biological properties are incompletely understood. There is, for example, no comprehensive report on the sea's fisheries, despite the awareness of stock depletion. There has been some cooperation between nations—China began joint oil explorations with foreign oil companies in 1979—but the political tension in the region since World War II has inhibited the sharing of scientific information. Thus, it has been difficult to evaluate the state of the sea's marine environment. (M.U./M.J.V.)

BIBLIOGRAPHY

General works: Comprehensive summaries of information about the Pacific Ocean and its seas are found in ALASTAIR COUPER (ed.), *The Times Atlas and Encyclopaedia of the Sea*, 2nd ed. (1989), with excellent maps and text covering the ocean environment, resources, ocean trade, strategic use of the seas, law of the sea, problems of pollution, and scientific research; and MARTYN BRAMWELL (ed.), *The Rand McNally Atlas of the Oceans* (1977, reprinted 1987), with specific sections on bathymetry, structural geology, reefs and islands circulation, mineral resources, and living resources. See also M. GRANT GROSS, *Oceanography, a View of the Earth*, 5th ed. (1990), offering topical rather than regional coverage, but with numerous examples based on the Pacific Ocean; RHODES W. FAIRBRIDGE (ed.), *The Encyclopedia of Oceanography* (1966), with articles on the Pacific and its seas; and the articles pertaining to the

Pacific in the periodical *Oceanus* (quarterly), particularly vol. 32, no. 4 (Winter 1989/90), which is devoted to the Pacific.

Physical environment: OTIS W. FREEMAN, *Geography of the Pacific* (1951), surveys the physical features of the ocean; and ALAN E.M. NAIRN and FRANCIS G. STEHLI (eds.), *The Ocean Basins and Margins*, vol. 7, *The Pacific Ocean*, 2 vol. (1985–88), is comprehensive and highly detailed. ZVI BEN-AVRAHAM (ed.), *The Evolution of the Pacific Ocean Margins* (1989); and H.W. MENARD, *Marine Geology of the Pacific* (1964), explore marine geology and geophysics. See also BRUNO WAUTHY, *Physical Ocean Environment in the South Pacific Commission Area* (1986), a short but valuable summary of the oceanography of the central and South Pacific, prepared as a regional report under the United Nations Environment Programme.

Economic aspects: A detailed review of Pacific Ocean minerals, including those contained in seawater and those on or beneath the ocean floor, is offered in G.P. GLASBY, "Marine Minerals in the Pacific," *Oceanography and Marine Biology* 24:1–64 (1986). Information on economic and other resources of the ocean areas is also found in such works as *Asia & Oceania*, vol. 4 of the *Worldmark Encyclopedia of the Nations*, 7th ed., 5 vol. (1988); FILLMORE C.F. EARNEY, *Marine Mineral Resources* (1990); and *FAO Yearbook: Fishery Statistics*. JOHN P. CRAVEN, *The Management of Pacific Marine Resources* (1982), offers well-written, scholarly coverage of resources and their management, or in some cases mismanagement; details on fisheries, shipping, scientific research, and maritime law are given in EDWARD MILES *et al.*, *The Management of Marine Regions: The North Pacific* (1982); and PETER N. NEMETZ (ed.), *The Pacific Rim* (1987), studies commerce, economic conditions, foreign investments, and resources in the Pacific Rim countries. Another valuable overview of economic conditions, international business enterprises, marine resources, and regionalism is ENDEL-JACOB KOLDE, *The Pacific Quest: The Concept and Scope of an Oceanic Community* (1976); and HENRY S. ALBINSKI *et al.*, *The South Pacific* (1989), studies the "New Pacific" and the economic, political, and social problems of island nations that have achieved independence since World War II.

Study and exploration: ANDREW SHARP, *The Discovery of the Pacific Islands* (1960, reprinted 1985), summarizes the work of 121 explorers of the area and their contributions to charting the Pacific. J.C. BEAGLEHOLE, *The Exploration of the Pacific*, 3rd ed. (1966), and *The Life of Captain James Cook* (1974), are classics on the subject. ERNEST S. DODGE, *Beyond the Capes: Pacific Exploration from Captain Cook to the Challenger, 1776–1877* (1971), provides a thorough coverage of this important period. (Jo.E.B./J.R.Mo.)

Marginal seas: For the Bering Sea, see P.L. BEZRUKOV (ed.), *Geographical Description of the Bering Sea: Bottom Relief and Sediments*, trans. from Russian (1964); DAVID M. HOPKINS (ed.), *The Bering Land Bridge* (1967); A.P. LISITSYN, *Recent Sedimentation in the Bering Sea* (1969; originally published in Russian, 1966); L.K. COACHMAN, K. AAGAARD, and R.B. TRIPP, *Bering Strait: The Regional Physical Oceanography* (1975); and relevant sections in YVONNE HERMAN (ed.), *Marine Geology and Oceanography of the Arctic Seas* (1974). Materials on the Sea of Okhotsk are published primarily in Russian, although English-language articles can be found in *Oceanus*. (A.V.A./K.T.B.)

For the East and South China seas, see DENNIS E. HAYES (ed.), *The Tectonic and Geologic Evolution of Southeast Asian Seas and Islands*, 2 vol. (1980–83); JOHN M. WAGEMAN, THOMAS W.C. HILDE, and K.O. EMERY, "Structural Framework of East China Sea and Yellow Sea," *American Association of Petroleum Geologists Bulletin* 54(9):1611–1643 (1970); CHOON-HO PARK, *East Asia and the Law of the Sea* (1983); and DOUGLAS M. JOHNSTON, *Environmental Management in the South China Sea: Legal and Institutional Developments* (1982). The periodical *Progress in Oceanography* (eight times a year) includes, among other relevant writings, selections of papers presented at the workshops of the Japan and East China Seas Study group, which take place from time to time in Japan. (E.C.LaF.)

On the Sea of Japan, see MARK J. VALENCIA (ed.), *International Conference on the Sea of Japan* (1989), which discusses oceanography, fisheries, petroleum and minerals, trade and shipping, and environment; and GLENN T. TREWARTHA, *Japan: A Geography* (1965), which offers useful information on the climatic influence of the Sea of Japan. The Sea of Japan and other regions of the northwest Pacific are discussed in S. CHIKUNI, *The Fish Resources of the Northwest Pacific* (1985); and maritime policies are addressed in TSUNEO AKAHA, *Japan in Global Ocean Politics* (1985). (J.R.Mo.)

Much of the information on the Yellow Sea is published in Chinese. Useful English-language works include Y.A. PARK, O.H. PILKEY, and S.W. KIM (eds.), *Proceedings of Korea–U.S. Seminar and Workshop of Marine Geology and Physical Processes of the Yellow Sea* (1984); and MARK J. VALENCIA (ed.), *International Conference on the Yellow Sea* (1987). (M.J.V.)

The Art of Painting

The art of painting is the expression of ideas and emotions, with the creation of certain aesthetic qualities, in a two-dimensional visual language. The elements of this language—its shapes, lines, colours, tones, and textures—are used in various ways to produce sensations of volume, space, movement, and light on a flat surface. These elements are combined into expressive patterns in order to represent real or supernatural phenomena, to interpret a narrative theme, or to create wholly abstract visual relationships. An artist's decision to use a particular medium, such as tempera, fresco, oil, watercolour, ink, gouache, encaustic, or casein, as well as the choice of a particular form, such as mural, easel, panel, miniature, manuscript illumination, scroll, screen or fan, panorama, or any of a variety of modern forms, is based on the sensuous qualities and the expressive possibilities and limitations of those options. The choices of the medium and the form, as well as the artist's own technique, combine to realize his or her own unique visual image.

Earlier cultural traditions—of tribes, religions, guilds, royal courts, and states—largely controlled the craft, form, imagery, and subject matter of painting and determined its function, whether ritualistic, devotional, decorative, entertaining, or educational. Painters were employed more as skilled artisans than as creative artists. Later, the Far East and Renaissance Europe saw the emergence of the fine artist, with the social status of scholar and courtier, who signed his work, who decided its design and often its subject and imagery, and who established a more personal, if not always amicable, relationship with his patron.

During the 19th century, painters in Western societies began to lose their social position and secure patronage. Some artists countered the decline in patronage support by holding their own exhibitions and charging an entrance fee. Others earned an income through touring exhibitions of their work. The need to appeal to a marketplace had replaced the similar (if less impersonal) demands of patronage, and its effect on the art itself was probably similar as well. Generally, artists can now reach an audience only through commercial galleries and public museums, although their work may be occasionally reproduced in art periodicals. They may also be assisted by financial awards or commissions from industry and the state. They have, however, gained the freedom to invent their own visual language and to experiment with new forms and unconventional materials and techniques. For example,

some painters have combined other media, such as sculpture, with painting to produce three-dimensional abstract designs. Others have attached real objects to the canvas in collage fashion or used electricity to operate coloured kinetic panels and boxes. Conceptual artists express their ideas in the form of a proposal for an unrealizable project, while performance artists are an integral part of their own compositions. The restless endeavour to extend the boundaries of expression in Western art produces continuous international stylistic changes. The often bewildering succession of new movements in painting is further stimulated by the swift interchange of ideas by means of international art journals, travelling exhibitions, and art centres.

This article is concerned with the elements and principles of design in painting and with the various mediums, forms, imagery, subject matter, and symbolism employed or adopted or created by the painter. ELEMENTS AND PRINCIPLES OF DESIGN

The design of a painting is its visual format: the arrangement of its lines, shapes, colours, tones, and textures into an expressive pattern. It is the sense of inevitability in this formal organization that gives a great painting its self-sufficiency and presence.

The colours and placing of the principal images in a design may be sometimes largely decided by representational and symbolic considerations. Yet it is the formal interplay of colours and shapes that alone is capable of communicating a particular mood, producing optical sensations of space, volume, movement, and light and creating forces

Formal interplay of colours and shapes

Figure 1: *Linear design.*

(Top) The linear design of Georges Seurat's oil painting "La Parade," 1887–88, composed of ovals and rectangles arranged in an overall grid pattern, based on the Golden Mean system of proportions. In the Metropolitan Museum of Art, New York City. 1 m x 1.5 m. (Bottom) The interwoven, linear pattern of Leonardo da Vinci's panel painting "Virgin and Child with St. Anne," c. 1501–12. In the Louvre, Paris. 1.68 m x 1.3 m.

of both harmony and tension, even when a painting's narrative symbolism is obscure.

Elements of design. *Line.* Each of the design elements has special expressive qualities. Line, for example, is an intuitive, primeval convention for representing things; the simple linear imagery of young children's drawings and prehistoric rock paintings is universally understood. The formal relationships of thick with thin lines, of broken with continuous, and of sinuous with jagged are forces of contrast and repetition in the design of many paintings in all periods of history. Variations in the painted contours of images also provide a direct method of describing the volume, weight, spatial position, and textural characteristics of things. The finest examples of this pictorial shorthand are found in Japanese ink painting, where an expressive economy and vitality of line is closely linked to a traditional mastery of calligraphy.

In addition to painted contours, a linear design is composed of all of the edges of tone and colour masses, of the axial directions of images, and of the lines that are implied by alignments of shapes across the picture. The manner in which these various kinds of line are echoed and repeated animates the design (Figure 1). The artist, whether acting consciously or intuitively, also places them in relationship to one another across the picture, so that they weave a uni-

fying rhythmic network throughout the painting (Figure 1).

Apart from the obvious associations of some linear patterns with particular actions—undulating lines suggesting buoyant movement, for instance—emotive sensations are produced by certain linear relationships. Thus, lines moving upward express feelings of joy and aspiration, those directing the eye downward evoke moods of sadness or defeat, while lines at angles opening to the right of a design are more agreeable and welcoming than those spreading outward to the left.

Shape and mass. Shape and mass, as elements of design, include all areas of different colour, tone, and texture, as well as individual and grouped images.

Children instinctively represent the things they see by geometrical symbols. Not only have sophisticated modern artists, such as Paul Klee and Jean Dubuffet, borrowed this primitive imagery, but the more arresting and expressive shapes and masses in most styles of painting and those to which most people intuitively respond will generally be found to have been clearly based on such archetypal forms. A square or a circle will tend to dominate a design and will therefore often be found at its focal centre—the square window framing Christ in Leonardo da Vinci's "Last Supper," for example, the hovering "sun" in an Adolph Gottlieb abstract, or the halo encircling a Chris-

Response to archetypal forms

tian or Buddhist deity. A firmly based triangular image or group of shapes seems reassuring, even uplifting, while the precarious balance implied by an inverted triangular shape or mass produces feelings of tension. Oval, lozenge, and rectangular forms suggest stability and protection and often surround vulnerable figures in narrative paintings.

There is generally a cellular unity, or "family likeness," between the shapes and masses in a design similar to the visual harmony of all units to the whole observed in natural forms—the gills, fins, and scales in character with the overall shape of a fish, for example.

The negative spaces between shapes and masses are also carefully considered by the artist, since they can be so adjusted as to enhance the action and character of the positive images. They can be as important to the design as time intervals in music or the voids of an architectural facade.

Colour. In many styles and periods of painting, the functions of colour are primarily decorative and descriptive, often serving merely to reinforce the expression of an idea or subject communicated essentially in terms of line and tone. In much of modern painting, however, the full-spectrum range of pigments available has allowed colour to be the primary expressive element.

The principal dimensions of colour in painting are the variables or attributes of hue, tone, and intensity. Red, yellow, and blue are the basic hues from which all others on the chromatic scale can be made by mixtures. These three opaque hues are the subtractive pigment primaries and should not be confused with the behaviour of the additive triads and mixtures of transparent, coloured light. Mixtures of primary pairs produce the secondary hues of orange, violet, and green. By increasing the amount of one primary in each of these mixtures, the tertiary colours of yellow-orange, orange-red, red-violet, violet-blue, blue-green, and green-yellow, respectively, are made. The primary colours, with their basic secondary and tertiary mixtures, can be usefully notated as the 12 segments of a circle (Figure 2). The secondary and tertiary colour segments between a pair of parent primaries can then be seen to share a harmonious family relationship with one another—the yellow-orange, orange, and orange-red hues that lie between yellow and red, for example.

Figure 2: Colour. (Left) Colour wheel made up of the primary colours and their basic secondary and tertiary mixtures. (Right) Colour wheel with approximate, inherent tonal values.

Local hues are the inherent and associative colours of things. In everyday life, familiar things are described by particular colours, and these often are identified by reference to familiar things; the green of grass and the grass green of paint, for instance. Although, as the Impressionists demonstrated, the inherent colours of forms in the real world are usually changed by effects of light and atmosphere, many of the great primitive and classical styles of representational painting are expressed in terms of local hues.

Tone is a colour's relative degree, or value, of lightness or darkness. The tonal pattern of a painting is shown in a monochrome reproduction. A painting dominated by dark colours, such as a Rembrandt, is in a low tonal key, while one painted in the pale range of a late Claude Monet is said to be high keyed. The tonal range of pigments is too

Figure 3: An example of the early oil method of (left) colour glazing a (right) monochrome painting.

narrow for the painter to be able to match the brightest lights and deepest darks of nature. Therefore, in order to express effects of illumination and dense shadow, he must lower the overall tonal key of his design, thus intensifying the brightness value of his lightest pigment colours.

The Greco-Roman, Renaissance, and Neoclassical method of representing volume and space in painting was by a system of notated tonal values, the direction of each plane in the design being indicated by a particular degree of lightness or darkness. Each tonal value was determined by the angle at which a plane was meant to appear to turn away from an imaginary source of light. The tonal modelling, or shading, of forms was often first completed in a monochrome underpainting. This was then coloured with transparent washes of local hues, a technique similar to that of colour tinting a black-and-white photograph (Figure 3).

Each hue has an intrinsic tonal value in relation to others on the chromatic scale; orange is inherently lighter than red, for instance, and violet is darker than green (Figure 2). Any reversal of this natural tonal order creates a colour discord. An optical shock is therefore produced when orange is juxtaposed with pink (a lighter tone of red) or pale violet is placed against dark green. Such contrasts as these are deliberately created in paintings for the purpose of achieving these dramatic and disturbing effects.

The intensity of a colour is its degree of purity or hue saturation. The colour of a geranium, therefore, is said to be more intense, more highly saturated with pure orange-red than is mahogany. The pigment vermilion is orange-red at maximum intensity; the brown earth pigment burnt sienna is grayer and has a lower degree of orange-red saturation.

Intense hues are termed chromatic colours. The achromatic range is made up of hues reduced in intensity by the addition of white, making the tints, or pastel colours, such as cream and pink; or of black, producing the shades, or earth colours, such as mustard and moss green; or of both white and black, creating the neutralized hues, or colour-tinged grays, such as oatmeal and charcoal.

An achromatic colour will seem more intense if it is surrounded by neutralized hues or juxtaposed with its complementary colour. Complementaries are colour op-

posites. The complementary colour to one of the primary hues is the mixture of the other two; the complementary to red pigment, for example, is green—that is, blue mixed with yellow. The colour wheel (Figure 2) shows that the tertiaries also have their colour opposites, the complementary to orange-red, for instance, being blue-green. Under clear light the complementary to any chroma, shade, or tint can be seen if one “fixates,” or stares at, one colour intently for a few seconds then looks at a neutral, preferably white, surface. The colour afterimage will appear to glow on the neutral surface (Figure 4). Mutual enhancement

Figure 4: Coloured afterimages: if a person stares for about 30 seconds at the coloured disk under a clear light and then fixes upon the empty space of the adjacent circle, coloured afterimages will appear.

Enhancement of colour intensity

of colour intensity results from juxtaposing a complementary pair, red becoming more intensely red, for instance, and green more fiercely green when these are contiguous than either would appear if surrounded by harmonious hues. The 19th-century physicist Michel-Eugène Chevreul referred to this mutual exaltation of opposites as the law of simultaneous contrast. Chevreul's second law, of successive contrast, referred to the optical sensation that a complementary colour halo appears gradually to surround an intense hue. This complementary glow is superimposed on surrounding weaker colours, a gray becoming greenish when juxtaposed with red, reddish in close relationship with green, yellowish against violet, and so on (Figure 5).

Hues containing a high proportion of blue (the violet to green range) appear cooler than those with a high content of yellow or red (the green-yellow to red-violet range). This difference in the temperature of hues in a particular painting is, of course, relative to the range and juxtaposition of colours in the design. A green will appear cool if surrounded by intense yellow, while it will seem warm against blue-green (Figure 5). The optical tendency for warm colours to advance before cold had been long exploited by European and Oriental painters as a method of suggesting spatial depth. Changes in temperature and intensity can be observed in the atmospheric effects of nature, where the colours of distant forms become cooler, grayer, and bluish, while foreground planes and features appear more intense and usually warmer in colour.

The apparent changes in a hue as it passes through zones of different colour has enabled painters in many periods to create the illusion of having employed a wide range of pigment hues with, in fact, the use of very few. And, although painters had applied many of the optical principles of colour behaviour intuitively in the past, the publication of research findings by Chevreul and others stimulated the Neo-Impressionists and Post-Impressionists and the later Orphist and Op Art painters to extend systematically the expressive possibilities of these principles in order to create illusions of volume and space and vibrating sensations of light and movement. Paul Cézanne, for example, demonstrated that subtle changes in the surface of a form and in its spatial relationship to others could be expressed primarily in facets of colour, modulated by varying degrees of tone, intensity, and temperature and by the introduction of complementary colour accents.

While the often-complex religious and cultural colour symbolologies may be understood by very few, the emotional response to certain colour combinations appears to

be almost universal. Optical harmonies and discords seem to affect everyone in the same way, if in varying degrees. Thus, an image repeated in different schemes of colour will express a different mood in each change (Figure 6).

Texture. Pointillism was a term given to the Neo-Impressionist system of representing the shimmer of atmospheric light with spots of coloured pigment. This technique produced an overall granular texture. As an element of design, texture includes all areas of a painting enriched or animated by vibrating patterns of lines, shapes, tones, and colours, in addition to the tactile textures created by the plastic qualities of certain mediums. Decorative textures may be of geometrical repeat patterns, as in much of Indian, Islāmic, and medieval European painting and other art, or of representations of patterns in nature, such as scattered leaves, falling snow, and flights of birds.

Volume and space. The perceptual and conceptual methods of representing volume and space on the flat surface of a painting are related to the two levels of understanding spatial relationships in everyday life.

Perceptual space is the view of things at a particular time and from a fixed position. This is the stationary window view recorded by the camera and represented in the later periods of ancient Greek and Roman paintings and in most Western schools of painting since the Renaissance. Illusions of perceptual space are generally created by use of the linear perspectival system, based on the observations that objects appear to the eye to shrink and parallel lines and planes to converge as they approach the horizon, or viewer's eye level (Figure 7).

Young children and primitive artists, however, do not understand space in this way and represent it conceptually. Their paintings, therefore, show objects and surroundings independently of one another and from the views that best present their most characteristic features. The notion of scale in their pictures is also subjective, the relative size of things being decided by the artist either by their degree of emotional significance for him or by their narrative importance in the picture (interest perspective).

The conceptual, polydimensional representation of space has been used at some period in most cultures. In much of ancient Egyptian and Cretan painting, for example, the head and legs of a figure were shown in profile, but the eye and torso were drawn frontally. And in Indian,

Perceptual and conceptual levels of understanding spatial relationships

(Top) By complementary action, the same gray pigment will appear greenish when adjacent to red but reddish if adjacent to green. (Bottom) A green hue will seem cool if surrounded by yellow but warm when surrounded by blue-green.

Figure 6: Emotive colour relationships: an identical pattern of shapes may express a different emotional mood through each colour variation.

Islamic, and pre-Renaissance European painting, vertical forms and surfaces were represented by their most informative elevation view (as if seen from ground level), while the horizontal planes on which they stood were shown in isometric plan (as if viewed from above) (Figure 7). This system produces the overall effect that objects and their surroundings have been compressed within a shallow space behind the picture plane.

By the end of the 19th century Cézanne had flattened the conventional Renaissance picture space (Figure 7), tilting

horizontal planes so that they appeared to push vertical forms and surfaces forward from the picture plane and toward the spectator (Figure 8). This illusion of the picture surface as an integrated structure in projecting low relief was developed further in the early 20th century by the Cubists. The conceptual, rotary perspective of a Cubist painting shows not only the components of things from different viewpoints but presents every plane of an object and its immediate surroundings simultaneously. This gives the composite impression of things in space that is gained by having examined their surfaces and construction from every angle.

In modern painting, both conceptual and perceptual methods of representing space are often combined. And, where the orbital movement of forms—which has been a basic element in European design since the Renaissance—was intended to hold the spectator's attention within the frame (Figure 7), the expanding picture space in late 20th-century mural-size abstract paintings directs the eye outward to the surrounding wall, and their shapes and colours seem about to invade the observer's own territory (Figure 9).

Time and movement. Time and movement in painting are not restricted to representations of physical energy, but they are elements of all design. Part of the viewer's full experience of a great painting is to allow the arrangement of lines, shapes, and accents of tone or colour to guide the eye across the picture surface at controlled tempos and rhythmic directions. These arrangements contribute overall to the expression of a particular mood, vision, and idea.

Centuries before cinematography, painters attempted to produce kinetic sensations on a flat surface. A mural of 2000 BC in an Egyptian tomb at Beni Hasan, for instance, is designed as a continuous strip sequence of wrestling holds and throws, so accurately articulated and notated that it might be photographed as an animated film cartoon. The gradual unrolling of a 12th-century Japanese hand scroll produces the visual sensation of a helicopter flight along a river valley, while the experience of walking to the end of a long, processional Renaissance mural by Andrea Mantegna or Benozzo Gozzoli is similar to that of having witnessed a passing pageant as a standing spectator.

In the Eastern and Western narrative convention of continuous representation, various incidents in a story were depicted together within one design, the chief characters in the drama easily identified as they reappeared in different situations and settings throughout the painting. In Byzantine murals and in Indian and medieval manuscript paintings, narrative sequences were depicted in grid patterns, each "compartment" of the design representing a

Kinetic sensations on a flat surface

visual chapter in a religious story or a mythological or historical epic.

The Cubists aimed to give the viewer the time experience of moving around static forms in order to examine their volume and structure and their relationships to the space surrounding them. In paintings such as "Nude Descending a Staircase," "Girl Running on a Balcony," and "Dog on Leash," Marcel Duchamp and Giacomo Balla combined the Cubist technique of projected, interlocking planes with the superimposed time-motion sequences of cinematography. This technique enabled the artists to analyze the structural mechanics of forms, which are represented as moving in space past the viewer.

Principles of design. Because painting is a two-dimensional art, the flat pattern of lines and shapes is an important aspect of design, even for those painters concerned with creating illusions of great depth. And, since any mark made on the painting surface can be perceived as a spatial statement—for it rests upon it—there are also qualities of three-dimensional design in paintings composed primarily of flat shapes. Shapes in a painting, therefore, may be balanced with one another as units of a flat pattern and considered at the same time as components in a spatial design, balanced one behind another. A symmetrical balance of tone and colour masses of equal weight creates a serene and sometimes monumental design, while a more dynamic effect is created by an asymmetrical balance.

Geometrical shapes and masses are often the basic units in the design of both "flat patterns," such as Byzantine and Islāmic paintings, and "sculptural compositions," such as Baroque and Neoclassical figure tableaux. The flat, overlapping squares, circles, and triangles that create the pattern of a Romanesque mural, for example, become the interlocking cubic, spherical, and pyramidal components that enclose the grouped figures and surrounding features in a Renaissance or a Neoclassical composition (Figure 10).

An emphasis upon the proportion of the parts to the whole is a characteristic of Classical styles of painting. The Golden Mean, or Section, has been used as an ideal proportion on which to base the framework of lines and shapes in the design of a painting. The Renaissance mathematician Lucas Pacioli defined this aesthetically satisfying ratio as the division of a line so that the shorter part is to the longer as the longer is to the whole (approximately 8 to 13). His treatise (*Divina proportione*) influenced Leonardo da Vinci and Albrecht Dürer. The Neo-Impressionists Georges Seurat (Figure 1) and Paul Signac based the linear pattern of many of their compositions upon the principle of this "divine proportion." Golden Mean proportions can be discovered in the design of many other styles of paint-

ing, although often they may have been created more by intuitive judgment than by calculated measurement.

Tension is created in paintings, as it is experienced in everyday life, by the anticipation of an event or by an unexpected change in the order of things. Optical and psychological tensions occur in passages of a design, therefore, when lines or shapes almost touch or seem about to collide, when a harmonious colour progression is interrupted by a sudden discord, or when an asymmetrical balance of lines, shapes, tones, or colours is barely held.

Contrasts in line, shape, tone, and colour create vitality; rectilinear shapes played against curvilinear, for instance, or warm colours against cool. Or a painting may be composed in contrasted overall patterns, superimposed in counterpoint to one another—a colour scheme laid across contrasting patterns of lines and tones, for example (Figure 11).

Design relationships between painting and other visual arts. The philosophy and spirit of a particular period in painting usually have been reflected in many of its other visual arts. The ideas and aspirations of the ancient cultures, of the Renaissance, Baroque, Rococo, and Neoclassical periods of Western art and, more recently, of the 19th-century Art Nouveau and Secessionist movements were expressed in much of the architecture, interior design, furniture, textiles, ceramics, dress design, and handicrafts, as well as in the fine arts, of their times. Following the Industrial Revolution, with the redundancy of handcraft-

Tension in paintings

manship and the loss of direct communication between the fine artist and society, idealistic efforts to unite the arts and crafts in service to the community were made by William Morris in Victorian England and by the Bauhaus in 20th-century Germany. Although their aims were not fully realized, their influences, like those of the short-lived de Stijl and Constructivist movements, have been far-reaching, particularly in architectural, furniture, and typographic design.

Michelangelo and Leonardo da Vinci were painters, sculptors, and architects. Although no artists since have excelled in so wide a range of creative design, leading 20th-century painters have expressed their ideas in many other mediums. In graphic design, for example, Pierre Bonnard, Henri Matisse, and Raoul Dufy produced posters and illustrated books; André Derain, Fernand Léger, Marc Chagall, Mikhail Larionov, Robert Rauschenberg, and David Hockney designed for the theatre; Joan Miró, Georges Braque, and Chagall worked in ceramics; Braque and Salvador Dalí designed jewelry; and Dalí, Hans Richter, and Andy Warhol made films. Many of these, with other modern painters, have also been sculptors and printmakers and have designed for textiles, tapestries, mosaics, and stained glass, while there are few mediums of the visual arts that Pablo Picasso did not work in and revitalize.

In turn, painters have been stimulated by the imagery, techniques, and design of other visual arts. One of the earliest of these influences was possibly from the theatre, where the ancient Greeks are thought to have been the first to employ the illusions of optical perspective. The discovery or reappraisal of design techniques and imagery in the art forms and processes of other cultures has been an important stimulus to the development of more recent styles of Western painting, whether or not their traditional significance have been fully understood. The influence of Japanese woodcut prints on Synthetism and the Nabis, for example, and of African sculpture on Cubism and the German Expressionists helped to create visual vocabularies and syntax with which to express new visions and ideas. The invention of photography introduced painters to new aspects of nature, while eventually prompting others to abandon representational painting altogether. Painters of everyday life, such as Edgar Degas,

Henri de Toulouse-Lautrec, Édouard Vuillard, and Bonnard, exploited the design innovations of camera cutoffs, close-ups, and unconventional viewpoints in order to give the spectator the sensation of sharing an intimate picture space with the figures and objects in the painting.

TECHNIQUES AND METHODS

Whether a painting reached completion by careful stages or was executed directly by a hit-or-miss *alla prima* method (in which pigments are laid on in a single application) was once largely determined by the ideals and established techniques of its cultural tradition. For example, the medieval European illuminator's painstaking procedure, by which a complex linear pattern was gradually enriched with gold leaf and precious pigments, was contemporary with the Sung Chinese Zen practice of immediate, calligraphic brush painting, following a contemplative period of spiritual self-preparation. More recently, the artist has decided the technique and working method best suited to his aims and temperament. In France in the 1880s, for instance, Seurat might be working in his studio on drawings, tone studies, and colour schemes in preparation for a large composition at the same time that, outdoors, Monet was endeavouring to capture the effects of afternoon light and atmosphere, while Cézanne analyzed the structure of the Montagne (mountain) Sainte-Victoire with deliberated brush strokes, laid as irrevocably as mosaic tesserae (small pieces, such as marble or tile).

The kind of relationship established between artist and patron, the site and subject matter of a painting commission, and the physical properties of the medium employed may also dictate working procedure. Peter Paul Rubens, for example, followed the businesslike 17th-century custom of submitting a small oil sketch, or *modella*, for his client's approval before carrying out a large-scale commission. Siting problems peculiar to mural painting, such as spectator eye level and the scale, style, and function of a building interior, had first to be solved in preparatory drawings and sometimes with the use of wax figurines or scale models of the interior. Scale working drawings are essential to the speed and precision of execution demanded by quick-drying mediums, such as *buon' fresco* (see below *Mediums: Fresco*) on wet plaster and acrylic resin

Figure 11: Visual counterpoint in design.

on canvas. The drawings traditionally are covered with a network of squares, or "squared-up," for enlarging on the surface of the support. Some modern painters prefer to outline the enlargement of a sketch projected directly onto the support by epidiastroscope (a projector for images of both opaque and transparent objects).

In Renaissance painters' workshops, pupil assistants not only ground and mixed the pigments and prepared the supports and painting surfaces but often laid in the outlines and broad masses of the painting from the master's design and studies.

The inherent properties of its medium or the atmospheric conditions of its site may themselves preserve a painting. The wax solvent binder of encaustic paintings (in which after application, the paint is fixed by heat [see below *Mediums*], for example) both retains the intensity and tonality of the original colours and protects the surface from damp. And, while prehistoric rock paintings and buon' frescoes are preserved by natural chemical action, the tempera pigments thought to be bound only with water on many ancient Egyptian murals are protected by the dry atmosphere and unvarying temperature of the tombs. It has, however, been customary to varnish oil paintings, both to protect the surface against damage by dirt and handling and to restore the tonality lost when some darker pigments dry out into a higher key. Unfortunately, varnish tends to darken and yellow with time into the sometimes disastrously imitated "Old Masters' mellow patina." Once cherished, this amber-gravy film is now generally removed to reveal the colours in their original intensity. Glass began to replace varnish toward the end of the 19th century, when painters wished to retain the fresh, luminous finish of pigments applied directly to a pure white ground. The air-conditioning and temperature-control systems of modern museums make both varnishing and glazing unnecessary, except for older and more fragile exhibits.

The frames surrounding early altarpieces, icons, and cassone panels (painted panels on the chest used for a bride's household linen) were often structural parts of the support. With the introduction of portable easel pictures, heavy frames not only provided some protection against theft and damage but were considered an aesthetic enhancement to a painting, and frame making became a specialized craft. Gilded gesso moldings (consisting of plaster of paris and sizing that forms the surface for low relief) in extravagant swags of fruit and flowers certainly seem almost an extension of the restless, exuberant design of a Baroque or Rococo painting. A substantial frame also provided a proscenium (in a theatre, the area between the orchestra and the curtain) in which the picture was isolated from its immediate surroundings, thus adding to the window view illusion intended by the artist. Deep, ornate frames are

unsuitable for many modern paintings, where the artist's intention is for his forms to appear to advance toward the spectator rather than be viewed by him as if through a wall aperture. In contemporary Minimal paintings, no effects of spatial illusionism are intended; and, in order to emphasize the physical shape of the support itself and to stress its flatness, these abstract, geometrical designs are displayed without frames or are merely edged with thin protective strips of wood or metal.

MEDIUMS

By technical definition, mediums are the liquids added to paints to bind them and make them workable. They are discussed here, however, in the wider meaning of all the various paints, tools, supports, surfaces, and techniques employed by painters. The basis of all paints is variously coloured pigment, ground to a fine powder. The different expressive capacities and characteristic final surface texture of each medium are determined by the vehicle with which it is bound and thinned, the nature and surface preparation of the support, and the tools and technique with which it is handled.

Pigments are derived from various natural and artificial sources. The oldest and most permanent pigments are the blacks, prepared from bone and charcoal, and the clay earths, such as raw umber and raw sienna, which can be changed by heating into darker, warmer browns. In early periods of painting, readily available pigments were few. Certain intense hues were obtainable only from the rarer minerals, such as cinnabar (orange-red vermilion), lapis lazuli (violet-blue ultramarine), and malachite (green). These were expensive and therefore reserved for focal accents and important symbolic features in the design. The opening of trade routes and the manufacture of synthetic substitutes gradually extended the range of colours available to painters.

Tempera. A tempera medium is dry pigment tempered with an emulsion and thinned with water. It is a very ancient medium, having been in constant use in most world cultures, until in Europe it was gradually superseded, during the Renaissance, by oil paints. Tempera was the original mural medium in the ancient dynasties of Egypt, Babylonia, Mycenaean Greece, and China and was used to decorate the early Christian catacombs. It was employed on a variety of supports, from the stone stelae (or commemorative pillars), mummy cases, and papyrus rolls of ancient Egypt to the wood panels of Byzantine icons and altarpieces and the vellum leaves of medieval illuminated manuscripts.

True tempera is made by mixture with the yolk of fresh eggs, although manuscript illuminators often used egg white and some easel painters added the whole egg.

Preservation of a painting

Sources of pigments

Other emulsions have been used, such as casein glue with linseed oil, egg yolk with gum and linseed oil, and egg white with linseed or poppy oil. Individual painters have experimented with other recipes, but few of these have proved successful; all but William Blake's later tempera paintings on copper sheets, for instance, have darkened and decayed, and it is thought that he mixed his pigment with carpenter's glue.

Distemper is a crude form of tempera made by mixing dry pigment into a paste with water, which is thinned with heated glue in working or by adding pigment to whitening, a mixture of fine-ground chalk and size. It is used for stage scenery and full-size preparatory cartoons for murals and tapestries. When dry, its colours have the pale, mat, powdery quality of pastels, with a similar tendency to smudge. Indeed, damaged cartoons have been retouched with pastel chalks.

Egg tempera is the most durable form of the medium, being generally unaffected by humidity and temperature. It dries quickly to form a tough film that acts as a protective skin to the support. In handling, in its diversity of transparent and opaque effects, and in the satin sheen of its finish, it resembles the modern acrylic resin emulsion paints.

Traditional
process of
tempera
painting

Traditional tempera painting is a lengthy process. Its supports are smooth surfaces, such as planed wood, fine set plaster, stone, paper, vellum, canvas, and modern composition boards of compressed wood or paper. Linen is generally glued to the surface of panel supports, additional strips masking the seams between braced wood planks. Gesso, a mixture of plaster of paris (or gypsum) with size, is the traditional ground. The first layer is of gesso grosso, a mixture of coarse, unslaked plaster and size. This provides a rough, absorbent surface for ten or more thin coats of gesso sottile, a smooth mixture of size and fine plaster previously slaked in water to retard drying. This laborious preparation results, however, in an opaque, brilliant white, light-reflecting surface, similar in texture to hard, flat icing sugar.

The design for a large tempera painting traditionally was executed in distemper on a thick paper cartoon. The outlines were pricked with a perforating wheel so that when the cartoon was laid on the surface of the support, the linear pattern was transferred by dabbing, or "pouncing," the perforations with a muslin bag of powdered charcoal. The dotted contours traced through were then fixed in paint. Medieval tempera painters of panels and manuscripts made lavish use of gold leaf on backgrounds and for symbolic features, such as haloes and beams of heavenly light. Areas of the pounced design intended for gilding were first built up into low relief with gesso duro, the harder, less absorbent gesso compound used also for elaborate frame moldings. Background fields were often textured by impressing the gesso duro, before it set, with small, carved, intaglio wood blocks to create raised, pimpled, and quilted repeat patterns that glittered when gilded. Leaves of finely beaten gold were pressed onto a tacky mordant (adhesive compound) or over wet bole (reddish-brown earth pigment) that gave greater warmth and depth when the gilded areas were burnished.

Colours were applied with sable brushes in successive broad sweeps or washes of semitransparent tempera. These dried quickly, preventing the subtle tonal gradations possible with watercolour washes or oil paint; effects of shaded modelling had therefore to be obtained by a crosshatching technique of fine brush strokes. According to the Italian painter Cennino Cennini, the early Renaissance tempera painters laid the colour washes across a fully modelled monochrome underpainting in terre vert (olive-green pigment), a method developed later into the mixed mediums technique of tempera underpainting followed by transparent oil glazes.

The luminous gesso base of a tempera painting, combined with the accumulative effect of overlaid colour washes, produces a unique depth and intensity of colour. Tempera paints dry lighter in value, but their original tonality can be restored by subsequent waxing or varnishing. Other characteristic qualities of a tempera painting, resulting from its fast drying property and disciplined technique,

are its steely lines and crisp edges, its meticulous detail and rich linear textures, and its overall emphasis upon a decorative flat pattern of bold colour masses.

The great Byzantine tradition of tempera painting was developed in Italy in the 13th and 14th centuries by Duccio di Buoninsegna and Giotto. Their flattened picture space, generously enriched by fields and textures of gold leaf, was extended by the Renaissance depth perspectives in the paintings of Giovanni Bellini, Piero della Francesca, Carlo Crivelli, Sandro Botticelli, and Vittore Carpaccio. By that time, oil painting was already challenging the primacy of tempera, Botticelli and some of his contemporaries apparently adding oil to the tempera emulsion or overglazing it in oil colour.

Following the supremacy of the oil medium during succeeding periods of Western painting, the 20th century saw a revival of tempera techniques by such U.S. artists as Ben Shahn, Andrew Wyeth, and George McNeil and by the British painter Edward Wadsworth. It would probably have been the medium also of the later hard-edge abstract painters had the new acrylic resin paints not proved more easily and quickly handled.

Fresco. Fresco (Italian: "fresh") is the traditional medium for painting directly onto a wall or ceiling. It is the oldest known painting medium, surviving in the prehistoric cave mural decorations and perfected in 16th-century Italy in the buon' fresco method.

The cave paintings are thought to date from about 20,000–15,000 bc. Their pigments probably have been preserved by a natural sinter process of rainwater seeping through the limestone rocks to produce saturated bicarbonate. The colours were rubbed across rock walls and ceilings with sharpened solid lumps of the natural earths (yellow, red, and brown ochre). Outlines were drawn with black sticks of wood charcoal. The discovery of mixing dishes suggests that liquid pigment mixed with fat was also used and smeared with the hand. The subtle tonal gradations of colour on animals painted in the Altamira and Lascaux caves appear to have been dabbed in two stages with fur pads, natural variations on the rock surface being exploited to assist in creating effects of volume. Feathers and frayed twigs may have been used in painting manes and tails.

These were not composite designs but separate scenes and individual studies that, like graffiti drawings, were added at different times, often one above another, by various artists. Paintings from the Magdalenian period (c. 10,000 bc) exhibit astonishing powers of accurate observation and ability to represent movement. Women, warriors, horses, bison, bulls, boars, and ibex are depicted in scenes of ritual ceremony, battle, and hunting. Among the earliest images are imprinted and stencilled hands. Vigorous meanders, or "macaroni" linear designs, were traced with fingers dipped in liquid pigment.

Fresco secco. In the fresco secco, or lime-painting, method, the plastered surface of a wall is soaked with slaked lime. Lime-resistant pigments are applied swiftly before the plaster sets. Secco colours dry lighter than their tone at the time of application, producing the pale, mat, chalky quality of a distempered wall. Although the pigments are fused with the surface, they are not completely absorbed and may flake in time, as in sections of Giotto's 14th-century S. Francesco murals at Assisi. Secco painting was the prevailing medieval and early Renaissance medium and was revived in 18th-century Europe by artists such as Giovanni Battista Tiepolo, François Boucher, and Jean-Honoré Fragonard.

Buon' fresco. Buon', or "true," fresco is the most durable method of painting murals, since the pigments are completely fused with a damp plaster ground to become an integral part of the wall surface. The stone or brick wall is first prepared with a brown trullisatio scratch coat, or rough-cast plaster layer. This is then covered by the arriccio coat, on which the linear design of the preparatory cartoon is pounced (see above *Tempera*) or engraved by impressing the outlines into the moist, soft plaster with a bone or metal stylus. These lines were usually overworked in reddish sinopia pigment. A thin layer of fine plaster is then evenly spread, allowing the linear design to show

20th-century
revival of
tempera
techniques

Arriccio
coat

through. Before this final intonaco ground sets, pigments thinned with water or slaked lime are applied rapidly with calf-hair and hog-bristle brushes; depth of colour is achieved by a succession of quick-drying glazes. Being prepared with slaked lime, the plaster becomes saturated with an aqueous solution of hydrate of lime, which takes up carbonic acid from the air as it soaks into the paint. Carbonate of lime is produced and acts as a permanent pigment binder. Pigment particles crystallize in the plaster, fusing it with the surface to produce the characteristic lustre of buon' fresco colours. When dry, these are mat and lighter in tone. Colours are restricted to the range of lime-resistant earth pigments. Mineral colours such as blue, affected by lime, are applied over earth pigment when the plaster is dry.

The intonaco coat is laid only across an area sufficient for painting before the plaster sets. The joins between each successive "day piece" are sometimes visible. Alterations must be made by immediate washing or scraping; minor retouching to set plaster is possible with casein or egg tempera, but major corrections necessitate breaking away the intonaco and replastering. The swift execution demanded stimulates bold designs in broad masses of colour with a calligraphic vitality of brush marks.

No ancient Greek buon' frescoes now exist, but forms of the technique survive in the Pompeian villas of the 1st century AD and earlier, in Chinese tombs at Liaoyang, Manchuria, and in the 6th-century Indian caves at Ajantā. Among the finest buon' fresco murals are those by Michelangelo in the Sistine Chapel and by Raphael in the Stanze of the Vatican. Other notable examples from the Italian Renaissance can be seen in Florence: painted by Andrea Orcagna in the Museo dell'Opera di Sta. Croce, by Gozzoli in the chapel of the Palazzo Medici-Riccardi, and by Domenico Ghirlandajo in the church of Sta. Maria Novella. Buon' fresco painting is unsuited to the damp, cold climate of northern countries, and there is now some concern for the preservation of frescoes in the sulfurous atmosphere of even many southern cities. Buon' fresco was successfully revived by the Mexican mural painters Diego Rivera, José Orozco, and Rufino Tamayo.

Sgraffito. Sgraffito (Italian *graffiare*, "to scratch") is a form of fresco painting for exterior walls. A rough plaster undercoat is followed by thin plaster layers, each stained with a different lime-fast colour. These coats are covered by a fine-grain mortar finishing surface. The plaster is then engraved with knives and gouges at different levels to reveal the various coloured layers beneath. The sintered-lime process binds the colours. The surface of modern sgraffito frescoes is often enriched with textures made by impressing nails and machine parts, combined with mosaics of stone, glass, plastic, and metal tesserae.

Sgraffito has been a traditional folk art in Europe since the Middle Ages and was practiced as a fine art in 13th-century Germany. It has been recently revived in northern Europe.

Oil. Oil paints are made by mixing dry pigment powder with refined linseed oil to a paste, which is then milled in order to disperse the pigment particles throughout the oil vehicle. According to the 1st-century Roman scholar Pliny the Elder, whose writings the Flemish painters Hubert and Jan van Eyck are thought to have studied, the Romans used oil colours for shield painting. The earliest use of oil as a fine-art medium is generally attributed to 15th-century European painters, such as Giovanni Bellini and the van Eycks, who glazed oil colour over a glue-tempera underpainting. It is also thought probable, however, that medieval manuscript illuminators had been using oil glazes in order to achieve greater depth of colour and more subtle tonal transitions than their tempera medium allowed.

Oils have been used on linen, burlap, cotton, wood, hide, rock, stone, concrete, paper, cardboard, aluminum, copper, plywood, and processed boards, such as masonite, pressed wood, and hardboard. The surface of rigid panels is traditionally prepared with gesso and that of canvas with one or more coats of white acrylic resin emulsion or with a coat of animal glue followed by thin layers of white-lead oil primer. Oil paints can be applied undiluted to these prepared surfaces or can be used thinned with

pure gum turpentine or its substitute, white mineral spirit. The colours are slow drying; the safest dryer to speed the process is cobalt siccative.

An oil glaze is a transparent wash of pigment, traditionally thinned with an oleoresin or with stand oil (a concentrate of linseed oil). Glazes can be used to create deep, glowing shadows and to bring contrasted colours into closer harmony beneath a unifying tinted film. Scumbling is the technique of scrubbing an undiluted, opaque, and generally pale pigment across others for special textural effects or to raise the key of a dark-coloured area.

Hog-bristle brushes are used for much of the painting, with pointed, red sable-hair brushes generally preferred for outlines and fine details. Oils, however, are the most plastic and responsive of all painting mediums and can be handled with all manner of tools. The later works of Titian and Rembrandt, for example, appear to have been executed with thumbs, fingers, rags, spatulas, and brush handles. With these and other unconventional tools and techniques, oil painters create pigment textures ranging from delicate tonal modulations to unvarying, mechanical finishes and from clotted, impasto ridges of paint to barely perceptible stains.

The tempera-underpainting-oil-glaze technique was practiced into the 17th century. Artists such as Titian, El Greco, Rubens, and Diego Velázquez, however, used oil pigments alone and, employing a method similar to pastel painting, applied them directly to the brownish ground with which they had tinted the white priming. Contours and shadows were stained in streaks and washes of diluted paint, while lighter areas were created with dry, opaque scumbles, the tinted ground meanwhile providing the halftones and often remaining untouched for passages of local or reflected colour in the completed picture. This use of oil paint was particularly suited to expressing atmospheric effects and to creating chiaroscuro, or light and dark, patterns. It also encouraged a bravura handling of paint, where stabs, flourishes, lifts, and pressures of the brush economically described the most subtle changes of form, texture, and colour according to the influence exerted by the tinted ground through the varying thicknesses of overlaid pigment. This method was still practiced by the 19th-century painters, such as John Constable, J.M.W. Turner, Eugène Delacroix, and Honoré Daumier. The Impressionists, however, found the luminosity of a brilliant white ground essential to the alla prima technique with which they represented the colour intensities and shifting lights of their plein air (open air) subjects. Most oil paintings since then have been executed on white surfaces.

The rapid deterioration of Leonardo's 15th-century "Last Supper," which was painted in oils on plaster, possibly deterred artists from using the medium directly on a wall surface. And the likelihood of eventual warping also prohibited using the large number of braced wood panels required to make an alternative support for an extensive mural painting in oils. Canvas, however, can be woven to any length, and, since an oil-painted surface is elastic, mural paintings could be executed in the studio and rolled and restretched on a wooden framework at the site or marouflaged (fastened with an adhesive) directly onto the wall surface. In addition to the immense studio canvases painted for particular sites by artists such as Jacopo Tintoretto, Paolo Veronese, Delacroix, Pierre-Cécile Puvis de Chavannes, and Monet, the use of canvas has made it possible for mural-size, modern oil paintings to be transported for exhibition to all parts of the world.

The tractable nature of the oil medium has sometimes encouraged slipshod craftsmanship. Working over partly dry pigment or priming may produce a wrinkled surface. The excessive use of oil as a vehicle causes colours to yellow and darken, while cracking, blooming, powdering, and flaking can result from poor priming, overthinning with turpentine, or the use of varnish dryers and other spirits. Colour changes may also occur through the use of chemically incompatible pigment mixtures or from the fading of fugitive synthetic hues, such as the crimson lakes used by Pierre-Auguste Renoir.

Watercolour. Watercolours are pigments ground with gum arabic and gall and thinned with water in use. Sable

Deterioration of Leonardo's "Last Supper"

Earliest use as a fine-art medium

and squirrel ("camel") hair brushes are used on white or tinted paper and card.

Three hundred years before the late 18th-century English watercolourists, Albrecht Dürer had anticipated their technique of transparent colour washes in a remarkable series of plant studies and panoramic landscapes. Until the emergence of the English school, however, watercolour became a medium merely for colour tinting outlined drawings or, combined with opaque body colour to produce effects similar to gouache (see below) or tempera, was used in preparatory studies for oil paintings.

The chief exponents of the English method were Thomas Girtin, John Sell Cotman, John Robert Cozens, Richard Parkes Bonington, David Cox, and Constable. Their contemporary J.M.W. Turner, however, true to his unorthodox genius, added white to his watercolour and used rags, sponges, and knives to obtain unique effects of light and texture. Victorian watercolourists, such as Birket Foster, used a laborious method of colour washing a monochrome underpainting, similar in principle to the tempera-oil technique. Following the direct, vigorous watercolours of the French Impressionists and Postimpressionists, however, the medium was established in Europe and America as an expressive picture medium in its own right. Notable 20th-century watercolourists have been Wassily Kandinsky, Paul Klee, Dufy, and Georges Rouault; the U.S. artists Thomas Eakins, Maurice Prendergast, Charles Burchfield, John Marin, Lyonel Feininger, and Jim Dine; and the English painters John and Paul Nash, Eric Ravilious, Edward Bawden, Edward Burra, and Patrick Proctor.

The "pure" watercolour technique

In the "pure" watercolour technique, often referred to as the English method, no white or other opaque pigment is applied, colour intensity and tonal depth being built up by successive, transparent washes on damp paper. Patches of white paper are left unpainted to represent white objects and to create effects of reflected light. These flecks of bare paper produce the sparkle characteristic of pure watercolour. Tonal gradations and soft, atmospheric qualities are rendered by staining the paper when it is very wet with varying proportions of pigment. Sharp accents, lines, and coarse textures are introduced when the paper has dried. The paper should be of the type sold as "handmade from rags"; this is generally thick and grained. Cockling is avoided when the surface dries out if the dampened paper has been first stretched across a special frame or held in position during painting by an edging of adhesive tape.

Ink. Ink is the traditional painting medium of China and Japan, where it has been used with long-haired brushes of wolf, goat, or badger on silk or absorbent paper. Oriental black ink is a gum-bound carbon stick that is ground on rough stone and mixed with varying amounts of water to create a wide range of modulated tones or applied almost dry, with lightly brushed strokes, to produce coarser textures. The calligraphic brush technique is expressive of Zen Buddhist and Confucian philosophies, brush-stroke formulas for the spiritual interpretation of nature in painting dictating the use of the lifted brush tip for the "bone," or "lean," structure of things and the spreading belly of the hairs for their "flesh," or "fat," volumes. The Far Eastern artist poises the brush vertically above the paper and controls its rhythmic movements from the shoulder. Distant forms represented in landscapes painted on silk were sometimes brushed on from the reverse side.

In the Western world, ink has been used rather more for preparatory studies and topographical and literary illustrations than as a medium for easel paintings. Western artists have generally combined ink washes with contours and textures in quill or steel pen. Among the finest of these are by Rembrandt, Nicolas Poussin, Francisco Goya, Samuel Palmer, Constable, and Édouard Manet. Claude Lorrain, Turner, and Daumier and, in the 20th century, Braque, Picasso, Reginald Marsh, Henri Michaux, and John Piper are some of those who have exploited its unique qualities. Modern artists also use ballpoint and felt pens.

Gouache. Gouache is opaque watercolour, known also as poster paint and designer's colour. It is thinned with water for applying, with sable- and hog-hair brushes, to white or tinted paper and card and, occasionally, to silk. Honey, starch, or acrylic is sometimes added to retard its

quick-drying property. Liquid glue is preferred as a thinner by painters wishing to retain the tonality of colours (which otherwise dry slightly lighter in key) and to prevent thick paint from flaking. Gouache paints have the advantages that they dry out almost immediately to a mat finish and, if required, without visible brush marks. These qualities, with the capacities to be washed thinly or applied in thick impasto and a wide colour range that now includes fluorescent and metallic pigments, make the medium particularly suited to preparatory studies for oil and acrylic paintings. It is the medium that produces the suede finish and crisp lines characteristic of many Indian and Islamic miniatures, and it has been used in Western screen and fan decoration and by modern artists such as Rouault, Klee, Dubuffet, and Morris Graves.

Encaustic. Encaustic painting (from the Greek: "burnt in") was the ancient method, recorded by Pliny, of fixing pigments with heated wax. It was probably first practiced in Egypt about 3000 BC and is thought to have reached its peak in Classical Greece, although no examples from that period survive. Pigments, mixed with melted beeswax, were brushed onto stone or plaster, smoothed with a metal spatula, and then blended and driven into the wall with a heated iron. The surface was later polished with a cloth. Leonardo and others attempted unsuccessfully to revive the technique. North American Indians used an encaustic method whereby pigments mixed with hot animal fat were pressed into a design engraved on smoothed buffalo hide.

A simplified encaustic technique uses a spatula to apply wax mixed with solvent and pigment to wood or canvas, producing a ridged, impasto surface. This is an ancient and most durable medium. Coptic mummy portraits from the 1st and 2nd centuries AD retain the softly blended, translucent colouring typical of waxwork effigies. In the 19th century, Vincent van Gogh also used this method to give body to his oil pigment; the Neo-Impressionist artist Louis Hayet applied encaustic to paper, and it was used by the U.S. painter Jasper Johns for his Pop art canvases. Coloured wax crayons have also been used by modern painters such as Picasso, Klee, Arshile Gorky, and Hockney (see above *Mediums: Fresco*).

Casein. Casein, or "cheese painting," is a medium in which pigments are tempered with the gluey curd of cheese or milk precipitate. For handling, an emulsion of casein and lime is thinned with water. The active element of casein contains nitrogen, which forms a soluble caseate of calcium in the presence of lime. It is applied in thin washes to rigid surfaces, such as cardboard, wood, and plastered walls.

Casein colours dry quickly, although lighter in tone than when first applied. Since they have more body than egg-tempera paints, they can be applied with bristle brushes to create impasto textures not unlike those of oils. Casein paints were used in ancient Rome. They are now available ready-made in tubes and have been used by such modern artists as Robert Motherwell and Claes Oldenburg.

Casein is also an ingredient of some charcoal and pastel fixatives and was a traditional primer for walls and panels.

Synthetic mediums. Synthetic mediums, developed by industrial research, range from the Liquitex fabric dyes used on canvas by the U.S. abstract painter Larry Poons to the house enamel paints employed at times by Picasso and Jackson Pollock.

The most popular medium and the first to challenge the supremacy of oils is acrylic resin emulsion, since this plastic paint combines most of the expressive capabilities of oils with the quick-drying properties of tempera and gouache. It is made by mixing pigments with a synthetic resin and thinning with water. It can be applied to any sufficiently toothed surface with brush, roller, airbrush, spatula, sponge, or rag. Acrylic paints dry quickly, without brush marks, to form a mat, waterproof film that is also elastic, durable, and easily cleaned. They show little colour change in drying, nor do they darken in time. While they lack the surface textural richness of oil or encaustic, they can be built up with a spatula into opaque impastos or thinned immediately into transparent colour glazes. Polyvinyl acetate (PVA) is applied for priming, although it is claimed that acrylic paints can be safely applied directly

Medium particularly suited to preparatory studies

Acrylic resin emulsion

onto unprepared raw canvas or cotton. The wide range of intense hues is extended by fluorescent and metallic pigments. Polymer paints are particularly suitable for the precise, immaculate finish demanded by Op art, Minimalist, and Photo-realist painters such as Bridget Riley, Morris Louis, Frank Stella, and Richard Estes.

Other mediums. *French pastels.* French pastels, with the sharpened lumps of pigment used by Ice Age artists, are the purest and most direct painting materials. Pastel pigments are mixed only with sufficient gum to bind them for drying into stick molds. Generally, they are used on raw strawboard or on coarse-grained tinted paper, although vellum, wood, and canvas have been also employed. These colours will not fade or darken, but, since they are not absorbed by the surface of the support, they lie as pigment powder and are easily smudged. Unfortunately, pastel colours lose their luminosity and tonality if fixed with a varnish and so are best preserved in deep mounts behind glass. Degas often overcame the fragile nature of true pastel painting by the unorthodox method of working on turpentine-soaked paper, which absorbed the powdery pigment.

Eighteenth-century portrait pastellists, such as Maurice-Quentin de La Tour, Jean-Baptiste Peronneau, Jean-Étienne Liotard, and Anton Raphael Mengs, blended the pigment with coiled paper stumps so the surface resembled that of a smooth oil painting. Later pastel painters, such as Degas, Toulouse-Lautrec, Mary Cassatt, Everett Shinn, Odilon Redon, and Arthur Dove, contrasted broad masses of granular colour, spread with the side of the stick, with broken contours and passages of loose cross-hatching and smudging. They often used the tinted ground as a halftone, and, according to the amount of manual pressure exerted on the chalk, they varied the degree of pigment opacity to extract a wide range of tints and shades from each pastel colour.

Oil pastels. Oil pastels are pigments ground in mastic with oil of turpentine, spermaceti, and poppy oil. They are used in a similar way to that of French pastels but are already fixed and harder, producing a permanent, waxy finish. Oil-pastel paintings are generally executed on white paper, card, or canvas. The colours can be blended if the surface of the support is dampened with turpentine or if they are overworked with turpentine. They are popular for small preparatory studies for paintings.

Glass paintings. Glass paintings are executed with oil and hard resin or with watercolour and gum on glass sheets. These have been a folk art tradition in Europe and North America and, from the 15th to the 18th century, were regarded as a fine art in northern Europe, where they have been more recently revived by such painters as Willi Dix, Ida Kerkovius, Lily Hildebrandt, Klee, Oskar Schlemmer, and Heinrich Camperdonck. Colours are applied from the back in reverse order. Unpainted areas of glass are often coated with mercury, providing a mirror background to the coloured images; this creates the kind of illusionary, bizarre spatial relationship between the viewer and picture space sought by the modern artist Michelangelo Pistoletto with his use of photographic images fixed to a polished steel sheet. The colours seen through glass appear translucent, jewel-like, and, since they cannot be touched, even magical.

Ivory painting. Ivory painting was practiced in the 18th and 19th centuries in Europe and America for portrait miniatures. These were generally oval-shaped and designed as keepsakes, lockets, and mantle pictures. They were painted under a magnifying glass in fairly dry watercolour or tempera stippling, with sable- or marten-hair brushes on thin, semitranslucent ivory pieces. Corrections were made with a needle. The velvet quality of their colours was enhanced, on the thinner ivories, by the glow produced by a gold leaf or tinted backing.

Lacquer. Lacquer has been a traditional Chinese medium for more than 2,000 years. It combines painting with intaglio relief. Linen-covered wood panels are coated with chalk or clay, followed by many thin layers of black or red lacquer-tree resin. The surface is polished and a design engraved, which is then coloured and gilded or inset with mother-of-pearl. Layers of compressed paper

or molded papier-mâché have also provided supports. In China and Japan, lacquer has been used principally for decorating shrine panels, screens, caskets, panniers (large baskets), and musical instruments.

Sand, or dry, painting. Sand, or dry, painting is a traditional magic art of the North American Indians; it is still practiced in healing ceremonies among the Navajos of New Mexico and Arizona. Ground sandstone, natural ochres, mineral earths, and powdered charcoal are sprinkled onto a pattern marked into an area covered with yellow-white sand. The patient sits in the centre of this vivid symbolic design of coloured figurative and geometrical shapes. Following the ritual, the painting is destroyed. These "floor" pictures influenced Jackson Pollock in his horizontally spread "action paintings."

Paper. From the end of the 18th century, profiles and full-length group portraits were cut in black paper, mounted on white card, and often highlighted in gold or white. A silhouette ("shade") might be first outlined from the sitter's cast shadow with the aid of a physionotrace.

Collage. Collage was the Dada and Synthetic Cubist technique of combining labels, tickets, newspaper cuttings, wallpaper scraps, and other "found" surfaces with painted textures simulating wood graining and marbling. Among the most lyrical and inventive works in this magpie medium are the so-called *Merz* collages by Kurt Schwitters. Frottage was Max Ernst's method of taking paper rubbings from surfaces, unrelated to one another in real life, and combining them to create fantasy landscapes. Cut paper shapes, hand coloured in gouache, were used by Matisse for his monumental last paintings; Piet Mondrian composed his famous "Victory Boogie Woogie" (1942–43) in coloured-paper cutouts.

Mechanical mediums. The use of mechanical mediums in painting has run parallel to similar developments in modern music and drama. In the field of cybernetics, painters have programmed computers to permute drawings, photographs, diagrams, and symbols through sequences of progressive distortion; and light patterns are produced on television screens by deliberate magnetic interference and by sound-wave oscillations. Artists have also explored the expressive and aesthetic possibilities of linear holograms, in which all sides of an object can be shown by superimposed light images. Painters are among those who have extended the boundaries of filmmaking as an art form. Following the Surrealist film fantasies created by Berthold Bartosch, Jean Cocteau, Hans Richter, and Salvador Dalí, by Schlemmer's filmed ballets and Norman McLaren's hand-painted abstract animations, some painters and other graphic artists are now experimenting with video cassettes for television.

For some Conceptual artists the typewriter is the only equipment used when visual ideas are expressed in the form of instruction sheets alone. For example, typed proposals for defining the real space of an exhibition area with painted lines might invite the active participation of visitors (see below *Forms of painting: Modern forms*).

Mixed mediums. Some pictures are first painted in one medium and corrected or enriched with colour and texture in another. Examples of this kind of mixed mediums are the Renaissance tempera-oil technique, William Blake's relief etchings colour-printed in glue tempera and hand-finished in watercolour, and Degas's overpainted monotypes and his combinations of pastel, gouache, and oil. More recent examples are Richard Hamilton's photographs overpainted in oil colour, Dubuffet's patchwork assemblages of painted canvas and paper, and Klee's alchemy in mixing ingredients such as oil and distemper on chalk over jute and watercolour and wax on muslin stuck on wood.

FORMS OF PAINTING

Mural painting. Mural painting has its roots in the primeval instincts of people to decorate their surroundings and to use wall surfaces as a form for expressing ideas, emotions, and beliefs. In their universal manifestation in graffiti and in ancient murals, such as Ice Age cave paintings and protodynastic Egyptian frescoes, symbols and representational images have been spread freely and

Early mural decorations

indiscriminately across walls, ceilings, and floors. But, in more disciplined attempts to symbolize the importance and function of particular buildings through their interior decoration, murals have been designed for the restricted framework of specific surface areas. They therefore have to be painted in close relationship to the scale, style, and mood of the interior and with regard to such siting considerations as light sources, eye levels, the spectators' lines of sight and means of approach, and the emotive scale relationship between spectators and the painted images.

Early mural decorations for tombs, temples, sanctuaries, and catacombs were generally designed in horizontal divisions and vertical axes. These grid patterns were in harmony with the austere character of the interiors, and their geometrical plan enabled the artist to depict clearly the various episodes and symbols of a narrative subject. In these early traditions of mural design, in China, India, Mexico, Egypt, Crete, and Byzantium, no illusionary devices were used to deny the true flatness of the wall surface; images were silhouetted against a flatly painted ground framed by decorative dados (the decoration adorning the lower part of an interior wall) of stylized motifs in repeat patterns. By the early Renaissance, however, innovators such as Giotto, Masaccio, and Fra Angelico were placing figures within architectural and landscape settings, painted as if extensions to the real dimensions of the interior. The peak of technical skill and artistic expression was reached in the 15th and 16th centuries with the frescoes of Piero della Francesca, Michelangelo, and Raphael. The irregular shapes of wall areas and the distortions produced by convex surfaces were inventively exploited in the design. Intruding doors and windows, for example, were skillfully circumvented by sweeping pattern rhythms or were incorporated as features in the painting, and figures were foreshortened so as to appear to float across or to rise into cupolas (rounded vaults that form ceilings), lunettes (rounded spaces over doors or windows), and apses (domed projections of a church, usually at the east end or altar), the curving surfaces of which might be painted to simulate celestial skies. Existing structural wall features provided the divisions between narrative episodes. These were often supplemented by *trompe l'oeil* ("deceive the eye") columns, pilasters, arcading, balustrading, steps, and other architectural forms that also served to fuse the painted setting with the real interior.

With the increasing dependence upon tapestry hangings and stained glass as primary forms of interior decoration, mural painting suffered a decline in the Western world. Except for those given to Rubens, Tiepolo, Delacroix, and Puvis de Chavannes, there were relatively few important mural commissions in the period following the High Renaissance. In the 20th century, however, enlightened patronage has occasionally enabled leading modern artists to execute paintings for specific sites: Monet's "Water-Lilies" series for the Paris Orangerie, for example, and other murals in France by Vuillard, Matisse, Léger, Chagall, and Picasso; in Mexico and the United States by Orozco, Rivera, Tamayo, and David Siqueiros, and also in the U.S. by Matisse, Shahn, and Willem de Kooning; in Britain by Sir Stanley Spencer and Bawden; in Norway by Edvard Munch; in Holland by Karel Appel; and in Italy by Afro Basaldella.

Easel and panel painting. The easel, or studio, picture was a form developed during the Renaissance with the establishment of the painter as an individual artist. Its scale and portability enabled European artists to extend the range of themes, previously restricted to those suitable to mural decoration. Easel and panel forms include still life, portraiture, landscape, and genre subjects and permit the representation of ephemeral effects of light and atmosphere that the more intimate forms of Oriental art had already allowed the painters of scrolls, screens, and fans to express. Although easel paintings are occasionally commissioned for a special purpose, they are generally bought as independent art objects and used as decorative focal features or illusionary window views in private homes. They are also collected as financial investment, for social prestige, for the therapeutic escapism their subject may provide, or purely for the aesthetic pleasure they afford.

Panel paintings, by strict definition, are small pictures designed for specific sacred or secular purposes or as part of a functional object. Although these wooden boards are sometimes categorized as a form of "decorative" rather than "fine" art, the best examples justify their place in museums alongside great easel paintings. Among the functions they originally served were as predellas (the facings to altar-step risers); devotional and ceremonial icons; portable, folding diptych and triptych altarpieces; shop and tavern signboards; mummy cases; and panel decorations of carriages, musical instruments, and cassoni. Many of them were painted by acknowledged masters, such as Fra Angelico, Paolo Uccello, and Antoine Watteau, as well as by anonymous folk artists.

Miniature painting. Miniature painting is a term applied both to Western portrait miniatures and to the Indian and Islamic forms of manuscript painting discussed below. Portrait miniatures, or limnings, were originally painted in watercolour with body colour on vellum and card. They were often worn in jewelled, enamelled lockets. Sixteenth-century miniaturists, such as Hans Holbein, Jean Clouet, Nicholas Hilliard, and Isaac Oliver, painted them in the tradition of medieval illuminators. Their flat designs, richly textured and minutely detailed, often incorporated allegorical and gilded heraldic motifs. In 17th- and 18th-century Western portrait miniatures, the two-dimensional pattern of rich colours was developed by atmospheric tonal modelling into more naturalistic representations; these were sometimes in pastel and pencil or painted in oils on a metal base. Pantographs (reducing and enlarging copying instruments made on the lazy-tongs lever principle) might be used to transfer a drawing. Among the exponents of this naturalistic style were Francisco Goya, Fragonard, Samuel Cooper, John Hoskins, François Dumont, and the U.S. miniaturists Robert Field and Edward Green Malbone. The introduction of painted ivory miniatures was followed, in the 19th century, by a decline in aesthetic standards, although a classical simplicity was achieved by unsophisticated itinerant limners and by the German miniaturist Patricius Kittner. The painted miniature was eventually superseded by the small, hand-tinted photograph (see above *Mediums: Ivory painting*).

Manuscript illumination and related forms. Among the earliest surviving forms of manuscript painting are the papyrus rolls of the ancient Egyptian Book of the Dead, the scrolls of Classical Greece and Rome, Aztec pictorial maps, and Mayan and Chinese codices, or manuscript books. European illuminated manuscripts were painted in egg-white tempera on vellum and card. Their subjects included religious, historical, mythological, and allegorical narratives, medical treatises, psalters, and calendars depicting seasonal occupations. In contrast to the formalized imagery of Byzantine and early Gothic manuscript painters, Celtic illuminators developed a unique, abstract style of elaborate decoration, the written text being overwhelmed by intricate latticework borders, with full-page initial letters embraced by interlacing scrolls. The medieval Gothic style of illumination, in sinuous, linear patterns of flattened forms isolated against white or gilded grounds, had developed, by the end of the 15th century, into exquisitely detailed, jewel-like miniatures of shaded figures and spatial landscapes. These were often framed by gilded initial letters as vignettes or by margin borders in simulated half relief. With the advent of printing in the 15th century and a final, brilliant period of Flemish and Italian illumination, European manuscript painting survived only in official documents, maps, and in the form of hand-coloured, block-printed pages. Pennsylvania-German birth and baptismal certificates in the U.S. and William Blake's hand-coloured engravings to the Bible and to his own poems were isolated revivals of those forms.

Indian and Islamic miniature painting, however, was practiced into the 19th century; and 11th-century Oriental albums of poem paintings in ink, on leaves of silk or paper, represent a tradition that was continued into modern times. The subjects of Near Eastern miniatures included religious and historical narrative, cosmic maps, and medical, palmistry, and astrological charts, as well as illustrations to poems, songs, and romantic epics. These

Panel paintings

Abstract style of Celtic illuminators

Tempera

"Wind from the Sea," egg tempera painting by Andrew Wyeth, 1947. In a private collection. 47 × 70 cm.

"Christ Discovered in the Temple," panel painting in egg tempera with gold leaf by Simone Martini, 1342. In the Walker Art Gallery, Liverpool. 49.5 × 35 cm.

"King Khusrau Seated upon His Throne," Persian miniature in glue tempera from the *Khamse of Nizami*, 1524-25. In the Metropolitan Museum of Art, New York City. 32 × 23 cm.

A leaf from the *Calendar of a Book of Hours* (April), manuscript illumination in egg tempera by Simon Bennick, early 16th century. In the Victoria and Albert Museum, London. 14 × 9.6 cm.

Fresco of a court scene from the *Mahājanaka Jataka*, Cave I, Ajantā, India, 600–700.

"Fowling in the Marshes," detail of a wall painting from the tomb of Nebamun, Thebes, Egypt, c. 1450 BC, XVIII dynasty. In the British Museum.

Frescoes by Giovanni Battista Tiepolo, 1750–52, decorating the Kaisersaal Residenz, Würzburg, West Germany, designed by Balthasar Neumann, 1719–44.

"The Creation of Adam," detail of the ceiling fresco in the Sistine Chapel, Vatican, by Michelangelo, 1508–12.

Wall painting

Fresco cycle depicting scenes from the life of the Virgin and the life of Christ by Giotto in the Arena Chapel, Padua, Italy, c. 1305–09.

Folk art fresco on the Adam and Eve house, Ardez, Switzerland, 1647.

Frescoes by José Clemente Orozco, 1938–39, decorating the ceiling and drum of the dome of the Hospicio Cabañas, Guadalajara, Mexico.

Oil and encaustic

"Smaragd Red and Germinating Yellow," oil painting by Hans Hofmann, 1959. In the Cleveland Museum of Art. 1.4 × 1 m.

Detail from "Water Lilies," oil on canvas by Claude Monet, 1904. In the Musée de Jeu de Paume, Paris. Entire painting 90 × 92 cm.

"Salisbury Cathedral," oil painting by John Constable, c. 1825. In the National Gallery, London. 53 × 77 cm.

"Venus and the Lute Player," oil painting by Titian, c. 1560. In the Metropolitan Museum of Art, New York City. 1.7 × 2.1 m.

Plate 4. By courtesy of (top left) the Contemporary Collection of the Cleveland Museum of Art, (top right) the trustees of the National Gallery, London, (bottom) the Metropolitan Museum of Art, New York, Munsey Fund, 1936; photograph. (centre right) SCALA/Art Resource, NY

Plate 5. By courtesy of (top left) the Rijksmuseum, Amsterdam, (top right) the Metropolitan Museum of Art, New York, gift of Edward S. Harkness, 1917–18, (bottom left) the National Gallery of Art, Washington, D.C., Andrew W. Mellon Collection, 1937, (bottom right) the Fogg Art Museum, Harvard University, purchase, Alpheus Hyatt Fund

Detail from "The Bridal Couple," oil painting by Rembrandt, c. 1665. In the Rijksmuseum, Amsterdam. Entire painting 1.2 × 1.7 m.

Detail from "The Annunciation," oil painting by Jan van Eyck, c. 1434/36. In the National Gallery of Art, Washington, D.C. Entire painting 93 × 36.5 cm.

Portrait of a boy, encaustic painting from al-Fayyūm, Egypt, probably 2nd century. In the Metropolitan Museum of Art, New York City. 33 × 18.5 cm.

Detail from "Quos Ego" ("Neptune Calming the Tempest"), oil painting by Peter Paul Rubens, c. 1635. In the Fogg Art Museum, Harvard University. Entire painting 49 × 64 cm.

"A Young Man Among Roses," watercolour miniature by Nicholas Hilliard, c. 1588. In the Victoria and Albert Museum, London. 13.4 × 7.4 cm.

"The Annunciation," anonymous Austrian or Swabian woodcut, hand-coloured with watercolour, 1450–70. In the National Gallery of Art, Washington, D.C. 27.3 × 19.2 cm.

"The Burning of the Houses of Parliament," watercolour painting by J.M.W. Turner, 1834. In the British Museum. 23.4 × 32.4 cm.

Ink, gouache, and watercolour

"The Monumental Turf," watercolour painting by Albrecht Dürer, 1503. In the Albertina, Vienna. 41 × 31.5 cm.

Plate 6: By courtesy of (top left) the Victoria and Albert Museum, London, (bottom left) the National Gallery of Art, Washington, D.C., Rosenwald Collection, (bottom right) the Albertina, Vienna; photograph, (top right) Hans Hinz, Basel

"Kirkstall Abbey, Yorkshire—Evening," watercolour painting by Thomas Girtin, 1801. In the Victoria and Albert Museum, London. 30.4 × 51 cm.

"Landscape," detail of a Japanese handscroll, ink on paper by Sesshū (1420–1506). In the National Museum, Tokyo. Dimensions of entire scroll 147.3 × 35.6 cm.

French fan, gouache on paper, sticks of carved mother-of-pearl inlaid with gilt and set with pastes, c. 1750. In the Victoria and Albert Museum, London.

"The Return of Wen-chi to Ying-chuan," scene from the Chinese handscroll "The Life of Lady Ts'ai-chi," anonymous, ink and colour on silk, 12th century, Sung dynasty. In the Museum of Fine Arts, Boston. Detail of the scroll 25 × 55.8 cm.

"Union I," epoxy paint and fluorescent alkyd painting by Frank Stella, 1966. In the Detroit Institute of Arts. 2.6 × 4.5 m.

Modern forms

"Breakfast," pasted paper, crayon, and oil paint collage by Juan Gris, 1914. In the Museum of Modern Art, New York City. 81 × 60 cm.

"First Landing Jump," combine painting by Robert Rauschenberg, 1961. In the Museum of Modern Art, New York City. 2.3 × 1.8 m.

"Grossinger's Bakery," oil painting by Richard Estes, 1972. In the Allan Stone Gallery, New York City. About 89 × 61 cm.

were generally painted in gouache on paper, with occasional gold- or silver-leaf embellishment. The linear design was first drawn with a brush in delicate contours and soft shading. Landscape and architectural detail was as well observed as in that of the principal figures.

The *rapprochement* established between text, painted borders, margin spaces, and illustration is characteristic of both Eastern and Western manuscript paintings. In Indian and Islāmic miniatures, for example, the panels of decorative script are integrated within the overall pattern as areas of textural enrichment; and, with the margin and inset frames, these panels serve also as concrete screens and prosceniums to the action depicted, the participants in the narrative episode making their exits and entrances across or behind them.

Scroll painting. Hand scrolls, traditional to China and Japan, are ink paintings on continuous lengths of paper or silk. They are unrolled at arm's length and viewed from right to left. These generally represent panoramic views of rivers, mountain and urban landscapes, and domestic interiors. They also illustrate romantic novels, Taoist and Buddhist themes, and historical and genre subjects. Narrative poetic commentaries were included as integral textures in the flowing design. The scrolls are remarkable for their vitality, the lyrical representation of atmospheric space, and for the rising and dipping viewpoints that anticipate the zooming motion-picture camera. The earliest surviving scrolls, such as Ku K'ai-chih's "Admonitions of the Instructress to the Court Ladies," date from the 4th century AD. Oriental hanging scrolls and Indian and Tibetan temple banners are forms similar to those of Western easel and panel paintings. Their subjects range from the seasons, domestic interiors, landscapes, and portraits to Vishnu epics, mandalas (symbolic diagrams of the universe), and temple icons. They are painted in ink or gouache on silk and paper and are usually mounted on embroidered or block-printed silk. The dramatic interplay of bold, flattened images against the open space of an unpainted or gilded ground influenced 19th-century Western Art Nouveau decoration.

Screen and fan painting. Folding screens and screen doors originated in China and Japan, probably during the 12th century, and continued as a traditional form into the 20th. They are in ink or gouache on plain or gilded paper and silk. Their vivid rendering of animals, birds, and flowers and their atmospheric landscapes brought nature indoors. In some screens each panel was designed as an individual painting, while in others a continuous pattern flowed freely across the divisions. Japanese screens were often painted in complementary Yin and Yang pairs. Large 12-panel Chinese coromandel lacquer screens were imported into Europe during the 17th and 18th centuries. French Rococo boudoir screens depicting *fêtes champêtres* (townspeople enjoying rural surroundings) and *toile de Jouy* (landscape or floral) pastoral themes were painted on silk or on wood panels in a flamboyantly scrolled, gilded framework. The designs of Art Nouveau screens were inspired by the Japanese tradition. Sidney Nolan's screens on Greek themes and the pastiches of Victorian paper-scrap screens by Pop art painters are recent Western revivals. Traditional to the Greek and Russian Orthodox churches is the iconostasis screen, which stands between the nave and sanctuary and displays icon panel paintings representing the Virgin, the saints, and narrative subjects.

Rigid fans are depicted in the paintings and reliefs of ancient Egypt, Assyria, Greece, and Rome, but the oldest surviving specimens are the round and folding fans from Japan and China. These were painted in India ink and colour on paper, card, and silk, the ground often sprinkled with gold dust or laid with gold or silver leaf. Spread freely across the mount, a calligraphic design depicted seasonal landscapes, genre scenes, and bird, flower, and animal motifs, with accompanying poems and commentaries. Leading Oriental painters produced much of their finest work in this form. In Europe, however, where fan painting had been rarely practiced until the 17th century, it was considered a minor art, and designs were often based on frescoes and easel paintings. The richest and most elegant of these were painted in France and

Italy during the 18th century. Watercolour and gouache paintings and hand-coloured engraved designs were made on paper, card, kid, and gauze. Allegories and romantic pastoral landscapes were frequently designed as separate vignettes, linked by floral swags and border scrolls. Both sides of the mount might be painted. The guards and sticks of the spoke framework were in delicately carved wood or ivory, inlaid with gold leaf or mother-of-pearl. Round hand-screens of parchment, mounted on handles like lollipops, were popular in early 19th-century English society. Charles Conder was a notable *fin de siècle* ("end of the century," characterized by effete sophistication) fan painter, and, more recently, Oskar Kokoschka decorated a lively set of fans on an autobiographical narrative theme.

Panoramas. Panoramas were intended to simulate the sensation of scanning an extensive urban or country view or seascape. This form of painting was popular at the end of the 18th century. Notable examples are "The Battle of Agincourt" (1805), by R.K. Porter, and "Scheveningen," by Hendrik Willem Mesdag. Panoramas might be compared to Cinerama films and enjoyed as a stimulating optical entertainment, along with cyclorama drums (large pictorial representations encircling the spectator), *trompe l'oeil* diorama peep shows, and the show box, for which Thomas Gainsborough painted glass transparencies. More serious forms of panoramic painting are exemplified in Chinese Buddhist sanctuary frescoes, Oriental hand scrolls, Dürer's watercolour townscapes, Andrey Rublyov's 14th-century mural of Moscow, and Uccello's original sequence of three panels depicting the Battle of San Romano.

Modern forms. The concept of painting as a medium for creating illusions of space, volume, texture, light, and movement on a flat, stationary support has been challenged by many modern artists. Some recent forms, for example, have blurred the conventional distinctions between the mediums of sculpture and painting. Sculptors such as David Smith, Eduardo Paolozzi, and Philip Sutton have made multicoloured constructions; painters such as Jean Arp and Ben Nicholson have created abstract designs in painted wood relief, and Richard Smith has painted on three-dimensional canvas structures the surfaces of which curl and thrust toward the spectator. And, rather than deny the essential flatness of the painting support by using traditional methods of representing volume and texture, Robert Rauschenberg and Jim Dine have attached real objects and textures to the painted surface, and Frank Stella and Kenneth Noland have designed their irregularly shaped canvases to be seen as explicitly flat art objects. Rejecting earlier painting methods of reproducing effects of light with tonal contrasts and broken pigment colour, some artists have made use of neon tubes and mirrors. Instead of simulating sensations of movement by optical illusion, others have designed kinetic panels and boxes in which coloured shapes revolve under electric power. The traditional definition of painting as a visual, concrete art form has been questioned by recent aspects of Conceptual art, in which the painter's idea might be expressed only in the form of documented proposals for unrealized and often unrealizable projects. In "performance art" and "happenings," which employ techniques akin to those used in theatre, the artists themselves become a kind of medium.

IMAGERY AND SUBJECT MATTER

The imagery and subject matter of paintings in early cultures were generally prescribed by tribal, religious, or dynastic authorities. In some Eastern countries, traditional models survived into the 18th century and even later. With the Renaissance, however, images and themes in Western painting, reflecting the new spirit of Humanistic, objective curiosity and scientific research, came to be decided by the artist and his patron and, in more recent periods, by the artist alone.

Kinds of imagery. Within the various cultures the art of representing things by painted images has rarely shown a continuously developing pattern toward greater realism. More often, religious and philosophical precepts have determined the degree of naturalism permitted. Rules governing portrayals of the human figure have been particularly stringent in certain traditions of representational painting,

Attitudes
toward
the cosmic
signifi-
cance
of man

reflecting different attitudes to the cosmic significance of man. For example, a belief in the inferiority of man in relation to an almighty deity is expressed in the faceless figures in early Jewish painting and in the dehumanized stylizations of Byzantine imagery; and his insignificance against the dynamic forces of nature is symbolized in Chinese landscape paintings by his puny scale within a monumental setting. An earlier view, which instead sought to glorify the spiritual, intellectual, and physical attributes of mankind, is typified in the noble figures of Greco-Roman art and in the renewed celebration of human physical beauty in the Renaissance and subsequent Neoclassical styles. The uniqueness of man among living things and the expression of his individual physical and emotional characteristics are exemplified in Japanese and northern European narrative and genre painting. Concomitant with the antipathy toward figurative representation in some cultures was a general distaste for the portrayal of all things of the exterior world, animals, landscape features, and other natural forms rarely appearing except as stylized images signifying spiritual forces of good and evil. The representational imagery of modern painting borrows freely from ancient and contemporary sources such as primitive and child art, Classical mythology, commercial advertising, press photography, and the allegories and fantasies of the motion picture and the comic strip. Nonrepresentational imagery is not restricted to modern painting but appears also in earlier forms such as Aurignacian (Paleolithic) decorative meanders, the scrollwork of Celtic illuminations, and the patterns of Islāmic Kūfic calligraphy (an angular variety of the Arabic alphabet). And the abstraction of natural forms into rudimentary symbols, characteristic of modern painting, is echoed in the "pin-men" conventions of Magdalenian caves, in Aztec pictograms, and Indian and Tibetan cosmic-diagram paintings.

Kinds of subject matter. *Devotional.* The range and interpretation of subjects in different forms of devotional painting express a particular attitude to the relationship between man and his deity. Early Christian and Buddhist murals, for example, portrayed an all-powerful, remote, and mysterious being, painted as a flat, formalized head or figure whose stern gaze dominated the interiors of temples, churches, and sanctuaries. Christian Last Judgments and Oriental hell paintings were intended to frighten the believer, while subjects such as the Virgin enthroned, the Assumption, and Buddha descending from Paradise sustained his faith with hopes for salvation and rewards of blissful immortality.

Narrative. When the autocratic ecclesiastical control over Western painting weakened under Renaissance Humanism, the religious narrative picture became a window onto a terrestrial rather than a celestial world. Both emotional and physical relationships between the figures depicted were realistically expressed, and the spectator was able to identify himself with the lifelike representation of a worldly space inhabited by Christ, his disciples, and saints, wearing updated dress and moving naturally within contemporary settings. This kind of narrative interpretation persists in the modern religious paintings of Sir Stanley Spencer, where biblical environments are represented by the clipped hedgerows, the churchyards, and the front parlours of his neat, native English village of Cookham.

Allegorical
narrative
subjects

Allegorical narrative subjects might exalt the sensuous arts, as in the symbolic muses portrayed by Poussin and Luca Signorelli and the paradisiac gardens of 15th-century French illuminated manuscripts. But they might also carry warnings. In the 16th century, Pieter Bruegel the Elder, for example, combined overt and often grotesque symbols with subtle visual metaphors to point stern morals in such paintings as "The Triumph of Death" (alluding to the "wages of sin"), "The Land of Cockaigne" (attacking gluttony and sloth), and "Mad Meg" (ridiculing covetousness). Even Bruegel's apparently straightforward genre subjects, such as "The Peasant Dance" and the festival of "The Fight Between Carnival and Lent," conceal parables on man's follies and sins, while Hieronymus Bosch introduced abstruse, allegorical phantasmagoria into such traditional narratives as "The Temptation of St. Antony" and "The Prodigal Son" and made his "Garden of De-

lights" an expression of disgust rather than of joy. Botticelli's late paintings, probably produced under the influence of the 15th-century Italian monk and reformer Girolamo Savonarola, are other savagely pessimistic allegories: "The Story of Virginia Romana" and "The Tragedy of Lucretia," representing virtue upheld only by death, and "The Calumny of Apelles," in which envy, suspicion, deceit, guile, repentance, and truth are identified, like medieval mummifiers, by their costume, pose, and gesture. Rubens, however, found in allegorical symbolism a means of dramatizing mundane state commissions, such as "The Union of Scotland and Ireland" and "The Bounty of James I (Triumphing over Avarice)." Among famous 19th-century allegories are Delacroix's "Liberty Leading the People" and Pierre-Paul Prud'hon's "Crime Pursued by Vengeance and Justice."

Possibly the highest achievements in narrative illustrations to poetry and literature are found in Eastern miniatures and Oriental scrolls, such as the Persian paintings of Ferdowsi's 11th-century national epic poem, the *Shāhnāme*, and the 12th-century Japanese scrolls of the *Genji monogatari* and the *Story of Ben Dainagon*. An example of modern literary painting is Sidney Nolan's narrative series portraying the Australian folklore hero Ned Kelly.

Ancient Greek and Roman mythologies have provided Western artists with rich sources of imagery and subject matter and with opportunities for painting the nude. Historical narrative painting includes Classical mythology and heroic legend, as well as the representation of contemporary events; examples include Benjamin West's "Death of Wolfe," Théodore Géricault's "Raft of the Medusa," and Goya's "The 3rd of May in Madrid."

Portraiture. The earliest surviving portraits of particular persons are probably the serene, idealized faces painted on the front and inside surfaces of dynastic Egyptian sarcophagi. The human individuality of the Roman mummy portraits of the 1st and 2nd century AD, however, suggests more authentic likenesses. Although portraits are among the highest achievements in painting, the subject poses special problems for the artist commissioned to paint a notable contemporary. The portraits of patrons by artists such as Raphael, Rubens, Hyacinthe Rigaud, Antoine-Jean Gros, Jacques-Louis David, and Sir Thomas Lawrence were required to express nobility, grace, and authority, just as the sultans and rajahs portrayed on frontispieces to Persian and Indian illuminated books and albums had understandably to be flattered as benevolent despots. Such concessions to the sitter's vanity and social position seem to have been disregarded, however, in the convincing likenesses by more objective realists such as Robert Campin, Dürer, Jan van Eyck, Velázquez, Goya, and Gustave Courbet. Probably the finest are the self-portraits and studies of ordinary people by Rembrandt and Van Gogh, where psychological insight, emotional empathy, and aesthetic values are fused. A more decorative approach to the subject is seen in the flattened portraits by Holbein, the Elizabethan and itinerant naïve U.S. limners, and the Far Eastern paintings of ancestors, poets, priests, and emperors. Like these paintings, the full-length portraits by Boucher, Gainsborough, Kees van Dongen, and Matisse display as much regard for the texture and form of their sitters' dress as for their facial features.

Since the development of photography, however, portraiture has been rarely practiced for its own sake as a serious art form, except where artists such as Cézanne and Braque have used it as a subject for structural research or—like Amedeo Modigliani, Chaim Soutine, and Francis Bacon—for the expression of a personal vision beyond the scope of the camera.

Genre. Genre subjects are scenes from everyday life. Hunting expeditions and tribal rituals figure in prehistoric rock paintings. Domestic and agricultural occupations, with banquet scenes of feasting, dancing, and music, were traditional subjects for ancient Egyptian tomb murals. Far Eastern hand scrolls, albums, and screens brilliantly describe court ceremonies, the bustle of towns, and the hardships of the countryside. The depiction of earthly pursuits was forbidden under the strict iconography prescribed by the early Christian Church, but the later illu-

Photo-
graphs and
painted
portraits

minated Books of Hours provide enchanting records of the festivals and occupations of northern European communities. In Renaissance painting, genre subjects were generally restricted to background features of portraits and historical narratives. Domestic scenes, however, not only provided Bruegel with subjects for moral allegories but, as with Rembrandt, were used to counterpoint the emotional intensity of a dramatic religious theme. The withdrawal of religious patronage in northern Europe directed painters toward secular subjects. The rich period of genre painting in 17th-century Holland is represented by the interiors, conversation pieces, and scenes of work and play by David Teniers the Younger, Frans Hals, Jan Steen, Gerard Terborch, Pieter de Hooch, Adriaen van Ostade, and, the finest, by Jan Vermeer. Pictures of rustic life had a special appeal for collectors in 18th-century France and England; these were the somewhat picturesque representations of peasant life painted by Jean-Baptiste Greuze, Boucher, George Morland, and Gainsborough. Jean-Baptiste-Siméon Chardin's paintings of servants and children, however, exhibit a timeless dignity and grandeur. The harsher realities of working life were depicted by Jean-François Millet, Daumier, Courbet, Van Gogh, and Degas; the robust gaiety of cafés and music halls was captured by Toulouse-Lautrec, John Sloan, Everett Shinn, and Walter Richard Sickert; and intimate domestic scenes were recorded by Bonnard and Vuillard. Modern genre movements have included the American Scene painters, the Ashcan and Kitchen Sink schools (represented by such painters as George Wesley Bellows, Jack Smith, and Derrick Greaves), the Camden Town and Euston Road groups (Frederick Spencer Gore, Sir William Coldstream, and Victor Pasmore), and the Social Realists in England and in the United States (Robert Henri, Stuart Davis, and Maurice Prendergast).

Landscape. Idealized landscapes were common subjects for fresco decoration in Roman villas. Landscape painting (as exemplified by a Chinese landscape scroll by Ku K'ai-chih dating from the 4th century) was an established tradition in the Far East, where themes such as the seasons and the elements held a spiritual significance. In Europe, imaginary landscapes decorated 15th-century Books of Hours. The first naturalistic landscapes were painted by Dürer and Bruegel. Landscapes appeared in most Renaissance paintings, however, only as settings to portraits and figure compositions. It was not until the 17th-century Dutch and Flemish schools—of Rembrandt, Jacob van Ruisdael, Meindert Hobbema, Aelbert Cuyp, Rubens, and Hercules Seghers—that they were accepted in the West as independent subjects. The most significant developments in 19th-century painting, however, were made through the landscapes of the Impressionists and the Neo-Impressionists and Postimpressionists. Styles in landscape painting range from the tranquil, classically idealized world of Poussin and Claude, the precise, canal topography of Francesco Guardi and Canaletto, and the structural analyses of Cézanne to the poetic romanticism of Samuel Palmer and the later Constables and Turners and the exultant pantheism of Rubens and Van Gogh. Modern landscapes vary in approach from the Expressionism of Oskar Kokoschka's cities and rivers, Maurice de Vlaminck's wintry countrysides, and John Marin's crystalline seascapes to the metaphysical country of Ernst, Dalí, and René Magritte and the semi-abstract coastlines of Nicolas de Stael, Maria Helena Vieira da Silva, and Richard Diebenkorn.

Still life. The earliest European still-life painting is usually attributed to Jacopo de' Barbari (*i.e.*, "Dead Bird," 1504). In Western paintings, still life often appears as a minor feature of the design; but until the 17th century it was not generally painted for its own sake, although it was already traditional to Far Eastern art. The subject is particularly associated with northern European painting, and the choice of objects very often has a religious or literary significance: wine, water, and bread symbolizing the Passion; skulls, hourglasses, and candles, the transience of life; and selected flowers and fruits, the seasons. Flower painting, especially, held a spiritual and emotional meaning for Japanese artists and for 19th-century European painters, such as Odilon Redon, Paul Gauguin, and Van

Gogh. Still life has been expressed in many different ways: Giuseppe Arcimboldo's witty arrangements of fruit, flowers, and vegetables made into fantastic allegorical heads and figures; the sensuous representation of food by Frans Snyders, Goya, and William Merritt Chase; the trompe l'oeil illusionism of François Desportes and William Harnett; the formal decoration of folk artists or primitives such as Henri Rousseau and Séraphine and of modern painters such as Matisse, Dufy, and Pat Caulfield; the semi-abstract designs of Picasso, Gris, and William Scott; and, probably at its highest level of expression, the majestic still lifes of Chardin, Cézanne, and Giorgio Morandi.

Other subjects. Since ancient times, animals and birds have provided the primary subject matter of a painting or have been included in a design for their symbolic importance. In the paintings of prehistoric caves and dynastic Egyptian tombs, for example, animals are portrayed with a higher degree of naturalism than human figures. Their texture, movement, and structure have provided some artists with a primary source of inspiration: the classical, anatomical grace of a George Stubbs racehorse and a more romantic interpretation in the ferocious energy of a Rubens and Géricault stallion; the vivid expression of rhythmically co-ordinated movements of deer by Tawaraya Sotatsu and Antonio Pisanello; the weight and volume of George Morland's pigs and Paul Potter's cows; the humanized creatures of Gothic bestiaries and of Edward Hicks's "Peaceable Kingdom"; and, finally, Dürer's "The Hare," which is possibly as famous as Leonardo's "Mona Lisa."

Increasing interest is shown in notable painters' versions of other artists' works. These are not academic copies (such as the study made by Matisse, when a student, of Chardin's "La Raie"), but creative transcriptions. Examples that can be appreciated as original paintings are those by Miró of Sorgh's "Lute Player"; by Watteau of Rubens' "Apotheosis of James I"; by Degas of Bellini's "Jealous Husband"; by Caulfield of Delacroix's "Greece Expiring on the Ruins of Missolonghi"; by Larry Rivers of Jean-Auguste-Dominique Ingres's "Mlle Rivière"; and by Picasso of Manet's "Déjeuner sur l'herbe," Velázquez' "Las Meñinas," and Delacroix's "Woman of Algiers" (which produced Roy Lichtenstein's "Femmes d'Alger, After Picasso, After Delacroix"). Picasso has also painted free versions of works by El Greco, Lucas Cranach, Poussin, and Courbet, as Rubens had of Mantegna and Titian, Rembrandt of Persian and Indian miniatures, Cézanne of Rubens and El Greco, and Van Gogh of Millet, Gustave Doré, and Delacroix.

In an abstract painting, ideas, emotions, and visual sensations are communicated solely through lines, shapes, colours, and textures that have no representational significance. The subject of an abstract painting may be therefore a proposition about the creative painting process itself or exclusively about the formal elements of painting, demonstrating the behaviour of juxtaposed colours and shapes and the movements and tensions between them, their optical metamorphosis and spatial ambiguities. Many abstracts, however, are more than visual formal exercises and produce physical and emotional reactions in the spectator to illusions of shapes and colours that appear to rise and fall, recede and advance, balance and float, disintegrate and re-form; or of moods created of joy, sadness, peace, or foreboding; or of effects produced by light or by flickering or throbbing movement. Some abstracts evoke the atmosphere of a particular time, place, or event; and then their titles may be significant: "Pancho Villa, Dead and Alive" (Robert Motherwell); "Late Morning" (Bridget Riley); "Broadway Boogie Woogie" (Mondrian); "Gold of Venice" (Lucio Fontana); "Capricious Forms" (Kandinsky).

SYMBOLISM

Most early cultures developed iconographic systems that included prescriptions for the site, design, function, form, medium, subject matter, and imagery of their painting. The siting of early Byzantine murals, for instance, echoed the symbolic, architectural planning of the basilica. Thus, a stylized, linear image of Christ, surrounded by heavenly

The subject of an abstract painting

Subject matter of still lifes

hosts, occupied the central dome; the Virgin was represented in the apse; and stiff figures of apostles, prophets, martyrs, and patriarchs occupied the aisle walls. The format of early devotional paintings was also prescribed, Christian and Buddhist deities being placed in the focal centre of the design, above the eye level of the audience and larger than surrounding figures. And, in the conventional arrangement of a Christian subject such as the Holy Trinity, a central, bearded, patriarchal God, flanked by archangels, presented Christ on the cross; between them was a dove, representing the Holy Spirit. In a rendering of the risen Christ, the Son faced the audience, with the Virgin Mother on the left and St. John on the right of the design. In the Far East a traditional format depicted Buddha on a lotus throne or in a high chariot drawn by oxen across clouds, surrounded by figures representing the planets. Deities generally appear against undefined grounds of white (signifying eternity or nothingness), blue (the celestial vaults), or gold (representing heavenly light by radiating lines or the spiritual aura by a nimbus). The elaborate surface preparation of supports and the painstaking execution with the finest materials symbolized the intention that paintings dedicated to a deity should last forever. The imagery, subject matter, and form might also have a mystical function: the realistic rendering of animals in contrast to the perfunctory human representations in Ice Age rock paintings, thought to signify a wishful guarantee for success in hunting; the earthly pleasures depicted on ancient Egyptian tomb murals intended to secure their continuance for the deceased; and the North American Indian sand paintings designed for magic healing ceremonies and the Tantric (relating to Tantrism, a school of Mahāyāna Buddhism) mandalas used for meditation and enlightenment.

Symbolism in Eastern painting—intended to deepen the experience of a picture's mood and spirituality—is more generalized and poetic than in Western art. Both the execution and the subject matter of Buddhist Chinese and Japanese painting have a religious or metaphysical significance: the artist's intuitive, calligraphic brush movements symbolizing his mystical empathy with nature and his cyclic landscape and flower subjects expressing his belief in the spiritual harmony of natural forms and forces. Much of Indian symbolism is visually emotive, images such as snakes, plantain leaves, twining creepers, and rippling water being overtly sexual. And, although symbolic attributes and colour codes identify Indian mythological characters (for example, the four arms of the terrible goddess Kālī and the blue skin of the divine lover Krishna), the formal character and colour scheme of settings generally reflect the narrative's emotional mood (for example, vibrant, dark-blue, cloudy skies and embracing, purple-black glades evoking amorous anticipation and red grounds expressing the passions of love or war).

Western symbolic systems, however, are more intellectually directed, their imagery having precise literary meanings and their colour codes intended primarily for narrative or devotional identification. The iconographic programs of the early Christian churches, for example, laid down complex formulas for the viewpoints, gestures, facial expressions, and positions of arms, hands, and feet for religious figures. An elaborate Ethiopian Christian iconographic system was followed until very recently, and elsewhere traditional methods survive of identifying archangels and saints by their attributes and by the symbols of martyrdom that they display: distinguishing white-bearded St. Peter from black-bearded St. Paul, for example, and portraying St. Catherine with a wheel and St. Bartholomew with a knife and skin. Christian iconography adopted and elaborated Greco-Roman and Jewish symbolic imagery: the pagan signs of the vine and the fish, for example, and the image of Christ as the Good Shepherd based on the Greek Hermes Kriophoros. Medieval and Renaissance writings define an immense vocabulary of symbolic images, such as the crescent, sea urchin, and owl signifying heresy, the toad and jug representing the devil, and the egg and bagpipes as erotic symbols (all of which appear in Hieronymus Bosch's 15th-century narrative moralities). Angels and devils, hellfire and golden

paradise, heavenly skies and birds in flight representing spirituality and rebirth are examples of the similarity of symbolic meaning for many religious, mythological, and allegorical traditions. The significance of images common to several cultures, however, may also be very different: the dragon representing avarice in European medieval allegory symbolizes friendliness in Japanese Zen painting; and the snake, symbol of temptation and eroticism in the West, signifies, by its skin shedding, the renewal of life in Far Eastern iconography.

(P.D.O.)

The History of Western Painting

Painting, the execution of forms and shapes on a surface by means of pigment (but see also **DRAWING** for discussion of depictions in chalks, inks, pastels, and crayons), has been continuously practiced by humans for some 20,000 years. Together with other activities that may have been ritualistic in origin but have come to be designated as artistic (such as music or dance), painting was one of the earliest ways in which man sought to express his own personality and his emerging understanding of an existence beyond the material world. Unlike music and dance, however, examples of early forms of painting have survived to the present day. The modern eye can derive aesthetic as well as antiquarian satisfaction from the 15,000-year-old cave murals of Lascaux—some examples testify to the considerable powers of draftsmanship of these early artists. And painting, like other arts, exhibits universal qualities that make it easy for viewers of all nations and civilizations to understand and appreciate.

The major extant examples of early painting anywhere in the world are found in western Europe and the Soviet Union. But some 5,000 years ago, the areas in which important paintings were executed shifted to the eastern Mediterranean Sea and neighbouring regions. For the purposes of this article, therefore, Western painting is to be taken as signifying painting not only in Europe but also

in regions outside Europe that share a European cultural tradition—the Middle East and Mediterranean Basin and, later, the countries of the New World.

Western painting is in general distinguished by its concentration on the representation of the human figure, whether in the heroic context of antiquity or the religious context of the early Christian and medieval world. The Renaissance extended this tradition through a close examination of the natural world and an investigation of balance, harmony, and perspective in the visible world, linking painting to the developing sciences of anatomy and optics. The first real break from figurative painting came with the growth of landscape painting in the 17th and 18th centuries. The landscape and figurative traditions developed together in the 19th century in an atmosphere that was increasingly concerned with “painterly” qualities of the interaction of light and colour and the expressive qualities of paint handling. In the 20th century these interests contributed to the development of a third major tradition in Western painting, abstract painting, which sought to uncover and express the true nature of paint and painting through action and form.

European Stone Age

Upper Paleolithic. During the Upper Paleolithic Period, just before the final retreat of the glaciers at the end of the last Ice Age (15,000–10,000 BC), much of Europe was peopled by small bands of nomadic hunters preying on the migratory herds of reindeer, cattle, bison, horses, mammoth, and other animals whose bodies provided them with food, clothing, and the raw materials for tools and weapons. These primitive hunters decorated the walls of their caves with large paintings of the animals that were so important for their physical well-being. Most surviving examples of such murals have been found in France and Spain (see PREHISTORIC PEOPLES AND CULTURES), but similar figures from caves in the Ural Mountains in the Soviet Union may indicate that the practice was more widespread than has been supposed.

Ever since the first examples of these paintings came to light in the late 19th century, they have excited admiration for their virtuosity and liveliness. The simplest figures are mere outline drawings, but the majority combine this technique with sophisticated shading and colour washes that modulate the surface and suggest the differing textures of pelts, horn, and bone. Volume is indicated by carefully controlled changes in the thickness of brushstrokes, and the astonishingly advanced draftsmanship conveys a considerable sense of movement and life. Most of the animals were originally depicted as individual figures without narrative import, and what appear to the modern observer to be sophisticated groupings of figures are, in reality, the end result of a long additive process.

The lack of a clear narrative element in these paintings has caused problems in their interpretation. Man is seldom portrayed, and depictions of human figures unambiguously interacting with the numerous animal figures are rare. One of the few exceptions to this rule is a scene at Lascaux in southern France depicting a bison butting a falling male figure. The "Sorcerer" at Les Trois Frères, also in southern France, is more characteristic. Although he is draped in the skin of an animal and seems to be engaged in stalking or a ritual dance, his complete isolation from any other figure leaves his exact significance unclear. It is also interesting that, in contrast to the obvious care taken in the detailed portrayal of animals, the few human figures are usually executed in a perfunctory and schematized fashion. Sometimes the only hint of man is provided by depictions of darts wounding or killing a few of the animal figures. These projectiles have been interpreted as exercises in sympathetic magic designed to induce success in a future hunt. Conversely, they might just as easily commemorate past kills. But certain features suggest that such simple explanations do not tell the whole story: first, such portrayals are rare (in inverse proportion to the amount of scholarly discussion they have engendered) and, second, the beasts that are shown as wounded—indeed the vast majority of the species depicted on the cave walls—were not significant items in the diet of the cave artists. Contemporary habitation deposits indicate that most of the meat consumed came from reindeer, and reindeer appear almost as infrequently as man himself among the surviving paintings. One fact is clear: individual initiative seems paramount, both in the execution of the animal figures and in the recording of the activities of the isolated humans. Any hint of social interaction is absent, and it has been assumed that society as such existed at a relatively low level. Nature provided the impetus for change, and in the art of the following period man finally emerged as part of a community.

Mesolithic. At the end of the Ice Age the great herds that had provided sustenance for the Paleolithic hunters disappeared from France and Spain. Forests cloaked the landscape and harboured much smaller groups of deer and related species. These were fleet and elusive and, in consequence, much more difficult to hunt and kill. Thus, although the climate was warmer than before, it was much harder to live by hunting alone. Man had to modify his hunting techniques and forage for the seeds and fruits that the forests provided, or the fish and shellfish that he could find in rivers or on the coasts. Cooperation was

essential, and the new situation is clearly reflected in the art of the period.

In the southern and eastern parts of what is now Spain, small bands of such hunter-gatherers left a record of their activities in the rock shelters where they camped periodically. In some ways the new paintings resemble the old. Although a simple silhouette technique for the most part replaced the outline and shading techniques of the Paleolithic style, facility of brushwork and accuracy of observation continued to imbue the new creations with a vivacity and sense of movement similar to those of their predecessors. There are obvious conceptual differences between the two artistic complexes, however. The new paintings constitute the first real compositions having a clear narrative meaning, and man finally emerges as the chief actor in the dramas played out on the rock walls. At Remigia three hunters are depicted stalking a leaping ibex, while at Los Caballos a line of archers fires arrows into a small herd of panic-stricken deer, presumably driven into the ambush by beaters. Scenes of battle or groups of dancers also occur, while social status is implied in a carefully executed archer found at Santolea: he is dressed in painstakingly portrayed finery and is flanked by two other figures. This emphasis on man is new, but even more significant is the element of cooperation as part of a group whose social cohesion in warfare, hunting, or ritual was probably necessary if the group was to survive and prosper.

Social
status
implied

Neolithic. The subsequent Neolithic Period saw the introduction from western Asia of farming and the raising of domesticated animals. The new way of life appeared in the Balkans sometime before 6000 BC and rapidly spread across Europe. For the first time man was able to live a relatively settled village life and accumulate a wide range of household goods. So far as large-scale painting is concerned, however, this period is something of a disappointment. Thus far, there is no evidence that the farming communities decorated their house walls with painted designs, in this at least failing to imitate their Asiatic mentors whose walls, as in the shrines at Catalhöyük in Turkey, were often embellished with ambitious decorative schemes. In different places and at different times the European farmers did indeed indulge their aesthetic drive by producing highly decorated painted pottery whose patterns reflect contemporary basketwork or textiles. Few of these styles include human or animal figures and, despite their undoubted charm, these vases are the products of craft traditions that have little to do with large-scale art.

Aegean and eastern Mediterranean Metal Age

In Greece and the Aegean, influence from the adjacent areas of western Asia helped promote the rise of small towns by about 3000 BC. The cultural development is usually divided into three separate strands: Minoan on Crete, Cycladic on the islands of the central Aegean, and Helladic on the Greek mainland. A fourth area, Cyprus, is often included in this development, though its culture was closer to those of Syria and Asia Minor and it was only during the 13th century BC that Greek invaders brought Cyprus fully into the Aegean orbit. (P.J.C.)

The Metal Age in Europe started in the early 3rd millennium BC, when the peoples around the Aegean Sea began to work copper, under the influence of the neighbouring peoples of western Asia. By 2500 BC coppersmiths were also active across the Alps. Bronze began to be used in Europe at the beginning of the 2nd millennium BC, and iron was used in Greece by the 11th century BC and north of the Alps by the 8th century BC. Bronze was always a luxury item because the sources of its constituent metals, tin and copper, occurred in scattered deposits, often far from the producing centres. Its use, therefore, encouraged trade. But iron, when it came into use, was cheaper and easier to work; moreover, the ore lodes were often close at hand. Its use, especially for agricultural implements, allowed more intensive exploitation of the countryside, especially those areas where heavy soils had precluded farming with more primitive tools. The end of this period is usually placed at the point where written records supplement the archaeo-

logical record. In Greece and Italy this happened during the 8th century BC or a little later, whereas in northwestern Europe the Celtic and Germanic peoples had to wait for the Roman conquests of the 1st century BC before emerging into history. Beyond the imperial frontiers old patterns continued longer. Throughout this long period it was the Mediterranean, with its flourishing towns and cities, that produced major works of painting.

(O.K.-J./P.J.C.)

EARLY BRONZE AGE (3000–2000 BC)

Early Minoan. In Crete the Early Minoan peoples lived in small towns and villages with a basically agricultural economy. Although traces of their houses have been preserved, it is clear that they did not paint their walls with decorative designs. The fine plaster introduced at this time, however, did provide the basis for later developments. Their pottery was at first plain or decorated with simple, arresting patterns of straight lines. (Pottery is an important source for modern knowledge of painting in the last three millennia BC because, although fired clay objects—even when decorated—may be broken, they are not easily pulverized, so many fragments have survived.) In the following phase (2500–2200 BC) a similar style flourished, though other vases with a mottled surface imitating variegated stones were produced. During the third phase (2200–2000 BC) most fine vases were decorated with designs in white or cream paint on a dark ground. Elegant running spirals and other curvilinear motifs, as well as the occasional use of other colours, revolutionized the style and paved the way for the greater advances of the Middle Minoan period.

Early Cycladic. In the islands there was little interest in painted designs. Most decoration consisted of incised or impressed geometric schemes, though there were some vases with similar designs in paint. The typical pottery of the second and third phases (2500–2000 BC) was decorated in semilustrous paint, either as an all-over wash or in angular patterns.

Early Helladic. On the Greek mainland there was a similar lack of interest in painted decoration on pots. Although monumental buildings have been found in the Peloponnese dating to the Early Helladic II period (2500–2200 BC), none of these had decorated walls. New settlers arrived about 2200 BC and destroyed the old centres of power. Their houses were primitive affairs and only a few of their finer vases bore painted designs, these being of straight lines or other simple patterns.

MIDDLE BRONZE AGE (2000–1600 BC)

Middle Minoan. The Middle Minoan period saw the evolution of a monarchical society based on palaces situated in the most fertile districts of Crete. There were undoubtedly frescoes in these large buildings before 1600 BC, but little survived the disastrous earthquake of about 1700 BC, and once again it is the pottery that gives the best idea of contemporary aesthetics. The decorative style is basically a development of the previous period's. Curvilinear patterns in white, yellow, and red swirl around the surfaces of these bulbous vases. The latest Middle Minoan style is similar, but its static formality seems better suited to wall decoration, and it is likely that monumental frescoes from the old palaces influenced the vase painter. The combination of modeled flowers and animals with painted motifs on the vases certainly reflects similar developments in wall painting, where stucco reliefs were combined with simple painted backgrounds.

Middle Cycladic and Middle Helladic. On the mainland and in the islands, native styles of plain or simply painted pottery continued to be executed, but Cretan influence was felt toward the end of the period in both areas, and they began to be drawn into the wider cultural orbit characteristic of the following period.

LATE BRONZE AGE (1600–1100 BC)

Wall paintings. The three separate areas of the Aegean were brought into intimate contact during the Late Bronze Age; indeed the whole eastern Mediterranean saw intense cross connections and cultural diffusion. Great palaces

arose on the Greek mainland and Crete and even on some of the lesser islands. Although there were probably differences in the natures of the societies that built them (resulting in fortified structures on the Greek mainland and unfortified ones on Crete), the palaces and great houses were decorated with complex frescoes whose style was based on Cretan models. Many of the figured scenes are merely decorative and depict landscapes with birds and animals or figures gathering flowers. Others show ceremonies connected with a cult or the court (Plate 1, "The Toreador Fresco") and were probably useful in bolstering the power of the royal or priestly classes. The style is a combination of dark outline drawing, to delimit the object shown, and solid painted areas within it. On some birds and animals the feathers or pelts are imitated by slightly more impressionistic brushstrokes. Most of these frescoes are in fragmentary condition, but a better idea of what they must once have looked like can be gained from the house walls at Akrotiri on Thera (one of the Cyclades of the southern Aegean). Thera was destroyed by volcanic eruption during the 15th century BC and is often referred to as the Greek Pompeii. The wall paintings there were heavily influenced by those of Crete, both as to style and subject matter, though the popularity of outline figures on a pale background stemmed from the local pottery tradition. One of the most exciting discoveries is a long frieze depicting a fleet of gaily decorated ships sailing against a backdrop of hilly islands with towns, shepherds, and hunters scattered along the shores or set upon the forested peaks among gushing streams. Another painting shows a group of women at a religious festival and—in the first known instance at this period—ordinary people: two boys boxing and a fisherman proudly displaying his catch (Plate 1). These paintings decorated well-to-do houses. In the great palaces of Crete and on the Greek mainland many of the scenes are rather more formal. At Knossos on Crete there are long lines of offering bearers in the vestibule leading to the state rooms. The throne in one ritual chamber is flanked by fresco paintings of griffins whose presence must have had a protective value. Griffins also flank the throne at Pylos in Greece, and the same site has produced fragments of another fresco showing battle scenes. Mycenae (also on the Greek mainland) possesses a small sanctuary whose walls are decorated with ritual episodes, and religious ceremonies do indeed appear to have been an important part of the wall painters' repertoire. There are, however, none of the historical or annalistic scenes so characteristic of the palaces and temples of western Asia and Egypt. In particular there are no depictions of investitures or battles with accompanying inscriptions; in short, Aegean paintings are far less bombastic than their Middle Eastern equivalents. This is not to say that the visitor would have been less impressed by the ruler's power in these first great European civilizations, merely that the iconographic emphases were different. (P.J.C.)

Vase paintings. *Late Minoan.* The light-on-dark style of pottery was by now replaced by dark-on-light ornamentation. At first (roughly 1600–1500 BC), curvilinear patterns and simple designs of vegetation predominated. Between 1500 and about 1450 BC, however, there flourished the Marine style, possibly the most successful of all Minoan pottery styles (Figure 1). Nearly every form of marine life is accurately reproduced in a riotous all-over arrangement: octopuses, argonauts, dolphins, and fish, against a background of rocks and waves. In the 70 or 80 years after 1450 BC, the spontaneity of the early Marine style degenerated into a rigid formality. Subsequently, Late Minoan pottery became little more than a provincial version of Mycenaean ware.

Late Mycenaean. For about two and a half centuries after around 1600 BC, Mycenaean pottery painting echoed Minoan. After the eclipse of Knossos, however, Minoan influence declined, and Mycenaean potters fell back on their own resources. Minoan plant and marine motifs became simpler until virtually unrecognizable as representations of anything in real life. A figure style also developed. Adapted at first from frescoes and later from textiles, this style is seldom successful, however. Unlike the classical Greeks who came later, the Mycenaean potters were not

able to adapt their fresco style so as to form a convincing figure style for vases.

Late Cypriot. The Cypriot pottery of the Late Bronze Age is of three main kinds: (1) a handmade ware with a glossy brown surface called base-ring ware, vases and statuettes of humans and animals being the most common examples of this type, (2) white-slip ware, in which handmade vases of a leathery appearance are decorated with patterns in black on a white slip (slip is liquid clay covering the pottery body), and (3) local imitations, made on the wheel, of imported Mycenaean pottery, which was evidently popular. (R.A.H./P.J.C.)

Ancient Greek

At the root of Greek art was the desire to explore man and the nature of his experience. Even divine subjects were cast in terms of human behaviour, and both gods and epic heroes could at times stand as representations of and models for contemporary political achievement. The seemingly naturalistic outward forms characteristic of Greek art have continued to fascinate Western artists to the present day, and the history of Western painting is full of classical revivals that have aimed at recapturing the spirit of the Greek original. Art, however, is deeply rooted in the society that creates it, and these classical revivals usually say more about those who are attempting the revival than they do about the Greek art that served as the model. Attempts to re-create the spirit and form of antique art do serve, however, as a reminder that a mere description of form does not reveal the whole truth about the art of an ancient culture. This section defines, therefore, the reasons for certain developments as well as the technical advances themselves.

A major stumbling block has been the difficulty in defining the ancient Greek attitude to art. Certainly it is clear that there was no concept of "art for art's sake" before the Hellenistic period (roughly the last three and a quarter centuries BC). Great works of art were functional: they served as gifts to the gods, monuments to the dead, or commemorations of events in the life of a city. The Greek language itself made no distinction between art and craft: both were called *technē*; a great work of art was simply an exceptional piece of workmanship (*aristourgēma*). This lack of linguistic variety should not be made too much of, however, for the actions of the artists indicate that they were exceptionally proud of their work. For the first time in the history of art, painters signed their works, and both painters and sculptors explored new means of expression. The greatest sculptors sometimes wrote books detailing

their philosophy of art, and there was obviously a body of philosophical thought behind the more important advances in the painter's technique during the 5th and 4th centuries BC. By the late 5th century BC this became a basis for discussion by the philosophers themselves, indicating that, by then at least, a theory of art coexisted with the corpus of workshop techniques that might reasonably be called the practice of art. (P.J.C.)

Paintings on wall plaster, wood, and marble panels are easily eradicated, and most ancient paintings were destroyed long ago. Many fine examples, some of the highest quality, have survived, however. These are the funerary paintings on stelae (decorated stone slabs) or burial chamber walls in northern Greece and Macedonia, whose rich kings and nobles could afford the best talents from the southern cities. Contemporary vase paintings—so long as vase painting continued—often depict the same subjects and sometimes faintly reflect the style and composition of monumental frescoes, but they were in no sense accurate or even deliberate copies. The paintings on vases, now the main evidence for the development of Greek draftsmanship, were hardly mentioned by ancient writers and, although in great demand, were evidently not considered important works of art. (B.As./P.J.C.)

DARK AGES (1200–900 BC)

During the 13th century BC the great palatial centres of the Aegean world came to a violent end. Both internal dissension and foreign invasion seem to have played a part in this development, and, if the exact course of events is still obscure, the end result is quite clear: Greece was severely depopulated and impoverished. The small, scattered settlements that took the place of the great Mycenaean and Minoan kingdoms were not able to support the luxury arts that had flourished in the Bronze Age palaces. No wall paintings are known from this period, and the sophisticated Bronze Age aesthetics was lost. Before the end of the 11th century BC Greece began a steady recovery, and a secure basis was laid for all future developments. At Athens, a city that had won a position of importance in Greece only at the end of the Bronze Age, the potters invented a new painted style, which has been called the Proto-geometric. Old Bronze Age shapes persisted, but they became tauter and better proportioned. In addition, the old patterns were executed with a new finesse, aided by improved equipment—a multiple brush and compasses. Using these, the painter decorated selected zones of the vase with distinctive concentric circles and semicircles, simple zigzags, and wavy lines. The vases were well potted and restrained and successful in their decoration. The simple precision of their patterns is a quality that remained dominant in Greek vase painting as well as in the other arts. Other Greek cities besides Athens adopted the Proto-geometric style as well.

Proto-geometric patterns

GEOMETRIC PERIOD (C. 900–700 BC)

The Geometric style arose in Athens about 900 BC. It built upon the foundations of the previous period, though the area covered by painted patterns expanded and new motifs were incorporated into the painters' repertoire. The meander, swastika, and crenellation (battlement) patterns were prominent and, together with the older concentric circles, were used by the painters to push back the large areas of solid black characteristic of Proto-geometric vases and to create a pleasing halftone decorative effect. A few human and animal figures were introduced into this otherwise severely geometric scheme, but it was not until about 760 BC that a renewed interest in figures became paramount. The major achievement in this development was that of the Dipylon Master, who specialized in monumental vases used as markers over the graves of rich Athenians (Figure 2). These vases incorporated scenes with animal and human figures: funerals, battles, and processions as well as files of deer or goats. The figures were not conceived in realistic terms; rather, they were formalized into geometric shapes whose schematic appearance did the least possible damage to the overall decorative pattern. That this was deliberate is indicated by the fact that newly introduced types, such as sows and piglets, are more naturalistic at

Allison Frantz

the time of their first appearance than in their subsequent development, when the artists learned how to cast them in a more formalized mold. Nevertheless, the introduction of schemes involving figures marked the beginning of the end for the Geometric style, for later painters became more and more fascinated with this aspect of decoration, and the older pattern work languished. By the end of the 8th century BC the figures had become much more naturalistic and were joined by floral patterns introduced from western Asia, leading to the rise of new styles in which men and gods occupied the most important positions.

The reasons for the introduction of figures, even the exact significance of such decoration, are problematic. On the simplest level, the subject matter is a factor: battles and funerals can be related to the lives of the aristocratic patrons whose graves were marked out by the Dipylon

vases. Some scholars believe, however, that the figured scenes include episodes from the heroic past or that the whole of the new iconography was cast in a heroic mold, indicating a basic identification between the aristocrats of the 8th century BC and their epic forebears. Athens in the Geometric period remained the centre from which the vase-painting studios of other cities took their inspiration.

ORIENTALIZING PERIOD (C. 700–625 BC)

About 700 BC important changes took place in vase painting. Floral motifs, animals, and monsters borrowed from the art of Syria and Phoenicia delivered the coup de grace to an already debased Geometric style. In Athens the new style is called Proto-Attic and includes, for the first time, scenes referring unambiguously to Greece's heroic past. The exploits of Heracles, Perseus, and other heroes were painted, often on large vases used as burial containers. The bodies of men and animals were depicted in silhouette, though their heads were drawn in outline; women were drawn completely in outline. The brushwork is bold, even sloppy on occasion, and the general effect is monumental and very impressive.

At Corinth, painting followed a different course during the 7th century BC. Corinthian painters also borrowed Oriental motifs, but their predilection for small vases, whose surfaces were divided into horizontal registers and covered with numerous tiny and beautifully drawn figures, created a miniaturist style called Proto-Corinthian (Figure 3). By the end of the century human or mythological figures were rare, and the backgrounds of the animal and narrative scenes were filled with incised floral rosettes. Corinthians introduced the black-figure technique, which, although seeming to owe something to Asian influence, is essentially native to Greece. In black-figure technique figures were painted on the naturally pale clay surface of the vase in a lustrous black pigment and then incised to indicate details of anatomy and drapery. Added colours enhanced the liveliness of these scenes. The high quality of these Proto-Corinthian vases led to a flourishing export trade, and in the later 7th century BC they were exported throughout the Mediterranean.

ARCHAIC PERIOD (C. 625–500 BC)

Corinth remained the leading exporter of Greek vases until about 550 BC, though mass production quickly led to a drop in quality. These later vases were decorated with unambitious and stereotyped groups of animal or human figures; there was little or no interest in narrative. By the late 7th century BC Athenian artists had adopted many of the stylistic features of Corinthian pots, as well as the black-figure technique. Files of animals became popular at Athens, but the artists always maintained an interest in the narrative scenes that had been so popular in the Proto-Attic style. The finest example of the marriage of Corinthian discipline and Attic invention is the François vase (in the Archaeological Museum in Florence), produced about 570 BC and exported to Etruria in Italy. Its surface is divided into horizontal friezes containing hundreds of carefully drawn, tiny figures showing episodes from Greek myth. The professionalism of the Attic masters, so clearly displayed on this and other contemporary vases, contrasted with the laziness of the Corinthian painters, and it is hardly surprising that the Attic products soon captured the foreign markets.

The first generation of Athenian painters after 500 BC concentrated on large-scale narrative scenes. One, Exekias, was fond of heroes. His superb draftsmanship and sense of the monumental was emphasized by exceedingly detailed use of incision to indicate the patterns on drapery, weapons, and anatomy (Figure 4). The Amasis Painter, on the other hand, preferred the wild cavortings of the wine god, Dionysus, and his band of drunken followers.

In general, many old conventions were retained. Men were still painted in black on the red ground of the vase; women had white skins. But some of the work of the Amasis Painter and his contemporaries used an outline technique for women and certain other figures, and it must soon have become obvious that the brush allowed greater freedom than the graver. By about 530 BC several

Important changes in vase painting

Many old conventions retained

painters took the momentous decision to dispense with the old black-figure technique entirely and show all their figures in outline, the details being indicated only with the brush. The background of the vase was now painted solid black and the figures stood out dramatically against this sombre field. This is called the red-figure technique, and, in the hands of artists such as Euthymides and Euphronius, the style rapidly gained ground. It had several advantages over black-figure. Incising the older decoration was painfully laborious, and it was almost impossible to vary the thickness or intensity of the incised lines. The painted line, however, could be made thicker or thinner depending on the amount of pressure applied and the amount of paint on the brush; it could also be made lighter by diluting the glaze. Red-figure artists took advantage of all these tricks and found that it was possible to depict complicated groups of overlapping figures or incidents involving violent action. Cities other than Athens and Corinth had studios producing black-figure vases; of these the most distinguished were in Sparta and eastern Greece. By the end of the Archaic period, however, only Athens was producing and exporting finely decorated pottery in any quantity.

It has always been assumed that vase painting in the Orientalizing and Archaic periods mirrored developments in monumental art, and to a certain extent this seems to be true. Not many paintings on monuments survive, but a sufficient number exist to give a general idea of their form and technique. Temple models of the late Geometric and Orientalizing periods are decorated in a way that suggests that temples had paintings on their walls; fragments of such paintings have actually been found at the temple of Poseidon at the Isthmus of Corinth. The earliest reasonably well-preserved temple decoration, however, comes from the temple of Apollo at Thermon, in central Greece, and dates from the later 7th century BC. The temple roof was decorated with a series of square terra-cotta frieze plaques, called metopes, bearing mythological scenes. Although there are several similarities to contemporary vases, there are also important differences: black-figure incision is confined to relatively minor details of drapery, and the figures themselves are drawn in outline, the women then being overpainted in white. Among vases of this period, only the brightly painted drinking cups from the island of Chios seem at all similar in technique. Other terra-cotta plaques painted in a similar, though more developed, style have been found in Italy at Caere (where they decorate the interior walls of a temple) and on the Acropolis at Athens, indicating that there was probably a continuous tradition in this technique.

More important, because more numerous, are the many paintings on stucco. These are found in Italy and Asia Minor, as well as in Greece. They were painted by Greeks or artists working under intense Greek influence. At Pitsa,

near Corinth, votive plaques covered in stucco and then painted have been found. There was a flourishing school of Greek painters who decorated tombs in the colonies of southern Italy. In Asia Minor, two tombs dating from the Late Archaic period have been found near Elmalı, in ancient Lycia (what is now southwestern Turkey). Although depicting scenes from the life of a Lycian prince, they were certainly painted by Greeks. With the exception of the plaque from Pitsa, a minor work, all these paintings come from provincial areas of the Greek world and probably do not represent the very finest of paintings then in existence, but many are highly competent pieces of work and they do give some idea of the state of monumental painting at the time. As on the vases, the greatest emphasis was on finely controlled line. Colours were applied in flat, undifferentiated masses, and there was no attempt at shading, perspective, or illusionistic treatment. At Karaburun, near Elmalı, variety was introduced by the use of finely detailed motifs on the clothing of the prince, an effect closer to the work of Exekias than to the practices of the early red-figure vase painters.

Stucco paintings more numerous

CLASSICAL PERIOD (C. 500–323 BC)

Early Classical (c. 500–450 BC). The Early Classical period is deemed to have begun after Athens' double defeat of the Persian invaders in 490 and 479 BC, but a new feeling of self-confidence was already in the air about 500 BC, possibly as a result of the firm establishment of democracy in Athens 10 years earlier. By now the Archaic colour and pattern were gone from vase painting, to be replaced by sobriety and dignity. The artist's ability to render anatomy in line had reached the point where he could accurately indicate the roundness of a figure without shading. The artist was still bound, however, to a strict profile view of heads, with few frontal, and even fewer three-quarter, views of the features. The vase painters of the first quarter of the 5th century BC included some of the finest Athens was ever to produce. One, the Cleophrades Painter, has often been called the "painter of power" since his intense, majestic subjects are rich in psychological insight. Although not all his vases concern scenes of violence, perhaps the vase that captures his spirit best is the kalpis, or wine jar, depicting the sack of Troy. It has been suggested that the extreme cruelty and tragedy present in this scene may well reflect Greek shock at the brutal sack of Miletus by Persian troops in 494 BC.

Another artist of this period was the Berlin Painter. His finest vases are almost completely covered in black glaze. Isolated or small groups of overlapping figures of extreme delicacy are posed on each side of the vases. The brushwork is exceptionally fine, and in these vases there is a sombre mood of introspection that also characterizes many contemporary sculptures. The work of this fine artist, though, is a relatively isolated phenomenon, except in funerary art where inaction and otherworldliness are appropriate. Most vase painters preferred a more narrative approach, and these narratives often reflected contemporary political developments. In 510 BC the tyranny (a tyrant at that time was a ruler, not necessarily brutal, who ruled unconstitutionally) of the Peisistratids had been overthrown in Athens, and the new democratic rulers, seeking among the heroes of the past a suitable patron, chose Theseus, an ancient king of Athens who had been credited with the union of the whole of Attica under the rule of its chief city. The new democracy fought off attempts to reinstate the tyrants, as well as defeating the two Persian invasions. It is therefore hardly surprising that the vase painters responded to the general enthusiasm and civic pride by adopting Theseus as a frequent subject. This development was reflected in monumental painting. About 460 BC the Painted Stoa at Athens was decorated with a series of paintings representing famous battles, including both legendary and historical events involving Athenians. Thus, probably for the first time in Greek history, painters placed their talents at the service of the state—moreover, a state that used them to decorate purely secular buildings. Panaenos, the brother or nephew of the sculptor Phidias, executed a picture of the Battle of Marathon for the Painted Stoa and, sometime later, included a painting of

Exceptionally fine brushwork

Greece and Salamis personified on the throne for the cult statue of Zeus at Olympia. This brought the depiction of political achievement into the very temples of the gods.

None of the Early Classical architectural paintings has survived, but a reasonable idea of what they might have looked like may be gleaned from the work of various vase painters who seem to have been working under the influence of the monumental artists. The great wall painter Polygnotus is said to have depicted figures at different depths in his compositional field, and similar compositions occur in the work of the Niobid Painter (Figure 5), although the lack of scope for such compositions on vases generally makes this something of an isolated example. Micon was another celebrated wall painter; both he and Polygnotus worked in Athens and Delphi. Ancient descriptions of their work dwell on features and moods that are easy to envisage in the light of extant contemporary vase painting and the Olympia sculptures, to which they seem to have been similar in spirit. The effect of wall paintings on white plaster may also be imagined by examining various white-ground vases intended for the tomb, where there is a concentration on calligraphic line and colour applied in flat areas without any use of shading. In other words, for all its achievements, Greek painting was still closer to drawing than anything that might today be regarded as exhibiting true painterly qualities.

High Classical (c. 450–400 BC). Because Greek vase painting consists essentially of the delineation of form by line, it could not follow monumental wall or panel painting once the latter began to depart significantly from their common traditions. This happened during the second half of the 5th century BC, and vase painting, while surviving for a time by looking to sculpture as a source of inspiration, went into a swift decline from about 400 BC.

There were certainly revolutionary changes in monumental painting technique. The Athenian painter Apollodorus introduced *skiagraphia* (literally “shadow painting”), or shading technique. In its simplest form this consists of hatched areas that give the illusion of both shadow and volume. A few of the white-ground vases exhibit this technique in a discreet fashion, but its true potentialities may be seen in the great cycle of wall paintings that decorate the small royal tomb at Vergina, in Macedonia. The paintings (Plate 2), executed in the 4th century BC, represent the abduction of Persephone by Hades. The figures are defined less by an outline technique than by complicated patterns of shading and contour lines. Another technique that also may have been included within the concept of *skiagraphia* by the ancient Greeks can be found in the treatment of Persephone’s drapery: the reddish pink mantle is overlaid with slabs of darker red to create realistic patterns of light and shade, and then still darker lines are used to indicate the folds. This tomb is of the utmost importance for understanding the development of Greek painting, since it contains the earliest first-rate monumental wall painting to have survived. It indicates, among other things, how rash it is to generalize about the state of painting at that time

from either vase painting or later Roman works, which, it has been argued, were based on Greek originals.

Late Classical (c. 400–323 BC). All authorities agree that the Late Classical period was the high point of ancient Greek painting. Within its short span many famous artists were at work, of whom Zeuxis, Apelles, and Parrhasius were the most famous. Considerable advances in technique were made at this time. Zeuxis built on the discoveries of Apollodorus, and his pupil Apelles, who lived in the later 4th century BC, worked along the same lines but achieved even greater fame. They appear to have added the concepts of highlighting and subtle gradations of colour. Late Classical monuments such as the Great Tomb at Leukadia, in Macedonia, suggest that one of the means at their disposal was the juxtaposition of lines of different colours to create optical fusion; in other words, a true painterly style in the modern sense of the term. Parrhasius, in contrast, was a conservative and insisted on the priority of something called linear style, which is assumed to be closer to drawing than painting. His influence has been detected in the figure of Hermes at Leukadia and in the Lion Hunt and Dionysus mosaics at Pella, also in Macedonia.

In Athens, red-figure vase painting was in decline, and the majority of vases were painted with showy scenes, using much added colour and gilding. Occasionally there is a glimpse of brilliant line drawing, but the technique barely survived the century.

HELLENISTIC PERIOD (c. 323–1ST CENTURY BC)

The Hellenistic period began with the incorporation of the Persian Empire into the Greek world, and specifically with the death of Alexander the Great (323 BC). In art history terms, however, a new relationship of painter and patron had begun slightly earlier. Apelles executed works depicting the tyrant of Sicyon and was later court painter to Alexander the Great. His career, in fact, spans the division between the two periods. The major monument for the new period is the Great Tomb at Vergina, whose exact date should lie between the death of Philip II of Macedon, in 336 BC, and the death of his son Philip III, in 317 BC. The facade of the tomb is decorated with a large wall painting depicting a royal lion hunt. The background was left white, landscape being indicated by a single tree and the ground line. The figures themselves were painted in the fashion Apelles is assumed to have introduced, and there are sophisticated examples of optical fusion and light and shadow. Very similar in style is the famous Alexander mosaic from Pompeii, almost certainly a copy of an original painting executed about the same time as that at Vergina. Apart from the interesting developments in technique discernible during the 4th century BC, an important change in patronage and choice of subject matter occurred. The great patrons were kings and tyrants, and many paintings exalted their claims to rule. After the 4th century BC there were few advances until the Roman period. One Demetrius of Alexandria is said to have specialized in “topographic” paintings, but the exact meaning of this word remains unclear. All other surviving Hellenistic works are of low quality. (Jo.Bo./P.J.C.)

Western Mediterranean

In the Metal Age, western Mediterranean cultures were similar at many points. The area occupied by them extended from Illyria (an area roughly the same in extent as modern Yugoslavia) in the east to the Atlantic shores of the Iberian Peninsula in the west, and from the shores along the Gulf of Lion and the Ligurian Sea (*i.e.*, the coasts of what are now southern France and northwestern Italy) and the top of the Adriatic in the north to a line stretching from Sicily to Gibraltar in the south. Of the earliest painting in classical antiquity, however, little remains except the frescoes on the tombs of the Etruscans. (R.Bl./P.J.C.)

ETRUSCAN

During the 8th and 7th centuries BC the Greeks founded many colonies in southern Italy, partly in order to ex-

pand their trade with the native peoples of Etruria, who controlled rich mineral deposits. In the Archaic period (6th century BC) these native settlements, scattered across the landscape of present-day Tuscany and Lazio in the area north of Rome, evolved into flourishing city-states whose culture was heavily dependent on influences from Greek art. More in the way of Etruscan painting has survived than in the case of Greek painting. The Etruscans buried their dead in large chamber tombs cut into bedrock; in many of these, especially in central Italy at Tarquinii (modern Tarquinia), Clusium (modern Chiusi), and Caere (modern Cerveteri), the walls of the tomb chambers were covered with plaster, and lively scenes were painted on them. Although some of these frescoes show scenes from Greek mythology, the overwhelming majority depict events in the lives of the Etruscans themselves. Funeral games were very popular subjects; perhaps the best-known depictions are those on the Tomb of the Augurs at Tarquinii, with its scenes of wrestlers, dancers, musicians, and a banquet. These paintings date from the late 6th century BC and, although the style of painting changed somewhat in later periods, the types of scene represented remained standard. The Archaic period saw the gradual evolution of an Etruscan style of wall painting whose inspiration is probably to be found in the Ionian colonies of southern Italy. By the early 5th century BC, however, the Athenian style began to predominate, and it ushered in the Classical period as well. There are many classical tombs at Clusium, including the Tomb of the Monkey. This inland city seems to have taken a cultural lead during the 5th century BC; certainly it contains competently executed works that made use of the new stylistic discoveries of mainland Greece—shading, hatching, and simple dimensional effects. There are few surviving later classical monuments in Etruria, and they seem to add little to the style established during the 5th century BC. It was only with the advent of Roman political and cultural influence during the Hellenistic period that an Etruscan renaissance in painting took place. The earliest examples of the new style are the Orcus tomb at Tarquinii and the Golinia tombs at Orvieto (south of Clusium), where there is some use of chiaroscuro effects as well as simpler means of shading. Tombs in Vulci and Tarquinii of the 1st century BC carry the development of these techniques even further. In the François Tomb at Vulci there is a celebrated fresco known as the "Sacrifice of the Trojan Prisoners." It is next to a historical scene showing wars between Etruscan and Roman princes during the Archaic period. This renewed interest in mythological or legendary equivalents of actual historical events is yet another hint that the Greek Hellenistic allegorical tradition was beginning to take hold. The same sacrificial scene and others depicting the deaths of the Theban princes during the war of the Seven Against Thebes were extremely popular on the ash urns that were used as burial jars by the late Etruscans, and it may very well have been through them that a taste for myth allegory was imparted to the Romans at this time.

ROMAN

Etruscan
influence

Pagan. During the Archaic period Rome was ruled by Etruscan and Etruscanized kings. The city's temples were built and decorated in the Etruscan manner and most features of Etruscan culture were present. Although the Romans did not build painted tombs for their dead, they may have employed Etruscan artists to decorate the painted walls of the temples. When the republic was founded at the end of the 6th century BC, much of this Etruscan influence survived, especially the tendency to use painting for political purposes. Accounts of temple decoration during the 4th and 3rd centuries BC mention depictions of triumphal processions. The probable style of these is visible in the contemporary tombs of Tuscany. It was to Greek artists that the Romans turned when, in the 3rd century BC, they first came into contact with the flourishing Greek cities of southern Italy and the eastern Mediterranean. Contact was usually in the form of war, and soon Greek works of art were being brought to Rome as booty in order to decorate the temples set up as memorials to victorious campaigns. Greek artists followed the works of art as it became

increasingly clear that Rome offered the best and most consistent source of patronage. In 168 BC Lucius Aemilius Paullus, the victor over the Macedonian king Perseus at the Battle of Pydna, employed Metrodorus, an Athenian painter, to execute panels depicting events in his victorious campaign. It is significant, perhaps, that Metrodorus was a philosopher as well as a painter and that he was also employed by Paullus in educating his children. Tradition states that Demetrius, an Alexandrian "place painter" (*topographos*), was working in Rome by 164 BC. The exact meaning of his title is problematic, but it could mean that he painted landscapes, later to become a favourite motif in the decoration of Roman houses. Some Alexandrian tombs of the 2nd century BC do indeed represent gardens and groves as seen through colonnades or windows in the wall of the tomb chamber. A late Hellenistic version of the type is preserved on floor mosaics from Pergamum in Asia Minor and from Italy itself. Paintings on Delos show floral motifs in an illusionistic style against a dark ground. This was later to become the Roman garden scene, usually set against a cool, dark background, that is found so often in the colonnades of Pompeian courtyards. (P.J.C.)

Wall paintings of the Roman period, for instance those from Pompeii, vary so much in their treatment of any one subject that it is hazardous to conjecture which version is likely to be closest to any earlier Greek painting, even supposing there was definite copying. With the exception of the Alexander mosaic already mentioned (see above *Hellenistic period*)—evidently a direct copy of a painting of the 4th century BC—there is nothing in painting to correspond to the straightforward copying of Greek statues that was apparently so abundant under the Roman Empire.

(B.As./P.J.C.)

Virtually the only example of painting in Rome and Latium to have survived from before the 1st century BC is a fragment of a historical tomb painting with scenes from the Samnite Wars, found in a family tomb on the Esquiline and probably dating from the 3rd century BC (Palazzo dei Conservatori, Capitoline Museums, Rome). In addition to Metrodorus and Demetrius, ancient writers mention the names of three painters, each of whom worked in a temple: Fabius Pictor, in the Temple of Salus in Rome at the end of the 4th century; Pacuvius, a dramatist and native of Brundisium, in the Temple of Hercules in the Forum Boarium in Rome during the first half of the 2nd century; and Lycon, an Asiatic Greek, in the Temple of Juno at Ardea in the late 3rd or early 2nd century. Nothing is known about the work of these artists.

At Pompeii during the 2nd century BC the interior walls of private houses were decorated in a so-called *Incrustation*, or *First*, style; that is, the imitation in painted stucco of veneers, or *crustae* ("slabs"), of coloured marbles. But in the second half of the 1st century BC, there suddenly appeared in Rome and in the Campanian cities (the most famous of which is probably Pompeii) a brilliant series of domestic mural paintings of the so-called *Second* style, the aim of which was to deny the walls as solid surfaces confining the room space. This was sometimes done by covering the whole area of the walls with elaborate landscapes, in which depth, atmosphere, and light are rendered in a highly pictorial, illusionistic manner. Such are the *Odyssey* paintings (Plate 1) found in a Roman house on the Esquiline (now in the Biblioteca Apostolica Vaticana, Vatican City), which consist of a continuous flow of episodes that unfold, filmlike, beyond a colonnade of pilasters, with vertical, bird's-eye-view perspective and human figures strictly subordinated to their settings. Other wall paintings, such as those in a room from Livia's Villa at Prima Porta (transferred to the Museo Nazionale Romano), represent a great park or garden filled with trees, shrubs, flowers, and birds, with no pilasters in the foreground to interrupt the prospect and no human figures to distract attention.

The possibility of Hellenistic models for this type of painting has already been mentioned, though the surviving Hellenistic precursors were no preparation for the important Roman developments. Most examples of the type, which survived into the Fourth style, have been found on the back walls of the colonnades running around

real gardens. The cool painted scenes would have given the illusion that an idler in this part of the house was surrounded by shrubs or groves of trees. Another type of landscape combined sacred and idyllic features and was often placed as though behind elaborate stage buildings. These monotone compositions held sacred columns or rustic shrines and were closely related to other illusionistic scenes peopled with little figures whose antics, the written sources make clear, were a source of endless amusement for the householder and his guests.

Frieze in
the Villa
of the
Mysteries

A celebrated frieze of life-size figures, depicting Dionysiac initiation rites and the prenuptial ordeals of a bride, in the so-called triclinium of the Villa of the Mysteries (or Villa Iam) outside the Herculaneum gate of Pompeii, also belongs to the Second style (Plate 2). There the walls are denied by the device of substituting for them a narrow stage on which the figures carry out the ritual before a drop scene of continuous painted panels. But the most common Second-style paintings are known as Architectural and show a threefold horizontal division of the wall into dado, central area, and cornice, combined with a triple vertical scheme of design that consists of a large central panel (in the main, intermediate horizontal area), framed by flanking columns and a pediment, and two smaller panels on either side. The central panel and often the lateral panels as well are views seen through windows that break through the walls and link the spectator with the world outside, as in the house of Augustus on the Palatine in Rome.

In the Third style, which covers most of the Augustan period, the central panel picture on a wall is no longer thought of as a scene through a window but as a real picture hung on or inserted into a screen or woven into a tapestry, which partially conceals an architectural vista behind it. The columns, entablatures, and so on are completely unreal and so complicated that this Third style is sometimes dubbed Ornate.

The Fourth style, which runs from the close of the Augustan Age to the destruction of Pompeii and its fellow Campanian cities in AD 79, is less homogeneous than its predecessors and exhibits three main variants: first, an architectural design soberer and more realistic but still with a central screen or tapestry partly covering a retreating vista; second, an architectural layout that imitates a *scaena* ("stage background"); and third, a method (sometimes known as "intricate") by which the whole surface of the wall is covered with a flat, white, neutral ground painted with an allover, latticelike pattern of fantastic architectural elements, arabesques, grotesques, small figure motifs, or small panels containing pictures. This third type of Fourth-style painting came into vogue at Pompeii between an earthquake of AD 63 and the catastrophic volcanic eruption of 79, and one of its most impressive exponents is the Golden House of Nero in Rome.

The subjects of the panel pictures of the Second, Third, and Fourth styles are for the most part drawn from Greek mythology. Some of them recall literary descriptions of famous classical Greek and Hellenistic paintings or show motifs that suggest their originals were painted on the Greek mainland or in Asia Minor. It is certain that many masterpieces of Greek painting did make their way to Rome as the booty of Roman generals of republican days, and wall painters could have studied them at first hand. But often those artists must have had to rely only on sketches of the celebrated pictures, and it is not known how faithfully the Roman and Campanian murals reproduce the prototypes. Other panel pictures present scenes from contemporary religious ritual, and a few show themes from Roman legend. Frequently, in the case of the Greek mythological subjects and those taken from rustic religious cults, the artist produced landscape with figures, as in the *Odyssey* frescoes (Plate 1), not figures with landscape, as on Trajan's Column. These late republican and early imperial set pieces are competently executed, remarkably vivid, and extremely naturalistic. But, with a few exceptions, they reveal that the principles of a single vanishing point and unified lighting from a single source of illumination either were not understood by Roman painters or did not interest them.

Late
republican
and early
imperial
set pieces

The flat, uniform background of the last phase of the Fourth style remained a constant feature of mural painting in houses, tombs, temples, and other religious shrines throughout the 2nd, 3rd, and 4th centuries. The decoration, which stands out against that ground, takes any of several forms: (1) latticelike, allover patterns, as in many pagan tombs; (2) small groups of figures or figure panels spread out at intervals across the field, as in the Christian catacombs of Rome; (3) a mixture of large human figures and extensive scenes with small-scale figures, as in the early 3rd-century Hypogeum of the Aurelii on the Viale Manzoni in Rome, the interesting painted content of which is Gnostic or crypto-Christian; or (4) large scenes with relatively large figures, such as a group of marine deities in a 2nd-century Roman house under the Church of SS. John and Paul on the Caelian, a late 2nd- or early 3rd-century leopard hunt on the south wall of the frigidarium of the hunting baths at Leptis Magna (on the coast of modern Libya), or the early 3rd-century biblical scenes from a baptistry at Doura-Europus, an important archaeological site on the Euphrates in what is now Syria.

In the case of the Roman tombs, cross- or barrel-vaulted ceilings, where preserved, normally carry out the painted decoration of the walls, showing either a latticelike pattern or a series of small, spaced-out, figured panel pictures. At Trier (in what is now West Germany) remains have been found of a flat, coffered ceiling with panels of painted plaster from an early 4th-century imperial hall destroyed to make room for a Christian basilica. Large portions of eight painted panels are preserved. Four depict female busts—three of them with nimbi—which may be either personifications or portraits of members of the imperial family; the other four show pairs of dancing or sporting cupids. As the skillful modeling and lively naturalism of these figures show, late Roman painting could reach high standards.

Roman portrait painting comes only a short way behind portrait sculpture in technical skill and realism. One of the earliest extant examples is a group of Terentius Neo and his wife, from Pompeii (National Archaeological Museum, Naples). Both figures recall mummy portraits in Egypt, being painted in encaustic (a technique by which colours are mixed with liquid wax and fixed by heat) and ranging in date from the Flavian period to the 3rd century. A circular portrait group of frontal figures painted on wood, probably in Egypt (now in the Staatliche Museen Preussischer Kulturbesitz, West Berlin), seems to have originally depicted the emperors Septimius Severus and Caracalla, Julia Domna (Septimius Severus' wife), and Geta (Caracalla's brother); but Geta (so it seems) was subsequently washed out (perhaps most consequent upon his murder by Caracalla). Particularly attractive are the portraits done on gold-glass medallions, which in the exquisite refinement of their treatment may be compared to 16th-century European miniatures. A medallion in the Museum of Christian Antiquities, Brescia, dating from the 3rd century and carrying a portrait group, is a veritable masterpiece (Plate 2).

Early Christian. It is customary to distinguish early Christian painting of the West or Latin part of the late Roman Empire from the Christian painting of regions dominated by the Greek language and to consider the latter as proto-Byzantine. The Western strain of early Christian painting may be said to have ended with the collapse of the empire in the West at the end of the 5th century. In the East, until the 6th and even the 7th century, painting in many regions followed the paths traced by Christian painting at its beginnings. Exceptions to the above schematization are Doura-Europus and early Christian paintings in Egypt (see below).

Early Christian painting did not have a distinct existence until about the end of the 2nd century AD. There are several reasons for this. First, there can have been few, if any, monumental churches before that time capable of taking decoration showing Christian themes. Second, Christianity did not at first make great headway among those able to afford large painted tombs where examples of Christian iconography might be expected to appear. Third, early Christianity was much closer to Judaism than

Myth as
allegory

in later years and may have retained the Judaic distaste for the painted image, especially if it referred to the Godhead. Lastly, even Christians prized classical education, which was, after all, the only sound basis for a public career, and they could appreciate classical works of art even if they rejected pagan subject matter. This was made easier for them by the concept of myth as allegory, according to which depictions of mythological scenes were not so much statements of a religious position as moral lessons whose messages could be appreciated by any educated man. Because most surviving early Christian painting is funerary, it is hardly surprising that purely Christian subjects at first made little headway in a field already crowded with edifying moral messages based on the Greek myths. These may have been pagan, but they did emphasize the common belief in life beyond the grave. It was only in the 3rd century AD, when the idea of Judaic or Christian allegories gained legitimacy, that any real development could begin. Even so, some rather odd compromises took place: representations of Christ as the victorious Sun God or as a philosopher occur in early Christian tomb paintings. Even the emperor Constantine, who by the Edict of Milan (AD 313) established toleration for Christianity throughout the Roman Empire and who himself professed Christianity, seems to have worshiped both in his lifetime.

The new elements, then, consisted not of form but of content. As the power of the church over public and private life grew, these new elements tended to gain in importance, but they never quite ousted the pagan scenes. The latter were often drawn undiminished from plays or epics whose prestige remained long after Christianity became the official religion of the Roman Empire.

Catacomb
paintings
and the
beginnings
of
Christian
iconog-
raphy

With the growth of Christian communities, the catacombs—underground burial places—became veritable subterranean cities, their rooms linked by corridors. The most important extant examples are in Rome, with others in Naples, Sicily, Malta, North Africa (specifically in what is now Tunisia), and Egypt. Pictorial decoration of the catacombs, limited to only a few rooms, followed pagan models. Delicate lines on the ceilings and walls trace circles and squares in which decorative motifs are inserted: garlands, birds, four-legged animals, cupids, images of the seasons, and figures of ambiguous significance (pagan or Christian)—praying figures and a shepherd carrying a sheep on his shoulders, generally called “The Good Shepherd” (Figure 6).

As early as the first half of the 3rd century, however, scenes of purely Christian meaning were added to these neutral subjects. The oldest are located in Rome in the cemeteries of Domitilla (the gallery of the Flavians), of

Priscilla (the Greek Chapel), and of Calixtus (the Chapel of the Sacrament). Stories from the Old Testament are joined by stories from the Gospels. These images present examples of the succour brought to the faithful by God the Father and Christ the Son. Even the baptism and the adoration of the Magi can be interpreted in this manner; as revelations of Christ's divinity, they announce man's salvation.

The style and quality of these paintings vary. Some of those from the beginning of the 3rd century are light in touch and charmingly elegant (e.g., gallery of the Flavians), comparable to the best pagan paintings. In others (e.g., cemetery of Priscilla, mid-3rd century) there is a somewhat heavier element, with a passion of expression that seems to match the aspirations of the new faith. In the 4th century the style becomes firmly contoured.

The frescoes in the baptistry of Doura-Europus, executed between 230 and 240, differ only in style from those of the catacombs in the West. Scenes from the Old and New Testaments are used to explain the significance of baptism: the death of the old Adam and his rebirth to a new life through the baptismal bath. The back wall of the baptismal pool bears the images of Adam and Eve, recalling the Fall, as well as that of the Good Shepherd (who in this case is Christ, Saviour of souls). Illustrations on the longitudinal walls are of David fighting Goliath and of incidents from the Gospels—Christ walking on water, the healing of the paralytic, the holy women at the tomb, and Christ and the Samaritan—and were probably inspired by readings that accompanied the rite of baptism. Stylistic elements that recall the paintings in the Roman catacombs are the juxtaposition of scenes without apparent connection and the conciseness of the narrative.

Among the latest examples of early Christian funerary art are paintings dating from the 5th century in the tomb of el-Bagaouat at al-Khārijah, in Egypt.

(He.S./P.J.C./Ed.)

Book illustration in antiquity. That book illustration existed as far back as the late Hellenistic world can be inferred from some of the so-called Megarian bowls, imitations in clay of gold or silver vessels that date from the 3rd century BC to the 1st century AD. They often bear on their exteriors scenes in relief from literary texts that are sometimes accompanied by Greek quotations. They must, in part at least, have served as models for Roman artists. Book illustration is known to have existed in Rome comparatively early—examples include 700 pictures illustrating the early 1st-century-BC scholar and satirist Marcus Terentius Varro's 15 books of *Hebdomades vel de imaginibus* and a portrait of Virgil prefixed to an edition of

his poems. Miniatures in the codex of the *Iliad* in the Biblioteca Ambrosiana, Milan, were painted probably at the end of the 5th or beginning of the 6th century AD but reflect pictures of the 3rd, 2nd, and even 1st centuries AD, as do those of the Codex Virgilius Vaticanus in the Biblioteca Apostolica Vaticana (No. 3225), written around 400. Miniatures in the second great illustrated Codex Virgilius Romanus in the Biblioteca Apostolica Vaticana (No. 3867), written around 500, are still Roman in spirit, if less classical in style; the tenacious influence of Greco-Roman painting can be clearly traced in the illustrations of certain early Byzantine books. A most remarkable, if aesthetically crude, mid-4th-century mosaic pavement, found in a Romano-British villa at Low Ham, Somerset, and showing scenes from the first and fourth books of the *Aeneid*, is undoubtedly based on the copybook illustrations used for some Virgilian codex. (J.M.C.T.)

The only Christian illuminated manuscript surviving from before the 6th century is a fragment of the Book of Judges from Quedlinburg (Staatsbibliothek Preussischer Kulturbesitz, West Berlin). (He.S./Ed.)

Eastern Christian

A new artistic centre was created in the eastern Mediterranean with the foundation in the early 4th century AD of Constantinople (modern Istanbul) on the site of Byzantium. The term Byzantine is normally used to identify the art of this city and of the Orthodox Christian empire that was controlled from it and that survived from 330 until its capture in 1453 by the Ottoman Turks. From the reign of Justinian I (527–565) there were relatively clear political and ecclesiastical differences between the Byzantine world and the West, and the term Byzantine art from this period onward broadly reflects these differences. In practice, the division of Mediterranean art into two polarities is not always easy to maintain, as artistic contacts were frequent and each “sector” influenced the other. For instance, by the 12th century Byzantine influence had made itself felt outside the empire, as, for example, in the mosaics of Sicily and Venice; and the Byzantine style had been adopted by the Orthodox states that were growing up in Russia, Bulgaria, and the western Balkans. During the first half of the 13th century, when Constantinople was in Latin crusader hands, it was in these outlying areas that the most important developments in painting took place. Once the Greek emperors had returned to Constantinople in 1261, developments there began anew, and fine Byzantine mosaics and paintings date from this last phase. In the study of Byzantine art, mosaics are frequently included with painting, but here painting is treated alone; for mosaics, see DECORATIVE ARTS AND FURNISHINGS.

By 1460 or a short while after, the little that remained of the empire following Constantinople's fall in 1453, together with the independent Orthodox states (except Russia), was in Turkish hands. Nevertheless, painting in the Byzantine tradition continued in Greece, the western Balkans, and Bulgaria, for Orthodox Christian art was not banned by the new Muslim rulers. Indeed, works of great technical sophistication were still produced, and a number of painters of icons and church paintings are known through signed and dated works. In Russia a national art of great quality saw continuous development from a Byzantine basis throughout the Middle Ages and up to the end of the 17th century, when Peter I the Great imposed western fashions.

In general, Byzantine painters may perhaps have retained Greco-Roman traditions more faithfully than did medieval painters in the West. There is so much variation of expression in the history of Byzantine painting, however, that it would be misleading to describe it as a “style”; the term is better seen as the label for a period and for the patronage of an Orthodox Christian society. Because most surviving work is religious in content, Byzantine painting does have some distinctive features. Icons, or painted panels depicting holy figures, were a major item of production, and the most important churches have their walls decorated in mosaic. On the other hand, the production of illuminated books was limited. The range of subject matter in

Byzantine works is more restricted than that of the medieval West; scenes and figures from the New Testament and the history of the early church are perhaps the most popular choices.

Byzantine painting was a highly effective Christian art, expressing a new view of the divine and a new spirituality. On the whole, Byzantine emphasis concentrated less on presenting a naturalistic narrative than on suggesting the existence of a supernatural and timeless Christian realm; painters retained the pictorial devices of classical antiquity, even if they aimed at portraying a more abstract version of the world. It has been felt that Byzantine art as a result always contains a tension between naturalistic and abstract modes of expression.

EARLY BYZANTINE PERIOD (330–717)

Icons. Until quite recently very little was known about the icons of this age, but due to the cleaning of several in Rome and to the discovery of hundreds in the monastery of St. Catherine on Mount Sinai, much material is now available for study. Enough examples are now known for it to be possible to prove how important icons were at this time.

The icons in Rome (large cult images such as that of the Virgin from the Pantheon) represent Christian images at their most formal and monumental. The Sinai icons are more intimate, and many must have been intended for private devotions as well as church display. Among the finest are icons that represent Christ, St. Peter, and the Virgin and saints.

Illuminated manuscripts. It is now thought that illuminated manuscripts were relatively few in number even at the time they were produced. Certainly very few religious or classical texts survive. Of the latter, a copy of the pharmacological treatise *De materia medica* by Pedanius Dioscorides, a Greek physician of the 1st century AD, is certainly Constantinopolitan; it was done for Juliana Anicia, the founder of the church of St. Polyeuktos, and is dated 512. A copy of the *Iliad* at Milan may perhaps have been copied and illustrated in a Byzantine scriptorium. Of the religious manuscripts, the most important is a copy of the book of Genesis (known as the Vienna Genesis) at the Österreichische Nationalbibliothek, Vienna (Plate 3); there is a fragmentary copy of the Gospels in the Bibliothèque Nationale—usually known as the Sinop fragment, for it came from Sinop, in Turkey—and another at Rossano, in southern Italy. There is also another copy of Genesis, the Cotton Genesis, in the British Museum, but it was

severely damaged by the fire that destroyed part of the Cotton Collection. There has been dispute as to where these manuscripts were written and painted, but either Constantinople or Syria is the normal attribution. A fifth religious manuscript, the Rabula Gospels, whose text is framed in elaborate architectural and floral motifs (Figure 7), was copied at Zagba, in Syria, in the year 586 and was executed in a more sketchy, informal style.

ICONOCLASTIC AGE (717–843)

By the early 8th century so great an importance had accrued to the depiction of the saintly and divine forms that one body of opinion in the state feared the population was in danger of lapsing into idolatry. As a countermeasure, a decree forbidding representation of saintly or divine forms in religious art was promulgated, and from about 717 until 843 there reigned emperors who are called Iconoclasts. To most of them, representation of the saintly or divine in religious art was genuinely anathema. In spite of the ban, pictorial decoration was not in itself forbidden. The church of Ayia Sophia (literally "Divine Wisdom") at Salonika (modern Thessaloníki, Greece) was decorated under the patronage of Constantine VI (780–797); his monogram survives, and in the apse there are indications that there was a great cross like that which is preserved in the Church of St. Irene (Eirene) at Constantinople and which dates from the 740s. The survival of the 6th- and 7th-century figural mosaics in St. Demetrius at Salonika suggests that the ban was not strictly enforced everywhere. In any case, it was strongly opposed in the monasteries. But in Constantinople the ban seems to have been universal, and religious mosaics and paintings in all the churches were removed, including all those in Hagia Sophia.

Figural
church
decoration

MIDDLE BYZANTINE PERIOD (843–1204)

"Icon
lovers"

Icons. With the return to power of the "icon lovers," as they were called, in 843, figural art once more became important in the churches. Elaborate representational decorations in mosaic were set up in the more important buildings, painted ones in the poorer. The next two or three centuries were an age of great brilliance and represent the acme of Byzantine culture. The empire's frontiers were far-flung, its wealth was enormous, and its general culture was far in advance of the rest of Europe. After the death of Basil II (976–1025), a slow decline set in.

Icons were regularly produced throughout this period. The largest number are to be found in the Sinai monastery. These were mostly for Orthodox use but include a 12th- and 13th-century group done in a mixed East-West style by Western painters who were active in the Latin crusader kingdoms of the region and who copied Byzantine models. Others exist in various museums in the Soviet Union, where they were brought from provincial Russian churches and monasteries for cleaning and conservation. Some of these were imported from Constantinople; one of the finest, an icon of the Virgin known as "Our Lady of Vladimir" (Plate 3), was painted for a Russian patron about 1130. It is of considerable importance in the history of painting, for it not only is a work of outstandingly high quality but also is in a new, more human style, anticipating the late style that flourished between 1204 and 1453. It was at this time that the cult of the icon really came into its own, partly because richer materials became rare but mostly because the interior decoration of churches changed with the introduction of a screen called an iconostasis (*i.e.*, a screen that was to be covered in icons).

Wall painting. Wall paintings were important during this period, but only one decoration by trained artists in a larger building is known, namely that in the Church of St. Sophia at Ohrid, Macedonia (Yugoslavia). The majority of the scenes that survive were drawn from the Old Testament. They date from about 1050. More numerous are the paintings that decorate numerous rock-cut chapels in Cappadocia (in what is now Turkey); these were executed by lay painters for the monks who lived there alone or in small communities. This material is most important for understanding the character and varieties of Byzantine painting and for giving records of the near-complete decoration of churches. Some churches (such as the 10th-

century Tokalı kilise in the Göreme Valley, in central Turkey) represent the best achievements of the period. Some artists who painted the Cappadocian churches must have traveled out from Constantinople or other cities; others probably made their living locally. All levels of quality were found there; indeed Cappadocia contains a whole range of the subjects depicted in Byzantine painting of this period.

Illuminated manuscripts. Two magnificent manuscripts of this period survive: the Paris Psalter (Figure 8) and a book of sermons (*Homilies of St. Gregory of Nazianzus*), both in the Bibliothèque Nationale, Paris. The former contains 14 full-page miniatures in a grand, almost classical style, which led scholars at one time to date it to the earliest Byzantine period. The miniatures in the other book are more varied in style, some of them recalling the narrative art of Cappadocia, but this latter book represents nevertheless the grandest type of Byzantine manuscript of the age. It was done for Basil I about 880. During the following centuries many illuminated psalters, octateuchs (the first eight books of the Old Testament), homilies, and copies of the Gospels were produced. (Gospels formed the most numerous category.) Notable examples include the Bible of Leo and the Ménologion (a liturgical book

Grandest

relating lives of saints) of Basil II (976–1025), both in the Vatican, a psalter done for the same emperor and now in the Biblioteca Nazionale Marciana at Venice, and *The Homilies of St. John Chrysostom* in the Bibliothèque Nationale. A few of them contain many small-scale illustrations, as in a famous set of the Gospels in the Biblioteca Medicea-Laurenziana at Florence. The most common type of Gospel book had only a few illustrated scenes or only portraits of the Evangelists. The work is usually of high quality. Some psalters contained marginal illustrations referring to contemporary events (*i.e.*, the Iconoclastic Controversy). The 10th-century Joshua Roll (Figure 9) is interesting as an example of Byzantine illuminated manuscript that shows the tenacious influence of Greco-Roman painting.

In 1204 Constantinople was sacked by crusaders, its treasures were destroyed or dispersed, and the brilliant middle period of Byzantine art was brought to an end.

LATE BYZANTINE PERIOD (1204–1453)

Icons. Painted panels assumed a new importance in the last phase of Byzantine art. The most sophisticated work was done at Constantinople, some of it for patrons from elsewhere (notably Russia), and a number of icons survive

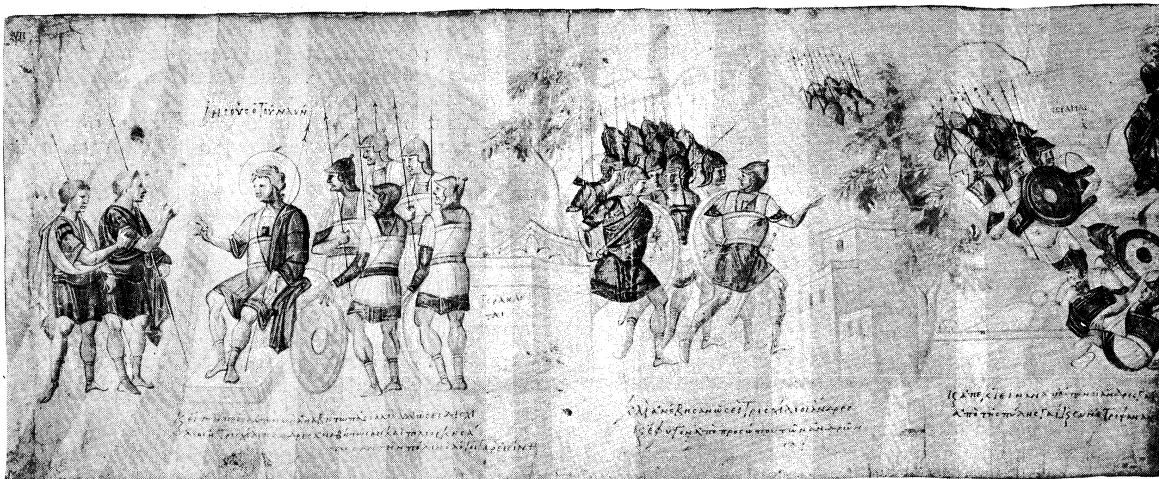

Figure 9: The attack on Ai, from the Joshua Roll (Josh. 7:3–5), Byzantine, 10th century. In the Biblioteca Apostolica Vaticana.

By courtesy of the Biblioteca Apostolica Vaticana

that can be associated with Constantinople on the basis of literary evidence or inscriptions. A particularly fine double-sided icon, with the Virgin on one face and the Annunciation on the other, now in the museum at Skopje, Yugos., was brought from Constantinople about 1300.

At this period the Russian school was the most important outgrowth of Byzantine icon painting; after the 13th century the influence of Byzantine models continued to be felt more in Russian icons than in the frescoes, but both wall and icon painting were showing local characteristics as early as the 13th century itself. The rigid Byzantine patterns, the dark colours, and the austere lines gradually became graceful, bright, and less solemn. Novgorod's style of icon painting, for example, gradually strengthened and took shape: the severity of faces was softened, composition was simplified, the silhouette became bold and increasingly important, and the palette was lightened by bright cinnabar, snow-white, emerald-green, and lemon-yellow tones.

Icons were produced in numerous other places, notably at Salonika, on Mount Athos, and in many other centres in what are now Bulgaria, Greece, Yugoslavia, and the Soviet Union. In a few instances icons can be assigned to a definite centre, thanks to inscriptions or other records, but the study of these panels has not progressed far enough to permit any reliable classification under localities on the basis of style alone. After the Turkish conquests of the mid-15th century, icons continued to be painted in large numbers in every part of the Orthodox world. In the 16th century Crete became an important centre, and many Cretan painters worked also in Venice, where there was a large Greek colony; many of the products of this school are to be found there today in the museum attached to the Church of St. George of the Greeks.

Wall painting. The last phase really began in the 12th century with the decoration at Nerezi in Macedonia (1164). It was done for a Byzantine patron and is in the same emotional style as "Our Lady of Vladimir." Work in a similar style is to be found in Russia from the late 12th century, and these models were followed by local craftsmen. In the 13th century new styles predominated in such paintings as those at Mileševa (1235) and Sopoćani (c. 1265), in what is now Yugoslavia, and in the church of Hagia Sophia at Trebizond (c. 1260; Trabzon), on the Black Sea.

It is probable that artists who had fled the capital after 1204 established themselves in a number of different areas and that wall paintings such as those mentioned above were the work of men they had trained. By the end of the century one can begin to speak of local art in the Byzantine Empire, as, for example, the regional art of Salonika. Examples of this last school are found in the Chapel of St. Eugenius, attached to the Church of St. Demetrius at Salonika, in the Protaton (*i.e.*, the First Church, in the

sense of the first in rank, c. 1300), at Kariai (Karyae) on Mount Athos, on the north coast of the Aegean, and in some of the monasteries there, as well as in a number of churches in Serbia and Macedonia decorated under the patronage of King Stephen Uroš II Milutin at the end of the 13th and in the early years of the 14th century. There has been some dispute among authorities as to whether King Milutin's painters were Greeks from Salonika or local Slavs. Throughout the 14th century a great deal of work was done by painters in what is now Yugoslavia and in Greece. Somewhat similar work was done in Bulgaria.

In Russia the Mongol invasion about the middle of the 13th century disrupted previous centres of production, such as Kiev and Vladimir-Suzdal. Only in the northern regions of Russia—particularly in the Novgorod district—did painting continue to develop. The city of Novgorod had as early as the second half of the 12th century developed an individual style, combining Byzantine severity with a folk art picturesqueness. (Examples are the frescoes in the Church of St. George in Staraya Ladoga [c. 1180] and the Church of Nereditsa.) Novgorod escaped damage by the Asiatic hordes and became virtually the metropolis and cultural centre of old Rus after the fall of Kiev (1240). Together with the city of Pskov and other north-western Russian population centres, it harboured many Greek artists, who continued to work in the traditions of Byzantium.

A prominent figure in Russian painting was Theophanes the Greek, a native of Constantinople who moved to Russia after about 1370. His paintings, though closely adhering to Byzantine styles, show distinctive Russian features, notably elongated proportions and delicacy of detail. Such features can be seen in his Novgorod frescoes and especially in the central part of the iconostasis in the Cathedral of the Annunciation in the Moscow Kremlin.

Among the immediate followers and collaborators of Theophanes was Andrey Rublyov, whose religious types are imbued with a fresh spirituality. His best-known work is the icon "The Old Testament Trinity" (c. 1410), painted for the Trinity-St. Sergius Monastery at Zagorsk. The subject—popular in Byzantine iconography—is the visit of three angels to Abraham and Sarah. But the severe symbolism of the old Byzantine tradition is transformed into something more human. It is one of the great creations of medieval Russian painting.

Another inspired Novgorod painter of the 15th century was Dionisi, whose art is marked by the extreme elongated stylizing of his figures as well as a subtle and glowing colour scheme. He and his predecessor Rublyov succeeded in expressing the aura of spirituality that is the essence of the Russian icon.

At Constantinople some paintings of outstanding quality were executed at the Monastery of the Chora, now known as Kariye Cami (Plate 3), and it is known from the

Continuity
in northern
regions

Elongated
stylizing

texts that similar paintings existed in a number of other churches there. Several were painted in the third quarter of the 14th century by Theophanes the Greek before he went to Russia. The same style was also introduced to Mistrás, in the Peloponnese, and there the wall paintings of the Brontocheion (early 14th century), the Church of the Peribleptos (c. 1350), and the Pantanassa (1428) are all of high quality. Paintings in the monasteries of the Morava Valley (in what is now Yugoslavia) done at the end of the 14th and beginning of the 15th centuries are in the same refined style.

Illuminated manuscripts. Illuminated manuscripts of the last Byzantine age are not as numerous as those of the middle period, but their quality is often just as high. A few seem to have been produced during the 13th century, both at Constantinople and in the cities where Orthodox nobles established themselves while the Latin crusaders were in possession of the capital, notably Nicaea and Trebizond. After the return to Constantinople in 1261 the noble families seem to have played a greater role than the emperors as patrons of all arts, and many of the more important works of art of the age were produced on their behalf. A copy of a work attributed to the 5th-century-BC Greek physician Hippocrates, now in the Bibliothèque Nationale, was made for the high admiral Alexius Apocaukos (Plate 3), and a beautiful copy of the Gospels in the same library was made for the emperor John VI Cantacuzenus between 1347 and 1355. Manuscripts were, of course, also copied and illuminated in the monasteries, and this process continued until printing made it obsolete. Few of the later ones contain illuminations of great quality. In the Slavic lands, however, fine work continued, and in Romania excellent manuscripts were executed in the 16th century. (A.Vo./D.T.R./R.S.Co.)

POST-BYZANTINE RUSSIA

In the 15th century major changes began to take place in Russian icon painting, leading to the birth of what may justifiably be called a national art. This evolution first became noticeable in the gradual elimination of the Mediterranean setting depicted in the background of icons, notably landscape and architecture. Greek basilicas with their porticoes and atria (patios or courts) were replaced by Russian churches with their cupolas and *kokoshniki* (literally "women's headdresses," but here, by extension, "gables"). Russian saints and episodes from their lives furnished subjects for the Russian artists; Muscovite types and native costumes began to appear in icon painting. The colours were extraordinarily brilliant, and there was particular emphasis on outline.

Many of the great icon and fresco painters in the 16th century worked first at Novgorod and later at Moscow, thus linking Novgorod and Moscow closely in artistic terms, and in particular introducing to Moscow features characteristic of the Byzantine and Novgorodian traditions. The literary movement of the 16th century strongly influenced contemporary painting, and artists looked to new subjects. Some illustrated church preoccupations and prayers or expressed the rites of the church in symbolic images; others represented parables and legends.

At the end of the 16th century the Stroganov school made its appearance in Moscow, introducing a small-scale manner of icon painting. The masters of the Stroganov school became famous for the elegant attitudes of their figures, their Eastern choice of colours, and their elaborate detail. Some of them—Prokopy Chirin, Nikifor, and Istoma Savin—were later to join the ranks of the icon-painting studios in the Kremlin armory in Moscow.

Moscow icons of the 17th century constitute the last authentically Russian painting. As early as 1650 much of their Russian character had disappeared. From the end of the century, western European influences spread rapidly.

(A.Vo./R.S.Co.)

REGIONAL VARIATIONS IN EASTERN CHRISTIAN PAINTING

Georgia. Christian painting in Georgia dates from the 4th century and shows both Eastern and Western influences owing to the position of the region as a crossroads of trade between Europe and India. From the beginning

of the 5th century the Georgian church approved the representation of the human form in religious painting. Accordingly Georgia was not affected by the wave of iconoclasm in the 8th and 9th centuries—a period that inhibited figural representation in most of Eastern Christendom for more than a century. In addition to a Christian tradition, Georgian painting also drew on a pagan one.

Until the 9th century, mosaics—more or less Byzantine in technique and design—were frequently used in the decoration of Georgian churches. By the 11th century the entire interior of Georgian churches was usually covered with frescoes instead. Many well-preserved examples survive from this period. Although following the Eastern Orthodoxy's general theological interest in church decoration, the Georgian murals deviated somewhat from Byzantine style and iconography, notably in extensive ornamentation between individual scenes.

The art of manuscript illumination flourished in Georgia from the 6th century onward, and numerous examples survive from all periods. Characteristic of the early works are two Gospel books, the Adishi Gospels (897) and the first set of Gospels of Dzhruchi (936–940). These are distinguished by their decorative treatment of draperies and their excellent drawing.

At the end of the 10th century Byzantine influence became strong in Georgia, and until the end of the 15th century Georgian manuscripts generally followed Byzantine models, differing only in an independent approach to the use of colour. These illuminations are of very high quality.

In the 16th century Persian influence from the East transformed Georgian manuscript illuminations. Ornamentation abounded, and the representation of figures and scenes was flat, decorative, and highly skillful. (Ed.)

Armenia. What little remains of the pagan art of Armenia strongly resembles late Greco-Roman art. With the establishment of Christianity as the official religion in the first years of the 4th century, however, a truly national art developed.

From an early period the interiors of Armenian churches were adorned with frescoes and mosaics showing scenes from the Gospels and images of Christ, the Virgin, and saints. Surviving examples are less plentiful than illustrated manuscripts, however. Important specimens of the latter exist in an almost uninterrupted series ranging from the late 9th to the 17th century. They are executed in ornamental designs of great richness and diversity. Floral, geometric, and animal motifs are painted in vivid colours on a gold background around the canon tables of the Gospel manuscripts (concordances of the four Gospels), on the headpieces, and in the margins and are ingeniously adapted to the capital letters.

As regards iconography, the Gospel scenes follow early Christian and Byzantine models, but the Armenian painters, especially those of the medieval kingdom of Little Armenia, often displayed a marked independence and interpreted traditional formulas in a more lively or dramatic manner. Two artistic trends can be discerned in manuscript painting: one, more Eastern in character, tends to simplify the human form and subordinate it to ornamental interest; the other, under Byzantine influence, shows a subtle blending of naturalism and stylization. This latter trend was predominant in Little Armenia, where a flourishing school of painting developed under the patronage of the court and the church. The 13th-century manuscripts, in particular, belong in the first rank of medieval illumination. Through contacts with the crusaders and the Mongols, the painters of this period became acquainted with the art of the Latin West and of the Far East, and as a result they produced richly imaginative works.

Manuscripts continued to be illustrated throughout the Middle Ages in Armenian monasteries and in the various centres outside the area of Little Armenia where Armenians had settled after the destruction of the kingdom in 1375. These works are often inferior to those of the earlier period, but some original schools developed—for instance, in the area of Lake Van, especially at Khizan and on Aghthamar (modern Akdamar). (S. Der N./R.S.Co.)

Coptic Egypt. Coptic painting—strictly speaking, that practiced by Christians in Egypt from the time when

Byzantine
influence
strengthens

Rapid
spread of
Western
influences

Christianity first took hold there—consists primarily of wall paintings in monasteries, the earliest foundations of which date from the 4th and 5th centuries.

Stylistically, Coptic painting differs from that of pagan Egypt in its emphasis on animal and plant ornamentation; less naturalistic rendering of the human form; simplified outline, colour, and detail; and increasingly monotonous repetition of a limited number of motifs.

In content, the wall paintings resemble other Christian examples of the genre around the eastern Mediterranean. The most usual theme is a frieze of saints with an enthroned figure of Christ or the Virgin. There is little variety of pose, though the features of individual saints are distinguishable. An unusually lively piece is a fragment from Wādī Sarga (now in the British Museum) depicting the Old Testament story of the three Hebrews in the fiery furnace; the Hebrews are dressed in Eastern garb and Phrygian hats and are shown as being protected from death by an angel (Figure 10). A celebrated set of wall paintings are those from Bawīt, now in the Coptic Museum at Cairo.

Figure 10: "The Three Hebrews in the Fiery Furnace"; fragment of a wall painting from a Coptic monastery at Wādī Sarga, Egypt, 6th century AD. In the British Museum, London.

Despite the 7th-century Muslim invasion of Egypt, there was no sudden break in the Coptic tradition. Indeed, some of the most notable surviving examples of manuscript illumination were produced during the first five centuries of Islāmic rule. It was only during the later Middle Ages that specifically Coptic painting ceased as Islāmic culture increasingly predominated. (A.F.Sh./R.S.Co.)

Western Dark Ages and medieval Christendom

DARK AGES

Ancient Roman civilization in western Europe foundered and fell apart in the second half of the 6th century, and the changes that took place between late antiquity and the succeeding period, the Dark Ages, were fundamental and catastrophic. Urban life collapsed, patronage of the arts all but ceased, and the centuries-old Mediterranean traditions of artistic training and production died out almost everywhere. It was only in a few places in Italy that artistic production continued unbroken, albeit much reduced. Increasingly the cultural fabric of northern Europe was determined by the various tribal peoples—Franks, Vandals, Goths, Angles, and Saxons—who migrated into the western provinces of the old Roman Empire during the 4th to 6th centuries and who established new patterns of settlement and centres of authority. Painting was not one of the traditional arts of these newcomers, though their craftsmen were expert workers of fine metals, leather, wood, and semiprecious stones (known as hardstones) such as garnet.

The reappearance of painting in northern Europe in the

late 7th century was determined by two overriding factors. The first was the conversion of these peoples to Christianity. By the 6th century the Christian church had developed an extensive iconographic repertory, and Christian images were in use everywhere: both as icons, which functioned as focal points of worship, and as symbolic and narrative compositions, which proclaimed the mysteries of the faith and instructed the unlettered in the stories of sacred scripture. Painted images had become an indispensable apparatus of orthodox Christianity, and for the newly converted they would have been one of its most arresting and tangible features. The second factor that induced the new masters of Europe to develop the art of painting and figural imagery was their fascination with, and desire to emulate, the culture of the late Roman world, in which painting had been widely employed.

Apart from a small number of images on wooden panels, two kinds of painting have survived from the early Middle Ages: large-scale painting on the walls of buildings and small-scale painting in manuscripts. These two genres involved differing techniques and, to a large extent, constituted separate artistic traditions. Only a tiny percentage has survived of the wall paintings originally to be found in almost every church and in many public buildings throughout the West. Exposed to the destructive agencies of light, moisture, fire, general wear and tear, and changes in fashion, paintings on walls have little chance of surviving for more than a few hundred years. Illuminated books of this period, on the other hand, have come down in large numbers. Made of resilient animal skin and protected by stout wooden boards, they last almost indefinitely, and their decoration usually remains in a remarkably good state of preservation. It is fortunate that book production and decoration were a major concern of the early medieval church. Christianity was the religion of the Book; the words of Jesus Christ, the Gospel, were written down in this book, which Christ, the Logos (literally the "Word"), and his saints are often represented as holding in their hands. Artists in the Middle Ages expended some of their greatest efforts on the illumination and embellishment of the Gospels, the books of the Old Testament, and the other liturgical, devotional, and instructional texts that the church required.

The history of early medieval painting in the West is best examined in the art produced in five areas: Italy, the British Isles, France, Germany and Austria, and Spain.

Rome and Italy, c. 600–850. Rome, the seat of the pope, was one place in the West where an unbroken tradition of artistic patronage and production endured from late antiquity into the high Middle Ages and beyond. This was of inestimable importance for the history of the period from about 600 to 850, since it was to Italy and to Rome that the people of northern Europe looked for direction and for example.

The antique tradition of illusionistic naturalism continued in painting in Rome through the early Christian period; but toward 600 it weakened, and figures became flat and insubstantial. Increasingly, Jesus Christ, the Virgin, and the martyred saints of the church are represented alone or in groups, in strict hieratic frontality (in which the figures are arranged facing forward), gazing out to catch the eye of the onlooker. This development accompanied and served the growing cult of saints and the widespread practice of addressing images as focuses of prayer and veneration.

In the 7th and early 8th centuries successive waves of Byzantine influence dominated Roman patronage and artistic production. Rome at this time was still under the rule of the Byzantine emperor, and contacts with the Eastern capital were close. Various distinct Eastern pictorial traditions seem to have flourished side by side: hieratic figures and strictly symmetrical compositions in mosaic at the church of Sant'Agnese (625–638) and the chapel of San Venzio at the Lateran Baptistery (642–649); faces carefully and vividly modeled to achieve astonishingly lifelike appearances at Santa Maria Antiqua (e.g., the "Pompeian" Annunciation and St. Anne, early 7th century); and elsewhere in the same church figures fleetingly but effectively rendered in delicate washes of colour, so that they seem to scarcely materialize out of a dense, light-

Rome's unbroken tradition of patronage

suffused atmosphere (e.g., Eleazar and Solomone and her seven sons, early 7th century).

Another strong and distinctive Byzantine wave hit Rome during the short papacy of John VII (705–707). Under his direct patronage, Eastern artists introduced an iconographic repertory new to the West, compositional schemes that were to endure for more than a century, and a vigorous new figural style (Figure 11).

Alinari/Art Resource, New York City

Figure 11: St. Andrew, wall painting in the presbytery of Santa Maria Antiqua, Rome, 705–707.

In the late 8th century a highly effective technique for representing the human figure was developed, in which modeling was almost completely eschewed and an eloquent system of brightly coloured lines was employed to define the clothed body. Examples include the painting of the Ascension (c. 850) in San Clemente, Rome, and the crypt (c. 830) of San Vincenzo al Volturno, in central Italy. In this technique wall painting was often used in conjunction with elaborate systems of white highlighting (e.g., the Harrowing of Hell in the lower church of San Clemente and paintings [c. 870] in the Temple of Fortuna Virile).

Some of the finest work in Italy of the 8th and the first half of the 9th century was done in the north. At Castelseprio, north of Milan, a Byzantine artist painted a wonderfully light and vigorous cycle of the early life of Mary and the Nativity of Christ in a manner that bafflingly recalls the fluid impressionistic painting of early imperial Rome. Other wall paintings of this time, by native Italian masters, are at Cividale del Friuli, in San Salvatore in Brescia, and at Müstair. Contemporary paintings in the south show clear connections with this new Byzantine-influenced art of northern Italy (e.g., San Vincenzo al Volturno, early 9th century).

England and Ireland, c. 650–850. It is recorded that Roman missionaries, who played a major role in the conversion of England to Christianity in the early 7th century, brought painted images with them; but next to nothing is known about painting on panels or walls in the British Isles during the Dark Ages. There is, however, a good deal of information about the illumination of manuscripts.

In the 6th and 7th centuries monasteries were founded and prospered, first in Ireland, later in England. In their scriptoria (writing rooms) manuscripts were written and decorated in increasingly elaborate fashion. In the Northumbrian double monastery of Monkwearmouth and Jarrow, Italian books and their illustrations were imitated extraordinarily faithfully (e.g., the Codex Amiatinus, a great Bible, c. 700). But artists in other Northumbrian centres in the late 7th century began to adapt the standard decorative apparatus of late antique Italian manuscripts to

very different effect. Portraits of the Evangelists became brilliant symbols, their bodies and clothes radically abstracted and brightly coloured; and, in the earliest books, they are sometimes shown in the guise of the four apocalyptic beasts, the man, the lion, the bull-calf, and the eagle, which represented the transcendental, celestial aspects of the four authors of the Gospels (e.g., the Durrow Gospels, c. 680; the Echternach Gospels, c. 700). Artists in the British Isles also introduced other new elements, the most striking being richly ornamented cross-pages, commonly called “carpet pages,” filled with ribbon interlace and wonderfully intertwined beasts, and large initial letters. The great full-page initial letters in Gospel books of the British Isles, besides articulating the text, serve as images, almost as icons, of the Word of God (Plate 4). These manuscripts are distinguished by their extraordinary ornamental repertory, drawn from the native Celtic tradition, from the Mediterranean, and from the tradition of fine metalworking introduced by Anglo-Saxon settlers in Britain in the 6th century.

In the 8th century there were flourishing scriptoria also in the south of England, and several manuscripts prepared at Canterbury have been identified (e.g., the Vespasian Psalter, c. 730–740; the Stockholm Codex Aureus, or “Golden Gospels,” c. 750). In early 9th-century books from the south, formal and iconographic elements introduced from Frankish scriptoria across the Channel are in evidence.

It is not yet possible to distinguish between different Irish schools of illumination. The outstanding manuscripts are the St. Gall Gospels (c. 750), the great Book of Kells (c. 800), the Gospels of Macregol (early 9th century), and a group of little “pocket Gospel books.”

The innovations of these early Irish and English scribes and artists left a lasting imprint on the subsequent development of book decoration throughout Europe. The elaborate initial letters that are found in nearly all later decorated manuscripts were first devised in the British Isles, and the decorative vocabulary of later continental illumination owed much to English and Irish invention.

Merovingian Gaul. It was only in the first half of the 8th century that manuscripts began to be elaborately decorated in the Frankish kingdom (an area roughly comprising northern France and southwestern Germany as far as the Rhineland). This production is known as Merovingian, after the Frankish dynasty that ruled, in name at least, until 751. In its subject matter, early Frankish illumination is decorative and symbolic rather than narrative. The idea of stressing the initial letters of a text was adopted from the British Isles, but the results were rather different. The strokes of letters are shaped like doves and fish with swelling bodies, or they are filled with simple ornamental motifs. A favoured frontispiece is a large cross standing within an arch, incorporating or surrounded by animals and birds of all kinds (e.g., the Gelasian Sacramentary [Figure 12]; St. Augustine, *Quaestiones in Heptateuchon*, Laon, c. 750). The rare instances of figural composition from mid-8th-century France are usually rather ungainly copies of late antique prototypes (e.g., the Gospels of Gundohinus, Laon, 754). It was only in the second half of the century, probably as a result of English influence, that figure drawing was subjected to a controlled linear discipline (as in the Flavigny Gospels). This development culminated about 800 in the wonderfully inventive historiated (decorated with figures of men or animals) initials in the Corbie Psalter.

EARLY MIDDLE AGES

Carolingian Empire. In the mid-8th century a new Frankish dynasty came to power. Under Charlemagne, whose long reign lasted from 768 to 814 and who was crowned the first emperor of the Romans in 800, a new courtly culture was created to rival those of late antique Rome and of contemporary Byzantium. The achievements of two groups of artists, members of both of which worked for the Emperor and his court, were to determine the overall development of painting in northern Europe for the next three centuries. One group, the so-called Court school, produced a series of splendidly rich Gospel books.

Figure 12: Frontispiece and initial page from the Gelasian Sacramentary, northern France, c. 750. In the Biblioteca Apostolica Vaticana, Vatican City (MS. Vat. Reg. Lat. 316, fol. 131v–132r). 26 × 17.1 cm.

Biblioteca Apostolica Vaticana, Vatican City

Their decoration is extremely inventive, even witty, and the figures, with carefully modeled limbs issuing from dense carapaces of brilliantly coloured, elaborately folded drapery, show a completely new mastery of the human form (Plate 4). The second group concentrated on figures dressed in archaic white garments, with faces and limbs modeled in dramatic chiaroscuro (contrasts of light and shade)—a conscious and very successful evocation of the painting of antiquity (e.g., the Coronation Gospels in Vienna, c. 795–800).

During the years from about 815 to 835 an extremely active and inventive scriptorium flourished at Rheims, under the patronage of the archbishop, Ebbo. Inspired by the masters of the Coronation Gospels, the Rheims artists aimed at producing work intentionally reminiscent of the art of classical antiquity. However, an extraordinary new spirit of linear excitement pervades their compositions, in such works as the Gospels of Ebbo, the Utrecht Psalter, and the Physiologus at Bern. These are some of the most vital and ecstatic creations of the early Middle Ages.

Leading schools of later Carolingian illumination were located at Tours, Saint-Amand (in what is now Belgium), Metz, St. Gall, and at an unidentified scriptorium from which Charlemagne's grandson, Charles the Bald, commissioned a number of extraordinarily lavishly decorated manuscripts in the 860s and 870s.

The early Carolingian artists reintroduced figurative painting and pictorial narrative to northern Europe. To achieve this, they studied monuments and manuscripts surviving from late antiquity and contemporary works from Italy, the British Isles, and Byzantium. They borrowed freely and exuberantly, but they were rarely mere copyists. Vitality and invention were always paramount. This remarkable achievement was the result of determined and demanding patronage and of intense creative effort.

The 10th century. The late 9th and the first half of the 10th century had been a time of economic depression, social upheaval, and political reorganization throughout western Europe. There had followed a period of reconstruction, with new ruling dynasties emerging and consolidating their power. Although production of wall paintings and manuscripts had continued, the energies of patrons had been directed elsewhere, and there had been a distinct decline in production. Only in the third quarter of the 10th century did renewed patronage lead to an outburst of artistic activity and invention.

Late Anglo-Saxon England. In England a coherent and magnificent style of book illumination was developed in the 960s in the scriptorium at Winchester. Narrative

compositions and initial letters are framed in arched and rectangular bossed (articulated with circular and square ornamental motifs) trellises of golden bars filled with rampant foliage; figures are clothed in shells of brittle broken drapery, with elaborate zigzagged contours and fluttering hems (e.g., King Edgar's Charter to the New Minster, Winchester, 966; the Benedictional [a book of episcopal Eucharistic blessings] of St. Ethelwold, 971–984 [Plate 4]). During the following century scriptoria in southern England produced a considerable number of books of this kind, filled with flickering colour and glinting gold and intended for ceremonial liturgical use. Behind this initiative in lavish book production lay a movement of religious reform, instituted by the leading churchmen of the realm and supported by the king.

In the scriptoria at Glastonbury and Canterbury a lively tradition of expressive outline drawing developed, and some of the most arresting Anglo-Saxon works of the period are filled with animated figures in flying ruffled drapery (e.g., the Leofric Missal, 970s; Harley Psalter, early 11th century).

English artists of this time delighted in iconographic invention. The results were sometimes startling, and the innovations often endured: the horns of Moses (for example, see Plate 5, although this is a much later work) and Christ disappearing into clouds at his Ascension were both English inventions of the early 11th century.

France. Continuing Carolingian traditions of illumination can be traced in many centres in France, but it is only at the very end of the 10th century that a new energy is apparent in scriptoria in the north, reflecting a reforming spirit in the church. At Fleury, Saint-Bertin, and Saint-Vaast at Arras, imported works from England and the presence of English artists gave a fresh impetus to manuscript illumination. Spirited outline drawings, inspired by English example, were set alongside frames and initial letters of Carolingian ancestry (e.g., the Psalter and Gospels of Odbert of Saint-Bertin, c. 1000; Bible of Saint-Vaast, early 11th century).

Ottonian Germany. In Germany, now under the Saxon Ottonian dynasty, concerted royal and ecclesiastical patronage also brought about a great revival in the arts. As in England, this revival followed a reform movement that touched all the leading monastic communities and revitalized religious life throughout the land.

Ottonian art, like Anglo-Saxon, was solidly based on earlier Carolingian invention; and the illustrations in one of the earliest Ottonian books, the Gospel Lectionary (a book of Gospel lessons for the church year) of Gero (c.

960), were copied line for line from a manuscript of Charlemagne's Court school. The dominant figure in the late 10th century was an artist known as the Master of the *Registrum Gregorii*, who seems to have been based at Trier. Drawing inspiration from both early Christian and Carolingian manuscripts, he developed a new manner of painting, in which meticulously detailed, smoothly modeled figures are placed in elaborate and precisely calculated spatial settings. In his work, volume and planar design interact in dynamic tension (as in the Letters of Gregory the Great, c. 983; the Gospel Lectionary of Egbert of Trier, from the 980s; and the Gospels of Sainte-Chapelle, c. 1005).

In about 1000, younger contemporaries of this man who had learned much from his art produced, on royal commission, a series of magnificently illuminated books in which brilliantly lighted figures move with a supernatural grandeur against golden grounds and bands of colour (examples include the Gospel Books of Otto III in Aachen and Munich, c. 1000; the Gospel Lectionary of Henry II, 1002–14; and the Apocalypse and Commentaries on Daniel and Isaiah, early 11th century). The portraits of the Evangelists and the imperial images in these books are remarkable for their formal subtlety and iconographic ingenuity (Plate 4).

During the first half of the 11th century, manuscript illumination flourished in various monastic scriptoria in Germany. The inventions and example of the Master of the *Registrum Gregorii* largely determined developments at Echternach and Cologne. At Cologne, Eastern painted books must also have been available as models, since the wonderfully fluid painterly compositions of the early works of the school appear to have been inspired by contemporary Byzantine painting (as in the Gospels of Abbess Hitda of Meschede, early 11th century). At Regensburg the splendid house style was based largely on one grand Carolingian book, the golden Gospels of Charles the Bald, in the possession of the Abbey of St. Emmeram. In this scriptorium, illustrations became vehicles for elaborate theological arguments, laid out in complex schematic compositions and glossed with explanatory inscriptions (e.g., the Sacramentary [a service book typically containing the celebrant's part of the mass together with various prayers] of Henry II, 1002–14; the Gospels of Abbess Uta, early 11th century). At Corvey, on the other hand, book illumination was ornamental and largely aniconic. The ornamentation consisted chiefly of darkly brilliant initial pages, with large gilded capital letters set on densely patterned purple grounds (as in the Wernigerode Gospels, c. 970).

From literary sources and fragmentary remains it is known that wall painting was common in Germany during this period. But only one extensive program survives, in the Church of St. George on the island of Reichenau, in Lake Constance. This dates from the late 10th century and consists of a sequence of the miracles of Christ's ministry, narrated with great drama and psychological intensity.

ROMANESQUE

In the second half of the 11th century in many parts of Europe new energies and new initiatives are apparent in painting, sculpture, and architecture. It is impossible to categorize these changes fully or to reduce them to a common denominator, but in many places there was a tendency toward greater schematization and bold configurations in design, in which strong and abstract structures of line and colour predominate. The surfaces of clothed bodies are enlivened by intricate schemes of folds and pleats and highlights in regular patterns of reiterated parallel and converging lines. These developments are partly explained by the arrival in the West of examples of recent Byzantine painting, with its elaborate patterned highlighting. Another factor seems to have been an aesthetic that defined beauty in terms of symmetry and order and the juxtaposition of pure, bright saturated colours.

Italy. In Italy the critical role played by Byzantine art is clearest of all. It is evident both in the north, particularly in Venice, and in the south at Montecassino, where Byzantine artists were summoned by the abbot Desiderius

in the 1060s to work on the decoration of his new abbey church. The wall paintings commissioned by the same Desiderius at Sant'Angelo in Formis, near Capua, are the outstanding surviving example of the consequent fusion of Eastern and Western traditions (Plate 5). In Rome and central Italy in the first decades of the century, the dominant fashion was for figures whose garments hung in a multitude of fine parallel pleats (as in the triptych of the Redeemer in the cathedral at Tivoli and in the wall paintings at Castel Sant'Elia di Nepi and in Santa Pudenziana in Rome). In the 12th century Italian artists took an increasing interest in ancient Roman art, nowhere more so than in Rome itself, where there was a veritable renaissance of classical and early Christian compositional formulas, motifs, and even styles.

France. An early Romanesque art emerged in scriptoria throughout France in the late 11th century—at Saint-Omer in the north, at Mont-Saint-Michel in the northwest, at the abbey of Saint-Aubin at Angers in the west, at Limoges in central France, and at Toulouse in the south.

In the early 12th century, major schools of painting flourished in Burgundy, at the great Benedictine abbey of Cluny, and at the newly founded Cistercian house of Cîteaux. From Cluny there is a lectionary in which Byzantine influence is strong and a copy of St. Ildefonsus' treatise on the virginity of Mary, with stiff, gorgeously coloured and gilded compositions owing more to late Ottonian examples than to Byzantium. There are also wonderful wall paintings in the Cluniac chapel at Berzé-la-Ville, where the various compositions are filled with energy and colour, and a tumult of fine sweeping folds and flickering highlights plays over the surface of the drapery. At Cîteaux the early manuscripts show evidence of strong Norman and English influence in their decoration and a satirical delight in observation (as in Gregory the Great's *Moralia* in Job, 1111). Later, in a group of manuscripts of the second quarter of the century, the illustrations are colour-washed drawings with slender, lyrically conceived figures whose drapery falls in cascades of parallel rounded pleats, apparently inspired by contemporary southern Italian work (e.g., St. Jerome's Commentary on Isaiah, the Cîteaux Lectionary).

The most complete surviving set of early Romanesque wall paintings in France is in the church of Saint-Savin-sur-Gartempe, where the compositions show great narrative vigour and inventiveness. Quite startling formal mannerisms sometimes occur in provincial French painting of the first half of the 11th century. Two examples are the wonderfully highlighted and emphatically banded and pleated figures at Vicq-sur-Saint-Chartrier and the violently expressive gesturing figures on the vaults of the crypt of Saint-Nicolas at Tavant. In general, wall painters in the early Middle Ages had very limited means at their disposal, and it is remarkable how skilled artists were able to deploy three or four colours to impressive and unifying effect. An example of this is at Montcherand, in the Swiss Jura, where simple hues of brown, ochre, dull blue, and white have been used to depict ecstatically disputing Apostles beneath a huge Christ in Majesty, in a composition of bright abstract subtlety and strength.

England. In the 1120s in England artists at the abbey of St. Albans, drawing on earlier English traditions and Ottonian painting from Germany, devised cycles of full-page scenes with large, emphatically gesturing figures set off against rectangular panels of colour, often within architectural settings. In structural density, in their use of accumulated motifs and bright areas of colour, and in the intensity of their storytelling, these images (e.g., the Psalter in St. Godhard, Hildesheim, and the Life of St. Edmund) have few parallels in earlier English art.

In the second quarter of the century acquaintance with contemporary Byzantine painting—probably via illuminated manuscripts—and recent developments on the Continent led English artists to a more organic, if expressively attenuated, conception of the human body. Drapery is now stretched and gathered, with sinuous folds isolating curving islands of taut cloth (so-called damp-fold drapery) to describe three-dimensional forms in torsion. Faces are more heavily modeled than before, and glances and ges-

Cluny

tures are even more piercing and insistent. This is first seen about 1130 in the great Bible of the Abbey of St. Edmund at Bury (Plate 5); later stages of the development can be traced in a series of magnificent manuscripts from southern English scriptoria (e.g., the Dover Bible, the Lambeth Bible, the Psalter of Henry of Blois, and the Bodleian Terence) and in the wall painting of St. Paul and the viper in St. Anselm's Chapel in Canterbury cathedral (1160s).

In the late 11th century in southern England and in northern France a type of initial letter emerged in which men, monsters, beasts, and birds climb and struggle in "tanglewoods" of rinceaux (ornamental motifs consisting of sinuous and scrolling foliate branches). These ingenious constructions, full of movement and variety, fired the imaginations of artists throughout Europe. On the surface they are an expression of that love of joyously outlandish, grotesque, and even warring imagery that is a ubiquitous feature of 12th-century art; but at a deeper level they are concerned with man's unending conflict with sin and the Devil (Figure 13).

Figure 13: Initial letter U to the Book of Job in a Bible from Winchester, c. 1160. In the Bodleian Library, Oxford (MS. Auct. E. Infra I, fol. 304r). 14.3 × 14 cm.

Spain. An extraordinary and idiosyncratic tradition of manuscript illumination evolved in Spain in the 10th and 11th centuries. The chief vehicle for this art was the commentary on the book of Revelation of Beatus of Liebana, a text that seems to have been taken by contemporaries as a symbol of Christian resistance to the Muslim Arabs who dominated much of the Iberian Peninsula in the early Middle Ages. The Arab cultural presence in Spain was all-pervasive, and—even if it did not account for the strongly patterned, sometimes barbaric compositions and for the brilliant jarring use of colour—it was responsible for particular motifs adopted by these illuminators (such as the horseshoe arch) and for the common practice of recording in a manuscript's colophon the scriptorium, the scribe and artist, and the date of the manuscript itself.

Northern Spain also produced some of the most splendid Romanesque wall paintings. Spanish artists favoured formal symmetrical and hieratic compositions and strong, barely modulated colours. The human form and the stiff, banded drapery that encases it are consistently more idealized and abstracted than in other European painting of the time. At their finest, these works possess a hypnotic numinous power (Plate 5).

The Meuse Valley. The results of the great increase in artistic production, the sudden intensification of patronage, and the wealth of artistic invention found throughout Europe in the late 11th and early 12th century are nowhere

more clear than in the valley of the Meuse, in what is now eastern Belgium. One of the leading centres of artistic production was the abbey of Stavelot. The decoration of the outstanding early manuscript from its scriptorium, the Stavelot Bible, of about 1094–97, is the work of various hands and is a perfect microcosm of the influences and interests that gave rise to the first Romanesque painting. The majestic enthroned Christ clearly has his ancestry in Ottonian compositions from the nearby scriptorium at Echternach. Some of the historiated initials are inhabited by delicately drawn figures that seem to stem from the old English tradition of outline drawing. Others incorporate large, darkly modeled figures that look strikingly Byzantine. And the great initial of the book of Genesis has a complex program in which scenes from the Old and New Testaments are juxtaposed in a tree of medallions to demonstrate the scheme of Redemption. The concept of expounding a theological argument in a composition of diagrammatic complexity is something that was dear to the 12th century.

Germany and Austria. Full-page compositions of complex iconography in elaborate formal settings are also a characteristic of north German manuscripts of the 12th century. They are found above all in a group of books associated with the all-powerful duke of Saxony Henry the Lion (1142–95) and prepared in the abbey of Helmshausen on the Weser River. This scriptorium's masterpiece is a Gospel book presented by Henry and his wife Matilda to Brunswick cathedral in 1173–75. The illumination is extraordinarily rich and dense, with a solemn and magisterial palette of gold, purple, dark green, azure, ochre, and white. The elaborate iconographies are glossed in long scrolls, which form undulating accents across the pages (Plate 5).

A very different art was practiced in the southeast, where Salzburg was the leading centre. A strong Italian element is detectable in the illustrations in books of the first half of the 12th century, such as the giant Bible at Michaelbeuern and the Admont Bible of 1140–50. The latter manuscript—which features large, full-page compositions dominated by tall turning figures, unreal landscapes, and bright colours—is a parallel phenomenon to the great contemporary English books, such as the Lambeth Bible and the Psalter of Henry of Blois. Each shows a preoccupation with Byzantine models for figures and faces. But the strong Italian influence in the Salzburg scriptorium ensured that the German figures are calmer and more solid than their exuberant English cousins. In the middle of the century a wonderfully elegant art of pen drawing emerged at Salzburg, with expressive swaying and gesticulating figures set against backgrounds of blue and green (the Antiphonary of St. Peter's at Salzburg).

A number of early wall paintings survive in Austria and Germany, but many of those in Germany have suffered disastrously from over-restoration. In Austria the major monument is the late 11th-century Christological cycle in the west choir of the abbey Church at Lambach, apparently by artists from Salzburg. This work was strongly influenced by the contemporary Byzantinizing art of the Veneto. Salzburg painting of the 1150s can be seen in a lyrical female figure personifying the Third Hour, in the monastic Church of St. Peter.

In Germany well-preserved paintings of the early 12th century at Idensen, in lower Saxony, have strong four-square compositions and clearly contoured, stern-faced figures, which stem from late Ottonian tradition. Half a century later, on the lower Rhine, a new spirit and mentality were expressed in two splendid but drastically repainted cycles at Schwarz Rheindorf and at Brauweiler, near Cologne, where elegantly drawn figures play against panels and frames of blue and green, illustrating recondite and complicated iconographic programs.

LATE 12TH CENTURY

In the late 12th century two broad developments took place in wall painting and manuscript illumination throughout the West. On the one hand, forms became smoother and more fluent, and a less abstract and less aggressively patterned interpretation was put on nature. On the other

Minoan and Greek painting

Youthful fisherman with his catch, fresco on the wall of the West House at Akrotiri, Thera, Greece, 15th century bc.

"The Toreador Fresco," restored wall painting from the Palace at Knossos, Crete, c. 1550 bc. In the Archaeological Museum, Iraklion, Crete. Height (including borders) 81 cm.

"Three Companions of Odysseus Encountering the Daughter of Antiphatis, King of the Laestrygones," Roman Second-style wall painting from a house on the Esquiline Hill, Rome, possibly based on a Hellenistic painting, c. 1st century bc. In the Biblioteca Apostolica Vaticana, Vatican City. Height 1.4 m.

Greek and Roman painting

The family of Vunnerius Keramus, medallion of gold and glass, c. AD 250. In the Museum of Christian Antiquities, Brescia, Italy. Diameter 6 cm.

Hades abducting Persephone, wall painting in the small royal tomb at Vergina, Macedonia, 4th century BC.

Dionysiac initiation rites and prenuptial ordeals of a bride, wall painting, Second style, c. 50 BC. In the Villa of the Mysteries, Pompeii, Italy.

"Anastasis" ("Christ Ascending from Hell"), apse fresco, c. 1320. In the Church of St. Saviour at the Monastery of the Chora (Kariye Cami), Istanbul.

"Our Lady of Vladimir," tempera on wood, from Constantinople, c. 1130. In the State Tretyakov Gallery, Moscow. 78 × 55 cm.

Rebekah at the well, illuminated miniature from the Vienna Genesis, 6th century. In the Österreichische Nationalbibliothek, Vienna (Cod. theol. graec. 31, fol. 7).

Portrait of the high admiral Alexius Apocaukos, illuminated manuscript page from the Hippocrates Manuscript, c. 1342. In the Bibliothèque Nationale, Paris (Cod. Gr. 2144). 41.5 × 35 cm.

Byzantine painting

St. Mark, illuminated manuscript page from the Gospel Book of the Court school of Charlemagne, c. 810. In the Stadtbibliothek, Trier, W.Ger. (Cod. 22, fol. 59v). 36.6 × 24.5 cm.

Nativity, Benedictional of St. Ethelwold, Winchester, Hampshire, 971-984. In the British Library, London (Add. MS. 49598, fol. 15v). 29.3 × 22.5 cm.

Early Medieval and Romanesque painting

Liber Generationis, initial page from the beginning of St. Matthew in the Lindisfarne Gospels, c. 700. In the British Library, London (Cotton MS., Nero D.IV, fol. 27r). 34 × 24.5 cm.

St. Luke, illuminated manuscript page from the Gospel Book of Otto III, school of Reichenau, c. 1000. In the Bayerische Staatsbibliothek, Munich (CLM. 4453, fol. 139v). 24 × 19 cm.

Ascension, illuminated manuscript page from the Gospels of Henry the Lion, from the abbey of Helmarshausen, c. 1173–75. In the Herzog August Bibliothek, Wolfenbüttel, W.Ger. (Cod. Guelf. 105 Noviss. 2^a). 34.2 × 25.5 cm.

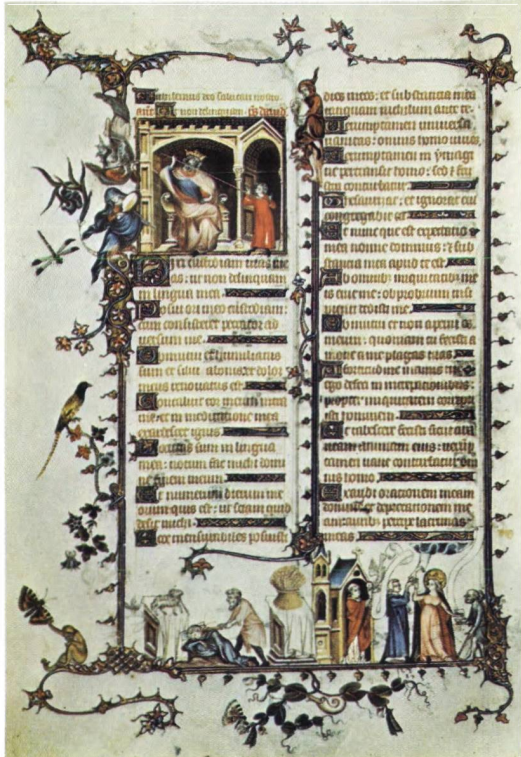

"Christ in Majesty," apse fresco from San Clemente, Tahull, Spain, by the Master of Tahull, 1123. In the Museum of Catalan Art, Barcelona.

Moses expounding the law of the unclean beasts, illuminated manuscript page from the Bury Bible, about 1130. In Corpus Christi College, Cambridge (MS. 2, fol. 94r). 51 × 35.7 cm.

Jesus at Bethany in the house of Simon the leper, detail of a fresco in Sant'Angelo in Formis, near Capua, Italy, second half of the 11th century.

David before Saul, page from the Belleville Breviary, illuminated manuscript attributed to Jean Pucelle, c. 1325. In the Bibliothèque Nationale, Paris (MS. lat. 10 483, fol. 24v). 24 × 18 cm.

Joshua bidding the Sun stand still, illuminated miniature from the Psalter of St. Louis, c. 1260. In the Bibliothèque Nationale, Paris (MS. lat. 10 525, fol. 46). 12 × 9 cm.

Angel blowing the trumpet, illuminated miniature from the Douce Apocalypse, c. 1270. In the Bodleian Library, Oxford (Douce MS. 180, p. 26). 15 × 11 cm.

"Annunciation," tempera on wood by Simone Martini, 1333 (saints on either side of the central panel by Lippo Memmi). In the Uffizi, Florence. 3.1 × 2.7 m.

"Adoration of the Magi," tempera on wood by Gentile da Fabriano, 1423. In the Uffizi, Florence. 3 × 2.8 m.

Initial letter of the Magnificat, from the Book of Hours of Gian Galeazzo Visconti, illuminated manuscript page by Giovannino de' Grassi, c. 1385. In the Biblioteca Nazionale Centrale, Florence (Fondo Landau-Finaly MS. 22, fol. 147v).

Cuer reading the inscription on the magic fountain, page from *Le Livre du coeur d'amours épris*, illuminated manuscript attributed to René of Anjou, 1465. In the Österreichische Nationalbibliothek, Vienna (MS. 2597, fol. 15r). 29 × 21 cm.

October, from the *Très Riches Heures du duc de Berry*, illuminated manuscript page by the Limburg brothers, c. 1416. In the Condé Museum, Chantilly, Fr. (fol. 10v). 29 × 21 cm.

"Descent from the Cross," tempera on wood by Rogier van der Weyden, c. 1435-40. In the Prado, Madrid. 2.2 × 2.7 m.

"The Resurrection," open right panel of the "Isenheim Altarpiece," oil on wood by Matthias Grünewald, completed before 1516. In the Unterlinden Museum, Colmar, Fr. 2.7 × 1.4 m.

Gothic painting in Germany and the Low Countries

"Madonna with Chancellor Rolin," oil on wood by Jan van Eyck, c. 1435. In the Louvre, Paris. 66 × 82 cm.

"Hell," open right panel of the "Garden of Delights" triptych, oil on wood by Hieronymus Bosch, c. 1505-10. In the Prado, Madrid. 2.2 m × 97 cm.

"Flagellation of Christ," oil on wood by Piero della Francesca, late 1450s. In the National Gallery of the Marches, Urbino, Italy. 59.5 × 82 cm.

"Arrival of Cardinal Francesco Gonzaga," fresco by Andrea Mantegna, completed 1474. In the Camera degli Sposi, Palazzo Ducale, Mantua, Italy.

Renaissance painting of the 15th century in Italy

"The Tribute Money," fresco by Masaccio, 1425. In the Brancacci Chapel, Santa Maria del Carmine, Florence. 2.5 × 6 m.

"The Primavera," tempera on wood by Sandro Botticelli, 1477-78. In the Uffizi, Florence. 2.1 × 3.2 m.

"The Bacchanal," oil painting by Titian, 1518-19. In the Prado, Madrid. 1.8 × 1.9 m.

"The Tempest," oil painting by Giorgione, c. 1505. In the Gallerie dell'Accademia, Venice. 77 × 74 cm.

"Madonna of the Meadows," oil on wood by Raphael, 1505. In the Kunsthistorisches Museum, Vienna. 1.1 m × 87 cm.

"The Last Supper," fresco by Leonardo da Vinci, 1495-97. In the refectory of the convent of Santa Maria delle Grazie, Milan. 8.8 × 4.6 m.

"Assumption of the Virgin," oil painting by El Greco, 1577. In the Art Institute of Chicago. 4 × 2.3 m.

"The Last Judgment," fresco by Michelangelo, 1533–41. In the Sistine Chapel, Vatican, Rome. 14.5 × 13.5 m.

Renaissance painting of the 16th century in Italy and Spain

"The Last Supper," oil painting by Tintoretto, 1594. In the chancel, S. Giorgio Maggiore, Venice. 3.5 × 5.6 m.

"Madonna dal Collo Lungo" ("Madonna of the Long Neck"), oil on wood by Parmigianino, c. 1535. In the Uffizi, Florence. 2.2 × 1.3 m.

"Peasant Dance," oil on wood by Pieter Bruegel the Elder, c. 1568. In the Kunsthistorisches Museum, Vienna. 1.1 × 1.6 m.

**Renaissance painting of the 16th century
in Germany and the Low Countries**

"Four Apostles," oil on two wood panels by Albrecht Dürer, 1526. In the Alte Pinakothek, Munich. Each panel 2.2 m × 77 cm.

"Venus in a Landscape," oil on wood by Lucas Cranach the Elder, 1529. In the Louvre, Paris. 38.1 × 25.9 cm.

"Portrait of the Merchant Georg Gisze," oil and tempera on wood by Hans Holbein the Younger, 1532. In the Staatliche Museen Preussischer Kulturbesitz, West Berlin. 96.3 × 86 cm.

hand, the perennial interest that Western artists had shown in contemporary Byzantine art grew more intense, and this sometimes led to the opposite extremes of turbulent and mannered design. Both of these tendencies probably aimed at representing human actions and interactions with greater conviction and increased psychological power.

In England a new soft style is apparent in the later hands responsible for illuminating the great Winchester Bible in the 1170s. There, all traces of the elaborately patterned damp-fold drapery of mid-century painting have vanished, to be replaced by material that falls in tiny ripples and soft irregular undulations to reveal firm limbs beneath. A later, simplified, mannered, and frenzied version of this style is found in the illustrations of a bestiary from the Midlands of soon after 1200 (Figure 14). But the rounded, billowing drapery of the enthroned Christ in the contemporary Westminster Psalter seems to have left the 12th century far behind. This is pure Early Gothic painting.

The Bodleian Library, Oxford

Figure 14: "The Unicorn," miniature from an English Bestiary, early 13th century. In the Bodleian Library, Oxford (MS. Ashmole 1511, fol 14v). 10.4 x 11.5 cm.

A similar evolution can be traced in northern France, in books such as the Capucin's Bible from Champagne and in the Souvigny Bible from central France, in which Byzantine influence is strong. A variation, which originated in the Meuse Valley, was the so-called *Muldenfaltenstil*, named after the small, troughlike folds into which drapery breaks (e.g., the Psalter of Queen Ingeborg, northern France, c. 1200). In Germany this style is found in manuscripts made on the middle Rhine and at Regensburg.

The other major factor in European art around 1200 was a widespread interest in Byzantium. Byzantine mosaicists in the late 12th century undertook vast commissions in Venice and Sicily, and these provided Western artists with the opportunity of studying monumental Byzantine art of the finest quality at first hand. Imported Byzantine illuminated manuscripts and panel paintings, enamels, and ivory carvings were also available as models. The purest and most striking instances of Byzantinizing painting are found in Italy. In Venice local craftsmen, trained by Byzantine masters, designed and laid mosaics that are almost indistinguishable from genuine Byzantine work; and in the cathedral at Aquileia the standing prophets and saints painted on the vaults of the crypt look as if they had walked straight out of an Eastern atelier. In Rome and its environs, too, the development of painting in the first half of the 13th century was determined largely by the extensive new programs of mosaics in Norman Sicily, at Palermo, Cefalù, and Monreale.

This swirling, contrived Byzantine art of the middle to late 12th century gave rise to many experiments in

northern Europe. It strongly affected artists at Salzburg (e.g., the drawing of Christ in Majesty in Vienna, Österreichisches Nationalbibliothek, MS. 953) and on the upper Rhine (e.g., the Gospel Lectionary from Speyer of 1196, in Karlsruhe), and it underlies the many figures in the great Tree of Jesse on the ceiling of the Church of St. Michael at Hildesheim, figures conceived in elaborate three-dimensional attitudes, with angular broken drapery. Finally, the *Zackenstil*—the new, elegant, early Gothic, jagged style of early 13th-century Germany, most magnificently exemplified in the Saxon Gospels in Goslar—was directly inspired by contemporary Byzantine painting.

In the early Middle Ages, wall painters had largely been laymen, whereas the illumination of manuscripts had been practiced almost exclusively in monastic scriptoria. In the late 12th century the production of books began to be taken up by lay scribes and painters working in their own shops. At the same time, illuminated books of private devotion and both religious and secular illustrated texts became increasingly popular. This process continued in the 13th century, when growing literacy and learning among laymen and the rise of the universities created a demand for illuminated and illustrated texts of all kinds. (Jo.B.M.)

GOTHIC

Gothic is the term generally used to denote the style of architecture, sculpture, and painting that developed from the Romanesque during the 12th century and became predominant in Europe by the middle of the 13th century. The many variations within the style are usually distinguished by the use of chronological or geographical terms (for example, early, high, Italian, International, and late Gothic).

Early Gothic. One of the moves away from Byzantine influence took the form of a softer, more realistic style, whose general characteristics survived until the middle of the 13th century. In France the style is particularly noticeable in a series of magnificent Bibles *Moralisées* (books of excerpts from the Bible accompanied by moral or allegorical interpretations and illustrated with scenes arranged in eight paired roundels, resembling stained glass windows) done probably for the French court c. 1230–40. In England the new style appears in numerous manuscripts; for instance, the psalter done for Westminster Abbey (British Museum, London; Royal MS. 2a XXII) and the Amesbury Psalter (c. 1240; All Souls College, Oxford). A particularly individual application of it is found in the manuscripts attributed to the chronicler Matthew Paris and in a series of illustrated manuscripts of the Apocalypse (Plate 6).

In Germany the graceful pictorial style did not become popular. Instead the successor to the Byzantine conventions of the 12th century was an extraordinarily twisted and angular style called the *Zackenstil*. In the Soest altar (c. 1230–40; now in the Staatliche Museen Preussischer Kulturbesitz, West Berlin), for example, the drapery is shaped into abrupt angular forms and often falls to a sharp point, like an icicle.

High Gothic. Certain characteristics of high Gothic sculpture spread to influence painting about 1250–60. Probably the first place where this became evident was Paris, where Louis IX (St. Louis) was a leading patron (Plate 6). In an evangelary (a book containing the four Gospels) prepared for use at the Sainte-Chapelle (Louis IX's palace chapel), one can see the early Gothic pictorial style superseded quite abruptly by a drapery style incorporating the large, rather angular folds of the Joseph Master (Bibliothèque Nationale). Combined with this style was a growing emphasis on minute detail almost as an end in itself; faces, in particular, became tiny essays in virtuoso penmanship.

Although details such as faces and hands continued to be described chiefly by means of line, in a subsequent development drapery and other shapes were modeled in terms of light and shade. This "discovery of light," partial and piecemeal as it was, began around 1270–80 but is particularly associated with a well-known Parisian royal illuminator called Master Honoré, who was active about 1288–1300 or later.

It is possible that this new use of light was stimulated

Pictorial style

New use
of light

by developments in Italian painting. However that may be, Italian influence emerged quite clearly in the second quarter of the 14th century, in the workshop of the Parisian artist Jean Pucelle (Plate 6). More than a dozen books have been associated with this artist; most show an awareness of the recent Italian discovery of perspective in the portrayal of space and some an awareness of Italian iconography.

The French style was introduced fairly rapidly into England. Although Henry III apparently was not a bibliophile, various manuscripts executed for his immediate family contain echoes of the dainty and minute style of Louis IX's artists. Some large-scale paintings that demonstrate similar stylistic traits, notably the "Westminster Retable," survive in Westminster Abbey.

Subsequent changes in English painting involved greater decorative elaboration. A number of large psalters, such as the Queen Mary Psalter (in the British Museum), survive from the first half of the 14th century, many of them done for East Anglian patrons and almost all laying heavy emphasis on marginal decoration. Although some books with elaborate border decorations date from as early as the 13th century, such decorations became much more lavish in the 14th. There are occasional indications of Italian influence in figure poses and compositions but nothing really comparable to that found in books from Jean Pucelle's Parisian workshop.

Italian influence reached other European countries. An Italianate style of painting developed in Spain in the 14th century and, to a lesser extent, parts of German-speaking Europe—in Austria, for instance, paintings in the Italianate style were added around 1324–29 to make up the present Klosterneuburg altarpiece.

Italian Gothic. In the 13th century both Rome and Tuscany had flourishing pictorial traditions, and both, until the middle of the century, were strongly influenced by Byzantine art. The transitional period 1250–1300 is poorly documented. Since much of the Roman work was subsequently destroyed, evidence for what was happening in Rome must be sought outside the city. The most important location where such evidence exists is Assisi, where the upper church of St. Francis was decorated by Roman-trained fresco painters between about 1280 and 1300. In Tuscany the stylistic changes are probably best revealed by Duccio di Buoninsegna's "Maestà" (1308–11), formerly the high altarpiece of Siena cathedral.

As with all Gothic decorative art, the changes are in the direction of greater realism. By the end of the 13th century, painters in Rome, such as Pietro Cavallini and probably Duccio in Tuscany, had discovered, like their contemporaries in Paris, the use to which light could be put in figure modeling. The Italian painters also made sudden and unexpected advances in the manipulation of perspective to describe the space of the scenes they were painting. More than this, the best painters developed an extraordinary ability to create figures that really look as if they are communicating with each other by gesture and expression; the work of the Isaac Master in the upper church at Assisi is an especially good example.

How far the Italian tradition of painting on a large scale magnified problems such as perspective, it would be hard to say. The survival of a large-scale mural tradition certainly marks Italy off from the north. Italian mural paintings were executed with a technique involving pigment applied to, and absorbed by, lime plaster that was still fresh (hence the name of this type of painting—fresco). It was with work in this medium as much as in tempera (a substance binding powdered pigments, usually made from egg at this date) on panel that artists in Italy won their reputations. The typical subjects of fresco painting were series of biblical or hagiographic narratives. The painting of such fresco narratives (in Italian, *istorie*, hence "history painting") was to be regarded in the 15th century as the most important part of an artist's work by Leon Battista Alberti, an architect, painter, sculptor, and the founder of "modern" or "Renaissance" art theory. In making such claims, Alberti had in mind the work of the painter Giotto di Bondone, better known as simply Giotto, of the late 13th to early 14th century.

Trained in Rome, Giotto executed his first important surviving work for the papal financier Enrico Scrovegni at the latter's family palace in Padua. The palace chapel, called the Arena Chapel (decorated c. 1305–13), is a masterpiece in which all the lessons of Roman mural painting were translated into a narrative sequence of great economy and expressiveness. In spite of the apparent realism of Giotto's work, however, the Byzantine past makes itself felt in the extremely strong sense of pattern and design noticeable throughout the compositions.

In Tuscany somewhat similar developments took place. Duccio's altarpiece, the "Maestà," contains a large number of small narrative scenes reminiscent of Giotto's fresco paintings. The figures, which have firmly modeled faces and expressive gestures, are arranged in buildings or landscapes that convincingly enclose them. Duccio's interest in realistic space, however, was much weaker than Giotto's. Although Duccio's scenes feature a variety of action and wealth of detail that, on the whole, is lacking in Giotto's early work, they do not make the same simple but dramatic impact.

These conflicts are inherent in all realistic painting. In Giotto's work a shift in the balance between the two conflicting elements takes place. He completed two chapels in Santa Croce, Florence (c. 1315–30), of which one, the Bardi Chapel, is smaller but not unlike the Arena Chapel. The other, the Peruzzi Chapel, tends toward greater detail and less stability in the settings.

Subsequent Florentine and Sienese painters also moved in this direction. Of the Sienese, Simone Martini was probably the most famous, since he worked outside Italy at the papal court in Avignon and was a friend of the great Italian poet Petrarch. His painting has strong suggestions of northern influence in its elegance and grace, but his care over detail is reminiscent of Duccio, and the careful structure of his setting recalls Giotto and the Roman painters. His major surviving work is now in Siena and Assisi, but some impressive remains have been recovered at Avignon (Plate 6).

Among other Tuscan painters were the brothers Pietro and Ambrogio Lorenzetti, who worked for almost their entire lives in that part of Italy. Their major works are in Siena, but, again, there are important frescoes at Assisi, where, probably, it was Pietro Lorenzetti and his workshop who decorated a transept in the lower church (c. 1330). Ambrogio Lorenzetti is especially famous for an enormous landscape, illustrating the effect of good government, painted in the Palazzo Pubblico Siena (1338–39). Historically, it is the first large, realistic landscape in which Byzantine conventions were entirely discarded. It had strangely few imitators, suggesting that the process of discarding convention and using the evidence of the eye is a slow one.

By the middle of the 14th century, Italian painters had achieved a unique position in Europe. They had made discoveries in the art of narrative composition that set them quite apart from painters anywhere else. Their achievements in capturing reality were not easily ignored. Many subsequent changes in northern painting consist of the adaptation of Italian compositional realism to northern purposes.

International Gothic. The style of European painting prevalent during the last half of the 14th century and the early years of the 15th is frequently called International Gothic. There were certainly at that time features common to European painting generally. In particular, figures were elegant and graceful, yet at the same time there was a certain artificiality about such figures, and a taste grew for realism in detail, general setting, and composition. The degree of internationalism about this phase of Gothic painting owes something to the fact that much of the most important work was executed under court patronage, and most European royal families were closely linked by marriage ties. Local idiosyncracies, however, persisted; seldom can the art of Paris, for example, be mistaken for that of Lombardy.

The main European courts were those of the Holy Roman emperors (who had nominal suzerainty over central Europe and who at this time had their capital at Prague),

Giotto

The
Lorenzetti
brothers

the Visconti of Milan, the Valois of France, and the Plantagenets of England. But other sources of patronage existed—in Florence, for example, where the art of Lorenzo Ghiberti and Lorenzo Monaco merged with that of the early Renaissance. And an extraordinary number of important painters were associated about 1350–1400 with the linguistic area of Low Germany—the Low Countries and Westphalia especially—and the Rhineland.

The patronage of Charles IV

Under the Holy Roman emperor Charles IV and his son Wenceslas, Prague was the seat of a flourishing and enlightened court for about 60 years. Brought up in Paris, Charles had also traveled in Italy. Indeed, his main palace chapel at Karlštejn Castle near Prague, which is the chief monument to Charles's patronage, had an altarpiece by an Italian painter called Tommaso da Modena. The chapel itself was decorated chiefly by a local painter called Theodorik of Prague, whose work is Italianate. A group of his panel paintings, especially the altar of Vyšší Brod (c. 1350), shows a curiously Sienese character, though he did not achieve the delicacy associated with paintings from Siena. The emphasis instead is on heavily modeled faces and thick, heavy drapery. Theodorik's style seems to have initiated the "soft style" that remained a part of German painting well into the 15th century. He certainly determined the character of Bohemian panel painting up to the outbreak of the disastrous Hussite wars (1419).

Charles IV apparently did not collect manuscripts. His ministers and courtiers, however, stimulated an important school of manuscript painting, influenced by French and Italian styles but with distinctive decorative characteristics. Two of the more important manuscripts were a missal (a book containing the office of the mass) done for the chancellor Jan of Streda (c. 1360; Prague, National Museum Library, MS. XIII. A. 12) and a huge Bible begun for Charles's son Wenceslas (1390s; Vienna, Österreichische Nationalbibliothek, Cod. 2759–2764).

Styles similar to this Bohemian painting soon appeared elsewhere—the paintings of Master Bertram of Minden at Hamburg (c. 1380), for example.

In Paris a style appeared that had some of the characteristics of Bohemian work, especially a strong emphasis on faces and facial expression. An early example, probably executed before 1364, is a portrait of John II (Louvre, Paris), which is firmly modeled in a rather Italianate manner. More important, however, is the workshop of the master of the "Parement de Narbonne" (1370s; Louvre; Figure 15), an altar hanging (*parement*) found at the Cathedral of St. Justin Narbonne. These artists, who were active c. 1370–1410, worked in a very distinctive style: their figures, while graceful, have markedly heavy heads and expressive faces. That some interest in settings had developed is suggested by the care that must have been taken to render them reasonably three-dimensional. In this respect the works have much in common with earlier Italian painting.

An interest in the settings of paintings was shared by panel painters such as Melchior Broederlam, who executed the Dijon altar wings (1390s; Museum of Fine Arts, Dijon). The interest quickly spread during the early 15th century to the manuscript painters, who produced a series of extremely impressive landscape and architectural settings. Especially fine are the so-called Brussels Hours (Brussels, The Belgian National Library, MS. 11060–1) and the *Hours of the Maréchal de Boucicaut* (Jacquemart-André Museum, Paris). The best of the manuscript painters worked for the royal family, among whom Jean, duc de Berry, the brother of King Charles V of France, has achieved permanent fame as a patron. The most notable painters who enjoyed his patronage were Pol de Limburg and Pol's two brothers. Their illuminations are frequently reminiscent of contemporary Italian painting. The largest and most sumptuous work, the *Très Riches Heures du duc de Berry* (left unfinished in 1416, Condé Museum, Chantilly, Fr.), includes calendar pictures representing each month in terms of the seasonal activities of nobility and peasants (Plate 7). At least one Italian artist—identified tentatively as Zebo da Firenze—was painting in Paris at this period (c. 1405). Manuscripts associated with him are usually sumptuously, if erratically, decorated. In-

deed, in the matter of erratic decoration they seem to have had a baleful influence. The border decoration of Parisian manuscripts c. 1410–25, such as those of the artist called the Master of the Duke of Bedford, often seems to run wild and to lack the restraint characteristic of Parisian painting up to this date.

The most eminent Italian artist of this period was perhaps Gentile da Fabriano. Trained probably in Venice, he painted there in the Doges' Palace (first decade of the 15th century) and also at Brescia. Subsequently he moved to Florence and thence to Rome, where he died. Most of his north Italian work has been destroyed, and his style must be assessed chiefly by the work done in Tuscany (Plate 7), the "Adoration of the Magi" altar (1423; Uffizi, Florence). His faces and drapery tend to have a soft, rounded modeling, somewhat reminiscent of the northern "soft style." The subject matter of his painting includes detailed studies of birds, animals, and flowers.

His style forms an interesting contrast to that of Lorenzo Monaco in Florence, who, though equally an International Gothic artist, tended to draw figures with finer, more incisive lines. In many ways Gentile's style resembles painting done at the Milanese court during this period. Many illustrated manuscripts survive, giving an impression of a transition about 1370–1410 from a strongly traditional Lombard style to something that has much in common with northern work. In particular, Michelino da Besozzo seems as court artist to have worked in a soft style similar to that of Gentile. Also dating from around 1400 is a distinguished group of illuminated manuscripts including the Book of Hours of Gian Galeazzo Visconti (Plate 7), herbals (manuals containing botanical drawings), and a famous sketchbook (c. 1395) containing a large number of drawings of animals (Bergamo, Municipal Library, Δ VII 14) from the workshop of an earlier court artist, Giovannino de' Grassi.

In England the decoration of the royal Chapel of St. Stephen's (c. 1360) was apparently, for the period, outstandingly Italianate. (Surviving fragments are in the British Museum, London.) Subsequently, however, in the Chapter House of Westminster Abbey (probably executed c. 1370) there was strong Germanic influence, which has been tentatively compared with the work of Master Bertram at Hamburg.

The court style of the second half of the 14th century is

Change
in English
manuscript
painting

best illustrated by a series of manuscripts done for members of the Bohun family and by a sumptuous missal given to Westminster Abbey by its abbot, Nicholas Litlington, in 1383–84. The work is decoratively lavish, but the figure style conveys only distant reflections of Italian painting. A great change in English manuscript painting occurred about 1400 and is associated with an artist named Herman Scheerre, who seems to have come from the region of Cologne. His figures have a rather plump softness that brings them into line with stylistic developments elsewhere; he also had a command of perspective and compositional structure lacking in the work of most previous artists in England. The style of John Siferwas, another painter active during this period, is similar, but his page decoration is usually more lavish; he produced a series of beautiful bird studies reminiscent of Lombard work. It should be noted, however, that this sort of realistic observation had long been a feature of English work—in the 14th-century East Anglian manuscripts, for example, and in English embroidery from about 1300.

In view of the number of good painters who came from the region of the Low Countries, Westphalia, and the Rhineland, it is puzzling that these areas should themselves have produced little important painting from the period about 1350–1410. Judging from the surviving works, easily the most distinguished of the painters active in this part of Europe was the Duke of Burgundy's painter, Melchior Broederlam, who lived and worked at Ypres. Other artists, such as Konrad von Soest, who executed the "Niederwildungen Altar" about 1403, seem to have reflected developments elsewhere without pioneering anything strikingly new. It was not until the 1420s that the Low Countries became the centre of intense pictorial development.

Late Gothic. The key to much 15th-century painting in northern Europe lies in the Low Countries. The influence of Paris and Dijon decreased, partly because of the renewal of the Hundred Years' War between England and France and partly because of the removal of the Burgundian court, after the mid-1420s, from Dijon to Brussels, which subsequently became the centre of an extensive court patronage.

The
Flemish
school of
painting

The founder of the Flemish school of painting seems to have been Robert Campin of Tournai. The works of Campin, his pupil Rogier van der Weyden, and Jan van Eyck remained influential for the whole century. One of the most important discoveries of the period of about 1430—especially in the work of van Eyck—was the multifarious effects a painter can achieve by observing the action of light (Plate 8). These early Flemish artists found that light can define form, shape, and texture and that, when captured in a landscape, it can help convey a mood. Rogier van der Weyden also explored the problems of conveying emotion (Plate 8). A development in the rendering of the drapery—the so-called crumpled style of hard angular folds—is particularly clear in the paintings of Campin. Portraiture made dramatic progress during this period. Portraits were obviously not new; sculptors were already experimenting in the 14th century with life—and death—masks. But the brilliant use of lighting gives the portraits of Jan van Eyck, for instance, a vivid life hitherto quite unknown.

A great deal of later 15th- and 16th-century Flemish painting seems to play variations on these themes. Although there were painters with distinctly individual styles, such as Hugo van der Goes, with his highly accomplished technique and somewhat contemplative depictions, Hans Memling was more typical (despite having been born in the Rhineland).

The influence of van Eyck's paintings was felt to a limited extent outside the Low Countries; for example, by Konrad Witz of Basel, Switz., by the Master of the Aix Annunciation (1442) of Aix-en-Provence, Fr., and by the Neapolitan artist Colantonio and his illustrious pupil Antonello da Messina. In the course of the century, however, the style of Rogier van der Weyden and his immediate successors, such as Dirck Bouts, became more influential, being felt in Germany, England, Spain, and Portugal. Evidence of Rogier van der Weyden's influence can be seen

in the works of Hans Pleydenwuff of Nürnberg, in the wall paintings in Eton College Chapel (c. 1480), and in the paintings of Nuno Gonçalves in Portugal. This new "international style" also influenced the great German engraver Martin Schongauer and, ultimately, the outstanding representative of the German Renaissance school of painting, Albrecht Dürer.

Any individualists at this time were usually painters who chose to go to the extreme of emphasizing the bizarre or the horrifying. Hugo van der Goes veered in this direction. Much more disquieting is the painting of Hiëronymus Bosch, whose strange scenes still puzzle and perplex (Plate 8). The work of Matthias Grünewald, whose main surviving work is the altarpiece for a monastery at Isenheim, Ger. (Unterlinden Museum, Colmar, Fr.; Plate 8) is grotesque and horrifying.

Hiëronymus Bosch

A very different sort of extreme individuality is found in the work of the Tirolean painter and sculptor Michael Pacher. His pictorial work is so strongly marked by a concern with the structure of the composition and with effects of perspective—particularly foreshortening—that it seems clear he knew the work of Andrea Mantegna of Padua. Although virtually free of antique motifs, Pacher's painting demonstrates the growing fascination of Italian Renaissance art for northern artists.

Rather different were the French painters of the 15th century (Plate 7). Court art revived, especially during the reign of Louis XI (1461–83), as exemplified by the illuminated manuscript *Le Livre du coeur d'amours épris* (1465; Österreichische Nationalbibliothek, Vienna). The most interesting painter was probably Jean Fouquet, who, apparently early in his career, visited Italy. Italian details certainly appear in his work, but, as is evident in the *Hours of Étienne Chevalier* (Condé Museum, Chantilly) and the "Melun Diptych" (now divided between the Staatliche Museen Preussischer Kulturbesitz, West Berlin, and the Museum of Fine Arts, Antwerp), he still painted within the northern tradition. The restrained and somewhat reticent character of much French painting is interestingly similar to much of the sculpture. (A.Ma./Ed.)

Renaissance

The term Renaissance was first used by French art historians of the late 18th century in reference to the reappearance of antique architectural forms on Italian buildings of the early 16th century. The term was later expanded to include the whole of the 15th and 16th centuries and, by extension, to include sculpture, painting, and the decorative arts. There is still considerable disagreement among art historians as to whether the term should be restricted to a phenomenon that had its origins in Italy and then spread through western Europe (the point of view taken here) or whether directly contemporary developments north of the Alps, and especially in the Low Countries, should be included on an equal footing with what was happening in Italy.

The controversies that raged after the publication of Jacob Burckhardt's *Civilization of the Renaissance in Italy* (English translation, 1878) have abated, and the time span of the Renaissance is generally accepted as the period from roughly 1400 to about 1600, although certain geographical areas and certain art forms require greater latitude. This period is characterized as a rebirth or, better, the birth of attitudes and aims that have their closest parallel in the art of classical antiquity. Classical literature and, less often, classical painting were invoked as a justification for these new aims. The theoretical writings on art from the period indicate that man was the dominant theme. In religious painting, drama and emotion are expressed in human terms. From the late Middle Ages the theme of the Madonna enthroned with Christ Child is presented in an earthly setting peopled by mortals. This strongly humanistic trend serves to explain, at least in part, the development of portraiture as an independent genre and the ever-increasing number of profane, usually classical mythological, subjects in the art of the Renaissance. The painting of landscapes, as the earthly setting of man's activity, has its first modest beginnings in this period.

The role of art and of the artist began to take on modern form during the Renaissance. Leon Battista Alberti's *De pictura* (*Della pittura*), a treatise on the theory of painting, as opposed to the techniques of preparing and applying colours, appeared in Florence in 1435–36. The directions that art and art theory were to follow for the next 470 years are already present in this little book. The artist is considered to be a creator rather than a technician because he uses his intellect to measure, arrange, and harmonize the elements of his creation. The intellectual activity of art is demonstrated, by a series of comparisons, to be equivalent to that of the other liberal arts. Influences such as Alberti's book led to a new evaluation of the artist, with painters and their works being sought after by the rulers of Europe (Michelangelo and Titian were actually ennobled); the result was that great collections containing the works of major and minor masters were formed. At the same time the artist slowly began to free himself from the old guild system and to band together with his colleagues, first in religious confraternities and later in academies of art, which, in turn, were to lead to the modern art school. During the Renaissance, practitioners of all the arts evolved from anonymous craftsmen to individuals, often highly respected ones. Painting became more intellectual, sometimes to its own disadvantage, and changed from serving as a vehicle for didacticism or decoration to becoming a self-aware, self-assured form of expression.

For the sake of convenience, painting of the Renaissance is divided into three periods, although there is considerable overlap depending upon the painter and the place. The early Renaissance is reckoned to cover the period from about 1420 to 1495. The High Renaissance, or classic phase, is generally considered to extend from 1495 to 1520, the death of Raphael. The period of Mannerism and what has more recently been called late Renaissance painting is considered to extend from the 1520s to approximately 1600.

EARLY RENAISSANCE IN ITALY

The early Renaissance in Italy was essentially an experimental period characterized by the styles of individual artists rather than by any all-encompassing stylistic trend as in the High Renaissance or Mannerism. Early Renaissance painting in Italy had its birth and development in Florence, from which it spread to such centres as Urbino, Ferrara, Padua, Mantua, Venice, and Milan after the middle of the century.

The political and economic climate of the Italian Renaissance was often unstable; Florence, however, did at least provide an intellectual and cultural environment that was extremely propitious for the development of art. Although the direct impact of humanist literary studies upon 15th-century painting has generally been denied, three writers of the 15th century (Alberti, Filarete, and Enea Silvio Piccolomini, later Pope Pius II) drew parallels between the rebirth of classical learning and the rebirth of art. The literature of antiquity revealed that in earlier times both works of art and artists had been appreciated for their own intrinsic merits. Humanist studies also fostered a tendency, already apparent in Florentine painting as early as the time of Giotto, to see the world and everything in it in human terms. In the early 15th century Masaccio emphasized the human drama and emotions in his painting "The Expulsion" (Brancacci Chapel, Santa Maria del Carmine, Florence) rather than the theological implications of the act portrayed. Masaccio in his "Trinity" (Santa Maria Novella, Florence) and Fra Angelico in his San Marco altarpiece seem to be much more concerned with the human relations between the figures in the composition than with the purely devotional aspects of the subject. In the same way, the painter became more and more concerned with the relations between the work of art and the observer. This latter aspect of early 15th-century Florentine painting relies in great part on the invention of the one-point perspective system, which derives in turn from the new learning and the new vision of the world. The empirical system devised through mathematical studies by the architect Filippo Brunelleschi was given theoretical form and universal application by Alberti in *De pictura*.

In this system all parts of the painting bear a rational relation to each other and to the observer, for the observer's height and the distance he is to stand from the painting are controlled by the artist in laying out his perspective construction. By means of this system the microcosm of the painting and the real world of the observer become visually one, and the observer participates, as it were, in what he observes. To heighten the illusion of a painting as a window on the world, the Italian artists of the early 15th century turned to a study of the effects of light in nature and how to represent them in a painting, a study of the anatomy and proportions of man, and a careful observation of the world about them. It is primarily these characteristics that separate early Renaissance painting from late medieval painting in Italy.

Masaccio has rightly been called the father of Renaissance painting, for every major artist of the 15th and 16th centuries in Florence began his career by studying Masaccio's murals in fresco. Masaccio is the artistic heir of Giotto, yet there is no indication of direct borrowing from the older master. He was also a friend of Brunelleschi and from him may have learned perspective and the concept of a clear and rationally articulated space. He was a friend, too, of the Florentine sculptor Donatello and may have learned from him the effectiveness of simple drapery folds over a full and powerful figure. Whatever his artistic sources, Masaccio's extant work reveals a concern with large and simple figures clad in simple draperies. He was concerned with light and the way it gives the illusion of solidity to the painted figure. He created a deep and clearly articulated space in his paintings, and he was above all concerned with his actors as humans carrying out some purposeful human activity. The only extant work by Masaccio that can be clearly dated is the Pisa altarpiece of 1426 (the central panel depicting the Madonna enthroned with Christ Child and angels, now in the National Gallery, London, is the largest surviving section). Although Masaccio continued the medieval tradition of using a gold background, the architectural elements of the throne indicate his awareness of the influence of Roman antiquity on the architecture of his friend Brunelleschi. The Madonna is no longer an elegant queen of heaven but an earthly mother with a human child on her lap. The figure of the Christ Child is a clear demonstration for future generations of the way light and shade can be manipulated in a painting to give the illusion of a solid three-dimensional body. In this painting Masaccio laid the foundations for one major current in all Florentine painting. His concern with the sculpturally conceived figure, bathed in light and presented in a strong and simple manner, created a work of quiet dignity and great monumentality in that it appears to be larger than it really is.

Masaccio's great fresco series in the Brancacci Chapel of Santa Maria del Carmine in Florence adds yet another dimension to early Renaissance painting. In this narrative sequence devoted to the life of St. Peter, he chose the most important moment in the narrative and then emphasized the drama by the human reactions to it. "The Tribute Money" is a simple yet powerful illustration of Christ's words, in which each apostle reacts individually to the tax collector's claim and Christ's reply (Plate 9). In this same chapel Masaccio also demonstrated his awareness of the real world, for the light of the paintings, indicated by the cast shadows, is the same as the natural light falling into the chapel.

"The Trinity" in Santa Maria Novella, Florence, provides a summary of Masaccio's brief career and indeed of the aesthetic principles of early Renaissance painting generally. The simple sculptural figures have acquired even greater dignity. The drama and emotion are presented in touching human terms as the Madonna turns to the observer to point out her crucified Son. In addition to the use of light to unite the space of the painting with the space of the observer, Masaccio also employed what appears to be the earliest practical example of the one-point perspective system, later to be formulated in words by Alberti. All the highest aims of early Renaissance painting are here: simplicity, strength, monumentality; man as observer, as actor, and as participant in the work of art.

Father of Renaissance painting

Masaccio's awareness of the real world

Invention of a perspective system

Masaccio had no true followers or successors of equal stature, though there was a group of other Florentine painters who were about the same age as Masaccio and who followed in his footsteps to a greater or lesser degree: Fra Filippo Lippi, Fra Angelico, and Paolo Uccello.

Fra Filippo Lippi was a Carmelite monk who spent his youth and early manhood at Santa Maria del Carmine, where Masaccio's work was daily before his eyes. His earliest datable work, the "Madonna and Child" (1437) from Tarquinia Corneto, relies on the Madonna from the Pisa altarpiece, but in his Christ Child Fra Filippo already reveals an earthiness and sweetness unlike anything by Masaccio. "The Madonna and Child with Two Angels" (Uffizi, Florence)—with its urchin-angels, lumpy Christ Child, and elegant Madonna—is perhaps one of his best-known late works; the placement of the Madonna before an open window is one of the key sources for later Renaissance portraiture, including Leonardo da Vinci's "Mona Lisa," while the elegance and sweetness of the Madonna were to have their greatest reflection in the work of Fra Filippo Lippi's student, Botticelli.

Born about the same time as Masaccio, Fra Angelico was a Dominican monk who lived at Fiesole (just outside Florence) and at San Marco in Florence. His earliest documented work, the "Linaiuoli Altarpiece" (Museum of San Marco, Florence) of 1433, continues much that is traditional to medieval art, although the male saints in the wings (side pieces of a composite painting, typically a tripartite altarpiece) already reveal the influence of Masaccio. The altarpiece that he executed between 1438 and 1440 for the high altar of San Marco is one of the landmarks of early Renaissance art. It is the first appearance in Florence of the *sacra conversazione*, a composition in which angels, saints, and sometimes donors occupy the same space as the Madonna and Christ Child and in which the figures seem to be engaged in conversation. In addition to inaugurating a new phase of religious painting, the altarpiece reveals the influence of Masaccio in the sculptural treatment of the figures and an accurate awareness of the perspective theories of painting expressed by Alberti in his treatise. At about the same date, Fra Angelico was commissioned to decorate the monks' cells in San Marco. The nature of the commission—traditional devotional images whose execution required assistants—apparently turned Fra Angelico toward the religious and didactic works that characterize the end of his career; e.g., the Chapel of Nicholas V in the Vatican.

Paolo Uccello's reputation as a practitioner of perspective is such that his truly remarkable gifts as a decorator tend to be overlooked. Studies of his extant works suggest that he was more interested in medieval optics than in the rational perspective system of Alberti and Brunelleschi. His earliest documented work, the "Sir John Hawkwood" fresco of 1436 in Florence cathedral, is a decorative work of a very high order and one that respects the integrity of the wall to which it is attached. Uccello is perhaps best known for the three panels depicting "The Battle of San Romano," executed about 1456 for the Medici Palace (now in the National Gallery, London; the Louvre, Paris; and the Uffizi). The paintings were designed as wall decoration and as such resemble tapestries: Uccello is concerned only with creating a small boxlike space for the action, for he closes off the background with a tapestry-like interweaving of men and animals. His primary concern is with the rhythmic disposition of the elements of the composition across the surface, an emphasis that he reinforces with the repetition of arcs and circles. Uccello's concern with the decorative and linear properties of painting had a great impact on the cassone (chest) painters of Florence and found its greatest reflection and refinement in the work of Botticelli.

Masaccio's greatest impact can be seen in the works of three younger painters, Andrea del Castagno, Domenico Veneziano, and Piero della Francesca. Castagno was the leader of the group. His "Last Supper" of about 1445, in the former convent of Sant'Apollonia in Florence, reveals the influence of Masaccio in the sculptural treatment of the figures, the painter's concern with light, and his desire to create a credible and rationally conceived space. At the

same time Castagno betrays an almost pedantic interest in antiquity, which roughly parallels a similar development in letters, by the use of fictive marble panels on the rear wall and of sphinxes for the bench ends, both of which are direct copies of Roman prototypes. In the last years of his life, Castagno's style changed abruptly; he adopted a highly expressive emotionalism that paralleled a similar development in the work of his contemporaries. His "The Trinity with Saints" in the church of the Santissima Annunziata, Florence, was originally planned with calm and balanced figures, as the underpainting reveals. In the final painting, however, the figures, though sculpturally conceived, project an agitation heightened by the emaciated figure of St. Jerome and the radically conceived figure of the crucified Christ. The optimism, rationality, and calm human drama of earlier Renaissance painting in Florence were beginning to give way to a more personal, expressive, and linear style.

One aspect of this new direction is met in the work of the enigmatic Domenico Veneziano, the second of the three principal painters who looked to Masaccio. His name indicates that he was a Venetian, and it is known that he arrived in Florence about 1438. He was associated with Castagno, and perhaps Fra Angelico, and helped to train the somewhat younger Piero della Francesca. His St. Lucy altarpiece of about 1445–50 (Uffizi) is an example of the *sacra conversazione* genre and contains references to the painting of Masaccio and the early 15th-century sculpture of the Florentine Nanni di Banco. The colour, however, is Domenico's own and has no relation to the Florentine tradition. His juxtaposition of pinks and light greens and his generally blond tonality point rather to his Venetian origins. In the painting he has lowered the vanishing point in order to make the figures appear to tower over the observer, with the result that the monumentality of the painting is enhanced at the expense of the observer's sense of participating in the painting.

Piero della Francesca received his early training in Florence but spent the active part of his career outside the city in such centres as Urbino, Arezzo, Rimini, and his native Borgo San Sepolcro, in Umbria. His "Flagellation of Christ" (late 1450s), in the National Gallery of the Marches, Urbino, is a summary of early 15th-century interest in mathematics, perspective, and proportion (Plate 9). The calm sculptural figures are placed in clear, rational space and bathed in a cool light. This gives them a monumental dignity that can only be compared to early 5th-century-BC Greek sculpture. Much the same tendency can be seen in Piero's great fresco cycle in the church of San Francesco in Arezzo.

A hiatus occurred in Florentine painting around 1465–75. All the older artists had died, and the men who were to dominate the second half of the century were too young to have had prolonged contact with them. Three of these younger artists, Antonio Pollaiuolo, Sandro Botticelli, and Andrea del Verrocchio, began their careers as goldsmiths, which perhaps explains the linear emphasis and sense of movement noticeable in Florentine painting of the later 15th century.

As well as being a goldsmith, Antonio Pollaiuolo was a painter, sculptor, engraver, and architect. His work indicates his fascination with muscles in action, and he is said to have been the first artist to dissect the human body. In the altarpiece "The Martyrdom of St. Sebastian" (1475; National Gallery, London) he presents the archers from two points of view to demonstrate their muscular activity. His painting (formerly in the Uffizi but now lost) and small sculpture (Bargello, Florence) of "Hercules and Antaeus," like the engraving of "The Battle of the Nudes," depict struggle and violent action. "The Rape of Deianira" (Yale University Art Gallery, New Haven, Conn.) emphasizes yet another new element in Florentine painting, the landscape setting, in this case a lovely portrait of the Arno Valley with the city of Florence in the background.

A similar concern with moving figures, a sense of movement across the surface of the panel, and landscape is found in the earlier works of Sandro Botticelli. In his well-known painting "The Primavera" (Uffizi) he uses line in depicting hair, flowing draperies, or the contour of an arm

Expressive emotionalism among Florentine painters

Introduction of the *sacra conversazione*

Elegance
and
grace of
Botticelli's
works

to suggest the movement of the figures (Plate 9). At the same time the pose and gesture of the figures set up a rising and falling linear movement across the surface of the painting. Botticelli's well-known paintings of the Madonna and Child reveal a sweetness that he may have learned from Fra Filippo Lippi, together with his own sense of elegance and grace. A certain nervousity and pessimistic introspection inherent in Botticelli's early works broke forth about 1490. His "Mystic Nativity" of 1501 (National Gallery, London) is even, in one sense, a denial of all that the Renaissance stood for. The ambiguities of space and proportion are directed toward the unprecedented creation of a highly personal and emotionally charged statement.

Florentine painters active in the closing decades of the 15th century include Andrea del Verrocchio, who is best known as the master of Leonardo da Vinci and Perugino. There was also Filippino Lippi, who was apparently apprenticed to Botticelli when his father, Fra Filippo Lippi, died; he painted a group of madonnas that are easily confused with Botticelli's early work. By 1485, however, he had developed a somewhat nervous and agitated style that can be seen in the highly expressive "Vision of St. Bernard" in the Badia, Florence. His last works, such as the series of frescoes he painted in Santa Maria Novella (1502), reveal a use of colour and distortion of form that may have influenced the later development of Mannerism in Florence a generation or so later. Another painter active at this time was Domenico Ghirlandajo, whose artistic career was spent as a reporter of the Florentine scene. The series of frescoes on the "Life of the Virgin" in Santa Maria Novella (finished 1490) can be viewed as the life of a young Florentine girl as well as a religious painting. His art was already old-fashioned in his own time, but he provided a large number of Florentine artists, among them Michelangelo, with training in the difficult art of fresco painting.

Diffusion
of the in-
novations
of the
Florentine
school

The discoveries and innovations of the early 15th century in Florence began to diffuse to other artistic centres by mid-century. Siena painters in general continued the traditions of the 14th century except for such artists as Matteo di Giovanni, Neroccio di Bartolomeo, and Vecchiotta, who alone in that city were to a certain degree under Florentine influence. In Ferrara, Cosimo Tura, Francesco del Cossa, and Ercole de' Roberti felt the influence of Florence as transmitted by Piero della Francesca. Only in Padua and Venice, however, did painters arise who could actually challenge the preeminence of Florence.

Andrea Mantegna was influenced by the sculpture executed by Donatello in Padua, the art of antiquity around him, and the teaching of his master, Francesco Squarcione. The frescoes he completed in 1455 in the Ovetari Chapel of the Eremitani Church in Padua (destroyed in World War II) grew out of the traditions of Florence, traditions to which Mantegna gave his own special stamp, however. His space is like that devised by the Florentines except that he lowers the horizon line to give his figures greater monumentality. His sculptural and often stony figures descend from Donatello and from ancient Roman models. His use of decorative details from antiquity reveals the almost archaeological training that he had received from Squarcione. By 1460 Mantegna had moved to Mantua, where he became court painter for the Gonzaga family, executing a number of family portraits (Plate 9) and pictures depicting ancient myths. His altarpieces, interpretation of antiquity, and engravings made him preeminent in northern Italy and a strong influence on his contemporaries and successors.

The Bellini
family

The Bellini family of Venice forms one of the great dynasties in painting. The father, Jacopo, who had been a student of Gentile da Fabriano, adopted a style that owed something to both that prevailing in the Low Countries and that in Italy; he also compiled an important sketchbook (British Museum; Louvre). A daughter of Jacopo's was married to Mantegna, and the two sons—Gentile and, more especially, Giovanni Bellini—dominated Venetian painting until the first decade of the 16th century. Gentile followed more closely in his father's footsteps and is perhaps best known for his portraits of doges and sultans of Constantinople and his large paintings of Venetian reli-

gious processions. Giovanni early fell under the influence of Mantegna. The paintings each executed of "The Agony in the Garden" (both in the National Gallery, London) indicate how close they were stylistically and also their common reliance on Jacopo Bellini's sketchbook. At an unknown point in his career, Giovanni was in addition introduced to Flemish painting. These different influences permitted him about 1480 to evolve a highly personal style that greatly influenced the work of subsequent Venetian painters. This style consists above all of a softly diffused Venetian light that can only be achieved in an oil medium. Giovanni's work in the traditional medium for painting on panels—egg tempera—retains the crispness of contour and tightness of composition that the medium seems to require. The oil paintings, however, emphasize by their use of light the textures of the objects represented, softening the outlines and creating an elegiac mood. The "Madonna and Child with Saints" of 1488, in Santa Maria dei Frari, Venice, derived its composition from the Florentine *sacra conversazione* and two earlier altarpieces by Mantegna in which the Madonna and attendant saints are located in a unified but compartmentalized architectural setting. Giovanni's greatest innovation is the way in which the soft light suffuses the entire space, an effect particularly remarkable where it strikes the golden half dome of the apse and the ample draperies of the figures, which seem almost palpable. The "Enthroned Madonna from San Giobbe" (Gallerie dell'Accademia di Venezia) of about the same date goes even further in defining a composition and a way of painting that endured in Venice for centuries. The painting of "St. Francis in Ecstasy" (c. 1480; Frick Collection, New York City) adds yet another dimension to Giovanni's art. The observer's eye tends to wander from the saint and his cell into the distant landscape, for Giovanni was one of the greatest 15th-century masters of landscape painting. Figures, animals, trees, and buildings provide a series of guideposts leading the eye back into space. Giovanni influenced several Venetian painters: Lorenzo Lotto and Vittore Carpaccio and also, more importantly, Giorgione and Titian.

The richness, the variety, and even the inherent contradictions of 15th-century Florentine painting are both embodied and transformed in the art and the person of the multifaceted genius Leonardo da Vinci. Although he devoted a great deal of his career to a theoretical treatise on the art of painting, he was above all interested in the appearance of things and in the way they operated. This curiosity led him to a study of the flight of birds, the movement of water, the features of the land, the mechanical advantage obtainable in gears and gear trains, the growth of plants, the anatomy of man, and many other things. His consummate skill as a draftsman made it possible for him to record these discoveries as no man before him had done. All the knowledge that he gained was directed toward enriching his art, for Leonardo thought of himself primarily as a painter.

As a youth Leonardo was apprenticed to Verrocchio, in whose shop he learned to draw, prepare and mix colours, and paint. He probably also learned how to model in wax and clay and how to cast bronze. He may even have been introduced to the art of sculpting in marble, although he clearly stated in his writings that he did not relish this difficult craft. Leonardo's genius is already apparent in his collaboration with Verrocchio in the "Baptism of Christ" (c. 1474–75; Uffizi), in which his contributions to the landscape and his figure of an angel clearly reveal his superiority. The unfinished "Adoration of the Magi" (Uffizi) for the monastery of San Donato a Scopeto outside the walls of Florence, together with the preparatory drawings (Louvre; Uffizi), is at once a summary of 15th-century Florentine painting and a forecast of the High Renaissance style. In his studies Leonardo reveals his debt to Pollaiuolo and Botticelli and his awareness of the rational compositions of the first half of the century, with their strong sense of perspective. In the painting, however, he makes a synthesis of these divergent tendencies and creates a composition that is at once ordered and free, calm and full of movement, simple and varied. Pose, gesture, and glance in the attendant figures create a movement leading

Leonardo's
interest
in the
appearance
and
operation
of nature

toward and coming to rest in the figure of the Madonna and Christ Child. The figures are placed in a free yet ordered space that gives a sense of grandeur and expansion, the expansion in turn being balanced by the concentration of the group around the Madonna. The appearance of the finished painting and the final direction Leonardo's planning would have taken can only be guessed, yet the nature of the composition and the preparatory underpainting of the figures and landscapes clearly demonstrate that Leonardo had advanced so far beyond his contemporaries that his innovation would only be comprehended by the group of younger painters who emerged some 20 to 25 years later.

(J.R.Sp./Ed.)

In 1481 Leonardo wrote a famous letter to the Duke of Milan offering his services. The offer was accepted, and for the next 18 years he remained in Milan, where he executed a number of paintings and innumerable drawings, worked on a never-completed equestrian monument to the Sforza dynasty, planned additions to the canal systems of the city, designed costumes for ducal entertainments, and wrote extensively. "The Virgin of the Rocks" (Louvre), painted in Milan about 1483, stands at the threshold of the High Renaissance. In this painting Leonardo introduced the pyramidal composition that was to become a hallmark of the High Renaissance. The placement of the Madonna, the Christ Child, the young St. John the Baptist, and the angel creates a movement that the eye willingly follows, yet the movement is contained within the implied pyramid, giving a sense of stability and calm grandeur to the composition. The mysterious landscape that surrounds them implies adequate space in which the figures can exist and move and an extension into depth that the eye cannot follow. The light that falls on the figures delicately models them in a subtle juxtaposition of light and shade. The contours of the figures seem to dissolve into the background, and the light seems to flow gently over a surface. The subtle and delicate modeling and the suggestive smoky atmosphere are known as *sfumato* and were much imitated, but what was more important and eventually more influential was Leonardo's use of light and shade as a unifying compositional factor. This was unprecedented in painting. It was achieved by the tonal continuity of the shadows—a tonal continuity conditional upon a severe restriction of local colour.

These effects, as well as the softly diffused light characteristic of Venetian painting, were only possible in the oil medium, which, because of its lengthy drying period, enables all parts of a painting to be advanced and adjusted together and the transparent glazes of which make possible unity of atmosphere and *chiaroscuro*. The rich effects of *impasto* (deliberately rough and thick paint textures) were also made possible in oil and were particularly exploited in Venice, where the use of canvas as a support first became truly popular. But there is no doubt that oil painting is a technique that originated in the Low Countries.

(J.R.Sp./N.B.P.)

Leonardo's attempts to transfer this new concept of painting to the difficult genre of murals led to the triumph and the tragedy of "The Last Supper." Because the traditional technique of fresco painting was too final for Leonardo's method of working, he invented a new technique—still not fully understood—that permitted him to revise in the manner of oil painting. The technique was not permanent, and the painting began to deteriorate in Leonardo's own lifetime. Despite its deterioration the painting stands as one of man's greatest achievements. All elements of the painting lead the eye to the calm and pyramidal figure of Christ. The room is depicted according to the rules of perspective, with all the direction implied by the lines of the architecture meeting at the vanishing point in the head of Christ. In this painting Leonardo has combined the sense of drama of the groups of disturbed apostles, the sculptural figure of Christ, and the rationally constructed space of the first half of the 15th century with the movement and emotion of the second half, achieving a new synthesis that goes far beyond anything his predecessors had dreamed was possible. Leonardo's "The Last Supper" marks the actual beginning of the High Renaissance in Italy (Plate 10).

HIGH RENAISSANCE IN ITALY

In painting, the style called High Renaissance or classic is, in a sense, the culmination of the experiments of the 15th century, for it is above all characterized by a desire to achieve harmony and balance. Movement is important and necessary, yet the eye is always given a point of focus and rest. The composition is self-contained and conforms to Alberti's definition of beauty as "that harmony of parts to which nothing can be added or taken away without destroying the whole." Although there is movement implied in the poses of the figures and movement across the surface of the composition, it is always dignified movement, giving the impression of calm. The style exhibits variety and richness, yet maintains simplicity and unity. It is never as self-conscious as 15th-century painting had been, nor is it as laboured as much of Mannerist painting. It is frequently compared to Greek art of the 5th century BC for its calm and monumentality. Its greatest practitioners were the Florentines Leonardo da Vinci (although Leonardo's earlier work is usually assigned to the early Renaissance) and Michelangelo, the Urbino-born Raphael, and the Venetian Titian. Other artists, such as Andrea del Sarto and Fra Bartolomeo in Florence, Correggio in Parma, and Giovanni Bellini and Giorgione in Venice, were more or less attracted to the style at some point in their careers.

The new style of painting that Leonardo had invented in Milan was continued with modifications by Bernardino Luini and others. It had no immediate repercussions in his native Florence, although the example of his unfinished "Adoration" remained there. It is true that Botticelli, Ghirlandajo, and Filippino Lippi borrowed the broad outlines of the composition, but they did not penetrate completely to the innovational features inherent in it. The full impact of Leonardo's art was felt only upon his return to Florence in 1500. Crowds flocked to the church of the Santissima Annunziata to see his cartoon (a full-scale study for a finished painting) of "The Virgin and Child with St. Anne." Leonardo's great mural of the "Battle of Anghiari" (1503–06) pitted him against his rival Michelangelo in a competition to record the history of the city in the seat of city government. Neither painting was finished. Yet, despite the inconclusive nature of the works partially executed during his brief Florentine stay, Leonardo left a deep impression on that city. The "Mona Lisa" (Louvre) revolutionized portrait painting. Leonardo's drawings encouraged fellow artists to make more and freer studies for their paintings and encouraged connoisseurs to collect those drawings. Through the drawings his Milanese works were made known to the Florentines. Finally, his reputation and stature as an artist and thinker spread to his fellow artists and assured for them a freedom of action and thought similar to his own.

The painter who benefited most from the example of Leonardo was undoubtedly Raphael. Born Raphael Sanzio, he was as a youth under the influence of Perugino. He was already a successful and respected artist when, at the age of 21, he came to Florence only to discover that all he had learned and practiced was old-fashioned and provincial. He immediately set about learning from the Florentines. His drawing style changed from the tight contours and interior hatching he had learned from Perugino toward the freer, more flowing style of Leonardo. From Leonardo's "Virgin of the Rocks" he evolved a new Madonna type seated in a soft and gentle landscape, such as "The Madonna of the Goldfinch" in the Uffizi or those in the Louvre and the Kunsthistorisches Museum, Vienna (Plate 10). He adopted the "Mona Lisa" format for his portraits, and he also studied closely the sculpture of Michelangelo. By 1509, when he departed for Rome, Raphael had assimilated all Florence had to offer and was ready to make his own unique statement.

The Stanza della Segnatura (the first of a series of rooms in the Vatican constituting Pope Julius II's apartments), particularly the "School of Athens," which Raphael painted between 1508 and 1511, is one of the clearest and finest examples of the High Renaissance style. In the "School of Athens" Raphael, like Leonardo before him, made a balance between the movement of the figures and the ordered

and stable space. He peopled this space with figures in a rich variety of poses yet controlled poses and gestures to make one group lead to the next in an interweaving and interlocking pattern, bringing the eye to the central figures of Plato and Aristotle at the converging point of the perspective construction. The unity, variety, and harmony of High Renaissance felicitously combine in the frescoes that decorate the Stanza della Segnatura.

The
painting of
the Sistine
Chapel
ceiling

At about the same time Raphael was working in the papal apartments in the Vatican, Michelangelo had undertaken the formidable task of decorating the ceiling of the Sistine Chapel (1508–12), also for Pope Julius II. In 1481–82 under Pope Sixtus IV, the uncle of Julius, the chapel had been completed and the walls decorated with frescoes depicting scenes from the life of Moses and the life of Christ executed by Botticelli, Ghirlandajo, Perugino, and others. Against his will Michelangelo was assigned to paint in fresco scenes from the creation. Although he had been trained in fresco painting in the shop of Ghirlandajo and although he had already executed a few paintings of considerable power, Michelangelo thought of himself as a sculptor. He engaged a group of his former colleagues from the shop of Ghirlandajo and with them began to paint the “Drunkenness of Noah” above the entrance to the chapel. Michelangelo had little patience with his less gifted associates, dismissed them, and executed the entire ceiling alone. The scenes were painted in reverse chronological order, beginning with the “Drunkenness of Noah” over the door and ending with the act of creation over the altar. In the first three frescoes Michelangelo seems to be feeling his way. With the second three—“Temptation and Expulsion,” “Creation of Eve,” “Creation of Adam”—he returns to the models of his youth (Masaccio for the “Expulsion” and Jacopo della Quercia for the “Creation of Eve”) to create a powerful High Renaissance composition. The balance between the kinetic energy of God the Creator with his whirlwind of figures around him and the flaccid lifeless form of Adam comes to a focus in the two hands and the significant void between them. In the final three scenes of creation, Michelangelo moves beyond his contemporaries to a highly personal statement without parallel in the art of the 16th century. The Sistine ceiling was recognized as a masterpiece in its own time. The artist was judged to be a superhuman being and earned the title “the divine Michelangelo.” Contemporaries spoke of the *terribilità*, or awesome power, of the frescoes and their creator. Michelangelo, Leonardo, and Raphael raised the artist and his art to a position of esteem perhaps never enjoyed (or deserved) either before or since. Certainly their soaring levels of achievement made it difficult for succeeding artists to follow in their footsteps and impossible to surpass them. Hence, the “anticlassic style,” as it has been called, emerged in their own lifetime—even in some of Raphael’s late works—and provided one of the sources of Mannerism.

By 1513, when Julius II died and Leo X was elected pope, the three great painters of the Florentine-Roman High Renaissance style became involved in projects that diverted them from the paths they had hitherto been following. Leonardo had been since 1506 at the French court in Milan, where he continued to refine his portrait of “Mona Lisa” and where he devoted a great deal of time to his treatises and his projects for the French king. Michelangelo returned to the sculpture of the tomb of Julius II and in 1516 began to work in Florence on a number of architectural and sculptural projects for its Medici rulers. Raphael became more and more involved with purely administrative duties as architect in charge of the new St. Peter’s and as surveyor of antiquities. The great number of commissions he received led him more and more to rely on talented assistants, such as Giulio Romano, and on the workers in the shop for the actual execution of his later works. In the few works in which Raphael’s hand clearly appears, he seems to be moving away from the “School of Athens” toward a new style that had not completely developed at the time of his death in his 37th year.

Raphael’s frescoes (1512–14) in the Stanza d’Elidoro (“Heliodorus Room,” the second of the rooms in Julius

II’s apartments) already reveal Mannerist tensions in “The Expulsion of Heliodorus from the Temple” and an almost Baroque concern with light and shade in the “Liberation of St. Peter.” The succeeding rooms were largely decorated by assistants. It is only in such works as the “Triumph of Galatea” (1511; Villa Farnesina, Rome), the “Sistine Madonna” (1513?; Gallery of Old Masters, Staatliche Kunstsammlungen Dresden, E.Ger.), or Raphael’s final unfinished work, the “Transfiguration” (1517; Vatican Museum), that he can be seen to move toward a nascent Mannerism and then away from it toward a more relaxed, more personal, and deeply moving reconsideration of High Renaissance ideals.

When Michelangelo returned to painting in 1534, he had already had some experience of Mannerism in Florence. The past few years had not been entirely a matter of aesthetic enrichment, however, for they had witnessed the sack of Rome and the siege of Florence. Some of the horror of those events emerges in “The Last Judgment,” painted in fresco on the altar wall of the Sistine Chapel (Plate 11). Commissioned by Pope Clement VII, the work was executed during the pontificate of Paul III. The Christ in Judgment is a thundering god in the way the pagan supreme god of the Romans, Jupiter, was, rather than a Christian saviour, more concerned with damning the human race than in welcoming the blessed into heaven. The figures falling into hell and the torments of the damned attract the eye by their power and the emotions they reveal. It is as though a new Dante had been born to depict hell with a brush rather than a pen. Though the fresco met with strong but mixed reactions when it was unveiled in 1541, Pope Paul was pleased enough to commission two frescoes representing the “Conversion of St. Paul” and the “Crucifixion of St. Peter” for his own private chapel, the Pauline Chapel. Since this chapel has never been open to the general public, and since Michelangelo had already moved into his highly personal late style, these frescoes had little impact on the painting of the time.

The ideals of the High Renaissance as it appeared in the works of Leonardo, Raphael, and Michelangelo continued to develop independently in areas outside Rome and Florence. In Parma the painter Antonio Allegri, better known as Correggio, formed his art under the influence of Mantegna and Leonardo’s Milanese followers. His “Rest on the Flight into Egypt” (Uffizi) and the “Madonna of the Bowl” (c. 1525; National Gallery, Parma) are clearly painted in the High Renaissance idiom. Yet Correggio is perhaps best known for his frescoes at Parma in the cathedral and in the church of San Giovanni Evangelista, which seem to prefigure the style of painting found in the Baroque, and for his late series of sensuous paintings on the loves of Jupiter, all executed between about 1530 and 1534, consisting of “Danae” (Borghese Gallery, Rome), “Leda” (Staatliche Museen Preussischer Kulturbesitz, West Berlin), and “Jupiter and Io” and “The Rape of Ganymede” (Kunsthistorisches Museum, Vienna).

In the late 15th century, painting in Venice traveled much the same paths toward the High Renaissance as in Florence, while still maintaining a purely Venetian flavour. Giovanni Bellini’s Madonnas of 1505–10 (Pinacoteca di Brera, Milan; and the National Gallery, London) are stylistically similar to the Madonnas that Raphael was painting in Florence at about the same time. The San Zaccaria altarpiece (“Enthroned Madonna with Four Saints”) of 1505 carries the *sacra conversazione* fully into the High Renaissance. Inasmuch as Giovanni Bellini dominated Venetian painting, his style influenced the younger painters Giorgione and Titian, yet he was receptive enough to learn in turn from them and inventive enough to maintain his position of dominance.

Giorgione, having learned from Bellini, then went beyond his master to bring to Venetian painting a treatment of landscape that can only be compared to pastoral poetry. In his brief career (all his extant paintings date from the last five years of his life) this highly inventive young artist taught his contemporaries and successors how to exploit the medium of oil paint to create the illusion of textures, light, and air in their paintings. His earliest known painting, the “Madonna and Child with SS. Francis and Lib-

Giorgione’s
treatment
of
landscape

erale" (c. 1504; Castelfranco cathedral, Italy), derives from the style of the mature work of Bellini. In only a few years Giorgione passed from this style of painting, through the turbulence of the dramatic landscape with storm clouds of "The Tempest" (c. 1505; Gallerie dell'Accademia di Venezia; Plate 10), to the dreamy landscape of the "Pastoral Concert" (c. 1510; Louvre). In the latter, Giorgione reveals the Venetians' love of textures, for he carefully renders almost palpable the appearance of flesh, fabric, wood, stone, and foliage. The soft, typically Venetian diffused light, together with the landscape, its hills stretching into the distance and all harsh or sharp contours removed (whether of landscape or figures), creates a gently pastoral mood. The use of landscape to create a mood and the use of figures in the landscape to reflect or intensify that mood is an innovation characteristic of Venetian painting of the 16th century and one of great importance to the development of Baroque art. (J.R.Sp./Ed.)

Whatever the significance of the figures in Giorgione's painting "The Tempest," it is certain that the picture soon came to be regarded merely as a landscape, and it is one of the first European paintings, certainly the first by a great artist, to make this sort of "background" material its subject matter. Landscape painting was to become a specialization of artists only toward the close of the 16th century, and even then chiefly in northern Europe.

(N.B.P.)

The impact of Giorgione on Venetian art was immediate and direct. Bellini's last works, such as "The Feast of the Gods" (National Gallery of Art, Washington, D.C.), owe much to Giorgione, but Giorgione's greatest impact was on Titian (Tiziano Vecelli). Although Titian was never a student of Giorgione, he worked with him on one project and finished a number of his paintings. The so-called "Sacred and Profane Love" of 1512–15 (Borghese Gallery, Rome) is, in a sense, Titian's trial piece in which he shows himself capable of rivaling and surpassing Giorgione in Giorgione's own terms. The influence of Giorgione is especially marked in the profane paintings just as the religious paintings are marked by the influence of Bellini, Titian's teacher and rival until his death, when Titian himself emerged as the leader of Venetian painting.

Titian's great masterpiece, the "Assumption of the Virgin" (1516–18; Santa Maria dei Frari, Venice), established his reputation as Bellini's successor. In the painting he exhibits the Venetians' love of colour and texture, but he succeeds in achieving a balanced and moving composition that can only be compared to Raphael's "School of Athens" in its grandeur. The environment is both earth and heaven, yet it is created and defined by light and atmosphere in a typically Venetian way, rather than by architecture, as would have been more common in Florence. This painting, together with the "Sacred and Profane Love," "Entombment" (Louvre), and the "Pesarò Madonna" (1519–26; Santa Maria dei Frari), typifies Titian's contribution to the High Renaissance.

Upon the completion of the "Assumption" Titian undertook to execute a series of paintings on mythological themes for the court of Ferrara. "The Bacchanal" (1518–19; Prado, Madrid) was soon joined by the "Worship of Venus" (1518–19; Prado) and "Bacchus and Ariadne" (1520–23; National Gallery, London). In "The Bacchanal" Titian reveals his mastery in treating mythological subjects (Plate 10). The bacchantes are disposed about the miraculous stream of wine that flows through an island, dancing, singing, and drinking. The movement of the figures, the juxtaposition of nude and clothed, of male and female, creates a revel in which even the landscape seems to participate—only a Venetian could have created such a pagan, earthy, and hedonistic glorification of life.

On a trip to Rome in 1545 Titian succeeded in rivaling Raphael's "Portrait of Leo X with Cardinals Giulio de' Medici and Luigi de' Rossi" (Uffizi) and Michelangelo's "Leda and the Swan" (copy; National Gallery, London), while demonstrating that Venetian painting in its own unique way was the equal of the Florentine-Roman tradition. The portrait of "Pope Paul III and His Grandsons Ottavio and Cardinal Alessandro Farnese" (1546; Museo e Gallerie Nazionali di Capodimonte, Naples) is a free

variation on Raphael's "Leo X," but Titian altered the composition and introduced a narrative dimension more dramatic and compelling than that in any of his earlier portraits. The "Danae with Nursemaid" (1553–54; Prado), from the same period, poses the colourism and sensuousness of Venetian painting against the sculptural and restrained tradition of Michelangelo for succeeding centuries to judge.

In his late works Titian carried the oil medium to new heights. He used loosely juxtaposed patches of colour, sometimes allowing the prepared canvas to show through. He applied paint freely and loosely with the brush and sometimes reworked it with his fingers. Although his paintings have a fresh quality that makes them appear to have been painted quickly in the heat of inspiration, it is known from his biographers and friends that each work had been carefully studied, criticized, and reworked before the artist was satisfied.

Two works from this late period reveal the scope of Titian's genius. The "Martyrdom of St. Lawrence" (Church of the Jesuits, Venice) was begun about 1548 after his return from Rome and before a trip to Augsburg and the court of the Holy Roman emperor Charles V. Although Titian was nearly 60, he painted with all the enthusiasm of youth. There is a certain amount of Mannerist foreshortening and exaggeration, but Titian used these aspects of Mannerist vocabulary, together with the Venetians' skill in the use of light, to emphasize the dramatic and emotional content of the painting. Drama, light, and colour were used in the late "Rape of Europa" (c. 1559–62; Isabella Stewart Gardner Museum, Boston) in a way that prefigured the work of Rubens and the Baroque.

Titian's genius, given full rein in his long and productive career, deeply influenced Venetian painting. The two most outstanding painters of the end of the 16th century, Veronese and Tintoretto, each took a different aspect of Titian's style and developed it. Paolo Caliari, called Veronese (he was born in Verona), is best known for the rich colour and interweaving compositions he learned from Titian. His frescoes at the Villa Barbaro at Maser northwest of Venice are important for Venetian Mannerism and for landscape painting, but the richness of his palette is best seen in the mythologies, such as "Mars and Venus United by Love" (Metropolitan Museum of Art, New York City), or the "Marriage of St. Catherine" (Gallerie dell'Accademia di Venezia). With Tintoretto he decorated the chambers of the Doges' Palace in Venice, partially supplanting the aging and busy Titian as official painter of the city; his "Apotheosis of Venice" (c. 1585) in the Sala del Maggior Consiglio in the Doges' Palace is a bold and successful use of dramatic foreshortening and rich colour to express the vigour and vibrancy of Venice. Splendid also are his extremely large paintings crowded with figures, such as the "Feast in the House of Levi" (1573; Gallerie dell'Accademia di Venezia).

Jacopo Robusti, called Tintoretto, was most interested in Titian's use of dramatic light and heightened emotion. By 1548 he had established his reputation as a leading artist of the younger generation with his "San Marco Freeing the Slave" (Gallerie dell'Accademia di Venezia). He decorated several chambers of the Doges' Palace with a number of inventive mythological scenes. A great part of his career and energy was devoted to the decoration of the Great School of San Rocco, Venice (1564–c. 1588). Perhaps the crowning achievement of his career can be found in "The Last Supper" of 1594, painted for the church of San Giorgio Maggiore, Venice (Plate 11). In this painting Tintoretto made use of all the rapidly receding diagonals and dramatic foreshortenings of the Mannerist vocabulary, but he brought to the painting the Venetians' love of light effects to define the forms and heighten the drama. The head of Christ is bathed in light that is repeated in the smoky lamps so that its true source cannot be known. Light is used, as in the work of Titian, to pick out certain forms, throw others into darkness, and create a sense of movement within the composition. The comparison of this painting with Leonardo's "Last Supper" of 100 years earlier reveals the differences between the High Renaissance and the late 16th century.

With the death of Titian, Tintoretto, and Veronese, Venice became a school for 17th-century painters, where great works of the past were studied but few great works were produced until the 18th century. The influence of 16th-century Venetian painting on such diverse Baroque artists as Annibale Carracci, Peter Paul Rubens, and Nicolas Poussin was not negligible, but they came to Venice only to learn; they made their major contributions in other centres. (J.R.Sp./Ed.)

ITALIAN MANNERISM AND LATE RENAISSANCE

The first reaction against Leonardo, Michelangelo, Raphael, and Andrea del Sarto occurred in Florence between 1515 and 1524, during which time the painters Giovanni Battista (called Rosso Fiorentino) and Jacopo Carucci Pontormo decisively broke away from the harmony and naturalism of the High Renaissance style. Their movement, particularly what might be called their aesthetic anarchy, attracted the sympathetic attention of some 20th-century art historians, largely because of affinities such art historians saw between their work and modern trends, particularly Expressionism. After the lead given by the German art historian Max Dvořák in his book *Über Greco und der Manierismus* (1921), these 16th-century nonconformists came to be known as Mannerists. Recent historians have suggested, however, that the term Mannerism can more accurately be applied to a very different style initiated in Rome about 1520. Roman Mannerism, which subsequently spread throughout Europe, is characterized by a display of the artificiality of art, a thoroughly self-conscious cultivation of elegance and facility, and a sophisticated delight in the bizarre.

The term Mannerism is ultimately derived from the Italian word *maniera* (literally "style"). It was in the 16th century that *maniera* was first consistently used in art criticism to indicate a definable quality—that of stylishness. Giorgio Vasari, who is known chiefly for his biographies of artists (some of whom were his contemporaries) but who was also an architect and painter, indeed a Mannerist himself, attributed this absolute quality of stylishness to Leonardo, Michelangelo, and Raphael, and, above all, to artists of his own day who had learned their styles from studying these great masters. Standing at the head of the enormous representational discoveries of the Renaissance and with an increased knowledge of antiquity, Vasari was convinced that his contemporaries were in a position to understand the secret of true artistic style. This was the *maniera*.

Taking Vasari's quality of *maniera* as the key to Mannerism, it is possible to outline some of its hallmarks. In figure style, the standard of formal complexity had been set by Michelangelo and that of idealized beauty by Raphael. In the art of their followers, obsession with style in figure composition often outweighed the importance of the subject matter. The highest value was placed upon the apparently effortless solution of considerable artistic problems, such as the portrayal of the nude figure in complex poses. Specifically, the finished work was not supposed to betray signs of the labour that lay behind it.

While depending heavily upon ancient Roman art for many of its decorative motifs and for many of its standards of design, Mannerist style commonly exploited a certain degree of license within the classical vocabulary—what Vasari and contemporary literary theorists called "a departure from the normal usage."

It was in the intellectualizing atmosphere of the Italian courts that Mannerism met with the greatest favour. There the conscious intricacies of Mannerist compositions and the eloquent quotations from antiquity were well appreciated; court literature of this period displayed many analogous features. Mannerism was first and foremost a connoisseur's art—certainly not one that appealed to a churchman. It is not surprising that the later Mannerist painters were censured by the church during the Counter-Reformation for painting altarpieces that were intended to demonstrate the virtuosity of their creators rather than illustrate a religious story. Even Michelangelo was attacked, one critic calling him "the inventor of obscenities, who cultivated art at the expense of devotion."

Factors such as these caused the style to fall into general disrepute, and, when in 1662 the French writer on architectural theory Fréart de Chambray coined the word *Maniériste* (translated six years later as "Mannerist" by the English diarist John Evelyn), he applied it in disparaging fashion to Vasari and his contemporaries, the practitioners of the *maniera*. If, therefore, Mannerism is identified with the *maniera*, it can be historically related to a particular 16th-century style; but if it is applied strictly to early Rosso and Pontormo, as it was by Dvořák, it has no firm grounding in the way people in the 16th century thought about painting.

During the second decade of the 16th century, Andrea del Sarto had emerged as the foremost practitioner of High Renaissance naturalism in Florence. The subtle and ambiguous emotional tension present beneath the harmony of Andrea's forms and colours was greatly accentuated by one of his pupils, Jacopo da Pontormo. In Pontormo's Visdomini altarpiece (1518), the tension approaches the breaking point; the composition is vertical and lacking in a sense of space; and a host of similar but clashing centres of action create an impression of agitation. Pontormo persisted with this expressive style, becoming increasingly influenced by the angular forms of Albrecht Dürer's German engravings and by the more tortured aspects of Michelangelo's figure style. Vasari made it quite clear that Pontormo's development was in direct contradiction to the later ideals of Mannerism.

The second of Andrea's important pupils, Rosso Fiorentino, began in a not dissimilar spirit of expressive rebellion. His highly unconventional "Madonna with SS. John the Baptist, Anthony Abbot, Jerome and Stephen" for Santa Maria Nuova (1518; Uffizi) displays an aesthetic anarchy bolder than anything by Pontormo, and by the 1520s he was creating works of savage emotionality (e.g., the Volterra "Deposition," 1521). In 1523 Rosso journeyed to Rome. There he was overwhelmed by three experiences: Michelangelo's ceiling in the Sistine Chapel, the late style of Raphael, and the art of the newly arrived Parmigianino.

Parmigianino brought with him from Parma three sample pictures to display his virtuosity to Roman patrons. His style, based originally upon that of Correggio, already possessed much of the attenuated elegance for which he became famous (Plate 11). In Rome Parmigianino was hailed as the new Raphael and specifically as a painter capable of reproducing the sophisticated grace of Raphael's late "St. Michael" (Louvre). Raphael had died in 1520, but his most authoritative late work in the Vatican *stanze* (papal apartments) was continued and developed by his foremost pupils, Giulio Romano (who left for Mantua in 1524) and Perino del Vaga. Their Roman styles rely upon a direct though refined use of the art of classical antiquity as a source of inspiration and upon an ingenious exploitation of different levels of pictorial reality within a single decorative scheme. The underlying artificiality of their manner was reinforced by the latent academicism of Michelangelo's Sistine ceiling nudes.

Rosso's encounter with the latest painting Rome offered resulted in a radical realignment of his style. His "Dead Christ with Angels" (c. 1526; Museum of Fine Arts, Boston), a subject that he would earlier have been inclined to treat with exceptional angularity of form, is executed with a new feeling for rarefied beauty. Emotion is now expressed less overtly, and his handling of paint is less aggressive. Rosso, Parmigianino, and Raphael's pupils undoubtedly influenced each other during the mid-1520s, but in 1527 Rome was sacked, and the artists of Pope Clement VII's court became scattered. Parmigianino fled to Bologna, returning after four years to his native Parma, where he continued to develop his personal form of mannered beauty (e.g., "Madonna of the Long Neck," Uffizi). Perino found employment with the ruling family at Genoa, and Rosso visited a number of Italian cities before settling in France.

The sophisticated Mannerism that evolved in Rome before 1527 became the chief formative influence upon the styles of a number of important younger artists. Vasari and Francesco Salviati had passed their period of ap-

Artistic dispersion resulting from the sack of Rome

prenticeship in Andrea del Sarto's Florence. They parted in 1527 but resumed their close acquaintance in Rome (1531), and it was the Roman style that influenced their subsequent development. Vasari, Salviati, and Jacopino del Conte, who worked with Salviati on the frescoes for San Giovanni Decollato, Rome, attempted to combine the formal and narrative artifice of the late Raphael decorations with the complex figure style of Michelangelo. The result in Vasari's case is undeniably eclectic, but Salviati created an individual *maniera* of enormous facility and inventiveness (e.g., "Peace," Palazzo Vecchio, Florence). The Raphaelesque element in the Roman style was reinforced by Perino's return to Rome in about 1538.

Salviati's career was unsettled—he worked in Florence, Rome, Venice, and France—but Vasari returned to Florence to the court of the Medici duke Cosimo I, who had replaced in 1537 the unpopular (and assassinated) Alessandro de' Medici. Cosimo and his Spanish wife, Eleonora de Toledo, whose formal Iberian tastes influenced the artistic life of the court, shrewdly embarked on an ambitious series of propagandistic projects to consolidate his political position. Vasari became the "stage manager" for much Medicean propaganda. His success as a painter and architect after 1555 was considerable, but his most important contribution to Mannerism was undoubtedly his advocacy of Mannerist ideals in his *Lives*, first published in 1550 and revised and extended in 1568. As Vasari realized, the most important painter in Cosimo's court was Il Bronzino, a pupil of Pontormo.

Bronzino had, from the first, reduced the emotional content that had been an important feature of Pontormo's style, and, during the 1530s in Florence, he began to establish a reputation as a court portrait painter. His mature portraits are elegant, perfectly finished, ingenious in detail, and aloofly formal, reflecting the Spanish etiquette of Cosimo's court. Bronzino was adopted as favourite artist by Eleonora, receiving the commission to decorate her small private chapel in the Palazzo Vecchio. The resulting frescoes are in no sense spiritually expressive, but they are brilliantly stylish, with references to antiquity, which displayed the erudition of both artist and sitter, and to Raphael and Michelangelo. Bronzino was later influenced by the teachings of the Counter-Reformation, adopting a more modest narrative style, but his underlying aesthetic art remained a sense of *maniera*.

A number of later Mannerists responded similarly to the Counter-Reformation—Santi di Tito is particularly important in this respect—but it was only with Federico Barocci that the ideals of Mannerism were abandoned in favour of an all-pervasive piety in religious painting. Barocci's attractively fluent and softly coloured style, based largely upon Correggio, may be considered as an exceptional precursor of the Baroque style. Barocci abandoned his Roman Mannerism as early as 1575, but the majority of his contemporaries in Rome and Florence continued to develop the eclectic aspects of the original *maniera*. Daniele da Volterra and Pellegrino Tibaldi painted in an explicitly Michelangesque manner, while Cavaliere d'Arpino (Giuseppe Cesari) and Federico Zuccari, at the end of the century, investigated the complex intellectual conceits of the Raphael studio style. Zuccari—a painter, designer, and theorist—is the most representative figure of this late phase, and his travels (to Rome, Venice, Spain, England, France, and Antwerp) underline the internationalism of late Mannerist style.

Outside Florence and Rome, many of the major Italian cities succumbed to the spreading influence of Mannerism after 1527. Siena, under the lead of Domenico Beccafumi, developed a bizarre form of emotional Mannerism, but only Venice maintained a steady, independent Mannerism. Venice was certainly receptive to Mannerist influence—as seen in the works of Titian after 1530, Tintoretto, and Veronese—but, with the exception of Andrea Meldolla (Schiavone), Venetian painting continued to be dominated by non-Mannerist ideas in colouring and expression. Vasari's disparaging remarks about Tintoretto's lack of good design show clearly that the differences between Romano-Florentine and Venetian painting remained fundamental.

The early and High Renaissance style as developed in Italy did not immediately dominate all European painting. A few northern artists adopted Renaissance motifs but used them in a piecemeal manner without full comprehension of Italian compositional methods. After 1520, however, northern and Spanish artists came increasingly to understand and adopt Mannerist ideas, and highly individual schools of Mannerism began to appear in various centres outside Italy. Regional styles of considerable decorative flamboyance resulted from the fusion of the intricacies of the late Gothic style with the complexities of Mannerism.

RENAISSANCE OUTSIDE ITALY

France. Francis I, despite his military reverses in Italy, was enamoured of all things Italian. He commissioned the celebrated goldsmith Benvenuto Cellini to execute both tableware and sculpture and prevailed upon friendly rulers in Italy to send him works by Titian and Bronzino and casts of sculpture. He also imported Italian artists to design, build, and decorate his palaces, the Château de Madrid and Fontainebleau, both outside Paris. Rosso arrived in France in 1530, followed two years later by his fellow Italian, the Mannerist Francesco Primaticcio. In the gallery of Francis I at Fontainebleau, Rosso initiated a new and intricate decorative system in which stucco and painting form a richly luxuriant complex—the plastic realization of the late Raphaelesque decorative manner. Primaticcio, who had been trained by Giulio Romano at Mantua and influenced by Parmigianino, took over Rosso's leading position on the latter's death in 1540. His Ulysses Gallery at Fontainebleau continued and refined Rosso's elaborate system of painted narratives surrounded by convoluted strapwork, elegant figures, and swags in stucco. French artists at the court, such as the two Jean Cousins and Antoine Caron, quickly adopted aspects of Italian Mannerism to create a style of painting characterized as the school of Fontainebleau. Less of a tendency to mimic the fashion was noticeable in Corneille de Lyon and Jean and François Clouet, whose portraits, while exhibiting some Mannerist qualities, recalled 15th-century court portraiture. (M.J.Ke./Ed.)

Spain. During the first decade of the 16th century, Fernando Yáñez, who may have assisted Leonardo da Vinci on the "Battle of Anghiari" in 1505, executed works showing a good knowledge of Italian Renaissance developments. Further Italianate tendencies emerged strongly in the Valencian works of Juan de Macip and his son Juan de Juanes. Full-fledged Mannerism made its appearance in the Seville cathedral in the "Descent from the Cross" (1547) by Pedro Campaña (Pieter de Kempeneer), an artist from Brussels, and subsequently in the refined court portraiture of Anthonis Mor (Sir Anthony More) and Alonso Sánchez Coello, whose royal portraits possess an elegance reminiscent of Bronzino's Florentine style. Although Campaña's paintings are Mannerist in composition, they also foreshadow the expressiveness characteristic of Spanish style in the hands of Luis de Morales and El Greco.

From 1546 until his death in 1586, Morales remained almost exclusively in the provincial isolation of Badajoz, developing a highly individual art of great spiritual intensity, radically separated from the Mannerist mainstream. El Greco, though born in Crete, was more fully conversant with Italian painting, having studied with Titian in Venice and later residing in Rome for two years. His Spanish paintings exploit the anatomical attenuations of Roman Mannerism, but the vividly emotional qualities of his colour and paint handling depend almost entirely upon Venetian precedents—Tintoretto and Jacopo Bassano in particular. Under the influence of Counter-Reformation mysticism in Toledo after 1575, he developed an increasingly personal and nonrealistic manner, indulging in space and supernatural light effects (Plate 11). The narrative fervour of his style stands in sharp contrast to the stylish formalism of international Mannerism.

Germany. Albrecht Dürer was the first important German artist who displayed a profound understanding of Italian Renaissance art and theory. Trained in Nürnberg in the late Gothic tradition, he had ambitions even as a

youth far beyond the narrow confines of his native city and the late medieval style. He traveled to Switzerland and the Rhine Valley and may have been in the Low Countries. Shortly after his marriage in 1494 he made a brief trip to Italy, where he studied the works of Mantegna and the Venetians. In 1505–07 he was again in Italy and was on intimate terms with Giovanni Bellini. Dürer was interested in what he felt to be the “secrets” of Italian art and in the new humanism carried north by such friends as the German humanist Willibald Pirckheimer. As a result, his paintings maintain the northerners’ love of detail, rendered meticulously in oil, but he joined to it the Italian interest in broadly conceived compositions. In “The Paumgärtner Altarpiece” of 1502–04 (Alte Pinakothek, Munich), for example, the saints in the wings are depicted with the scrolls and a complexity of composition more reminiscent of a heraldic achievement, while the broad planes of the architecture and the large, simple figures of the adoration shown on the central panel suggest an Italianate conception. The “Four Apostles” (Alte Pinakothek) of 1526 (Plate 12) ultimately derives from the wings of Bellini’s Frari altarpiece. Dürer’s close association with the Venetian painter and admiration for his art can be seen in the broad simple folds of the drapery, the breadth of handling of the heads, and the quality of the light depicted.

Although he executed a large number of important paintings, Dürer is perhaps best known for his woodcuts and engravings, by which he raised printmaking from a minor to a major art (see PRINTMAKING). Dürer’s prints, paintings, and writings had such a profound influence on 16th-century art in Germany that it is sometimes difficult to realize that he died in 1528.

In the 16th century the Renaissance as far as German painting was concerned tended to follow the lines established by Dürer. Two artists of note do emerge, but their styles are so individual that they do not represent a national school.

Lucas Cranach the Elder was deeply influenced by Dürer and the Danube school, an early 16th-century tradition of landscape painting that was in some ways a transition between the styles of Gothic and Renaissance painting. By 1505 he had moved to Wittenberg and become court painter to the electors of Saxony. There his style changed radically, epitomizing the dichotomy that existed in 16th-century northern European painting. He developed in Wittenberg the full-length portrait in which the sitter is rendered with consummate skill and fidelity. Cranach was a personal friend of Martin Luther and is probably best known for his portraits of the great reformer. At the same time his “Reclining River Nymph at the Fountain” of 1518 (Museum of Fine Art, Leipzig) illustrates his knowledge of Giorgione and Venetian painting and points the way to the group of highly erotic female nudes of his later works (Plate 12).

Hans Holbein the Younger was trained by his father in Augsburg but took up residence in Basel, Switz., around 1515. He early developed a portrait style that was greatly sought after by the burghers of Basel. His portraits of Burgomaster Meyer and his wife (1516; Kunstmuseum-Öffentliche Kunstsammlung Basel) or of Bonifacius Amerbach (1519; Kunstmuseum-Öffentliche Kunstsammlung Basel) show his gift for characterization. In 1526 he made his first trip to London, where he painted “Sir Thomas More with His Household” (1527). In 1532 religious troubles in Basel were so intense that he accepted a position at the English court and left the city forever. He is perhaps best known for his portraits of Henry VIII, Henry’s bride Anne of Cleves (1539; Louvre), and Christina of Denmark (1538; National Gallery, London), at one time considered by the King as a possible bride. “Jean de Dinteville and Georges de Selve” (“The Ambassadors,” 1533; National Gallery, London), which depicts two French ambassadors to the English court, is probably the greatest tour de force of his years in England. The two sitters are rendered faithfully in a well-defined room and are surrounded by the trappings of 16th-century humanism—e.g., books, globes, musical instruments. Holbein’s portraits were all painted with a great understanding of the sitter and often have a note of Italian elegance. His surfaces tend to be tight and

Holbein's

London

hard, yet there is a certain expansiveness created by the positioning within the frame (Plate 12). He established a portrait tradition in England and also contributed to the popularity of the miniature in that country.

Low Countries. In the Low Countries there emerged early in the 16th century a group of painters misleadingly lumped together as the Antwerp Mannerists. Their exaggerated and fanciful compositions descend in great part from the decorative excesses of late Gothic art, generally with some Italianate details probably transmitted by architects’ and goldsmiths’ pattern books.

Jan Gossaert, called Mabuse, visited Rome in 1508. At first he continued his ornate late Gothic style, but by 1514 he began to adopt the great innovations occurring in Italian painting. His mythological paintings, such as the “Neptune and Amphitrite” (Staatliche Museen Preussischer Kulturbesitz, West Berlin) of 1516, indicate that he was able to understand only the superficialities and not the motivation and *terribilità* of Michelangelo’s nudes. Bernard van Orley remained in Brussels and learned of Italy through Raphael’s cartoons, which were sent to Brussels to be woven into tapestries. Before the end of the century, painters such as Jan van Scorel, Maerten van Heemskerck, and Sir Anthony More (a Utrecht-born portraitist knighted by Queen Mary I of England) were absorbing Italian influences, in van Scorel’s case a specifically Venetian influence, yet creating an art that was their own. Joachim Patinir’s depiction of the world around him, particularly of landscape, parallels Italian developments in northern terms and greatly influenced Pieter Bruegel the Elder.

Pieter Bruegel the Elder visited Italy in 1551–53 but was more influenced by the Italian and particularly Alpine landscape than by Italian painting. His two-dimensional sources are to be found rather in the popular prints of the time, the landscapes of Patinir, and the fantasies of Bosch. He was also a great observer of peasant life. Bruegel spent his adult life in the company of learned humanists, yet he showed no real interest in classical mythological subjects or antiquity. His paintings illustrating Low Countries’ proverbs, children’s games, or “The Fight Between Carnival and Lent” (1559; Kunsthistorisches Museum, Vienna) reveal an interest in popular themes and common life, rather than in the pedantic Romanizing compositions of some of his contemporaries. This choice of subject matter, latent from the early 15th century in the Low Countries, was given new dimensions by Bruegel. His series of depictions of the months is at once a revival of the labours of the months found in the portal sculptures of Gothic cathedrals and medieval books of hours and at the same time a new treatment of rural landscape and the peasants who work the land. His “Harvesters” (1565; Metropolitan Museum of Art, New York City) displays a remarkable sensitivity to colour and pattern. The intense golden yellow of the ripe wheat sets up a bold pattern across the lower half of the picture and contrasts with the cool greens and blues of the limitless plain stretching off into the distance. Some figures move across a lane cut through the wheat, while others cut into what seems a solid space. The sleeping peasants resting after their noon meal are disposed in patterns and poses that make one feel the heat and calm of the summer’s day. This sympathetic view of peasant life, with its bold geometric patterns, runs throughout the series of the months and recurs in “The Wedding Dance” (1566; Detroit Institute of Arts) and “Peasant Dance” (Plate 12) and “Peasant Wedding” (both in the Kunsthistorisches Museum, Vienna).

Bruegel brought to an end the 16th century in the north and prepared the way for the Baroque. His sons and grandsons were important painters who helped to train some of the leading artists of the 17th century in the Low Countries. It was the elder Bruegel, however, who made landscape and peasant life an accepted subject for painting in the Renaissance. (J.R.Sp.)

The Mannerist style was not comprehended as soon in the 16th century in the Low Countries as it had been in France or Spain. With the notable exception of Frans Floris, it was not until the generation of artists born during the middle years of the century that Mannerism was

and old
artistic and
cultural
traditions

Dutch
centres of
Mannerism

fully assimilated. This generation of Flemish and Dutch Mannerists was influenced chiefly by the Italian Mannerists of the second half of the century: Frederik Sustris studied with Vasari; Hendrik Goltzius was an associate of Taddeo Zuccari, Federico's older brother; Johann von Aachen remained in Rome between 1574 and 1588; and Bartholomaeus Spranger collaborated with Federico Zuccari. Haarlem and Amsterdam became the early centres for northern Mannerism. Spranger's style was diffused throughout Europe by the engravings of his colleague Goltzius. Finally, as a late flowering of international Mannerism, Carel van Mander founded a Vasarian academy in Haarlem, in 1604 publishing his biographies of Netherlandish artists in direct emulation of Vasari.

(M.J.Ke./Ed.)

Bohemia. By far the most ambitious patron of Mannerist art in Europe north of Italy was the Holy Roman emperor Rudolf II, who in the late 1570s established his court at Prague. Between the end of the 16th century and the beginning of the 17th, Rudolf employed architects, sculptors, and painters to create impressive artistic works for his court, much as Cosimo de' Medici had done in Florence. Spranger's "Allegory of Rudolf II" indicates the quality of Rudolf's court art and its clear Mannerist sympathies—sensually graceful figures clad in the dress of classical antiquity and a cultivated facility in composition and execution.

(J.R.Sp./Ed.)

Baroque

Baroque is a term loosely applied to European art from the end of the 16th century to the early 18th century, with the latter part of this period falling under the alternative stylistic designation of Late Baroque. The painting of the Baroque period is so varied that no single set of stylistic criteria can be applied to it. This is partly because the painting of Roman Catholic countries such as Italy or Spain differed both in its intent and in its sources of patronage from that of Protestant countries such as Holland or Britain, and it is partly because currents of classicism and naturalism coexisted with and sometimes even predominated over what is more narrowly defined as the High Baroque style.

The Baroque style in Italy and Spain had its origins in the last decades of the 16th century when the refined, courtly, and idiosyncratic style of Mannerist painting had ceased to be an effective means of artistic expression. Indeed, Mannerism's inadequacy as a vehicle for religious art was being increasingly felt in artistic circles as early as the middle of that century. To counter the inroads made by the Reformation, the Roman Catholic Church after the Council of Trent (1545–63) adopted an overtly propagandistic stance in which painting and the other arts were intended to serve as a means of extending and stimulating the public's faith in the church and its doctrines. The church thus adopted a conscious artistic program, the products of which would make an overtly emotional and sensory appeal to the faithful. The Baroque style of painting that evolved from this program was paradoxically both sensuous and spiritual; while naturalistic treatment rendered the painted religious image more readily comprehensible to the average churchgoer, dramatic and illusory effects were used to stimulate piety and devotion. This appeal to the senses manifested itself in a style that above all emphasized movement and emotion. The stable, pyramidal compositions and the clear, well-defined pictorial space that were characteristic of Renaissance paintings gave way in the Baroque to complex compositions surging along diagonal lines. The Baroque vision of the world is basically dynamic and dramatic; throngs of figures possessing a superabundant vitality energize the painted scene by means of their expressive gestures and movements. These figures are depicted with the utmost vividness and richness through the use of rich colours, dramatic effects of light and shade, and lavish use of highlights. The ceilings of Baroque churches thus dissolved in painted scenes that presented convincing views of the saints and angels to the observer and directed him through his senses to heavenly concerns.

(Ed.)

EARLY AND HIGH BAROQUE IN ITALY

By the last decades of the 16th century the Mannerist style had ceased to be an effective means of expression. Indeed, in Florence a conscious reassessment of High Renaissance painting had taken place as early as mid-century. This tendency gathered momentum in the last decades of the century, particularly with the Bolognese painters Lodovico Carracci and his cousin Annibale. The Roman Catholic Church's reaction to the Reformation, known as the Counter-Reformation, reaffirmed the old medieval concept of art as the servant of the church, adding specific demands for simplicity, intelligibility, realism, and an emotional stimulus to piety. For the zealots of the Counter-Reformation, works of art had value only as propaganda material, the subject matter being all important; and in Rome there was as a result a sharp decline in artistic quality. Under austere Counter-Reformation popes such as Paul IV and Pius V, most official patronage favoured the dry and prosaic; this late 16th-century style is best called Counter-Reformation Realist. A similar process took place in Florence, where a strong movement away from Mannerist conventions is seen in the paintings of Ludovico Cigoli, and in Milan, where the dominant artistic personalities were the painters Giovanni Crespi (known as Il Cerano) and Pier Francesco Mazzucchelli, known as Il Morazzone.

In contrast, late 16th-century Venetian painting was as little influenced by the Counter-Reformation as it had been by Mannerism; and the workshops of Tintoretto, Paolo Veronese, and Palma Giovane remained active until the plague of 1629–30.

Michelangelo Merisi, better known by the name of his birthplace, Caravaggio, a small town near Milan, was active in Rome by about 1595. His earliest paintings are conspicuous for the almost enamel-like brilliance of the colours, the strong chiaroscuro called Tenebrism, and the extraordinary virtuosity with which all the details are rendered. But this harsh realism was replaced by a much more powerful mature style in his paintings for San Luigi dei Francesi, Rome, begun in 1597, and Santa Maria del Popolo, Rome, executed about 1601 (Plate 13). His selection of plebeian models for the most important characters in his religious pictures caused great controversy, but the utter sincerity of the figures and the intensity of dramatic feeling are characteristic of the Baroque. Although Caravaggio had no direct pupils, "Caravaggism" was the dominant new force in Rome during the first decade of the 17th century and subsequently had enormous influence outside Italy.

Parallel with Caravaggio's was the activity of Annibale Carracci in Rome. During Annibale's years in Bologna, his brother and cousin had joined with him in pioneering a synthesis of the traditionally opposed Renaissance concepts of *disegno* ("drawing") and *colore* ("colour"). In 1595 Annibale took to Rome his mature style, in which the plasticity of the central Italian tradition is wedded to the Venetian colour tradition. The decoration of the vault of the gallery in the Palazzo Farnese, Rome (1597–1604), marks not only the high point in Annibale's career but also the beginning of the long series of Baroque ceiling decorations. The third important painter active in Rome during the first decade of the 17th century was the Low Countries' painter Peter Paul Rubens, who became court painter to the duke of Mantua in 1600. He came under the influence of Raphael and Titian, as well as that of Caravaggio, during a journey to Spain in 1603. The rich colours and strong dramatic chiaroscuro of his altarpieces for Santa Maria in Vallicella (New Church), Rome (1606–07), show how much he contributed to the evolution of Italian Baroque painting.

Just as the first decade tended to be dominated by the "Caravaggist" painters, the second decade in Rome was the heyday of the Bolognese classicist painters headed by Guido Reni (Plate 13), Domenichino, and Francesco Albani, all of whom had been pupils of the Carracci. The crucial developments that brought the High Baroque into being took place in the third decade.

The little church of Santa Bibiana in Rome harbours three of the key works that ushered in the High Baroque,

Effects

and colour

all executed in 1624–26: Gian Lorenzo Bernini's facade and the marble figure of Santa Bibiana herself, over the altar, and Pietro da Cortona's series of frescoes of Bibiana's life, painted on the side wall of the nave. The rich exuberance of the compositions is a prelude to the gigantic "Allegory of Divine Providence and Barberini Power," which Pietro was to paint on the vault of the Great Hall of the Palazzo Barberini, Rome (1633–39). Pietro continued with this style of monumental painting for the remainder of his career, and it became the model for the international grand decorative style, which by the close of the 17th century was to be found in Madrid, Paris, Vienna, and even London.

Controversy between the Baroque and classicism

Despite the continued triumph of High Baroque illusionism and theatricality in the hands of Bernini and Pietro da Cortona from the 1630s, the forces of classicism, now headed by the painter Andrea Sacchi and the Flemish-born sculptor François Duquesnoy, gained the upper hand in the 1640s after the death of Pope Urban VIII; and for the remainder of the century the Baroque-versus-classicism controversy raged in the Academy in Rome. Sacchi and the classicists, including the Frenchman Nicolas Poussin, held that a scene must be depicted with a bare minimum of figures, each with its own clearly defined role, and compared the composition to that of a tragedy in literature. But Pietro and the Baroque camp held that the right parallel was the epic poem in which subsidiary episodes were added to give richness and variety to the whole, and hence the decorative richness and profusion of their great fresco cycles. The lyrical landscapes of the French painter Claude Lorrain are among the finest expressions of High Baroque classicism; and they exerted a continual influence throughout the 18th century, particularly in Britain. Even in Rome itself, however, a number of painters of importance succeeded in remaining more or less independent of the two main camps. Sassoferrato (1609–85), for example, painted in a deliberately archaizing manner, carefully reproducing Raphaelesque formulas. The cryptically romantic movement, centred on Pier Francesco Mola, Pietro Testa, and Salvator Rosa, was more important and, together with the landscapes of Gaspard Dughet, was to have considerable repercussions in the 18th century. Claude Lorrain also adopted an independent stand, despite the highly developed classicism of his poetic landscapes and seascapes (Plate 17), both of which, but especially the latter, featured much splendid architecture.

The first two-thirds of the 17th century in Italy were dominated by the Roman Baroque, and few painters elsewhere provided serious competition. Reni, who returned to Bologna from Rome in 1614 and remained there until his death in 1642, remained the strongest artistic personality in that northern city but steadily abandoned the strong plasticity of the Carracci for a much looser style with a pale tonality (Plate 13). When Guercino, in turn, left Rome in 1623, he returned to his native Cento, just north of Bologna, and not until the death of Reni did he decide to settle in Bologna. Guercino's early, fiery style slowly gave way to a much more calm and classical outlook. Venetian painting took a new direction with the rich colours and free brushwork of Domenico Fetti, who had worked in Mantua before moving to Venice. In the hands of Johann Liss (or Jan Lys) the groundwork was laid for the flowering of the Venetian school of the 18th century. Venetian painting was also enriched by the pale colours and flickering brushwork of Francesco Maffei from Vicenza, whereas Bernardo Strozzi in 1630 carried to Venice the saturated colours and vigorous painterly qualities of the Genoese school. Giovanni Benedetto Castiglione also began his career in Genoa and, after a period in Rome, worked from 1648 as court painter in Mantua, where his brilliant free etchings and brush drawings anticipated the Rococo. Naples, under its Spanish viceroys, remained strongly influenced by the "Caravaggesque" tradition, particularly in its best-known painter, a Spaniard, José de Ribera, who settled there in 1616; the two most important native painters of the period, Massimo Stanzione and Bernardo Cavallino, both died in the disastrous plague of 1654.

The most conspicuous aspect of the last phase of the

High Baroque in Italy is provided by the series of great fresco cycles, which were executed in Rome during the last decades of the 17th century. Pietro da Cortona's decoration of Santa Maria in Vallicella (1647–55) is the link with the earlier phase of the Baroque, and his decoration of the gallery of the Palazzo Pamphili in Rome (1651–54) points the way to the decorations of Giovanni Coli and Filippo Gherardi in the Palazzo Colonna (1675–78) and to those of the vault of the gallery of the Palazzo Medici-Riccardi in Florence by Luca Giordano (1682). Bernini's dynamic and theatrical schemes of decoration reached their climax in the nave vault of the Gesù, Rome, painted in 1674–79 by Giovanni Battista Gaulli (Baciccio) under the direct tutelage of Bernini. The fresco bursts out of its frame and creates an overwhelming dramatic effect, with painted figures flooding over the gilt stucco architectural decoration of the ceiling into the space of the church (Plate 13). After this, the "Allegory of the Missionary Work of the Jesuits," painted by Andrea Pozzo on the nave vault of San Ignazio, Rome (1691–94), seems almost an anticlimax, despite its gigantic size and hypertrophic illusionism. Concurrently, the Baroque-versus-classicism controversy took on a new lease on life, with Gaulli heading the Baroque party in opposition to Sacchi's pupil Carlo Maratta. By the last decades of the century the Baroque was triumphant, and Maratta's Baroque classicism appears almost to be a compromise between Pietro da Cortona and Sacchi. Maratta's style, however, was to provide one of the most important sources for the grand manner of the 18th century.

The essential characteristics of Late Baroque painting can be identified first in the frescoes (1661) of Mattia Preti at the Palazzo Pamphili, Valmontone (southeast of Rome); but the transition between the High Baroque and the Late Baroque was a continuous process and occurred at different dates with different artists. At Valmontone the sense of dynamic structure characteristic of the High Baroque frescoes of Pietro da Cortona yields to a more decorative scheme in which the figures are scattered across the ceiling, giving the painting an overall unity without identifying any specific area as the focal point. Francesco Cozza used this scheme in the Pamphili Library, Rome (1667–73), but among the finest Late Baroque decorations of this type are ceilings painted in Genoa by Gregorio de' Ferrari and Domenico Piola, while Giordano took the style to Spain. The breakdown of any sense of direction in the composition is paralleled by a loosening in the design of individual figures; once again the unity is decorative rather than structural.

LATE BAROQUE AND ROCOCO

Symptomatic of the changing status of the papacy during the 17th century was the fact that the Thirty Years' War was ended by the Peace of Westphalia in 1648 without papal representation in the negotiations. Concurrently, the influence of Spain also declined. The commencement of the personal rule of Louis XIV in 1661 marked the beginning of a new era in French political power and artistic influence, and the French Academy in Rome (founded 1666) rapidly became a major factor in the evolution of Roman art. Late Baroque classicism, as represented in Rome by Maratta, was slowly transformed into a sweet and elegant 18th-century style by his pupil Benedetto Luti, while Francesco Trevisani abandoned the dramatic lighting of his early paintings in favour of a glossy Rococo classicism. In the early 18th century, Neapolitan painting under Francesco Solimena developed from the brilliant synthesis of Pietro da Cortona's grand manner and Venetian colour that Giordano had evolved in the late 17th century. The impact, also, of Preti is revealed by his predilection for brownish shadows; but, compared to the pupils and followers of Maratta in Rome, Solimena's style has a greater strength and vitality despite the characteristic Late Baroque fragmentation of the composition. He himself supplied large paintings to patrons all over Europe, and his pupils occupied key positions in the mid-18th century. Francesco de Mura took the style to Turin, where he was court painter; Corrado Giaquinto, as court painter in Madrid, turned increasingly toward the Rococo, and Sebastiano Conca worked in Rome, falling increas-

Transition between High and Late Baroque

Co-existence of Late Baroque classicism and the Rococo

New currents of painting in Venice

ingly victim to the academic classicism dominant there. Anton Domenico Gabbiani practiced a particularly frigid classicism in Florence, and it was mainly in Bologna and Venice that real attempts were made to break away from the confines of Late Baroque classicism.

Revitalization of the Venetian school

Giuseppe Maria Crespi (called *Lo Spagnolo*, "The Spaniard") turned instead toward the early paintings of Guercino and evolved a deeply sincere style, remarkable for its immediacy and sensibility. In Bologna he had no real successors, but in Venice his work provided one of the bases for the brilliant flowering of Venetian painting in this period. While Giovanni Battista Piazzetta looked toward Crespi for the basis of his expressive Tenebrist style, Sebastiano Ricci took his cue from Giordano. The brilliant lightness and vivacity of his frescoes in the Palazzo Marucelli-Fenzi, Florence, mark the beginning of a great tradition of Venetian decorative painting, a tradition that was to be carried all over Europe by Giovanni Antonio Pellegrini, Giambattista Pittoni, and, above all, Giovanni Battista Tiepolo. The vast majority of the finest decorations (e.g., frescoes) carried out by the Venetian 18th-century painters were executed outside the Veneto (the region of which Venice is the principal city), but the opposite is true of the flourishing Venetian school of landscape, *vedute* ("views"), and genre painters. Giovanni Antonio Canal, called Canaletto, developed the views of Venice painted by Luca Carlevaris into an industry almost entirely dependent upon foreign tourists; and his nephew Bernardo Bellotto spent most of his career painting views in central Europe. Francesco Guardi avoided the cool precision of the *vedute* of Canaletto and Bellotto and instead evolved a much lighter and more lyrical Rococo style with a strong sense of the picturesque (Plate 13) and, occasionally, the bizarre. In Rome a similar contrast existed between the brilliant, precise *vedute* of Giovanni Paolo Pannini and the strange, almost Romantic *vedute* in the form of etchings by Giovanni Battista Piranesi.

Tenacity of Gothic ideas in the Iberian Peninsula

Spain and Portugal. Two fundamental and ostensibly opposed streams permeate Spanish painting and separate it from that of the rest of Europe—ecstatic mysticism and sober rationalism. These qualities are essentially Gothic in spirit, and the Iberian Peninsula is remarkable for the tenacity with which Gothic ideas were retained and for the relatively small influence of Renaissance humanist ideas. The early 17th-century still lifes of Sánchez Cotán, with their strong realism and harsh, mysterious lighting, illustrate these contrasts admirably, whereas Luis Tristán abandoned the Mannerist style of his master El Greco for a much more careful realism. Francisco Pacheco, the teacher and father-in-law of Velázquez, was a more important writer than painter, and his writings laid down a theoretical basis for the Spanish approach to spirituality through naturalism. The early works of José de Ribera show a synthesis of Spanish realism and ideas drawn from both Annibale Carracci and Caravaggio; the fierce darkness of these paintings formed the basis of the Tenebrist style that dominated Neapolitan painting during the first half of the 17th century. Ribera himself, however, developed away from this style in his later paintings and moved toward a softer and more even handling of light (Plate 18). Francisco de Zurbarán was active mainly in Seville until his removal to Madrid in 1658, and unlike Ribera he painted throughout his life in the stark Spanish realist style. The massive solemnity of his figures and simple, clear-cut compositions are wholly in sympathy with the demands of the Counter-Reformation, and only in Madrid did he come under substantial Italian influence (Plate 18).

Diego Velázquez was almost the exact contemporary of Zurbarán, but, unlike Zurbarán, who spent almost all his life in the company of monks in the provinces, Velázquez' time from 1623 was spent in the Spanish court in Madrid. His early *bodegones* (scenes of daily life with strong elements of still life in the composition) were painted in Seville and belong to the Spanish realist tradition, but at court he saw the Titians collected by Philip II and also Rubens' paintings. After he visited Italy in 1629–31, there was greater freedom in the way he handled paint, more interest in colour, and increased depth to his analyses of character (Plate 18).

The early works of the Seville painter Bartolomé Esteban Murillo again follow the Spanish realist tradition in their cool detachment, but in his late works his style softened and sweetened into a sentimentality that proved immensely popular (Plate 18). Alonso Cano formed his early painting style in Seville on the simple monumentality of Zurbarán, but after he moved to Madrid in 1638 his paintings took on a new elegance and gracefulness. (Cano was also active as a sculptor and architect in Granada [1652–57]). Antonio del Castillo and Juan de Valdés Leal were the most important painters active in Andalusia after Murillo, and the works of both reveal that liveliness of handling, with accents of strong local colour, which replaced the sober realism popular in the first half of the century.

Portugal was ruled by Spain until 1640, when John IV was proclaimed king. But economic conditions hampered serious patronage of the arts until the reign of John V, when the most distinguished painter was Francisco Vieira de Matos. Unfortunately, the Lisbon earthquake of 1755 destroyed much of the best art collected in the Portuguese capital at that time.

Low Countries. *The Spanish Netherlands.* The year 1566 saw the Netherlands in open revolt against Philip II of Spain, and, inasmuch as this revolt had a Protestant as well as a nationalist aspect, a wave of iconoclasm swept across the area. By 1600 the area had become divided into the Spanish-dominated, Catholic, southern provinces—broadly modern Belgium—and the independent, predominantly Calvinist United Provinces of the north—broadly the modern Netherlands, or colloquially Holland; the boundary between the two remained fluid, however. In the southern provinces throughout the 16th to 18th centuries Brussels, headed by viceroys, remained the centre of court patronage, while Antwerp, with its great patrician families, was the commercial centre.

Painting in the southern provinces before 1610 was intensely conservative; the Mannerist conventions were never accepted as fully as in the north. Instead, Italianate ideas were joined with the late Gothic tradition.

Peter Paul Rubens arrived back in Antwerp from Italy late in 1608. In the following year he was appointed court painter to the archduke Albert and the archduchess Isabella, with special permission to reside in Antwerp, to help repair damage caused by the iconoclasm of 1566. The necessary ingredients were present for a brilliant flowering of the Baroque art that Rubens had evolved in Italy, and his studio became an artistic centre not only for the Netherlands but for England, Spain, and central Europe as well. The monumentality of Rubens' forms, with their impulsive drawing, restless movement, and dramatic lighting, provided the touchstone for the High Baroque in the Catholic areas of northern Europe (Plate 14). By Rubens' death, Philip IV of Spain had acquired more than 130 paintings by him. A diplomatic visit to England (where he found so much favour with Charles I that the latter knighted him) in 1630 had resulted in the commission to decorate the ceiling of the Banqueting Hall in Whitehall, one of the most monumental commissions of Rubens' last period.

Anthony Van Dyck, a pupil and assistant of Rubens, was a much less forceful personality than his master; and this is reflected in the quieter, more introspective note characteristic of his paintings. His greater sympathy for the sitter made him the most successful portrait painter of his time. Between 1625/26 and 1632 he was active, mainly as a portrait painter, in the entourage of Rubens, but the last years of his life (1632–41) were spent in England as court painter to Charles I, from whom he, too, received a knighthood (Plate 15). The elegant, relaxed, aristocratic portrait style he introduced was outstandingly successful and rendered obsolete the stiff portraits of Daniel Mytens and the straightforward, unpretentious portraits of Cornelius Johnson, two other painters of Low Countries origin active in England at this time. Van Dyck's death coincided with the outbreak of the Civil War in England; and the portraitists William Dobson and Robert Walker, in the troubled years 1641–60 the only painters of note active in England, reveal a considerable debt to him. Jacob Jor-

Rubens' studio: a European artistic centre

daens also worked as an assistant in Rubens' workshop in Antwerp and took it over after his death. His handling of the Rubensian idiom moved increasingly away from the control of Rubens himself toward a much more boisterous and vulgar style with an emphasis on large genre scenes populated with rough plebeian types.

The remaining members of Rubens' studio, such as Cornelis de Vos and Caspar de Crayer, were much weaker artistic personalities, and one of the few painters of genius relatively independent of Rubens was Adriaen Brouwer, who painted in the tradition of Pieter Bruegel the Elder. Best known for his low-life pictures (Plate 14), Brouwer also painted very expressive landscapes; his work is characterized by the sensitive use of a heavily loaded brush. In comparison, David Teniers the Younger was a minor master, and with him the influence of Dutch painting became increasingly strong. The impact of Rubens' landscape style is felt in the paintings of Jan Wildens and Lucas van Uden, while in contrast Jan Brueghel the Younger turned the making of copies and pastiches of his father's works into something approaching an industry. Still-life and animal painting reached new heights in the works of Frans Snyders as a result of the influence of Rubens, and in a much quieter vein Snyders' pupil Jan Fyt continued the tradition, which was to last into the 18th century. Jan Davidsz de Heem was also active in Holland, but he is important as one of the creators of the elaborate, fully developed Baroque still life, and as such he had a host of followers and imitators.

The United Provinces. Dutch painting of the 17th century shares roots with that of the Spanish Netherlands. Holland, however, was independent, rapidly prospering, and almost entirely Protestant. In the last decades of the 16th century the great port of Haarlem was the most active artistic centre, and the remarkable flowering of Mannerist painting there, as exemplified by Cornelis van Haarlem and Hendrik Goltzius, is without a parallel south of the border. In the later pictures of Abraham Bloemaert, Mannerism gave way to the much more straightforward realist style characteristic of the earliest phase of Dutch 17th-century painting. The influence of the figure paintings of Adam Elsheimer on this generation of artists was considerable; his particularly Italianate style, with sharply delineated forms painted in rich, deep colours and with a pronounced element of fantasy, is reflected by the early paintings of Leonard Bramer and, even more importantly, Pieter Lastman, the master of Rembrandt. Elsheimer's poetic little landscapes were also extremely important for the group of Dutch artists active in Rome about 1620. This group was headed by Cornelis van Poelenburgh and Bartolomeus Breenbergh, and back home it provided an additional source of Italian influence. The most striking influence of Italy was provided, however, by the Dutch followers of Caravaggio, who had seized eagerly upon the harsh dramatic lighting and coarse plebeian types they had seen in his paintings during their stays in Italy and brought the style to the north to form the so-called Utrecht school. Gerrit van Honthorst, Hendrik Terbrugghen (Plate 15), and Dirck van Baburen were leading champions of this style, but after 1628 Honthorst turned away in the direction of Van Dyck.

Frans Hals was born in Antwerp, but almost all of his life was spent in Haarlem, where he evolved his characteristic bravura style of portraiture (Plate 15). The stiff solemnity of earlier Dutch portraits gave way to the capture of fleeting changes of expression and superb textural effects, though Hals never succeeded in attaining the degree of psychological penetration characteristic of the portraits painted by Rembrandt.

The early works of Rembrandt van Rijn, painted in Leiden (1625–31), show a progressive lessening of the influence of Lastman, and Rembrandt, together with his associate Jan Lievens, evolved an increasingly Baroque style, with strong contrasts of light and shade derived from the "Caravaggists." After he moved to Amsterdam in 1631, these tendencies developed to an opulent and highly Baroque climax in the late 1630s. Following the death of his first wife, Saskia, in 1642, difficult times and the changing tastes of art collectors culminated in

his bankruptcy in 1656. In his later works the dramatic Baroque panache gives way to a deep introspection and sympathy for his subjects (Plate 15), and his series of about 60 self-portraits reveals this process in intimate detail. Parallel to his development as a painter is that of his style as an etcher; Rembrandt is considered by many to be the greatest etcher of all time (see PRINTMAKING). During the years of his financial success, Rembrandt had the largest and most successful painting and printmaking studio in Holland.

The increasing use at this time of portable easel paintings as domestic ornaments, many of them made for sale by dealers rather than on commission by the consumer, is related to the extraordinary range of subjects in which Dutch painters specialized. Nevertheless, certain basic changes in style and taste occurred during the course of the 17th century, and, although many painters long persisted in outdated styles, the same fundamental changes can be traced in the various specialities. The earliest phase of simple realism held sway until the early 1620s; and the characteristic bright local colours, lack of spatial unity, sudden transition between different planes, and tendency toward high viewpoints are to be found in the genre paintings of Willem Buytewech, flower pieces of Jacob II de Gheyn and Roelant Savery, and marine paintings of Hendrick Cronelisz Vroom and Adam Willaerts. This gave way to a much more limited palette in the early 1620s when, by reducing the strength and range of the colours, an atmospheric unity was obtained. In landscapes and marine paintings the horizon tended to drop, and a continuous and coherent recession into depth was attained, particularly in the paintings of Esaias van de Velde, Jan van Goyen, Hercules Seghers, and Jan Porcellis. The same change is seen in still lifes by Pieter Claesz and Willem Claesz Heda, in which the colours are almost monochrome (Plate 14). Atmospheric unity having been mastered, the change to the heroic classical phase of the middle of the 17th century was gradual, but there was a tendency toward ever-increasingly dramatic Baroque contrasts, be they the leaden skies or great oaks of Jacob van Ruisdael (Plate 14), the vast panoramas of Philips de Koninck, the luminous pastures of Aelbert Cuyp, or the heavy gray seas of Simon de Vlieger. The monumentality of these scenes is paralleled by the rich splendour of the still lifes of Jan Davidsz de Heem, Abraham van Beyeren, and Willem Kalf and the classical calm and simplicity of the scenes by Jan Vermeer (Plate 14) and Pieter de Hooch painted in Delft. In the landscapes of Meindert Hobbema, Claes Berchem, and Adam Pijnacker the majesty of Jacob van Ruisdael's landscapes gives way to a much lighter, more picturesque style. Similarly, the vigorous social realism of Adriaen van Ostade yields to a much lighter and more frivolous treatment in the paintings of his younger brother Isack and Jan Steen and the elegant hunting scenes of Philips Wouwerman.

With the French invasion of 1672 and the subsequent Dutch economic collapse, the demand for paintings dropped heavily, and in the last decades of the 17th century many Dutch painters either stopped painting or, like the van de Velde Willem I and Willem II, left the country to work in England or Germany. Late 17th- and 18th-century taste tended toward the almost enamel-like brilliancy and intricate detail of the still lifes by Rachel Ruysch and Jan van Huysum; the same slightly dated flavour is characteristic of the marine paintings of Ludolf Backhuysen and of the hard figure subjects of Willem van Mieris and Adriaan van der Werff.

France. French-speaking painters continued the Mannerist conventions even later than did those at Haarlem, and at Nancy (capital of the independent duchy of Lorraine before 1633 and again from 1697 to 1766) a group of artists around Jacques Bellange and Jacques Callot was responsible for the last great flowering of the Mannerist style in Europe. By comparison, painting in Paris during the first decades of the 17th century was relatively insignificant, with the exception of that of Claude Vignon, who exchanged his Mannerist training for a style based on Elsheimer and to a lesser extent Lastman, and who in the 1620s revealed a remarkable knowledge of the earli-

Decline of
the Dutch
school

est paintings of Rembrandt. The return of Simon Vouet to Paris, however, marked the arrival of the Baroque in France. The earliest paintings from his stay in Rome are strikingly vigorous essays in the "Caravaggesque" style, but by 1620 he was painting in an eclectic, classicizing style based on the early Baroque painters active there, including Giovanni Lanfranco and Guido Reni. This style he brought back to France, enjoying until his death an immense success in Paris as a decorator and painter of large-scale altarpieces; even the return of Nicolas Poussin failed to shake his position. Poussin's activity in Paris is of relatively little importance compared with the remainder of his career in Rome, but the large number of works commissioned by French patrons then and subsequently was an important factor in the formation of the French predilection for classicism (Plate 16).

The influence of the highly Baroque paintings depicting the life of Marie de Médicis that Rubens had executed for the Luxembourg Palace in Paris was small. But Philippe de Campaigne evolved a grave and sober Baroque style that had its roots in the paintings of Rubens and Van Dyck rather than in Italy. Clear lighting and cool colours with an austere naturalism provided an alternative to the intellectual and archaeological classicism of Poussin. Georges de La Tour, a painter who had affinities with the Dutch "Caravagists" of Utrecht, was active in Lorraine; but although he exploited the Caravaggist system of lighting, his figures became increasingly detached and simplified, leading to an uncomfortable hardness (Plate 16). The paintings of the Le Nain brothers—Antoine, Louis, and Mathieu—again look to Dutch painting for their inspiration (Plate 17). Eustache Le Sueur began painting under the influence of Vouet, but after Poussin's brief return to Paris (1640–42) he turned to a much more rigorous classical style influenced by Raphael's tapestry designs, whereas Sébastien Bourdon was capable of painting in almost any current style on request.

Creation of
the Louis
XIV style

In the reorganization of the Academy of Painting and Sculpture in 1648, Charles Le Brun was appointed director and given the position of virtual dictator of the arts in France. An imaginative painter and designer, Le Brun was also a brilliant organizer, and the creation of the Louis XIV style, as exemplified by the Palace of Versailles, was above all due to him. The particular Baroque style that emerged was based on the Roman High Baroque but was purged of all theatricality and illusionism and modified to conform to the classical canons of French taste; this compromise solution struck the keynote for the frescoes of Le Brun and Pierre Mignard. The more full-blooded Baroque style of Pierre Puget received little official recognition, and his attempts to obtain major commissions at Versailles were thwarted, probably because of his difficult nature. During the last decades of the century, the full Baroque style took on a new lease on life, and the decorative paintings of Charles de La Fosse and Antoine Coypel clearly reveal the influence of Rubens. Even more Baroque are formal portraits by Hyacinthe Rigaud and Nicolas de Largillière, in which the strong contrapposto (twisting of the figure so that one half is in opposition to the other), rich settings, and floating masses of drapery reflect the pomp and swag of this era—which, significantly, came to be known as the Grande Époque.

The great formal portraits of Largillière and Rigaud are entirely Baroque in their approach, but in the late informal portraits of these masters a new atmosphere prevails. This atmosphere goes by the name of Rococo. The turn of the century marks the victory of Rubens' influence over the severe classicism of Poussin. The evolution of the Rococo style of decoration has been traced from its emergence at the beginning of the 18th century, and it must be emphasized that the Rococo is fundamentally a decorative style. It made relatively little impact on religious painting in France, and painters such as Pierre Subleyras continued to work in a Baroque idiom until the arrival of Neoclassicism in the second half of the century. It took the genius of Antoine Watteau to put together all the ideas current in Paris and to create the new style of painting. Rubens (in particular his oil sketches), the brush drawings and etchings of Castiglione, the naturalism of the Dutch

painters, and the fantasy of the French artist Claude Gillot all provided important source material for early Rococo painting. The delicate sketchlike technique and elegant figures of Watteau's wistful fantasies, called *fêtes galantes* (Plate 16), provided the models for the paintings of Jean-Baptiste Pater and Nicolas Lancret, both of whom conveyed a delicately veiled eroticism. Eroticism was more explicit in the sensuous nudes, both mythological and pastoral, of François Boucher (Plate 16). Another painter with whom amorous dalliance is a hallmark was Jean-Honoré Fragonard, in whose soft landscapes flirtation and even seduction are conducted with gallantry. Such paintings formed an intimate part of the decoration of Rococo interiors, and more than any earlier secular paintings they were intended as a kind of two-dimensional furniture.

Fantasy
and
eroticism

The furniture role also applies to the paintings of dead game and live dogs by François Desportes and Jean-Baptiste Oudry. But in the still lifes and tranquil scenes of domestic life painted by Jean-Baptiste-Siméon Chardin there is a sobriety of colour and composition (although great richness in the handling), an often relatively homely subject matter, and a concern to order the mind rather than dazzle the eye (Plate 17). Some of Chardin's subjects—the labours of the servant class, the care of children—were shared by Jean-Baptiste Greuze, who was, however, more interested in narrative and sentiment. Unlike Dutch painters of lower-class life, Greuze endowed his peasants with the sensibility of their social superiors. The edifying moral sympathy he intended to inculcate was, however, often subverted by a sly erotic interest he could not resist giving expression to.

Despite his great success, Greuze was judged to have failed in his attempt at painting heroic narrative from ancient history. But then it is true that the "higher" class of painting was generally less successfully practiced in France than were the "lower" genres in the 18th century. The mythologies and altarpieces of the Coypel family, Jean-François de Troy, or Jean-Marc Nattier may have been underestimated, but their names are not as familiar as those of still-life and genre painters such as Watteau or Chardin or even those of such accomplished painters of capricious ruin pieces or of landscapes and seascapes as Hubert Robert and Claude-Joseph Vernet.

The middle decades of the 18th century saw more accomplished portrait painters flourishing in France than perhaps ever before in any country. Yet it is the informal, the convivial, and the intimate that are associated with the portraiture of Jacques-André-Joseph Aved, François-Hubert Drouais, Louis Tocqué, Louis-Michel Van Loo, or Étienne Aubry. The heroic was seldom attempted and never achieved.

Britain. *The 17th century.* English painting during the 17th century had been dominated by a series of foreign-born practitioners, mostly portraitists (e.g., Rubens and Van Dyck), even before the Civil War. Sir Peter Lely and Sir Godfrey Kneller continued this trend after the Restoration. The vast majority of the painting executed by native artists remained thoroughly provincial. Lely began his activity in England during the Civil War, probably in 1641, but his portraits of the members of the court of Charles II set the pattern for English portraiture of the second half of the 17th century. British patrons in the 18th century sometimes collected paintings on religious or mythical themes by foreign artists, but at home they rarely commissioned anything other than portraits, landscapes, and marine paintings, although there was in the early 18th century a vogue for grand allegorical decorations in aristocratic houses. The Protestant church, however, did little to encourage painting. In fact, the preponderance of portraits is the most distinctive characteristic of old British collections. Gerard Soest, Jacob Huysmans, and Willem Wissing were also active in England as portrait painters close in style to Lely, whereas Jan Siberechts and Robert Streeter painted "portraits" of English country houses. The most distinguished painters to settle in England during this period were the van de Velde, from whom the tradition of British marine painting descends, headed by Peter Monamy and Samuel Scott.

English
portraiture
in the 17th
century

The Glorious Revolution of 1688 was followed by a brief

flowering of decorative painting under Sir James Thornhill, which was the closest that Britain ever approached to the developed Baroque style of the Continent. This process was in part due to the influx, following the end of the War of the Spanish Succession, of Italian painters, including the Venetians Giovanni Antonio Pellegrini and Jacopo Amigoni, and French ones, such as Charles de La Fosse. The German-born Kneller succeeded Lely as court portrait painter, but, although his portraits often have a certain liveliness, his rather heavy use of studio assistants resulted in a tendency to monotony.

Hogarth

The 18th century. Thornhill's son-in-law William Hogarth was, despite his chauvinism and virulently anti-French sentiments, heavily influenced by the continental Rococo style. Early in his career he succeeded in breaking away from the straitjacket of portraiture, and his moralizing paintings are superb evocations of life in the England of George I and George II (Plate 17). His rich, creamy paint handling and brilliant characterization of textures have a freshness and vitality unequalled in the work of any of his contemporaries. He invented a new form of secular narrative painting that imparts a moral. These paintings were often tragicomedies, although dependent upon no texts, and Hogarth's series of such works were always intended to be engraved for a large public as well as seen in a private picture gallery (just as plays were intended to be performed as well as read).

Despite Hogarth's considerable knowledge of and borrowings from continental old masters, he remained in the last analysis English through and through. This, however, was not the case with all the next generation of painters; and the Scottish-born Allan Ramsay studied in Rome and Naples in 1736–38 before settling in London in 1739. Until the return of Joshua Reynolds from Italy in 1752, Ramsay held undisputed sway as the most successful portrait painter in London; and to him must be given the credit for the initial marriage of the Italian "grand style" to English portraiture. Ramsay visited Italy again in 1755–57, and on his return his portraits took on a new delicacy and elegance and a silvery tonality. Reynolds possessed great ambitions and a more profound acquaintance with the old masters than any of his contemporaries. His colouring and handling can be compared with Rembrandt, Rubens, and Veronese, and his poses are indebted to the sculpture of antiquity and to Michelangelo. The *Discourses* that he delivered to the Royal Academy (founded in 1768 with Reynolds as its first president) are the most impressive statement in English of the central ideas of European art theory from the time of Leon Battista Alberti's treatise. Reynolds' own painting gained a genuine heroic power and elevated grace from his frustrated ambition to be a history painter, although for that very reason he occasionally tumbled into bathos.

Wilson's
Italianate
landscapes

The third major British painter of the period to study in Italy was a Welshman, Richard Wilson, who worked there from 1750 to about 1757 before settling in London. His landscape style was formed on Claude, Gaspard Dughet, and Cuyper; but the clear golden lighting of his Italian landscapes carries the conviction of an artist saturated with the Mediterranean tradition. A cooler clarity and classical simplicity pervade his northern landscapes; and, despite the uneven quality of his work, Wilson was the first British painter to lift the pure landscape above mere decorative painting and topography.

Thomas Gainsborough was in every way the antithesis to Reynolds. Trained entirely in England, he had no wish to visit Italy. Instead of the "grand style," his tastes in portraiture lay in the delicate flickering brushwork and evanescent qualities of the Rococo (Plate 17). He preferred landscape painting to portraiture, and the strong Dutch influence in his earliest works later gave way to spontaneous landscapes composed from models.

In the 1760s Francis Cotes was the most important fashionable London portrait painter after Reynolds and Gainsborough, a position succeeded to by George Romney, who, on returning to London from Italy in 1775, took over Cotes's studio. Romney's portraits deteriorated sadly in quality during the 1780s when the young Sir Thomas Lawrence began to make his mark.

Throughout the 18th century, portraiture remained the most important genre of British painting, despite the efforts of Reynolds and Gainsborough in their "fancy pictures." Even the taste for large-scale scenes illustrating Shakespeare and other themes—which were commissioned toward the end of the century from James Barry, James Northcote, and Edward Penny, among others—never spread far beyond a few patrons. Sporting and animal painting, however, took on an entirely new dimension in the work of George Stubbs. Joseph Wright of Derby was active outside London and, apart from his romantic portraits, is important for his series of paintings of scientific and industrial subjects with strong light effects. Johann Zoffany was born in Germany but moved to Britain about 1761 and became a founder-member of the Royal Academy, specializing in elaborate group portraits and theatrical scenes.

During the second half of the 18th century the evolution of British oil painting was to a great extent paralleled by the extraordinary flowering in watercolours. The early topographical drawings of Paul Sandby gave way to the delicate linear drawings of Francis Towne, with their patches of colour resembling maps, and, at the close of the century, to the atmospheric unity of the landscapes of John Robert Cozens.

Colonial Americas. *North America.* Painting in the Dutch and English colonies of North America reflected generally the portrait styles of the mother countries, though with a note of provinciality. In the late 17th and early 18th centuries the Dutch colony of New Amsterdam (New York) had painters whose names today are forgotten. Their work lives on, however, and is signified by names such as the Master of the De Peyster Boy. Gustavus Hesselius, Swedish born, was painting in Maryland, and Jeremiah Theüs, a Swiss, was at work in South Carolina. Peter Pelham and John Smibert arrived from England and in the second quarter of the 18th century were painting portraits in Boston, Mass. These two self-taught itinerant artists were succeeded by John Wollaston and Joseph Blackburn. Robert Feke, a native American painter, realized his forms more solidly and with greater originality than his predecessors had. Another native American, John Singleton Copley, worked in Boston until 1774, when he went to live permanently in England, and was responsible for the finest painting produced in the American colonies. Benjamin West, another important native figure in the history of American painting, was born in Pennsylvania but settled in London in 1763, where he became the second president of the Royal Academy. Although domiciled in London, he helped to mold the styles of two generations of American painters.

Central and South America. Baroque painting in Central and South America is basically an extension of that of Spain and Portugal, and even the best rarely rises to the general standard of the European schools. Important paintings and sculptures tended to be imported from Europe, and Zurbarán was particularly active in producing works for export, while local productions were more or less heavily influenced by the Indian traditions.

Central Europe. In central Europe the Mannerist tradition remained dominant until the Thirty Years' War (1618–48), particularly in Bohemia and Bavaria, where Italian influence was perhaps strongest.

The Rubensian Baroque became dominant after mid-century, and here the lead was taken by Silesia and Bohemia. Michael Willmann, originally from Königsberg (modern Kaliningrad) on the southeastern Baltic coast, developed a highly charged, emotional Baroque style, based on Rubens, at Lubiąż (modern Dorf Leubus, northwest of Wrocław) from 1661 to 1700 and in Prague after 1700. In Karel Škréta Šotnovský, Bohemia possessed a painter of European stature; his sombre portraits and religious scenes are filled with a deeply serious mystical fervour. The frescoes by Johann Michael Rottmayr in the castle of Vranov in Moravia (1695) and in Breslau (now Wrocław; 1704–06) constitute a prelude to the great development of Baroque painting in the Habsburg domains. There the vigorous and extremely colourful frescoes are closely integrated with the architecture. The

Influence
of Rubens

vast majority of the best central European Baroque painting outside portraiture is monumental in scale, and the concept of the *Gesamtkunstwerk* ("total work of art")—where painting, sculpture, and architecture are combined together into a single, unified, and harmonious ensemble—is of overwhelming importance.

Painting in Austria flourished, and Franz Anton Maulbertsch is arguably the greatest painter of the 18th century in central Europe. The vast majority of his brilliant fresco cycles are located in relatively inaccessible areas of Bohemia, Moravia, and northern Hungary. But the mystical intensity of his religious scenes and the joyous abandon of his secular subjects form a triumphant closing chapter to 18th-century central European painting. Maulbertsch's last frescoes at Strahov, Prague (1794), reveal, nevertheless, the impact of the Neoclassicism that descended in the last decades on all Austrian painters, including Troger's pupil Martin Knoller. But Austrian monumental painting remained fully Baroque in the hands of Daniel Gran, Paul Troger, and Bartholomäus Altomonte; and it was not until the latter part of the century that the Rococo made its impact.

Independent development of Bohemian painting

During the first four decades of the 18th century, Bohemian Baroque painting developed almost independently of Vienna, where the Habsburg rulers of Bohemia had their capital. The impetuous work of Jan Petr Brandl and the powerful realism of the portraitist Jan Kupecký, who worked in Rome, Venice, Vienna, and Nürnberg, always remained Bohemian in spirit. The frescoes of Wenzel Lorenz Reiner, however, show more Italian influence. One of the few important Baroque frescoes of the second half of the century is that by Jan Lučánský Kracker in St. Nicholas, Malá Strana ("Lesser Quarter"), Prague. The influence of Bohemian Baroque painting is frequently underestimated. Apart from Vienna and the surrounding area, it was dominant in Silesia and strong later in the century in Franconia.

After the death of Cosmas Damian Asam in 1739, Johann Baptist Zimmermann became the most important fresco painter in the Munich area; his lyrical handling of pale colours is typical of the Rococo period. Christian Wink continued to paint in the same style until the close of the century. In Georg Desmarées the court at Munich gained a painter in whose Rococo portraits there is more than a hint of decadence.

The centre of south German painting had by the late 1730s shifted from Munich to Augsburg in Swabia, where Johann Georg Bermüller became the director of the Academy in 1730; but his frescoes, as well as those of Franz Joseph Spiegler and Gottfried Bernhard Goetz, are perhaps more representative of the Late Baroque than the Rococo. The frescoes of Matthäus Günther, who became director of the Augsburg Academy in 1762, show a steady evolution from his early Baroque compositions, through the much lighter asymmetrical Rococo compositions, to the strongly sculptural quality of his late works, which reveal the onset of Neoclassicism.

In Franconia and the middle Rhineland the most important painters were Johann Zick and Carlo Carlone. Zick's frescoes at Würzburg (1749) had not been entirely successful, and in 1750 he was supplanted by Tiepolo; but at Bruchsal he produced one of the most brilliant series of Rococo frescoes in Germany (now destroyed). His son Januarius began painting in the Rococo style but under the influence of Anton Raphael Mengs produced some late frescoes that were strongly classical.

Prussian Rococo

The French tastes of Frederick I of Prussia at Berlin led him in 1710 to summon Antoine Pesne to court, where Pesne continued for the remainder of his life to paint in an entirely French Rococo style. The homely intimacy of the paintings of Daniel Chodowiecki, however, have a sensitivity and refinement more comparable to Chardin's.

Saxony under Augustus III produced few painters of real importance except Mengs, who rapidly turned from the Rococo to the Neoclassicism propounded by the influential art historian and classical archaeologist Johann Winckelmann.

Poland. King Władysław IV Vasa (reigned 1632–48) assembled an important collection of Italian and Flem-

ish Baroque paintings, but these promising developments were cut short by the destruction of the Swedish Wars in the middle of the 17th century. Under John III Sobieski (reigned 1674–96), a cultivated man, there was a considerable revival, and, although two of the painters active in Poland—Claude Callot and Michelangelo Pal-loni—were foreign-born and foreign-trained, native talent flourished with the work of Jerzy Eleuter Szymonowicz-Siemiginowski and Jan Tretko. In 1697 the crowns of Poland and Saxony were united under Augustus II, and he and his son Augustus III ruled over Poland until 1763. During this period, Polish painting formed part of the Saxon tradition, but during the reign of the last king of Poland, Stanisław II August Poniatowski (reigned 1764–95), Warsaw quickly became a centre of European importance. Although inclined to Neoclassicism in architecture, Stanisław's taste in painting was more conservative. Accordingly it is the late Rococo portraits of Marcello Bacciarelli that are particularly important. A nephew and pupil of Canaletto, Bernardo Bellotto, settled in Warsaw in 1767 and executed for Stanisław the great series of 26 views of the city that were intended to hang in the Royal Castle. (P.C.-B./Ed.)

Russia. The Baroque in Russia was imported from western Europe and outside court circles made little impact. Indeed the traditional production of icons for the Orthodox church by artists of the Novgorod and Moscow schools continued throughout the Baroque period. Nevertheless the foundation of St. Petersburg (1703) by Peter I the Great marked the beginning of the substitution of Western influence for Byzantine, an important change. During Peter's reign foreign painters began to go to Russia in increasing numbers; conversely, groups of young Russians were sent to Italy, France, Holland, and England to study painting. Western influence determined the character of Russian painting for more than two centuries.

Influx of foreign painters

The art of Peter's age shows almost no trace of Byzantine influence. Only in iconography did the old style persist for some time. Early in the 18th century, religious painting began to give way to secular painting, and the church prohibition of sculpture became ineffective. Dmitry Levitsky stands out as the only important Russian painter of the 18th century to work in the Western style.

Further westernizing occurred under the empress Elizabeth (reigned 1741–62), who had French tastes. A great number of vast and luxurious Rococo-style palaces were built, and painting was primarily concerned with their interior decoration—ceilings and walls. The work was carried on chiefly by Italians and Frenchmen.

In 1757 the Academy of Fine Arts was founded in St. Petersburg, and foreign artists—mostly French—were invited to direct the new school. These trained some remarkable native portraitists, such as Ivan Argunov, Anton Losenko, and Fyodor Rokotov. Their works reflected the ceremonial character of Elizabeth's tastes and showed little evidence of native Russian sensibility. (A.Vo./Ed.)

Scandinavia. In the 17th century, Scandinavian painting derived from traditions of the Low Countries and northern Germany. The works of art carried off as loot from Prague by Swedish soldiers during the Thirty Years' War might conceivably have broadened the outlook of Swedes at home, but the best of them were taken to Rome by Queen Christina when she abdicated in 1654. A generation later, under the influence of the fashionable Venetian woman pastelist Rosalba Carriera, a school of Rococo portraitists flourished in Scandinavia. One such portraitist was Carl Gustav Pilo, who, though trained in Stockholm, executed many frankly Venetian portraits during his years as court painter in Copenhagen. Another was Lorentz Pasch the Younger, who trained under Pilo in Copenhagen, although he subsequently worked mainly in Sweden. Other painters of Swedish origin were Alexander Roslin, who worked throughout Europe, and Georg Desmarées, who settled in Bavaria. The Scandinavian Rococo has a distinctive flavour that is also detectable in the work of two important miniaturists of the period, Niclas Lafrensen and Cornelius Höyer. At the close of the century the paintings of Jens Juel in Denmark bridge the transition from Rococo to Neoclassicism.

Neoclassical and Romantic

NEOCLASSICISM

Neoclassicism was a widespread and influential movement in painting and the other visual arts that began in the 1760s, reached its height in the 1780s and '90s, and lasted until the 1840s and '50s. In painting it generally took the form of an emphasis on austere linear design in the depiction of classical themes and subject matter, using archaeologically correct settings and costumes.

Neoclassicism arose partly as a reaction against the sensuous and frivolously decorative Rococo style that had dominated European art from the 1720s on. But an even more profound stimulus was the new and more scientific interest in classical antiquity that arose in the 18th century. Neoclassicism was given great impetus by new archaeological discoveries, particularly the exploration and excavation of the buried Roman cities of Herculaneum and Pompeii (the excavations of which began in 1738 and 1748, respectively). And from the second decade of the 18th century on, a number of influential publications by Bernard de Montfaucon, Giovanni Battista Piranesi, the Comte de Caylus, and Robert Wood provided engraved views of Roman monuments and other antiquities and further quickened interest in the classical past. The new understanding distilled from these discoveries and publications in turn enabled European scholars for the first time to discern separate and distinct chronological periods in Greco-Roman art, and this new sense of a plurality of ancient styles replaced the older, unqualified veneration of Roman art and encouraged a dawning interest in purely Greek antiquities. The German scholar Johann Joachim Winckelmann's writings and sophisticated theorizings were especially influential in this regard. Winckelmann saw in Greek sculpture "a noble simplicity and quiet grandeur" and called for artists to imitate Greek art. He claimed that in doing so such artists would obtain idealized depictions of natural forms that had been stripped of all transitory and individualistic aspects, and their images would thus attain a universal and archetypal significance.

Neoclassicism as manifested in painting was initially not stylistically distinct from the French Rococo and other styles that had preceded it. This was partly because, whereas it was possible for architecture and sculpture to be modeled on prototypes in these media that had actually survived from classical antiquity, those few classical paintings that had survived were minor or merely ornamental works—until, that is, the discoveries made at Herculaneum and Pompeii. The earliest Neoclassical painters were Joseph-Marie Vien, Anton Raphael Mengs, Pompeo Batoni, Angelica Kauffmann, and Gavin Hamilton; these artists were active during the 1750s, '60s, and '70s. Each of these painters, though they may have used poses and figural arrangements from ancient sculptures and vase paintings, was strongly influenced by preceding stylistic trends. An important early Neoclassical work such as Mengs's "Parnassus" (1761; Villa Albani, Rome) owes much of its inspiration to 17th-century classicism and to Raphael for both the poses of its figures and its general composition. Many of the early paintings of the Neoclassical artist Benjamin West derive their compositions from works by Nicolas Poussin, and Kauffmann's sentimental subjects dressed in antique garb are basically Rococo in their softened, decorative prettiness. Mengs's close association with Winckelmann led to his being influenced by the ideal beauty that the latter so ardently expounded, but the church and palace ceilings decorated by Mengs owe more to existing Italian Baroque traditions than to anything Greek or Roman.

A more rigorously Neoclassical painting style arose in France in the 1780s under the leadership of Jacques-Louis David. He and his contemporary Jean-François-Pierre Peyron were interested in narrative painting rather than the ideal grace that fascinated Mengs. Just before and during the French Revolution, these and other painters adopted stirring moral subject matter from Roman history and celebrated the values of simplicity, austerity, heroism, and stoic virtue that were traditionally associated with the Roman Republic, thus drawing parallels between that

time and the contemporary struggle for liberty in France. David's history paintings of the "Oath of the Horatii" (1784; Louvre, Paris) and "Lictors Bringing to Brutus the Bodies of His Sons" (1789; Louvre) display a gravity and decorum deriving from classical tragedy, a certain rhetorical quality of gesture, and patterns of drapery influenced by ancient sculpture. To some extent these elements were anticipated by British and American artists such as Hamilton and West, but in David's works the dramatic confrontations of the figures are starker and in clearer profile on the same plane, the setting is more monumental, and the diagonal compositional movements, large groupings of figures, and turbulent draperies of the Baroque have been almost entirely repudiated. This style was ruthlessly austere and uncompromising, and it is not surprising that it came to be associated with the French Revolution (in which David actively participated).

Neoclassicism as generally manifested in European painting by the 1790s emphasized the qualities of outline and linear design over those of colour, atmosphere, and effects of light. Widely disseminated engravings of classical sculptures and Greek vase paintings helped determine this bias, which is clearly seen in the outline illustrations made by the British sculptor John Flaxman in the 1790s for editions of the works of Homer, Aeschylus, and Dante. These illustrations are notable for their drastic and powerful simplification of the human body, their denial of pictorial space, and their minimal stage setting. This austere linearity when depicting the human form was adopted by many other British figural artists, including the Swiss-born Henry Fuseli and William Blake, among others.

Neoclassical painters attached great importance to depicting the costumes, settings, and details of their classical subject matter with as much historical accuracy as possible. This worked well enough when illustrating an incident found in the pages of Homer, but it raised the question of whether a modern hero or famous person should be portrayed in classical or contemporary dress. This issue was never satisfactorily resolved, except perhaps in David's brilliantly evocative portraits of sitters wearing the then-fashionable antique garb, as in his "Portrait of Madame Récamier" (1800; Louvre).

Classical history and mythology provided a large part of the subject matter of Neoclassical works. The poetry of Homer, Virgil, and Ovid, the plays of Aeschylus, Sophocles, and Euripides, and history recorded by Pliny, Plutarch, Tacitus, and Livy provided the bulk of classical sources, but the most important single source was Homer. To this general literary emphasis was added a growing interest in medieval sources, such as the pseudo-Celtic poetry of Ossian, as well as incidents from medieval history, the works of Dante, and an admiration for medieval art itself in the persons of Giotto, Fra Angelico, and others. Indeed, the Neoclassicists differed strikingly from their academic predecessors in their admiration of Gothic and Quattrocento art in general, and they contributed notably to the positive reevaluation of such art.

Finally, it should be noted that Neoclassicism coexisted throughout much of its later development with the seemingly obverse and opposite tendency of Romanticism. But far from being distinct and separate, these two styles intermingled with each other in complex ways; many ostensibly Neoclassical paintings show Romantic tendencies, and vice versa. This contradictory situation is strikingly evident in the works of the last great Neoclassical painter, Jean-Auguste-Dominique Ingres, who painted sensuous Romantic female nudes while also turning out precisely linear and rather lifeless historical paintings in the approved Neoclassical mode.

Britain. Hamilton—Scottish painter, archaeologist, and dealer—spent most of his working life in Rome, and his paintings include two series of large and influential canvases of Homeric subjects. West and the Swiss-born Kauffmann were the most consistent exhibitors of history pieces in London during the 1760s. James Barry and Fuseli also were important. Blake, poet and painter, was a Neoclassicist to some extent.

France. As well as being a painter, Vien was a friend of the archaeologist Caylus and a director of the French

David's
role in
French
Neo-
classical
painting

Academy in Rome. This generation also included Jean-Baptiste Greuze, who painted a few classical history subjects as well as the scenes from contemporary life for which he is best known; Jean-Jacque Lagrenée the Elder, like Vien a director of the French Academy in Rome; and Nicolas-Guy Brenet.

The outstanding and most influential of all French Neoclassicists and one of the major artists in Europe was Vien's pupil Jacques-Louis David. David's early works are essentially Rococo, and his late works also revert to early 18th-century types; his fame as a Neoclassicist rests on paintings of the 1780s and 1790s. After winning the Prix de Rome of the French Academy in 1774 (important in the history of French painting because it awarded a stay in Rome, where winners studied Italian paintings at first hand), he was in that city in 1775–81, returning there in 1784 to paint "Oath of the Horatii." David's contemporaries, or near-contemporaries, included Jean-Germain Drouais, whose history paintings almost equaled David's own in severity and intensity.

The slightly younger generation of painters included Jean-Baptiste Regnault, Louis-Léopold Boilly, and Louis Gauffier. They were followed by a more important group that included Pierre-Paul Prud'hon. Prud'hon blended in his paintings a mild classicism and the lyrical mood and soft lights of Correggio; he was patronized by the empresses Josephine and Marie-Louise. Baron Pierre-Narcisse Guérin painted in a style close to the Neoclassicism of David, although he was not one of his pupils.

David's
pupils

Of David's pupils, three became well-known and one became very famous. Baron François-Pascal-Simon Gérard had a high reputation as a portraitist under both Napoleon and Louis XVIII. Antoine-Jean Gros executed many large Napoleonic canvases and after David's death was the leading Neoclassicist in France. Anne-Louis Girodet de Roucy, known as Girodet-Trioson, won a Prix de Rome but stopped painting after 1812 when he inherited a fortune and turned to writing. The famous pupil was Ingres, who was important as a Neoclassicist in his subject paintings but not in his portraits.

Germany and Austria. Mengs was born in Aussig in Bohemia (modern Ústí nad Labem, Czech.) in 1728, the son of the court painter there. He was himself appointed Dresden court painter in 1745. In 1755 he met Winckelmann and subsequently he became a prominent figure in Roman Neoclassical circles. Mengs is important both as a painter and as a theorist. Apart from him, Germany's and Austria's main contribution to Neoclassicism was theoretical, not practical, however. The early Neoclassicists included Cristoph Unterberger; Anton von Maron, who married Mengs's sister; and Friedrich Heinrich Füger. After Unterberger, the most interesting painter was Johann Heinrich Wilhelm Tischbein, who executed both portraits and subject pieces. He was a director of the art academy in Naples and supervised the publication of engravings of the Greek vases in the collection of Sir William Hamilton, the British ambassador to Naples, who was a notable connoisseur.

The German painter Asmus Jacob Carstens worked in Berlin and was a professor at the Berlin Academy. Members of his artistic circle included the painters Karl Ludwig Fernow, Eberhard Wächter, Joseph Anton Koch (who was the most outstanding of this German group), and Gottlieb Schick.

Italy. One of the earliest Neoclassicists and one of the foremost painters of his generation in Italy was Batoni. His style blends Rococo with Neoclassical elements, and his work includes classical subject pieces as well as portraits in contemporary dress, the sitter posing with antique statues and urns, and sometimes amid ruins. The painter Domenico Corvi was influenced by both Batoni and Mengs and was important as the teacher of three of the leading Neoclassicists of the next generation: Giuseppe Cades, Gaspare Landi, and Vincenzo Camuccini. These artists worked mostly in Rome, the first two making reputations as portraitists, Landi especially being noted for good contemporary groups.

Rome was indeed the city where the principal Italian painters of this period were mostly active. One such was

Felice Giani, whose many decorations include Napoleonic palaces there and elsewhere in Italy (especially Faenza) and in France.

Important painters outside Rome include Andrea Appiani the Elder in Milan, who became Napoleon's official painter and executed some of the best frescoes in northern Italy. He was also a fine portraitist. One of his pupils was Giuseppe Bossi. Another leading Lombard painter was Giovanni Battista dell'Era, whose encaustic paintings were bought by Catherine the Great and others. Other good examples of Neoclassical decorative schemes outside Rome are in Florence (Pitti Palace) by the Florentine Luigi Sabatelli and by Pietro Benvenuti, who was born at Arezzo, and in Venice (Palazzo Reale) by Giuseppe Borsato, who was born in that city and was both painter and architect. Another painter of the time, though only given to a mildly Neoclassical style, was Domenico Pellegrini, born near Bassano, who traveled widely. The principal Neoclassicists in the south were the Sicilians Giuseppe Velasco, who did important frescoes in palaces in Palermo, and Giuseppe Errante.

Other countries. The main Danish painter who produced original Neoclassical works was Nicolai Abraham Abildgaard. Other Danish painters include Abildgaard's and David's pupil Christoffer Wilhelm Eckersberg. David was very influential in Brussels, where he retired late in life. The paintings of his Belgian pupil François-Joseph Navez, for example, are pure French Neoclassicism. The two main Neoclassical artists in The Netherlands were Humbert de Superville and Jan Willem Pieneman. The principal Neoclassicist in Spain was José de Madrazo y Agudo. (D.I./Ed.)

ROMANTICISM

Romanticism is a term loosely used to designate numerous and diverse changes in the arts during a period of more than 100 years (roughly, 1760–1870), changes that were in reaction against Neoclassicism (but not necessarily the classicism of Greece and Rome) or against what is variously called the Age of Reason, the Augustan Age, the Enlightenment, or 18th-century materialism. In the sense of a personal temperament Romanticism had always existed, but in the sense of an aesthetic period it meant works of art whose prime impulse and effect derived from individual rather than collective reactions. Romanticism can generally be said to have emphasized the personal, the subjective, the irrational, the imaginative, the spontaneous, the emotional, and even the visionary and transcendental in works of art. The Romantic movement first developed in northern Europe with a rejection of technical standards based on the classical ideal that perfection should be attained in art.

It was writers and poets who gave initial expression to Romantic ideas; painters, while subject to similar feelings, acquired fundamental inspiration from the literature of the period. There was an increasing awareness generally of the way the various arts interacted. The Frenchman Eugène Delacroix and the German Philipp Otto Runge explored the implications of musical analogies for painting, and everywhere writers, artists, and composers could be found in close association.

Romantic critics agreed that experience of profound inner emotion was the mainspring of creation and appreciation of art. Received ideas, and especially aesthetic values sanctioned by the authority of official institutions, were distrusted, and the individual was pitted against society. The artist asserted the right to evolve his own criteria of beauty and in so doing encouraged a new concept of artistic genius. The genius whom the Romantics celebrated was one who refused to conform, who remained defiantly independent of society, and whose chief virtues were novelty and sincerity. This sometimes led to bizarre and extravagant projects in which the intention to shock, excite, and involve struck a melodramatic, almost hysterical note that failed to convince by its very lack of restraint.

As in the literature of the period, tragic themes predominated in Romantic painting, and interest turned sharply from classical history and mythology to medieval subjects, although an interest in the primitive was sometimes com-

mon to both. The fascination with the Middle Ages combined with strong nationalist tendencies, disposing artists to a concern with the history and folklore of their own countries. At the same time they often sought themes or styles that were distant in place as well as time. Accounts of foreign travel and the literary works of Dante, Shakespeare, Byron, Goethe, Sir Walter Scott, and the supposed Celtic bard Ossian greatly influenced painters. Study of medieval culture imbued some painters with a Christian ideal of simplicity and moral integrity.

A salient feature of Romantic sensibility was awareness of the beauties of the natural world. Artists identified their personal feelings with nature's changing aspects. An almost reverential affection, animated by the belief that the divine mind was immanent in nature, engendered at times a Christian or theistic naturalism. The artist was seen as the interpreter of hidden mysteries, to which end imaginative insight must combine with absolute fidelity and sincerity. In Britain and Germany especially, the moral implications inherent in the appreciation of natural or artistic beauty tended to outweigh aesthetic considerations. Interest in transitory phenomena led painters to devote themselves to an accurate study of light and atmosphere and their effects on the landscape. Concern to preserve the spontaneity of the immediate impression brought about a revolution in painterly technique, with the rapid notation of the sketch carried into the final conception. Whether emphasizing expressive or purely visual considerations, the landscape paintings of the period display dazzling colour.

Curiosity about the external world and a spirit of what might be called scientific inquiry led many painters to explore the minutiae of nature. Technological advance also excited artistic interest, though painting was affected less than architecture and the decorative arts; and the humanitarian sympathy and generosity so vital to the Romantic spirit gradually effected a reconciliation between art and life. The political and social upheavals of the 19th century involved many painters in revolutionary movements and stimulated a solicitude toward the helpless and downtrodden that found most passionate and powerful expression in the works executed during and immediately after the Revolutions of 1848.

Britain. In the late 1760s and '70s a circle of British painters in Rome had already begun to find academic precepts inadequate. James Barry, the brothers John and Alexander Runciman, John Brown, George Romney, and the Swiss-born Henry Fuseli favoured themes—whether literary, historical, or purely imaginary—determined by a taste for the pathetic, bizarre, and extravagantly heroic. Mutually influential and highly eclectic, they combined, especially in their drawings, the linear tensions of Italian Mannerism with bold contrasts of light and shade. Though never in Rome, John Hamilton Mortimer had much in common with this group, for all were participants in a move to found a national school of narrative painting. Fuseli's affiliations with the German Romantic *Sturm und Drang* writers predisposed him, like Flaxman, toward the "primitive" heroic stories of Homer and Dante. Flaxman himself, in the two-dimensional linear abstraction of his drawings, a two-dimensionality implying rejection of Renaissance perspective and seen for instance in the expressive purity of "Penelope's Dream" (1792–93), had important repercussions throughout Europe.

William Blake absorbed and outstripped the Fuseli circle, evolving new images for a unique private cosmology, rejecting oils in favour of tempera and watercolour, and depicting, as in "Pity" (1795; Tate Gallery, London), a shadowless world of soaring, supernatural beings (Plate 19). His passionate rejection of rationalism and materialism, his scorn for both Sir Joshua Reynolds and the Dutch Naturalists, stemmed from a conviction that "poetic genius" could alone perceive the infinite, so essential to the artist since "painting, as well as poetry and music, exists and exults in immortal thoughts." The spiritual, symbolical expression of Blake's complex sympathies, his ability to recognize God in a single blade of grass, inspired Samuel Palmer, who, with his friend Edward Calvert, extracted from nature a visionary world of exquisite, though short-lived, intensity.

Empiricism and acceptance of the irrational, however, were not mutually exclusive, and each profoundly affected attitudes toward nature. Susceptible to the ideas of Blake and other radical theorists and animated by a growing spirit of inquiry into natural phenomena, painters slowly abandoned the picturesque desire to compose and became willing to be moved, awestruck, and terrified by nature unadorned. Early artists of the sublime, such as Alexander Cozens or Francis Towne, worked largely in watercolours and solved the problem of scale by abstraction—use of broad areas of colour to suggest the vast scope of natural forces—an approach developed by Thomas Girtin and John Sell Cotman.

By the early 19th century, the watercolourist John Varley was echoing current practice when he told his pupils John Linnell, William Mulready, and William Henry Hunt: "Go to nature for everything." But already two outstanding British landscape painters, John Constable and J.M.W. Turner, were going still further. Both men, while admiring the classical landscapes of Claude Lorrain and Poussin, believed that personal feeling was the mainspring of artistic activity and felt an almost mystical sympathy for the natural world. They made atmosphere almost palpable and painted everything from clouds to lichens with astonishing technical diversity. Constable considered himself before all else a "natural" painter and sought, in his own words, to capture "light—dews—breezes—bloom—and freshness" with scientific precision and deepest affection. For Constable, light clarified and enlivened, and his nostalgia for the Suffolk countryside is personal and explicit (Plate 20). With Turner, light increasingly diffused the objects illuminated, and only a more literary expression satisfied his concept of the sublime, drawing him to mountain grandeur, raging seas, storms, and conflagrations (Plate 21). The technical innovations of these two men were better understood in France than in Britain; even John Ruskin's passionate defense of Turner, with its emphasis on absolute fidelity to nature, helped deflect Turner's and Constable's successors onto a very different course.

George Stubbs's anatomical studies and accurate delineations of animals were echoed a generation later by Thomas Bewick's bird studies, themselves harbingers of the drawings of Edwin Landseer and Ruskin's closely observed renderings of naturalistic detail. Stubbs's empathy for the animal world reemerged in the work of James Ward, together with an exultation in the power of nature, shared by Philip James de Loutherbourg. Demand for information about distant places partially superseded the taste for picturesque European scenes, and following William Hodges, who accompanied Captain James Cook's second voyage (1772–75), such painters as Richard Parkes Bonington, Samuel Prout, John Frederick Lewis, and Edward Lear traveled widely, recording scenes of historic or exotic interest.

In portraiture an interest in extremes of mood found most eloquent expression in the work of Sir Thomas Lawrence, who combined in portraits such as those of Richard Payne Knight (1794; Whitworth Art Gallery, Manchester) and Pope Pius VII (1819; Royal Collection, Windsor Castle) brilliant freedom of handling, at times approaching exhibitionism, with dramatic expression and setting, at times almost melodramatic.

History painting, too, was transformed: Bonington's "Henri III and the English Ambassador" (1827–28; Wallace Collection, London), while testifying to a sustained delight in the medieval world, already betrays commensurate interest in period detail and the finer points of human insight. The authentic, domestic treatment of biblical themes at the hands of William Dyce and the Pre-Raphaelites (see below) contrasts sharply with the earlier apocalyptic fantasies of John Martin and Francis Danby. Inspired by David Wilkie's mellow, unassuming representation of country life subject matter, William Mulready turned to contemporary scenes of daily life, adopting the brilliant palette that distinguished British painting for the next half-century. The high Victorian Age saw much narrative painting, a genre that was practiced with accurate and sympathetic observation, from the panoramic activ-

Constable considered a "natural" painter

Blake

ity of William Powell Frith's "Derby Day" (1858; Tate Gallery) to such intimate glimpses of reality as "The Travelling Companions" (1862; City Museum and Art Gallery, Birmingham), by Augustus Egg. Painting as a vehicle for social or moral comment was provided by Sir Luke Fildes and Frank Holl, in whose work a tendency to sentimentality is redeemed by a genuine regard for the sufferings of the poor. In the 1850s the Pre-Raphaelites gave expression to the painting of contemporary life with such memorable images as "The Blind Girl" (1856; City Museum and Art Gallery, Birmingham), by John Everett Millais, or "The Stonebreaker" (1857–58; Walker Art Gallery, Liverpool), by John Brett.

The Pre-Raphaelite movement

The Pre-Raphaelite movement, echoing that of the Nazarenes (a group of religiously minded painters who sought to revive medieval workshop practices; see below), reiterated many earlier Romantic ideals. Literary inspiration and a passion for the Middle Ages were tempered for the Pre-Raphaelites by a moral outlook that recoiled from sophistication and virtuosity and demanded rigorous studies from natural life. These painters handled literary, historical, biblical, and contemporary themes with the same sincerity and fidelity that yielded the sparkling precision of Pre-Raphaelite landscape. Their earnest pursuit of truth, whether in depicting painful social realities or concentrating on the foreground blades of grass in a landscape, entailed a denial of many orthodox artistic pleasures. Together with Ford Madox Brown, the Pre-Raphaelites sustained the devotion to colour and light in painting that underlies the finest endeavours of English Romanticism.

Germany. In Germany also there was a reaction against classicism and the academies, and, as elsewhere, it involved all aspects of the arts. Again, as elsewhere, theory preceded practice: *Herzensergiessungen eines kunstliebenden Klosterbruders* ("Effusions of an Art-Loving Monk"), by Wilhelm Heinrich Wackenroder, had an immediate and widespread influence upon its publication in 1797. Wackenroder advocated a Christian art closely related to the art of the early German masters and provided the artist with a new role as interpreter of divine inspiration through his own feelings.

The painter Philipp Otto Runge had been reared on 17th-century German mysticism, and he proved susceptible to the ideas of writers such as Wackenroder when introduced to them in Dresden at the very end of the 18th century. In Dresden he formed a close association with the leading German landscape painter Caspar David Friedrich (Plate 21). Like Friedrich he was fascinated by the potential symbolic and allegorical power of landscape, which he used as a vehicle for religious expression. His vision of nature was pantheistic (as was Friedrich's), and in his portraits his aim was to capture the soul of the individual as part of the universal soul of nature. "The Artist's Parents and Children" (1806; Hamburger Kunsthalle, Hamburg) reflects not only his constant search for truth but also his admiration for the early German masters, through whose work he was made aware of the expressive power of line and colour. His interest in the German past, including folklore and fairy tales, was reflected in a bizarre fairylike quality in much of his work (e.g., "Night," 1803), and it was this quality that was taken up and popularized by his two most important followers, Moritz von Schwind and Adrian Ludwig Richter, in whose hand the intensity of the first generation declined into popular genre paintings (usually small pictures depicting everyday life, as opposed to some idealized existence) and the comfortable Romanticism of the Biedermeier period (1815–48).

Friedrich was a deeply religious man whose vision demanded complete subjection to the spirit of God in nature; in suggesting through landscape the eternal presence of the Creator, he intended to induce in the beholder a state of religious awe. Among his pupils was Carl Gustav Carus, a physician, philosopher, and self-taught painter, whose chief contribution was as a theorist; *Neun Briefe über Landschaftsmalerei* (1831; "Nine Letters on Landscape Painting") elucidates and expands the ideas of Friedrich, adding Carus' own more-scientific approach to natural phenomena. Also influenced by Friedrich were Ernst Fer-

dinand Oehme, a landscape painter, and Georg Friedrich Kersting, who captured in his stark interiors something of the master's atmosphere of silent worship. Two other pupils of Friedrich subsequently abandoned tragic landscapes; one, the Norwegian Johan Christian Dahl, reverted to naturalism; the other, Karl Blechen, joined the Romantic realists.

Whereas Runge, Friedrich, and their followers interpreted Wackenroder in a highly personal way, others were inspired to communal activity. A number of young painters in Vienna founded in 1809 a group they called the Guild of St. Luke. The founding members were Johann Friedrich Overbeck (their leader), Franz Pforr, Joseph Wintergerst, Joseph Sutter, and Georg Ludwig Vogel. In 1810 they moved to Rome, where they were soon joined by Peter von Cornelius, Julius Schnorr von Carolsfeld, Friedrich Olivier, the brothers Philipp and Johannes Veit, Wilhelm von Schadow, Johann Evangelist Scheffer von Leonhartshoff, and Josef von Führich. Their semi-monastic existence occasioned the nickname Nazarenes.

The Guild of St. Luke

In general, their highest aspirations—toward monumental history painting—produced the least successful results, and they came closest to realizing their intentions on a small scale in highly finished watercolours and drawings, as in Overbeck's "The Raising of Jairus' Daughter" (1814). Only Joseph Anton Koch and Cornelius, who were both older and more experienced, achieved great vigour in their history paintings, combining medievalizing tendencies with the powerful classicism of Carstens (see above *Neoclassicism: Germany and Austria*), as seen in Cornelius' "The Recognition of Joseph by His Brethren" (1815–16; National Gallery, West Berlin). Even Overbeck, an articulate leader and a lucid draftsman, could not escape, in his "Joseph Being Sold by His Brethren" (1816–17; National Gallery, West Berlin), the self-conscious naïveté common to many of the Nazarenes. This naïveté is also noticeable in Pforr's "The Entry of the Emperor Rudolf of Habsburg into Basel in 1273" (c. 1809; Städtisches Kunstinstitut, Frankfurt am Main) and Schnorr's "The Procession of the Three Magi" (1819; Museum of Fine Art, Leipzig). Alfred Rethel, a late arrival, however, manages to avoid such an effect in his haunting "King David with His Harp" (c. 1831; Museum of Art, Düsseldorf). Not long afterward there was a move toward the more dramatic, though no less nostalgic, approach of von Schadow and his pupil Karl Friedrich Lessing.

Portraiture required less self-consciousness than history painting, and there are a number of highly sensitive portraits, mainly of their friends, by Overbeck, Schnorr, Scheffer von Leonardshoff, and Carl Philipp Fohr ("Portrait of Wilhelm von Schadow" [1818; Museum of the Palatinate, Heidelberg]). The Nazarenes' greatest contribution, however, was to landscape painting: inspired by the heroic landscapes of Koch (e.g., "Bernese Oberland" [1816; Gallery of Modern Paintings, Staatliche Kunstsammlungen Dresden]), by the German "primitives," and by their own concept of truth to nature, they renounced the conventional Italianate solution and turned instead to the countryside around them and to memories of Germany and German painting. As the movement gathered momentum, the possibilities for development expanded, and the Nazarene landscape was valuable to later painters of the Biedermeier period and to painters of naturalistic landscape, Romantic realism, and secular historical subjects.

France. The French Revolution greatly stimulated interest in the depiction of contemporary events, although richly documented and highly detailed paintings of topical patriotic events were being painted in London by West and John Singleton Copley even before the Revolution. Encouraged by David's example, however, painters in France sought to represent authentically the crucial moments of their own time. Napoleon I enthusiastically endorsed this awareness of modern heroism and demanded pictorial celebration of the glorious achievements of the empire. David recorded the ceremonies of the imperial court with scrupulous precision. Napoleon's potent hold on the artistic imagination is well illustrated by Gros's "Napoleon Visiting the Pesthouse at Jaffa" (1804; Louvre), where he

Depiction of contemporary events

"Aurora," ceiling fresco by Guido Reni, 1613–14. In the Casino Rospigliosi, Rome.

Baroque painting in Italy

"View of the Lagoon," oil painting by Francesco Guardi (1712–93). In the Museo di Castelvecchio, Verona, Italy. 33 × 51 cm.

"The Conversion of St. Paul," oil painting by Caravaggio (1573–1610). In Sta. Maria del Popolo, Rome. 2.3 × 1.8 m.

"The Triumph of the Name of Jesus," ceiling fresco by Giovanni Battista Gaulli (Baciccio), 1674–79. In the Gesù, Rome.

"Young Woman with a Water Jug," oil painting by Jan Vermeer, c. 1658-60. In the Metropolitan Museum of Art, New York City. 46 × 41 cm.

"Still Life," oil on wood by Willem Claesz Heda, 1634. In the Museum Boymans-van Beuningen, Rotterdam. 43 × 57 cm.

"The Rape of the Daughters of Leucippus," oil painting by Peter Paul Rubens, 1617. In the Alte Pinakothek, Munich. 2.2 × 2.1 m.

"The Smokers," oil on wood by Adriaen Brouwer, c. 1630. In the Metropolitan Museum of Art, New York City. 46 × 38 cm.

"Waterfall," oil painting by Jacob van Ruisdael, c. 1670? In the Uffizi, Florence. 52.3 × 61.7 cm.

"Calling of St. Matthew," oil painting by Hendrik Terbrugghen, c. 1617. In the Centraal Museum, Utrecht, The Netherlands. 1 × 1.4 m.

"Portrait of Charles I Hunting," oil painting by Sir Anthony Van Dyck, 1635. In the Louvre, Paris. 2.8 × 2.2 m.

"Gypsy Girl," oil on wood by Frans Hals, c. 1628–30. In the Louvre, Paris. 57.8 × 52.1 cm.

Baroque painting in the Low Countries

"Jacob Blessing the Sons of Joseph," oil painting by Rembrandt, 1656. In the Staatliche Kunstsammlungen, Kassel, West Germany. 1.8 × 2.1 m.

"La Partie Quarrée," oil painting by Antoine Watteau, 1713-14. In the collections of the Fine Arts Museums of San Francisco. 50 × 65.2 cm.

"Cupid a Captive," oil painting by François Boucher, 1754. In the Wallace Collection, London. 1.7 m × 85 cm.

"St. John on Patmos," oil painting by Nicolas Poussin, 1645-50. In the Art Institute of Chicago. 1 × 1.4 m.

"The Lamentation over St. Sebastian," oil painting by Georges de La Tour, 1645. In the Staatliche Museen Preussischer Kulturbesitz, West Berlin. 1.6 × 1.3 m.

"The Embarkation of the Queen of Sheba," oil painting by Claude Lorrain, 1648. In the National Gallery, London. 1.5 × 1.9 m.

"Mrs. Sheridan," oil painting by Thomas Gainsborough, c. 1785. In the National Gallery of Art, Washington, D.C. 2.2 × 1.5 m.

"The Countess's Morning Levée," oil painting, part of the "Marriage à la Mode" series, by William Hogarth, 1743-45. In the National Gallery, London. 69 × 90 cm.

Baroque painting in France and Britain

"Family of Country People," oil painting by Louis Le Nain, c. 1640. In the Louvre, Paris. 1.1 × 1.6 m.

"The Grace," oil painting by J.-B.-S. Chardin, 1740. In the Louvre, Paris. 48 × 40 cm.

"The Holy House of Nazareth," oil painting by Francisco de Zurbarán, c. 1630. In the Cleveland Museum of Art. 1.7 × 2.2 m.

Baroque painting in Spain

"Infanta Margarita," oil painting by Diego Velázquez, 1660. In the Prado, Madrid. 2.2 × 1.5 m.

"Boys Eating Grapes and Melon," oil painting by Bartolomé Esteban Murillo, c. 1650. In the Alte Pinakothek, Munich. 1.5 × 1 m.

"The Martyrdom of St. Bartholomew," oil painting by José de Ribera, 1630/39. In the Prado, Madrid. 2.4 × 2.4 m.

"Pity," colour print finished in pen and watercolour by William Blake, 1795. In the Tate Gallery, London. 44 × 55 cm.

"Valpinçon Bather," oil painting by Jean-Auguste-Dominique Ingres, 1808. In the Louvre, Paris. 1.4 m × 99 cm.

"Goethe in the Campagna," oil painting by Johann Heinrich Wilhelm Tischbein, 1787. In the Städelisches Kunstinstitut, Frankfurt am Main, Germany. 1.6 × 2 m.

Neoclassical and early Romantic painting

"Oath of the Horatii," oil painting by Jacques-Louis David, 1784. In the Louvre, Paris. 4.3 × 3.4 m.

"Boatbuilding near Flatford Mill," oil painting by John Constable, 1815. In the Victoria and Albert Museum, London. 50.8 × 61.6 cm.

"The Third-Class Carriage," oil painting by Honoré Daumier, c. 1862. In the Metropolitan Museum of Art, New York City. 65 × 90 cm.

"The Death of Sardanapalus," oil painting by Eugène Delacroix, 1827. In the Louvre, Paris. 3.7 × 4.9 m.

"Souvenir de Mortefontaine," oil painting by Camille Corot, 1864. In the Louvre, Paris. 64 × 90 cm.

Romantic
and Realist painting

"The Raft of the Medusa," oil painting by Théodore Géricault, c. 1819. In the Louvre, Paris. 5 × 7.2 m.

"Man and Woman Gazing at the Moon," oil painting by Caspar David Friedrich, c. 1824. In the Nationalgalerie, West Berlin. 34 × 44 cm.

"The Gross Clinic," oil painting by Thomas Eakins, 1875. In the Jefferson Medical College, Thomas Jefferson University, Philadelphia. 2 × 2.5 m.

"Snow Storm—Steam-Boat off a Harbour's Mouth . . .," oil painting by J.M.W. Turner, 1842. In the Tate Gallery, London. 92 cm × 1.1 m.

"The Starry Night," oil painting by Vincent van Gogh, 1889. In the Museum of Modern Art, New York City. 74 × 92 cm.

**Impressionism,
Postimpressionism,
and Art Nouveau**

"Mont Sainte-Victoire," oil painting by Paul Cézanne, 1904. In the Philadelphia Museum of Art. 72 × 93 cm.

"The Kiss," oil painting by Gustav Klimt, 1908. In the Österreichische Galerie, Vienna. 1.8 × 1.8 m.

"Sunday Afternoon on the Island of La Grande Jatte," by Georges Seurat, 1884–86. In the Art Institute of Chicago. 2.1 × 3.1 m.

"Impression: Sunrise," oil painting by Claude Monet, 1872. In the Marmottan Museum, Paris. 50 × 67 cm.

"The Cry," oil and tempera on wood by Edvard Munch, 1893. In the Nasjonalgalleriet, Oslo. 91 × 74 cm.

"Le Moulin de la galette," oil painting by Pierre-Auguste Renoir, 1876. In the Louvre, Paris. 1.3 × 1.8 m.

"Te Rerioa" ("The Dream"), oil painting by Paul Gauguin, 1897. In the Courtauld Institute Galleries, London. 96 cm × 1.3 m.

is endowed with godlike authority and the humanitarian sensibility of the true Romantic hero. At the same time, other artists—such as Gérard, Girodet-Trioson, and Ingres—readily responded to the Emperor's admiration for the stories of Ossian. After the fall of Napoleon few were disposed to depict contemporary subjects. Théodore Géricault was something of an exception, but he was separated from his immediate predecessors both by temperament and by the sincerity of his approach. Individual suffering rather than collective drama is vividly portrayed in "The Raft of the Medusa" (c. 1819; Louvre; Plate 21). This, Géricault's masterpiece, echoes in its strenuous forms the school of Caravaggio in the 17th century. His studies of the poor, aged, and insane are realistically observed and have a sympathetic intensity unmatched before the generation of Honoré Daumier and Gustave Courbet.

The paintings of Delacroix frequently disrupted the salons of the 1820s and '30s with their tumultuous colour and emotive energy. To many young men after 1815, France appeared to settle into a bourgeois respectability that implicitly disparaged the exhilarating years of the republic and the empire. In consequence, the art of the period often seems melancholic and introverted, the discontent expressing itself in historical and exotic themes or in a passionate concern with the humble and rejected members of society. Delacroix has justly been acclaimed the leader of the Romantic school in France. His fertile imagination, embracing a novel range of literary and historical themes and fastening with a characteristic sense of the sadness of life on moments of death, defeat, and suffering, together with his prodigious technical resources exemplify Romanticism in its most obvious aspects. His vigorous handling of paint and expert use of colour values for both description and expression were important for the later development of French painting. "The Massacre at Chios" (1824; Louvre) transposes contemporary events into a realm of tragic fiction soon established unrestrainedly with such melodramatic works as "The Death of Sardanapalus" (1827; Louvre), a riot of brilliant colour and ebullient forms (Plate 20).

Exoticism
of setting

Delacroix's Moroccan paintings released a flood of North African subjects, although, in the hands of lesser artists—such as Eugène Fromentin, Ary Scheffer, and Eugène Delvère—the treatment is less effective. Alexandre-Gabriel Decamps, whose small canvases have a delicate, jewellike quality, provided the most refreshing variations on the theme. But Delacroix was not the first to handle Oriental subjects; Ingres had already done so with a reticence that belies the sensuous delight in "Valpinçon Bather" (1808; Louvre; Plate 19) and in "La Grande Odalisque" (1814; Louvre). Early in his career Ingres made notable contributions to the historical genre with episodes from medieval French history painted in a style of linear purity that parallels the methods of Flaxman and Blake in Britain and the Nazarenes in Germany. Under the spell of Raphael he returned to the academic fold, but his portraits always retained that trenchant simplicity and lucid insight that make him such a memorable exponent of lyric realism. The career of Ingres and in a converse sense that of Paul Delaroche well illustrate the imprudence of too readily distinguishing between academic and Romantic artists. Delaroche, perhaps the most popular representative of the Romantic school, specialized in highly charged narratives with royal and child characters, of which "The Children of Edward" (c. 1830; Louvre) is a typical example, being executed with a flatness that lacks either linear or colouristic inspiration. In comparison, the work of Théodore Chassériau is animated by powerful emotional overtones reminiscent of Delacroix. "The Cossack Girl Finding the Body of Mazeppa" (1851; Museum of Fine Art, Strasbourg) shows a similarly expressive use of paint, together with poignant imagery, both characteristic of his regretably slender oeuvre. At the end of the century, Gustave Moreau and Odilon Redon transformed these features, along with others in Louis Boulanger's work, into whimsical, haunting fantasies that delighted the Symbolist poets.

In the 1830s and '40s it was Honoré Daumier, more than any other artist, who portrayed relatively lowly members of society, expressing in numerous drawings and paint-

ings their patient resignation (Plate 20). In contrast, his truly excoriating depiction of the weaknesses and vices of the privileged classes, particularly officialdom, often displeased authority, which had long identified Romanticism with liberalism—and with good reason. A strain of poetic realism in the 1840s, essentially Romantic in approach, gathered sudden momentum with the Revolution and short-lived republic of 1848. Jean-François Millet and Gustave Courbet depicted peasant life, investing it with a certain timeless quality. Courbet's "Stone-Breakers" (1849; destroyed during World War II) and Millet's harrowing "Quarriers" (c. 1847; Toledo Museum of Art, Ohio) powerfully express their creators' concern for the poor. Courbet created a sombre monument to his own village in "Burial at Ornans" (1849; Louvre), and Millet succeeded in conferring an epic grandeur on scenes of rural life.

Strain of
poetic
realism

A new approach to the familiar and unsophisticated occurs in the landscape painting of the 1830s and '40s; for, although French Romanticism produced no Turner, it did give rise to the Barbizon school, a group of naturalist painters who were particularly active in the forest of Fontainebleau. In this period the charm of the spontaneous sketch as opposed to the finished study was recognized: painters readily set up their easels in the open air and scrutinized the scene before them. A direct approach to nature and an interest in transitory moments, especially the changing effects of light, were features common to Romantic landscape painters throughout Europe and the United States. Paul Huet, a friend of Delacroix and Bonington and a painter closely associated with the Romantic school, represented dramatic, stormy scenes of solitude; yet, though scarcely a naturalist, he was deeply impressed by the works of Constable, several of which he copied and which inspired him to adopt a broken style of brushwork with dabs of bright pigment. The changed attitude to landscape is aptly expressed in the words of Théodore Rousseau, the most controversial representative of the new school: "Our art can only attain pathos through sincerity." Rousseau attempted to render nature as he found it, though his melancholic temperament is inevitably reflected in the desolate panoramas and gloomy sunsets in which he expressed an almost pantheistic feeling for the natural world. At the same time, his close attention to detail and painstaking accuracy in the delineation of plants and grasses betray the scientific concern shared by many Romantic artists. A similar penetration informed his studies of light, and both he and Charles-François Daubigny repeated virtually the same subjects under different weather conditions in order to capture the ephemeral effects of light and atmosphere. The freedom and freshness of Constable's handling is echoed in Daubigny's flickering treatment of sunset and light over water. A particularly poetic insight into nature was that of Narcisse-Virgile Diaz de La Peña and Constant Troyon. The work of Camille Corot, despite the restrained classicism of his style, is similarly enlivened by an instinctive feeling for naturalistic landscape (Plate 20). For, while they laid the foundation for the painterly revolution of the Impressionists, the Barbizon painters always retained the generous appreciation of natural beauty and emotional involvement with their subject that everywhere distinguish the Romantic temperament.

Barbizon
school

United States. American Romantic painters were largely influenced by trends in late 18th-century Europe, especially Britain, but the absence of an indigenous artistic tradition permitted a much more intuitive development. At the same time, their work, like that of the early French Romantics, is closely associated with the new spirit fostered by a national revolution. The American Revolution, by reinforcing the democratic ideal, inspired a unique brand of Romantic realism that was a strong force in American painting from the late 18th century onward and that anticipated the emergence in Europe by a whole generation. Benjamin West, in addition to his contribution to Neoclassicism, developed a style of narrative painting with dramatic subjects taken from contemporary life; while he painted his most significant work in Britain, it was on American rather than English artists that it made the most impact. John Trumbull undertook a series of 12 scenes

realism

from the American Revolution, in which careful studies of the principal participants were incorporated into colourful, baroque compositions. At their best, these works, for example "Sortie from Gibraltar" (1789; Museum of Fine Arts, Boston), carry great conviction, even if they tend to be somewhat theatrical. In 1784 one of the most candid portraitists of the period, Charles Willson Peale, completed a similarly ambitious project in his paintings of the leading figures of the Revolution. A more limited enthusiasm for precise naturalistic study informs the work of Alexander Wilson, whose devoted love of birds emerges in the freshness and simplicity of the plates to his *American Ornithology* (9 volumes; 1808–14). His achievement has been overshadowed by his greater successor, John James Audubon, who combined scientific precision with a delight in his specimens that transforms his watercolour drawings of birds into works of rare and delicate beauty.

Develop-
ment of an
American
style of
portraiture

At the beginning of the Romantic period, artists were still influenced by British painting, but this influence grew less and less perceptible as the 19th century progressed. For instance, the portrait of "Colonel Thomas Handasyd Perkins" (1831–32; Boston Athenaeum), by Thomas Sully, the leading exponent of a new portraiture supposedly expressive of mood, has touches of Sir Thomas Lawrence in the delicately brushed surface, strong contrasts of light and dark, and exquisite elegance of pose. But though Samuel F.B. Morse, Samuel Waldo, William Page, and others also practiced an emotive style, portraits of the 19th century increasingly tended to endorse the native tradition of solid characterization.

The career of the landscape painter Washington Allston reflects the development of American painting in his lifetime. Absorbed by German and English Romantic poetry, he began on a note of high drama, moving in cosmopolitan artistic circles in Rome and producing a number of early landscapes that seem to have played a part in winning the friendship of the English Romantic poet Samuel Taylor Coleridge. At this point, what was obviously an impetuous and brooding strain in Allston's temperament found expression by depicting nature in the darker, more destructive moods dear to Turner. "The Deluge" (1804; Metropolitan Museum of Art, New York City) is a typical macabre invention, with bodies in a raging tempest swept ashore to where wolves and serpents lurk. On his return to the United States, however, his work assumed a quieter, more pensive aspect. "The Flight of Florimell" (1819; Detroit Institute of Arts) illustrates this later style.

An uncomplicated love for their own natural scenery emerges in the work of a succession of landscape painters who frequently strike a contemplative, lyrical note. Thomas Cole reverently recorded scenes in the valley of the Hudson River that echo the loneliness and mystery of the North American forests. With his generous humanitarian sympathies, Asher B. Durand gave a serene and artless account of nature. His feeling for space and finely diffused light renders "Kindred Spirits" (1849; New York Public Library) a touching tribute to the friendship of Cole with the American Romantic poet William Cullen Bryant. An interest in light and atmosphere was shared by George Loring Brown, FitzHugh Lane, Frederick Edwin Church, and George Harvey; all followed Durand and painted in the open. Simplicity and reticence distinguish the landscapes of Thomas Doughty, who concentrated on painting the Hudson River valley as he knew and loved it. The details of country life that fill the stories of Washington Irving are portrayed with affection by William Sidney Mount, who in "Eel Spearing at Setanket" (1845; New York State Historical Association, New York City) transcends the merely anecdotal. George Caleb Bingham approached the life of the frontier without the passionate concern that motivated many contemporary French artists. Solemn and severe in style and glowing with colour, his "Fur Traders Descending the Missouri" (c. 1845; Metropolitan Museum of Art) captures the silence and solitary grandeur of frontier life. The wildness of the frontier caught the imagination of many 19th-century artists: George Catlin, Seth Eastman, John M. Stanley, Alfred Jacob Miller, and Karl Bodmer all discovered a picturesque drama and excitement in Indian life. The Romantic period witnessed the emergence

Painters of
the frontier

of a truly national school of painting in the United States, where events and scenery provided a constant source of stimulation for artists content to distill their own poetry from the world around them. (S.E.B./Ed.)

Russia. Napoleon's invasion of Russia (1812) had far-reaching consequences. It marked the revival of national consciousness and the beginning of a widespread cult of Russian separateness from Europe, thus precipitating the long controversy between "Westerners" and "Slavophiles" that ran through so much of Russian 19th-century literature and thought. At the same time, Russia shared in the Romanticism that during the era of the Napoleonic Wars gripped Europe in the shape of France and Germany. This is reflected in the paintings of Orest Kiprensky and Vasily Tropinin. The most notable contribution to the Romantic spirit, however, was made by Karl Pavlovich Bryullov, with his monumental painting "The Last Days of Pompeii" (1830–33; State Russian Museum, Leningrad). A completely different trend appears in the work of Aleksandr Ivanov, the first Russian painter to express religious emotions in a western European manner. Other outstanding artists of that period were Aleksey Venetsianov and Pavel Fedotov, the forerunners of Realist painting in Russia.

The second half of the 19th century saw the maturing of Realism in Russia. A sympathetic attitude toward the hard life of the people is reflected in the works of most of the painters and sculptors of that time. The new trend in art had as its basis the populist revolutionary ferment prevalent toward the end of the 1850s and the beginning of the 1860s, much of it inspired by the writers Nikolay Dobrolyubov and Nikolay Chernyshevsky. Chernyshevsky's dissertation *Esteticheskiye otnosheniya iskusstva k deystvitel'nosti* (1855; "The Aesthetic Relations of Art to Reality"), the main thesis of which was that art must not only reflect reality but also explain and judge it, provided a starting point for contemporary artists.

From the last third of the 19th century onward, the history of Russian art is the history of a series of school struggles: the Slavophiles against the Westerners; the Academy against the Peredvizhniki ("Wanderers"); and later the joint effort of the last two against a new movement, born in the 1890s and directed by the art review *Mir Iskusstva* ("The World of Art").

The Peredvizhniki was a society formed in 1870 by a group of essentially Romantic artists who, however, regarded themselves as Realists. They seceded from the Academy in 1863 in protest against alien dogmatic formulas and the constricting programs of the Academy's annual competitions. Most prominent among the Peredvizhniki were Ivan Kramskoy, Ilya Repin, Vasily Ivanovich Surikov, Vasily Perov, and Vasily Vereshchagin. The society attached far more importance to the moral and literary aspects of art than to aesthetics. Its artistic creed was realism, national feeling, and social consciousness. Art was to be placed at the service of humanitarian and social ideals; it was to be brought to the people. Accordingly the society organized mobile (*peredvizheniye*) exhibitions—hence the name.

The Pere-
dvizhniki
society

The influence of the Peredvizhniki spread throughout Russia and was dominant for nearly 30 years. But, by the end of the century it had greatly declined. (A.Vo./Ed.)

Modern

The term modern art has come to denote the innovating and even revolutionary developments in Western painting and the other visual arts since the second half of the 19th century. It embraces a wide variety of movements, styles, theories, and attitudes, the modernity of which resides in a common tendency to repudiate past conventions and precedents in subject matter, mode of depiction, and painting technique alike. Not all the painting of this period has made such a departure; representational work, for example, has continued to appear, particularly in connection with official exhibiting societies. Nevertheless, the idea that some current types of painting are more properly of their time than others, and for that reason are more interesting or important, applies with particular force to the painting of the last 150 years.

By the mid-19th century, painting was no longer basically in service to either the church or the court but rather was patronized by the upper and middle classes of an increasingly materialistic and secularized Western society. This society was undergoing rapid change due to the growth of science and technology, industrialization, urbanization, and the fundamental questioning of received religious dogmas. Painters were thus confronted with the need to reject traditional, historical, or academic forms and conventions in an effort to create an art that would better reflect the changed social, material, and intellectual conditions of emerging modern life. Another important, if indirect, stimulus to change was the development from the early 19th century on of photography and other photomechanical techniques, which freed (or deprived) painting and drawing of their hitherto cardinal roles as the only available means of accurately depicting the visual world. These manually executed arts were thus no longer obliged to serve as the means of recording and disseminating information that they once had been and were eventually freed to explore aesthetically the basic visual elements of line, colour, tone, and composition in a nonrepresentational context. Indeed, an important trend in modern painting has been that of abstraction—i.e., painting in which little or no attempt is made to accurately depict the appearance or form of objects in the realm of nature or the existing physical world. The door of the objective world was thus closed, but the inner world of the imagination offered seemingly infinite possibilities for exploration, as did the manipulation of pigments on a flat surface for their purely intrinsic visual or aesthetic appeal.

The beginnings of modern painting cannot be clearly demarcated, but it is generally agreed that it started in mid-19th-century France. The paintings of Gustav Courbet, Edouard Manet, and the Impressionists represent a deepening rejection of the prevailing academic traditions of Neoclassicism and Romanticism and a quest for a more truthful naturalistic representation of the visual world. These painters' Postimpressionist successors—notably Paul Cézanne, Vincent van Gogh, Edgar Degas, and Paul Gauguin—can be viewed as more clearly modern in their repudiation of traditional subject matter and techniques and in their assumption of a more subjective and personal vision. From about the 1890s a succession of varied styles and movements arose that are the core of modern painting and are also one of the high points of the history of the Western visual arts in general. These modern movements include Neo-Impressionism, Symbolism, the Nabis, Fauvism, Cubism, Expressionism, Futurism, the Ashcan School, Suprematism, Constructivism, Orphism, Metaphysical painting, de Stijl, Purism, Dada, Surrealism, Social Realism, Abstract Expressionism, Pop Art, Op Art, Minimalism, and Neo-Expressionism. (F.W.W.-S./Ed.)

ORIGINS IN THE 19TH CENTURY

As long ago as 1846 the qualities proper to a specifically modern art were discussed by the French writer Charles Baudelaire in an essay on the French Salon. He argued that colour would be foremost among these modern qualities (a prediction that subsequent events confirmed), but he still saw the new art in the context of the Romantic movement. Subsequent modernity came to be seen as necessitating not only a new style but also contemporary subject matter, and in 1863 Baudelaire praised the draftsman Constantin Guys as "le peintre de la vie moderne" ("the painter of modern life"). In 1862, with Baudelaire's support, the French painter Édouard Manet brought together a subject from contemporary social life and an unconventional style in "Concert in the Tuileries Gardens" (National Gallery, London). This painting, though rather isolated in his work of the time, was influential in establishing a new outlook. Another literary figure whose critical writings were influential was the French novelist Émile Zola, though Zola had limited sympathy for what he called the "new manner in painting" of Manet; nevertheless he contributed from 1866 onward to the emergence of the Impressionist group. The first appearance of the phrase "modern art" in the relatively permanent form of a book title was in 1883, when it was used by the French

writer Joris-Karl Huysmans, a friend of Zola's, to describe the theme of various reviews of painters' work he had collected. Other books on the subject followed, such as the Anglo-Irish novelist George Moore's *Modern Painting* (1893). It was about this time that the term *avant-garde* was introduced by the critic Théodore Duret, who used it of certain young painters. From then on, modernity was to be a recurrent concern of artists and critics. Public acceptance of the new standpoint was slow, however. The first museums dedicated specifically to modern art grew out of the fervour of individual collectors—e.g., the Folkwang Museum at Essen, W.Ger., and the Kröller-Müller State Museum at Otterlo, Neth., both largely consisting of collections built up before 1914. The Museum of Modern Art in New York City, the outstanding public collection in the field, was founded in 1929, and the Western capital that lacks a museum explicitly devoted to modern art is rare.

The conflict between the new forces and the established academic tradition in France came into the open in 1863. The jury of the official Salon, which had long exercised great despotism in matters to do with painting, rejected more than 4,000 canvases—an unusually high figure. The resulting outcry prompted the emperor Napoleon III to order that the rejected works, if the painters agreed, be shown in a special exhibition known as the Salon des Refusés. The exhibition included works by Manet; Johan Barthold Jongkind, an older Dutch painter who was working in a tonal and summary style from nature; Camille Pissarro and Paul Cézanne, who had met two years before at the Académie Suisse; Armand Guillaumin; James McNeill Whistler; and others. One of the greatest scandals was caused by Manet's painting "The Luncheon on the Grass" (Louvre, Paris), which was considered an affront to decency as well as taste. The younger painters became aware of their common aims. Claude Monet, whose landscape style had been influenced from the outset by the atmospheric sketches of the Channel coast of Eugène Boudin, as well as by Jongkind (whom he described to Boudin, as "quite mad"), had met Pierre-Auguste Renoir, Alfred Sisley, and Jean-Frédéric Bazille studying in the studio of Charles Gleyre. Abandoning academic study, they worked together outdoors in the forest of Fontainebleau, where contacts with the Barbizon painters Narcisse-Virgile Diaz de La Peña and Charles-François Daubigny strengthened their direction.

The implicit acceptance of the visual scene on which the new style was based owed something to the example of Courbet, who influenced Renoir in particular in the next few years. The *plein air* ("open-air") paintings of the Barbizon painters also had an effect, but the suggestion of an art based on the notation of pure colour was suggested by several sources. The example of Eugène Delacroix had a deep significance for the 19th century in France, and the reliance on separate, undisguised touches of the brush in the form that became characteristic of Impressionism is perhaps first apparent in sketches of the sea at Dieppe painted by Delacroix in 1852. The economy of Manet's touch in the 1860s was affected by Spanish and Dutch examples as well as by Delacroix, but his seascapes and racecourse pictures of 1864 are also important. The full Impressionistic style did not develop until the end of the 1860s.

Though the figurative aims of Impressionism can be regarded as the conclusion of 19th-century Realism, the method, which made no attempt to hide even the most basic means of preparing a finished painting, was an original one. Brushstrokes did not pretend to be anything but dashes of paint, thus conveying their coloured message without any disguise or effect at individual illusion. It was in this respect and in the all-embracing unity of colour and handling that resulted, rather than its realism, that Impressionism founded modern painting. Other developments in the 1860s had no immediate sequels in Impressionism. The presentation of some of Manet's figures, such as "The Fifer" (Louvre) of 1866, as vignettes or decorative designs shading into virtually blank backgrounds was a radical departure from the coherent pictorial construction of Western tradition since the Renaissance; it is the first

sign of the form built outward from a central nucleus without reference to the classic frame that has appeared repeatedly in modern art. Honoré Daumier is supposed to have said that "The Fifer" reduced painting "to faces on playing cards," and in 1865 Courbet compared Manet's "Olympia" (1863; Louvre) to "the Queen of Spades after a bath." The possibility of making an image out of the bare, almost heraldic juxtaposition of flat colours was neglected while the complex notation of Impressionism held sway, but it came to be regarded with interest as Impressionism receded. Other unconventional principles of design—suggested equally by Japanese prints, such as those that Manet placed in the background of his portrait of Zola (Louvre) in 1868, and by the chance arrangements of photography—appeared in the work of Edgar Degas, who sympathized with the aims of the new group, associating himself with them in seven of their eight exhibitions, which he largely helped to organize.

Other qualities that Baudelaire in 1846 had specified as the qualities of modern art—spirituality and aspiration toward the infinite—evolved quite apart from Impressionism. The visionary implications of Romantic painting were explored by Gustave Moreau, whose elaborate biblical and mythological scenes, weighed down with sumptuous detail, gave colour an imaginative and symbolic richness. His example had a special value to the next generation. The imagination of Pierre Puvis de Chavannes was of the opposite order, preserving the large-scale clarity of mural painting, a policy that made him appreciated when a reaction against Impressionism set in.

Another possibility of Romanticism was pursued in isolation by the Marseille painter Adolphe Monticelli. The richness of his colour is thought to have contributed something crucial to Cézanne's development. The counterpart of Moreau in Britain was Sir Edward Burne-Jones. The intricate and perverse linear formulations that he developed from the Pre-Raphaelites greatly influenced the international Symbolist style of the last decades of the century.

The influence of the trend in the direction of the modern in France, together with its controversial element, was introduced to Britain by Whistler, whose concern was narrowly aesthetic rather than analytic. The harmonies he developed were close to being monochromatic; his use of Spanish and Japanese elements had little of the radical originality of Manet and Degas. His influence dominated and also limited the development of avant-garde painting in Britain for many years. John Singer Sargent, like Whistler an American who came to live in Britain, popularized a less-discriminating version of the Impressionistic style.

In Germany a Romantic strain coexisted with a Realistic style that remained unaffected by the most advanced French painting. Anselm Feuerbach, one of the Romantics, was influenced by Delacroix. In 1855 he went to Italy where the effect of the 16th century came to predominate in his work. The landscapes of Hans von Marées were also essentially Romantic. He had visited France but spent most of his working life in Italy; the frescoes he executed in Naples echo Puvis de Chavannes in their style. Realism found exponents in Wilhelm Leibl and Hans Thoma. In Italy the reaction against the academies was centred in Florence, where a group known as the *Macchiaioli* (from *macchia*, "patch") worked from 1855, producing landscapes, genre paintings, and Romantic costume pieces executed in the highly visible brushstrokes that gave the group its name.

In the United States, Thomas Eakins developed a broadly handled, powerful Realist style that became almost Expressionistic in his later years (Plate 21). He had visited Paris in 1866, and the influence of Manet can be detected in his paintings. His interest in anatomy and perspective gave him a role analogous to that of Degas. The early development of Winslow Homer, who was in France a year later, ran parallel to Monet's style in the 1860s. The work of Albert Pinkham Ryder was, by contrast, introverted and visionary. He was among the artists who adapted the Romantic vocabulary to the symbolic purposes of modern art.

In France in the mid-1860s Monet produced a series of

large-scale open-air conversation pieces in which elements derived from Courbet and Manet were fused with a wholly original expression of dappled light in solid paint. The approach of Pissarro, who had arrived in Paris from the West Indies in 1855, was more delicate; influenced by Camille Corot as well as Courbet, he recorded pure landscape motives in a limited range of tones, though with a natural lyricism of feeling. The starting point of Cézanne was, by contrast, vigorous to the point of violence. In 1866 he evolved a style in which paint was applied in thick dabs with a palette knife; this combined a handling (a technical term in painting meaning the individual's manipulation of materials in the execution of a work; it has been likened to a person's signature in handwriting) derived from Courbet with the gray tonality of Manet; its rough-hewn crudity has a consistency that was essentially new. His alternative style in the 1860s, with curling brushstrokes related to Daumier, is equally virile and was often applied to subjects of violent eroticism. The unbridled force of Cézanne's early work gave the first sign of qualities that were to become characteristic of modern painting. Though exceptional, it was not unique; in Italy during the 1860s the Russian painter of historical and scriptural themes, Nikolay Nikolayevich Ge, produced sketches with loose, expressive brushwork sometimes resembling Cézanne's.

Impressionism. The first steps toward a systematic Impressionist style were taken in France in Monet's coast scenes from 1866 onward, notably the "Terrace" (1866; Metropolitan Museum of Art, New York City), in which he chose a subject that allowed use of a full palette of primary colour. The decisive development took place in 1869, when Monet and Renoir painted together at the resort of La Grenouillère on the Seine River. The resulting pictures suggest that Monet contributed the pattern of separate brushstrokes, the light tonality, and the brilliance of colour; Renoir the overall iridescence, feathery lightness of touch, and delight in the recreation of ordinary people. Working at Louveciennes from 1869, Pissarro evolved the drier and more flexible handling of crumbly paint that was also to be a common feature of Impressionist painting.

It was in the environs of Paris after the Franco-Prussian War that there developed the fully formed landscape style that remains the most popular achievement of modern painting. An exhibition held in the studio of the photographer Nadar (Gaspard-Félix Tournachon) in 1874 included Monet's picture "Impression: Sunrise" (Marmottan Museum, Paris; Plate 23), and it was this work that, by being disparaged as mere "impressionism," gave a name to an entire movement. The exhibition itself revealed three main trends. The Parisian circle around Monet and Renoir had developed the evanescent and sketchlike style the furthest. The vision of those working near Pissarro in Pontoise and Auvers was in general more solid, being firmly rooted in country scenes. A relatively urbane, genre-like trend was detectable in Degas's picture of Paul Valpinçon and his family at the races called "Carriage at the Races" (1870–73; Museum of Fine Arts, Boston) and Berthe Morisot's "The Cradle" (1873; Louvre). Manet himself was absent, hoping for academic success; his "Gare Saint-Lazare" (1873; National Gallery of Art, Washington, D.C.), influenced by the Impressionist palette, was accepted at the Salon. Modeling himself on Pissarro, Cézanne sublimated the turbulent emotions of his earlier work in pictures that were studied directly and closely from nature; he followed the method for the rest of his life.

The experiment of an independent exhibition was repeated in 1876, though with fewer participants. Monet now began to make studies of the Gare Saint-Lazare. Renoir used effects of dappled light and shadow to explore genre subjects such as "Le Moulin de la galette" (1876; Louvre; Plate 23). In 1877 only 18 artists exhibited. The major painters began to go their separate ways, particularly as there were disputes about whether to continue with the independent exhibitions. Cézanne, who did not exhibit with the Impressionists again, was perhaps the first to realize that a critical stage had been reached. For the first time, a style had been based on the openly individual character of a technique rather than on the form of a particular subject or the way it was formulated. A style that

Early developments in Britain and Germany

The beginning of modern art in the United States

The first Impressionist exhibition

admits to painting as being only a matter of paint raises in a peculiarly acute form the question of how far the qualities of art are intrinsic. Impressionism in the 1870s was inseparable from heightened visual experience of a sensuously satisfying world. But the blocklike shapes in Cézanne's pictures, such as the portrait of his patron Victor Chocquet (c. 1877; Columbus Museum of Art, Ohio), suggest that for him the relationship between the colour patches on his canvas was equally important. In the years that followed, he systematized his technique into patterns of parallel brushstrokes that gave a new significance to the pictorial surface. An unassuming series of still lifes and self-portraits by Cézanne were painted in 1879–80, and these, when they became known, profoundly impressed the younger generation, who reckoned them to be as monumental as the great art of the past, yet in a subtly different way that was inherent in the actual manner of painting.

The style of the 1870s was formless from a traditional standpoint, and at the beginning of the next decade Renoir decided that he had gone to the limit with Impressionism and "did not know either how to paint or draw." Following a trip to Italy, he set about acquiring a wiry, linear style that was the direct opposite of his relaxed, freely brushed manner of earlier years.

The appearance of a new generation posed a fresh challenge. Georges Seurat was moving away from the empirical standpoint of Impressionism toward a technique (Pointillism) and a form that were increasingly deliberately designed. Paul Gauguin, taking his starting point from Cézanne's style of about 1880, passed from a capricious personal type of Impressionism to a greater use of symbols. He exhibited with the Impressionists from 1880 onward, but it was soon evident that group shows could no longer accommodate the growing diversity. In 1884, after the Salon jury had been particularly harsh, the Société des Artistes Indépendants was formed. The last Impressionist group show was held in 1886. Only Monet and Armand Guillaumin, to whose efforts the group owed much of its eventual recognition, were now in the strict sense Impressionists. Monet, who had exhibited only once since 1879, continued to build on the original foundation of the style, the rendering of visual impression through colour in paintings that studied a single motif in varying lights. For him the formlessness and the homogeneity of Impressionism were its ultimate virtues. In his last series of "Water Lilies," painted between 1906 and 1926, the shimmering of light eventually lost its last descriptive content, and only the colour and curling movement of his brush carried a general all-pervading reference to the visual world. Renoir's later work was equally expansive; his sympathetic vision of humanity revealed its own inherent breadth and grandeur.

Impressionism, in one aspect, continued the main direction of 19th-century painting, and after 1880 the movement was an international one, taking on independent national characteristics. Russia produced an exponent in Isaak Ilich Levitan, and Scotland one in William MacTaggart. In Italy Telemarco Signorini and in the United States such painters as Childe Hassam developed modified forms of the style. In France, and to some extent in Germany with Max Liebermann, Impressionism provided a basis for the styles that followed.

Symbolism. During the decades before 1900, the Symbolists were the avant-garde, and one of quite a new kind, influencing not only the arts but also the thought and spirit of the epoch. Maurice Denis, their theoretician, enunciated in 1890 the most famous of their artistic principles:

Remember that a picture—before being a war-horse, a nude or an anecdote of some sort—is essentially a flat surface covered with colours assembled in a certain order.

Such ideas inspired a group of young painters, among whom was Denis himself, to call themselves Nabis (from the Hebrew word for "prophet"). They were in revolt against the faithfulness to nature of Impressionism; in addition, largely because they were in close touch with Symbolist writers, they regarded choice of subject as important. They included Paul Ranson, who gave the style a decorative and linear inflection; Pierre Bonnard; and Édouard Vuillard.

Other than the Nabis, one of the chief Symbolists was Odilon Redon, who moved from the same starting point as the Impressionists—the landscape style of the Barbizon school—but in precisely the opposite direction. Redon's visionary charcoal drawings (which he called his black pictures) led to successive series of lithographs that explored the evocative, irrational, and fantastic orders of creation that Impressionism excluded. Redon later wrote:

Nothing in art can be done by will alone. Everything is done by docile submission to the coming of the unconscious . . . for every act of creation, the unconscious sets us a different problem.

Redon established one of the characteristic standpoints of modern art, and his influence on the younger Symbolists was profound. In 1888 Gauguin, already affected by a trip to Martinique, settled at Pont-Aven in Brittany. The influential style he developed there was based on the juxtaposition of flat areas of colours enclosed by black contours, the total effect suggesting cloisonné enamel (a technique in which metal strips differentiate the colour areas of the design, thereby creating an outline effect), hence the name Cloisonnisme used to describe this style. The spirit in which Gauguin rendered Breton scenes was mystical. He wrote:

Do not copy nature too much. Art is an abstraction; derive this abstraction from nature while dreaming before it, but think more of creating than of the actual result.

At Pont-Aven, Gauguin was joined by Émile Bernard and Louis Anquetin, who had lately begun to work in a similar way. Paul Sérusier painted under Gauguin's direction a little sketch entitled "Bois d'amour" that appeared more independent of appearances and bolder in its synthesis of pattern than anything that had been seen before; it became known in Paris as "The Talisman." The liberation of Synthetism, as the new style was called, indeed worked like a charm, and after the Café Volpini exhibition of 1889 it spread rapidly. The movement was linked with literature and, in particular, with drama; it inspired its own periodical, *La Revue Blanche*, and *Le Théâtre de l'Oeuvre* (both founded in Paris in 1891); there were exhibitions twice a year at a Paris gallery, Le Barc de Boutteville, from 1891 to 1897.

The decorative style known as Art Nouveau, or Jugendstil, spread across Europe and the Americas in the 1890s. The pursuit of natural and organic sources for form still further alienated art from the descriptive purpose that had been the basis of figurative style, and an artistic movement without taint of historicism that molded the fine arts, architecture, and craftsmanship in a single, consistent taste recovered the creative unity that had been lost since the early 18th century. In The Netherlands the *fin de siècle* ("end of the century"; specifically the end of the 19th century, and a phrase that has overtones of a rather precious sophistication and world-weariness) style and sense of purpose appeared in the paintings of Johan Thorn Prikker and Jan Toorop. The Viennese Gustav Klimt made bolder and more arbitrary use of pattern (Plate 22). In Russia the demonic genius of Mikhail Aleksandrovich Vrubel had points of contact with the Art Nouveau style. It even affected Seurat and his circle, who were known as the Neo-Impressionists; the popular imagery of Seurat's later works, such as "The Circus" (1890–91; Louvre), was expressed in sinuous rhythms not far from Art Nouveau, and the Belgian Henry van de Velde passed from Neo-Impressionism by way of *fin de siècle* decorations that were near abstraction to a place among the founders of 20th-century architecture. A strange and beautiful blend of Symbolism with an alpine clarity of colour close to Neo-Impressionism appeared in compositions such as "The Unnatural Mothers" by the Italian Giovanni Segantini.

The end of the 19th-century tradition. Until Seurat no painter had expressly founded a style on the intrinsic reactions of colour to colour and a codified vocabulary of expressive forms. The consistent granulation of colour in Seurat's work from 1885 onward was specific to the picture, not to the sensation or the subject (Plate 22). The coherent images of space and light that he made out of this granulation ended with him. Seurat's followers, grouped as Neo-Impressionists under the leadership of Paul Signac,

Cloisonnisme

The last Impressionist exhibition

The Nabis

Neo-Impressionists

developed his technique rather than his vision. Seurat's influence was nonetheless widespread and fertile; his system in itself supplied a clarity that painters needed. It was Neo-Impressionism that was in the ascendant when the Dutch painter Vincent van Gogh arrived in Paris in 1886. The emotional travail evident in van Gogh's early work was marvelously lightened in the new aesthetic climate. But in his hands the dashes of pure colour turned and twisted, trading invisible and unstable lines of force. They were woven into rhythmical and convulsive patterns reflecting the mounting intensity of his own feelings. Such patterns converted the Neo-Impressionist style into something quite different—a forerunner of what was to be known as Expressionism (Plate 22). Other painters were less radical in their approach. Pissarro assimilated the Neo-Impressionist method to the vision of the older generation; Henri-Edmond Cross and Maximilien Luce gave it the characteristic economy of the age that followed. Henri Matisse's repeated experiments with it, culminating in his contact with Signac and Cross in 1904, finally converted the pure colour of Impressionism to the special purposes of 20th-century art.

In the meantime, the older Impressionists were producing the broadly conceived works that crowned their artistic achievement and formed, as it seems in retrospect, the great traditional masterpieces of modern art. Degas's lifelong absorption in the human body as a subject led him to produce a series of bathing scenes and drawings from the nude in which the form expanded to an amplitude that filled the picture. Fullness of form was an effect that Renoir also achieved. Cézanne announced a determination "to do Poussin over again from nature" and was reckoned to have fulfilled that aim with his "Great Bathers" and the series of landscapes of Mont Sainte-Victoire (Plate 22). In the pictures of Henri de Toulouse-Lautrec, the style and standpoint derived from Degas, but his graphic work reflected the aims of the Symbolist generation. The most original contribution of Édouard Vuillard lay in the evocative patterning of the little pictures that he painted before 1900. The art of Pierre Bonnard, on the other hand, developed throughout his life. His subjects and his method remained, on the surface, those of the Impressionist tradition, but they were re-created from memory and imagination; Bonnard's pictures have the quality of a cherished private order of experience.

Developments outside France

Developments outside France were not of comparable importance. In Britain in the 1880s, Philip Wilson Steer painted a small group of landscapes with figures that were among the earliest and loveliest examples of the fin de siècle style. The work of Walter Sickert revolved around an idiosyncratic fascination with the actual touch of a brush on canvas. His affinities remained essentially with the tonal Impressionism of the earliest stages of the modern movement rather than with the art of colour that developed from it, though he eventually made the transition in old age. In Germany the artists of the Postimpressionist generation, such as Lovis Corinth and Max Slevogt, working with the peculiar recklessness that is endemic to German painting, laid the technical foundations of Expressionism. Ferdinand Hodler in Switzerland developed a painterly Symbolist style in the 1890s. The Belgian painter James Ensor abandoned Impressionism at the end of the 1880s for a bitter and fantastic style that was a pioneer example of extreme expressive alienation.

The most remarkable painter of the fin de siècle outside France, however, was the Norwegian Edvard Munch. "The Cry" (Nasjonalgalleriet, Oslo; Plate 23), the famous picture in which the rhythms of Art Nouveau were given a hysterical expressive force with hardly a vestige of the Impressionist description of nature, was painted in 1893. For many years before a breakdown interrupted his development in 1907, he worked abroad. He was particularly influential in Germany.

In the United States, Maurice Prendergast transformed Impressionism into pattern. In Russia the fin de siècle styles of Léon Bakst and the Mir Iskusstva ("World of Art") group, as well as a vivid revival of folk decoration, flourished, later becoming known internationally through their connection with the Russian ballet.

THE 20TH CENTURY

By 1903 the impetus of Symbolism was expended and a new and enigmatic mood was forming. The new attitude drew on a vein that was comic, poetic, and fantastic, exploring an irrational quality akin to humour inherent in the creative process itself, as well as on a reserve of ironic detachment. The new painters drew strength from unexpected sources. The work of Henri Rousseau, a former clerk in the Paris municipal customs service who was known as "Le Douanier" accordingly, and who had exhibited at the Indépendants since 1886, attracted attention. The apparent innocence of his pictures gave them a kind of imaginative grandeur that seemed beyond the reach of any art founded on sophistication (Plate 25).

The art of supposedly primitive peoples had a special appeal in the early years of the 20th century. Gauguin, who had made direct contact with it in his last years, proved prophetic not only in the forms he adopted but in the spirit of his approach (Plate 23). Maurice de Vlaminck and André Derain, who met in 1900, evolved a style together based on crude statements of strong colours. Matisse had been moving more circumspectly in the same direction (Plate 25). The apparent ferocity of the works that the three exhibited in 1905 earned them the nickname of the Fauves ("Wild Beasts"). It appears that Matisse was responsible for introducing Pablo Picasso to African sculpture. Picasso had already shown signs of dissatisfaction with existing canons; his use of fin de siècle styles in his earliest works has a quality close to irony. Primitive art, both African and Iberian, provided him with an austerity and detachment that led after 1906 to a radical metamorphosis of the image and style hitherto habitual in European art. In 1904 Ernst Ludwig Kirchner, at Dresden, discovered the art of the Pacific Islands as well as African art. His first reflection of the primitive spirit was parallel to that of the Fauves and may have depended on them, if only partially.

The idea of art, first and last, as a matter of expression (in contrast to Impressionism) was common to Germany and France in the first decade of the 20th century; it appears in Matisse's *Notes of a Painter*, published in 1908. Matisse, in fact, hardly differentiated expression from decoration; his ideal of art as "something like a good armchair in which to rest" explicitly excluded the distortion and disquiet that earned the style of Kirchner and Die Brücke ("The Bridge") group, which was founded in 1905, the label of Expressionism. The worldly subjects of Kirchner represented only one aspect of the group; the earthy Primitivism of Emil Nolde and the emphatic pictorial rhetoric of Karl Schmidt-Rottluff are more typical. Both Nolde and Max Pechstein (another member of the group) traveled to the Pacific. The development of the Austrian Oskar Kokoschka, who was influenced by members of Die Brücke, spanned the first two-thirds of the 20th century; the tempestuous emotion of his finest pictures places them among the masterpieces of painting of the German-speaking world in his time.

The transformation of painting after 1907 was particularly apparent in works executed in Germany. Wassily Kandinsky had come to Munich from Moscow at the age of 30 in 1896. His earliest mature works were painted in a jewellike, fairy-tale Cloisonniste style. He later told how one evening in his studio he came upon "an indescribably beautiful picture, drenched with an inner glowing . . . of which I saw nothing but forms and colours . . ." (from R.L. Herbert [ed.], *Modern Artists on Art*, 1965). It was one of his own works, standing on its side, so that its content was incomprehensible. Kandinsky's first nonfigurative watercolour was painted in 1910, and in the same year he wrote much of *Concerning the Spiritual in Art*, which converted the aesthetic doctrines of Goethe to the purposes of the new art. The series of "Improvisations" that followed preserved reminiscences of figuration, made illegible by the looseness of the pictorial structure; their diffuse and amorphous consistency had little connection with the main objectives of painting at the time (Plate 24). In the first decade of the 20th century, the idea of painting implied by Postimpressionism and that of a reasoned structure analogous to the structure of nature, if not to

The attraction of naive and "primitive" painting

Concept of art as expression

Development of non-figurative painting

appearances, were far from exhausted. The influence of Kandinsky's "Improvisations" from 1911 onward, though delayed, was nonetheless great and pointed in a direction that abstract painting was to take 40 years later.

The Munich group *Der Blaue Reiter* ("The Blue Rider"), named after one of Kandinsky's earlier pictures, was formed in 1911 to represent the new tendencies when Kandinsky and Franz Marc withdrew from the heterogeneous *Neue Künstlervereinigung* ("New Artists' Association"). The group soon became, in its turn, a broadly based assembly of the international avant-garde artists of the day, although the stylizations of Marc himself now appear commonplace. Among the early members of the group, the Russian Alexey von Jawlensky evolved a structured form of Expressionism that culminated in the 1930s in a series of abstractions of a head, but the chief importance of the group was as a stage in the development of the Swiss painter Paul Klee.

Cubism and its consequences. Picasso's Primitivism, joined to the influence of Cézanne's "Great Bathers," culminated in 1907 in the enigmatic and famous picture "Les Femmes d'Alger" (O.J. No. 1) (Museum of Modern Art, New York City). Those who saw it were astonished and perplexed, not only by the arbitrary disruption in the right-hand part of the picture of the continuity that had always united an image but also by the defiant unloveliness, which made it plain that the traditional beauties of art, the appeal of the subject, and the credibility of its imitation were now, at any rate to Picasso, finally irrelevant. "What a loss to French art!" a Russian collector said, and Picasso himself was not sure what to think of the picture; it was not reproduced for 15 years or publicly exhibited for 30. Nevertheless, the effect on his associates was profound. Matisse and Georges Braque, who, unlike Picasso, had been experimenting with Fauvism, immediately started painting female nudes of similar stridency. Subsequently, however, Matisse turned back toward relatively traditional forms and the flooding colour that chiefly concerned him. Braque, on the other hand, became more and more closely associated with Picasso, and Cubism, as the new style was labeled by one of Braque's hostile critics in the following year, was the result of their collaboration. In the first phase, lasting into 1909, the focus of their work was the accentuation and disruption of planes (Plate 24). In the next two years Braque went to paint at Cézanne's old sites, and the inspiration of Cézanne's style at this stage is indubitable. In the second phase, from 1910 to 1912, the irrelevance of the subject, in any integral form, became evident. It was no longer necessary to travel in search of a motif; any still life would do as well. The essence of the picture was in the treatment. If Analytical Cubism, as this phase is generally labeled, analyzed anything, it was the nature of the treatment. The great Cubist pictures were meditations on the intrinsic character of the detached Cézannesque facets and contours, out of which the almost-illegible images were built. Indeed, the objects were not so much depicted as denoted by linear signs, a spiral for the scrolled head of a violin or the trademark from a label for a bottle, which were superimposed on the shifting, half-contradictory flux of shapes. The element of paradox is essential; even when it approaches monumental grandeur, Cubism has a quality that eludes solemn exposition. Subtle and elegant geometric puns build up into massive demonstrations of pictorial structure, demonstrations that its complex parallels and conjunctions build nothing so firmly and so memorably as the picture itself. This proof that figurative art creates an independent reality is the central proposition of modern art, and it has had a profound effect not only on painting and sculpture, as well as on the arts of design that depend on them, but also on the intellectual climate of the age.

The experimental investigation of what reality meant in artistic terms then took a daring turn that was unparalleled since pictorial illusion had been isolated five centuries earlier. The Cubists proceeded to embody real material from the actual world within the picture. They included first stenciled lettering, then pasted paper, and later solid objects; the reality of art as they saw it absorbed them all. This assemblage of material, called collage, led in 1912

to the third phase of the movement, Synthetic Cubism, which continued until 1914. The textured and patterned planes were composed into forms more like pictorial objects in themselves than recognizable figurations. In the later work of Picasso and Braque, it is again possible to construe their pictorial code as referring plainly to the objective world—in the case of Braque, to still life chosen with an appreciation of household things and, with Picasso, to emotive yet enigmatic human subjects as well. The message of Cubism remained the same: meaning had been shown to reside in the structure of the style, the basic geometry implied in the Postimpressionist handling of life. The message spread rapidly.

The first theoretical work on the movement, *On Cubism*, by the French painters Albert Gleizes and Jean Metzinger, was published in 1912. It was argued that geometric and mathematical principles of general validity could be deduced from the style. An exhibition in the same year represented all Cubism's adherents except the two creators. The exhibition was called the *Section d'Or* ("Golden Section"), after a mathematical division of a line into two sections with a certain proportion to each other. Among the exhibitors were the Spaniard Juan Gris and the Frenchman Fernand Léger, who in their subsequent work were both concerned with combining the basic scheme of Synthetic Cubism with the renewed sense of a coherent subject. Cubism stimulated parallel tendencies in The Netherlands, Italy, and Russia. In The Netherlands, Piet Mondrian, on the basis of Cézanne and the Dutch painters of the *fin de siècle*, had reached a very simple, symbolic style analogous to the Dutch landscape. He first saw Cubist paintings in 1910 and moved to Paris two years later. The subsequent resolution of his sense of natural conflict into increasingly bare rectangular designs balancing vertical against horizontal and white against areas of primary colour is one of the achievements of modern art (Plate 25). In 1917 the *de Stijl* movement formed in The Netherlands around him, with lasting consequences for the architecture, design, and typography of the century.

In Italy in 1909 a program for all the arts was issued by the poet Filippo Marinetti, who called his exercise the Futurist manifesto. He rejected the art of the past and exalted energy, strength, movement, and the power of the modern machine. In painting, his ideas were taken up by Carlo Carrà. Umberto Boccioni, the most talented of the group, pursued its ideas not only in painting but also in sculpture. The most memorable serial images of movement were those of Giacomo Balla; they reveal that, under its vivid fragmentation, the vision of Futurism was not far from the photographic. Its imperative mood and disruptive tactics nonetheless had their effect, finding an echo in Britain in the Vorticist circle around Wyndham Lewis. Lewis' analytical intelligence and the toughness of his artistic temper marked equally his near-abstract early works and the incisive classical portraits he painted later. Among his early associates, David Bomberg developed from the Cubist idiom in 1912–13 images of a striking clarity and force; and William Roberts combined a Cubist formulation with social commentary analogous to that of the 18th-century painter William Hogarth.

In Russia, where Western developments were well known, the avant-garde, with its own roots in primitive art, had already evolved a simplified Expressionistic style. Kazimir Malevich produced formalized images of peasants at work that anticipated the later style of Léger. The strip-like and often abstract formulations of Mikhail Larionov and Natalya Gontcharova, to which they gave the name of Rayonism, date from 1911. In 1912 Malevich exhibited his first "Cubo-Futurist" works, in which the figures were reduced to dynamic coloured blocks, and in 1913 he followed these with a black square on a white background. This increasing tendency to abstraction reached its culmination in 1915 with the arrival of what he called Suprematism, in which simple geometric elements provided the whole dynamic force. The Russian movement, complicated by its own politics, was both accelerated and eventually broken by the Revolution, which gave it, for a time, a social function that the avant-garde has hardly achieved elsewhere. The Russian artists dispersed after

1922, however, and their legacy, the tradition of Constructivism, was transmitted to western Europe by El Lissitzky, Antoine Pevsner, and the latter's brother, Naum Gabo.

Prismatic colour, the element in Cézanne that the Cubists had neglected in dismantling his style, was taken up by Robert Delaunay. Delaunay's variety of Cubism was named Orphism, after Orpheus, the poet and musician of ancient Greek myth. The essential discovery of Orphism was proclaimed as a realization that "colour is both form and subject." After an exquisite series of "Windows," Delaunay freed himself from representation and based his designs on the effects of simultaneous colour contrast. These dictated the concentric patterns of his "Discs" and "Cosmic Circular Forms," which occupied him and his wife, Sonia, thenceforward. The Czech František Kupka painted his first totally abstract work at about the same time. Even the simplest of his subsequent works never quite lost the rhythms of the fin de siècle style. Delaunay realized that a new order of painting was beginning, but his immediate influence was strongest abroad. Two American followers, Stanton Macdonald-Wright and Morgan Russell, exhibited as "Synchromists" in 1913. The Munich group Der Blaue Reiter was in touch with Delaunay, who exhibited with them, and the subsequent development of Klee was founded on his conversion to Delaunay's ideal of colour.

Fantasy and the irrational. The identity of a work of art as a thing in itself, independent of representation, was on the way to general recognition when the outbreak of war in 1914 interrupted artistic life throughout most of Europe. The activities of a group of painters, writers, and musicians who sought refuge in Zürich reflected the disorientation and disillusion of the time. Dada, as the movement was called, owed much to the iconoclasm of the Cubists and to the polemical tactics of the Futurists. Nonetheless its attack on art was fundamentally artistic; one wing of the avant-garde has owed allegiance to the Dadaist tradition ever since. As well as the need continually to attack the limits of the fine arts, it was felt important to "épater ["shock"] les bourgeois." The Dadaists enlarged the field open to artists in three ways. They questioned the idea that some subjects were simply not relevant to painting, a question that had been hovering over art for some time, by the simple expedient of arguing that anything and everything was fair game. The repetitive and amorphous trends of Impressionism had in fact already given grounds for such a supposition. The next step was to make a reluctant public accept that any object was a work of art if an artist chose to proclaim it one. In 1914 Marcel Duchamp, the exhibitor of serial images of movement in the Section d'Or, produced a bottle rack bought in a Paris store. Better and more *épatant* still, he submitted a urinal to a New York exhibition under a pseudonym in 1917. Duchamp did not paint again, and this is perhaps the single Dadaist gesture that time has failed to reconcile with art. It was also the Dadaists who posed the question, if art (as Redon had realized) is not within the reach of will, how is it different from chance? Jean Arp made collages and then reliefs from random shapes obtained "according to the laws of chance." Of all modern artists, he examined most closely the side of art akin to humour. Similarly, the Dadaists explored such elements as incongruity and dissociation, a process that led the way to Surrealism. Finally and almost incidentally, they asked, if the presentation of movement is proper to art, why not movement itself? Viking Eggeling and Hans Richter, with animated drawings and film, made the first works in a kinetic tradition that even by the late 1980s showed no sign of abating.

The painter who, more than any other, focused on incongruity—a feature that in painting involves the re-statement of the subject, rather than its treatment, at the centre of art—was Giorgio De Chirico, an Italian born in Greece. De Chirico, rooted in the Mediterranean world, created from 1910 onward unforgettable images of its dereliction (Figure 16). In the immediate postwar years, he pioneered a style of emblematic, half-abstract still life called *pittura metafisica* ("metaphysical painting"), but by 1924, when the Surrealists began to work a similar vein

of fantasy, De Chirico had changed; and in later life he disavowed his early achievement. Metaphysical painting had one unexpected sequel, the serene realism of Giorgio Morandi. Meanwhile, Kurt Schwitters in Germany developed the mediums of collage and assemblage in the new spirit. Francis Picabia, who was associated with Duchamp in the United States during the war, joined forces with the Swiss Dadaists in 1918; his contribution was an epigrammatic elegance of style. The German Max Ernst was the most resourceful pictorial technician of the movement and a continually fertile inventor.

It was in 1917 that the term Surrealism was coined, when the poet Guillaume Apollinaire described the style of the ballet *Parade*, for which Picasso had painted the sets, as:

a sort of sur-realism in which I see a point of departure for a series of manifestations of that New Spirit which . . . promises to transform arts and manners from top to bottom with universal joy.

The manifesto of the Surrealist movement, which was composed by the poet André Breton, did not appear until 1924, however. Surrealism meant different things in different people's hands, but a common feature was absorption in the fantastic and irrational. The questions posed by Dada also preoccupied Surrealists, but for them the problem of the involuntary, fortuitous element in art, for example, was clearly open to psychological solution. The Surrealists demanded "pure psychic automatism"; the automatic drawings that the French artist André Masson made from 1925 onward and, on a more mechanical level, the frottage ("rubbing") devices of Ernst, which added to painting the evocative effect of fortuitously dappled textures, introduced an element that flourished even more fully 20 years later. Another discovery made in the wake of Dada was similarly delayed in its full impact: *Parade* had been the culmination of a series of musical compositions by Erik Satie that were based on ironic quotations of popular material. In the early 1920s the Americans Stuart Davis and Man Ray made paintings out of the designs on commercial packaging, foreshadowing the Pop Art of the 1950s.

The greatest achievement of Surrealist painting, however, was the invention of a new genre: fantastic realism—the prosaic, indeed quasi-photographic, rendering of the forms of fantasy and dream. The invention was the work, after De Chirico, of the Frenchman Yves Tanguy and the Spaniard Salvador Dalí. In the pictorial world of Dalí, everyday things undergo a transformation (Plate 25) that can be almost disturbing; in that of Tanguy, forms are more suggestive than related to actual objects. A different aspect of this dream realism, one that is particularly disturbing, was shown by the Belgian René Magritte.

In the years after 1918, a mood of classical consolidation affected some painters. In Germany a "New Objectivity"

(Die Neue Sachlichkeit) was imposed on Expressionism; the eventual synthesis appeared in the brutal paintings of Max Beckmann (Plate 24). In France the Italian-born Amedeo Modigliani, affected by the simplicity of the Romanian-born sculptor Constantin Brancusi, arrived at a delicate linear realism, the last of the great Postimpressionist styles.

The Expressionist tradition was developed to an extreme of agonized distortion by Chaim Soutine. Another Russian-born member of the school of Paris, Marc Chagall, who had been influenced both by Cubism and the Russian avant-garde, discovered in the 1920s an individual and inconsequent vein of pictorial fancy (Plate 25). The sombre and devotional art of the Frenchman Georges Rouault bore the marks of his training with Gustave Moreau and as a stained-glass maker. Its crude force had been developed in the context of Fauvism, but the vision was one of refined introspection. The vigour and freedom of Fauvism was developed in the opposite direction in the decorative, extrovert style of another French painter, Raoul Dufy. The classicizing trend of the 1920s had a remarkable sequel in the work of the mural painters of Mexico. One such, Diego Rivera, had learned the formal lessons of Cubism in Paris; José Clemente Orozco was more dependent on the folk art of his country. Their frescoes combined grandeur with a legibility and social awareness rare in modern art.

The greatest imaginative achievements between World Wars I and II were, however, again those of Picasso. In the years immediately following World War I he had painted a series of solidly modeled yet oddly ironic figure pictures. Then his mood changed, and in 1925 "The Three Dancers" (Tate Gallery, London) reintroduced an anarchic and convulsive quality. The ambiguities and transformations of his art, both in painting and sculpture, have an emotional character that is entirely his own, but the enlargement of the artistic language greatly influenced others. The metamorphosis of natural shape into abstracted forms that nevertheless curve and bulge with their own life, a metamorphosis initiated by Picasso, became the international style of the early 1930s. The Spaniard Joan Miró gave it his own clarity and gaiety (Plate 24). Biomorphic abstraction, in essence the method of Tanguy, extended the resources of Surrealism, and the Chilean Roberto Matta Echaurren, who began painting in 1938, used it with dramatic effect. A poetic version of the style, rooted in an emotional response to landscape, was evolved in England by Graham Sutherland. In the later 1930s, with "Guernica" (1937; Prado, Madrid; Figure 17) and other pictures, Picasso responded to specific events. Around 1940, two painters in the United States, Arshile Gorky and Willem de Kooning, gave the biomorphic style a new character: relaxed, diffuse, and clear.

The development of abstract painting between the wars

was comparatively slow. Klee (in 1921) and Kandinsky (in 1922) gravitated to the Bauhaus, the school in Germany whose work at Weimar and later at Dessau deeply influenced architecture and design as well as basic teaching. Oskar Schlemmer, whose simplified manner paralleled the Italian metaphysical painters, and Lyonel Feininger, an American-born painter working in a style developed from Cubism, were already teaching there. Kandinsky was concerned with refining the geometric ingredient of his work. Klee developed the poetic and fantastic elements of his art with an inconsequent fertility (Figure 18). The systematic purity of the Bauhaus approach survived longest in the work of Josef Albers, who moved to the United States in 1933. In 1940 Mondrian moved to New York City, and his last dynamic pictures reflect the new environment. Mondrian's work was appreciated by only a small circle, although a similar strength of purpose with a delicate re-

Mural painters of Mexico

sponsiveness to a broader range of forms appeared in the work of the British painter Ben Nicholson. In the 1930s some paintings were executed by artists who formed themselves into groups, such as Abstraction-Création in Paris, Unit One in London, and the Association of American Abstract Artists in New York City. The work of these groups attained wider recognition only after World War II.

After 1945. The postwar work of Braque developed a few basic themes. The space and content of "The Studio" series of five paintings were formulated in vertical phases of varying sombreness; a mysterious bird that featured in this series was a symbol expressive of aspiration. Nicolas de Stael, a friend of Braque who was born in St. Petersburg, reached in 1950 a style in which lozenges of solid paint were built into structures of echo and correspondence. Colour in itself provided the substance, and de Stael's influence was considerable. The painterly and basically traditional vein of abstraction pursued in Paris by such painters as Alfred Manessier remained at root decorative. In Italy, traditional trends in sculpture are reflected in the brilliant accomplished modeling of Giacomo Manzù; Marino Marini, devoting himself almost entirely to the single theme of horse and rider, gave a bald realistic style an oddly apocalyptic force.

The Expressionist tradition was revived in the new spirit by the "Cobra" group of painters from Copenhagen, Brussels, and Amsterdam who came together in Paris in 1948. In the work of Asger Jorn and Karel Appel, the image springs as if by chance from the free extempore play of brushstrokes. Surrealism proved remarkably durable. Among its adherents, the American Joseph Cornell had been evolving from the techniques of collage and assemblage a personal and evocative form of image; the Pole Hans Bellmer and the German Richard Lindner, working in Paris and New York, respectively, explored private and obsessive themes; they were recognized as among the most individual talents of their generation. In general, the most idiosyncratic and anarchic qualities of art were being developed as a new tradition, while geometric abstraction was seen to be the natural basis for the arts that are public and communal in purpose. Victor Pasmore in Britain, for instance, abandoned his earlier Postimpressionist standpoint to start afresh with constructional and graphic symbols deriving from Klee and Mondrian.

The presence of a number of the pioneer Surrealists in the United States during World War II affected later developments there. Surrealism's element of psychic automatism, particularly the spontaneous calligraphy of Masson, was particularly influential. The possibilities had, in fact, been implicit in modern painting for at least two decades; in Paris in the 1920s Jean Fautrier was already basing pictures on spontaneous and informal gestures with paint. In the United States in the 1940s, however, fresh impetus came from the impulsive play of colour in the work of the influential teacher Hans Hofmann. The movement that became known as Abstract Expressionism represented a decisive departure from its European sources, not only because the homogeneous consistency of a painted surface in itself took on a new meaning in the expansive U.S. conditions but at least equally because of the exceptional personality of Jackson Pollock. The style Pollock adopted in 1947 reflected an original involvement in the act of painting that transcended deliberation or control (Plate 26). The influential critic Harold Rosenberg wrote in 1952:

At a certain moment the canvas began to appear to one American painter after another as an arena in which to act—rather than as a space in which to reproduce, redesign, analyze or "express" an object, actual or imagined. What was to go on the canvas was not a picture but an event.

(*The Tradition of the New*)

In contrast to Pollock's work, that executed at the time by Willem de Kooning, though equally sweeping and ungovernable, showed a recurrent figurative reference; his series of alarming variations on the theme "Woman" began in 1950. Another Abstract Expressionist, Franz Kline, claimed, in executing his shapes like huge black and white ideograms, to be in some sense depicting figurative images. Rosenberg dubbed the group "action painters." In the course of the 1950s their influence was felt in almost

every country. The climate of artistic opinion that spread outward from New York made possible flamboyant gesture paintings such as those of the French-born Georges Mathieu.

The idea of painting as a homogeneous all-over fabric led at the same time to other quite separate developments. Prompted by the primitive and psychotic imagery that he called *l'art brut* ("raw art"), Jean Dubuffet embarked on an extraordinarily resourceful series of experiments in translating the raw material of the world into pictures. The energy that fills the works of the American painter Mark Tobey is by comparison gentle and lyrical and much influenced by East Asian art. Dubuffet's example inspired the abstract "matter" painting that developed in several countries around 1950. At its best, as in the work of the Catalan Antonio Tàpies, this style conveys a strong sense of natural substance.

New forms. In painting generally a new directness was strikingly combined with a new simplicity. Beginning at the age of 80, in the five years before his death in 1954, Henri Matisse made a series of large gouaches *découpées* in which the increasingly abstract images were created solely by the juxtaposition of sharply cut patches of brilliant colour. Their influence was widespread and by no means confined to painters, such as the American Ellsworth Kelly, who developed the vibrant interaction of hard-edge colour areas. Even from other starting points, painters were reaching similar conclusions. The very simple yet resonant colour combinations of the New York painter Mark Rothko (Plate 26) or the grand severity of another American, Barnett Newman, furnish examples.

Abstract painting was revealing far wider potentialities than had been apparent between World Wars I and II, but figurative styles showed a new freedom as well. The Swiss Alberto Giacometti, who had worked as a Surrealist, evolved in both sculpture and painting his sensation of the visual impact of figures in space. Francis Bacon in Britain uncovered unexpected and startling connotations in the apparition of a human likeness on canvas.

Painting in the 1960s not only sought originality; it took up a deliberately extreme position that may have seemed almost to pass the bounds of art. Paintings might be extremely large. Alternatively, they might be extreme in some other respect, such as the canvases of the Frenchman Yves Klein, which showed only a plain, arresting blue colour, or the black pictures of the American Ad Reinhardt, with variations so slight as to be hardly perceptible. The element of apparent chance in action painting explained the way the stains of colour in the work of the American painter Morris Louis appeared to flow and soak across the canvas as if of their own accord.

The tradition of Dada and its skepticism regarding what had once been the received definition of art prompted continual experiment with the techniques of assemblage. Robert Rauschenberg in the United States sought to place his subtly calculated "combine paintings" (collections of contrasting objects joined to make an ensemble) in the gap between reality and art, contrasting the significance of paint with the borrowed imagery and objects juxtaposed with it. Jasper Johns, an associate of Rauschenberg's, worked with preexisting designs such as targets and the U.S. flag, giving them an ironic look when subjected to incorporation in his works. In the borrowed imagery and popular quotations, on which much painting was based in the years that followed, the irony was intensified to the point of ceasing to be irony at all. Roy Lichtenstein took strip cartoons and other banal (even banally artistic) imagery as the motifs for pictures (Plate 26). Another American, Claes Oldenburg, began by reconstructing common things out of the random pictorial substance of Abstract Expressionism; his later reconstructions of the rigid furniture of everyday life are tailored out of limp plastic sheeting.

There is nothing random about the typical art of the 1960s. On the contrary, it was planned exactly and normally carried out by an efficient, almost mechanical-seeming system. Hard-edge painting developed into a wide range of planar styles having in common only their exploitation of optical reactions and the element of shock that

Op Art

is the visual concomitant of sharp contrast. The spread of this idiom was particularly influenced by the Hungarian-born Victor Vasarely, who worked in France; its most personal development was in the largely monochromatic work of Bridget Riley in Britain (Figure 19). Again, the initial tendency was to exclude such sensations from the aesthetic canon, but in the event a whole region of visual meaning, void for uncertainty since abstraction began, was reclaimed for painting. Optical art, or Op Art, emphasizes movement, whether potential, actual, or relative, and such effects have been ingeniously investigated by the *Groupe de Recherche d'Art Visuel* ("Group for Visual Research"), founded in Paris in 1960, and the Zero group in Düsseldorf, W.Ger. In the reliefs of the Venezuelan Jesús Raphael Soto, shifting vision is given a delicate order.

Figure 19: "Fall," by Bridget Riley, 1963. In the Tate Gallery, London. 1.41 × 1.41 m.

Other developments have proved more fertile. In the hands of the American painters Kenneth Noland and Frank Stella, painting discovered new shapes, both within the rectangular canvas and beyond it. The new value given to the painted plane did not benefit painting only. The British painter Richard Smith deployed it in three dimensions in painted constructions that re-create impressions of commercial packaging in terms of the spatial imagination of the arts.

Minimal art

The extreme in this reduction of means and sophistication of aesthetics was perhaps reached when a group of sculptors in the United States and England turned to investigate the possibilities of minimal and primary forms, normally the simplest geometric solids, alone or arranged in baldly repetitive series. Here, it is the spectator (as perhaps in a sense it always is) who brings the interpretation and supplies the art. The proposition had the apparent preposterousness expected of avant-garde art, yet it seemed likely, in its turn, to shed light on problems that are very much older. It is characteristic of sculpture and painting in the 20th century to deal more and more consciously and directly with the ultimate definition of art. The perennial compulsion to reverse previously accepted definitions has threatened ever more directly the recognizable identity of art. At the end of the 1960s the tendency to emphasize the systems and attitudes of art rather than its product led to a move in several countries to deny the validity of the art object. Instead artists prepared written specifications for ideal, imaginary art, the fulfillment of which was superfluous, or self-sufficient programs for performances paradoxically analogous to some aspect of the more familiar artistic acts. Conceptual art has opened the way to activities notable in their defiance of conventional expectations. The designs of earth art or earthworks are fulfilled by moving large amounts of soil, preferably in inaccessible places, perhaps in token of the potency of

traditional art to impose its shape on the world. Activities of this order may appear to belong as much to theory as to artistic creation itself; in the 1970s these distinctions, with other familiar cornerstones of artistic thought, were held to have lost their validity. (La.G./Ed.)

In the 1970s critical and public interest centred on the reductive constructions of Minimalism and the nihilistic questioning of conceptual art. The late 1970s and early 1980s, however, witnessed a resurgence of excitement in painting and a return to figurative representation. A new movement called Neo-Expressionism arose in New York City and in the art capitals of western Europe, especially in West Germany, combining the heavy paint surfaces and dynamic brushstrokes of Abstract Expressionism with the emotional tone of early 20th-century German Expressionism. The new movement's subject matter ranged from basically literal, though self-consciously primitive, treatments of the human figure to a range of imaginary subjects indicative of modern urban life, particularly its glamour, alienation, and menace. A notable characteristic of Neo-Expressionism was the newly prominent role played in its commercial acceptance by gallery owners and art dealers who adroitly publicized the movement's artists. Indeed, Neo-Expressionism's sudden success was an indication of the growing commercialization of the avant-garde and its unhesitating acceptance by wealthy, influential collectors and progressive-minded museum curators. Some critics voiced doubts over what they saw as the reflexive pursuit of artistic novelty under the influence of commercial pressures, and some even asserted that critical and public acclaim had to some extent become divorced from the goals of finding and patronizing painters whose works had lasting artistic significance. (Ed.)

General: Among the standard surveys of the history of Western art are HELEN GARDNER, *Gardner's Art Through the Ages*, 8th ed., edited by HORST DE LA CROIX and RICHARD G. TANSEY (1986); H.W. JANSON, *History of Art*, 3rd ed., revised and expanded by ANTHONY F. JANSON (1986); and DAVID M. ROBB and J.J. GARRISON, *Art in the Western World*, 4th ed. (1963). Among the major standard reference works are the *Encyclopedia of World Art*, 16 vol. (1959–83); ULRICH THIEME and FELIX BECKER (eds.), *Allgemeines Lexikon der bildenden Künstler von der Antike bis zur Gegenwart*, 37 vol. (1907–50, reprinted 1970–71); *McGraw-Hill Dictionary of Art*, edited by BERNARD S. MYERS, 5 vol. (1969); HAROLD OSBORNE (ed.), *The Oxford Companion to Art* (1970, reprinted 1984); and the *Praeger Encyclopedia of Art*, 5 vol. (1971). See also ARNOLD HAUSER, *The Social History of Art*, trans. from German, 4 vol. (1962); ELIZABETH G. HOLT (ed.), *A Documentary History of Art*, 3 vol. (1957–66, vol. 1 and 2 reprinted in 1982); PETER MURRAY and LINDA MURRAY, *A Dictionary of Art and Artists*, 4th ed. (1976); and E.H. GOMBRICH, *The Story of Art*, 14th rev. ed. (1984). An extensive bibliography may be found in E. LOUISE LUCAS, *Art Books: A Basic Bibliography on the Fine Arts* (1968). Later reference works include the *Larousse Dictionary of Painters* (1981; originally published in French, 1976); and DAVID PIPER (ed.), *The Random House Library of Painting and Sculpture*, 4 vol. (1981). F. DAVID MARTIN, *Sculpture and Enlivened Space: Aesthetics and History* (1981), examines the comparative importance of painting and sculpture in Western art.

European Metal Age cultures: STUART PIGGOTT, *Ancient Europe, from the Beginnings of Agriculture to Classical Antiquity* (1965); and WALTER TORBRUGGE, *Prehistoric European Art*, (1968; originally published in German, 1968), provide general surveys. There is a vast literature on the Aegean and eastern Mediterranean, including SPYRIDON MARINATOS, *Crete and Mycenae* (1960; originally published in Greek, 1959), photographs by MAX HIRMER; REYNOLD HIGGINS, *Minoan and Mycenaean Art*, rev. ed. (1981); and SPYRIDON MARINATOS, "Life and Art in Prehistoric Thera," *Proceedings of the British Academy*, vol. 57 (1972). SIR ARTHUR EVANS, *The Palace of Minos: A Comparative Account of the Successive Stages of the Early Cretan Civilization as Illustrated by the Discoveries at Knossos*, 4 vol. in 6 (1921–35, reissued 1964), is a classic work but is superseded in part by RICHARD W. HUTCHINSON, *Prehistoric Crete* (1962, reprinted 1968); SINCLAIR HOOD, *The Minoans: The Story of Bronze Age Crete* (1971); and KEITH BRANIGAN, *The Foundations of Palatial Crete* (1970). For Hellenic art, the best works are GEORGE E. MYLONAS, *Mycenae and the Mycenaean Age* (1966); and LORD WILLIAM TAYLOR, *The Mycenaean Age*, rev. ed. (1983). For Cyprus, see VASSOS KARAGEORGHIS, *Cyprus* (1969), with a useful bibliography. Among the numerous works on the western Mediterranean are the

following: ANTONIO ARRIBAS, *The Iberians* (1964); L. BERNABÒ BREA, *Sicily Before the Greeks* (rev. ed., 1966; originally published in Italian, 1966); DAVID H. TRUMP, *Central and Southern Italy Before Rome* (1966); DAVID RANDALL-MACIVER, *The Iron Age in Italy: A Study of Those Aspects of the Early Civilization Which Are neither Villanovan nor Etruscan* (1927, reprinted 1974) and *Villanovans and Early Etruscans: A Study of the Early Iron Age in Italy as It Is Seen near Bologna, in Etruria and in Latium* (1924); MARIO MORETTI and GUGLIELMO MAETZKE, *The Art of the Etruscans* (1970; originally published in Italian, 1969); P.J. RIIS, *An Introduction to Etruscan Art* (1953; originally published in Danish, 1948); RAYMOND BLOCH, *The Etruscans* (1958; originally published in French, 1958); MASSIMO PALLOTINO, *Etruscan Painting*, trans. from French (1952), and *Art of the Etruscans*, trans. from French (1955); MARGARET GUIDO, *Sardinia* (1964); and JOHN D. EVANS, *Malta* (1959). For northern European art, see PAUL JACOBSTHAL, *Early Celtic Art*, 2 vol. (1944, reprinted 1970). See also JOHN E. PFEIFFER, *The Creative Explosion: An Inquiry into the Origins of Art and Religion* (1982); ANDRÉ LEROI-GOURHAN, *The Dawn of European Art: An Introduction to Palaeolithic Cave Painting* (1982; originally published in Italian, 1981); and PIERRE AMIET et al., *Art in the Ancient World: A Handbook of Styles and Forms*, trans. from French (1981).

Ancient Greek: Important general works include JOHN D. BEAZLEY and BERNARD ASHMOLE, *Greek Sculpture and Painting to the End of the Hellenistic Period* (1932, reprinted 1966); JOHN BOARDMAN, *Greek Art*, new rev. ed. (1985); JOHN BOARDMAN et al., *Greek Art and Architecture* (1967; originally published in German, 1966), with photographs by MAX HIRMER; RHYS CARPENTER, *The Esthetic Basis of Greek Art of the Fifth and Fourth Centuries B.C.*, rev. ed. (1959); GISELLA RICHTER, *A Handbook of Greek Art*, 8th ed. (1983), and *Archaic Greek Art Against Its Historical Background* (1949); GEORGE BOAS (ed.), *The Greek Tradition* (1939), a collection of essays published in connection with an exhibition and accompanied by its catalog, GEORGE BOAS et al., *The Greek Tradition in Painting and the Minor Arts* (1939); BERNHARD SCHWEITZER, *Greek Geometric Art* (1971; originally published in German, 1969); and VINCENT J. BRUNO, *Form and Color in Greek Painting* (1977). Among the standard studies on vase painting are PAOLO E. ARIAS, *A History of 1000 Years of Greek Vase Painting* (1962; originally published in Italian, 1960), with photographs by MAX HIRMER; JOHN D. BEAZLEY, *The Development of Attic Black-Figure* (1951, reprinted 1986), *Potter and Painter in Ancient Athens* (1944), *Attic Black-Figure Vase-Painters* (1956, reprinted 1978), and *Attic Red-Figure Vase-Painters*, 2nd ed., 3 vol. (1963, reissued 1984); ERNST BUSCHOR, *Greek Vase Painting* (1921, reprinted 1971; originally published in German, 1913); JOSEPH V. NOBLE, *The Techniques of Painted Attic Pottery* (1965); and MARTIN ROBERTSON, *Greek Painting* (1959; reissued 1979). See also MANOLIS ANDRONIKOS, *Vergina: The Royal Tombs and the Ancient City* (1984; originally published in Greek, 1984). MARTIN ROBERTSON, *A Shorter History of Greek Art* (1981), is an excellent condensed study of Greek art from the Geometric through the Hellenistic periods.

Roman: General surveys include GEORGE M.A. HANFMANN, *Roman Art: A Modern Survey of the Art of Imperial Rome* (1964, reissued 1975); HEINZ KÄHLER, *The Art of Rome and Her Empire* (1963; originally published in German, 1962); GERMAN HAFNER, *Art of Rome, Etruria, and Magna Graecia*, trans. from German (1969); G.A. MANSUELLI, *The Art of Etruria and Early Rome*, trans. from Italian (1965); JOCELYN M.C. TOYNBEE, *Art in Roman Britain* (1962); and SIR MORTIMER WHEELER, *Roman Art and Architecture* (1964, reissued 1985). More detailed information on painting may be found in AMEDEO MAIURI, *Roman Painting*, trans. from French (1953); and WLADIMIRO DORIGO, *Late Roman Painting* (1971; originally published in Italian, 1966). BERNARD ANDREA, *The Art of Rome* (1978; originally published in German, 1973), is a comprehensive survey; and OTTO J. BRENDL, *Prolegomena to the Study of Roman Art* (1979), includes criticism of previous writings on the subject.

Early Christian, Byzantine, Armenian, Georgian, and Coptic: VIKTOR LAZAREV, *Storia della pittura bizantina* (1967; originally published in Russian, 2 vol., 1947–48), is a well-annotated general survey, now seriously out of date but still useful. Good coverage is provided by a combination of two books: BEAT BRENN (ed.), *Spätantike und frühes Christentum* (1977); and WOLFGANG F. VOLBACH and JACQUELINE LAFONTAINE-DOSOGNE, *Byzanz und der christliche Osten* (1968). See also WOLFGANG F. VOLBACH, *Early Christian Art*, with photographs by MAX HIRMER (1962; originally published in German, 1958); and D. TALBOT RICE, *Byzantine Art*, rev. ed. (1968); THOMAS F. MATHEWS, *The Byzantine Churches of Istanbul: A Photographic Survey* (1976); and CYRIL MANGO, *The Art of the Byzantine Empire, 312–1453: Sources and Documents* (1972, reprinted 1986).

A number of books consider the art of the period as a whole

and propose various ways of interpreting the material: ANDRÉ GRABAR, *Christian Iconography: A Study of Its Origins* (1968, reprinted 1980; originally published in French, 1957; 2nd rev. French ed., 1984), *The Beginnings of Christian Art*, 200–395 (1967; originally published in French, 1966), *Byzantium: From the Death of Theodosius to the Rise of Islam*, trans. from French (1967), and *Byzantine Painting: Historical and Critical Study*, trans. from French (1953, reissued 1979); ERNST KITZINGER, *Byzantine Art in the Making: Main Lines of Stylistic Development in Mediterranean Art, 3rd–7th Century* (1977); CLIVE FOSS and PAUL MAGDALINO, *Rome and Byzantium* (1977); and CYRIL MANGO, *Byzantium, the Empire of New Rome* (1980). HENRY MAGUIRE, *Art and Eloquence in Byzantium* (1981), discusses art as influenced by sermons and other theological writings; alternatively, ROBIN CORMACK, *Writing in Gold: Byzantine Society and Its Icons* (1985), interprets Byzantine art as a major element in the Byzantine outlook.

A number of helpful publications cover some of the specialist areas: KLAUS WESSEL, *Coptic Art* (1965; originally published in German, 1963); GUISEPPE BOVINI, *Ravenna: Its Mosaics and Monuments* (1956, reissued 1970; originally published in Italian, 1956); HEINZ KÄHLER, *Hagia Sophia* (1967; originally published in German, 1967); ANTHONY BRYER and JUDITH HERRIN (eds.), *Iconoclasm* (1977); KURT WEITZMANN, *The Icon: Holy Images—Sixth to Fourteenth Century* (1978); and KURT WEITZMANN et al., *The Icon* (1982; originally published in Italian, 1981).

Early medieval and Romanesque: The most satisfactory survey of the whole period is provided in ANDRÉ GRABAR and CARL NORDENFALK, *Early Medieval Painting from the Fourth to the Eleventh Century*, trans. from French and German (1957), and *Romanesque Painting from the Eleventh to the Thirteenth Century*, trans. from French and German (1958). The most exhaustive study on wall painting is still EDGAR W. ANTHONY, *Romanesque Frescoes* (1951, reprinted 1971). For manuscript illumination, see ALBERT BOECKLER, *Abendländische Miniaturen bis zum Ausgang der romanischen Zeit* (1930); a stimulating discussion by OTTO PÄCHT, *Book Illumination in the Middle Ages: An Introduction* (1986; originally published in German, 1984); and a survey by CHRISTOPHER DE HAMEL, *A History of Illuminated Manuscripts* (1986). An excellent short introduction to the subject is contained in ERNST KITZINGER, *Early Medieval Art, with Illustrations from the British Museum and British Library Collections*, rev. ed. (1983). The 9th through 12th centuries are covered in JOHN BECKWITH, *Early Medieval Art: Carolingian, Ottonian, Romanesque*, rev. ed. (1969, reprinted 1985); and C.R. DODWELL, *Painting in Europe, 800 to 1200* (1971). The most comprehensive modern overview of Dark Age and early medieval painting is CARLO BERTELLI, “Traccia allo studio delle fondazioni medievali dell’arte italiana,” in *Storia dell’arte italiana*, part 2, *Dal medioevo al novecento*, vol. 1, *Dal medioevo al quattrocento*, pp. 3–163 (1983). For Rome, see RICHARD KRAUTHEIMER, *Rome, Profile of a City, 312–1308* (1980). The best survey of early Anglo-Saxon art is still T.D. KENDRICK, *Anglo-Saxon Art to A.D. 900* (1938, reprinted 1972). For book illumination in Britain and Ireland, see J.J.G. ALEXANDER, *Insular Manuscripts, 6th to the 9th Century* (1978); CARL NORDENFALK, *Celtic and Anglo-Saxon Painting: Book Illumination in the British Isles, 600–800* (1977); FRANÇOISE HENRY, *Irish Art in the Early Christian Period, to 800 A.D.* (1965), *Irish Art During the Viking Invasions, 800–1020 A.D.* (1967), and *Irish Art in the Romanesque Period, 1020–1170 A.D.* (1970; originally published in French together in a set of 3 vol., 1963–64).

Merovingian illumination is discussed in JEAN HUBERT, JEAN PORCHER, and WOLFGANG F. VOLBACH, *Europe in the Dark Ages* (1969; U.S. title, *Europe of the Invasions*; originally published in French, 1967). There are several good surveys of Carolingian painting: WOLFGANG BRAUNFELS, *Die Welt der Karolinger und ihre Kunst* (1968); JEAN HUBERT, JEAN PORCHER, and WOLFGANG F. VOLBACH, *Carolingian Art* (1970; U.S. title, *The Carolingian Renaissance*; originally published in French, 1968); and FLORENTINE MÜTHERICH and JOACHIM E. GAEHDE, *Carolingian Painting* (1976). Excellent particular studies can be found in WOLFGANG BRAUNFELS and HERMANN SCHNITZLER (eds.), *Karolingische Kunst* (1965). Late Anglo-Saxon art is considered in ELZBIETA TEMPLE, *Anglo-Saxon Manuscripts, 900–1066* (1976); JANET BACKHOUSE, D.H. TURNER, and LESLIE WEBSTER (eds.), *The Golden Age of Anglo-Saxon Art, 966–1066* (1984); and C.R. DODWELL, *Anglo-Saxon Art: A New Perspective* (1982). HANS JANTZEN, *Ottotonische Kunst* (1947, reissued 1963), is an excellent review of Ottonian art; and ADOLPH GOLDSCHMIDT, *German Illumination*, vol. 2, *Ottotonian Period* (1929, reprinted as part of a 1-vol. edition, 1970; originally published in German, 1928), is still valuable. A brief survey is LOUIS GRODECKI et al., *Le Siècle de l’an mil* (1973). C.R. DODWELL and D.H. TURNER, *Reichenau Reconsidered: A Re-assessment of the Place of Reichenau in Ottonian Art* (1965), offers a stimulating but

contested examination of late 10th-century Ottonian illumination. The Romanesque period is surveyed in FRANÇOIS AVRIL, XAVIER BARRAL I ALTET, and DANIELLE GABORIT-CHOPIN, *Le Temps des Croisades* (1982), and *Les Royaumes d'Occident* (1983); HANNS SWARZENSKI, *Monuments of Romanesque Art: The Art of Church Treasures in North-Western Europe*, 2nd ed. (1967, reissued 1974); OTTO DEMUS and MAX HIRMER, *Romanesque Mural Painting* (1970; originally published in German, 1968); and WALTER CAHN, *Romanesque Bible Illumination* (1982). The best study of French Romanesque illumination is JEAN PORCHER, *Medieval French Miniatures* (1960; U.K. title, *French Miniatures from Illuminated Manuscripts*; originally published in French, 1959).

For England, there is an excellent survey of manuscripts: C.M. KAUFFMANN, *Romanesque Manuscripts, 1066–1190* (1975); and a later discussion in the exhibition catalog, GEORGE ZARNECKI, JANET HOLT, and TRISTRAM HOLLAND (eds.), *English Romanesque Art, 1066–1200* (1984). The standard work on early Spanish illumination, in English, is J. DOMÍNGUEZ BORDONA, *Spanish Illumination* (1930, reissued 1969; originally published in Spanish, 1930); see also JOHN WILLIAMS, *Early Spanish Manuscript Illumination* (1977). Illumination in north-west Germany is surveyed in two exhibition catalogs, *Rhein und Maas, Kunst und Kultur, 800–1400*, 2 vol. (1972–73); and ANTON LEGNER (ed.), *Ornamenta ecclesiae: Kunst und Künstler der Romanik*, 3 vol. (1985). The Gospels of Henry the Lion are discussed in *The Gospels of Henry the Lion, Count of Saxony, Duke of Bavaria* (1983), an auction catalog of Sotheby Parke Bernet Inc.; and HORST FUHRMANN and FLORENTINE MÜTHERICH (eds.), *Das Evangelium Heinrichs des Löwen und das mittelalterliche Herrscherbild* (1986). The standard work on Salzburg illumination is still the masterly GEORG SWARZENSKI, *Die Salzburger Malerei von den ersten Anfängen bis zur Blütezeit des romanischen Stils: Studien zur Geschichte der deutschen Malerei und Handschriftenkunde des Mittelalters*, 2nd ed., 2 vol. (1969). The best survey of the art of the late 12th century is found in the three volumes of *The Year 1200*, a set published in conjunction with an exhibition: vol. 1, *A Centennial Exhibition at the Metropolitan Museum of Art: A Catalog*, edited by K. HOFFMANN (1970); vol. 2, *A Background Survey*, edited by F. DEUCHLER (1970); and vol. 3, *A Symposium*, texts by FRANÇOIS AVRIL et al. (1975). OTTO DEMUS, *Byzantine Art and the West* (1970), discusses the influence of Byzantine art on western Europe throughout the Middle Ages.

Gothic: General social and intellectual studies of Gothic art include JOAN EVANS (ed.), *The Flowering of the Middle Ages*, new ed. (1985); and JOHAN HUIZINGA, *The Waning of the Middle Ages: A Study of the Forms of Life, Thought and Art in France and the Netherlands in the XIVth and XVth Centuries* (1924, reprinted 1985; originally published in Dutch, 1919). See also ANDREW MARTINDALE, *Gothic Art* (1967, reprinted 1985); GEORGE HENDERSON, *Early Medieval* (1972), and *Gothic* (1967); EMILE MALE, *Religious Art in France, the Thirteenth Century: A Study of Medieval Iconography and Its Sources* (1984; originally published in French, 9th rev. ed., 1958), and *Religious Art from the Twelfth to the Eighteenth Century* (1949, reprinted 1970; originally published in French, 1945); TERESA G. FRISCH, *Gothic Art 1140–c. 1450* (1971); and JACQUES DUPONT and CESARE GNUDI, *Gothic Painting* (1954, reissued 1979; originally published in French, 1954).

For a discussion of Italian Gothic painting, see EVE BORSOOK, *The Mural Painters of Tuscany: From Cimabue to Andrea del Sarto*, 2nd rev. ed. (1980); MILLARD MEISS, *Painting in Florence and Siena After the Black Death* (1951, reprinted 1978); JOHN WHITE, *Art and Architecture in Italy, 1250–1400* (1966), and *The Birth and Rebirth of Pictorial Space*, 2nd ed. (1967); and FREDERICK ANTAL, *Florentine Painting and Its Social Background: The Bourgeois Republic Before Cosimo de' Medici's Advent to Power, XIV and Early XV Centuries* (1948, reprinted 1986). CHARLES D. CUTTLER, *Northern Painting from Pucelle to Bruegel: Fourteenth, Fifteenth, and Sixteenth Centuries* (1968), is an introductory work. No adequate monograph on International Gothic art exists, but, for France, see MILLARD MEISS, *French Painting in the Time of Jean de Berry: The Late Fourteenth Century and the Patronage of the Duke*, 2 vol. (1967), *French Painting in the Time of Jean de Berry: The Limbours and Their Contemporaries*, 2 vol. (1974), and *French Painting in the Time of Jean de Berry: The Boucicaut Master* (1968).

For late Gothic art, French painting is surveyed in GRETE RING, *A Century of French Painting, 1400–1500* (1949, reprinted 1979). Netherlandish painting is dealt with in MAX J. FRIEDLÄNDER, *Early Netherlandish Painting*, 14 vol. (1967–76; originally published in German, 1924–37); the best monograph on this early period is ERWIN PANOFSKY, *Early Netherlandish Painting, Its Origins and Character*, 2 vol. (1953, reprinted 1971). ANNE SHAVER-GRANDELL, *The Middle Ages* (1982), is an introduction to medieval art intended for the general reader; WALTER OAKESHOTT, *The Two Winchester Bibles* (1981), is a scholarly

study of 12th-century painting; RICHARD I. ABRAMS and WARNER A. HUTCHINSON, *An Illustrated Life of Jesus* (1982), includes an analysis of 94 paintings from the collection of the National Gallery of Art in Washington, D.C., with background notes on the artists; and PETER S. BEAGLE, *The Garden of Earthly Delights: Illustrations Taken from the Paintings of Hieronymus Bosch* (1982), is a creative and entertaining introduction to the artist's works.

Renaissance: (Italy): General works include CREIGHTON GILBERT, *History of Renaissance Art: Painting, Sculpture, Architecture Throughout Europe* (1973); MICHAEL LEVEY, *Early Renaissance* (1967, reprinted 1979), and *High Renaissance* (1975); and ROBERT KLEIN and HENRI ZERNER, *Italian Art, 1500–1600: Sources and Documents* (1966). A useful introduction to the theorists of the period is provided by SIR ANTHONY BLUNT, *Artistic Theory in Italy, 1450–1600* (1940, reprinted 1982). See also SYDNEY J. FREEDBERG, *Painting of the High Renaissance in Rome and Florence*, new rev. ed., 2 vol. (1985), and *Painting in Italy, 1500 to 1600*, 2nd ed. (1983), a fine survey of the often-complex movements in 16th-century Italian painting; JAMES BECK, *Italian Renaissance Painting* (1981), a historical survey of works of individual masters; and BRUCE COLE, *The Renaissance Artist at Work: From Pisano to Titian* (1983).

(Northern Renaissance): OTTO BENESCH, *Art of the Renaissance in Northern Europe: Its Relation to the Contemporary Spiritual and Intellectual Movements*, rev. ed. (1965), and *German Painting, from Dürer to Holbein*, trans. from German (1966); WOLFGANG STECHOW, *Northern Renaissance Art, 1400–1600: Sources and Documents* (1966); and ALBERT CHÂTELET, *Early Dutch Painting: Painting in the Northern Netherlands in the Fifteenth Century* (1981; originally published in French, 1980). **(France):** SIR ANTHONY BLUNT, *Art and Architecture in France, 1500 to 1700*, 4th ed. (1980), is an authoritative survey. **(Spain and Portugal):** GEORGE KUBLER and MARTIN SORIA, *Art and Architecture in Spain and Portugal and Their American Dominions, 1500 to 1800* (1959), is the only scholarly study in English. **(Central Europe and Russia):** G.H. HAMILTON, *The Art and Architecture of Russia*, 3rd ed. (1983), is a survey of all the arts of Russia.

Many studies have been done since the 1960s dealing exclusively with Mannerism. The most coherent view as a whole is JOHN SHEARMAN, *Mannerism* (1967). See also FRANZSEPP WÜRTEMBERGER, *Mannerism: The European Style of the Sixteenth Century* (1963; originally published in German, 1962); and GIULIANO BRIGANTI, *Italian Mannerism* (1962; originally published in Italian, 1961).

Baroque and Rococo: The classic study of Baroque art, HEINRICH WÖLFFLIN, *Renaissance and Baroque* (1964, reprinted 1984; originally published in German, 1888), remains an important basic study. MICHAEL KITSON, *The Age of Baroque* (1966), provides an excellent modern summary. JOHN RUPERT MARTIN, *Baroque* (1977), is a fuller survey. GERMAIN BAZIN, *Baroque and Rococo*, trans. from French (1964, reprinted as *Baroque and Rococo Art*, 1974), covers the entire period in less detail, but it has in no way replaced the basic study by FISKE KIMBALL, *The Creation of the Rococo* (1943, reprinted as *The Creation of the Rococo Decorative Style*, 1980). ARNO SCHÖNBERGER and HALLDOR SOEHNER, *The Age of Rococo* (1960; U.S. title, *The Rococo Age: Art and Civilization of the 18th Century*; originally published in German, 1959), has excellent illustrations and detailed notes. Patronage during the period has been analyzed in depth by FRANCIS HASKELL, *Patrons and Painters: A Study in the Relations Between Italian Art and Society in the Age of the Baroque*, rev. ed. (1980). **(Italy):** DENIS MAHON, *Studies in Seicento Art and Theory* (1947, reprinted 1971), is of fundamental importance for an understanding of Baroque art in Italy. RUDOLF WITTKOWER, *Art and Architecture in Italy, 1600 to 1750*, 3rd rev. ed. (1973, reprinted with corrections 1980), surveys the 17th century with clarity and includes a massive bibliography. ELLIS WATERHOUSE, *Italian Baroque Painting*, 2nd ed. (1969), provides an introduction to the principal painters and stylistic movements of the time; a similar role is performed by MICHAEL LEVEY, *Painting in Eighteenth-Century Venice*, 2nd rev. ed. (1980). **(Latin America):** PAL KELEMEN, *Baroque and Rococo in Latin America*, 2nd ed., 2 vol. (1967), is an introduction to the art of the 17th and 18th centuries, with an exhaustive bibliography. **(Flanders):** The only comprehensive introduction to this period available in English is provided by HORST GERSON and E.H. TER KUILE, *Art and Architecture in Belgium, 1600 to 1800* (1960; originally published in German, 1942). **(Holland):** JAKOB ROSENBERG, SEYMOUR SLIVE, and E.H. TER KUILE, *Dutch Art and Architecture, 1600 to 1800*, 3rd ed. (1977), provides an excellent survey of the period and a large bibliography; while WOLFGANG STECHOW, *Dutch Landscape Painting of the Seventeenth Century*, 2nd ed. (1968, reprinted 1981), is a particularly detailed and valuable study of this important facet of Dutch painting. INGVAR BERGSTRÖM, *Dutch Still-Life Painting in the Seventeenth Century* (1956, reprinted 1983; originally published

in Swedish, 1947), provides a survey of this group of paintings. (France): Important surveys are WEND GRAF KALNEIN and MICHAEL LEVEY, *Art and Architecture of the Eighteenth Century in France* (1972); and PHILIP CONISBEE, *Painting in Eighteenth-Century France* (1981). (England): ELLIS WATERHOUSE, *Painting in Britain, 1530 to 1790*, 4th ed. (1978); and MARGARET WHINNEY and OLIVER MILLAR, *English Art, 1625-1714* (1957), are both well-illustrated and include bibliographies. (Central Europe): The best introduction to Baroque art in central Europe, available in English, is undoubtedly EBERHARD HEMPEL, *Baroque Art and Architecture in Central Europe: Germany, Austria, Switzerland, Hungary, Czechoslovakia, Poland*, trans. from German (1965). (Scandinavia): Most of the information available on Scandinavian art of the 17th and 18th centuries is to be found in museum and exhibition catalogs devoted to wider subjects, but the monograph by GUNNAR W. LUNDBERG, *Roslin: Liv och verk*, 3 vol. in 2 (1957), is available, together with the relevant sections in TORBEN HOLCK COLDING, *Aspects of Miniature Painting: Its Origins and Development* (1953).

Neoclassicism, Romanticism, and Realism: Important works on the period in general are WALTER FRIEDLAENDER, *David to Delacroix*, trans. from German (1952, reprinted 1980); and FRITZ NOVOTNY, *Painting and Sculpture in Europe, 1780-1880*, 2nd ed. (1971, reissued 1980). Among the many general studies of Neoclassical art are HUGH HONOUR, *Neo-classicism* (1968, reprinted 1977), a sound introduction; ROBERT ROSENBLUM, *Transformations in Late Eighteenth Century Art* (1967), one of the best studies of the period; and DAVID IRWIN, *English Neoclassical Art: Studies in Inspiration and Taste* (1966), a book dealing exclusively with Neoclassical painting and sculpture in Britain. Among the most important works covering Romanticism are MARCEL BRION, *Art of the Romantic Era: Romanticism, Classicism, Realism* (1966; originally published in French, 1963); WERNER HOFMANN, *The Earthly Paradise: Art in the Nineteenth Century* (1961; originally published in German, 1960); FRANCIS D. KLINGENDER, *Art and the Industrial Revolution*, rev. ed., edited by ARTHUR ELTON (1968); EDGAR P. RICHARDSON, *The Way of Western Art, 1776-1914* (1939, reprinted 1969); FREDERICK ANTAL, *Classicism and Romanticism, with Other Studies in Art History* (1966); T.J. CLARK, *The Absolute Bourgeois: Artists and Politics in France, 1848-1851* (1973, reprinted 1982), and *Image of the People: Gustave Courbet and the 1848 Revolution* (1973, reprinted 1982); ALBERT BOIME, *The Academy and French Painting in the Nineteenth Century* (1971); HUGH HONOUR, *Romanticism* (1979); and MICHEL LE BRIS, *Romantics and Romanticism*, trans. from French (1981). LINDA NOCHLIN, *Realism and Tradition in Art, 1848-1900: Sources and Documents* (1966), and *Realism* (1971), are provocative studies. See also BARBARA NOVAK, *American Painting of the Nineteenth Century: Realism, Idealism, and the American Experience*, 2nd ed. (1979).

Modern: Among the numerous surveys of modern art are H.H. ARNASON, *History of Modern Art: Painting, Sculpture, Architecture, Photography*, 3rd rev. ed., updated by DANIEL WHEELER (1986); JOHN CANADAY, *Mainstreams of Modern Art*, 2nd ed. (1981); JEAN CASSOU, EMILE LANGUI, and NIKOLAUS PEVSNER, *Gateway to the Twentieth Century: Art and Culture in a Changing World* (1962); SAM HUNTER, *Modern American Painting and Sculpture* (1959), *Modern French Painting, 1855-1956* (1956), and *American Art of the 20th Century: Painting, Sculpture, Architecture* (1973); SAM HUNTER and JOHN JACOBUS, *Modern Art: Painting, Sculpture, Architecture*, 2nd ed. (1985); MARCEL BRION et al., *Art Since 1945* (1958); and ROBERT L. HERBERT (ed.), *Modern Artists on Art* (1964). See also BEVERLY WHITNEY KEAN, *All the Empty Palaces: The Merchant Patrons*

of Modern Art in Pre-Revolutionary Russia (1983), an original study of important developments in the history of European art; and SIEGFRIED WICHMANN, *Japonisme: The Japanese Influence on Western Art in the 19th and 20th Centuries* (1981; originally published in German, 1980), a broad study including treatments of individual artists.

Important works dealing with modern painting include: WERNER HAFTMANN, *Painting in the Twentieth Century*, 2nd ed., 2 vol. (1965; originally published in German, 1965); BERNARD S. MYERS, *Mexican Painting in Our Time* (1956); GUIDO BALLO, *Modern Italian Painting: From Futurism to the Present Day* (1958; originally published in Italian, 1956); ALAN GOWANS, *The Restless Art: A History of Painters and Painting, 1760-1960* (1966); and HERBERT READ, *A Concise History of Modern Painting*, 3rd rev. ed. (1975). See also PAUL VOGT, *Expressionism: German Painting, 1905-1920* (1980; originally published in German), and *Contemporary Painting* (1981; trans. from German), a survey of international painting mostly of the 1950s and 1960s; GEORGE H. ROEDER, JR., *Forum of Uncertainty: Confrontations with Modern Painting in Twentieth-Century American Thought* (1980); JOHN RUSSELL, *The Meanings of Modern Art*, rev. ed. (1981); FRANK H. GOODYEAR, JR., *Contemporary American Realism Since 1960* (1981); and ABRAHAM A. DAVIDSON, *Early American Modernist Painting, 1910-1935* (1981).

(*Pre-Raphaelites*): CHRISTOPHER WOOD, *The Pre-Raphaelites* (1981); and *Pre-Raphaelites and Academics* (1981), a catalog of the exhibition organized in celebration of the publication of Wood's work. (*Impressionism and Postimpressionism*): LINDA NOCHLIN (ed.), *Impressionism and Post-Impressionism, 1874-1904: Sources and Documents* (1966); HORST KELLER, *Watercolors and Drawings of the French Impressionists and Their Parisian Contemporaries* (1982; originally published in German, 1980); JOHN REWALD, *The History of Impressionism*, 4th rev. ed. (1973, reprinted 1980), and *Post-Impressionism, from van Gogh to Gauguin*, 3rd rev. ed. (1978). (*Fauvism*): GEORGES DUTHUIT, *The Fauvist Painters* (1950; originally published in French, 1949). (*German Expressionism*): PETER SELZ, *German Expressionist Painting* (1957, reprinted 1974). (*Cubism*): JOHN GOLDING, *Cubism: A History and an Analysis, 1907-1914*, 2nd ed. (1968); CHRISTOPHER GRAY, *Cubist Aesthetic Theories* (1953); and ROBERT ROSENBLUM, *Cubism and Twentieth-Century Art*, rev. ed. (1966, reissued 1976). (*Futurism*): MARIANNE W. MARTIN, *Futurist Art and Theory, 1909-1915* (1968, reprinted 1978). Pakistan

Pakistan (the Islāmic Republic of Pakistan; Urdu: Islām-i Jamhūriya-e Pākistān) is a country in South Asia. It is bounded to the west by Iran, to the north by Afghanistan, to the northeast by China, to the east and southeast by India, and to the south by the Arabian Sea. The territory has an area (excluding the Pakistani-held part of Jammu and Kashmir) of 307,374 square miles (796,095 square kilometres). The capital is Islāmābād.

Pakistan was brought into being at the time of the Partition of British India in 1947 in order to create a separate homeland for India's Muslims in response to the demands of Islāmic nationalists, demands that were articulated by the All India Muslim League under the leadership of Mo-

hammed Ali Jinnah. From independence in 1947 until 1971, Pakistan (both de facto and in law) consisted of two regions—West Pakistan, in the Indus River basin, and East Pakistan, located more than 1,000 miles (1,600 kilometres) away in the Ganges River delta. In response to grave internal political problems, however, an independent state of Bangladesh was proclaimed in East Pakistan in 1971.

Since 1947 the territory of Jammu and Kashmir, along the western Himalayas, has been disputed between Pakistan and India, with each holding sectors. The two countries have gone to war over the territory three times, in 1948–49, 1965, and 1971.

Physical and human geography

THE LAND

Relief and drainage. Pakistan is situated at the western end of the Indo-Gangetic Plain, which is bounded to the north by the mountain wall of the Great Himalayan mountain ranges and their offshoots. It is situated in the northwestern part of the southern Asian subcontinent and may be divided into six natural regions—the northern mountains, the submontane plateau, the Indus Plain, the Balochistān Plateau, the western bordering mountains, and the desert areas.

The northern mountains. The western ranges of the Himalayan mountains occupy the entire northern end of Pakistan, extending about 200 miles (320 kilometres) into the country; they are among the youngest mountains on Earth, having attained their present elevation only within the past one million years. Four of the peaks exceed an elevation of 26,000 feet (8,000 metres), and most rise to heights of more than 15,000 feet. These include such towering peaks as Nānga Parbat (26,660 feet [8,126 metres]; located in Jammu and Kashmir) and K2, also called Godwin Austen (28,251 feet [8,611 metres]). Beyond the Karakoram Range in the extreme north lies the Chinese Uighur Autonomous Region of Sinkiang; to the northwest, beyond the Hindu Kush, are the Pamirs—the “Roof of the World”—where only a narrow strip of Afghan territory separates Pakistan from the Soviet Union. The Himalayan massif (mountainous mass) that isolates the South Asian subcontinent from Soviet and Chinese Central Asia was pierced in 1970 when a road was completed across the Karakoram Range, linking the town of Gilgit in Pakistan with Kashgar in Sinkiang, China. This road carries considerable commerce between Pakistan and China.

The northern mountain barrier influences the rainfall pattern in Pakistan by intercepting monsoon (rain-bearing) winds from the south. Melting snow from the mountains

also feeds rivers, including the Indus, which emerge from the east-west aligned ranges to flow southward.

The population in this inhospitable region is generally sparse, although in a few favoured places it is dense. In most of the tiny settlements of this region, the usual crop is barley; fruit culture, especially of apricots, is of special importance. Timber, mainly pine, is found in some parts, but its occurrence varies with rainfall and altitude. Many slopes have been denuded of cover by excessive timber felling and overgrazing.

The submontane plateau. Lying below the Himalayas, the submontane plateau has four distinct divisions—the Trans-Indus plains, the Potwar Plateau, the Salt Range, and the Siālkot region.

The Trans-Indus plains, west of the Indus, comprise the hill-girt plateaus of the Vale of Peshāwar, Kohāt, and Bannu, which are oases in the arid, scrub-covered landscape of the North-West Frontier Province. Of these, the Vale of Peshāwar is the most fertile. It was once a flourishing centre of Greco-Buddhist culture. Much of the area is covered by gravelly or clayey alluvial detritus. Rainfall is generally only between 10 and 15 inches (250 and 380 millimetres). Most of the cultivated area in the Vale of Peshāwar is irrigated from canals.

Kohāt is less developed than the Vale of Peshāwar. Rainfall is about 16 inches. Only a small percentage of the cultivated area is canal-irrigated. Nor is its groundwater adequately exploited, although the water table is generally high. Much of the area consists of scrub and poor grazing land. The region is much broken by limestone ridges, and the uneven limestone floor is variously filled with lacustrine clays, gravel, or boulders.

In Bannu, soils are sandy or gravelly, except for rich silts that occur in places. About a fourth of the cultivated area is irrigated. Rainfall is low, amounting to about 11 inches. In Kohāt and Bannu, fat-tailed sheep, camels, and donkeys are raised; wool is an important cash crop.

The
Himalayan
sector

The
Vale of
Peshāwar

The Potwar Plateau lies at a height of 1,200 to 1,900 feet and covers an area of about 5,000 square miles east of the Indus and west of the Jhelum River, in the Punjab. It is an open, undulating country, which is mainly of sandstone and is covered by varying thicknesses of loess (a loamy deposit formed by the wind), which erodes easily. Rainfall is between 15 and 20 inches, being higher in the northwest; the southwest is very arid. The landscape is dissected and eroded by streams that, during the rains, cut into the land and wash away the soil. The streams are generally deep-set and are of little or no use for irrigation. It is generally a poor agricultural area, with an excessive pressure of population upon its resources.

The Salt Range lies at the southern edge of the Potwar Plateau and has an average height of 2,200 feet, the highest peak being at Sakesar (4,992 feet). It is an extremely arid territory that sharply marks the boundary between the submontane region and the Indus Plain to the south. The Salt Range is of interest to geologists, as it contains the most complete geologic sequence in the world, in which rocks from the Cambrian period (570 to 505 million years ago) to the Pleistocene epoch (1,600,000 to 10,000 years ago) are represented.

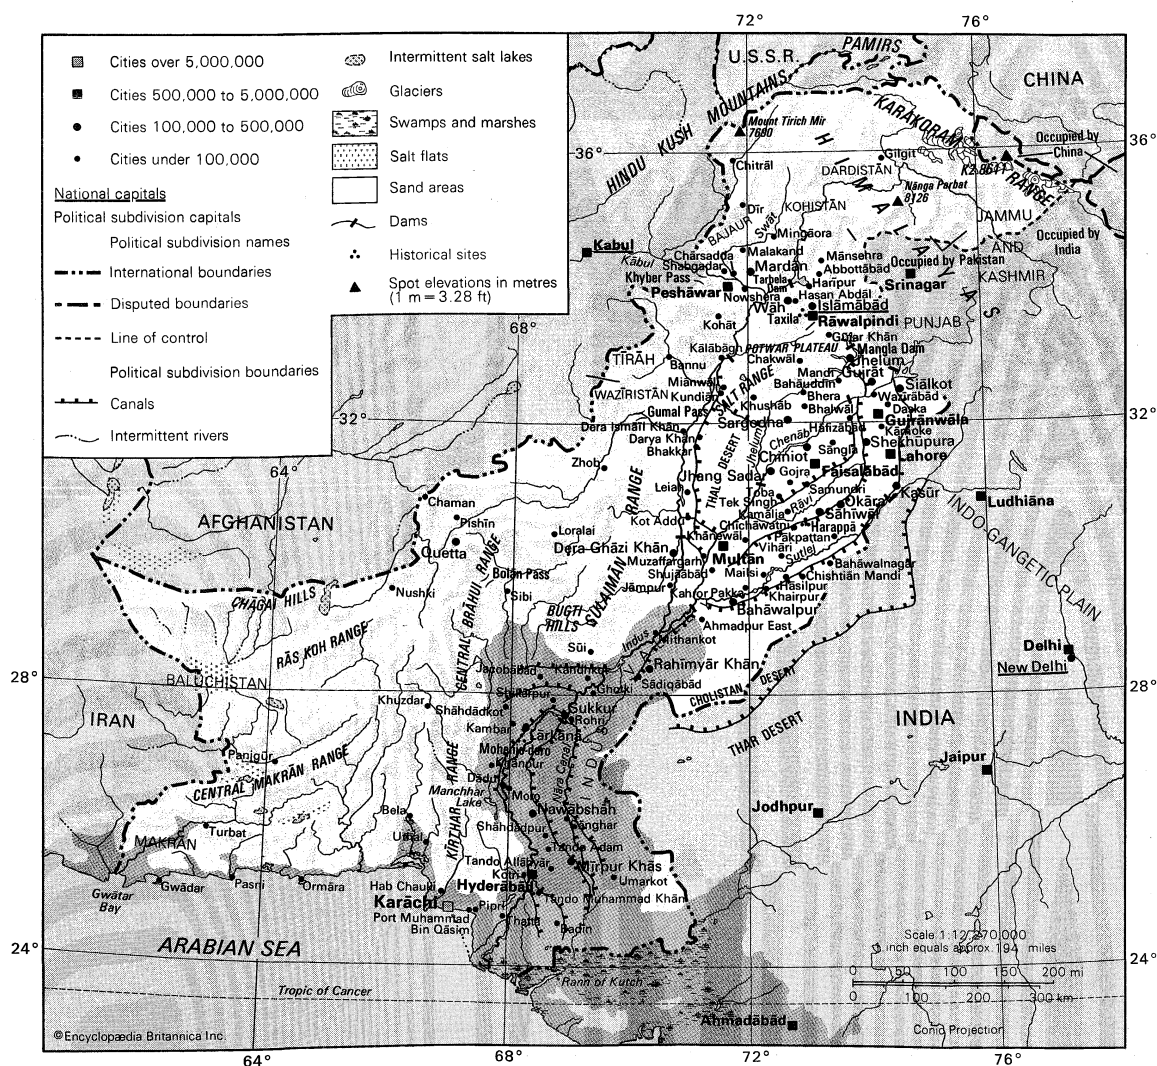

The Siālkot region is a narrow submontane area in the northeast. Unlike the Potwar Plateau, it is a rich agricultural region. Rainfall varies from 25 to 35 inches (650 to 900 millimetres), and the water table is high, facilitating well (and tube-well) irrigation; the soil is heavy and very fertile. The population distribution is dense, and the land is divided into small farms on which intensive cultivation is practiced.

The Indus Plain. The Indus Plain, which covers an area of about 200,000 square miles, is Pakistan's most prosper-

ous agricultural region. It is an unrelieved featureless plain of fertile alluvium extending for 650 to 700 miles from the rim of the Potwar Plateau southward to the Arabian Sea. The province of Punjab (literally, "Five Waters") is located in its northern zone, which is enclosed by the Indus and its five lower tributaries (the Jhelum, the Chenāb, the Rāvi, the Beās, and the Sutlej), the tributaries converging to their confluence with the Indus at Mithankot. The northern zone is divided into several interfluvies (lands situated between streams) called *doābs*. The largest but the poorest of them is the Sindh Sāgar Doāb, situated between the Indus and the Chenāb rivers, which is mostly a desert. The *doābs* that lie to the east of it, however, are the richest agricultural lands in the country. Until the advent of irrigation, at the end of the 19th century, much of the area was a desolate waste, for there is little rainfall. But irrigation has been a mixed blessing; it has also caused waterlogging and salinity in some places. This problem is being addressed by the construction of the Left Bank Outfall Drain, which, when completed, will be a river the size of the Indus, carrying salt water from the plains of Punjab and Sindh to the Arabian Sea.

In the southern zone of the Indus Plain lies the province of Sindh, which is named after the Indus, or Sindhu, River. There, the size of the Indus—its waters augmented by the contribution of its five lower tributaries—is very great; its average annual discharge at Sukkur, in northern Sindh, is more than five trillion cubic feet (140 billion cubic metres), including a large amount of waterborne silt. The land in Sindh, consisting of alluvial sands and clays, tends to give way before the Indus flood, and the river frequently changes course. Manchhar, a marshy lake west of the Indus, has an area of 14 square miles at low water

The *doābs*

but extends for no less than 200 square miles when full; on such occasions, it is one of the largest freshwater lakes in South Asia. The quality of groundwater in the Indus Plain varies, that in the southern zone (Sindh) being mostly saline and unfit for agricultural use. Extensive areas in both the northern and southern zones of the Indus Plain have been affected by waterlogging and salinity. In the south the Indus delta (in marked contrast to the Ganges delta) is a wild waste. When high tides and Indus floods coincide, the littoral is flooded for 20 miles inland.

The Balochistān Plateau. The Balochistān Plateau extends westward, averaging more than 1,000 feet in elevation, with many ridges running across it from northeast to southwest. It is separated from the Indus Plain by the Sulaimān and Kirthar ranges. It has a remarkable indigenous method of irrigation called the karez, which consists of underground channels and galleries that collect subsoil water at the foot of hills and carry it to the fields and villages. The water is drawn from the channels through shafts that are sunk into the fields at suitable intervals. Because the channels are underground, the loss of water by evaporation is minimized. The technology for the construction of the karez probably came from western China, brought into Balochistān by the Buddhist monks who traveled back and forth over the Karakoram Range. The plateau is an extremely arid country and is the most sparsely populated region in Pakistan. Pastoral activity supplements a primitive form of agriculture. True pastoral nomadism survives in the northwest. Goats and fat-tailed sheep account for the majority of the stock, and much of

the local traffic consists of camels and donkeys, although trucks and buses are in use on the new roads.

The western bordering mountains. These mountains run south from the Hindu Kush, in several parallel ranges, outside the path of the monsoons. Elevations in the Hindu Kush exceed 24,000 feet, but peaks are less lofty in the south. Rainfall is low, and there is little vegetation. Occasional heavy rain in the mountains results in destructive torrents, washing away the soil. Cultivation is practiced beside streams and along riverbanks or (where conditions permit) by terracing hillsides. Three minor ranges run south from the Hindu Kush to the Kābul River, south of which lies the Khyber Pass, at the frontier with Afghanistan. Farther south the Sulaimān Range, with peaks averaging 6,000 to 7,000 feet, runs southward for about 300 miles, after which the generally lower Kirthar Range, from 4,000 to 8,000 feet, runs down to the Arabian Sea coast. These hills separate the Indus Plain from Balochistān. The people of these arid hills are tribal. The area in general is very poor; only a minimum of crops are grown in favoured valleys, which are generally malarial. Large numbers of sheep and goats are kept. The mule is the main beast of burden in this broken country.

The desert areas. The desert areas include the steppes of the Sindh Sāgar Doāb (at its centre is the Thal, which has true desert conditions) and Cholistān in the Bahāwalpur region (Punjab), which is known as the Nāra or Registān in the Khairpur region (Sindh) and as the Thar Desert in the Thar Parkar region of southeastern Sindh. All these areas are extensions of the Thar Desert of western India.

Soils. Pakistan's soils are classified as pedocals, which comprise a dry soil group with a high content of calcium carbonate and a low content of organic matter; they are characteristic of a land with low and erratic rainfall. The soils of the Indus Plain consist of alluvium, old and new, whereas in the desert areas and most of Balochistān they consist either of windblown deposits known as loess or else of loess mixed with alluvium. The soils of the Thar Desert area are mostly sandy loams with patches of clay and larger areas of pure sand. Some of the virgin soils respond generously to irrigation, and an extensive reclamation scheme has made much progress in the Thal region.

Climate. As Pakistan is located on a great landmass north of the tropic of Cancer (between latitudes 24° and 37° N), it has a continental type of climate characterized by extreme variations of temperature, both seasonally and daily. Very high altitudes modify the climate in the cold, snow-covered northern mountains; temperatures on the Balochistān Plateau are somewhat higher. Along the coastal strip, the climate is modified by sea breezes. In the rest of the country, temperatures reach great heights in the summer; the mean temperature during June is 100° F (38° C) in the plains, where the highest temperatures can exceed 117° F (47° C). In the summer, hot winds called *loo* blow across the plains during the day. Trees shed their leaves to avoid loss of moisture. The dry, hot weather is broken occasionally by dust storms and thunderstorms that temporarily lower the temperature. Evenings are cool; the diurnal variation in temperature may be as much as 20° to 30° F (11° to 17° C). Winters are cold, with minimum mean temperatures of about 40° F (4° C) in January.

The characteristics of different regions are determined by variations in rainfall and irrigation rather than by temperature. Although the country is dominated by monsoon winds, it is extremely arid, except for the southern slopes of the Himalayas and the submontane tract, which have a rainfall from 30 to 35 inches (750 to 900 millimetres). The 20-inch (500-millimetre) precipitation line, which runs northwest from near Lahore, marks off the Potwar Plateau and a part of the Indus Plain in the northeast; these areas

receive enough rainfall for dry cropping (farming without irrigation by taking measures to conserve water). South of this region, cultivation was confined mainly to riverine strips until the advent of irrigation.

Plant and animal life. Natural vegetation, except for wooded mountain slopes, is largely limited to tough, wiry grass and stunted bushes with only a few scattered trees, except for a few plantations in forest reservations and ubiquitous orchards of fruit trees. In Balochistān the Salt Range and the western-bordering-mountains vegetation is mostly limited to xerophytic plants (plants adapted for growth under dry conditions). The deserts are virtually devoid of vegetation. The Indus Plain is very fertile when watered. Wheat is the principal winter crop, the main summer crops being cotton and rice. Widespread installation of tube wells (also called driven wells, which are built by driving a casing into the ground), especially in the Punjab and increasingly in Sindh and the North-West Frontier Province, has led to substantial changes in cropping patterns, encouraging substitution of wheat for less valuable drought-resisting crops, such as gram (chick-pea).

Wildlife abounds in the northern mountains and includes brown bear, black Himalayan bear, leopard, the rare snow leopard, Siberian ibex, and varieties of wild sheep. Buffalo rather than cows are kept as dairy cattle, and bullocks are used for plowing, although occasionally camels are also used for that purpose. Donkeys are the traditional beasts of burden. The Manchhar Lake in Sindh has many water birds, including mallards, teals, shovelers, spoonbills, geese, pochards, and wood ducks; desert gazelles are also found in the region. Crocodiles, pythons, and wild boars inhabit the delta area. Jackals, foxes, wild cats, and a variety of rodents and reptiles are found throughout the country. There are no game reserves, and indiscriminate hunting is threatening the survival of several species.

Settlement patterns. *Traditional regions.* The traditional regions of Pakistan, shaped by ecological factors and historical evolution, are reflected in the administrative division of the country into the four provinces of Sindh, Punjab, the North-West Frontier Province, and Balochistān. The encroachment of the Cholistan Desert and of the western bordering mountains narrows down the Indus Plain below Mithankot, thus separating the destinies of Sindh and Punjab, each of which has a distinct language, culture, and history. Although the four provinces of Pakistan are separate, both linguistically and culturally, they were brought together from 1955 to 1970 under an administrative arrangement known as "One Unit" that established a single province of West Pakistan.

In the Punjab, until the advent of irrigation, most of the population was restricted to the *bārānī* ("land dependent on rainfall for cultivation") region—the Potwar Plateau and the upper Indus Plain—which receives more than 20 inches of rainfall. The Canal Colony areas of southern Punjab were formerly large tracts of uncultivated land in the Indus Plain that were irrigated by canals and populated by colonists drawn from every part of the Punjab. They now form the richest agricultural region of the country. Agricultural wealth is concentrated in the area around Lahore (in the *bārānī* region) that has benefited from irrigation, together with the Canal Colony areas and Sindh. These regions contain most of the rural population of Pakistan and produce more than half of its wheat and virtually all of its cotton and rice. Landholdings are larger in the Canal Colony areas of the Punjab and in Sindh.

Elsewhere, in the overpopulated and poor districts of the *bārānī* region, which moreover do not benefit from irrigation, holdings are exceedingly small and fragmented. In these districts there is a great pressure to migrate from the villages to find employment in towns or in the armed forces. These districts were the source of most of the migrants (largely men) who went from Pakistan to the Middle East during the 1970s and '80s to take advantage of the economic boom resulting from the increase in the price of oil. Unlike the richer agricultural areas, this impoverished and overpopulated region maintains a close symbiotic relationship with urban economy and society. Educational levels in these districts are higher than they are in the richer agricultural areas.

Tube wells

Land-holding patterns

Rural settlement. Two-thirds of the rural population of Pakistan lives in nucleated villages or hamlets (*i.e.*, in compact groups of dwellings). Sometimes, as is generally the case in the North-West Frontier Province, the houses are placed in a ring with blank outer walls, so that each complex resembles a protected fortress with a few guarded entrances. Dispersed habitation patterns in the form of isolated single homesteads are rare, occurring only in a few mountainous areas. But it is not uncommon to find numerous satellite hamlets of varying sizes near larger villages; such hamlets are occupied either by a landlord, with his servants and sharecroppers, or else by members of a lineage living together in adjoining houses. The spread of tube wells in the Punjab has increased the tendency for such dispersal, for people often prefer to live near their tube wells in order to guard the valuable machinery. The concept of village, therefore, often tends to be equivalent to that of the *mawza'* (an area of land that, together with a village and its satellite hamlets, forms a unit in land-revenue records). It is difficult to speak of an average size of village, for patterns of habitation are complex. Most groups of dwellings have a minimum of a dozen or a score of houses, and there are usually a few hundred dwellings in each "village." Large villages rarely have a population exceeding 2,500 persons.

Three basic types of village layout are to be found. Most of the older villages are of the "spiderweb" form, having at least one focal point, such as the village mosque, some shops, or a well from which lanes radiate. A few villages follow the contours of hill slopes and other natural features. Finally, in the Canal Colony areas, villages are of a regular rectangular pattern, with a well, a mosque, and a school, as well as the house of the village headman, at the centre and with the houses being arranged in a series of concentric rectangles. Houses are built from available local materials; the vast majority are of mud, a material that is not only cheap and reasonably durable in the dry climate but also provides better insulation from extremes of heat and cold than brick or stone. Houses usually have walled courtyards where animals are tethered and where people sleep in the open in the hot summer.

Urban settlement. The urban population of Pakistan represents about a third of the total. Two cities have a dominating position—Karāchi and Lahore. Since the 1960s, government policy has been directed toward the dispersal of industry, which had become heavily concentrated in Karāchi. As a consequence, urban growth has been more evenly distributed among several cities. Karāchi, the principal port and centre of commerce and industry, was also the national capital until 1959, when the new capital at Islāmābād, 750 miles to the northeast, began to function.

Urban
living
conditions

Rapid and unplanned urban expansion has been paralleled by a deterioration in living conditions, particularly in the housing conditions of lower income groups. Many urban households are unable to pay rent for the cheapest form of available housing and live in makeshift shacks. Water supply and sewerage systems are inadequate, and in many areas residents have to share communal water taps. Inadequate urban transport is also a major problem.

Karāchi experienced serious ethnic conflict between the *muhajirs* (immigrants who moved to Pakistan from India following partition) and Sindhis and between the Sindhis and Punjabis in the latter part of the 1980s and the early 1990s. Discouraged by civil strife, businesses—both industrial and commercial—began to relocate in Punjab, particularly in and around the city of Lahore. After Karāchi and Lahore, the principal cities are Faisalābād (called Lyallpur until 1979), Rāwalpindi, and Peshāwar. Karāchi is the provincial capital of Sindh, Lahore of Punjab, Peshāwar of the North-West Frontier Province, and Quetta of Balochistān. The capital city of Islāmābād adjoins Rāwalpindi, where the army's general headquarters and the offices of the president of Pakistan are located.

THE PEOPLE

Ethnic composition. Race as such plays little part in defining regional or group identity in Pakistan, and no ideal racial type is accepted by all Pakistanis. The population is a complex mixture of indigenous peoples, many

racial types having been introduced by successive waves of migrations from the northwest, as well as by internal migrations across the subcontinent of India. Aryans, Persians, Greeks, Pathans (Pashtuns), and Mughals came from the northwest and spread across the Indo-Gangetic Plain, while the Arabs conquered Sindh. All left their mark on the population and culture of the land. During the long period of Muslim rule, immigrants from the Middle East were brought in and installed as members of the ruling oligarchy. It became prestigious to claim descent from them, and many members of the landed gentry and of upper-class families are either actually or putatively descended from such immigrants. In 1947, when Pakistan and India became independent, there was another massive migration, of a different character, when millions of Muslim refugees were uprooted from different parts of India and settled in Pakistan; an equal number of Hindus were uprooted from Pakistan and driven across to India. This development further complicated the racial mixture of the population of the various regions of Pakistan.

By the early 1990s Pakistan's population was divided into five ethnic groups, defined broadly. The Punjabis constitute the majority, with more than 55 percent of the population; the Sindhis account for another 20 percent, the Pathans and the *mujahirs* for about 10 percent each, and the Balochs for about 5 percent. There are subgroups within each of these five categories. The Arains, Rajputs, and Jats—all Punjabis—regard themselves as ethnically distinct. Some groups overlap the five categories: for instance, there are Punjabi Pathans as well as Hazarvi Pathans. Some smaller groups, such as the Brohis in Sindh and the Seraikis in Punjab, are also ethnically distinct.

Linguistic composition. Pakistan is in general linguistically heterogeneous, and no single language can be said to be common to the whole population. Each of its principal languages has a strong regional focus, although statistics show some languages to be distributed between various provinces because administrative boundaries cut across linguistic regions. The picture is also complicated by the fact that, especially in Sindh, there are substantial numbers of Urdu- and Punjabi-speaking immigrants (*muhajirs*) who moved from India following partition. The languages claimed as mother tongue include Urdu, Punjabi, Sindhi, Pashto, Balochi, and Brahui.

Urdu is the youngest of the nation's languages and is not indigenous to Pakistan; it is very similar to Hindi, an official language of India. Although the two languages have a common base, in its literary form Urdu emphasizes words of Persian and Arabic origin, whereas Hindi emphasizes words of Sanskrit origin. Urdu is written in a modified version of the Persian script (written from right to left), whereas Hindi is written in Devānagari script from left to right. Because it is preeminently the language of the educated Muslims of northern India, including the Punjab, Urdu has strong associations with Muslim nationalism; hence the ideological significance of Urdu in Pakistani politics.

Urdu

The 1956 constitution prescribed the use of English for official purposes for 20 years, and the 1962 constitution made the period indefinite. The 1973 constitution, however, designated a 15-year transition period to Urdu, after which English would no longer be used for official purposes. English is spoken by only a small percentage of the people. Urdu is the mother tongue of only a small percentage of the population of Pakistan; it is taught in the schools along with the regional languages.

Punjabi has its own script, Gurmukhi, but it is mainly used in India. In Pakistan, Punjabi is mainly spoken rather than written; it is also a predominantly rural rather than an urban language. Urdu, rather than Punjabi, is the first language taught in schools in Punjab, so that every educated Punjabi reads and writes Urdu. There was a movement for the promotion of the Punjabi language in the 1980s and '90s, and some Punjabi literature is being published using the Urdu script; among the works published are Punjabi classics that have hitherto been available in Gurmukhi script or preserved in oral tradition.

Sindhi is derived from the Virachada dialect of Prākṛit; it has fewer dialects than Punjabi. It is written in a spe-

cial variant of the Arabic script. Most of the educated middle class in Sindh were Hindu, and their departure to India in 1947 had a traumatic effect on Sindhi culture. Vigorous efforts were therefore directed toward a recovery and preservation of the rich Sindhi literary and cultural heritage. Large numbers of Urdu-speaking refugees settled in Sindh, and they now constitute the majority of the population of its larger towns. As a consequence, the movement for the promotion of Sindhi language and culture was sometimes expressed as opposition toward Urdu. The Sindhi population feared that their language and culture would be overrun by the language and culture of the *muhajir* community; this fear led to the language riots of 1972 and to the government's decision to grant special status to the Sindhi language. The rise of militant ethnic politics in the 1980s can be traced to this decision.

Pashto, the language of the Pathans (Pashtuns, or Pakhtuns) of the North-West Frontier Province, has no written literary traditions although it has a rich oral tradition. There are two major dialect patterns within which the various individual dialects may be classified; these are Pakhto, which is the northern (Peshāwar) variety, and the softer Pashto spoken in southern areas. As in the Punjab, Urdu is the language taught in schools, and educated Pathans read and write Urdu. Again, as in the case of Punjabi, there was a movement for developing the written language in Persian script and increasing the usage of Pashto. From 1979 onward, as many as 3.5 million largely Pashto-speaking refugees arrived in Pakistan from Afghanistan. While most were accommodated in refugee camps in and around Peshāwar, a number of them settled in Karāchi, further complicating the city's ethnic and linguistic picture.

The two main spoken languages of Balochistān are Balochi and Brahui. Makrani is an important dialect of Balochi; it is spoken in Makrān, the southern region of Balochistān, bordering on Iran.

Religions. Almost all the people of Pakistan are Muslims. Most of them belong to the Sunni sect, the major branch of Islām, with a significant representation among the Shī'ite branch. There is also a very small, though influential, sect called Aḥmadiyah, or Qadianis, which does not regard the prophet Muḥammad as the final prophet,

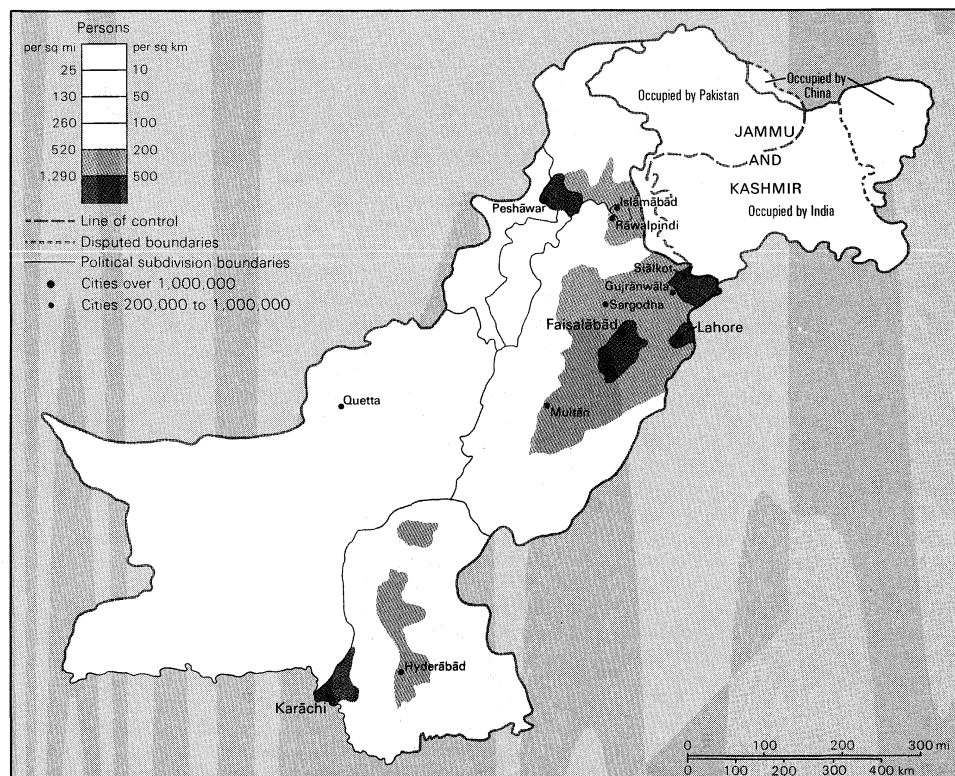

a basic tenet of Islām. A 1974 constitutional amendment declared the Aḥmadiyah community to be non-Muslims. Since then the community has experienced considerable persecution, particularly during the administration of General Mohammad Zia ul-Haq (1977–88). The majority of Pakistani Sunnites belong to the orthodox Ḥanafī school, which is one of four schools or subsets of Sunnism. Shī'ites are also divided into numerous subsets; among them are Ismā'ilīs (the followers of the Aga Khan), as well as the Twelvers (Ithnā 'Asharis) and Bohrās, which are prominent communities in commerce and industry. The principal business communities among Sunnite are Gujarati Memons and Chiniotis from Punjab.

With the exception of some sects, such as Dawoodi Bohrās, there is generally no ordained priesthood among Pakistan's Muslims. Anyone who leads prayers in mosques may be appointed imam. Those who are trained in theology are given the title of mullah or *mawlānā* or, collectively, *ulama*. There are powerful hereditary networks of "holy men" called pirs, who receive great reverence, as well as gifts in cash or kind, from a multitude of followers. An established pir may pass on his spiritual powers and sanctified authority to one or more of his *murīds* ("disciples"), who may then operate as a pir in his own right. There are also many self-appointed pirs who practice locally without being properly inducted into one of the four Shī'ite orders. Pirs who occupy high positions in the pir hierarchy wield great power and play an influential role in public affairs.

The number of Hindus in Pakistan was greatly reduced as a consequence of the exodus of refugees to India in 1947. Both Hindus and Christians constitute only a tiny percentage of the population.

Demographic trends. The rate of population growth is extremely high; it increased from less than 2 percent in the decade following independence to slightly more than 3 percent in the 1980s. In 1986 Pakistan's population crossed the 100 million mark. The fertility rate, estimated at about 6.5 children per woman, has not declined, in spite of government-sponsored family planning programs. Internal migration has had a significant impact on Pakistan's demography. The 1947 influx of Muslim refugees from India brought eight million newcomers to what was then West Pakistan. When Pakistan took its first population

Muslim
sects

Population density of Pakistan and disputed areas. Data not available for areas occupied by China and Pakistan.

Afghan
refugees

census in 1951, one out of every four of West Pakistan's residents was a migrant. Minor migrational shifts occurred between India and West Pakistan following the 1965 border hostilities. After the founding of Bangladesh, thousands of non-Bengali Muslims emigrated from Bangladesh to Pakistan and an almost equal number of Bengalis moved to Bangladesh from Pakistan. A second major wave of Muslim immigration began when thousands of refugees began to flee Afghanistan, occupied by the Soviet Union in 1979, to live in camps and settlements along the Pakistani border. By the close of the 1980s, as many as 3.5 million Afghan refugees had arrived in the country. Emigration also has had demographic, as well as economic and social, effects. Millions of single male Pakistanis went to work in the Middle East in the 1970s and '80s, creating a pool of workers that, at its peak, numbered three million.

Regional distribution of the population is uneven. The population is dense in the fertile Indus valley, especially in the extreme northeast, around Lahore. By contrast, in the vast region of Balochistān, the population densities are relatively low.

A trend toward urbanization has been accompanied by a faster rate of growth of the larger cities as compared to the smaller ones; this reflects the influence of the location of industry in the pattern of urban growth. By the year 2000 the population of Karāchi, Pakistan's largest city, is expected to exceed 10 million, and Lahore, with its satellite cities, is also likely to have roughly the same number of people.

THE ECONOMY

Pakistan operates a mixed economy in which the state-owned enterprises (including industrial corporations, trading houses, banks, insurance companies, institutions of higher learning, medical schools and hospitals, and transport companies) account for nearly half of the gross national product (GNP). In addition, the state, with the help of an intricate system of industrial licensing and trade regulations, controls new private investments. The state also has at its disposal labour, health, and tax laws to oversee the functioning of the private sector. The balance between the public and private sectors of the economy was altered in favour of the former in 1972–74 as a result of a series of nationalization measures. Until then, and unlike most other developing countries, Pakistan had regarded the private sector as the leading sector of the economy.

The economy, which was primarily agricultural at the time of independence, is now considerably diversified. Agriculture, although still the largest sector, now contributes less than one-fourth of the GNP, while manufacturing provides almost one-fifth. In terms of the structure of its economy, Pakistan resembles the middle-income countries of East and Southeast Asia more than the poor nations of the Indian subcontinent. Economic performance compares favourably with that of many other developing countries; the GNP has increased at an average rate of more than 5 percent a year since independence. At the same time, there has been a relentless increase in population, so that, despite a real growth in the economy, output per capita has risen slowly. By 1990 Pakistan's economy was four times as large as it was at the time of independence in 1947, its population was three and a half times as large, and its per capita income was twice as large. In general, although the GNP per capita is relatively low, Pakistan does not have a high incidence of absolute poverty (the level below which a minimally adequate diet and other essential requirements are not affordable); the proportion of the population living in absolute poverty is considerably smaller than in other South Asian countries. The relative prosperity of the industrialized regions around Karāchi and Lahore contrasts sharply with the poverty of the Punjab's *bārāni* areas, the semiarid Balochistān, and the North-West Frontier Province.

One of the paradoxes of Pakistan's economic situation is that, in spite of a healthy increase in its GNP and in spite of its success in alleviating the worst forms of poverty, it has continued to experience a very low level of social development. The social status of Pakistani women is particularly low. The country has a high rate of infant

mortality, losing before they reach one year of age more than 100 children out of every 1,000 born; its maternal mortality rate, at 6 per 1,000 live births, is among the highest in the world; the rate of literacy, with only one of every seven women able to read and write, is very low compared to that of other developing countries.

A system of medium-term planning was introduced in 1958 with the belated publication of the first five-year plan (1955–60). In the following decades a series of five-year plans were formulated, but these met with varying degrees of success.

During the 1980s a movement toward an "Islāmic economy" was announced by the Pakistani government. This movement involved the purging of economic practices outlawed by Muslim theology, such as *riba* (interest), and the mandatory reinstatement of the *zakat* (an annual tax on several types of personal financial assets that is used to provide aid for the poor) and the *ushr* (the *zakat* on land), which had not been universally adhered to but remained central tenets of Islāmic law. General Zia had promised further Islāmization of the economy, but he died before these steps could be taken. Under Benazir Bhutto, his successor, the Islāmization movement slowed, although the government was obliged to keep on the books most of the legislation enacted during the Zia period.

Taxation accounts for more than three-quarters of government revenue, and government expenditures exceed revenues by a large amount. Income tax rates have been comparatively high, but the tax base has been so small that individual and corporate income tax revenues have remained substantially less than excise, sales, and other indirect taxes. The government has been able to maintain heavy expenditure on development and defense because of the inflow of foreign aid and the remittances sent by Pakistanis working abroad. In the 1970s and '80s external capital inflows were equivalent to as much as one-tenth of the GNP and financed well over half of the total domestic investment. In allowing this dependence on foreign capital to persist, however, the country has accumulated an enormous foreign debt, the financing of which has been a major problem.

The trade union movement dates to the late 19th century, but, because Pakistan's industrial sector (inherited at independence) was so small, organized labour as a proportion of total employment is still in a minority. This has not prevented it from becoming an important political force. Before the 1971 civil war, there were well over 1,000 registered unions, most of them organized within individual establishments. Countrywide unions based on a common craft or industry were very few. Most of the unions were situated in the urban centres and were affiliated to one of three national labour confederations. After the civil war and the emergence of Bangladesh, the number of unions declined to a few hundred, affiliated to one umbrella organization, the Pakistan National Federation of Trade Unions. Because of the high rates of unemployment, employers remained in a strong position, and many of them were able to bypass working agreements and laws. Only the unions in the bigger industries (e.g., cotton textiles) had the necessary coherence to fight back. Labour laws introduced in 1972 met some of the demands (job security, social welfare, pensions) of organized labour but also sought to control political activity by industrial workers. Labour union activity was severely constrained by the military government of 1977–88 but was revived by the administration of Benazir Bhutto.

Resources. *Mineral resources.* The exploration of Pakistan's mineral wealth is far from complete, but more than 20 different types of minerals have been located. Coal mining is one of the country's oldest industries. The quality of the coal is poor, and the mines work below capacity because of the lack of demand. Iron ore deposits are also mostly of poor quality. The most extensive known reserves are situated in the Kālābāgh region in western Punjab. Other low-grade ore reserves have been found in Hazāra in the North-West Frontier Province. Small reserves of high-grade iron ore have been identified in Chitrāl and in the Chilghāzi area (located in northwestern Balochistān), also in the North-West Frontier Province. Deposits of copper

Trade
unionsSocial
develop-
ment

ore, equaling or surpassing the reserves of iron ore, have been located, but most sites remain unexploited. There are enormous reserves of easily exploited limestone that form the basis of a growing cement industry, the largest component of the manufacturing sector. Other minerals that are exploited include chromite (mostly for export), barite (a white, yellow, or colourless mineral resembling marble), celestite (strontium sulfate), antimony, aragonite (a mineral resembling calcite [calcium carbonate]), gypsum, rock salt, and marble. Radioactive minerals have been found in southwestern Punjab.

Pakistan also has small quantities of oil and some very large natural gas fields. The first oil discovery was made in 1915. Pakistan intensified the search for oil and natural gas in the 1980s and was rewarded with the discovery of a number of new oil fields in the Potwar Plateau region and in Sindh. The oil fields near Badin, in Sindh, are particularly promising. Oil fulfills a substantial portion of Pakistan's energy requirements, and the search for new and richer fields has continued. The largest natural gas deposits are at Süi (on the border between Balochistān and the Punjab), discovered in 1953. A smaller field, at Māri, in the northwest of Sindh province, was found in 1957. A number of smaller natural gas fields were discovered in the 1980s. A network of gas pipelines links the fields with the main consumption areas: Karāchi, Lahore, Multān, Faisalābād (Lyallpur), and Islāmābād.

Biological resources. The variety of climates and soils has given rise to a wide diversity in biological resources. As Balochistān is mostly desert, only in the small areas of intensive cultivation do crops and orchards thrive. In Sindh and Punjab, where the annual rainfall is also low, most of the vegetation is basically xerophilous, except for the riverine forests along the Indus and its tributaries. Parts of the coastal region have mangrove forests. Regular rain and snow in the Himalayan foothills of the north have given them a variety of vegetation and animal life ranging from the Mediterranean to the Alpine types. There is a fishing industry centred in Karāchi, and part of the lobster and other shellfish catch is exported.

Hydroelectric and other power resources. Although energy production has grown faster than the economy as a whole, it has not kept pace with demand, and as a result there are shortages of fuel and electric power. Great progress, however, has been made in the development of the hydroelectric potential of Pakistan's rivers. A giant hydroelectric plant is in operation at the Mangla Dam on the Jhelum River in Azad Kashmir (the part of the disputed states of Jammu and Kashmir under Pakistan's control). Another such source is the giant Tarbela Dam on the Indus River.

The generation, transmission, and distribution of power is the responsibility of the Pakistani Water and Power Development Authority (WAPDA), a public-sector corporation. WAPDA lost its monopoly over generation after Pakistan signed an agreement in 1989 with a consortium of foreign firms to produce power from giant oil-fired plants to be located at Hub, near Karāchi. The majority of Pakistan's energy requirements are now fulfilled by oil, mostly imported, and by natural gas. Nuclear power provides a very small percentage of the total energy used; it is supplied primarily to Karāchi. In 1989 Pakistan concluded agreements with China and France to set up additional nuclear power-generating plants. These reactors are to be located inland on the Indus River to serve the rapidly increasing demand of Punjab.

Agriculture, forestry, and fishing. Agriculture, forestry, and fishing provide employment for at least one-half of the official labour force and a livelihood for an even larger proportion of the population. Land-reform programs implemented in 1959, 1972, and 1977 began to deal with the problems of large-scale, often absentee ownership of land and the excessive fragmentation of small holdings by introducing maximum and minimum area limits. The commercialization of agriculture has also resulted in fairly large-scale transfers of land, concentrating its ownership among middle-class farmers.

The attention given to the agricultural sector in development plans has brought about some radical changes

in centuries-old farming techniques. The construction of tube wells for irrigation and salinity control, the use of chemical fertilizers and scientifically selected seeds, and the gradual introduction of farm machinery have all contributed to the notable increase in productivity. Early on, one of the prime objectives of agricultural development programs was self-sufficiency in wheat, which Pakistan achieved in the early 1970s.

Pakistan experienced a "green revolution" during the late 1960s. In this period wheat production increased dramatically, leaving a surplus over domestic consumption that was partly shipped to East Pakistan (Bangladesh) and partly exported. Cotton production also rose. Yields remain low by international standards, but increasing amounts are processed locally; in addition, much of Pakistan's edible oil is produced from cottonseed. Rice is the second major food staple and one of the country's important export crops. By the end of the 1980s, Pakistan had become the third largest exporter of rice in the world, after the United States and Thailand. Large domestic sugar subsidies have been the main cause for the increase in sugarcane production.

Animal husbandry provides important domestic and export products. Apart from the supply of meat and dairy products for local consumption, it includes production of wool for the carpet industry and for export and of hides and skins for the leather industry. The contribution of forestry to national income remains negligible, but that of fisheries has risen.

Industry. Mining and quarrying account for a small percentage of gross domestic product and of total employment. Manufacturing, however, accounts for a healthy proportion. The beginning of the main industrialization effort dates to the cessation of trade between India and Pakistan in 1949 soon after the two countries gained independence. Initially it was based on the processing of domestic agricultural raw materials for the home market and for export. This led to the setting up of cotton textile mills—a development that now accounts for a large part of the total employment in industry. Woolen textiles, sugar, paper, tobacco, and leather industries also provide many jobs for the industrial labour force.

The growing trade deficit in the mid-1950s compelled the government to cut down on imports, which encouraged the establishment of a number of import-substitution industries. At first these industries produced mainly consumer goods, but gradually they came to produce intermediate goods and a range of capital goods, including chemicals, fertilizers, and light engineering products. Nevertheless, Pakistan still has to import a large proportion of the capital equipment and raw materials required by industry. In the 1970s and early 1980s Pakistan set up an integrated iron and steel mill at Pipri, near Karāchi, with the financial and technical assistance of the Soviet Union. A new port, Port Qāsim (officially Port Muhammad Bin Qāsim), was built to bring iron ore and coal for the mill.

Initially Karāchi was the centre of Pakistan's industrialization effort, but in the late 1960s and early 1970s Lahore and the cities around it began to industrialize rapidly. Karāchi's ethnic problems in the late 1980s and early 1990s accelerated this process, and Punjab increasingly became Karāchi's competitor in industrial output.

Finance. Pakistan has a fairly well-developed system of financial services. The State Bank of Pakistan has overall control over the banking sector, which consists of a number of commercial banks and specialist credit institutions. The State Bank acts as banker to the central and provincial governments and administers official monetary and credit policies, including exchange controls. It has sole currency-issuing rights and has custody of the country's gold and foreign-exchange reserves. Pakistan has a number of commercial banks, called scheduled banks, which are subject to strict State Bank requirements as to paid-up capital and reserves. They account for the bulk of total deposits, collected through a network of branch offices. A few specialist financial institutions provide medium- and long-term credit for industrial, agricultural, and housing purposes and include the Pakistan Industrial Credit and Investment Corporation, the Industrial Development

Industrial-
ization

WAPDA

Bank of Pakistan, the Agricultural Development Bank of Pakistan, and the House Building Finance Corporation. A new financial institution, the National Development Finance Corporation, was set up in the 1970s to finance industries managed by the state. The Karāchi and Lahore stock exchanges deal in stocks and shares of registered companies. The Investment Corporation of Pakistan and the National Investment Trust have helped to channel domestic savings into the capital market. As part of the return to an "Islamic economy," interest-free banking and financing practices have been instituted.

Trade. Although there has been a trend toward increasing exports, overall trade has remained heavily in deficit. Over the years, important changes have taken place in the composition of foreign trade. In particular, while the proportion of total exports from primary commodities, including raw cotton, has fallen, the share of manufactures has greatly increased. But the bulk of the manufactured products coming into the export trade consists of cotton goods, so that Pakistan remains as dependent as ever on its leading cash crop. The other manufactures exported come mostly from industries based on agriculture, such as leather and leather goods and carpets. The shift toward manufactured agricultural exports, which have a higher added-value content than primary commodities, has been encouraged by the government. The trade deficits and shortages of foreign exchange have made it necessary for the government to restrict imports and to provide financial incentives to promote export trade.

Transportation. The dominant role of rail as the principal long-distance carrier has been displaced by the bus and truck. A program of deregulation of the road transport industry was undertaken in 1970; it encouraged the entry of a large number of independent operators into the sector. Motor trucks and tractor-drawn trailers are also displacing the traditional bullock cart for local transport of produce to markets.

The main arterial road, which runs from Karāchi to Peshāwar via Lahore and Rāwalpindi, is 1,080 miles (1,740 kilometres) long. The main rail route runs more than 1,000 miles north from Karāchi to Peshāwar, via Lahore and Rāwalpindi. Another main line branches northwestward from Sukkur to Quetta.

In the early 1990s the limitations of the transportation system emerged as a major constraint on the modernization of the economy, prompting the government to undertake large-scale investments in the highway sector. Private entrepreneurs were also invited to participate on the basis of a "build-operate-transfer" (BOT) approach, which has become popular in developing countries. (In the BOT system, private entrepreneurs build and operate infrastructure facilities such as ports, highways, and power plants and then recover their costs by charging tariffs from the users. Once the investors have recovered their outlay, the facility created is transferred to the government.)

Pakistan International Airlines (PIA), established in 1954, is the sole carrier of internal air traffic. PIA also runs international flights to Europe, the Middle East, Africa, and East Asia, as well as to neighbouring Afghanistan. The principal airports are at Karāchi, Lahore, Rāwalpindi, Quetta, and Peshāwar. Karāchi and Port Qāsim are the principal ports; in addition, a number of small harbours along the Makran Coast handle the small boats that ply between Pakistan and the Persian Gulf states.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. The political system of Pakistan has undergone several far-reaching changes since independence. In 1971 its turbulent politics culminated in the secession of its eastern region (having more than 54 percent of the total population at that time), which established itself as the independent state of Bangladesh. In the aftermath of that event, Pakistan (now reduced to what was previously West Pakistan) faced a number of political and economic problems and uncertainties about its future.

Several conflicts have left their mark on the politics of Pakistan. The first of these, initially obscured by the paraphernalia of a parliamentary form of government but later made manifest by overt seizure of power by men at the

head of the military and bureaucratic establishment, was a continuing struggle between political leadership and a military-bureaucratic oligarchy for supremacy and authority in the state; ideologically, this struggle was expressed as a struggle for democracy. The military-bureaucratic oligarchy triumphed for a while and set up three military administrations, in 1958–69, 1969–71, and 1977–88.

A second and quite distinct conflict was a struggle between regional groups. Because it was directed against centralized authority, it merged with the democratic struggle. But its express aims were to secure greater regional representation in the bureaucratic and military establishment, especially in the higher echelons, and to achieve effective decentralization of powers within a federal governmental structure by emphasizing regional autonomy. This struggle manifested itself first in the civil war between East and West Pakistan in 1971–72. It also brought to a virtual standstill the working of the first civilian government after the 1977–88 military administration.

A third conflict concerned the allocation of economic resources and burdens and the distribution of a greater share of the benefits of development among the more deprived regions and strata of the population. This resulted in a number of violent confrontations between the less-privileged segments of society and the state. Some of these confrontations, such as those in 1969 and 1977, led to the fall of constitutional governments and the imposition of martial law.

A fourth conflict was between the landed interests that had dominated Pakistan's political and economic life for much of the country's history and the new urban interests that began to assert themselves in the late 1980s and the 1990s. One manifestation of this was the struggle between Punjab and the federal government in the late 1980s. Under the Islamic Democratic Alliance, the Punjab government continued to represent the interests of the landed aristocracy, while the government of Benazir Bhutto, with a more liberal bent and a wider support base, espoused the economic and social interests of urban groups and nonpropertied classes. The two governments often clashed in the late 1980s, creating serious economic management problems.

The constitutional framework. The task of framing a constitution was entrusted in 1947 to a Constituent Assembly that was also to function as the interim legislature under the 1935 Government of India Act, which was to be the interim constitution. Pakistan's first constitution was enacted by the Constituent Assembly in 1956. It followed the form of the 1935 act, allowing the president far-reaching powers to suspend federal and provincial parliamentary government. It also included the "parity formula," by which representation in the National Assembly for East and West Pakistan would be decided on a parity, rather than population, basis. (A major factor in the political crisis of 1970–71 was abandonment of the "parity formula" and adoption of representation by population, giving East Pakistan an absolute majority in the National Assembly.)

In 1958 the constitution was abrogated and martial law was instituted. A new constitution, promulgated in 1962, provided for the election of the president and national and provincial assemblies by an electoral college composed of members of local councils. Although a federal form of government was retained, the assemblies had little power, which was, in effect, centralized through the authority of governors acting under the president. In April 1973 Pakistan's third constitution was adopted by the National Assembly; it was suspended in 1977. In March 1981 a Provisional Constitutional Order was promulgated, providing a framework for government under martial law. Four years later a process was initiated for reinstating the constitution of 1973. By October 1985 a newly elected National Assembly had passed an amended constitution, giving extraordinary powers to the president, including the authority to appoint any member of the National Assembly as prime minister. With the end of military rule in 1988 and following elections to the National Assembly held in November of that year, the new president used these powers to appoint a prime minister to form a civilian government under the amended 1973 constitution.

Political stresses

Growth of manufactures

Structure of government

The amended constitution provides for a president as head of state and a prime minister as head of government; both must be Muslims. The president is elected for a term of five years by the National Assembly, the Senate, and the four provincial assemblies. The prime minister is elected by the National Assembly. The president acts on the advice of the prime minister.

The National Assembly has 237 seats. Of these, 217 are filled by direct popular election; 207 are for Muslim candidates and 10 for non-Muslims. The remaining 20 seats are reserved for women who are chosen by the elected members. Members of the National Assembly serve five-year terms. The Senate has 87 members who are chosen by the provincial assemblies for six-year terms. One-third of the senators relinquish their seats every two years.

Political parties. The role of Islām in the political and cultural unification of Pakistan has been controversial. Some factions have argued that Islāmic ideology is the only cement that can bind together its culturally diverse peoples. Opposing factions have argued that the insistence on Islāmic ideology, in opposition to regional demands expressed in secular and cultural idiom, has alienated regional groups and eroded national unity.

The Pakistan People's Party (PPP) was formed in 1968 by Zulfikar Ali Bhutto, working with a number of socialists who wanted Pakistan to disregard the idiom of religion in politics in favour of a program of rapid modernization of the country and the introduction of a socialist economy. The PPP emerged as the majority party in West Pakistan in the elections of 1970 and was invited to form a government after the collapse of the second military administration in 1972. The PPP was suppressed under the military government of 1977–88 but returned to power in 1988.

In 1962 the Muslim League, which had spearheaded the Pakistan movement under Mohammed Ali Jinnah, splintered into two parts, the Pakistan Muslim League and the Council Muslim League. In the elections of 1970 it almost disappeared as a political party, but it was resurrected in 1985 and became the most important component of the Islāmic Democratic Alliance, which took over Punjab's administration in 1988. The Islāmic Assembly, founded in 1941, commands a great deal of support among the urban lower-middle classes. Two other religious parties, the Assembly of Islāmic Clergy and the Assembly of Pakistani Clergy, have strong centres of support, the former in Karāchi and the latter in the rural areas of the North-West Frontier Province. Ethnic interests are served by organizations such as the Muhajir National Movement in Karāchi and Hyderābād, the Sindhi National Front in Sindh, and the Balochistān Students Union in Balochistān.

Local government and administration. Pakistan's four provinces are divided into divisions, districts, and tahsils (subdistricts), which are run by a hierarchy of administrators, such as the divisional commissioner, the deputy commissioner (in the district), and the subdivisional magistrate, subdivisional officer, or tahsildar, at the tahsil level. The key level is that of the district, where the deputy commissioner, although in charge of all branches of government, shares power with the elected chairman of the district council. In addition to the provinces, Pakistan has 11 federally administered tribal areas, which are overseen by agents responsible to the federal government; the Islāmābād Capital Territory; and a number of tribal areas that are administered by the provincial governments.

Justice. There is a formal division between the judiciary and the executive branches of government. The judiciary consists of the Supreme Court, the provincial high courts, and (under their jurisdiction and supervision) district courts that hear civil cases and sessions courts that hear criminal cases. There is also a magistracy that deals with cases brought by the police. The district magistrate (who, as deputy commissioner, also controls the police) hears appeals from magistrates under him; appeals may go from him to the sessions judge. The Supreme Court is a court of record. It has original, appellate, and advisory jurisdictions and is the highest court in the land. At the time of independence, Pakistan inherited legal codes and acts that have remained in force, subject to amendment.

The judicial system also began a reorientation to Islāmic

tenets and values designed to make legal redress inexpensive and accessible to all persons. A complete code of Islāmic laws was instituted, and the Federal Shariat Court, a court of Islāmic law (Shari'ah), was set up in the 1980s.

Education. Pakistan's literacy rate is substantially lower than that of many developing nations; only about a fourth of all adults are literate. A significant percentage of those who are literate, however, have not had any formal education. Educational levels for women are much lower than those for men. The share of females in educational levels progressively diminishes above the primary school level.

Education in Pakistan is not compulsory. Since independence Pakistan has increased the number of primary and secondary schools, and the number of students enrolled has risen dramatically. Teacher training has been promoted by the government and by international agencies. Higher education is available at vocational schools, technical schools, and colleges throughout the country. The oldest university is the University of the Punjab, established in 1882, and the largest universities are Allama Iqbal Open University in Islāmābād, the University of Peshāwar, and the University of Karāchi. Universities established during the 20th century include the University of Azad Jammu and Kashmir (1980), the North-West Frontier Province Agricultural University in Peshāwar (1981), the International Islāmic University in Islāmābād (1980), the Aga Khan University in Karāchi (1983), and the Lahore University for Management Sciences (1986). Most university classes are taught in Urdu or English.

Education suffered a major setback in the 1970s as a result of the nationalization of private schools and colleges. The reversal of this policy in the 1980s led to a proliferation of private institutions, particularly in the large cities. In the 1980s the government also began to focus on the Islāmization of the curriculum and the increased use of Urdu as the medium of instruction. The more Westernized segments of the population prefer to send their children to private schools, which continue to offer Western-style education and instruction in English. A number of private schools offer college entrance examinations administered by educational agencies in the United States and the United Kingdom, and many graduates of these schools are educated abroad. The division of the educational system into a private, Westernized section and a state-run Islāmized section has thus caused social tensions and exacerbated the problem of "brain drain," the emigration to the West of many of the better-educated members of the population.

Health and welfare. Although Pakistan has made progress in improving health conditions, a large part of the population does not receive modern medical care. There are insufficient numbers of doctors and nurses, especially in rural areas. Sanitation facilities are also inadequate; only a small percentage of the population has access to safe drinking water and sanitary sewage disposal facilities. Malaria, tuberculosis and other respiratory diseases, and intestinal diseases are among the leading causes of death; drug addiction is an increasingly serious problem.

Pakistan was among the first developing countries to establish a state-funded family planning program. This effort began in the early 1960s when the Family Planning Organization was organized. The program ran into political difficulties in the late 1960s as a result of opposition by fundamentalist Islāmic groups. The regimes of Zulfikar Ali Bhutto, Zia ul-Haq, and Benazir Bhutto gave family planning a relatively low priority. Consequently, Pakistan's total fertility and population growth rates are among the highest in the world.

The *zakat* and *ushr* taxes are used to provide social welfare funds, which go to provincial, division, and district committees for distribution among organizations engaged in social welfare activities or directly to needy persons. *Zakat* funds are also used for scholarships.

CULTURAL LIFE

Pakistan shares influences that have shaped the cultures of South Asia. There are thus wider regional similarities extending beyond the national boundaries. On the other hand, the specific regional cultures of Pakistan present a

Islāmization of the legal system

The *zakat* and *ushr*

picture of rich diversity. It is difficult, therefore, to speak of a single Pakistani culture.

Family organization is strongly patriarchal, as in most agrarian societies, and most people live in large extended families. A woman's place in society is low, and she is restricted to the performance of domestic chores and to fulfilling the role of a dutiful wife and mother. In wealthy peasant and landowner households and in urban middle-class families, women are kept in seclusion (*pardah*); on the rare occasions on which they set foot outside their houses, they must be veiled. Among poor peasants, women have duties on the farm as well as in the house and do not observe *pardah*. In the Punjab, cotton picking is exclusively a woman's job, and women keep the money thus earned for their own purposes. Houses of those who practice *pardah* have a men's section (*mardānah*) at the front of the house, so that visitors do not disturb the women, who are secluded in the women's section (*zanānah*).

Among the very rich, Western education and modes of living have eliminated *pardah*, but, in general, even among this group, attitudes toward women in society and the family are akin to those of Victorian England. Change is coming most rapidly among the urban middle-income group, inspired by increasing access to the West as well as by the entry of women into the work force. An increasing number of women do not observe *pardah*, and the education of women has been encouraged. Some women have gained distinction in the professions; some of Pakistan's leading politicians, journalists, and teachers are women.

Social organization revolves around kinship rather than caste. *Berādari* (patrilineage) is the most important social institution. A preferable marriage for a man is with his father's brother's daughter, and among many groups marriages are invariably within the *berādari*. The lineage elders constitute a council that adjudicates disputes within the lineage and acts on behalf of the lineage with the outside world—for example, in determining electoral allegiances.

Pakistan's cultural heritage dates back more than 5,000 years, to the epoch of the Indus civilization. But the emphasis on Islāmic ideology has brought about a strong romantic identification with Islāmic culture—not only that of the Indian subcontinent but of the whole of the Islāmic world. *Qawwālī*, a form of devotional singing, is very popular. Poetry is also a popular rather than an esoteric art, and public poetry recitations called *mushā'irahs* are organized like musical concerts. Urdu, Sindhi, and Pashto poets are regional and national heroes. Literature is the richest of all Pakistani art forms; music and, especially, dancing are less-developed arts. The visual arts, too, play little part in popular folk culture. Painting and sculpture, however, have made considerable progress as expressions of an increasingly sophisticated urban culture.

The cinema is the most popular form of entertainment. Many feature films are produced each year, mostly in Punjabi and Urdu. The songs and music used in the films have a distinctive character and are often reproduced on phonograph records and broadcast on the radio.

Government-owned radio and television have been used in an attempt to harness folk cultural traditions (especially in song, music, and drama) for political and nonpolitical propaganda purposes. Newspapers, in particular those published in Urdu, Sindhi, and English, have a wide readership. (H.A.A./S.J.B.)

For statistical data on the land and people of Pakistan, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

History

BACKGROUND TO PARTITION

The concept of a separate Muslim "nation" or "people," *qaum*, is inherent in Islām, but this concept bears no resemblance to a territorial entity. The proposal for a Muslim state in India was first enunciated in 1930 by the poet-philosopher Muḥammad Iqbal, who suggested that the four northwestern provinces (Sindh, Balochistān, Punjab, and the North-West Frontier Province) should be joined in such a state. It was left to a Cambridge student to coin a name for this grouping: *Pakistan*, from *Pun-*

jab, Afghania (North-West Frontier), *Kashmir*, and *Indus-Sind*. Alternatively the name was said to mean "Land of the Pure." (H.R.T.)

The Muslim League and Mohammed Ali Jinnah. The movement among the Muslim population of the India-Pakistan subcontinent that culminated in the creation of Pakistan stemmed from the historical fact that, for more than six centuries before the effective domination of the British in India, Muslim soldiers and administrators had controlled a population in which Hindus were a numerical majority, although mass conversions to Islām in economically backward areas like East Bengal (Bangladesh) produced local Muslim majorities. When the British replaced Muslim domination by their own, the tradition of rule prevented the Muslims from adapting themselves to the new situation as readily as the Hindus; but the failure of the risings of 1857 dashed Muslim hopes of a restoration of their authority. Later, while Hindus were pressing for constitutional reform through the Indian National Congress, the Muslims sought various guarantees to safeguard their minority position and finally founded their own political organization, the All-India Muslim League, at Dacca in 1906. For a more complete discussion of Pakistan under British rule and the history of Pakistan before British domination see INDIA: *History*.

The gradual clarification of the British intention to grant self-government to India along the lines of British parliamentary democracy aroused Muslim apprehensions regarding ultimate political subjection to the Hindu majority. Mohammed Ali Jinnah, as eager as any Hindu nationalist to bring British rule to an end, was at length driven to the conclusion that the only way to preserve Indian Muslims from complete subordination to the Hindus was to establish a separate Muslim state. By 1940 the demand for Pakistan had been formally endorsed by the Muslim League under his leadership.

British policy, supported by the weight of the Hindu nationalist movement, laboured hard to avoid disrupting the economic and political unity built up during British rule. None of the suggested alternatives to separation of Pakistan commended themselves to Jinnah, whose leadership of the bulk of the community was unchallenged; without his cooperation—of which the price was Pakistan—Indian independence was impracticable. His courage and implacable determination triumphed in the end.

Birth of the new state. Pakistan came into existence as a dominion within the Commonwealth in August 1947, with Jinnah as governor-general and Liaquat Ali Khan as prime minister. With West and East Pakistan separated by more than 1,000 miles of Indian territory and with the major portion of the wealth and resources of the British heritage passing to India, Pakistan's survival seemed to hang in the balance. Of all the well-organized provinces of British India, only the comparatively backward areas of Sindh, Balochistān, and the North-West Frontier came to Pakistan intact. The Punjab and Bengal were divided, and Kashmir became disputed territory. Economically, the situation seemed almost hopeless; the new frontier cut off Pakistani raw materials from the Indian factories, disrupting industry, commerce, and agriculture. The partition and the movement of refugees were accompanied by terrible massacres for which both communities were responsible. India remained openly unfriendly; its economic superiority expressed itself in a virtual blockade. The dispute over Kashmir brought the two countries to the verge of war; and India's command of the headworks controlling the water supplies to Pakistan's eastern canal colonies gave it an additional economic weapon. The resulting friction, by obstructing the process of sharing the assets inherited from the British raj (according to plans previously agreed), further handicapped Pakistan. (L.F.R.W.)

ISLĀMIC REPUBLIC OF PAKISTAN

Mohammed Ali Jinnah died in September 1948, within 13 months of independence. The leaders of the new Pakistan were mainly lawyers with a strong commitment to parliamentary government. They had supported Jinnah in his struggle against the Congress not so much because they desired an Islāmic state but because they had come to re-

The
Muslim
League

Poetry

Ambivalent attitudes toward Islām

garded the Congress as synonymous with Hindu domination. They had various degrees of personal commitment to Islām. To some it represented an ethic that might (or might not) be the basis of personal behaviour within a modern, democratic state. To others it represented a tradition, the framework within which their forefathers had ruled India. But there were also groups that subscribed to Islām as a total way of life, and these people were said to wish to establish Pakistan as a theocracy (a term they repudiated). The members of the old Constituent Assembly, elected at the end of 1945, assembled at Karāchi, the new capital.

Jinnah's lieutenant, Liaquat Ali Khan, inherited the task of drafting a constitution. Himself a moderate (he had entered politics via a landlord party), he subscribed to the parliamentary, democratic, secular state. But he was conscious that he possessed no local or regional power base. He was a *muhajir* ("refugee") from the United Provinces, the Indian heartland, whereas most of his colleagues and potential rivals drew support from their own people in Punjab or Bengal. Liaquat Ali Khan therefore deemed it necessary to gain the support of the religious spokesmen (the mullahs or, more properly, the ulama). He issued a resolution on the aims and objectives of the constitution, which began, "Sovereignty over the entire universe belongs to Allāh Almighty alone" and went on to emphasize Islāmic values. Hindu members of the old Constituent Assembly protested; Islāmic states had traditionally distinguished between the Muslims, as full citizens, and *dhimmi*s, nonbelievers who were denied certain rights and saddled with certain additional obligations.

Political decline. Liaquat Ali Khan fell to an assassin's bullet in October 1951. Into his place as prime minister stepped Khwaja Nazimuddin, the leading member of the family of the nawab of Dacca. He was a Bengali aristocrat and a man of extreme personal piety. Nazimuddin had followed Jinnah as governor-general under the interim constitution. He was succeeded as governor-general by Ghulam Mohammad, a Punjabi, so that the twin pillars of power represented the two main regional power bases in West Pakistan and East Pakistan.

With Nazimuddin in office, militant Muslims, led by the Ahrars, a puritanical political group, called for the purification of national life. In 1953 they demanded that the Ahmadiyah sect be outlawed from the Islāmic community. Nazimuddin temporized, and rioting and arson enveloped Lahore and other Punjabi towns. The secretary of defense, Colonel Iskander Mirza, pressed the Cabinet into sanctioning martial law in Lahore, and order was restored. Ghulam Mohammad decided that Nazimuddin must go, although he had the support of the Constituent Assembly. The dismissal was effected, and Mohammad Ali Bogra became prime minister.

In March 1954 a general election was held in East Bengal (East Pakistan) to choose a new provincial legislature. The contest was between the official Muslim League and a "United Front" of parties from the extreme right (orthodox religious) to extreme left (quasi-Marxist). There was a landslide defeat for the Muslim League. At the head of the victorious opposition stood two politicians who had previously kept one foot in the Muslim League and the other in the camp of the Congress and regional politics; these were the aged Fazl ul-Haq, with his Workers and Peasants Party, and Hussein Shaheed Suhrawardy, with a new party, the Awami League. This result was a dramatic demonstration of the gulf between West and East Pakistan.

The Constituent Assembly reflected the new political mood of Pakistan by attempting to curb the powers of the governor-general, Ghulam Mohammad, who retaliated by proclaiming the dissolution of that body. His action was validated by the Supreme Court, with the rider that a new assembly must be convened. This was produced by a system of indirect election. The ministry of Mohammad Ali Bogra was completely reorganized, and three newcomers were introduced as strongmen from outside politics: these were Major General Iskander Mirza, as minister of the interior, General Mohammad Ayub Khan, commander in chief, as minister of national defense, and Chaudhri Mohammad Ali, a senior civil servant, as minister of finance. Mohammad Ali Bogra had little support in the new as-

sembly, and he was replaced by Chaudhri Mohammad Ali.

Ghulam Mohammad, whose health had broken down, was replaced as governor-general in August 1955 by Iskander Mirza. Mirza had no regional power base and little in common with any of the politicians. He insisted that his fellow administrator Chaudhri Mohammad Ali remain prime minister, and the Chaudhri was able to succeed in one objective over which his three predecessors had failed: he induced the politicians to agree to a constitution (February 1956). To create a better balance between the West and East wings, the provinces and parts of West Pakistan were amalgamated into one administrative unit.

The constitution of 1956 embodied the Islāmic provisions of the "aims and objectives" resolution of 1949 and declared Pakistan to be an Islāmic republic. The national parliament was to comprise one house of 300 members, equally representing East and West. Ten seats were reserved for women. The prime minister and Cabinet were to govern according to the will of the parliament, with the president exercising only reserve powers.

Khan Sahib, a former premier of the North-West Frontier Province, was invited by the Muslim League to become the chief minister of the new "one unit" of West Pakistan. Soon after taking office, Khan Sahib was faced with a revolt against his leadership in the Muslim League, but he adroitly turned the tables by forming a new group, the Republican Party, out of dissident Muslim League assemblymen. In the National Assembly also, members adopted the Republican ticket, and Prime Minister Chaudhri Mohammad Ali found himself without a majority. He resigned in September 1956.

Iskander Mirza, then president, was compelled to accept an Awami League government headed by Suhrawardy but dependent on Republican support to retain office. For a time the combination worked, but the flimsy consensus of Pakistani politics soon began to dissolve into factionalism, regionalism, and sectarianism. Khan Sahib found his hold over the West Pakistan legislature slipping, and he asked the president to suspend the constitution. The East Pakistan legislature voted unanimously for autonomy in all matters except foreign affairs, defense, and currency. The country was to hold its first complete general election in 1958, but a dispute over the basis of the constituencies led to Suhrawardy's resignation. His successors proved ineffective, and the legislative process came to a halt.

Military government. President Mirza had made no secret of his dissatisfaction with the working of parliamentary democracy in Pakistan. On Oct. 7, 1958, a presidential proclamation announced that the political parties were abolished, the constitution abrogated, and the country placed under martial law, with General Mohammad Ayub Khan as chief martial-law administrator. Mirza announced that the martial-law period would be brief and that a new constitution would be drafted. On October 27 he swore in his new Cabinet.

General Ayub became prime minister, and three lieutenant generals were named to the Cabinet. The eight civilian members included businessmen and lawyers, one being a young newcomer, Zulfikar Ali Bhutto. On the evening of October 27 the new military ministers called on the president, with contingents of armed soldiers, and informed him that he was to resign. After a short interval, Mirza was exiled to London. A proclamation issued by Ayub announced his assumption of the presidency.

Martial law lasted 44 months. During that time a number of army officers took over vital civil-service posts. A number of politicians were excluded from public life under the Electoral Bodies (Disqualification) Order, or EBD. A similar purge took place among civil servants.

Ayub sought to create political institutions that would express Islāmic ideals and foster national development. He initiated a plan for "basic democracies," directly elected by the people, as local units of development. Elections took place in January 1960. The Basic Democrats, as they became known, were at once asked to endorse Ayub's presidency and to give him a mandate to frame a constitution. Of the 80,000 Basic Democrats, 75,283 affirmed their support for Mirza in a referendum in February 1960. A constitutional commission was asked to advise on a

The constitution of 1956

Electoral defeat of the Muslim League (1954)

Presidency of Mohammad Ayub Khan

suitable form of government. Ayub accepted some of its proposals and substituted some of his own, aiming, he said, for "a blending of democracy with discipline." In the early days of Ayub's regime there were notable reform measures, such as the Muslim Family Laws Ordinance of 1961, restricting polygamy, but later the president found it necessary to make concessions to Muslims in order to bolster his regime.

One feature of the Ayub regime was the quickening pace of economic growth. During the initial phase of independence, the growth rate was less than 3 percent per annum and scarcely moved ahead of the rate of population growth. During the mid-1950s even this rate declined, but from 1960 to 1965 the rate advanced to more than 6 percent per annum. Development was particularly vigorous in the manufacturing sector.

There was considerable imbalance between East and West; during the 1950s East Pakistan was becoming poorer in per capita terms every year, whereas the West was achieving positive growth. A continuing grievance was the contribution made by East Pakistan to foreign exchange by the export of jute and tea, from which it was felt the West reaped more advantage; the West was also the major beneficiary of foreign aid.

The outstanding example of favoured treatment for the West was the great Indus basin scheme for hydroelectric development. Pakistan skillfully negotiated for assistance from the World Bank, the United States, and other friends. In addition to economic aid, Pakistan also received a great deal of military aid from the United States.

The war over Kashmir in 1965 had more far-reaching effects on Pakistan than on India. Ayub received a new mandate in January when he won decisively against a spirited challenge from Fatima Jinnah, the sister of Mohammed Ali Jinnah. In the early days of his presidency, Ayub had moved freely among the rural people, talking to them face-to-face. After the war, he withdrew behind a curtain of dictatorship, becoming a remote figure in a bulletproof limousine. Bhutto, the chief exponent of struggle against India, was relieved of office in 1966. Mujibur Rahman (Sheikh Mujib), who had inherited the leadership of the Awami League, the major force in East Pakistan, was arrested and accused of conspiring with India.

Decline of
Ayub

Ayub's autocratic position was suddenly challenged in the autumn of 1968; an unsuccessful attempt on his life was followed by the arrest of Bhutto and other opposition leaders. Ayub summoned a conference of opposition leaders and withdrew the state of emergency under which Pakistan had been governed since 1965, but these concessions failed to conciliate the opposition, and in February 1969 Ayub announced that he would not contest the presidential election due in 1970. Protests and strikes flared everywhere, being especially militant in Bengal. At length, on March 25, 1969, Ayub resigned, handing over responsibility for governing to the commander in chief, General Agha Mohammad Yahya Khan. Once again the country was placed under martial law. Yahya assumed the title of president as well as chief martial-law administrator. He made it clear that his aim was an early general election, which took place in December 1970.

Civil war. The success of the Awami League in East Pakistan surprised even its friends. Sheikh Mujib emerged with a majority at his command among the membership of the new assembly (167 of the 300 total). But what upset all predictions was the victory in West Pakistan of Bhutto's Pakistan People's Party (PPP), which won particularly heavily in Punjab and gained a clear majority (83) of the representation from the West. Yahya's plan provided that when the new assembly met it must produce a constitution within 100 days. Mujib, however, stood out for complete independence for East Pakistan, except for foreign policy, though the East wanted to make its own aid, trade, and defense agreements. Bhutto rejected these terms and refused to bring his party to Dacca to participate in the assembly. On March 1, 1971, President Yahya announced that the National Assembly would be suspended indefinitely. Sheikh Mujib replied by ordering a boycott and general strike throughout East Pakistan. Bowing to the inevitable, Yahya proceeded to Dacca in mid-

March to negotiate a compromise that would concede the substance of Mujib's demands while retaining tenuous ties that might still preserve the name of Pakistan. But compromise proved impossible. President Yahya denounced Mujib and his men as traitors and launched a drive to "reoccupy" the East with West Pakistan troops.

Warfare between government troops and supporters of the Awami League broke out in the East in March. Sheikh Mujib and many of his colleagues were arrested, while others escaped to India, proclaiming East Pakistan an independent state under the name Bangladesh ("Bengal Land"). As fighting continued, the number of refugees crossing the border into India grew into the millions. In December 1971 India successfully invaded East Pakistan. The establishment of a Bangladesh government with Mujib as prime minister followed in January 1972.

Establishment of
Bangladesh

Bhutto's regime. Accepting responsibility for the defeat and breakup of Pakistan, President Yahya resigned on Dec. 20, 1971, and Bhutto became the undisputed leader of former West Pakistan. Bhutto's declared policy of Islamic socialism brought few tangible changes, but his populism was undeniably successful. He became increasingly autocratic, however, suppressing criticism, jailing opponents, and using militant methods against the restive Pathans and Balochis. A new constitution was adopted on April 10, 1973, and Bhutto became prime minister.

In January 1977 Bhutto announced that elections would be held within two months, unfolding a national charter of peasant reform. Nine opposition parties hastily patched together the Pakistan National Alliance (PNA) and launched a demand for the Islamic way of life in Pakistan. The campaign was marked by violence, with opposition candidates complaining of brutal discrimination. The results were a sweeping victory for Bhutto's PPP, although they were denounced as fraudulent by the PNA. Mounting protest soon brought chaos to Karachi and other major cities, where Bhutto was compelled to call out the army and proclaim martial law. He tried to buy peace by offering concessions to the PNA leaders (most of whom were under arrest), but they would accept nothing short of a new election.

Zia ul-Haq's regime. To avoid total chaos, the chief of staff of the army, General Mohammad Zia ul-Haq, took over as chief administrator of martial law on July 5, 1977. His early efforts to create an acceptable political alternative had only limited success. He announced that elections would be held in 90 days, but it was clear that Bhutto was the only politician of mass appeal. In early September Bhutto was arrested and charged with attempted murder; on March 18, 1978, he was sentenced to death, and, after Supreme Court review, he was hanged on April 4, 1979.

Zia's efforts to create an acceptable political alternative had only limited success. Thirteen months after taking over the martial-law administration, he announced the formation of a civilian Cabinet of administrators, technocrats, and some political leaders drawn from the Muslim League and the religious parties. The PNA was now split, with most elements forming an opposition that demanded early elections, withdrawal of the army from Balochistan, and the introduction of a full Islamic code of laws. A zealous Muslim, Zia had already imposed Islamic criminal punishments such as flogging and maiming (these were formally enacted as law in February 1979), but he declined to meet the full opposition demand. On Sept. 16, 1978, he was proclaimed president of Pakistan.

Pakistan became a "frontline state" when the Soviet Union occupied neighbouring Afghanistan in December 1979. A guerrilla war began between Afghan mujahideen (freedom fighters) and the Soviet forces, and millions of refugees fled into Pakistan. The mujahideen used a number of refugee camps and other areas inside Pakistan as bases for their activities. The conflict was further internationalized when the United States channeled massive arms supplies to the mujahideen via Pakistan. This program included renewed U.S. aid to Pakistan of \$4.2 billion for the years 1987 to 1992.

Another external pressure was the Islamic revolution in Iran. Partly in response, Zia extended his own Islamization program. In addition to Islamic criminal laws, this

Islamization

included interest-free banking and other measures in keeping with traditional Islāmic economic practice. A national referendum was held in December 1984 on the Islāmization measures, coupled with an endorsement of Zia's presidency for an additional five years; some 62 percent of those eligible were declared to have voted, with 98 percent of the voters in favour of both propositions. The opposition disputed this result, however, claiming that only 10 to 15 percent of the electorate had participated.

In February 1985, elections for the national and provincial assemblies were held. Political parties were not allowed to participate, but there was a high turnout, despite a boycott by the opposition. Zia chose as prime minister Muhammad Khan Junejo, a Sindhi politician who had previously served in Zia's Cabinet. Martial law was lifted in December 1985. In January 1986 Junejo announced the revival of the Pakistan Muslim League. Soon afterward, Benazir Bhutto, the daughter of Zulfikar Ali Bhutto, returned from abroad to re-form the PPP. She received an enthusiastic welcome, but her attempts to arouse popular protest met with little success.

In late 1986 Karāchi, Quetta, and Hyderābād were rocked by riots between the *muhajir* majority and Pathans, originally from the North-West Frontier Province and Afghanistan. Ethnic violence continued through the early 1990s and spread to involve other ethnic groups and other cities in Sindh province.

A deplorable feature of the late 1980s was the increase in the manufacture, use, and export of narcotics. It was calculated that the world's major source of heroin was the Afghan-Pakistan borderland. Annual production of opium was said to exceed 200 tons in some years, and it was estimated that as many as one million people were addicted to heroin.

In May 1988 Zia dissolved the national and provincial assemblies and dismissed the Junejo government, alleging that it was corrupt, weak, and inept. He announced that elections would be held within 90 days, but they were later postponed to November. In June a caretaker government was set up, with Zia acting as head of government.

The administration of Benazir Bhutto. On Aug. 17, 1988, Zia was killed in an airplane crash, together with his leading generals and the U.S. ambassador. Suspicion rested on Soviet agents, but nothing was proved. The chairman of the Senate, Ghulam Ishaq Khan, a long-standing Zia supporter, took over as acting president and announced that elections would be held in November as planned.

When the election results were counted, the PPP, led by Benazir Bhutto, had won 93 seats; the Islāmic Democratic Alliance, claiming the mantle of Zia, won 54 seats; and the remaining 58 seats were won by independents and candidates from minor parties. Support for Bhutto in the key province of Punjab, with 60 percent of the population, was weak, and in subsequent provincial elections the Islāmic Democratic Alliance held this key province. PPP candidates became chief ministers of Sindh and the North-West Frontier Province. Bhutto had a mandate, but it was incomplete. In subsequent negotiations conducted by Ishaq Khan, who was elected president in December 1988, she had to make concessions in important areas of policy. Thus, Pakistan's commitment to the Afghan mujahideen continued, and the army retained its premier place in the system. (Pakistan's armed forces numbered over half a million people in the late 1980s; some 480,000 of these were in the army.) In December 1988 Benazir Bhutto (the name Benazir means "Incomparable") became the first woman to lead an Islāmic state.

Given office without real power, Benazir Bhutto responded much as her father had: by projecting her image on the national and international stage without attempting to make fundamental changes at home. Social and economic conditions remained very much as at the end of British rule. Agriculture continued to be the staple of the economy, with the Punjab as the breadbasket of the country and the great landowners as the main force in rural society.

A major element in assisting Pakistan toward prosperity was the migration of hundreds of thousands of workers overseas, first to the United Kingdom in the 1960s and

'70s and later to the Gulf states and to Libya. These human exports were drawn from every level of society, including professional people (notably doctors, despite a severe shortage at home), manual workers (more than 80 percent of the emigrants), and—a peculiarly Pakistani export—military personnel. The Pakistani army gained a high reputation for professionalism in the Middle East, and Pakistani officers have been seconded to several Arab armies. Remittances to Pakistan from overseas workers rose to nearly \$3 billion during the early 1980s, thereafter leveling off. Most of the remittances went to Punjab. The military emigrants form an important component in Pakistan's foreign policy, directed to gaining leadership in the Islāmic world. (H.R.T.)

Palestine

Palestine is a small region of the eastern Mediterranean comprising parts of modern Israel and Jordan. The area is also known as the Holy Land and is held sacred among Christians, Jews, and Muslims. In the 20th century it has been the object of conflicting claims between Jewish and Arab national movements, and the conflict has led in several instances to warfare.

Palestine was named after the Philistines, who occupied a small pocket of land on the southern coast, between modern Tel-Aviv-Yafo and Gaza, in the 12th century BC. The area, first called Philistia, gave its name in the 2nd century AD to Syria Palaestina, the southern portion of the Roman province of Syria. The name Palestine was revived as an official title when the British were given a mandate for the government of the country after its release from Ottoman rule in World War I. It is still in popular use as a general term to define a traditional region, but this usage does not imply precise boundaries. In the modern period, the area of Palestine may perhaps best be defined, therefore, as extending from the Mediterranean on the west roughly to the Jordan River on the east and from Israel's international border with Lebanon in the north to its southernmost city, Elat.

Its area is small, about 280 miles (450 kilometres) long and a maximum of 80 miles wide, but its strategic im-

portance is immense, as through it pass the main roads from Egypt to Syria and from the Mediterranean to the hills beyond the Jordan River. On a broad view, Palestine incorporates a part of the high edge of the Arabian Plateau, and its chief physical features are the outcome of the following processes: uplift and moderate folding that have raised the main hill masses; fracture and subsidence, producing the deep rifts and clefts that have severed these hills into their present partitions; the eruption of lava in certain districts; and the silting of the maritime plain with sediment borne by the current that sweeps round from the mouths of the Nile. Palestine consequently includes regions of very distinct geographic character.

Settlement is closely dependent on water, which is almost never abundant. The rainfall, which arrives in the cool half of the year, decreases in amount in general from north to south and from the coast inland. Perennial rivers are few, and the shortage of water is aggravated by the porous nature of the limestone rocks over much of the country.

For further reading on the political units most closely associated with Palestine, see the *Macropædia* articles EGYPT; ISRAEL; JORDAN; and LEBANON. For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 911, 922, 96/11, and 978.

Physical and human geography

THE LAND

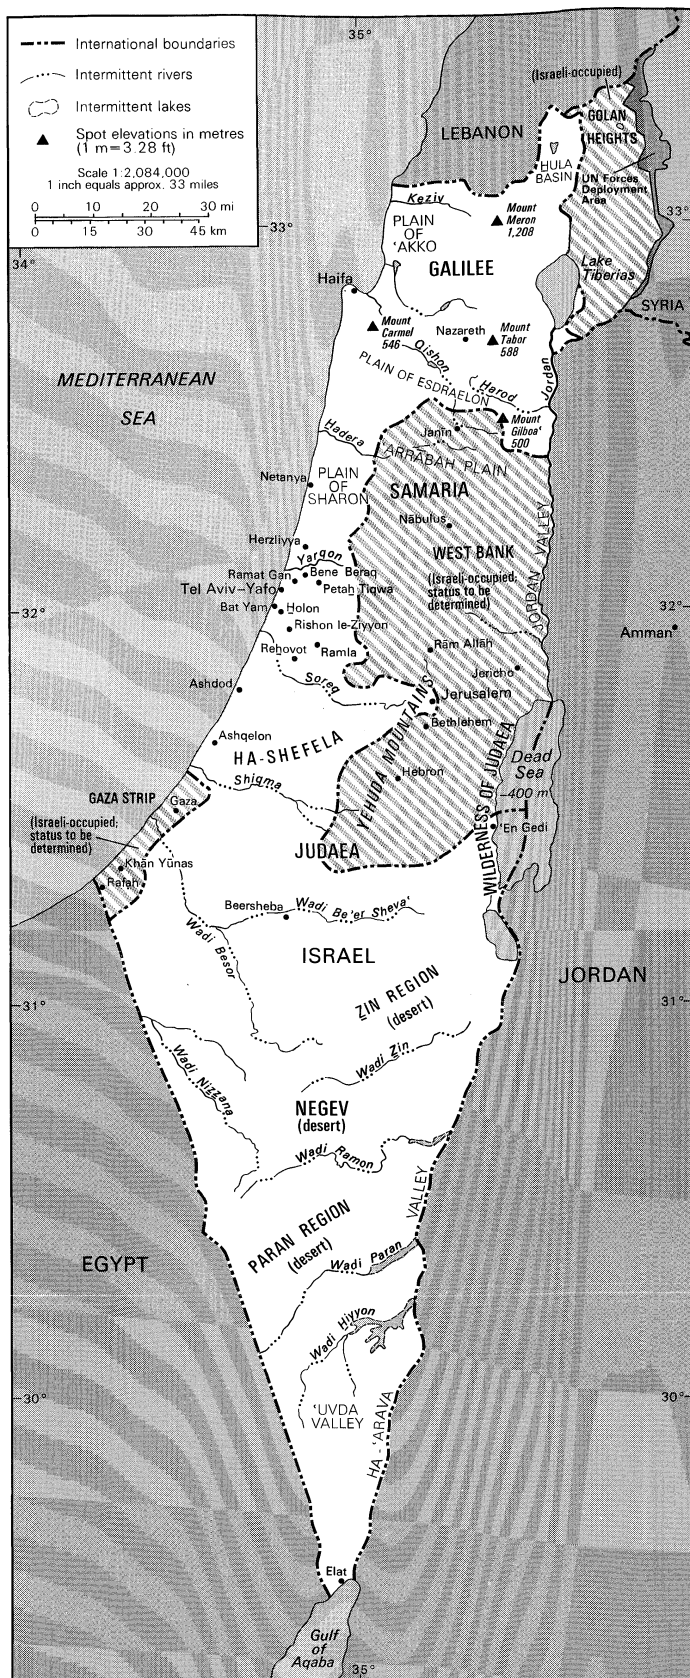

Of the coastal lowlands the most northerly is the Plain of 'Akko (Acre), which extends with a breadth of five to nine miles for about 20 miles from the Nāqūrah Headland in Lebanon in the north to the Carmel promontory, in Israel, in the south, where it is a mere 600 feet (180 metres) wide. Farther southward it opens out rapidly into the Plain of Sharon, about eight miles wide and extending south to the latitude of Tel-Aviv-Yafo. Once heavily forested in some sections and ill-drained and covered with marshes in others, the Sharon plain was reclaimed in the post-Exilic and Hellenistic period and is now a settled area. Fields and fruit groves are laid out between scattered sandstone ridges, on which villages have grown up. South of the spur of low hills that approaches the coast about Yafo, the maritime plain widens into the fertile region of Philistia, a district of orange groves, irrigated orchards, and fields of grain.

The Plain of Esdraelon ('Emeq Yizre'el), formed by subsidence along lines of faults, separates the hills of southern Galilee from the mountains of Samaria. The plain, 16 miles wide at most, narrows to the northwest, where the Qishon River breaks through to the Plain of 'Akko, and

to the southeast, where the river (the modern Harod), which rises at the Well of Harod ('En Harod), has carved the plain into the side of the Jordan Valley. Covered with rich basaltic soils washed down from the Galilean hills, Esdraelon is important both for its fertility and for the great highway it opens from the Mediterranean to the lands across the Jordan. The maritime plain connects with Esdraelon by the pass of Megiddo and several lesser routes between the mountain spurs of Carmel and Gilboa'.

The hill country of Galilee is better watered and more thickly wooded than that of Samaria or Judaea. North of the Plain of Asochis, Upper Galilee, with heights of 4,000 feet, is a scrub-covered limestone plateau and is thinly peopled. To the south, Lower Galilee, with its highest mountain, Tabor (1,929 feet), is a land of east-west ridges enclosing sheltered vales like that of Nazareth (Nazerat), with rich basaltic soils.

Samaria, the region of the ancient kingdom of Israel, is a hilly district extending from the Plain of Esdraelon to the latitude of Ramla. Its mountains, Carmel, Gilboa', Ebal, and Gerizim, are lower than those of Upper Galilee, while its basins, notably those of the 'Arrābah Plain and Nābulus (Shekhem), are wider and more gently contoured than their equivalents in Judaea. Samaria is easily approached

Palestine as defined in modern times, showing the boundaries of the State of Israel and territory occupied by Israel.

from the coast over the hills of Ephraim and from the Jordan by the Fāri'ah Valley. The city of Jerusalem has expanded rapidly along the mountain ridges.

From Ramla in the north to Beersheba in the south, the high plateau of Judea is a rocky wilderness of limestone,

with rare patches of cultivation, as around al-Birah and Mt. Hebron (al-Khalil). It is separated from the coastal plain by a longitudinal fosse and a belt of low hills of soft chalky limestone, about five to eight miles wide, known as ha-Shefela. The Judaeen plateau falls abruptly to the Jordan Valley, which is approached with difficulty along the wadis Kelt and Mukallik.

The Jordan Valley is a deep rift valley that varies in width from 1.5 to 14 miles. In its northern section the bed of the drained Lake Hula and Lake Tiberias (the Sea of Galilee) are blocked by natural dams of basalt. Descending to about 1,310 feet below sea level, the valley is exceedingly dry and overheated, and cultivation is restricted to irrigated areas or rare oases, as at Jericho or at 'En Gedi by the shore of the Dead Sea. (W.C.B./W.L.O.)

THE PEOPLE

The social geography of Palestine in the 20th century has been greatly affected by the dramatic political changes and wars that have brought this small region to the attention of the world. Since 1948 and the end of the British mandate, about three-fourths of geographic Palestine has been part of the State of Israel. Arabs constitute a minority of the population of Israel (about one-sixth in the late 1980s), while Jews constitute the rest of the citizenry. Hebrew is the predominant language, although Arabic is also an official language that can be used in government. The Jewish majority is increasingly composed of persons born in Israel itself, although hundreds of thousands of immigrants have arrived since independence. The Arab minority is descended from Arabs who lived in the area during the mandate period and, in most cases, for centuries before that time. A majority of both Jews and Arabs are now urbanized.

According to Jewish nationalists (Zionists), Judaism constitutes a basis for both religious and national (ethnic) identity. Arab Palestinian nationalists usually emphasize that their shared national identity or Arabness transcends the religious diversity of their community: Muslim Arabs are about 14 percent of the Israeli population, and Christian Arabs about 3 percent.

The other one-fourth of geographic Palestine not gained by Israel in 1948 was occupied by its forces in the Arab-Israeli war of 1967. The Arab majority resident in these territories—the West Bank, west of the Jordan River, and the Gaza Strip, along the Mediterranean coast—and the still larger number of Arab Palestinians living outside geographic Palestine (many in nearby countries such as Lebanon), have strongly opposed Israeli control and what they fear will be eventual annexation of these areas by Israel. Most Jewish Israeli settlers living in the occupied territories would like to have this annexation take place; they think the land ought to be part of Israel proper.

Both Zionists and Palestinian Arab nationalists have at various times in recent history claimed rightful possession of all of geographic Palestine. The rivalry between the two groups and their claims have been major causes of the numerous Arab-Israeli wars and the continuing crises in the region. Some members of each group still make such sweeping and mutually exclusive claims to complete control of Palestine, while others are now more willing to seek a peaceful compromise solution. (W.L.O.)

History

STONE AGE AND CHALCOLITHIC

The Paleolithic era of Palestine was first fully examined by the archaeologist Dorothy Garrod in her excavations of caves on the slopes of Mt. Carmel in 1929–34. The finds showed that at this stage Palestine was culturally linked with Europe, and human remains were recovered showing that the inhabitants were of the same group as the Neanderthal inhabitants of Europe. The Mesolithic period is best represented by a culture called Natufian, known from excavations at 'Ain Mallāha and Jericho. The Natufians lived in caves, as did their Paleolithic predecessors, but there is a possibility that they were experimenting in agriculture, for the importance to them of the collection of grain is shown by the artistic care that they lavished on the

Natufian culture

Farmland and mountain range near Nazareth, in Lower Galilee.

A.L. Goldman—Rapho/Photo Researchers

carving of the hafts of their sickles and in the provision of utensils for grinding. During the subsequent Neolithic period humans gradually undertook the domestication of animals, the cultivation of crops, the production of pottery, and the building of towns (e.g., Jericho by 7000 BC).

Excavations also have provided a picture of events in Palestine in the 5th–4th millennium BC, during which the transition from the Neolithic to the Chalcolithic (the first period of the Bronze Age) took place. It was probably in the 4th millennium that the Ghassulians immigrated to Palestine. Their origin is not known; they are called Ghassulians because the pottery and flints characteristic of their settlements first attracted attention in the excavations of Tulaylāt al-Ghassūl in the Jordan Valley. There was a permanent village site, with several successive layers of occupation, and the site probably was associated with reasonably efficient agriculture. The phase can be called Chalcolithic, since copper axes were found at Tulaylāt al-Ghassūl, and this is confirmed by the finds at sites near Beersheba, with pottery and a flint industry allied to those of Tulaylāt al-Ghassūl but not identical with them. At Beersheba there was a copper-working industry, which, presumably, imported ore from Sinai, and there was also evidence of an ivory-working industry, both proving the growth of a class of specialist craftsmen. Discoveries near 'En Gedi have revealed a shrine of this period, and basketry, ivory, leather, and hundreds of copper ritual objects were found in the Naḥal Mishmar caves of the Judaean desert.

The region in which the Ghassulian settlements have been found is mainly in the south of Palestine, with an extension up the coastal plain and its fringes. These settlements seem to have died out and disappeared in the last centuries of the 4th millennium, at about the same time as a new population immigrated, probably from the north. Thereafter, the composite elements in Palestine consisted of the indigenous Neolithic-Chalcolithic population, the Ghassulians, and these latest immigrants; in time the peoples were amalgamated into what was to become the sedentary urban population of the Early Bronze Age in the 3rd millennium.

Palestine dating is henceforth linked to Egyptian dating down to the time of the Hebrew monarchy; the interpretation of Egyptian dates in Rolf Krauss's *Sothis- und Monddaten* (1985) is followed in this article.

THE BRONZE AGE

Early Bronze Age. It was in the Early Bronze Age that most of the towns that are known in historic times came into existence. The growth of these towns can be approximately correlated chronologically with the development of the Old Kingdom in Egypt, Early Bronze I corresponding to the Late Predynastic period and Early Bronze II being cross-dated by finds to the time of the 1st dynasty, c. 2925 BC. Evidence of the early phases of the Early Bronze Age comes mainly from Megiddo, Jericho, Tell el Far'ah, Bet She'an, Khirbet Kerak, and Ai. All these sites are in northern or central Palestine, and it was there that the Early Bronze Age towns seem to have developed. The towns of southern Palestine, for instance Tell ed Duweir, Tell Beit Mirsim, and Tell el Hesi, seem only to have been established in Early Bronze III. The town dwellers, identified as the original Semitic population, can, for the sake of convenience, be called Canaanites, although the term is not attested before the middle of the 2nd millennium BC.

In the course of the 3rd millennium, therefore, walled towns begin to appear throughout Palestine. There is no evidence that the next step of unification under the leadership of a single town took place in Palestine, as it had in Mesopotamia and Egypt; Palestine's towns presumably remained independent city-states, except insofar as Egypt may at times have exercised a loose political control. By about the 23rd century BC, the whole civilization had ceased to be urban. The next phase was pastoral and was influenced by the settlement of nomads probably from east of the Jordan River. Among the nomads, Amorites from the Syrian desert may have predominated. It is not yet fully understood how these events are related to the creation of the Akkadian empire in Mesopotamia under Sargon of Akkad and his grandson Naram-sin (24th and 23rd centuries BC) and to the latter's destruction of the powerful kingdom of Ebla (modern Tall Mardikh) in neighbouring Syria, nor is the extent of Eblaite and Akkadian hegemony over Palestine in this period known. It does, however, seem reasonable to associate the incursion of nomads from the east with the invasions of Asiatics into Egypt that brought the Old Kingdom to an end. An initial date of 23rd–22nd century BC, depending on the interpretation of the Egyptian evidence, and a final date of the 20th century BC seem probable.

The picture of Palestine at this period is thus unequivocally that of a country occupied by a number of allied tribes; between them there are many features in common, but there are also many differences. The most significant point is that, with the possible exception of the northern group, they made no contribution at all to town life. The different groups had tribal centres, but they were essentially seminomadic pastoralists. This description fits well that in the Book of Joshua of the Amorites who lived in the hill country, as opposed to the Canaanites who lived in the plains and on the coast—areas favourable to agriculture.

Middle Bronze Age. It was, in fact, the next period—the Middle Bronze Age—that introduced the Canaanite culture as found by the Israelites on their entry into Palestine. The Middle Bronze Age (c. 2000–c. 1550 BC) provides the background for the beginning of the story of the Old Testament. The archaeological evidence for the period shows new types of pottery, weapons, and burial practices. Once more an urban civilization based on agriculture was established. It is not entirely clear whether the wave of urban development after the 20th century BC was the work of a new immigrant people accustomed to dwell in towns or of the local inhabitants themselves, some of whom may have adopted a sedentary life-style and begun, as in Mesopotamia and Syria, to establish dynasties. But where they settled, there grew up towns of the widespread Middle Bronze Age civilization of Palestine. This civilization was intimately connected with that of the towns of the Phoenician-Canaanite coast. Extant Egyptian documents provide valuable information about Palestine in the period of the Egyptian 12th dynasty (1938–1756 BC) and argue for significant Egyptian interest and influence in Palestine at this time. (Most notable are the popular literary work known as the *Story of Sinuhe*, detailing the hero's exile

in the Palestinian region, and the 20th–19th-century “Ex-ecration Texts,” inscriptions of names of Egypt’s enemies on pottery, which was ceremonially broken to invoke a curse.) The culture introduced at this stage was essentially the same as the culture found by the Israelites who moved into Palestine later, in the 14th and 13th centuries BC.

A large repertory of new forms in pottery arose, and for the first time in Palestine it was turned entirely on a fast wheel. Comparisons of Palestinian early Middle Bronze pottery forms with metallic and ceramic forms at Byblos, dated by Egyptian contacts, suggest that these forms were brought to Palestine around the 19th century from coastal Syria. Bronze weapons of a distinctive type, paralleled also on the Syrian coast, are found at Megiddo, Jericho, and Tell el ‘Ajjul. Town life in Palestine gradually expanded after the mid-19th century BC, but the material culture was essentially a direct development from the preceding stage. Several towns of Middle Bronze Age Palestine were defended by plaster-faced ramparts (clearly discernible at Jericho and many other sites), an imported method of fortification giving evidence of a new and alien influence superimposed upon the existing Canaanite culture. These were probably introduced by the Asiatic Hyksos, possibly related to the Amorites, who secured control of northern Egypt in about 1630. The Hyksos may have included elements of a grouping of people, largely Semitic, called the Habiru, or Hapiru (Egyptian ‘Apiru). (The term Habiru, meaning “outsiders,” was applied to nomads, fugitives, bandits, and workers of inferior status; the word is etymologically related to “Hebrew,” and the relationship of the Habiru [and aforementioned Hyksos] to the Hebrews has long been debated.) The Habiru appear to have established a military aristocracy in Palestine, bringing to the towns new defenses and new prosperity (as well as many Egyptian cultural elements) without interrupting the basic character of the local culture; this was to survive the destruction of Megiddo, Jericho, and Tell Beit Mirsim that followed the Egyptians’ expulsion of the Hyksos into Palestine at the end of the Middle Bronze Age (c. 1550).

(K.M.K./G.R.B.)

Late Bronze Age. There was no sharp break between the Middle and the Late Bronze ages in Palestine. Shortly before the death of Ahmose I (1514 BC), the first native pharaoh of the New Empire, the Egyptian armies began to conquer Palestine, probably completing their task during his successor’s reign. Under Queen Hatshepsut (1479–58), Palestine revolted against Egyptian domination, but the rebellion was put down firmly by her successor, Thutmose III, who established a stable administration, maintained through the reigns of his immediate successors. Egyptian administrative documents excavated in both Egypt and Palestine show in considerable detail how the provincial government was organized and even how it operated during the century 1450–1350 BC. Documents show, for example, that the land of Retenu (Syria-Palestine) was divided into three administrative districts, each under an Egyptian governor. The third district (Canaan) included all of Palestine from the Egyptian border to Byblos. This period is often known as the Amarna Age and is vividly illustrated by several hundred cuneiform letters found in Egypt at Tell el Amarna, site of the capital of the “heretic king” Akhenaton. The unusual concern of the pharaohs with the affairs of Palestine was chiefly a result of the fact that control of it was necessary for the defense of Phoenicia and southern Syria, menaced by Mitanni down to c. 1375 and by the Hittite Empire after that date.

In about 1292 BC the increasingly weak rule of the last pharaohs of the 18th dynasty was replaced by the strong arm of the second and third kings of the 19th dynasty, Seti I and Ramses II (1279–13 BC). These kings blunted the southward thrust of the Hittites and consolidated the crumbling Egyptian Empire. The exactions of foreign bureaucrats, however, combined with internal decay, had so enfeebled the Canaanite vassal princes of Palestine that it was comparatively easy for the incoming Israelites to occupy most of the hill country of both Transjordan and western Palestine in the course of the closing decades of the 13th century BC. Archaeological evidence suggests that the Israelite settlement in Palestine was much more

complex and disconnected than the biblical accounts indicate. During a short interlude of anarchy that followed the last weak kings of the 19th dynasty, Egyptian rule was completely extinguished, and the ephemeral victories of Ramses III in the early decades of the 12th century scarcely affected Palestinian history.

THE IRON AGE

The Israelites in Palestine. Though the Israelite tribes entered Palestine before the end of the Late Bronze Age, they did not become firmly established in their new home until the early decades of the 12th century. Their number was increased greatly during the settling of Canaan by seminomadic Hebrew tribes already in Palestine, as well as by many settled Canaanites (e.g., the Gibeonites), who joined the invaders against their sedentary neighbours. Excavation has made it clear that the Israelites began building amid the ruins of their precursors and that new settlements sprang up rapidly all through the hill country. Had events followed their normal course, the resurgent Canaanites, who had not been driven from the coastal plain or the Plain of Esdraelon, might have overwhelmed the scattered and unorganized Israelite clans, but this was prevented by the great invasion of the Sea Peoples in the time of Ramses III, in the early decades of the 12th century BC. Among the invaders from the Aegean basin were the Philistines, who were to conquer much of the region within a century and a half after their settlement in the southern coastal plain. (The Philistines have been identified with the so-called Peleset, who were used as garrison troops and mercenaries by Ramses III.) Meanwhile, three other peoples were settling down in southern Transjordan: the Edomites in the south, the Moabites east of the Dead Sea, and the Ammonites on the edge of the Syrian Desert east of Gilead. Considered by the Israelites as fellow Hebrews, these peoples had begun to settle down before the Israelite invasion, and they remained polytheists until the end of the Old Testament period.

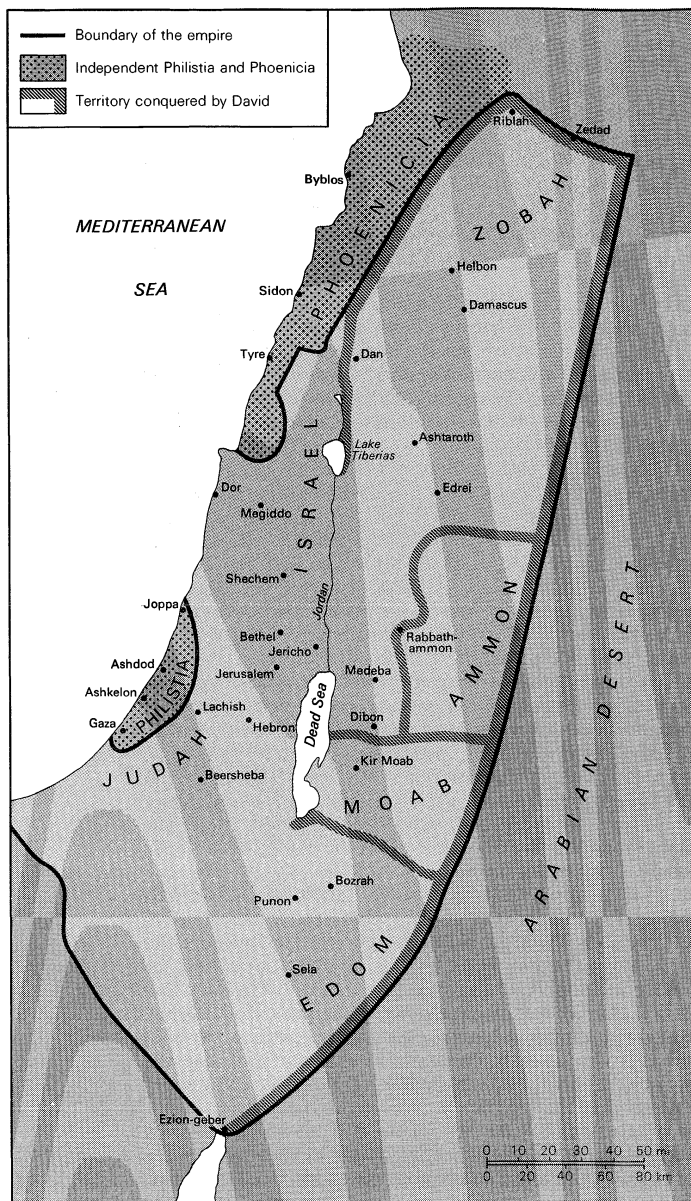

The early Israelites possessed a strong centralizing force in their monotheistic faith, combined with a stern code of ethics, which set them apart from all their neighbours. The Mosaic tradition of the covenant between Yahweh and Israel, made concrete by the tabernacle and its ritual, bound the tribes together in a cultic bond resembling the later Greek amphictyonies. Characteristic of all these organizations was a central sanctuary, surrounded by its worshipers. Straining against this religious bond were disruptive tribal forces held in leash by a loose alliance between the tribes, which was often severed by civil war. But for the constant attacks launched by its neighbours, Israel would perhaps never have attained any political solidarity. As it was, salvation from its foes lay only in union, and after abortive attempts had been made at one-man rule, Saul became king of all Israel (c. 1020 BC).

He defeated the Ammonites and the Philistines but was killed in battle against the latter in about 1000 BC and was succeeded by David. King David crushed the Philistines (c. 990) and conquered the three Hebrew states of Transjordan, after which the intervention of the Aramaeans from Syria forced him to defeat and annex the states of Aram as far north as the borders of Hamath on the Orontes. Farther east he established some sort of control over the nomadic tribes of the Syrian Desert as far as the Euphrates, though it is scarcely probable that Israelite domination was very effective. At home David organized a stable administration based largely on Egyptian models and, according to tradition, carried out a census of the population. He died before he could complete his plans, but they were put into effect by his successor, Solomon.

The reign of Solomon (mid-10th century) represents the culmination of Israelite political history. Though he gradually lost control over outlying territories conquered by David, he was extraordinarily successful in organizing the economic life of the country. He joined forces with Hiram of Tyre, who was leading the Phoenicians toward the exploitation of Mediterranean trade. Expeditions to Ophir, a region probably in either East Africa or India, brought rich products such as gold, peacocks, and sandalwood to Palestine. At the same time the Israelite king entered

into trade relations with the Arabs as far south as Sheba (Yemen). These activities would have been impossible but for the development of new principles in shipbuilding and for the recent domestication of the Arabian camel and its use in caravans. Among other undertakings of the King was his construction of a fortress or storehouse at a site near the head of the Gulf of Aqaba. The modern site, Tall al-Khalifah, may have been the biblical Ezion-geber. Most of the kingdom's wealth was spent in elaborate building operations, which included the Temple and royal palace in Jerusalem, as well as numerous fortified towns. The best-known of these are Megiddo, Hazor, and Gezer. But royal activities on such a vast scale cost more than was produced by foreign trade and the tribute of vassal states, and the Israelites themselves were forced to submit to conscription in royal labour gangs as well as to heavy levies of various kinds. It is not surprising that the people of northern Israel revolted after the great king's death, thus disrupting the united monarchy.

The rump kingdom of Israel lasted for two full centuries, sharing the worship of Yahweh and the Mosaic tradition with its smaller southern neighbour, Judah. After a period of intermittent warfare between Judah and Israel, King Asa of the former entered into an alliance with the growing

kingdom of Damascus by which the latter attacked northern Israel, thus relieving pressure on Judah. This move cost Israel its Transjordan territory north of the Yarmuk River and ushered in a long series of wars between Israel and Damascus, which did not end until the capture of Damascus by the Assyrians in 732.

The best-known phase of Israelite history is the period during which the great prophets, Elijah and Elisha, flourished, under the Omrides of the 9th century. Omri himself, founder of the dynasty, selected Samaria as his capital and began the construction of elaborate defenses and royal buildings, which have been uncovered by excavations. His son Ahab was alternately hero and villain of the principal stories of the prophets; he became involved in complex international maneuvers, which ended with his ignominious death at Ramoth-Gilead. The dynasty of Omri closed amid torrents of blood (c. 841 BC); it was followed by the dynasty of Jehu, which lasted for nearly a century. This was a period of extreme oscillations, from the catastrophic defeat of Israel (c. 815 BC) and the destruction of its army by Hazael, king of Damascus, to the triumphs of Jeroboam II (c. 786–746 BC). Meanwhile, Judah also oscillated between periods of prosperity and weakness; when it was strong it controlled Edom and the caravan routes of the south from Midian to the Mediterranean; when it was feeble it shrank behind its own narrow boundaries. Great kings like Asa, Jehoshaphat, and Uzziah alternated with weak kings.

In 741/740 the death knell of western independence was sounded by the capture of Arpad in northern Syria by the Assyrian king Tiglath-pileser III. Events followed with dizzying speed. In 738 Israel and Judah paid tribute to Assyria for the first time in decades; in 733 the Assyrians devastated Gilead and Galilee, turning the entire land into Assyrian provinces except for the territory of two tribes, western Manasseh and Ephraim; in 732 Damascus was captured and Aram ceased to exist as a state; in 725 the siege of Samaria began. Finally, in the first months of 722, Samaria was taken and Israel became politically extinct.

Assyrian and Babylonian rule. Judah was left the sole heir of the glories of David and Solomon. Hezekiah (c. 715–c. 686), lured by promises of Egyptian aid, attempted to resist Assyria but was defeated and compelled to pay a crushing tribute. It is possible that only the timely intervention of an epidemic that decimated the Assyrian army of Sennacherib saved Judah from total devastation. The eloquent guidance of Isaiah restored the morale of the people, and even the weakness of Hezekiah's son Manasseh did not bring complete ruin. Another strong king, Josiah (c. 640–609), arose in time to restore the ebbing fortunes of Judah for a few years, during which much of the ancient territory of united Israel was brought back under the rule of the Davidic dynasty. Assyria was rapidly declining in power, and in 612 its hated capital, Nineveh, was destroyed by the Medes. Josiah's successful rebellion ended when he fell in battle against a more powerful contender for the Assyrian succession, Necho of Egypt.

Meanwhile, the Chaldean kings of Babylonia were rapidly gaining strength. Nabopolassar of Babylon and Cyaxares of Media divided the old Assyrian Empire between them, and the former's son, Nebuchadnezzar, gained control of Syria and Palestine in swift campaigns. The defeated Egyptians, however, continued to intrigue in Palestine, whose native states repeatedly joined anti-Babylonian coalitions, all of which collapsed of themselves or were crushed by the Chaldean armies. Jerusalem was twice besieged, in 597 and after 589. Finally, about 587, it was stormed and destroyed. The prophet Jeremiah, who had foreseen the tragic denouement and had repeatedly warned his people against their suicidal policy, died in Egypt. Judah was devastated and almost depopulated.

The Persian Empire. In 539 Cyrus II of Persia followed up his triumph over Media by conquering Lydia and Babylonia, thus making himself ruler of the greatest empire thitherto known. In the administrative reforms implemented by Darius I (reigned 522–486 BC), Phoenicia, Palestine-Syria, and Cyprus constituted the fifth province (satrapy) of the Persian empire (Herodotus, *The History*, 3.91).

dynasty
of Omri

Comple-
tion of
the Second
Temple

One of Cyrus' first acts was to decree (c. 538) the restoration of Judah and the rebuilding of the First Temple of Jerusalem. A large number of Jewish exiles in Babylonia returned to Jerusalem, and work on the Second Temple was begun. The political situation was extremely unfavourable, however, since Judah south of Hebron had been occupied by Edomites escaping from Arab pressure, while the tiny remainder north of Hebron had passed under the control of the governor of Samaria. In spite of political intrigues to prevent completion of the work of rebuilding the Temple, the Jews took advantage of the civil wars and rebellions that racked the empire after the accession of Darius I to press forward with the work. They were urged on by the fiery prophets Haggai and Zechariah. In 515 bc the Second Temple was finished, but the Jews had meanwhile aroused the suspicion of the Persian authorities, and further efforts to improve their situation were discouraged.

Matters rested in this unsatisfactory state until about 445 bc, when the Jewish royal favourite, Nehemiah, deeply stirred by reports of the sorry condition of Judah and Jerusalem, succeeded in obtaining the Persian ruler's support for a mission to Palestine. Under Nehemiah's leadership Jerusalem's walls were rebuilt. Knowledge of the exact sequence of events is complicated by the confused state of the documentary sources, and the chronology of events in the time of Nehemiah and Ezra, who became a leader of the Jews who had returned to Jerusalem from Babylonia, is not certain. There is good evidence to suggest that Ezra's return to Jerusalem should be dated to 398 bc, early in the reign of the Persian king Artaxerxes II. The mention of Persian intervention in the priestly affairs of the high priest Johanan can reasonably be associated with Ezra's reform activities. In any event, Nehemiah and Ezra were able to establish both the religious autonomy of Judah and the practice of normative Judaism so firmly that they continued with little change for several centuries.

Information concerning the history of Palestine in the period following the age of Nehemiah and Ezra is very scanty. It is known that the province of Judah continued to be administered by high priests who struck their own coins and that the provinces of Samaria and Ammon remained under governors of the houses of Sanballat and Tobiah. In 343 Artaxerxes III Ochus is said to have devastated parts of Palestine in connection with his reconquest of Egypt. Eleven years later the country passed into Macedonian hands after Alexander's conquest of Phoenicia.

(W.F.A./G.R.B.)

FROM ALEXANDER THE GREAT TO AD 70

To Alexander, Palestine was, as to many before him, a corridor leading to Egypt, the outlying Persian province. Consequently, in his attack on that province after the Battle of Issus (333), he confined his attention, in his passage southward, to reducing the coastal cities that might form bases for the Persian fleet. The Jews he left undisturbed in their religion and customs. The high priest remained the head of the Jewish state, perhaps assisted by a council of elders.

The Ptolemies. After the death of Alexander in 323, Palestine, with much of Syria and Phoenicia, fell to Ptolemy, who established himself as satrap in Egypt in 323 bc and adopted the title of king by 304. (After the death of Ptolemy, the Ptolemaic dynasty ruled Egypt for 300 years.)

The successors of Alexander, including Ptolemy and Seleucus, defeated Antigonus Monophthalmus, one of Alexander's generals, who had almost succeeded in recreating under his sole rule Alexander's great empire, at Ipsus in Phrygia in 301 bc. This victory confirmed Ptolemy in his possession of his territory, although he had arrived too late for the battle, and Seleucus, whose participation in it had been decisive, at first disputed Ptolemy's claim to Syria and Phoenicia and actually occupied northern Syria. This early dispute laid the foundations of a century of bitter antagonism between the House of Ptolemy and that of Seleucus, an antagonism that led to war five times within a century and was finally stilled only by Palestine's passing in 200 bc into the hands of the Seleucid dynasty. The northern boundary of the kingdom established by

Ptolemy I lay apparently slightly north of the modern Tripoli, perhaps on the course of the Kabir River (ancient Eleutherus), and there are no signs of any important change in this frontier throughout the next century.

Of Ptolemaic rule in the southern part of this territory, Palestine, little is known. What little can be discovered, mainly from writers of a later period, especially the author of the First Book of Maccabees and Josephus, suggests that, unlike the northern region, known as Syria and Phoenicia, the area was left in much its previous state, with considerable power and authority in the hands of the native chieftains.

More is known of taxation than of administration. A story preserved by Josephus (*The Antiquities of the Jews*, xii, § 154 ff.) indicates that tax farming, whereby the right to collect taxes was auctioned or was awarded to privileged persons, was employed for the collection of local taxes. It seems likely that there were additional extraordinary taxes levied by edict from Egypt.

Knowledge of the economic and commercial life of Palestine in the middle of the 3rd century is, on the other hand, fuller and more reliable. It is drawn from the dossier of letters received and written by Zenon, the confidential business manager of the chief minister of Ptolemy II Philadelphus (285–246), who in 259 was sent to Palestine and Syria, where his master had commercial interests. These letters speak particularly of a trade in slaves, especially of young girls for prostitution, in whom there appears to have been a brisk trade, with export to Egypt. Zenon's records also testify to a considerable trade in cereals, oil, and wine. Inevitably, like all imports to Egypt, Palestinian exports worked under state monopoly, without which the internal monopolies of Egypt would have been undermined. Palestine, like Egypt and Syria, seems to have had no economic freedom under Ptolemaic rule; in all transactions the hand of the government's agents is clearly visible.

Of the material culture of Palestine in the Ptolemaic period, far less is known. The population seems, as in Syria, to have been divided between the Hellenized cities (*poleis*) of the coast, notably Ascalon and Joppa, and the rural population living in villages (*komai*). The fact that several cities had Ptolemaic dynastic names (Philadelphia, Philoteria, Ptolemais) must not lead to overemphasis of the desire of the early Ptolemies to urbanize and raise the standard of living of the people of Palestine. It seldom appears that they did more than rename a previously existing city (e.g., Scythopolis for Bet She'an)—a practice not uncommon in the Hellenistic world. In fact, unlike the Seleucids, the Ptolemies do not appear to have been great city builders. Nor do they appear to have encouraged the outward forms of independence in local government. It seems likely from the story of the Phoenician tax farmers mentioned above that considerable authority lay in the hands of the wealthy, yet the fact that both Ascalon and Joppa issued Ptolemaic regal coinage, but apparently no autonomous bronze coinage, suggests a rigid control. The absence of epigraphical evidence from the cities of Ptolemaic Palestine, however, renders any judgment about the conditions of the cities hazardous. Archaeology, too, helps but little, inasmuch as the buildings of Roman Palestine have swamped most of the Hellenistic remains. One exception must be noted: the tombs of the Hellenized Sidonian military settlers at Marisa in Idumaea, the walls of which are decorated with frescoes of fine hunting scenes, indicate that Hellenic civilization had penetrated deep into the non-Greek population in this period.

The chronic state of hostility between Egypt and the Seleucid house, which in much of the 3rd century bc had been concerned with the coastal regions of western Asia Minor, received a new impetus with the accession to the Seleucid throne of the energetic Antiochus III the Great (223–187), who aimed to win southern Syria and Palestine from Egypt, now weakly governed, and thereby establish the frontier to which Seleucus I had unwillingly renounced his claim in 301 bc. After his severe defeat by Ptolemy IV at Raphia in 217, however, Antiochus was for several years occupied with internal troubles, and it was therefore not until about 200 bc that he could think again of an

Zenon's
records
of life in
Palestine

attack on Egypt. There, a child—Ptolemy V Epiphanes—had recently ascended the throne, and the government was in the hands of overpowerful ministers who were more concerned with feathering their own nests than with preserving the integrity of the kingdom. At Panion, on the northern boundary of Galilee, the armies of Antiochus and Ptolemy met, and Ptolemy was defeated. Thus, the Ptolemaic possessions north of the Sinai desert, including Palestine, passed into the hands of the House of Seleucus.

The Seleucids. The Seleucids brought to the problem of the administration of Palestine a different tradition from that which had been behind Ptolemaic rule. The latter was based on that careful exploitation of territory that was possible in a small and closely knit land like Egypt and had thence been extended to the Ptolemaic provinces. This had never been possible for the Seleucids, who had always been masters of regions so vast as to render a unified and absolute control impossible. There is no sign of oppression in Seleucid government of the native peoples—they seem, on the contrary, to have aimed at improving the natives' status as far as possible, largely through bringing them into contact with Greek modes of urban existence.

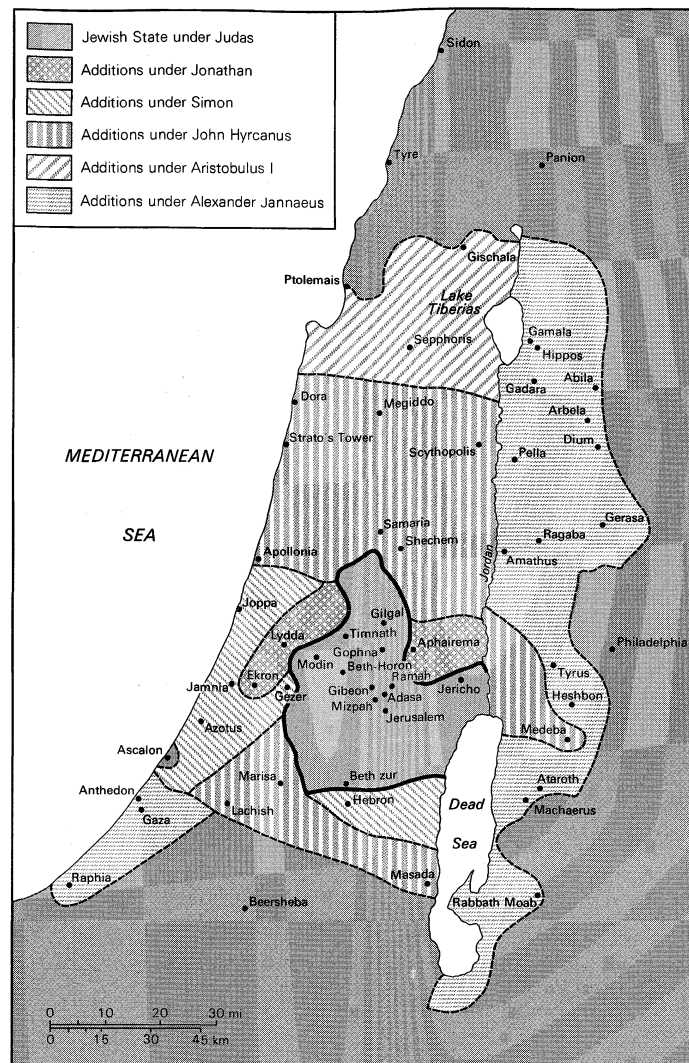

It might then be supposed that Seleucid rule would have been popular in Palestine. In fact, however, it was under Seleucid rule that the great uprising of the Jewish people, the revolt of the Maccabees, occurred. The explanation of this paradox is perhaps twofold. First, the Seleucids were in need of money, and second, the throne, at a critical time, was occupied by a tactless and neurotic king. Knowledge of Seleucid rule in Palestine before the accession of Antiochus Epiphanes is slight. The years from 188 BC onward were lean years for the dynasty, because the war with Rome, which had ended (in 189) in a complete Roman victory, had cost it not only almost the whole of Asia Minor but also a yearly indemnity of 15,000 talents. It is therefore not surprising that the first glimpse of Seleucid rule in Palestine tells of an attempt by Heliodorus, the leading minister of Seleucus IV (187–175), to deprive the Temple in Jerusalem of its treasure. His failure was soon ascribed to divine protection.

Antiochus
Epiphanes

With the accession of Antiochus Epiphanes in 175 BC, relations rapidly deteriorated. Antiochus appears to have aimed at a wholesale restoration of the Seleucid Empire in the east, including an occupation of Egypt, as a counter to the loss of the western province occasioned by the Peace of Apamea. He made an unwise beginning in Palestine by establishing a philhellene high priest, and it is clear from this and from his whole subsequent policy that he wished to extirpate Jewish religion from its central stronghold (there is no indication that he persecuted Jews of the Diaspora living in the cities of his kingdom).

Antiochus invaded Egypt in 170 or 169 BC, returning to Syria by way of Jerusalem, where he and his army despoiled the Temple of all its wealth. Two years later, after his humiliating expulsion from the gate of Egypt by the Roman legate, he sent a financial official to exact taxes from the cities of Judaea. Antiochus' official attacked the city of Jerusalem by guile and largely destroyed it. He then built a fortified position on the citadel, called by the Greeks the Akra. This became the symbol of Judah's enslavement, though in itself the presence of a royal garrison in a Hellenistic city was by no means unusual. Its imposition was followed by an open attack on religious practice; many rites were forbidden. Noncompliance with the order, which contained many items calculated to raise the bitterest resistance in the hearts of law-abiding Jews, such as the prohibition of circumcision and the abolition of the observance of the Sabbath, was punishable by death. Finally, on the 25th day of the Hebrew month Kislev (December), 168 BC, the "abomination of desolation," namely the altar of Zeus, was set up in the Temple in Jerusalem. It was this above all that summoned forth the resistance of the sons of the aged priest Mattathias; thus began the Maccabean Revolt, led by Judas Maccabeus.

The resistance, it must be emphasized, came from only a section of the population. The century and a half of Greek rule had Hellenized much of the upper class of Jerusalem, and some of the characteristic features of Greek city life, such as the ephebic institute, for the training of young

Palestine during the Maccabean period.

men, and the gymnasia, had been established on the initiative of this section of the ruling class, which was able to accept a less radical observance of Judaism and combine it with loyalty to the throne. Throughout the revolt, and indeed until the closing days of the Hasmonean dynasty established by the Maccabees, this Hellenized element had to be taken into account.

Judas Maccabeus proved himself a leader of high quality. He successfully resisted the weak forces sent by the Seleucid authorities, and after three years of intermittent warfare he succeeded in purifying the Temple (165 BC), though the Akra remained in Seleucid hands until 141 BC.

After the death of Antiochus Epiphanes in 164 BC, the numbers of claimants to the Seleucid throne made a continuous policy toward Palestine impossible, because each claimant felt the need to seek support wherever it might be found. Thus, Jewish high priests were bought and bribed by the kings and dynasts of Syria. This development enabled Judas and those who succeeded him to hold their own and eventually to establish a hereditary dynasty, known as the Hasmonean for their ancestor Hasmoneus. Soon after Antiochus Epiphanes' death, an agreement was reached with the Seleucid regent Lysias (who feared the appearance of a rival in Syria), through which the Jews received back their religious liberty. But at the same time the regular practice of pagan worship, beside the Jewish, was established, and a Seleucid nominee was appointed high priest. Thus were laid the seeds of fresh revolt.

Almost immediately Judas again took the field and scored a considerable victory over Nicanor, the Seleucid general, in which Nicanor was killed. Within two months, however, Demetrius I, the Seleucid king, sent Bacchides to

take up a position near Jerusalem, and in the engagement that followed Judas lost his life (160).

The Hasmonean priest-princes. In the following years, dynastic disputes within the Seleucid Empire prevented a succession of rulers from settling the Palestinian question. These circumstances allowed first Jonathan (160–143), the brother and successor of Judas and then his brother Simon (143–134) to attain power. In 153 one of the Seleucid pretenders, Alexander Balas, in order to outplay the legitimate king, Demetrius I, granted Jonathan the office of high priest and gave him the Seleucid rank of a courtier, thereby legitimizing his position. When Simon succeeded Jonathan, he acquired the status of a recognized secular ruler; the year of his assumption of rule was regarded as the first of a new era, and official documents were dated in his name and by his regnal year. He secured from the new Seleucid monarch, Demetrius II, exemption from taxation for the Jews.

In 142–141 Simon forced the Syrian garrison on the Akra to surrender, and the Jews passed a decree in his honour, granting the right of permanent incumbency to Simon and to his successors, until “an accredited prophet” should arise. It was thus in Simon’s reign that the rule of the priest-prince was transformed into a secular hereditary rule. The Seleucid king recognized this, granting Simon the right to issue his own coins.

Simon’s son, John Hyrcanus I (134–104), suffered an initial setback at the hands of the last great Seleucid king, Antiochus VII Sidetes, who set out to reconquer Palestine, but at the latter’s death John renewed his father’s expansionist program, resulting in the conquest and destruction of Samaria. In internal policy, however, he made the grave error of quarreling with one of the two main Jewish ecclesiastical parties, the Pharisees, who followed the Law with great strictness and with whom the Maccabean movement had in origin close affinity, and siding with their opponents, the more liberal Sadducees. This is an early instance of that denial of the revolutionary origin of the movement that became very obvious in the reign of Alexander Jannaeus. Hyrcanus I was succeeded by Aristobulus I (104–103), who extended Hasmonean territory northward and is said to have assumed the title of king (*basileus*), though on his coins he appears, like Hyrcanus I, as high priest.

The reign of his brother and successor, Alexander Jannaeus, was long (103–76) and largely filled with wars. He imposed his rule rigorously over an increasingly large area, including both Transjordan and the cities of the coast. Still more clearly than Hyrcanus I he attests the change in direction and aim of the Hasmonean house. He was the bitter enemy of the Pharisees, his coins bear Greek as well as Hebrew legends, and his title on them is simply “King Alexander.” He was succeeded by his widow, Salome Alexandra, who reversed his policy and was guided by powerful religious advisers, members of the Pharisaic movement. After her death in 67 BC her two sons Aristobulus II and Hyrcanus II fought for the succession. Hyrcanus was defeated but was encouraged to reassert his rights by Antipater, an Edomite, son of the governor of Idumaea and father of the future Herod the Great.

At this stage the Romans appeared on the scene. Pompey the Great, during his reorganization of the lands of the newly conquered Seleucid kingdom, also arranged the affairs of Palestine (63 BC). He attempted to arbitrate between the brothers and eventually, after he had laid siege to and captured Jerusalem, appointed Hyrcanus II as high priest without the title of king adopted by his predecessors. He also imposed taxes on the Jews and curtailed Jewish dominions, granting virtual autonomy to a group of 10 or 11 Hellenized cities in Syria and Palestine, thenceforth to be known as the Decapolis, and placing them under the jurisdiction of the newly appointed governor of Syria. Pliny the Elder lists these cities as Damascus, Philadelphia (modern Amman, Jordan), Raphana, Scythopolis, Gadara, Hippos, Dion, Pella, Gerasa, and Canatha. On the basis of evidence in inscriptions, Abila can be added to the list. Thus, despite the name Decapolis, the actual number appears to have been 11. All of these cities, except for Scythopolis, are located east of the Jordan River,

extending from Damascus in the north to Philadelphia in the south. Except for Damascus, all the other cities lie immediately to the west of Galilee, Samaria, and Judaea. Whether the Decapolis geographically belonged to Syria; to Coele Syria (“Hollow Syria”; *i.e.*, the southernmost region of Syria, which may include Palestine and is sometimes mistakenly limited to the modern al-Biqā’ valley); or to Arabia, often identified as the land east of the Jordan River, is not clear, especially in the ancient geographers. In any event, the Decapolis ended as a political entity when Arabia was annexed in AD 106; the cities were distributed among the three provinces of Arabia, Judaea, and Syria. It appears that Philadelphia, Gerasa, and probably Dion went to Arabia, Damascus certainly to Syria, and the rest to Judaea or Syria.

After the death of Pompey, however, the power of Antipater and his family greatly increased. Hyrcanus II became a figurehead of no importance, and Antipater himself, in return for services to Julius Caesar, received Roman citizenship and was awarded the title of “procurator of Judaea,” while his sons Phasael and Herod became governors (*strategoi*) of Jerusalem and Galilee, respectively. The unexpected occupation of Palestine by Parthian troops in 40 BC altered the situation. Antigonos, the son of Aristobulus and therefore a legitimate Hasmonean, won the favour of the Parthians and was established by them as king and high priest of Jerusalem. Phasael was reported to have committed suicide, while his brother Herod escaped to Rome.

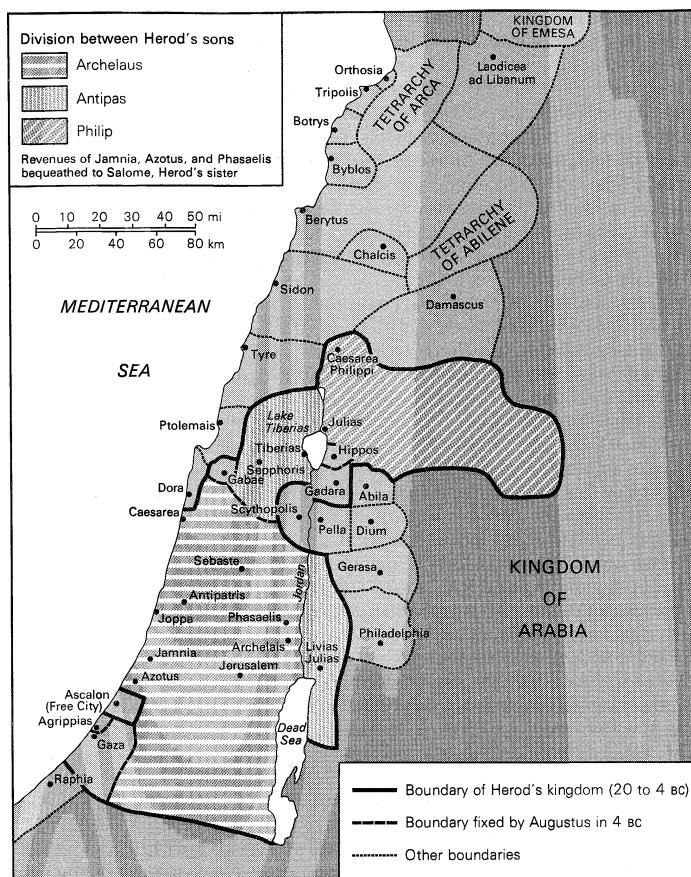

The Herodian house and the Roman procurators. Herod, in Rome, was recognized by the Senate, with the approval of Octavian and Mark Antony, as king of Judaea (40 BC) and returned to Palestine in 39 BC. Shortly afterward Roman troops expelled the Parthians, whose popularity in Palestine had been and subsequently remained considerable. After struggles against Antigonos, the Parthian nominee, in which he was assisted by Roman troops, Herod eventually captured Jerusalem. At about the same time he married a niece of Antigonos, thus probably consoling those who remained loyal to the memory of the almost defunct Hasmonean house. Antigonos, when he fell into the hands of his enemies, was executed by order of Mark Antony.

The accession of Herod, the Roman protégé and an Edomite, brought to Palestine the peace that in the years of independence it had often lacked. His long reign (37–4 BC) was marked by general prosperity; his new city of Caesarea Maritima received lavish praise from Josephus for its spectacular port and sewer system. Between 31 and 20, Augustus restored to him the Jewish territories that Pompey had taken away, and in this enlarged kingdom he created a sound administrative system of Hellenistic type. Toward the end of his life the complex demands of a vast family (he had 9 wives at least) led him into difficulties regarding the succession, and it was then that he developed into the gruesome and vicious figure that Christian tradition has made so familiar. He had Mariamne and several of his sons put to death to prevent them from succeeding him; and on his death in 4 BC the country again entered a period of divided rule, which led to the reestablishment of direct Roman government. Augustus decided later that year, in the presence of three surviving sons of Herod, that Archelaus should rule Judaea, Samaria, and Edom (*i.e.*, central and southern Palestine); Herod Antipas rule Galilee and Peraea (Transjordan); and Philip rule Trachonitis, Batanaea, and Auranitis (the area between the Decapolis and Damascus).

The fate of the rulers (of whom Philip and Herod Antipas were called tetrarchs, Archelaus ethnarch) and their territories was different. Philip, the most peaceable of the three, ruled the northern area until his death in AD 34. Antipas reigned in Galilee and Peraea until AD 39 but was then banished by Caligula on the ground that he had parleyed with Rome’s enemies. Archelaus reigned for 10 years only; he was removed at the request of his subjects in AD 6. The region under Archelaus’ rule (*i.e.*, Judaea, Samaria, and Edom) became the province of Judaea and passed to a series of undistinguished Roman prefects, the last of whom (Pontius Pilate, AD 26–36, under whom Je-

was crucified) lost office for the unnecessary massacre of some Samaritans. Palestine finally was united under the emperor Caligula's protégé, Herod Agrippa I, who succeeded Philip in the north in AD 37. The tetrarchy of Antipas was added soon after his removal in 39, and the territories of Judaea, Samaria, and Edom were added in 41, so that from 41 to his death in 44 Agrippa ruled the kingdom of his grandfather, Herod the Great, from Jerusalem. In 44 the entire kingdom passed under Roman rule and was reconstituted as the procuratorial province of Judaea.

Disturbances in the early years of procuratorial rule were frequent and largely caused by maladministration. Serious trouble arose under Ventidius Cumanus (48–52), and under his successor, the imperial freedman Felix (52–60), rebellion was open though sporadic. The incompetence and anti-Jewish posture of Gessius Florus, procurator 64–66, led in 66 to the decisive and final outbreak. Florus, the heir to a long tradition of hostility between the large Hellenized populations of Palestine and the Jews (also a problem in the Diaspora, most notably at Alexandria during the reign of Caligula), allowed the Greek population of Caesarea Maritima to massacre the Jews of that city with impunity. Greeks in other towns of Palestine repeated the assault. In turn, the Jews responded by slaughtering Gentiles in Samaria, Galilee, the Transjordan, and elsewhere. Soon Florus had lost control of the situation.

The organization of the Jews was better than it had previously been, and they were successful in an early engagement against the governor of Syria, who had advanced to Palestine with two legions to assist the hard-pressed procurator.

In 67, however, Vespasian, the future emperor, with his son Titus, arrived with a force of about 60,000 men, and the war became increasingly bitter. By the end of 67 Galilee was captured, and Judaea was reduced in three campaigns, which ended with the fall of Jerusalem in AD 70. The Temple was destroyed, though tradition recorded that Titus gave orders that it was to be spared, and the city

became the permanent garrison town of a Roman legion. By AD 73 all resistance had ceased. (P.M.F./G.R.B.)

ROMAN PALESTINE

After the destruction of Jerusalem a legion (X Fretensis) was stationed on the site, and the rank of the provincial governor was raised from *procurator* to *legatus Augusti*, signifying a change from equestrian to senatorial rank. Caesarea Maritima, the governor's residence, became a Roman colony, and as a reward for the loyalty of the Greeks in the revolt a new pagan city, Neapolis (modern Nablus), was founded at Shechem, the religious centre of the Samaritans. Another new city was founded at Joppa (Jaffa) on the coast.

The Jews, deprived of the Temple, founded a new religious centre in the rabbinical school of Jamnia (Jabneh). When a revolt broke out in AD 115, the Roman emperor Trajan appointed the first consular legate of Judaea, Lucius Quietus, to put it down. The rank of the legate confirms that two legions were stationed in Judaea, one at Jerusalem, the other at Caparcotna in Galilee, and thenceforth the province must have held consular status.

In AD 132 the emperor Hadrian decided to build a Roman colony, Aelia Capitolina, on the site of Jerusalem. The announcement of his plan, as well as his ban on circumcision (revoked later, but only for the Jews), provoked a much more serious revolt, led by Bar Kokhba. It was ruthlessly repressed by Julius Severus; almost 1,000 villages were destroyed and more than half a million people killed, according to certain accounts. In Judaea proper the Jews seem to have been virtually exterminated, but they survived in Galilee, which, like Samaria, appears to have held aloof from the revolt. Tiberias in Galilee became the seat of the Jewish patriarchs. The province of Judaea was renamed Syria Palaestina (later simply called Palaestina), and, according to Eusebius (*Historia Ecclesiastica* iv. 6), no Jew was thenceforth allowed to set foot in Jerusalem or the surrounding district. This prohibition apparently was relaxed some time later to permit Jews to enter Jerusalem on one day a year, a Day of Mourning. While this ban was officially still in force as late as the 4th century AD, there is some evidence that from the Severan period onward (after AD 193) Jews visited the city more frequently, especially at certain festival times, and even that there may have been some Jews in residence. Around the time the Bar Kokhba revolt was crushed (AD 135), Hadrian proceeded to convert Jerusalem into a Greco-Roman city, with a circus, an amphitheatre, baths, and a theatre and with streets conforming to the Roman grid pattern. He also erected temples dedicated to Jupiter and himself (Aelia was his clan name) on the very site of the destroyed Temple of Jerusalem. To repopulate the city, Hadrian apparently brought in Greco-Syrians from the surrounding areas and even perhaps some legionary veterans. The urbanization and Hellenization of Palestine was continued by the emperor Septimius Severus (reigned AD 193–211), except in Galilee, where the Jewish presence remained strong. New pagan cities were founded in Judaea at Eleutheropolis and Diospolis (formerly Lydda) and at Nicopolis (formerly Emmaus) under one of Severus' successors, Elagabalus (reigned AD 218–222). In addition, Severus issued a specific ban against Jewish proselytism.

With the conversion of Constantine I to Christianity early in the 4th century, a new era of prosperity began for Palestine. The Emperor himself built a magnificent church on the site of the Holy Sepulchre, the most sacred of Christian holy places; his mother, Helena, built two others—at the place of the Nativity at Bethlehem and of the Ascension in Jerusalem—and his mother-in-law, Eutropia, built a church at Mamre. Palestine began to attract floods of pilgrims from all parts of the empire. It also became a great centre of the eremitic life; men flocked from all quarters to become hermits in the Judaeian wilderness, which was soon dotted with monasteries. Constantine added the southern half of Arabia to the province, but in 357–358 (or perhaps as late as the 390s) the addition was made a separate province under the name of Palaestina or Salutaris (later Palaestina Tertia). At the end of the 4th century, an enlarged Palestine was divided into three

Bar
Kokhba's
revolt

provinces: Prima, with its capital at Caesarea; Secunda, with its capital at Scythopolis (Bet She'an); and Salutaris, with its capital at Petra or possibly for a time at Elusa. It is clear that the province of Palaestina underwent several territorial changes in the 4th century AD, but the details and the chronology remain obscure. The governor of Prima bore the high rank of proconsul from 382 to 385 and again from 535 onward. A dux of Palestine commanded the garrison of all three provinces.

The bishop of the civil capital, Caesarea, was, according to the usual rule, metropolitan of the province, but the bishops of Jerusalem were claiming special prerogatives as early as the Council of Nicaea. Eventually, Juvenal, bishop of Jerusalem from 421 to 458, achieved his ambition and was recognized by the Council of Chalcedon (451) as patriarch of the three provinces of Palestine.

There was a revolt of the Jews in Galilee in 352, which was suppressed by the Caesar Gallus. Under Marcian (reigned 450–457) and again under Justinian I (reigned 527–565) the Samaritans revolted. Palestine, like Syria and Egypt, was also troubled by the Monophysite controversy, a debate among Christians who disagreed with the Council of Chalcedon's assertion that the Person of Jesus Christ comprised two natures, human and divine. When Juvenal returned from Chalcedon, having signed the Council's canons, the monks of Palestine rose and elected another bishop of Jerusalem, and military force was required to subdue them. Gradually, however, the Chalcedonian doctrine gained ground, and Palestine became a stronghold of orthodoxy. Apart from these disturbances the country enjoyed peace and prosperity until 611, when Khosrow II, king of Persia, launched an invasion. His troops captured Jerusalem (614), destroyed churches, and carried off the True Cross. In 628 the Byzantine emperor Heraclius recovered Palestine, and he subsequently restored the True Cross to Jerusalem, but 10 years later Jerusalem fell to the Arabs. (A.H.M.J./G.R.B.)

FROM THE ARAB CONQUEST TO AD 1900

The rise of Islām. The successful unification of the Arabian Peninsula by the first caliph, Abū Bakr (AD 632–Aug. 23, 634), made it possible to channel the expansion of the Arab Muslims into new directions. Abū Bakr, therefore, summoned the faithful to a holy war (jihad) and quickly amassed an impressive army. He dispatched three detachments of about 3,000 (later increased to about 7,500) men each to start operations in southern and southeastern Syria. He died, however, before he could witness the results of these undertakings. The conquests he started were carried on by his successor, the caliph 'Umar I (634–644).

The first battle took place at Wadi al-'Arabah, south of the Dead Sea. The Byzantine defenders were defeated and retreated toward Gaza but were overtaken and almost annihilated. In other places, however, the natural advantages of the defenders were more effective and the invaders were hard pressed. Khālīd ibn al-Walīd, then operating in southern Iraq, was ordered to the aid of his fellow generals on the Syrian front, and the combined forces won a bloody victory on July 30, 634, at a place in southern Palestine that the sources call Ajnadain. All of Palestine then lay open to the invaders.

In the meantime, the emperor Heraclius was mustering a large army and in 636 dispatched it against the Muslims. Khālīd concentrated his troops on the Yarmuk, the eastern tributary of the Jordan River. The decisive battle that delivered Palestine to the Muslims took place on Aug. 20, 636. Only Jerusalem and Caesarea held out, the former until 638, when it surrendered to the Muslims, and the latter until October 640. Palestine, and indeed all of Syria, was then in Muslim hands. After the surrender of Jerusalem, 'Umar divided Palestine into two administrative districts (*jund*), similar to the Roman and Byzantine provinces: they were Jordan (al-Urdunn) and Palestine (Filasṭīn). Jordan included Galilee and Acre and extended east to the desert; Palestine, with its capital first at Lydda and later at Ramlah (after 716), covered the region south of the Plain of Esdraelon.

'Umar lost no time in emphasizing Islām's interest in the holy city of Jerusalem as the first *qibla* toward which

Muslims turned their faces in prayer and as the third holiest spot in Islām. On visiting the Temple area and finding the place suffering from neglect, he and his followers cleaned it with their own hands and declared it a sacred place of prayer.

Under the Umayyads, a Muslim dynasty that gained power in 661 from the Meccans and Medinans who had initially led the Islāmic community, Palestine formed, with Syria, one of the main provinces of the empire. Each *jund* was administered by an emir assisted by a financial officer. This pattern continued, in general, up to the time of Ottoman rule.

For various reasons, the Umayyads paid special attention to Palestine. The process of Arabization and Islāmization was gaining momentum there. It was one of the mainstays of Umayyad power and important in their struggle against both Iraq and the Arabian Peninsula. The caliph 'Abd al-Malik ibn Marwān (685–705) erected the Dome of the Rock in 691 on the site of the Temple of Solomon, which the Muslims believed had been the halting station of the Prophet on his nocturnal journey to heaven. This magnificent structure represents the earliest Muslim monument still extant. Close to the shrine to the south, 'Abd al-Malik's son, al-Walīd I (705–715), built the Aqsa mosque. The Umayyad caliph 'Umar II (717–720) imposed humiliating restrictions on his non-Muslim subjects, particularly the Christians. Conversions arising from convenience as well as conviction then increased. These conversions to Islām, together with a steady tribal inflow from the desert, changed the religious character of Palestine's inhabitants. The predominantly Christian population gradually became predominantly Muslim and Arabic-speaking. At the same time, during the early years of Muslim control of the city, a small permanent Jewish population returned to Jerusalem after a 500-year absence.

'Abbāsīd rule. Umayyad rule ended in 750. Along with Syria, Palestine became subject to 'Abbāsīd authority, based in Baghdad, and, like Syria, it did not readily submit to its new masters. Unlike the Umayyads, who leaned on the Yemeni (south Arabian) tribes, the 'Abbāsīds, in Syria, favoured and indeed used the Qays (north Arabian) tribes. Enmity between the two groups was, therefore, intensified and became an important factor in Palestinian politics. Pro-Umayyad uprisings were frequent and received Palestinian support. In 840/841 Abū Ḥarb, a Yemenite, unfurled the white banner of the Umayyads and succeeded in recruiting a large number of peasant followers, mainly among the Palestinians, who regarded him as the saviour whose appearance was to save the land from the hated 'Abbāsīds. Though the insurrection was put down, unrest persisted.

Under the 'Abbāsīds, the process of Islāmization gained momentum. The 'Abbāsīd rulers encouraged the settlement and fortification of coastal Palestine so as to secure it against the Byzantine enemy. During the second half of the 9th century, however, signs of internal decay began to appear in the 'Abbāsīd Empire. Petty states, and some indeed not so petty, mushroomed in different parts of the realm. One of the first to affect Palestine was the Tūlūnīd dynasty (868–905) of Egypt, which marked the beginning of the disengagement of Egypt and, with it, of Syria and Palestine from 'Abbāsīd rule. During this period Palestine also experienced the destructive operations of the Qarmāṭians, an Ismā'īlī Muslim sect that launched an insurrection in 903–906. After a brief restoration of 'Abbāsīd authority, Palestine came under Ikshīdīd rule (935–969).

The Fāṭimīd dynasty. In the meantime the Shī'ite Fāṭimīd dynasty was rising to power in North Africa. It moved eastward to seize not only Egypt but also Palestine and Syria and to threaten Baghdad itself. The Fāṭimīds seized Egypt from the Ikshīdīds in 969 and in less than a decade were able to establish a precarious control over Palestine, where they faced Qarmāṭian, Seljuq, Byzantine, and periodic Bedouin opposition. Palestine was thus often reduced to a battlefield. The country suffered even greater hardship, however, under the Fāṭimīd caliph al-Ḥākim (996–1021), whose erratic behaviour was at times extremely harsh, particularly on his non-Muslim subjects. He reactivated earlier discriminatory laws imposed upon

Construc-
tion
of the
Dome of
the Rock

Christians and Jews and added new ones. In 1009 he ordered the destruction of the Church of the Holy Sepulchre.

In 1071 the Seljuqs captured Jerusalem, which prospered as pilgrimages by Jews, Christians, and Muslims increased despite political instability. The Fāṭimids recaptured the city in 1098 only to deliver it a year later to a new enemy, the crusaders of western Europe.

The Crusades. A year after the capture of Jerusalem by the crusaders, the Latin kingdom of Jerusalem was established (Christmas day, 1100). Thereafter, there was no effective check to the expansion of the crusaders' power until the capture of their stronghold at Edessa (modern Urfa, Tur.) by the atabeg of Mosul, 'Imād ad-Dīn Zangī ibn Aq Sonqur, in 1144. Zangī's anticrusader campaign was carried on after his death by his son Nureddin (Nūr ad-Dīn Maḥmūd) and, more effectively, by the sultan Saladin, a protégé of the atabeg's family. After consolidating his position in Egypt and Syria, Saladin waged relentless war against the "infidel" Franks. On July 4, 1187, six days after the capture of Tiberias, he dealt the crusaders a crushing blow at the decisive battle of Hattin (Hittin). Most of Palestine was once again Muslim. Further attempts by the crusaders to regain control of Palestine proved ineffective, primarily because of incessant quarrels among the crusaders themselves. Ironically, it was left to an emperor of dubious Christian standing, Frederick II, to negotiate in 1229, while under excommunication, a 10-year treaty temporarily restoring Jerusalem, Nazareth, and Bethlehem to the Christians. In 1244, however, the Ayyūbid sultan aṣ-Ṣāliḥ Ayyūb definitively restored Jerusalem to Islam.

While the Ayyūbids of Saladin's house were losing ground to the Turkish-speaking Mamlūks in Egypt, the Mongol sweep westward continued, placing the crusaders, as it were, between two fires. To make matters worse, the crusaders themselves were hopelessly riddled with dissension. In 1260 the Mamlūk leader Baybars emerged as a champion of Muslim resurgence. After taking part in the defeat of the Mongols at 'Ayn Jalut in Palestine, he became sultan; in the years 1263 to 1271 he carried out annual raids against the harassed Franks. His task was resumed by the sultan al-Ashraf, during whose reign the last of the crusaders were driven out of Acre (May 18, 1291). A chapter in the history of Palestine thus came to an end. The Mamlūks and subsequent Muslim regimes ruled the area with only brief interruptions for the next 600 years.

Palestine under the Mamlūks in the 14th century saw a period of prosperity for some; this was especially notable in Jerusalem, where the government sponsored an elaborate program of construction of schools, lodgings for travelers and Muslim pilgrims, and renovation of mosques. Tax revenues, collected mainly from the villages, were spent largely on support of religious institutions. Palestine formed a part of the district of Damascus, second only to Egypt in the Mamlūk domains. The region suffered the ravages of several epidemics, including the great pestilence, the same Black Death that in 1347–51 devastated Europe. The fall of the Bahrī Mamlūks and the rise of the Burjī Mamlūks (1382–1517) ultimately helped lead to a deterioration in security and the economy. During the reign of the second Burjī sultan, Naṣīr Faraj (1398–1405), the last onslaught of the Mongols, which made the name of Timur (Tamerlane) a synonym of destruction and plunder, took place. Although Palestine was spared the pillage of his hordes, it could not escape its disastrous repercussions as the Mamlūks moved through in a vain attempt to defend Damascus against the invader. The death of Timur in 1405, and the weakness of Iran in the ensuing century, pitted the Mamlūks against the rising power of the Ottoman Turks for the control of western Asia. Hostilities broke out when Sultan Qait Bey contested, in 1486, with Bayezid II the possession of some border towns. The climax came three decades later on Aug. 24, 1516, when the Ottoman sultan, Selim I, routed the Mamlūk armies. Palestine began its four centuries under Ottoman domination.

Ottoman rule. Under the Ottoman Turks, Palestine continued to be linked administratively to Damascus until 1830, when it was placed under Sidon; then under Acre; then once again under Damascus until 1887–88, at which

time the administrative divisions of the Ottoman Empire were settled for the last time. The geographic region of Palestine was divided into the *mutasarrifiyats* of Nablus and Acre, both of which were linked with the vilayet of Beirut, and the autonomous *mutasarrifiyah* of Jerusalem, which dealt directly with Istanbul. With varying fortunes often accompanied by revolts, massacres, and wars, the first three centuries of Ottoman rule isolated Palestine from and insulated it against most outside influences. The prosperity of 16th-century Ottoman Palestine was followed by an economic and political decline in the 17th century. Ottoman control in the 18th century was indirect. Dāhīr al-'Umar (c. 1737–75) dominated the political life of northern Palestine for nearly 40 years. Aḥmad al-Jazzār, the Ottoman governor of Acre, had control of most of Palestine, and in 1799, with English and Ottoman help, he successfully defended Acre against Napoleon.

Both Dāhīr and al-Jazzār presided over a tightly controlled Palestine, where trade with Europe as well as taxation were both growing. They used their new wealth from these sources to gain influence in Istanbul, which allowed them to gain local autonomy and even intermittent control of many areas outside Palestine.

This period came to an end with Napoleon's abortive attempt (1798–1801) to carve for himself a Middle Eastern empire. Egypt, always a determining factor in the fortunes of Palestine, was placed, after the French withdrawal, under the rule of the viceroy Muḥammad (Meḥmet) 'Alī, who soon embarked upon a program of expansion at the expense of his Ottoman overlord. In 1831 his armies occupied Palestine, and for nine years he and his son Ibrāhīm gave it a centralizing and modernizing administration. Their rule increasingly opened the country to Western influences and enabled Christian missionaries to establish many schools; at the same time, however, taxes were increased, and urban rebellions broke out against the harshness of the regime. When in 1840 the British, the Austrians, and the Russians came to the aid of the Ottomans, the Egyptians were forced to withdraw and Palestine reverted to the Ottoman Empire. Increased European interest, however, led to the establishment of consulates by the powers in Jerusalem and in the ports.

After 1840 the reforms the Sultan promulgated gradually took effect in Palestine. Increased security in the countryside and the Ottoman Land Law of 1858 encouraged the development of private property, agricultural production for the world market, the decline of tribal social organization, growth of the population, and the enrichment of the notable families. As the Ottomans extended the central government's new military, municipal, judicial, and educational systems to Palestine, the country also witnessed a marked increase in foreign settlements and colonies, French, Russian, and German. By far the most important, in spite of their initial numerical insignificance, were the Zionist agricultural settlements, which foreshadowed later Zionist endeavours for the establishment of a Jewish national home and still later a Jewish state in Palestine. The earliest of these settlements was established by Russian Jews in 1882. In 1896 Theodor Herzl issued a pamphlet entitled *Der Judenstaat* (*The Jewish State*) and advocated an autonomous Jewish state, preferably in Palestine. Two years later, he himself went to Palestine to investigate its possibilities and, possibly, to seek the help of the German emperor William II, who was then making his spectacular pilgrimage to the Holy Land. (N.A.F./W.L.O.)

FROM 1900 TO 1948

In the last years of the 19th century and the early years of the 20th the Palestine Arabs shared a general Arab renaissance. Palestinians found opportunities in the service of the Ottoman Empire, and Palestine deputies sat in the Ottoman parliament of 1908. Several Arabic newspapers appeared in the country before 1914. They showed in their pages that Arab nationalism and opposition to Zionism were strong among some sections of the intelligentsia even before World War I. The Arabs sought an end to Jewish immigration and to land purchases by Zionists. The number of Zionist colonies, however, mostly subsidized by Baron Edmond de Rothschild, rose from 22 in 1900 to 47

Saladin's
wars
against
the
crusaders

Zionism

in 1918, even though the majority of the Jews were town-dwelling. The population of Palestine, predominantly agricultural, was about 690,000 in 1914 (535,000 Muslims; 70,000 Christians, most of whom were Arabs; and 85,000 Jews). Population decreased during the war.

World War I and after. Palestine was hard hit by the war, for to the destruction caused by the fighting were added famine, locusts, epidemics, and the punitive measures of the Ottomans against Arab nationalists. Major battles took place at Gaza before Jerusalem was captured by British and Allied forces under the command of General Sir Edmund (later Field Marshal Viscount) Allenby in December 1917. The rest of the country was occupied by the British by October 1918. The Arabs maintained that Palestine was included in the area the independence of which Britain promised in the exchange of correspondence in July–October 1915 between Sir Henry McMahon, high commissioner of Egypt, and Husayn ibn ‘Ali, then emir of Mecca. By May 1916 Britain, France, and Russia had reached an agreement according to which, *inter alia*, the bulk of Palestine was to be internationalized. In November 1917 Arthur Balfour, the British secretary of state for foreign affairs, addressed a letter to Lord Rothschild promising British support for the establishment in Palestine of a national home for the Jewish people on the understanding that “nothing shall be done which may prejudice the civil and religious rights of existing non-Jewish communities in Palestine. . . .”

Britain’s first postwar problem in Palestine was to secure international sanction for the continued occupation of the country in a manner consistent with its conflicting and ambiguous wartime commitments. A British military administration was set up after the capture of Jerusalem, and a general international framework existed for Britain in Article 22 of the Covenant of the League of Nations signed in June 1919. This article recognized the provisional independence of the former Ottoman Arab provinces, subject to the assistance of a mandatory power in whose selection the wishes of the communities themselves were to be consulted.

In July 1919 a general Syrian congress held at Damascus and attended by Palestinian delegates passed a resolution rejecting the Balfour Declaration and electing Fayṣal—son of Husayn ibn ‘Ali, who ruled the Hejaz—king of a united Syria (including Palestine). In April 1920, however, at the Conference of San Remo, the Allies divided the former territories of the defeated Ottoman Empire. Of the Ottoman provinces in the Syrian region, the northern half (Syria and Lebanon) was mandated to France, and the southern half (Palestine) was mandated to Great Britain. The French forced Fayṣal to give up his newly founded kingdom of Syria in July 1920. Thus the Arabs’ hope for a united greater Syria under the Hāshimite dynasty—descending from the Prophet Muḥammad—was at least temporarily thwarted. Uncertainty over the disposition of Palestine affected all its inhabitants and increased political tensions.

In April 1920 anti-Zionist riots in Palestine resulted in five Jews being killed and 200 wounded. A British commission of inquiry attributed the riots to Arab disappointment at the nonfulfillment of the promises of independence and to their fear of economic and political subjection to the Zionists. In July the military administration was ended and Sir Herbert (later Viscount) Samuel was appointed the first high commissioner of a new civilian administration.

The mandate. The terms of the mandate had yet to be settled, and both Britain and the Zionists worked for the incorporation of the Balfour Declaration into the mandate instrument. Although the mandate was not approved by the League of Nations until July 1922, the administration in Palestine proceeded with the implementation of the Balfour Declaration and in August 1920 announced a quota of 16,500 Jewish immigrants for the first year. This announcement aroused Arab opposition, which was organized in the form of Christian–Muslim associations throughout the country. In May 1921 anti-Zionist riots resulted in 46 Jews being killed and 146 wounded. A commission of inquiry attributed the riots to Arab fear of Jewish immigration. Impressed by Arab opposition, the

British government issued a White Paper in June 1922 containing an interpretation of its concept of a Jewish national home. The intention was not that Palestine as a whole should be converted into a Jewish national home but that such a home should be established in Palestine. Immigration would not exceed the economic absorptive capacity of the country, and steps would be taken to set up a legislative council. These proposals were rejected by the Arabs, both because they had a large majority of the total population of the mandate and therefore wished to dominate the instruments of government and rapidly gain independence and because, they argued, the proposals allowed Jewish immigration, which had a political objective, to be regulated by an economic criterion.

In July 1922 the mandate instrument for Palestine was approved by the League council, its preamble incorporating the Balfour Declaration and stressing the Jewish historical connection with Palestine. Article 2 made the mandatory (*i.e.*, the holder of the mandate) responsible for placing the country under such “political, administrative and economic conditions as will secure the establishment of the Jewish National Home . . . and the development of self-governing institutions.” Article 4 allowed for the establishment of a Jewish agency to advise and cooperate with the Palestine administration in matters affecting the Jewish national home. Article 6 required that the Palestine administration, “while ensuring that the rights and position of other sections of the population are not prejudiced,” under suitable conditions would facilitate Jewish immigration and close settlement of Jews on the land. Although Transjordan, all of which lay east of the Jordan River, was included in the British mandate of Palestine, under protest from the Zionists it was excluded from the clauses covering the establishment of a “Jewish national home.” On Sept. 29, 1923, the mandate came officially into force.

The Jewish national home. Several Arab organizations in the 1920s opposed Jewish immigration. These included the Palestine Arab Congress, Muslim–Christian associations, the Arab Executive, and the National Defense Party. Most Arab groups were led by the strongly anti-British Husayni family, while the National Defense Party was under the control of the more accommodating Nashashibi family. (The Husaynis and Nashashibis were prominent Jerusalem notables, long resident in the area, who had held numerous government posts in the late Ottoman period.)

During 1923 the British high commissioner tried to win Arab cooperation by the offer first of a legislative council and then of an Arab Agency. Both offers were rejected by the Arabs as falling far short of their national demands. The years 1923–29 were relatively quiet; Arab passivity was partly due to the drop in Jewish immigration in the years 1926–28. In 1927 Jewish emigrants exceeded the immigrants, and in 1928 there was a net Jewish immigration of only 10 persons. Nevertheless, the national home continued to consolidate itself in terms of urban, agricultural, social, cultural, and industrial development. Large amounts of land were purchased from Arab owners, often from absentee landlords. In August 1929 negotiations were concluded for the formation of an enlarged Jewish Agency to include non-Zionist Jewish sympathizers throughout the world.

This last development, while accentuating Arab fears, gave the Zionists a new sense of confidence. In the same month a dispute in Jerusalem concerning religious practices at the Western Wall—sacred to Jews as the only remnant of the Second Temple of Jerusalem—flared up into communal clashes in which 133 Jews were killed and 339 wounded, the Arab casualties, mostly at the hands of the military, being 116 killed and 232 wounded. The report of a commission of inquiry attributed the clashes to the fact that “the Arabs have come to see in Jewish immigration not only a menace to their livelihood but a possible overlord of the future.” In October a technical report by Sir John Hope Simpson established that there was at that time no margin of land available for agricultural settlement by new immigrants. These reports raised in an acute form the question of where Britain’s duty lay if its specific obligations to the Zionists under the Balfour Dec-

tion

laration clashed with its general obligations to the Arabs under Article 22 of the Covenant of the League of Nations.

Arab grievances. A statement of policy made by the colonial secretary in October 1930 accorded some priority to Britain's obligations to the Arabs. This was seen by the Zionists to cut at the root of their program, for if the right of the Arab resident were to gain priority over that of the Jewish immigrant, whether actual or potential, the Jewish national home would come to a standstill. In February 1931 the British prime minister, Ramsay MacDonald, addressed an explanatory letter to Chaim Weizmann, president of the Jewish Agency, which was virtually a return to the 1922 White Paper policy. This letter convinced the Arabs that recommendations in their favour made on the spot could be annulled in London by Zionist influence at the centre of power. In December 1931 a Muslim congress at Jerusalem was attended by delegates from 22 countries to warn against the danger of Zionism.

Increase
in Jewish
immigra-
tion to
Palestine

In the early 1930s a boycott of Zionist and British goods was proclaimed. At the same time the Nazi accession to power in Germany and the widespread persecution of Jews throughout central and eastern Europe gave a great impetus to Jewish immigration, which jumped to 30,000 in 1933, 42,000 in 1934, and 61,000 in 1935. The Arab population of Palestine also increased rapidly, largely because of a decrease in infant mortality. Most of the Arabs continued to be engaged in agriculture, despite successive crop failures. In November 1935 the Arab political parties collectively demanded the cessation of Jewish immigration, the prohibition of land transfer, and the establishment of democratic institutions. In December the British administration offered a legislative council of 28 members on which the Arabs (both Muslim and Christian) would have 14 seats and the Jews eight. Although not represented in the council in proportion to their numbers, some of the Arabs were willing to consider the proposal, but the Zionists criticized it bitterly as an attempt to freeze the national home through a constitutional Arab stranglehold. The failure of the council proposal, the example of rising nationalism in neighbouring Egypt and Syria, increasing unemployment in Palestine, and a poor citrus harvest touched off the long-smoldering Arab rebellion.

The Arab rebellion. In April 1936 the Arab political parties formed an Arab High Committee presided over by Amin al-Husayni, who was mufti of Jerusalem from 1921 and president of the Supreme Muslim Council. Nationalistic sentiment had grown rapidly in the Arabic press, schools, and literary circles. The Arab High Committee called for a general strike, which was maintained for six months (although it did not include Arabs who were government employees). Simultaneously with the strike, Arab rebels, joined by volunteers from neighbouring Arab countries, took to the hills, and by the end of the year the movement assumed the dimensions of a national revolt of the Arab peasantry. The strike was called off in October at the request of the heads of the neighbouring Arab states, but the armed rebellion continued.

The Peel
Commis-
sion

A royal commission of inquiry presided over by Lord Peel published its findings in July 1937. It attributed the revolt to the Arab desire for independence and fear of the Jewish national home. It declared the mandate unworkable and Britain's obligations to Arabs and Jews mutually irreconcilable. It therefore recommended the partition of the country.

The Zionist attitude to partition was ambivalent. For the first time a British official body explicitly spoke of a Jewish state: the area allotted to this state was immensely larger than the existing Jewish landholdings; and the commission had gone to the extent of recommending the forcible transfer of the Arab population from the proposed Jewish state. But the Zionists still needed mandatory protection for their further development and left the door open for an undivided Palestine. The Arabs were horrified by the idea of the dismemberment of the country and particularly at the suggestion of their forcible transfer. As a result the momentum of the revolt increased during 1937 and 1938, in spite of extensive British military operations and the outlawing in October 1937 of the Arab High Committee, most of the members of which (except Amin al-Husayni

and a few others who escaped arrest) were deported to the Seychelles Islands.

In September 1937 the League council authorized the mandatory to prepare a detailed partition plan. A technical commission entrusted with this task reported in November 1938 against the Peel Commission's plan, largely on the ground that the number of Arabs in the proposed Jewish state would be almost equal to the number of Jews, and put forward alternative proposals that drastically reduced the areas and sovereignty of the proposed states.

A British statement of policy announced the impracticability of partition and called for a round-table conference in London. Although the Arab revolt continued well into 1939, its casualties were high and it gradually lost its vigour under firm British measures. The Arabs of Palestine were unable to recover from their sustained effort of defiance of the British administration.

The White Paper of 1939. No agreement was reached at the London conference held during February-March 1939, and the British government in a White Paper in May 1939 made a unilateral statement of policy based upon the assumption that the Jewish national home pledge had already been substantially fulfilled. Within the next five years 75,000 Jews would be allowed into the country; thereafter, Jewish immigration would be subject to Arab "acquiescence." Land transfer would be allowed only in certain areas in Palestine, and an independent Palestinian state would be considered within 10 years. The Arabs, although in favour of the new policy, could not agree to it, largely because of mistrust of Britain and the provision for the extension of the mandate beyond the 10-year period. The Zionists were shocked by the statement, which they considered a deathblow to their program and to Jews who desperately sought refuge in Palestine from the persecution they endured in Europe. Britain was accused by the Zionists of callously appeasing the Arabs of the Middle East and of protecting its own strategic interests in the face of the deterioration of the international situation. The 1939 White Paper marked the end of the Anglo-Zionist entente.

The Jewish national home had, however, made remarkable progress since 1918. Although the majority of the Jewish population was urban, rural Zionist colonies had increased from 47 to about 200. Between 1922 and 1939 Jewish landholdings had risen from 148,500 acres to 383,350 acres and the Jewish population from 83,790 to 445,457 (almost 30 percent of the total population). Tel Aviv had developed into an all-Jewish city of 150,000 inhabitants, and £80,000,000 of Jewish capital had been introduced into the country. The Jewish literacy rate was high, schools were expanding, and the Hebrew language had become widespread. Despite the split in 1935 between the main-line Zionists, who were led by David Ben-Gurion, and the radical Revisionists, led by Vladimir Jabotinsky (who advocated the use of force to establish the Zionist state), Zionist institutions in Palestine became stronger in the 1930s and helped create the preconditions for the establishment of a Jewish state.

World War II. The Zionists found themselves in World War II in the paradoxical position of having to fight the 1939 White Paper policy while rallying to Britain's side against Germany, the common enemy. Publication in February 1940 of the new land transfer regulations and announcement in November 1940 of Britain's decision to accommodate illegal Jewish immigrants for the duration of the war outside Palestine caused a recrudescence of the activities of the Zionist underground organizations. Before the war the Haganah, a self-defense organization founded by Jabotinsky and sponsored by the Jewish Agency, practiced restraint, but the Irgun Zvai Leumi, a dissident group formed in 1931 and reorganized in 1936 by members of the Revisionist Party, had gone into action against the Arabs. After the battles of el-Alamein, and as news of the terrible tragedy that was befalling European Jewry percolated to the outside world, tension mounted in Palestine. The Irgun joined hands during 1944 with the Stern Gang, a splinter group, in widespread attacks, culminating in the murder of Lord Moyne, British minister of state in Cairo, in November 1944.

During the war years the Palestine Jewish community

The
Haganah
and the

Leumi

was vastly strengthened. The moderate Jewish community supported the British: in September 1944 a Jewish brigade attached to the British 8th Army was formed, a total of 27,000 Jews having enlisted in the British forces. Jewish industry in general was given immense impetus, and a Jewish munitions industry developed that manufactured antitank mines for the British forces. Equally important was the support won by the Zionists in the United States, to which they had shifted their major political effort after 1939. In May 1942, at a Zionist conference held at the Biltmore Hotel in New York City, David Ben-Gurion gained support for a program demanding unrestricted immigration and a Jewish army and the establishment of Palestine as a Jewish commonwealth. An increasing number of pro-Zionist statements were elicited from U.S. congressmen and politicians. In August 1945 President Harry S. Truman requested Clement Attlee, the British prime minister, to facilitate the immediate admission of 100,000 Jews into Palestine, and in December the U.S. Senate and House of Representatives asked for unrestricted Jewish immigration to the limit of the economic absorptive capacity of Palestine. This contributed to the internationalization of the question of Palestine, already under way with the involvement of the Arab states since the 1930s.

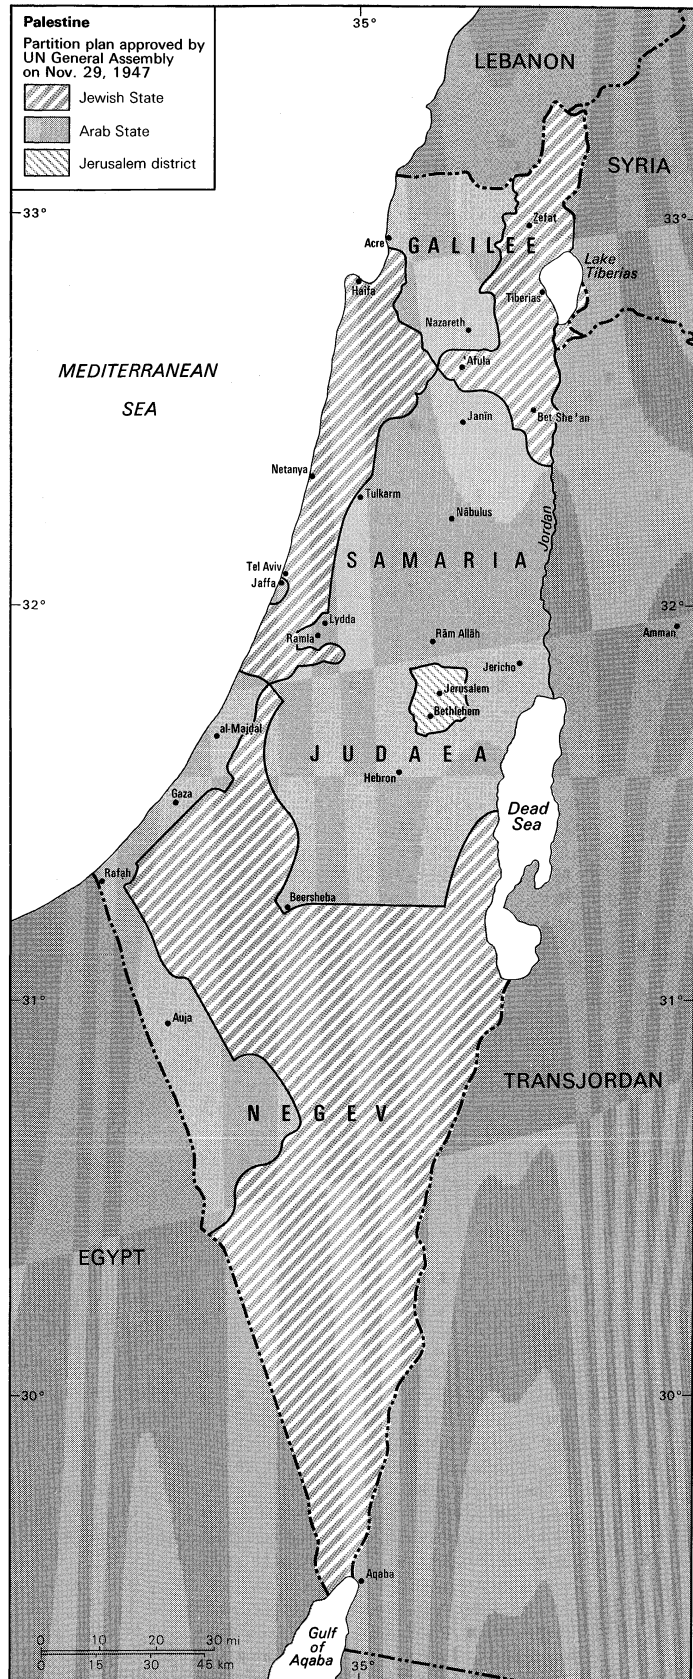

The Arabs of Palestine had remained largely quiescent throughout the war, although some supported the Axis powers and others enlisted in the British forces. Increases in agricultural prices benefited the Arab peasants, who began to pay accumulated debts. Amin al-Husayni had fled, by way of Iraq, Iran, Turkey, and Italy, to Germany, from which he broadcast appeals to his fellow Arabs to ally with the Axis powers against Britain and Zionism.

After the war the neighbouring Arab countries began to take a more direct interest in Palestine. In March the covenant of the League of Arab States was drawn up with an annex emphasizing the Arab character of Palestine. In December the Arab League declared a boycott of Zionist goods. The pattern of the postwar struggle for Palestine was emerging unmistakably.

Proposal for partition. In November 1945, in an effort to secure U.S. co-responsibility for a Palestine policy, Ernest Bevin, the British secretary of state for foreign affairs, announced the formation of an Anglo-American commission of inquiry. Pending the report of the commission, Jewish immigration would continue at the rate of 1,500 persons per month beyond the 75,000 limit set by the 1939 White Paper. A plan of provincial autonomy for Arabs and Jews was worked out in an Anglo-American conference in 1946, which became the basis for discussions in London between Britain and the representatives of Arabs and Zionists.

In the meantime Zionist pressure in Palestine was intensified by the unauthorized immigration of refugees on a hitherto unprecedented scale and by closely coordinated attacks by all Zionist underground forces. Jewish immigration was impelled by the burning memories of the Holocaust, the chaotic post-war conditions in Europe, and the growing possibility of the attainment of a Jewish state, where the victims of persecution could guarantee their own safety. The underground's attacks culminated in Jerusalem on July 22, 1946, when a part of the King David Hotel containing British government and military offices was blown up, with the loss of 91 lives. On the Arab side a meeting of Arab kings and heads of state at Inshās in Egypt in May 1946 reaffirmed the Arab character of Palestine, and at a meeting of the Arab League in Bludan, Syria, in June, secret resolutions were adopted threatening British and U.S. interests in the Middle East if Arab rights in Palestine were disregarded. With the failure of the London conference in February 1947, Britain, weakened by the world war and anxious to decrease its costly military presence, referred the Palestine question to the United Nations. A UN commission of inquiry recommended on August 31 in a majority report the partition of the country into Arab and Jewish states, which should retain an economic union. Jerusalem and its environs were to be international. These recommendations were substantially adopted by a two-thirds majority of the General Assembly in a resolution dated November 29, partly because of the

agreement of the United States and the Soviet Union on partition and partly because of pressure on some small states by Zionist sympathizers in the United States. All the Islamic Asian countries, however, voted against partition, and an Arab proposal to query the International Court of Justice on the competence of the General Assembly to

United Nations partition plan for Palestine adopted in 1947.

partition a country against the wishes of the majority of its inhabitants (there were 1,269,000 Arabs and 678,000 Jews in Palestine in 1946) was narrowly defeated.

The Zionists welcomed the proposed partition because of its recognition of a Jewish state and because 55 percent of Palestine was allotted to the Jewish state. As in 1937 the Arabs were violently opposed to partition both in principle and because a substantial minority of the population of the Jewish state would be Arab. Britain was unwilling to implement a policy that was not acceptable to both sides and refused to share the administration with the UN Palestine Commission, which was to supervise the transitional period. Britain set May 15, 1948, as the date of the end of the mandate.

Civil war. Soon after the UN resolution communal fighting broke out in Palestine. The Zionists mobilized their strength and redoubled their efforts to bring in immigrants. In December 1947 the Arab League pledged its support to the Palestinian Arabs and organized a force of 3,000 volunteers. Civil war spread and external intervention increased as the dismantling of the British administration progressed, and by mid-January 1948 some 2,000 casualties had resulted from the fighting.

Early in March 1948 the United States expressed its opposition to a forcible implementation of partition, and on March 16 the UN Palestine Commission reported its inability to implement partition because of Arab resistance and the attitude of the British administration.

On March 19 the United States called for the suspension of the efforts of the UN Palestine Commission and on March 30 for the declaration of a truce and the further consideration of the problem by the General Assembly.

The Zionists, insisting that partition was binding and anxious about the change in U.S. policy, made a major effort to establish their state. Operations "Nachshon" and "Jephtha" were launched on April 1 and 18, respectively. The success of these offensives coincided with the failure of an Arab attack on the Zionist settlement of Mishmar Haemek; the death in battle of an Arab national hero, 'Abd al-Qādir al-Ḥusaynī, in command of the Jerusalem front; and the massacre by Irgunists of 250 civilian inhabitants of the Arab village of Deir Yāsīn. On April 22 Haifa fell to the Zionists, and Jaffa, after severe mortar shelling, surrendered on May 13. Simultaneously with their military offensives the Zionists launched a campaign of psychological warfare. The Arabs of Palestine, badly led and reliant on the regular armies of the Arab states, collapsed.

On May 14 the last British high commissioner, General Sir Alan Cunningham, left Palestine. On the same day the State of Israel was proclaimed and within a few hours won de facto recognition from the United States. Early on May 15, units of the regular armies of Syria, Transjordan, Iraq, and Egypt crossed the frontiers of Palestine.

(W.A.K./W.L.O.)

In a series of campaigns alternating with truces between May and December 1948, the Arab units were routed. By the summer of 1949 Israel had concluded armistices with its neighbours. It had also been recognized by more than 50 governments throughout the world, had joined the United Nations, and had established its sovereignty over about 8,000 square miles of mandated Palestine west of the Jordan River. The remaining 2,000 square miles were divided between Transjordan and Egypt. Transjordan retained the lands on the west bank of the Jordan River, including East Jerusalem, which were all formally annexed in 1950. The name of the expanded country was changed to the Hashemite Kingdom of Jordan. Egypt retained control of, but did not annex, the Gaza Strip. "Palestine" ceased to exist.

PALESTINIANS AFTER 1948

If one element in the post-1948 pattern was embattled Israel and a second the unremitting hostility of its Arab neighbours, a third was the Palestinian refugees. The violent birth of Israel led to a mass exodus of Palestine Arabs. Between December 1947 and January 1949 some 700,000 took refuge in neighbouring Arab countries. Thenceforth, Palestinian Arabs lived in three different sets of circumstances, and their history began to diverge according to

their location. Most lived in nearby Arab countries, usually as stateless persons, while a minority lived in Israel as citizens of the Jewish state and others went to the Persian Gulf states, far removed from what had been Palestine.

The Palestinian refugees were recipients of UN aid and were a source of cheap labour in the "host" countries. Their cause was argued for them by others, and such political activity as they evinced was in relationship with one or another of the Arab states or leaders.

Palestinians constituted about two-thirds of the population of Jordan, where they were given citizenship as of 1949. One-half of the seats in the Jordanian Chamber of Deputies were reserved for the West Bank, but this measure and similar attempts to integrate the West Bank with the area lying to the east of the Jordan River were made difficult by the significant social, economic, educational, and political differences between the residents of each. Most Jordanian Palestinians, other than the notable families favoured by the King, tended to support the radical pan-Arab and anti-Israeli policies of Egypt's president, Gamal Abdel Nasser, rather than the more cautious and conciliatory position of Jordan's King Hussein. The successes of Nasser and the pan-Arab nationalist Ba'th Party of Syria and Iraq in the late 1950s and early 1960s encouraged Palestinians everywhere to fix upon them their hopes for return to their homeland and for the establishment of an independent Palestine. Those Palestinians who continued to live in refugee camps, often in conditions of extreme deprivation, felt a greater sense of alienation and anomie than the more fortunate who found jobs and housing and who became integrated into the national economies of the countries in which they resided. In Syria, Iraq, Lebanon, and the Persian Gulf states, Palestinians found employment, but only a few were able to become citizens. Often they were the victims of discrimination and were closely supervised by the respective governments so as to limit their political activities. In Israel most Israeli Arabs, while citizens of the state, were cut off from trends and events that affected their former compatriots and remained politically quiescent, although some accepted Zionist Israel as a reality and sought to ameliorate their circumstances by electoral participation, education, and economic integration. Egypt ruled the crowded Gaza Strip harshly, and the Palestinians living there were stateless (*i.e.*, not citizens of any nation) and had little real control over local administration. The rate of unemployment was high; many of the Palestinians there lived in refugee camps under the supervision of the United Nations Relief and Works Agency for Palestine Refugees in the Near East.

Some Gaza Strip Palestinians were able to leave the territory and gain education and employment elsewhere, but most had no alternative but to stay in the vicinity, despite its lack of natural resources and jobs. Egypt controlled Amīn al-Ḥusaynī's short-lived Government of All Palestine, which had been established in Gaza in 1948. The failure of this government, and the discrediting of al-Ḥusaynī because of his collaboration with the Axis powers during World War II, did much to weaken Palestinian Arab nationalism in the 1950s.

In 1964, however, an Arab summit meeting led to the formation of a Palestine Liberation Organization (PLO). Some time earlier, Palestinians had formed a secret organization called the Palestine National Liberation Movement (Ḥarakat at-Tahrīr al-Waṭani al-Filasṭīniyah), known from a reversal of its Arabic initials as al-Fatah. Both the PLO and al-Fatah undertook the training of guerrilla units for raids on Israel.

The Palestine National Council was established as the supreme body of the PLO, while an executive committee was formed to manage PLO activities. Aḥmad Shuqairi, a protégé of Egypt, became the first leader of the PLO. The National Council initially consisted of civilian representatives from various areas, including Jordan, the West Bank, the Gulf States, and other countries, and in 1968 representatives of guerrilla organizations were added. Al-Fatah was the largest and most influential group, while other major guerrilla organizations that emerged in the late 1960s were the Popular Front for the Liberation of Palestine (PFLP); the Popular Front for the Liberation of

of the
Arab
forces

Palestine-General Command (PFLP-General Command, a splinter group from the PFLP); al-Saiqa (Vanguard of the Popular Liberation War), backed by Syria; the Democratic Front for the Liberation of Palestine (DFLP); and the Popular Struggle Front (PSF). These groups joined forces inside the PLO despite their differences in ideology and tactics. In 1969 Yāsir 'Arafāt, leader of al-Fatah, became chairman of the PLO's executive committee and thus the chief of the Palestinian national movement.

The guerrilla organizations rejected any political settlement that did not include the total liberation of Palestine and the return of the refugees to their homeland, which was to be achieved through armed struggle. Palestinian spokesmen claimed, however, that while they aimed at dismantling Israel they had no intention of destroying or expelling the Jews but sought rather to establish a nonsectarian state in which Jews, Christians, and Muslims could live in equality. Most Israelis doubted the sincerity or practicality of this goal and viewed the PLO as terrorists who wished to destroy not only the Zionist state but also Israeli Jews.

The Arab-Israeli War of 1967 devastated the Arab nations. In six days in June, Israel not only dispatched the combined forces of Egypt, Syria, and Jordan but also overran vast tracts of Arab territory, including East Jerusalem, the West Bank (known to Israelis as Judea and Samaria), and Gaza—all of which had formerly been part of mandated Palestine. About 200,000 Arabs fled from the West Bank to eastern Jordan. Only about 1,000 East Jerusalem Arabs applied for Israeli citizenship, while the rest retained Jordanian passports, and the Arabs of the West Bank remained citizens of Jordan. More than 1,000,000 Arabs came under Israeli rule (in addition to the 350,000 already living in the state of Israel).

As the Arab states' total defeat demonstrated the hollowness of pan-Arabism and the inefficacy of revolutionary governments in Syria and Egypt, all the Arabs, both Palestinians and others, turned to the Palestinian commandos, who emerged as a new element of major importance in the Middle East. They raised the morale of all the Arabs after their humiliating defeat. When Israel launched one of its heavy reprisal raids against their bases in the Jordan Valley in March 1968, they fought back and inflicted heavy casualties on the Israelis. Within Jordan, militant Palestinians seemed to be forming a state within a state. An understanding was reached whereby the royal government allowed the commandos independent control of their own bases in the Jordan Valley, but relations between the government and the commandos remained uneasy. The commandos suspected Jordan's king Hussein—who had to face the damage inflicted upon his country by Israeli raids—of preparing to reach a direct settlement with Israel at their expense.

The escalation of an internal conflict between the Jordanian Army, loyal to King Hussein, and the Palestinian guerrilla movement led in 1970 to a brief but bloody civil war. On September 6–9 the PFLP hijacked to a Jordanian airstrip three airliners (U.S., Swiss, and British) with more than 300 people aboard. PFLP representatives threatened to destroy the aircraft, with the passengers aboard, unless Arab commandos detained in Europe and Israel were released. All the passengers were freed by September 30 when the PFLP secured its main demands (after destroying the airliners). This episode made civil war inevitable, since the PFLP hijackers had defied the Jordanian army's authority.

By September 17 the army was fighting the guerrillas in Amman and in northern Jordan, where the guerrillas were reinforced by Syrian armoured units. Formal hostilities ended on September 25, and the guerrillas were still in control of their northern strongholds. Total casualties were variously estimated at 1,500–5,000 killed and up to 10,000 injured. In 1971, however, the fighting resumed, and the Jordanian army established full control over the whole country and crushed the Palestinian military. From that point on, the King and the PLO were deeply suspicious of each other, while the majority of Palestinian Jordanians, especially those living under Israeli control, became highly critical of the King and his policies.

Driven from Jordan, the Palestinians intensified their activities in Lebanon. The presence of Palestinians was a source of tension and conflict in Lebanon, as it had been in Jordan. Palestinian activity against Israel was countered with Israeli raids, primarily into southern Lebanon. In December 1968 Israel launched a major attack on the Beirut International Airport and blew up most of the Lebanese commercial airfleet. This precipitated efforts by the government in 1969 to restrict the activities of the Palestinian guerrillas, which led to sporadic fighting between the Lebanese Army and the guerrillas. In November 1969 a cease-fire agreement between the Lebanese government and al-Fatah allowed the guerrillas limited freedom of operation in exchange for a promise not to interfere in Lebanese politics. During the early 1970s the Palestinian guerrillas continued to carry out attacks against Israel.

In 1973 the Palestinian movement suffered a severe blow in an Israeli commando attack on Beirut on April 10 that killed three of its leaders. During the year, several prominent Palestinians were assassinated in various European capitals by what were assumed to be Israeli counterterrorist agents.

Following the Israeli attack, the Lebanese Army attacked guerrilla bases and refugee camps throughout the country. An agreement was reached requiring the Palestinians to limit their activities in border areas near Israel and in refugee camps near urban centres.

In the war of October 1973 the Palestinians acknowledged that they were not directly involved because Egypt's and Syria's objectives were declared limited to recovering their own lost territory. Egyptian president Anwar el-Sādāt's insistence, however, that they be represented at any subsequent peace negotiations, as well as the growing world opinion that they must be a party to any settlement, sparked off a debate within the movement. Some of the guerrilla groups, called the "rejection front," who were supported by Iraq and Libya, continued to reject any suggestion of Israel's right to exist, but others, realizing that they were in danger of being isolated and abandoned if Egypt, Syria, and Jordan all subscribed to a peace settlement, were prepared to consider taking part in negotiations. The guerrillas did not, however, take part in the peace conference in Geneva in December; Israel would not deal with them.

After 1973 many Palestinians from Lebanon and Jordan moved to the increasingly prosperous and labour-hungry Arab oil states, such as Kuwait and Saudi Arabia. Israeli Arabs began to recover from their long period of inactivity and, following the 1973 war, took a greater part in Israeli institutions while also intensifying contacts with the Arabs of the West Bank and Gaza Strip. The latter were spurred to action by the increasing number and size of Israeli Jewish settlements in the occupied territories. The settlements were viewed by the Arabs as the prelude to Israeli annexation of the land and the permanent denial of the opportunity for the Arabs to determine their own national future.

In its international relations the PLO made important gains in the 1970s. By the end of the decade the organization had representatives in more than 80 countries. On Sept. 22, 1974, the UN General Assembly, overriding strong Israeli objections, included on its agenda for the first time "the Palestine question" as a subject for debate rather than as part of the general question of the Middle East. On November 13 the Assembly heard 'Arafāt, the head of the PLO, plead for the Palestinian people's national rights.

International recognition of the PLO had an important effect on the Arab summit conference held in Rabat, Mor., on Oct. 26–28, 1974. The chief item on the agenda was Palestinian representation at peace talks. Jordan had previously given notice that, if other Arab states decided to recognize the PLO as representing the Palestinians of the West Bank, it would consider itself released from all responsibility for negotiating an Israeli withdrawal. At Rabat, however, King Hussein came under the combined pressure of all the Arab states to accept the PLO's right to represent the Palestinians in any liberated territory. King Fayṣal of Saudi Arabia carried special weight with his argu-

War of
1973

Jordanian
civil war

ment that the Arabs could hardly do less than the United Nations. Finally, Hussein accepted a resolution that said that any liberated Palestinian territory "should revert to its legitimate Palestinian owners under the leadership of the PLO." The Rabat decision was denounced by the "rejection front," composed of the PFLP, the PFLP-General Command, the pro-Iraq Arab Liberation Front, and the Front for the Popular Palestinian Struggle. Although the decision was recognized as enhancing the position of the moderate PLO elements led by 'Arafat, the United States and Israel continued adamantly to refuse to recognize or deal with the PLO.

In 1975 Palestinian guerrilla activity against Israel was largely confined to the Lebanese border area, where it provoked heavy Israeli reprisals from air, land, and sea against Palestinian refugee camps that the Israelis alleged were used as guerrilla bases. Israeli raids, however, were overshadowed by the civil strife in Lebanon that developed along Muslim-Christian lines, with the Palestinians ultimately aligning with the Muslim leftists. The presence of some 400,000 stateless Palestinian Arabs was a contributing factor to the civil war.

Lebanon had to choose a policy on the PLO, either to repress it, as most of the rightist Christians wished, or to support it, as the leftists preferred. The PLO initially tried to stay out of the fighting, but by the end of 1975 groups within the overall organization, particularly the "rejection front" groups, were being drawn into an alliance with the Muslim leftists. During the first half of January 1976 there was fighting throughout the country as the Phalangist right-wing Christian forces blockaded the Palestinian refugee camps and the leftist Palestinian forces responded by attacking Christian villages on the coast. Syria, which had sworn to prevent Lebanon's partition by force if necessary, intervened by allowing Palestine Liberation Army forces (belonging to the PLO) under its control to enter the country. Syrian troops entered Lebanon in early April 1976 and supported the Lebanese right wing because of fears that a left-wing victory would result either in partition of Lebanon or in a Palestinian-dominated state, both of which would result in Israeli intervention. Christian forces besieged Palestinian refugee camps in June, and one of them, Tel az-Zaatar in eastern Beirut, became a symbol of Palestinian resistance. This fell on August 12-13, after seven weeks of siege and heavy loss of life. Heavy fighting continued until a peace agreement was negotiated in October 1976. The settlement provided for the creation of a 30,000-member Arab Deterrent Force (ADF), a ceasefire throughout the country and withdrawal of forces to positions held before April 1975, and implementation of a 1969 agreement that limited Palestinian guerrilla operations in Lebanon.

Although the Palestinian guerrillas suffered heavy losses in the war, they continued to wage their war of attrition against Israel in the late 1970s. They operated primarily from Lebanon, and Israel again responded with raids into southern Lebanon. In September 1977 Israeli troops crossed the border into southern Lebanon to support right-wing Christian forces opposing the Palestinians. On March 11, 1978, Palestinian guerrillas raided Israel, leaving 37 dead and 82 wounded, a move that was followed by the invasion of southern Lebanon by Israel on March 14.

On March 19 the UN Security Council passed Resolution 425, calling for an Israeli withdrawal and establishment of the UN Interim Force in Lebanon (UNIFIL). The Israelis withdrew in stages and had evacuated Lebanese territory by mid-June. They had been only partly successful in their aim of destroying Palestinian guerrillas and their bases south of the Litani River. Several hundred Palestinians were killed, but the bulk of them escaped northward.

The late 1970s were a period of more active negotiation on Arab-Israeli disputes. The Arab states supported Palestinian participation in an overall settlement providing for Israeli withdrawal from areas occupied since the 1967 war and establishment of a Palestinian state on the West Bank and the Gaza Strip. In March 1977, however, the Palestine National Council specifically rejected UN Security Council Resolution 242 of Nov. 22, 1967, which called for Israel's withdrawal from occupied territories but referred

to the stateless Palestinians as a "refugee problem," not as a national group.

The U.S. position toward the Palestinians was changing. In March 1977 President Jimmy Carter spoke of the need for a Palestinian homeland, and he later stated that it was essential for the Palestinians to take part in the peace process. The Israeli Cabinet continued to reject the participation of the PLO in the peace process but agreed not to look too closely at the antecedents of Palestinians who might be involved as members of delegations from Arab countries.

In November 1977 President Sadat traveled to Israel to address Israel's parliament, the Knesset. His visit initiated peace negotiations that led to the Camp David accords of 1978 and the Egyptian-Israeli peace treaty signed on March 26, 1979. Provisions of the accords included: the establishment of a self-governing authority in the West Bank and the Gaza Strip and a transitional period of not more than five years, in which time the inhabitants would become autonomous; and negotiations within three years of the beginning of the transitional period to determine the status of the West Bank and the Gaza Strip and to conclude a peace treaty between Israel and Jordan. The PLO and Jordan rejected the agreements: in their view Egypt was abandoning the Palestinian cause so as to regain Egyptian territory, while Israel maintained control of the remaining occupied territories.

During the Camp David process the Soviet Union recognized the PLO as the sole legitimate representative of the Palestinians, and in 1981 the Soviet Union extended formal diplomatic recognition. The PLO continued to seek U.S. diplomatic recognition, but the Carter administration honoured the secret commitment made by the former U.S. secretary of state Henry Kissinger to Israel not to deal with the PLO. In June 1980 the European Economic Community announced its support of PLO participation in peace negotiations.

The influence of the PLO was increasingly felt in the occupied territories, where PLO-supported candidates won the municipal elections of 1976, and separate Israeli and Jordanian attempts to encourage alternatives to the PLO failed in the 1980s. Active opposition to Israeli control in the West Bank spread, while frequent demonstrations, strikes, and other incidents occurred, particularly among students. A cultural renaissance among the Palestinians living under Israeli control and in exile was especially visible in the works of Mahmud Darwish and Ghassan Kanafani, who wrote nationalistic exhortations to remember the lost land. Israeli Arabs began on March 30, 1976, an annual observance of the "Day of the Land" to demonstrate their objections to Zionist appropriation of land in Israel and the occupied territories.

As Israeli occupation of the West Bank solidified, many Palestinians feared that their chances of regaining even part of their homeland were lessening. By the early 1980s the dominant factions inside the PLO favoured the creation of a "national authority," that is, a mini-state, perhaps linked to Jordan in some fashion. The possibility of peace and compromise was viewed with suspicion and disdain by the Likud party government of Israel, which, instead of adopting a policy of conciliation, chose to invade Lebanon on June 6, 1982, so as to crush the PLO and encourage the installation of a Lebanese government that would be friendly to Israel. The PLO and Syrian forces were defeated by Israeli troops, and the remaining PLO forces were contained in West Beirut. After a lengthy siege and bombardment by Israel, in late August some 11,000 Palestinian fighters were allowed to leave Beirut for various destinations, under international guarantees for their own safety and that of their civilian dependents. Despite these guarantees, after Israeli troops occupied West Beirut the Lebanese rightist allies of the Israelis massacred hundreds of Palestinian civilians in the refugee camps.

Israel in 1982 destroyed the PLO infrastructure in southern Lebanon, but it was unable to force all PLO guerrillas from the country, and, ultimately, the new government of Lebanon came under the sway of Syria. Syria sought to dominate but not annex Lebanon and, as a way of achieving this goal, ensured that no single Lebanese fac-

Camp
David
accords

Israel's
invasion of
Lebanon

tion would triumph completely over the other groups. By 1985 Israel and its backer, the United States, saw their Lebanon policy as a failure.

While Israel's military victory in Lebanon was not in the end decisive, the dispersal of the PLO did significantly weaken that group's military strength and political militancy. It was unable to operate freely from any of the nations bordering Palestine. U.S. President Ronald Reagan's peace proposal of September 1982 recognized the "legitimate rights of the Palestinians," but not the PLO, and Reagan urged a solution that would, in effect, restore Jordanian control to the West Bank. 'Arafāt and the other PLO leaders were also threatened by the emergence of a faction within al-Fatah encouraged by Syria. 'Arafāt was driven out of northern Lebanon in December 1983 by the Syrians and their protégés inside the PLO. As a result, the majority of the PLO turned to Egypt and Jordan for support against Syria and sought to use King Hussein of Jordan as an intermediary for negotiations with the United States and Israel that might lead to a mini-state and confederation with Jordan. This policy was seen most concretely in the meeting of the Palestine National Council in Amman in November 1984, the first time it had met there since Jordan crushed the PLO armed forces in 1970. The PLO-Jordan option, however, was hindered by doubt among many Palestinians that King Hussein was willing to see an independent political choice made by them; the fear of most Israelis that a Jordanian-PLO delegation in an international peace conference would involve unacceptable demands and risks; the reluctance of the United States to see the Soviet Union, a supporter of the PLO, have a major voice in the settlement; and PLO reluctance or inability to unite on a policy sufficiently accommodating to meet Israeli and American demands.

Instead of peace talks, violence escalated. West Bank Arabs rioted and engaged in strikes in 1982, before the invasion of Lebanon, and again in late 1986. Lebanese Shi'ites fought the PLO to stop its reemergence as an armed rival for supremacy in the chaotic situation prevalent in West Beirut and southern Lebanon. Palestinian guerrillas hijacked airliners and even a passenger cruise ship to publicize their cause. On Oct. 1, 1985, Israel bombed the PLO headquarters near Tunis.

In Israel itself several new developments seemed to strengthen Arab feelings of alienation from the Jewish majority. The Knesset approved a bill in 1985 banning any political party that endangered state security—*i.e.*, any party that was anti-Zionist. This reinforced the longstanding situation whereby most Israeli Arabs found that no legal political party could adequately reflect their national, economic, and political views. Equally frustrating for those Palestinians inside and outside Israel who wished to see a compromise peace was the Israeli rejection of a joint Jordanian-Palestinian delegation, whose membership had been approved by the United States in July 1985. Israelis in turn became more antagonistic toward Palestinians as armed attacks against Israel and Israelis living abroad increased in number.

The United States continued to support Israel fully but at the same time attempted to improve relations with some Arab states, such as Jordan, and to gain acceptance as an informal mediator from those Palestinians who were prepared to listen, despite the seemingly one-sided position of the United States in the Arab-Israeli dispute. The Reagan administration talked of improving the quality of life for Arabs living in the occupied territories and supported Jordan's announced plans to bring this about. In 1988 a new peace initiative was begun by U.S. Secretary of State George Shultz. The United States strongly opposed the PLO, however, and ordered that its offices in the United States be closed.

'Arafāt condemned U.S. policy, while officially disclaiming responsibility for attacks on Israeli civilians. He said that Syria and Libya (and the Palestinians the latter supported) were sponsoring such attacks to prevent a negotiated settlement with Israel. Aerial attacks by Israel on Palestinian guerrilla bases in Lebanon escalated.

In the middle and late 1980s the two chief Israeli political parties that dominated the Cabinet clearly reflected

differing positions on the future of the Palestinians in the occupied territories. The Likud party wished ultimately to annex the land, but not necessarily the people living thereon, fearing their voting power if they were to participate in Israeli elections. The Labour Party was willing to return some of the occupied territories to Jordan in return for full peace. Because the two parties could agree neither on goals nor on methods (such as the advisability of an international peace conference involving the nations permanently holding seats on the United Nations Security Council), no action was taken, and the status quo endured.

The PLO was also divided, despite the surface unity achieved in April 1987 when the mainline and radical pro-Syrian factions formally accepted a common program.

In the occupied territories small-scale Arab Palestinian demonstrations; university closings, arrests, and deportations by the Israeli authorities; riots; and occasional violence directed against Israelis ensued throughout 1987 as the Arabs saw no improvement in effective support of their aspirations from outside and no likely favourable change coming from the Israelis. Attacks by Arabs on Israeli settlers and by Israeli settlers on Arabs mounted, as the 20th year of Israeli occupation passed with no signs of significant change. Large-scale riots and demonstrations broke out on Dec. 9, 1987, and continued for months thereafter. When demonstrations turned to throwing stones at Israeli troops, the soldiers responded by shooting and arresting demonstrators. Many were killed, hundreds more were wounded, and some demonstrators were tortured by the Israeli armed forces. The persistent disturbances were initially spontaneous, but ultimately they came under the leadership of the United National Command of the Uprising, which may be linked to the PLO and to Islamic fundamentalists inside Gaza.

Tactics followed by the demonstrators were highly sophisticated. Strikes, commercial boycotts and closures, and demonstrations would be carried out in one part of the territories and then, after Israel reestablished its local power there, would be transferred to a previously unengaged area. Palestinian refugee camps provided major centres for the resistance, but Palestinian Arabs living in more affluent circumstances also participated, and some Israeli Arabs also showed their sympathy with the goals of the uprising. For the first time since Israel gained control of East Jerusalem in 1967, a general curfew was imposed by the Israeli authorities in some Arab sections of the city. The Arabs in the occupied territories killed some of their compatriots whom they accused of being collaborators with Israel; Arab police employed by Israel were required by public pressure of their fellow Arabs to resign from their posts.

Despite the yearning for a peaceful resolution of the turbulent history of the Palestinian people, the apparent failure of the American peace initiative early in 1988 implied a bleak future. As for the chief representative of the Palestinian Arabs, the PLO, the gains of the 1970s have not been completely lost. Arafāt showed considerable endurance, being widely regarded as the only Palestinian Arab figure who could command general support among his people. The PLO continued to be recognized widely, in the United Nations and elsewhere, as the legitimate voice of Palestinian nationalism. More importantly, international recognition of a separate Palestinian identity, and the growth of the Palestinian population worldwide to more than 4,000,000, showed continued vitality. The military and political strength of Israel, however, also increased. While some Israelis were prepared to accept to a limited degree Palestinian autonomy, most Israelis and Palestinians remained deeply reluctant to acknowledge the legitimacy of each other's claims. For Israel, to acknowledge Palestinian nationalism would cast doubt on the moral basis of the whole Zionist enterprise. For the Palestinian Arabs, to recognize Israel's right to exist would mean condemning their own nation to a small fraction of the former homeland. (W.L.O.)

For the periods of Muslim rule before 1516, see GUY LE STRANGE (trans.), *Palestine Under the Moslems: A Description of Syria and the Holy Land from A.D. 650 to 1500* (1890, reprinted

1975), a collection of medieval Arabic sources; SHLOMO D. GOITEIN, "Jerusalem in the Arab Period (638–1099)," *The Jerusalem Cathedral*, 2:168–196 (1982); and AMNON COHEN and GABRIEL BAER (eds.), *Egypt and Palestine: A Millennium of Association (868–1948)* (1984).

Among many recent works on Ottoman Palestine the following are the broadest and most valuable: MOSHE MA'OZ (ed.), *Studies on Palestine During the Ottoman Period* (1975); AMNON COHEN, *Palestine in the 18th Century: Patterns of Government and Administration* (1973); DAVID KUSHNER (ed.), *Palestine in the Late Ottoman Period: Political, Social, and Economic Transformation* (1986); and NEVILLE J. MANDEL, *The Arabs and Zionism Before World War I* (1976, reprinted 1980).

Some useful general studies that cover the 20th century are FRED J. KHOURI, *The Arab-Israeli Dilemma*, 3rd ed. (1985); HOWARD M. SACHAR, *A History of Israel*, 2 vol. (1979–87); BRUCE R. KUNIHOLM and MICHAEL RUBNER, *The Palestinian Problem and United States Policy: A Guide to Issues and References* (1986), with an extensive bibliography; and PAMELA ANN SMITH, *Palestine and the Palestinians, 1876–1983* (1984).

The period of the British mandate is covered by TARIF KHALIDI, "Palestinian Historiography: 1900–1948," *Journal of Palestine Studies*, 10(3):59–76 (Spring 1981); ADNAN MOHAMMED ABU-GHAZALEH, *Arab Cultural Nationalism in Palestine During the British Mandate* (1973); ANN MOSELY LESCH, *Arab Politics in Palestine, 1917–1939: The Frustration of a Nationalist Movement* (1979); Y. PORATH, *The Emergence of the Palestinian-Arab National Movement, 1918–1929*, trans. from Hebrew (1974), and *The Palestinian Arab National Movement: From Riots to Rebellion, 1929–1939*, trans. from Hebrew (1977); KENNETH W. STEIN, *The Land Question in Palestine, 1917–1939* (1984); DAN HOROWITZ and MOSHE LISSAK, *Origins of the Israeli Polity: Palestine Under the Mandate* (1978; originally published in Hebrew, 1977); and WM. ROGER LOUIS and ROBERT W. STOOKEY (eds.), *The End of the Palestine Mandate* (1985).

For coverage from 1948 to the present, publications of the Israeli government and the Palestine Liberation Organization (PLO) should be supplemented by articles drawn from the *Journal of Palestine Studies* (quarterly); and *The Jerusalem Quarterly*. Among the many studies on the Palestinian Arabs, the following are particularly worth consulting: HELENA COBBAN, *The Palestinian Liberation Organisation: People, Power, and Politics* (1984); SHAUL MISHAL, *The PLO Under Arafat: Between Gun and Olive Branch* (1986); DON PERETZ, *The West Bank: History, Politics, Society, and Economy* (1986); BARRY RUBIN, *The Arab States and the Palestine Conflict* (1981); EDWARD SAID, CHRISTOPHER HITCHENS, et al., *Blaming the Victims: Spurious Scholarship and the Palestinian Question* (1987); and two articles from the *Journal of Palestine Studies*—PAMELA ANN SMITH, "The Palestinian Diaspora, 1948–1985," 15(3):90–108 (Spring 1986); and RASHID KHALIDI, "The Palestinian Dilemma: PLO Policy After Lebanon," 15(1):88–103 (Autumn 1985).

(G.R.B./W.L.O.)

Paraguay

Paraguay is an independent republic of South America, located in the south central part of the continent. A landlocked country, it is dwarfed by the larger bordering countries of Bolivia to the northwest and north; Brazil to the east; and Argentina to the south-east, south, and west. It has an area of 157,048 square miles (406,752 square kilometres). The national capital of Asunción is located on the east bank of the Paraguay

River opposite the mouth of its chief western tributary, the Pilcomayo River. Rivers play a vital role in the nation's economic life, providing the country with access to the distant Atlantic Ocean and with sites for hydroelectric power plants. Indeed, the name of the country is said to derive from the Guaraní Indian word that means "place with a great river."

Physical and human geography

THE LAND

Relief. The Paraguay River, which runs from north to south, divides Paraguay into two distinct geographical regions—the Región Oriental (Eastern Region) and the Chaco Boreal (Northern Chaco), the latter officially comprising the Región Occidental (Western Region).

The Región Oriental, with an area of about 61,700 square miles, is an extension of the Brazilian Plateau and varies in elevation from about 165 feet (50 metres) above sea level in the southwest to a few hills that rise to 2,500 feet. The Cordillera de Amambay (Amambay Mountains) runs approximately north to south along part of the border with Brazil and then runs eastward as the Cordillera de Mbaracayú. From the northeast, other ranges extend southward toward Encarnación, diminishing to hills in the south. To the east of these mountains lies the Alto Paraná (Upper Paraná) River Valley. To the west lies the broad valley of the Paraguay River. The area from Encarnación northward to the Brazilian border, comprising one-third of eastern Paraguay, is called the Paraná Plateau. The western part of the Región Oriental and the Alto Paraná Valley north and east of Encarnación are the areas most favourable to human settlement.

The Chaco Boreal, which covers more than 95,000 square miles, about two-thirds of the country, forms the northern part of the Gran Chaco, a flat and largely featureless tropical region that also extends into Bolivia and Argentina.

Drainage. Four-fifths of the country's perimeter is traced by the Paraguay, Apa, Alto Paraná, and Pilcomayo rivers. The Alto Paraná forms both the eastern and southern borders of the country. Multiple tributaries cross the eastern and central regions. The mountain ranges of Amambay and Mbaracayú form the watershed between the Paraguay and the Alto Paraná rivers, which join to form the Paraná

at the country's southwestern corner. Important eastern tributaries of the Paraguay River include, from north to south, the Apa, Aquidabán, Yapané, Jejuí, and Tebicuary. Except for the Río Monday and Río Acaray systems, the rivers that flow into the Alto Paraná have little economic significance. The only important tributary flowing from the west is the unnavigable, poorly defined Pilcomayo, which joins the Paraguay just below Asunción. Rising to the northwest in Bolivia, the Pilcomayo forms the southern border of the Chaco Boreal. Other Chaco rivers are slow, sluggish, intermittent streams that drain into swamps or disappear during dry periods.

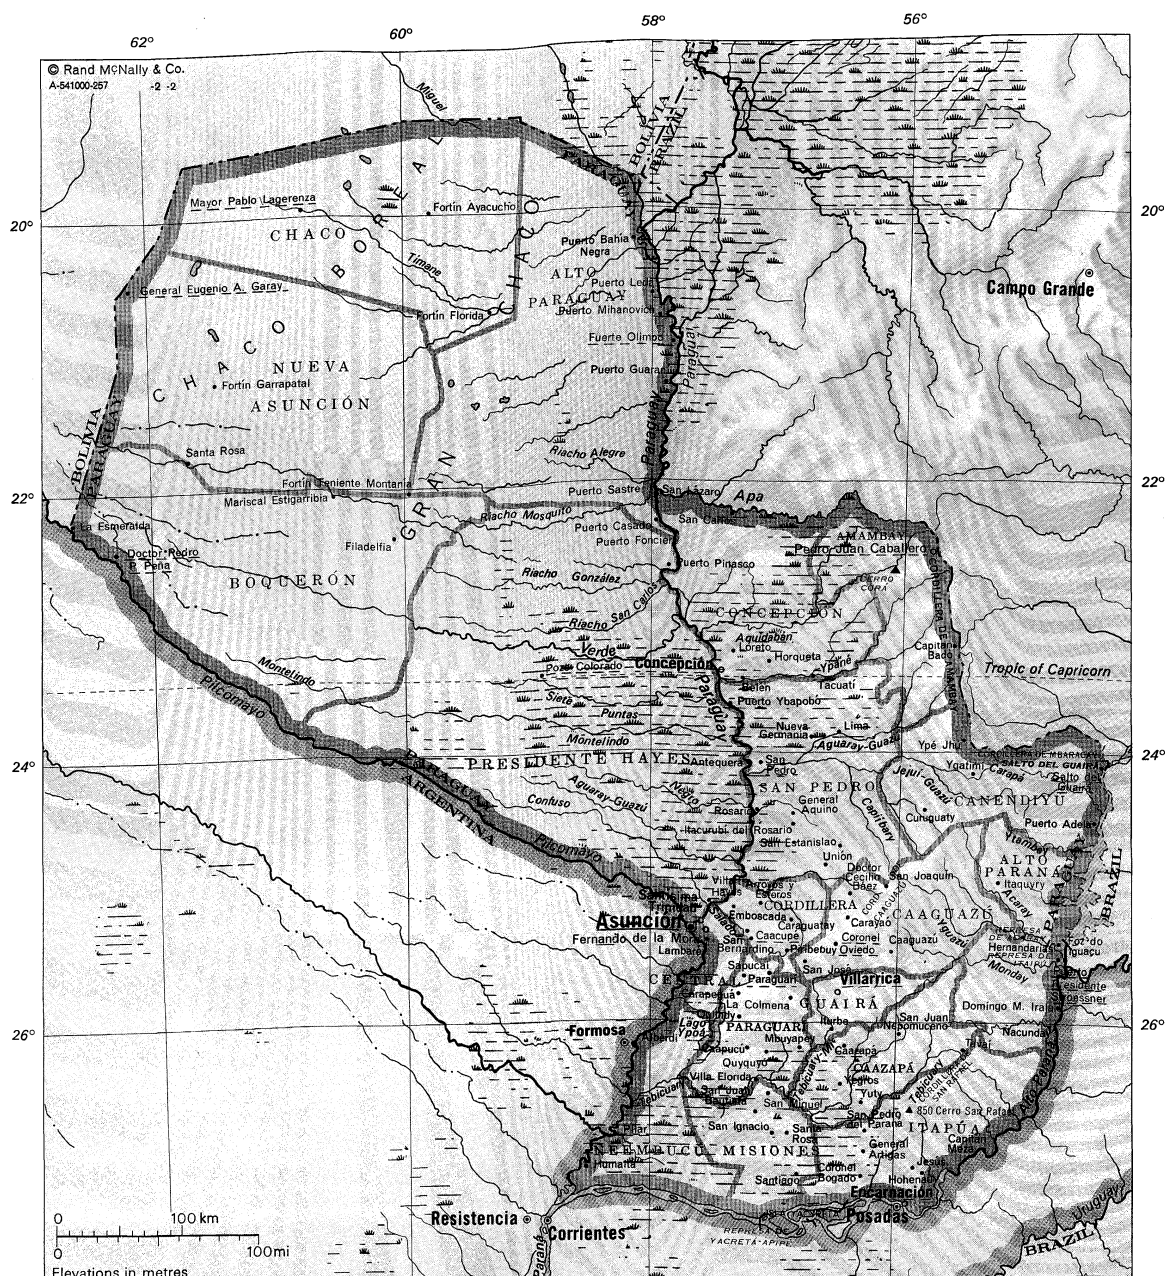

Paraguay has only two lakes of consequence. The largest, the swampy Lake Ypoá, which begins about 40 miles (65 kilometres) south of Asunción, merges into the Laguna Verá; it is drained by various channels of the Tebicuary and feeds the marshes of the Ñeembucú Plain. Lake Ypacaraí, about 18 miles east of Asunción, has a favourite summer resort at San Bernardino, a town founded in 1881 by German agricultural colonists.

Soils. A large part of eastern Paraguay is covered by a residual soil mantle so deep that bedrock is rarely exposed. This soil is generally red and sandy and is low in nitrogen and other basic plant foods. About 40 percent of eastern Paraguay, in a belt running from the Brazilian border south to the Tebicuary and including the Asunción area, is covered by soils underlain by sandstone. Soils from basaltic lava, which generally are the most fertile, cover the Paraná Plateau. Transported soils cover a band along the Paraguay River, extending from the Río Apa to the southern border and covering the Ñeembucú Plain. Soils of the Chaco are largely alluvial mud, clay, and sand that have been transported from the Bolivian highlands.

Climate. Paraguay's climate is subtropical, with most of eastern Paraguay lying south of the Tropic of Capricorn and most of the Chaco north. Masses of humid air blan-

The tropical forests

ket the country in the summers, and cold southern winds can make the winters miserable. Summer temperatures between October and March generally range between 77° F and 104° F (25° C and 40° C). Winter temperatures usually range between 50° F and 68° F (10° C and 20° C), although extremes of 30° F and 90° F (−1° C and 32° C) are not uncommon. Frost occurs every year somewhere in the country, but it is most common on the Paraná Plateau. The annual average rainfall in eastern Paraguay varies from 67 inches (1,700 millimetres) in the south-east to 55 inches along the Paraguay River. It diminishes gradually westward across the Chaco, averaging about 23 inches on the western border.

The entire country is subject to periodic floods and droughts, both of which cause severe agricultural losses. Plagues of locust frequently follow droughts.

Plant and animal life. About two-fifths of the Eastern Region and more than one-half of the Chaco are forested. More than 500 species of hardwoods have been identified, among which are the urunday, peterebi, curupay, lapacho, and many kinds of palms. This wealth of forest resources has made Paraguay a world leader in the export of forest products, most of which go to Argentina. The supply of cedars has been exploited extensively for furniture, boxes, and general use. Large stands of native yerba del Paraguay (*Ilex paraguayensis*) occur in many areas. Marshes in the river valleys, especially in the southwest, are covered with tall grasses. Forest resources of the Chaco include many species of hardwoods that yield tannin, of which the red quebracho (*quebracho colorado*) is the most important. Numerous palms, such as the caranday, are commercially useful. The very hard palo santo ("holy wood") yields a valuable oil. Much of the Chaco is covered by cacti and a thorny scrub growth similar to the *caatinga* of Brazil's northeast. Medicinal plants abound in Paraguay and formerly were the basis of an extensive native pharmacopeia. The wild pineapple is native to eastern Paraguay, as is the bitter orange, which grows in wild profusion. The sweet orange, introduced by Spaniards, produces such huge quantities of fruit as to be worth only a pittance.

The name Chaco means "hunting ground," and the area, like eastern Paraguay, teems with wildlife. The jaguar, locally known as the *tigre*, lives among herds of wild boar, capybara (water hog), and deer and ranges over both parts of the country. The armadillo and anteater are common in

the Chaco as is the otter and the coypu, a South American aquatic rodent. The varied birdlife includes ibis, herons, toucans, muscovy ducks, doves, partridges, parakeets, and parrots. Insect life is extensive and includes the deadly tarantula spider, as well as huge swarms of mosquitoes.

Animal life in the east is similar to that of Brazil and Argentina. There are various monkeys, tapirs, peccaries, puma, *tigres*, and deer. The more than 400 species of birds include eagles, falcons, partridges, pigeons, and herons. The waters of both regions abound with crocodiles, caymans, and a large variety of fish.

SETTLEMENT PATTERNS

Rural settlement. The principal areas of rural settlement are located in the east. There has been considerable development of agricultural colonies west of Puerto Presidente Stroessner and in the far northeast near Pedro Juan Caballero. Settlement in the Chaco is sparse. Except for the small town of Villa Hayes and a few ports serving industrial enterprises, there were no significant interior settlements to disturb the nomadic Indians until several Mennonite colonies were established about 120 miles west of Puerto Casado in the 1920s and 1930s.

Urban settlement. The largest urban concentration is found in the national capital, Asunción, and its suburbs. Puerto Presidente Stroessner, Fernando de la Mora, and Pedro Juan Caballero are the next largest centres of population, followed by Encarnación, Caaguazú, Pilar, Concepción, Villarrica, Coronel Oviedo, and Hernandarias.

THE PEOPLE

Ethnic composition. Paraguay has the most homogeneous population of any South American country. The vast majority of inhabitants are native Paraguayans; they pride themselves on their Guaraní descent, although the admixture of European strains is prominent.

The immigrant population is small. Immigrants have come largely from western Europe, principally Spain, but Japan, Korea, and Australia are also represented. Except in the case of Japanese immigrants, who have settled in such thriving agricultural colonies as La Colmena, most have been assimilated. Assimilation also has been resisted by the colonies of Mennonites and Hutterites, Christian sects that stress life-styles considerably different from those prevailing in Paraguay. These sects have received special privileges from the government, especially exemption from military service.

There is a small Indian population living in Paraguay, nearly all in the Chaco, where there are small groups of Toba, Maskoy, Tapieté, Nanaiguá, Mataco, Lengua, Chamacoco, Zamuco (Moro), and Chulupí, among others. Despite efforts of the National Indian Institute, these survivors from the Stone Age have, at times, been forcibly relocated and threatened with extinction.

Language groups. The constitution recognizes both Spanish and Guaraní as national languages, but Spanish is the official language. Spanish is the medium of instruction and is used in business and government, whereas Guaraní is mainly the language of the home. Most of the population is bilingual.

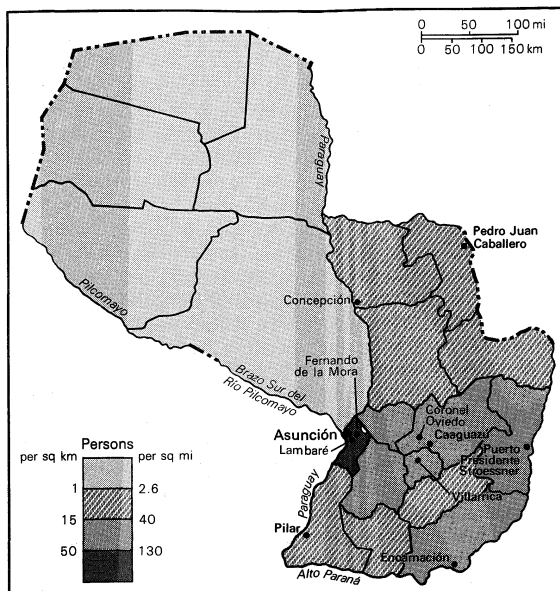

Religious groups. Roman Catholicism is the official religion, and its adherents constitute all but a small minority of Paraguayans. There is tolerance for other Christian sects, as well as for other religions that are practiced by the population.

Demography. Population estimates for Paraguay have always been the despair of demographers. The best available estimates place the population at about 400,000 in 1864; at 176,000 in 1872, after the Paraguayan War; and, a century later in 1972, at about 2,400,000. Although about one-half of the population is rural, migration to the cities has accelerated. There is a slight majority of females. Life expectancy at birth is higher than the average Latin-American country. The population is young, with the majority under 30 years of age. Infant mortality has decreased, but it remains high.

Distribution of persons is not uniform, with the highest density in the Asunción metropolitan area.

The rate of emigration has fluctuated, but it has been

The religious colonies

Population of Paraguay.

relatively high since 1870, especially among males seeking work in neighbouring countries. It is estimated that several hundred thousand Paraguayans have emigrated since 1940.

THE ECONOMY

Agriculture, cattle raising, forestry, and fishing. Agriculture, the most common economic activity, employs more than one-half of the population on a very small percentage of the arable land. The Rural Welfare Institute, through a program to legalize land tenancy, has greatly reduced the number of squatters. The overwhelming majority of farm units are occupied by owners, although small groups of tenant farmers and squatters still exist. The average farm is about 100 acres (40 hectares), although most of the arable land is held in very large units. A national agency provides short-term credit for agricultural production, while the Rural Welfare Institute gives aid and guidance to hundreds of government agricultural colonies and several private ones. Large-scale agriculture is in its infancy, since most of the land is used for grazing. Agriculture suffers several problems, including the high price of fertilizer and petroleum, and a relatively low price for many farm products. The most important crops are cassava, sugarcane, corn (maize), soybeans, and cotton, and among other crops are rice, wheat, coffee, tobacco, tung oil, and peanuts (groundnuts).

Some pigs, sheep, chickens, and horses are raised, but cattle are the most important livestock. Cattle raising is a traditional activity that contributes to both domestic consumption and to the export trade. Cattle are raised in the southern part of eastern Paraguay, in the Concepción area, and in the eastern and northeastern Chaco. Almost all cattle are raised for slaughter or for export. Contrary to popular belief, Paraguayans, unlike Argentines, are not great consumers of beef.

Forest products account for a significant portion of exports, and Argentine investment in the timber industry, as well as in cattle raising, is extensive. Many of the agricultural colonies have been carved out of heavily forested land, however, and there has been little effort to reforest denuded areas with desirable species.

There is no organized fishing industry, although the rivers teem with fish. Especially popular are the *surubí* and dorado, while other species provide the basis for a small commercial industry.

Resources. *Mining and quarrying.* Most mineral deposits are found east of the Paraguay River. Manganese is located near Emboscada; malachite and azurite (copper ores) near Caapucú, Encarnación, and San Miguel; feldspar and mica near Concepción; and talc and *piroflita* (hard, iron-bearing flagstone) near Caapucú and San Miguel.

Ochre is found in the Cordillera region, and gypsum and limestone near the Paraguay River; there is some peat near Pilar. Other minerals include marble, clay (kaolin), and salt, and uranium ores have been reported. Extensive drilling in the Paraguayan Chaco has failed to find any hydrocarbons.

Despite the varied mineral resources, mining and quarrying are the least developed economic activities. Limestone, cement, and lime are produced for the building trades, and clay (kaolin) and sand are quarried for use in ceramics and in glass. The government promotes electricity-intensive industries, including expansion of the cement industry.

Energy. Most electricity in Paraguay came from wood- and oil-burning thermoelectric plants in Asunción until the Acaray hydroelectric power plant began operating in 1968. The plant's capacity was expanded to 190,000 kilowatts. Paraguay's total production increased more than 20-fold from 1954 to 1984. Nearly all of this increase came from hydroelectric sources. Distribution of electricity is controlled by the National Electricity Administration, which was created in 1949.

A dramatic and far-reaching economic event in Paraguay's history was the construction of the hydroelectric project at Itaipú on the Alto Paraná, about 10 miles north of the International Friendship Bridge at Puerto Presidente Stroessner. Under a 1973 treaty a major portion of the cost was borne by Brazil. It was agreed that Paraguay would receive one-half of the electricity generated and would sell its excess power to Brazil. The United States supplied most of the equipment for the gigantic project. Financing, provided by both private and international banks, reached about \$20,000,000,000.

Work was completed in 1982 on the main gravity dam, 620 feet high and 4,045 feet long, spanning the Alto Paraná. The reservoir created by the dam covers about 870 square miles of Paraguayan and Brazilian territory. The dam is one of the largest in the world and has one of the world's highest planned generating capacities, greater than Grand Coulee Dam. Construction stimulated land investment, expanded banking and financial services, and created a shortage of workers elsewhere as labourers flocked to Itaipú.

The joint Paraguayan-Argentine hydroelectric project in the Yacyretá-Apipé islands zone of the Alto Paraná is smaller but still important, with a planned capacity of 3,700,000 kilowatts. Corpus, in the Itacus area, was designated in 1979 as the site for another Paraguayan-Argentine project. The supply of electricity will provide Paraguay with a basis for transforming and modernizing its economy.

Industry. Paraguay is one of the most industrially undeveloped countries in South America. Manufacturing includes the production of tannin extract, vegetable oils, petitgrain oil, ginned cotton, maté, and soybean meal. Other industries, encouraged by the Banco Nacional de Fomento (National Development Bank), include textiles, shoes, sugar, soap, furniture, plywood, matches, leather products, ice, and soft drinks. Large quantities of alcoholic beverages, especially *caña* and beer, are produced locally. The meat-packing industry is very dependent on foreign markets.

Finance. The main banking establishments are the Banco Central del Paraguay, which handles all monetary and foreign exchange functions, and the Banco Nacional de Fomento and Banco de Desarrollo del Paraguay, which grant credits to agricultural and industrial enterprises and conduct normal banking functions. There are also branches of other Latin-American, European, and U.S. banks. Foreign exchange reserves are limited, but generous loans are obtained from international development banks and associations.

Trade. The principal exports—cotton, soybeans, forest products, vegetable oils, and meat products—are chiefly marketed in Argentina, western Europe, Brazil, Japan, and Uruguay. Cotton and soybeans are the most important agricultural exports. Paraguay has become one of the world's largest producers and exporters of soybeans, which are grown mostly in the Itaipú and Alto Paraná departments.

Itaipú hydroelectric project

Land ownership

Forestry products

The main sources of imports—the United States, West Germany, and France—provide Paraguay with transportation equipment, fuel, heavy machinery, motors, chemicals, pharmaceuticals, foodstuffs, lubricants, and iron and iron products. Paraguay is a member of the Latin American Integration Association (LAIA; formerly the Latin American Free Trade Association [LAFTA]). An elaborate system of subsidies, surcharges, and multiple exchange rates prevents Paraguay's unfavourable balance of trade from becoming excessive.

The government's role in the economy

Administration of the economy. Although private initiative is encouraged, the government plays an important role in planning economic activities. It defines economic and social policy and participates directly in business life. The government holds a monopoly on the production of alcohol and operates a cement plant.

Taxation. Most of Paraguay's revenue is derived from customs duties and indirect taxes, and from income, sales, and service taxes. Profits derived from commerce, industry, finance, ranching, farming, and real estate are taxable, but income from rents, securities, and pensions is exempt.

Trade unions. There is one large, government-recognized trade union—the Confederation of Paraguayan Workers. There are other, smaller labour unions, some of which represent rural workers and farmers. The right to join unions is guaranteed by law. Strikes are prohibited until compulsory arbitration before the Permanent Board of Conciliation and Arbitration is exhausted and then are allowed only with strict limitations.

Economic policies and problems. Economic policy became inseparable from political policy under Pres. Alfredo Stroessner. The objectives of the Colorado Party, under Stroessner's control, were carried out to a remarkable degree, while political opposition was crushed or bypassed. Rather than impose the high taxes needed to finance development, the government preferred to borrow. Still, the public debt was kept within manageable limits, and the *guarani* became one of the more stable Latin-American currencies.

Transportation. Roads. The enormous economic transformation in Paraguay has been aided tremendously by construction of a sizeable road network equipped with adequate bridges. Paraguay's major highway connects Asunción with Puerto Presidente Stroessner, where the International Friendship Bridge spans the Alto Paraná and carries the highway into Brazil. This paved road continues to the port of Paranaguá, from which Paraguay exports most of its soybeans. Another major paved highway joins Asunción with Encarnación. A suspension bridge, part of the Pan-American Highway, links Asunción and Clorinda, Argentina. The Chaco is served by a paved highway that runs northwest from Villa Hayes through the Mennonite colonies and on to the Bolivian border. Other unpaved routes connect Asunción with the principal interior cities.

Railways. Most of the railway system is made up of the Ferrocarril (Railway) Presidente Carlos Antonio López, which runs for 274 miles from Asunción southeastward to Encarnación, where it connects with a train ferry to Posadas, Argentina. The Ferrocarril del Norte operates between Concepción and Horqueta. Short, privately owned narrow-gauge railways connect Chaco industries with ports on the Paraguay River.

Water transport. The chief method of transportation in Paraguay is by water. The Paraguay and Alto Paraná carry much international traffic. Paraguay's merchant fleet, the Flota Mercante del Estado, which was created in 1945, runs many cargo vessels and also has tankers, passenger ships, ferries, and a training ship. Ocean shipping is handled by the Compañía de Ultramar.

Air services. Air transport is provided by the government-owned national airline, Líneas Aéreas Paraguayas, which has greatly expanded its services since its creation in 1962. Líneas Aéreas de Transporte Nacional serves interior cities. An international airport at Asunción has greatly expanded service for Paraguay's rapidly increasing tourist and commercial traffic. There are domestic airports at major interior cities.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. Constitutional framework. The Constitution of 1967, amended in 1977, is the basic charter of Paraguay. The president is elected by direct vote for a five-year term and must be a Roman Catholic, a Paraguayan by birth, and more than 40 years of age. The prohibition on being reelected more than once was removed in 1977 to permit President Stroessner's reelection. The president has the usual powers of appointment, conducts foreign affairs, and may declare a state of siege and dissolve Congress, enact laws by decree, and mobilize the army. (Stroessner's role as actual, but not titular, head of the Colorado Party gave him complete political control of the country.)

The presidency

The Council of State is an advisory body appointed by the president. Its members include the Council of Ministers, as well as representatives of agriculture, manufacturing, and commerce; other members include the archbishop of Asunción, the rector of the National University, the presidents of the Banco Central and of the Banco Nacional de Fomento, and one retired officer from each of the three armed services. The council's functions include approval of measures proposed by the president.

The Congress is composed of the Chamber of Deputies and the Senate, all elected by popular vote for five-year terms. Congress can initiate legislation and may override a presidential veto by a two-thirds majority in each house.

Citizens and foreigners enjoy basic civil liberties, including freedom of expression, freedom of religion, and freedom to engage in professions and trades.

Local government. The country is divided into two provinces—the Occidental, to the west of the Paraguay River, and the Oriental, to the east. Occidental Province is divided into five departments; Oriental Province is divided into 14 departments and the federal district. Each department is further divided into *partidos*, or rural districts, that are controlled by the central government. *Partidos* are composed of units called *compañías*, which often correspond to areas inhabited by kin groups. The *compañías* often have Guaraní names. Areas with a minimum population of 3,000 and a central urban community may qualify as *municipios*.

The political process. Elections. Voting is compulsory for all men and women who are 18 years of age and older, excepting those in military service. Resident aliens are also allowed to vote in municipal elections. Elections for the executive and legislative branches of the central government are held every five years. If the president dissolves Congress, elections must be held within two months.

Political parties. Paraguay is constitutionally a multi-party state. Parties are legally free to organize, but they are closely regulated by the executive branch of the government. Between 1947 and 1962 only the Colorado Party was legally recognized. No party dedicated to the overthrow of republican representative democracy can be organized. No party may be subordinate to, or receive aid from, foreign sources, and parties may not boycott elections. To be recognized as a party, an organized group must have at least 10,000 affiliates.

The political process is, in effect, controlled by the party of the chief executive. Other parties are recognized, however, in the composition of the legislature. The party that wins a simple majority is awarded two-thirds of the seats of both houses, and the rest of the seats are proportionately distributed among the minority parties. While giving nominal recognition to the legal existence of other organizations, this process ensures executive control of the political life of the country.

Justice. The judicial system is headed by a Supreme Court of five members appointed by the president and confirmed by the Senate. Judges of lower courts and magistrates are appointed by the president with the approval of the Supreme Court. The judiciary is supervised by the Ministry of Justice, and judges can be tried by Congress.

The Supreme Court

Armed forces. Although Paraguay's armed forces are not large, military service is compulsory. A disproportionately large part of the budget, about 15 percent, is allocated to the police and armed forces, which also have received significant aid from the United States.

Education. Elementary education is free and compul-

sory for children between the ages of seven and 14. Despite large enrollments, the dropout rate is high, but it has been falling. The 3,500 elementary schools are supplemented by some 500 secondary schools, and there are centres for adult education in all departments. A school in Asunción prepares students for further training as secondary teachers. The two universities—the National University of Asunción (1890) and the private Catholic University (1960)—are located in Asunción; attendance is free at the National University. Paraguay also has schools of agriculture and veterinary science, as well as scientific institutes.

Health and welfare. The Ministry of Public Health and Social Welfare works to promote public health and to establish hospitals or clinics in the various parts of the country. There are also district and departmental health centres; clinics serve the rural population. In an effort to reduce the infant death rate, attention has been given to maternal and child care. The central government also has attempted to improve municipal water supplies. Except for Asunción, water and sewage services are inadequate in urban centres and are nonexistent in the countryside.

The police. Police chiefs, or *comisarios*, are appointed by the president and are important in maintaining his rule. The police in Asunción are responsible for the maintenance of dossiers on the country's citizens, for the prevention and investigation of crime, and for the maintenance of prisons. A secret Department of Investigations guards against subversive activities.

Wages and costs of living. Minimum wages were introduced by the Ministry of Labour in 1961. Per capita income figures are deceptive because so many subsistence farmers do not participate in the cash economy. Per capita income increased considerably in the late 20th century, however, although the cost of living also increased. More than one-third of the population is in the labour force. Nevertheless, the typical Paraguayan worker has not noticeably improved his standard of living.

Communications. The National Telecommunications Administration provides telephone service to Asunción and the other major cities. A satellite telephone system serves both domestic and international traffic. There is dependable telephone, telegraph, and telex service between Asunción and major cities in North and South America and in Europe. The domestic and international postal service is dependable and reasonably priced.

Health conditions. Heart diseases, infections, and lung diseases are the major causes of death. Inadequate shelter during the winter months is the chief factor in the prevalence of influenza, pneumonia, and tuberculosis. There is some malaria and leprosy.

CULTURAL LIFE

Guaraní
and
Spanish
traditions

The main characteristic of Paraguayan culture is its fusion of both the Guaraní and Spanish traditions. Folklore, the arts, and literature reflect this dual origin. The country's outstanding handicraft is the production of ñandutí lace, which is thought to represent a combination of 16th-century needlepoint lacemaking techniques from Europe with Guaraní traditions.

Cultural institutions. Paraguay's principal cultural institutions are located in Asunción. There are learned societies concerned with Paraguayan and Guaraní history and culture, as well as various other societies and research institutes. The Normal School of Music, the Conservatory of Music, the National Academy of Fine Arts, and the Asunción Symphony Orchestra are major arts organizations. Paraguay has museums of ethnography, natural history, and military history, as well as museums with collections of the work of Paraguayan artists and private collections of national memorabilia.

Library services are centred in Asunción. The largest collections are in the National Library and Archive and the Museum of Natural History and Ethnography; other government libraries include the Public Library of the Ministry of Defense and the Library of the Ministry of Foreign Affairs. The American Library is attached to the Godoi Museum. Scientific materials are collected by the Library of the Museum of Natural History and Ethnography and the Library of the Paraguayan Scientific Society.

The press and broadcasting. Although Paraguay's constitution guarantees freedom of the press, the public media exercises self-restraint in criticism of the government since censorship is used periodically. All newspapers and periodicals are published in Spanish. The most interesting newspapers are *ABC Color* (1967) and *La Tribuna* (1925), which, along with *Ultima Hora* (1977) and *Hoy* (1977), have the largest circulations. The Colorado Party publishes *Patria* (1946), and the Roman Catholic Church publishes *Comunidad*.

The National Telecommunications Administration oversees radio and television broadcasting. Radio Nacional is the government network, but there are many privately operated stations. Privately owned commercial television networks transmit from Asunción, Encarnación, and Puerto Presidente Stroessner. For statistical data, see the "Britannica World Data" section in the current *Britannica Book of the Year*. (J.P.P./H.G.W.)

History

EXPLORATION, SETTLEMENT, AND INDEPENDENCE

The Guaraní. Indian tribes speaking the Guaraní language occupied the region between the Paraguay and Paraná rivers long before the arrival of Europeans in the area. They were members of the Tupian language stock, which was widespread in South America, and in most respects resembled the other Indian tribes of the tropical forests. The women cultivated maize, manioc, and sweet potatoes, and the men hunted and fished. They were warlike, seminomadic people who lived in large thatched dwellings grouped in villages, and each village was surrounded by a large defensive palisade of upright logs. In the 15th century raiders from the poorer Gran Chaco region made frequent attacks upon Guaraní tribes. The Guaraní retaliated, crossing the Paraguay River, and subdued their enemies, carrying the conflict into the margins of the Inca Empire. They were, therefore, the natural allies of early European explorers who were seeking short routes to the mineral wealth of Peru. Alejo García, making his way from the Brazilian coast in 1524, and Sebastian Cabot, sailing up the Paraná in 1526, were the earliest of these explorers to reach the area.

Colonial period. The first colonial settlements were established by Domingo Martínez de Irala in the period 1536–56. The first Spanish colonists, unsuccessful in their search for gold, settled peacefully among the Guaraní in the region of Asunción, the present capital of Paraguay. These first settlers established their notorious "harems" of Guaraní women. Their racially mixed descendants gradually grew into the rural population of modern Paraguay, which still considers itself to be Guaraní in custom and habit. With Asunción as his principal base Irala laid the foundations of Paraguay and made it the centre of Spanish power in southeastern South America. From Asunción were founded such cities as Santa Fé, Corrientes, and Buenos Aires. Irala's colonization policy involved the delimitation of the boundary with Brazil by a line of forts against Portuguese expansion, the foundation of villages, the reduction of the Guaraní to provide food, labour, and soldiers, and extensive Guaraní-Spanish intermarriage. Rapidly a national and fairly homogeneous amalgam of Indian and Spanish cultures came into being.

From early in the 17th century, for more than 150 years, Jesuit communal missions in the Alto Paraná and Uruguay basins of southeastern Paraguay governed the lives of 100,000 Indians in 32 *reducciones*. These were centres of religious conversion, agricultural and pastoral production, and manufacturing and trade, which served also as strategic outposts against Portuguese expansion from southern Brazil. Isolated from the heart of Paraguay, which centred on Asunción, the mission became an autonomous military, political, and economic "state within a state," which increasingly excited the envy of the Spanish landowners in the Asunción area. In the period 1721–35 the latter waged a struggle to overthrow the Jesuit monopoly of Indian trade. Unaided, the *reducciones* had to defend themselves also against slave raiders from São Paulo and, in 1754–57, a combined Spanish-Portuguese attack designed to enforce

Jesuit
missions
to the
Indians

a territorial partition of the mission settlements. Defiance of such powerful groups paved the way for the expulsion of the Jesuits in 1767. The *reducciones* were abandoned; the Indians were absorbed either by the landed estates or the jungle; the settlements fell into ruin; economic activity ceased; and little permanent result survived of this period of Paraguayan history.

In 1776 the new Viceroyalty of Río de la Plata was created with its capital in Buenos Aires. This effectively made Asunción and all of Paraguay dependent on Buenos Aires, thus ending the region's colonial dominance.

Struggle for independence. As the power of Buenos Aires grew, the leaders of Paraguay began to resent the decline in their province's significance, and, although they had early challenged Spanish authority, they refused to accept the declaration of Argentine independence in 1810 as applying to Paraguay. Nor could an Argentine army under Gen. Manuel Belgrano enforce Paraguayan acceptance, as Paraguayan militia repulsed Belgrano's forces in 1811. Later, however, when the Spanish governor sought assistance from the Portuguese in defending the colony from further attacks from Buenos Aires, he underestimated the national spirit of the Paraguayans. Under the leadership of captains Pedro Juan Cabellero and Fulgencio Yegros, they promptly deposed the governor and declared their independence on May 14, 1811. (E.R.Se./G.J.B./Ed.)

ESTABLISHMENT OF THE NATION

The Francia regime. A governing junta was soon established, led by Yegros but in reality dominated by a civilian lawyer, José Gaspar Rodríguez de Francia. Francia proposed the idea of a confederation of equals to Buenos Aires, which, hoping for eventual domination, settled for a vague military alliance, signed in October 1811. This constituted de facto recognition of Paraguayan independence, and when Buenos Aires attempted to use the alliance to acquire Paraguayan troops for its own interprovincial quarrels, the accord became void. Buenos Aires' response was to blockade Paraguay. In the face of regional fragmentation, Buenos Aires sent Nicolás de Herrera to Asunción to frighten, bluff, or bribe Paraguay into a union of unequals. Francia responded by convening a congress, which on October 12, 1813, formally declared Paraguay an independent republic and rejected further treaties with Buenos Aires. A consulate of two men, Yegros and Francia, was established to rule the nation for a year.

At the end of that year, a new congress met and proclaimed Francia supreme dictator of the republic for a period of five years; in 1816 a third congress made him perpetual dictator, and his will was to be the law in Paraguay for a further 24 years. El Supremo, as he was known, prohibited any political activity, stripped the church of its holdings and power, confiscated the wealth of the small Spanish elite and forbade its members to marry within their own clique, abolished the municipal government of Asunción, and generally isolated Paraguay from its rather hostile neighbours. In 1820 El Supremo discovered a plot to depose him and restore the native elite to power. Hundreds of arrests were made, and in the following year at least 68 men of the traditional Paraguayan aristocracy (including Fulgencio Yegros) were executed. Their wealth in land and slaves became part of the national patrimony, and well before Francia's death (1840) the state owned a vast proportion of the nation. With the borders sealed, Paraguay became, of necessity, almost self-sufficient; and only a small, carefully regulated commerce was permitted with Argentina and Brazil. Uninvited foreigners were often held for years under loose arrest in the interior. Several governments and even the Great Liberator, Simon Bolívar himself, attempted to gain the release of a celebrated French scientist, Aimé Bonpland; but Francia failed to respond, only voluntarily releasing the scientist in 1831, after 10 years of detention.

Carlos Antonio López. When Francia died, he left behind a quietly prosperous nation that had adjusted well to what amounted to state socialism, but he also left a nation of rustics with no political experience and a strong tradition of dictatorial rule. In 1841 a second consulate emerged from the chaos in the figures of a civilian,

Carlos Antonio López, and a soldier, Mariano Roque Alonso. It was soon clear that López was the true ruler of Paraguay, and in 1844 a congress named him president. The same congress promulgated a constitution, notable for the extremely great powers accorded the president and the absence of the word liberty from its entire text. López devoted much of his two decades in power to opening the country slowly to the wider world and to modernization. Doing so caused international crises on an unprecedented scale, and it was not until after the fall of the Argentine dictator Juan Manuel de Rosas in 1852 that Argentina recognized Paraguayan sovereignty and eased its stranglehold on the rivers leading to the sea.

PARAGUAY'S CONFLICTS WITH ITS NEIGHBOURS

While he was "opening" his nation, López also had to handle border crises with ever-expanding Brazil and Argentina. These crises convinced López that Paraguayan modernization should proceed along military avenues. Thus hundreds of foreign engineers, medical men, scientists, machinists, and advisers were put to work on military projects. Iron foundries that cast enormous cannon and naval gear, a shipyard that turned out advanced, semimilitary vessels, railroad and telegraph systems, military clinics, a large arsenal, and the huge fortress complex of Humaitá, which dominated a bend of the Paraguay River—all these were constructed rapidly. López was threatened by a major Brazilian naval expedition on the Paraná River in 1855; in 1858 a large flotilla of the U.S. Navy appeared to force a solution to a complex diplomatic issue; and finally British war vessels captured and held for a time the flagship of the small Paraguayan Navy. In most of these contretemps, López was forced to give in, and the consequent humiliation lent greater urgency to his desire to strengthen Paraguay's defenses. By the time of his death, in September 1862, he had created a major regional military machine. A cautious man, however, he warned his eldest son, Francisco Solano López, who was to succeed him, not to use the new military might capriciously but to settle disputes through diplomacy and negotiation.

Francisco Solano López and the Paraguayan War. Francisco Solano López in 1862 was the inexperienced, spoiled son of an iron-willed dictator. He overestimated the military strength of his nation and felt that Paraguay should have a larger voice in the affairs of the region. Thus, when Uruguay, wracked by civil war, was threatened with intervention by Brazil, López took an increasingly bellicose position. When Brazil ignored his warnings and ultimatums and invaded Uruguay in August 1864 to support a pro-Brazilian faction in the civil war, López decided to use the strength of his military machine. In November he ordered the capture of a Brazilian war steamer and sent units of his army and navy north to invade the Mato Grosso, simultaneously preparing a larger army corps to strike south to destroy the Brazilian army in Uruguay. When Argentina denied his request for transit of a Paraguayan army, he declared war on Argentina as well, in March 1865. In May, as Paraguayan troops were approaching, a puppet Uruguayan government signed the Treaty of the Triple Alliance with Brazil and Argentina, committing all three to the war against Paraguay.

The Paraguayan force heading southward was destroyed at Uruguaiana, in Brazil, and a strike into northeast Argentina resulted in heavy Paraguayan casualties and the virtual destruction of López' fleet in 1865. Much of the rest of the war was fought in southwestern Paraguay, near and around Humaitá. In May 1866 López threw the cream of his army into suicidal attacks against allied forces at Tuyutí, losing almost 20,000 of his best men. Other lost battles in 1866–68, reinforced by widespread epidemics of Asiatic cholera, devastated the population of the country. In 1869 and 1870 the tragedy was completed as López, pursued by large allied forces, retreated through the interior of his nation with a shattered army and thousands of civilian refugees, dragging famine, disease, and death in his wake. Perhaps at this point unhinged, he ordered the executions of hundreds of people, including his own two brothers and two brothers-in-law and scores of his

Modernization of the military forces

Diplomatic and economic isolation

Destruction in the Paraguayan War

officer corps. Finally, on March 1, 1870, his last camp was attacked at Cerro Corá by Brazilian cavalry and López died in combat. His country by then lay in ruins, with half of its former population of 450,000 dead. A Brazilian occupation army remained, further draining the country, until 1876. This Paraguayan War, or War of the Triple Alliance, was the bloodiest in Latin-American history.

Reconstruction. Under a liberal constitution promulgated in 1870, Paraguay began a painful reconstruction. Only the mutual jealousies of Brazil and Argentina prevented the country from losing much of its territory. As a result, Brazil gained no lands that it had not actually occupied before the war, and Argentina's claims to most of the Chaco were reduced considerably when, in arbitration, U.S. Pres. Rutherford B. Hayes decided one important boundary issue in 1878 in favour of Paraguay. When the army of occupation was removed in 1876, it left a crowd of Paraguayan politicians known best for their corruption and drive for power. In 1887 Paraguay's two major political parties, the Liberales and the Colorados, were born. The Colorados were in power from 1887 until a Liberal revolt unseated them in 1904, and the Liberales, in their turn, dominated the presidency for the next 30 years.

The Chaco War. Paraguay's reconstruction was complicated by a dispute with Bolivia concerning boundaries in the Chaco. The dispute was exacerbated when in the 1880s Bolivia lost its seacoast in the War of the Pacific with Chile and, seeing the Chaco as a possible outlet to the sea via the Paraná River, began to penetrate it with soldiers and colonists. By the 1920s, armed clashes began to take place as Paraguay moved into the region in greater force. As Paraguay was frantically trying to arm itself, a Bolivian force stormed a Paraguayan fort on June 15, 1932, and the war began. Paraguayan president Eusebio Ayala gave a military *carte blanche* to Gen. José Félix Estigarribia, who used his smaller army to gradually push the Bolivians back until they were almost entirely ejected from the Chaco. Through foreign mediation, a cease-fire was attained on June 12, 1935, and a peace treaty was signed three years later. By its terms, Paraguay retained at least three-quarters of the Chaco.

SINCE THE CHACO WAR

In February 1936, Ayala and Estigarribia were imprisoned following a military coup, the Febrerista revolt, conducted by radical officers. The inept new government soon fell, however, and Estigarribia was elected president in 1939.

Estigarribia and Morínigo and their successors. On September 7, 1940, before he could actually implement a new constitution that gave him great authoritarian powers, Estigarribia was killed in an air crash. He was replaced by Gen. Higinio Morínigo, a harsh opportunist, who immediately began to persecute the Liberales and reward the Colorados. A revolt of Liberales and other groups in 1947 again devastated the land and left thousands dead. Morínigo was deposed by the Colorados themselves in 1948. In the next six years, Paraguay had six weak presidents, and then, in 1954, Gen. Alfredo Stroessner, supported by both Colorados and the army, seized power.

The Stroessner regime. The authoritarian Stroessner, with considerable aid from the United States and later Brazil, managed to stabilize one of the world's least stable currencies, attract foreign investment, and embark on large public works projects, such as a highway network to link the towns and villages of his nation with one another and with Argentina and Brazil. Paraguayan isolation was broken down. Very harsh rule was relaxed somewhat after 1960, and elections on all levels were permitted; however, the Colorado Party never lost, and Stroessner was duly reelected every five years. The church alone continued to raise a voice of objection to the repressive aspects of the regime, such as treatment of the Indian minority and censorship. Relations with the United States steadily deteriorated throughout the 1970s, and U.S. aid was much reduced. Partly because of this, the Stroessner government aligned itself closely with the authoritarian regime in Brazil,

which offered aid and political support. The two nations cooperated in the building of the Itaipú hydroelectric plant on their shared border. As a result of this project, the national economy briefly improved, but it took a downturn in the early 1980s, bringing some protests against the Stroessner regime. The government showed little tolerance for opposition to its policies, however, quickly clamping down on any movement before it could develop; most of the main opposition leaders were being kept forcibly in exile. Such repression focussed international attention on Paraguay for human rights violations, further hampering the country's foreign relations and intensifying economic stagnation. The aging Stroessner, who had been elected in 1983 for a seventh term, also had to deal with concerns in his own Colorado Party, where dissension was growing between traditionalist and militant factions over the succession to the presidency.

Dissension came to a head on February 2, 1989, when Stroessner was overthrown in a bloody coup by Gen. Andrés Rodríguez, a close associate since the 1954 coup and Paraguay's second highest military officer. Rodríguez favoured the traditionalist faction, which sought to adopt more liberal policies. He was formally elected president on May 1, 1989.

For later developments in the history of Paraguay, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

Physical and human geography: Although dated, general surveys of Paraguayan history, economics, and politics include: ADOLF N. SCHUSTER, *Paraguay, Land, Volk, Geschichte, Wirtschaftsleben und Kolonisation* (1929); HARRIS GAYLORD WARREN, *Paraguay, An Informal History* (1949); PHILIP RAINE, *Paraguay* (1956); EFRAÍM CARDOZO, *Paraguay independiente* (1949); and PAUL H. LEWIS, *Socialism, Liberalism, and Dictatorship in Paraguay* (1982). The best bibliography is DAVID LEWIS JONES, *Paraguay, A Bibliography* (1979). HENRY D. CEUPPENS, *Paraguay año 2000* (1971), is accurate and perceptive. JOSEPH PINCUS, *The Economy of Paraguay* (1968), is the best general survey in English. GEORGE PENDLE, *Paraguay: A Riverside Nation*, 3rd ed. (1967), is brief but informative. For agriculture, see ADLAI F. ARNOLD, *Foundations of an Agricultural Policy in Paraguay* (1971); and CARLOS PASTORE, *La lucha por la tierra en el Paraguay*, 2nd ed. (1972). The best work on General Stroessner is PAUL H. LEWIS, *Paraguay under Stroessner* (1980). For social conditions and culture, see PAN AMERICAN UNION, *Paraguay* (1965); and CARLOS R. CENTURIÓN, *Historia de la cultura paraguaya*, 2 vol. (1961). *Revista paraguaya de sociología* (triennial) is indispensable.

History: General treatments include EFRAÍM CARDOZO, *El Paraguay independiente* (1949) and *Breve historia del Paraguay* (1965); CARLOS R. CENTURIÓN, *Historia de la cultura paraguaya* (1961); and HARRIS G. WARREN, *Paraguay: An Informal History* (1949), with a useful bibliography. The best treatment of the independence epoch is FULGENCIO R. MORENO, *Estudio sobre la independencia del Paraguay* (1911). Also useful is RAFAEL ELADIO VELAZQUEZ, *El Paraguay en 1811* (1965). On the Francia period see JULIO CESAR CHAVES, *El supremo dictador*, 4th ed. (1964), and JOHN HOYT WILLIAMS, *The Rise and Fall of the Paraguayan Republic, 1800-1870* (1979), which also deals with the two Lópezes. The first López and his modernization of Paraguay are well handled in JUAN F. PEREZ ACOSTA, *Carlos Antonio López, obrero máximo, labor administrativa y constructiva* (1948); and JULIO CESAR CHAVES, *El Presidente López*, 2nd ed. (1968), permits a glimpse of a remarkable man. The War of the Triple Alliance is treated in EFRAÍM CARDOZO, *Visperas de la guerra del Paraguay* (1954), and his day-by-day chronicle of the war years, *Hace cien años* (1964-73); AUGUSTO TASSO FRAGOSO, *História da guerra entre a Tríplice aliança e o Paraguai* (1934), a five-volume account; and HARRIS G. WARREN, *Paraguay and the Triple Alliance: The Postwar Decade, 1869-1878* (1978). For the postwar era, see JOSE RODRIGUEZ ALCALA, *El Paraguay moderno* (1915); and HIPOLITO SANCHEZ QUELL, *El caricaturista Miguel Acevedo y su época* (1974). Coverage of the Chaco War can be found in DAVID H. ZOOK, JR., *The Conduct of the Chaco War* (1960); and ROBERTO QUEREJAZU CALVO, *Masamaclay* (1965).

Paris

Paris is the capital of France and one of Europe's largest conurbations. The city was founded more than 2,000 years ago on an island in the Seine River, some 233 miles (375 kilometres) upstream from the river's mouth on the English Channel. The modern city has spread from the island (the Île de la Cité) and far beyond both banks of the Seine. The City of Paris itself covers an area of 41 square miles (105 square kilometres); the

Greater Paris conurbation, formed of suburbs and other built-up areas, extends around it in all directions to cover approximately 890 square miles. Paris occupies a central position in the rich agricultural region known as the Paris Basin, and it constitutes one of eight *départements* of the Île-de-France administrative region. It is by far the nation's most important centre of commerce and culture.

Physical and human geography

CHARACTER OF THE CITY

For centuries Paris has been one of the world's most important and attractive cities. It is appreciated for the opportunities it offers for business and commerce, for study, for culture, and for entertainment: its gastronomy, haute couture, painting, literature, and intellectual community especially enjoy an enviable reputation. Its sobriquet "the City of Light" (la Ville Lumière), earned during the Enlightenment, remains appropriate, for Paris has retained its importance as a centre for education and intellectual pursuits.

Paris' site at a crossroads of both water and land routes significant to Europe as well as to France has had a continuing influence on its growth. Under Roman administration, in the 1st century BC, the original site on the Île de la Cité was designated the capital of the Parisii tribe and territory. The Frankish king Clovis took Paris from the Gauls by AD 494 and later made his capital there. Under Hugh Capet (ruled 987–996) and the Capetian dynasty the preeminence of Paris was firmly established, and Paris became the political and cultural hub as modern France took shape. France has long been a highly centralized country, and Paris has come to be identified with a powerful central state, drawing to itself much of the talent and vitality of the provinces.

The three main parts of historical Paris are defined by the Seine. At its centre is the Île de la Cité, which is the seat of religious and temporal authority (the word *cité* connotes the nucleus of the ancient city). The Seine's left bank (*rive gauche*) has traditionally been the seat of intellectual life; and its right bank (*rive droite*) contains the heart of the city's economic life, but the distinctions have become blurred in recent decades. The fusion of all these functions at the centre of France and, later, at the centre of an empire, resulted in a tremendously vital environ-

ment. In this environment, however, the emotional and intellectual climate that was created by contending powers often set the stage for great violence in both the social and political arenas (the years 1358, 1382, 1588, 1648, 1789, 1830, 1848, and 1870 being notable for such events).

In its centuries of growth Paris has for the most part retained the circular shape of the early city. Its boundaries have spread outward to engulf the surrounding towns (*bourgs*), usually built around monasteries or churches and often the site of a market. From the mid-14th to the mid-16th century the city's growth was mainly eastward; since then it has been westward. It comprises 20 *arrondissements* (municipal districts), each of which has its own mayor, town hall, and particular features. The numbering begins in the heart of Paris and continues in the spiraling shape of a snail shell, ending to the far east. Parisians refer to the *arrondissements* by number as the first (*premier*), second (*deuxième*), third (*troisième*), and so on. Adaptation to the problems of urbanization, such as immigration, housing, social infrastructure, public utilities, suburban development, and zoning, has produced the vast urban agglomeration. (Ed.)

THE LANDSCAPE

The city site: Paris and its river. Paris' city proper is small; no corner is farther than six miles from the square in front of Notre-Dame cathedral. The city occupies a depression hollowed out by the Seine, and the surrounding heights have been respected as the limits of the city. Elevation varies from 430 feet (130 metres) at Montmartre to 85 feet at Grenelle. The river flows for eight miles through the centre of the city and 10 of the 20 *arrondissements*. It enters the city at the southeast corner, flows northwestward, and turns gradually southwestward, eventually leaving Paris at the southwest corner. As a result, what starts out as the stream's east bank becomes its north bank and ends as the west bank, and the Parisians

The Eiffel Tower, from the Centre Beaubourg on the Right Bank, looking westward over the rooftops of the city.

Nancy Cohen—Black Star

The river
bank

therefore adopted the simple, unchanging designation of Right and Left Bank (when facing downstream). Specific places are usually indicated by *arrondissement* or by quarter (*quartier*).

At water level, some 30 feet below street level, the river is bordered—at least on those portions not transformed into expressways—by cobbled quays graced with trees and shrubs. From street level another line of trees leans toward the water. Between the two levels, the retaining walls, usually made of massive stone blocks, are decorated with the great iron rings once used to moor merchant vessels, and some are pierced by openings left by water gates for old palaces or inspection ports for subways, sewers, and underpasses. At intermittent points the walls are shawled in ivy.

The city is ringed with great forests of beech and oak; they are called the “lungs of Paris,” for they help to purify the air in the heavily industrialized region. Paris’ position at the centre of the Île-de-France region, bordered by the Seine, Oise, and Marne rivers, has long made it the dominant settlement.

Climate. In its location on the western side of Europe and in a plain relatively close to the sea, Paris benefits from the balmy influences of the Gulf Stream and has a fairly temperate climate. The weather can be very changeable, however, especially in winter and spring, when the wind can be sharp and cold. The annual average temperature is 53° F (12° C); the July average is about 67° F (19° C), and the January average is about 38° F (3° C).

The temperature drops below freezing about 35 days a year, and snow falls on an average of 15 days. Since the 1950s the city has taken measures to decrease air pollution, and a system of water purification has made tap water safe for drinking.

NEIGHBOURHOODS AND SIGHTS

Paris’ many old buildings, monuments, gardens, plazas, boulevards, and bridges compose one of the world’s grandest cityscapes. An impressive spot from which to view the city is the Chaillot Palace, which stands on a rise on the Right Bank of the Seine to the west, where the river begins its southwestward curve.

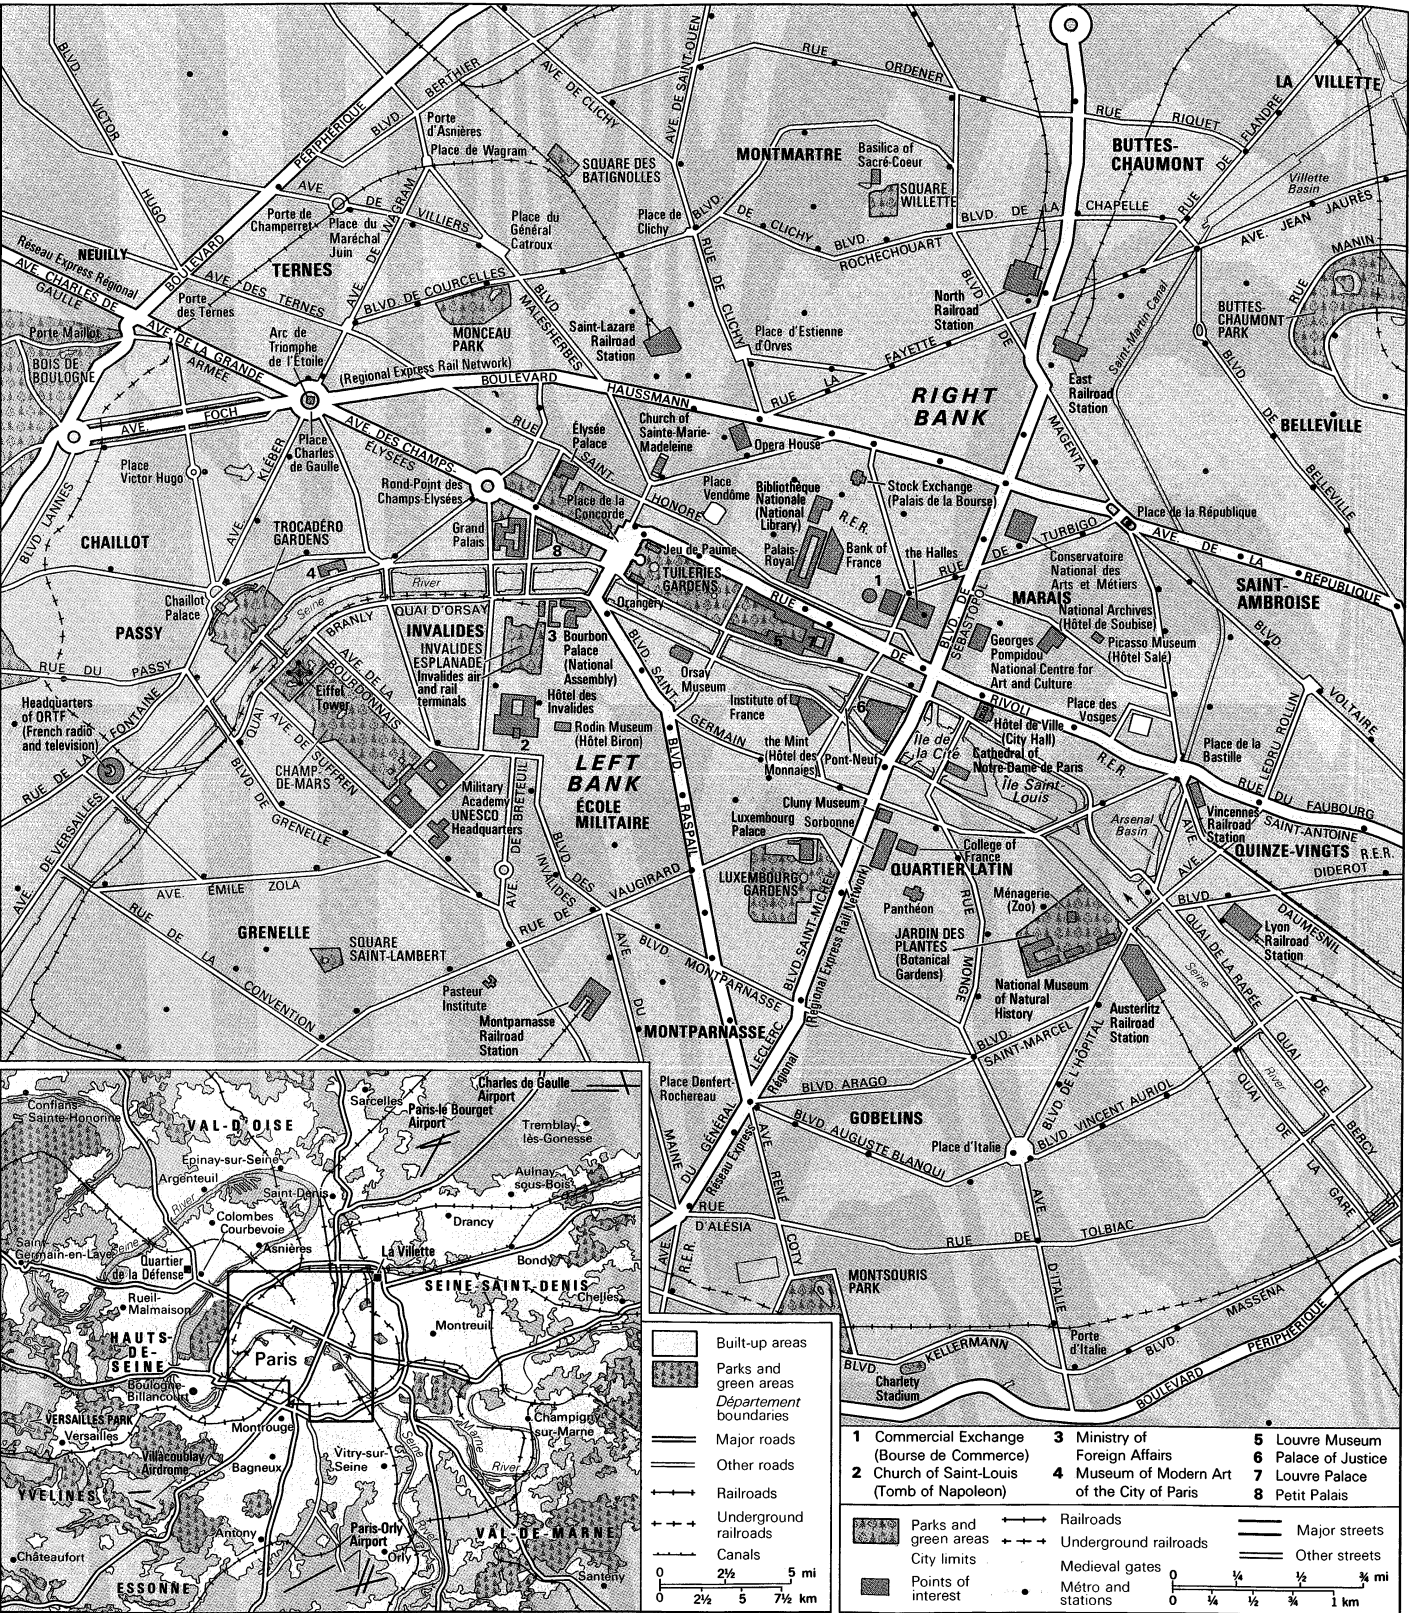

The Chaillot Palace. The Chaillot Palace dates from the International Exposition of 1937. It replaced the Trocadéro Palace, a structure left over from the 1878 International Exposition. The Chaillot Palace is made up of two separate pavilions, from each of which extends a curved wing. The Musée de l’Homme, the Naval Museum, the Museum of French Monuments, and the Cinema Museum are located there. Under the terrace that separates the two sections are two theatres, the National Theatre of Chaillot and a small hall that serves as one of the two motion-picture houses of the national film library.

The terrace, which is lined by statues, gives a splendid view across Paris. The slope descending to the river has been made into a terraced park, the centre of which is alive with fountains, cascades, and pools. The Trocadéro Aquarium is in a grotto a few steps away in the park.

The Eiffel Tower

From the bottom of the slope the five-arched Jena Bridge (Pont d'Iéna) leads across the river. It was built for Napoleon in 1813 to commemorate his victory at the Battle of Jena in 1806. On the Left Bank rises the Eiffel Tower, an unclad metal truss tower designed by Gustave Eiffel. The tower was built for the International Exposition of 1889, against the strident opposition of national figures who thought it unsafe or ugly or both. When the

exposition concession expired in 1909, the 984-foot (300-metre) tower was to have been demolished, but its value as an antenna for radio transmission saved it. Additions made for television transmission have added 56 feet to the height. From the topmost of the three platforms the view extends for more than 40 miles. From the two-acre base of the tower the Champ-de-Mars ("Field of Mars"), an immense field, stretches to

The city of Paris and (inset) its metropolitan area.

the Military Academy (École Militaire), which was built from 1769 to 1772 and is still used by the War College (École Supérieure de Guerre). The Champ-de-Mars, which originally served as the school's parade ground, was the scene of two vast rallies during the French Revolution: that of the Federation (1790) and that of the Supreme Being (1794). From 1798 there were annual national exhibitions of crafts and manufactures, which were followed by world's fairs between 1855 and 1900.

Behind the Military Academy stands the headquarters of the United Nations Educational, Scientific and Cultural Organization (UNESCO). The building, erected in 1958, was designed by an international trio of architects and decorated by artists of member nations.

The Invalides. One street to the northeast is the Hôtel des Invalides, founded by Louis XIV to shelter 7,000 aged or invalid veterans. The enormous range of buildings was completed in five years (1671–76). The gold-plated dome (1675–1706) that rises above the hospital buildings belongs to the church of Saint-Louis. The dome was designed by Jules Hardouin-Mansart, who employed a style known in France as “Jesuit” because it derives from the Jesuits’ first church in Rome, built in 1568. The churches of the French Academy (Académie Française), the Val-de-Grâce Hospital, and the Sorbonne, as well as three others in Paris, all of the 17th century, followed this style. By using the classical elements more freely than had been done in Rome, the French made it something recognizably Parisian.

In the chapels of Saint-Louis are the tombs of Napoleon’s brothers Joseph and Jérôme, of his son (whose body was returned from Vienna in 1940 by Adolf Hitler), and of the marshals of France. Immediately beneath the cupola is a red porphyry sarcophagus that covers the six coffins, one inside the other, enclosing the remains of Napoleon, which were returned from St. Helena in 1840 through the efforts of King Louis-Philippe. Napoleon’s uniforms, personal arms, and deathbed are displayed in the Army Museum at the front of the Invalides. A portion of the Invalides still serves as a military hospital; facilities have been modernized since World War II.

The vast, tree-lined Invalides Esplanade slopes gently to the Quai d’Orsay and the Alexandre III Bridge. The first stone for the bridge, which commemorates the Russian tsar Alexander III, was laid in 1897 by Alexander’s son, Tsar Nicholas II. The bridge was finished in time for the International Exposition of 1900, and it leads to two other souvenirs of that year’s fair, the Grand Palais and the Petit Palais. The buildings are still used for annual shows and for major visiting art exhibits.

The Louvre. Vikings camped on the Right Bank across from the western tip of the Île de la Cité in their unsuccessful siege of Paris in 885, and in about 1200 King Philip II had a square crusader’s castle built on the same site, just outside the new city wall, to buttress the western defenses. Over the following centuries many additions and renovations were made, and from the castle grew one of the world’s largest palaces, completed only in 1852. From the original square, known as the Cour Carrée (“Square Court”), two galleries extend westward for 1,640 feet, one along the river, the other along the rue de Rivoli. In 1871, only 19 years after the huge oblong was completed, its western face, the Tuileries Palace (begun 1563), was destroyed by the insurrectionists of the Commune.

Two of the facades of the Cour Carrée had strong influence on French architecture. Pierre Lescot began his inner courtyard facade in 1546, adapting the Renaissance rhythms and orders he had observed in Italy and adding purely French decoration to the classical motifs. The physician and architect Claude Perrault collaborated with Louis Le Vau, architect to the king, to design the outer east face of the palace in 1673. It, too, employs classic elements, making especially graceful use of coupled columns and a pediment.

The Louvre Museum occupies the four sides of the palace around the Cour Carrée as well as the south gallery, which stretches along the river. Among the treasures of the museum are the Victory of Samothrace, the Venus de Milo, and the Mona Lisa. The enormous collections

contain works from the 7th century BC to the mid-19th century, with a huge cultural and geographic spread. The north gallery, along the rue de Rivoli, houses a separate museum, the Museum of Decorative Arts, as well as the Ministry of Finance.

Extensive remodeling has been undertaken throughout the Louvre to increase space for art works. Construction began in the early 1980s to create a new main entrance and underground reception hall in the vast Napoleon Courtyard, between the two galleries; the 70-foot-high glass pyramid designed by I.M. Pei to cover the entrance aroused both strong support and spirited criticism.

The Arts Bridge (Pont des Arts), which crosses the Seine from the Louvre to the Left Bank, is one of the most charming of all the Parisian bridges. It was the first (1803) to be made of iron, and it has always been reserved for pedestrians: it provides an intimate view of riverside Paris and of the Seine itself.

The Institute of France. At the point where the Arts Bridge meets the Left Bank stands the Institute of France, which since 1806 has housed the five French academies. The site was originally occupied by the Nesle Tower (Tour de Nesle), a defense work for the Left Bank terminus of the city wall of 1220. Louis Le Vau designed the additional buildings in 1663 to house the College of the Four Nations (Collège des Quatre-Nations), paid for by a legacy from Louis XIV’s minister Cardinal Mazarin, who had brought the four entities in question—Piedmont, Alsace, Artois, and Roussillon—under the French crown. Le Vau based his designs on Italian models. The five contemporary academies are the French Academy (Académie Française), founded by Cardinal de Richelieu in 1635, which edits the official French dictionary, awards literary prizes, and has a membership of “40 Immortals”; the Academy of Inscriptions and Belles Lettres, founded in 1663 by Louis XIV’s finance minister, Jean-Baptiste Colbert; the Academy of Sciences, founded in 1666, also by Colbert; the Academy of the Fine Arts, two sections formed at different times by Mazarin and Colbert and joined in 1795; and the Academy of Ethics and Political Science, created by the Convention (a governing body during the French Revolution) in 1795 to ponder questions of philosophy, economics, politics, law, and history.

Almost next door is the Mint (Hôtel des Monnaies). In this sober late 18th-century building visitors may watch coins being struck and tour a museum of coins and medals.

Pont-Neuf (New Bridge). Despite its name, the Pont-Neuf, which was built from 1578 to 1604, is the oldest of the Paris bridges (others predate it but have been rebuilt). Its sturdiness has become axiomatic: Parisians still say, “Solid as the Pont-Neuf.” The bridge is supported in the middle by the tip of the Île de la Cité, to which it extends five arches from the Left Bank and seven from the Right. The parapet corbels are decorated with more than 250 different grotesque masks. The parapet curves out toward the water at each bridge pier, forming half-moon bays along what was the first sidewalk in Paris; in these bays street vendors set up shop. For 200 years this bridge was the main street and the perpetual fair of Paris. The custom of holding summer fairs on the bridge has been revived to some extent. Although the structure undergoes regular repair, in the main Pont-Neuf as it exists today is the original bridge.

Île de la Cité. Downstream and just below the bridge is the tip of the Île de la Cité, fashioned into a triangular gravel-pathed park bordered by flowering bushes, with rustic benches under the ancient trees. It is surrounded by a wide cobbled quay that is especially popular with sunbathers and lovers. Where the steps come onto the bridge from the park there is a bronze equestrian statue of King Henry IV, who insisted on completion of the Pont-Neuf. The statue is an 1818 reproduction of the 1614 original, which was the first statue to stand on a public way in Paris. Opposite is the narrow entrance to the Place Dauphine (1607), named for Henry’s heir, the future Louis XIII. The place was formerly a triangle of uniform red-brick houses pointed in white stone, but the row of houses along its base was ripped out in 1871 to make room for construction of part of the Palace of Justice.

Île de la Cité and Île Saint-Louis, on the Seine River at the heart of Paris.

By courtesy of the French Government Tourist Office

The ship-shaped Île de la Cité is 10 streets long and five wide. Eight bridges link it to the riverbanks and a ninth leads to the scow-shaped Île Saint-Louis, which lies to the southeast.

The palace of the early Roman governor (now the Palace of Justice) was rebuilt on the same site by Louis IX (St. Louis) in the 13th century and enlarged 100 years later by Philip IV the Fair, who added the grim, gray-turreted Conciergerie, with its impressive Gothic chambers. The Great Hall, which, under the kings, was the meeting place of the Parlement (the high court of justice), was known throughout Europe for its Gothic beauty. Fires in 1618 and 1871 destroyed much of the original room, however, and most of the rest of the palace was devastated by flames in 1776. The Great Hall now serves as a waiting room for the courts, in one of which, the adjoining first Civil Chamber, the Revolutionary Tribunal sat from 1793, condemning 2,600 persons to the guillotine. After sentencing, the victims were taken back down the stone stairs to the dungeons of the Conciergerie to await the tumbrils. The Conciergerie still stands and is open to visitors.

In the palace courtyards is found one of the great monuments of France, the 13th-century Sainte-Chapelle ("Holy Chapel"). Built at Louis IX's direction between 1243 and 1248, it is a masterpiece of Gothic Rayonnant style. With great daring, the architect (possibly Pierre de Montreuil) poised his vaulted ceilings on a trellis of slender columns, the walls between being made of stained glass. The exquisite chapel was designed to hold the Crown of Thorns, thought to be the very one worn by Jesus at his crucifixion. Louis IX had purchased the relic from the Venetians, who held it in pawn from Baldwin, the Latin king of Byzantium. Other holy relics, such as nails and pieces of wood from the True Cross, were added to the chapel's collection, the remnants of which are now in the treasury of Notre-Dame.

Under King Louis-Philippe (1830–48), the "sanitization"

of the island was begun, and it was continued for his successor, Napoleon III, by Baron Georges Haussmann. The project involved a mass clearing of antiquated structures, widening of streets and squares, and the erection of massive new government offices, including parts of the Palace of Justice. The portion of the palace that borders the Quai des Orfèvres—formerly the goldsmiths' and silversmiths' quay—became the headquarters of the Paris municipal detective force, the Police Judiciaire ("Judicial Police"), which keeps a small museum on the fourth floor.

Across the boulevard du Palais is the Police Prefecture, another 19th-century structure. On the far side of the prefecture is the Place du Parvis-Notre-Dame, an open space enlarged six times by Haussmann, who also moved the Hôtel-Dieu, the first hospital in Paris, from the riverside to the inland side of the square. Its present buildings date from 1868.

Notre-Dame de Paris. At the east end of the square is the cathedral of Notre-Dame de Paris, which is situated on a spot that Parisians have always reserved to the practice of religious rites. The Gallo-Roman boatmen of the *cité* erected their altar to Jupiter there (it is now in the Cluny Museum), and, when Christianity was established, a church was built on the temple site. The first bishop of Paris, St. Denis, became its patron saint. The red in the colours of Paris represents the blood of this martyr who, in popular legend, after decapitation, picked up his head and walked.

When Maurice de Sully became bishop in 1159 he decided to replace the decrepit cathedral of Saint-Étienne and the 6th-century Notre-Dame with a church in the new Gothic style. The style was conceived in France, and a new structural development, the flying buttress, which added to the beauty of the exterior and permitted interior columns to soar to new heights, was introduced in the building of Notre-Dame. Construction began in 1163 and continued until 1345.

Restoration
of Notre-
Dame

After being damaged during the French Revolution, the church was sold at auction to a building-materials merchant. Napoleon came to power in time to annul the sale, and he ordered that the edifice be redecorated for his coronation as emperor in 1804. Louis-Philippe later initiated restoration of the neglected church. The architect Eugène Viollet-le-Duc worked from 1845 to 1864 to restore the monument. Like all cathedrals in France, Notre-Dame is the property of the state, although its operation as a religious institution is left entirely to the Roman Catholic Church.

A few 16th- and 17th-century buildings survive north of the cathedral. They are what remains of the Cloister of the Cathedral Chapter, whose school was famous long before the new cathedral was built. Early in the 12th century, one of its theologians, Peter Abelard, left the cloister with his disciples, crossed to the Left Bank, and set up an independent school in the open air in the Convent of the Paraclete near the present Place Maubert. After a prolonged struggle with the monks of Saint-Denis the followers of Abelard in 1200 won the right, from both the king and the pope, to form and govern their own community. This was the beginning of the University of Paris.

City walls. After the Roman town on the Left Bank was sacked by barbarians in the 3rd century AD, the fire-blackened stones were freighted across to the Île de la Cité, where a defensive wall was constructed. Neglected in times of peace, it was rebuilt several times over the course of the centuries. The earliest of the bridges to the Left Bank, the Petit Pont (which has been rebuilt several times), was guarded by a fortified gate, the Petit Châtelet, and the bridge to the Right Bank, the Pont au Change, was guarded by the Grand Châtelet, which served as a fort, prison, torture chamber, and morgue until it was demolished in 1801.

From 1180 to 1225 Philip II built a new wall that protected the settlements on both banks. In 1367–70 the Right Bank enclosure was enlarged by Charles V, with the massive Bastille protecting the eastern approaches as the Louvre protected the west. In 1670 Louis XIV had the Charles V extensions transformed into the tree-planted Grands Boulevards, embellished at the Saint-Denis Gate (Porte Saint-Denis) and the Saint-Antoine Gate (Porte Saint-Antoine) with triumphal arches that still stand. (The word *bulwark*, related to “bulwark,” originally was a military engineering term for the platform of a defensive wall.)

A century later a new wall was begun. The wall was built with 57 tollhouses to enable the farmers-general, a company of tax “farmers,” or collectors, to collect customs duties on goods entering Paris. The tollhouses are still standing at Place Denfert-Rochereau.

The last wall, built by Adolphe Thiers for Louis-Philippe, was a genuine military installation with outlying forts. By the time it was finished it enclosed a number of hamlets outside Paris, among them Auteuil, Passy, Montmartre, La Villette, and Belleville. Post-Revolutionary rebuilding and post-Napoleonic economic recovery, with expansion of employment because of the Industrial Revolution, drew more and more people to Paris, and—as railways developed—with ever-increasing facility. Between 1852 and 1870 Haussmann razed the walls of the farmers-general and built the outer boulevards. The 1845 walls were finally knocked down, and the boulevards were extended in 1925.

Île Saint-Louis. In 1627 Louis XIII granted a 60-year lease on two mudbanks behind the Île de la Cité to a contractor, Christophe Marie, and two financiers. It was 37 years before Marie was able to unite the islets, dike the circumference, lay out a central avenue with 10 lateral streets, and rent space to householders. The church of Saint-Louis-en-l'Île was begun the same year, 1664, but one of the finest houses, by Louis Le Vau, had been completed as early as 1640. Another, the Hôtel de Lauzun, a few yards upstream on the Quai d'Anjou, was completed in 1657. The Marie Bridge to the Right Bank, which was completed as part of the contract, is the original span, although it has been modified for modern traffic. The Île Saint-Louis constitutes a tranquil neighbourhood in the centre of the busy city.

The Bastille. The road off the upper end of the Île Saint-Louis leads to the Place de la Bastille on the Right Bank. From the river to the *place* runs a canal, the Arsenal Basin, which formerly supplied water to the moat around the Bastille. At the Place de la Bastille the waterway goes underground for almost a mile, then emerges to form the Saint-Martin Canal, which, with its bridges and locks, and its barges sailing slowly down the centre of city streets, constitutes one of the least known and most picturesque sections of Paris.

The capture of the Bastille on July 14, 1789, was a symbolic blow at tyranny rather than an act of liberation for tyranny's victims. The prison, which had been virtually unused for years and was scheduled for demolition by the monarchy, held on that day only four counterfeiters, two madmen, and a young aristocrat who had displeased his father. The fortress was demolished after its capture.

Napoleon had the *place* laid out in 1803. A railway station was built there in 1859 and was razed in 1984 to allow construction of a new opera house (begun two years later).

The neighbourhood between the Bastille and the Place de la Nation, eastward along the rue du Faubourg Saint-Antoine, has been one of skilled craftsmen since the mid-15th century, when the self-governing royal abbey gave space within its wide domains to those cabinetmakers who refused to abide by the restrictions of Paris guilds as to styles and types of wood to be used. This neighbourhood was always among the first to revolt when revolution was in the air and was noted for the speed with which it raised barricades of impressive height. The character of the area has changed, however, as most of the small workshops have closed.

The Marais. To the west of the Bastille lies a triangular area with its base along the river up to the Hôtel de Ville (City Hall) and its apex just short of the Place de la République to the north. It keeps its name—*le marais* (“the marsh”)—from the Middle Ages, and, because it became the market garden of Paris, it gave its name to all market gardens in France (*culture maraîchère*). Extension of the city walls along the Right Bank led to diking of the shore and drainage of the soil. In 1107 the Knights Templar established their Paris Temple, a vast fortified enclosure, at the top of the triangle. In 1360 Charles V moved into his new royal residence in the lower right-hand corner, where the rue des Lions marks the former location of the menageries.

Charles VII preferred to live just behind the Bastille, in the Hôtel des Tournelles, which Henry II had enlarged and beautified by Philibert Delorme in 1550. Great nobles, such as the dukes of Guise and Lorraine, followed the King and had palaces built in the vicinity. When Henry II was killed in a joust on the rue Saint-Antoine in 1559, his widow, Catherine de Médicis, had the Tournelles razed. On the site in 1607 construction began on the first residential square to be designed in Paris. Henry IV had it built and reserved a house there for himself. The three-story houses are made of red brick with white-stone quoins (solid-corner angles) and window surrounds, and the ground floors form arcades over the sidewalks. The square was named Place Royale, but since 1800 it has been called Place des Vosges. Another wave of building by the rich, anxious to be close to a royal project, endowed the Marais with 200 more private palaces.

In 1792 the Knights Hospitaller of St. John of Jerusalem (also known as the Knights of Malta) were turned out of the Temple, which had been given to them in 1313 when the Templar order was dissolved. On Aug. 13, 1792, the royal family was incarcerated in the Temple's tower keep; the King was taken off to his death on Jan. 21, 1793, and the Queen was removed to the Conciergerie on August 2 (and executed on October 16). The Temple's tower was leveled in 1808 to discourage rallies there by royalists.

After the 17th-century construction boom the Marais remained virtually untouched. Three-quarters of the buildings there date from before 1870. Toward the end of the 19th century, while some of the oldest and most imposing of the palaces were being demolished by private developers, other owners managed to restore a few mansions, and the nation and the municipality also restored a handful of

The first
residential
square

The last
wall

fine buildings. Many Jewish refugees from eastern Europe settled in the district. Scores of fine houses were subdivided into tiny apartments to profit from the poverty-stricken newcomers, and workshops were installed on the lower floors and in courtyard sheds. Through centuries of neglect the Marais became one of the worst slums in Paris.

In 1969 the Municipal Council approved an urban renewal scheme for ending slum conditions while preserving the workaday life and animation and restoring the undeniable beauty of the quarter. The scheme has been very successful, and property prices in the Marais have soared.

Among the restored ancient buildings open to the public are the Museum of the History of Paris (Musée Carnavalet), built in 1545 and enlarged by François Mansart in 1645; the Museum of the History of France (National Archives, Hôtel de Soubise), parts of which date from 1375, 1553, and 1704–15; the Museum of Nature and the Hunt (Fondation Somer, Hôtel Guénégaud), built by François Mansart in 1648–51; the National Bureau of Historic Monuments (Caisse Nationale des Monuments Historiques, Hôtel de Sully) by Jean I Androuet du Cerceau; and the Picasso Museum (Hôtel Salé).

Closer to the Hôtel de Ville is the Gothic Hôtel de Sens, built at the end of the 15th century for the bishops of Sens, then also bishops of Paris. It was restored after 40 years of work and now serves as a city library of specialized collections. Nearby, behind facades of a much later date, two half-timbered medieval houses have been uncovered. In the Marais, portions of the 13th-century city wall, including one of the watchtowers, are still to be seen.

Hôtel de Ville. Three city halls have stood on this site, each grander than its predecessor. The present building (1874–82) replaces the Renaissance structure that was in use from the 16th century until it was burned by the insurrectionary Communards in 1871. The first was the House of Pillars (Maison aux Piliers), used by the municipality from 1357 to 1533. The present building contains the official apartments of the mayor of Paris.

The massacre of thousands of Protestants on St. Bartholomew's Day, 1572; the Day of the Barricades, May 12, 1588, when the Catholic League drove Henry III out of Paris; and the civil war known as the Fronde, 1648–53, all involved the Paris masses, but they were palace revolutions rather than popular uprisings. When the people rose in their own cause, the focus of their action was inevitably the Hôtel de Ville, as was indeed the case in 1789, 1830, 1848, 1871, and 1944.

In July 1789, for example, after killing the provost, the revolutionary mob took the Hôtel de Ville as it had already taken the Invalides and the Bastille. Three days later Louis XVI appeared on the balcony, wearing the tricolour cockade (royal white added to municipal red and blue), and was cheered by the crowd. Four years later the building was taken as headquarters for the Commune, which directed mob action to control the Convention. On 9 Thermidor, year II (July 27, 1794), the Convention's guards entered the Hôtel de Ville and seized Robespierre and his Communards; all were executed soon after.

In August 1830 Louis-Philippe appeared on the balcony and was acclaimed by the revolutionary crowd. The name of the square was changed in that year to Place de l'Hôtel de Ville. As the Place de Grève (*grève* meaning "strand," or "bank") it had been the principal port of Paris for centuries. (The refusal of boatmen to put out gave the French worker the phrase for going on strike: *faire la grève*.) From 1310 to 1832 it was Paris' principal place of execution.

In 1871, after Napoleon III's defeat at Sedan, a new republic was declared from the steps of the Hôtel de Ville, but, when the national government, in its turn, capitulated, Parisians refused to accept defeat and in March formed the Commune of Paris. In May troops of the government entered the town and fought sharp engagements with the Communards, who set fire to the Hôtel de Ville, the Tuileries Palace, the Palace of Justice, the Police Prefecture, the Arsenal, and other government buildings. The Communards executed 67 hostages, including the archbishop of Paris. The government subsequently rounded up and executed 20,000 Parisians, shipping thousands of others to penal colonies.

In 1944, as the city was being liberated from German occupation, the National Council of Resistance made the Hôtel de Ville its headquarters. At the climax of the Liberation General Charles de Gaulle appeared on the balcony and was acclaimed by the crowd.

The Halles. On the rue de Rivoli westward from the Hôtel de Ville is the Saint-Jacques bell tower (Tour Saint-Jacques), all that remains of a church in the Flamboyant Gothic style that was torn down in 1797. A few streets farther northwest toward the Louvre is the quarter of the Halles, from 1183 to 1969 the central market of Paris. When the markets moved out to a new location at Rungis, near Orly, the distinctive 19th-century iron-and-glass market halls—10 originals designed by Victor Baltard and built between 1854 and 1866, and two 1936 reproductions—and their neighbourhood were designated for renewal. The renewal projects were delayed for several years, however, by bitter disagreements over how the area—which had been thought of as the heart of Paris—should be used. The old market halls were used temporarily for exhibitions and cultural events, but in 1971 they were torn down. Their demolition left an enormous hole in the ground that became a symbol to many Parisians of the end of an era. Construction at the site began in 1971, and in 1977 a station linking the city's subway system (the Métro) with the regional express system was opened. The Forum des Halles, a partly subterranean, multistoried commercial and shopping centre, was opened in 1979. The nearby streets were converted to a traffic-free zone for pedestrians, and a small formal garden was laid out.

A few of the neighbourhood's old houses have been renovated or restored to keep some of the old flavour, but many buildings have been demolished and the area has been largely transformed. Many of its poorer residents were forced to move as renovation and improvement made the neighbourhood unaffordable. The church of Saint-Eustache (1532–1637) remains, as does the circular Grain Exchange (Halle au Blé; 1811–13), which was burned by the Commune and restored in the 1880s as the Commercial Exchange (Bourse de Commerce).

Another development in the area is the Georges Pompidou National Centre for Art and Culture, popularly called Centre Beaubourg, a vast glass-and-metal structure of distinctive design inaugurated in 1977. It soon proved its popularity and remains a successful attraction for Parisians and tourists alike. The centre houses the National Museum of Modern Art, temporary exhibits, the multimedia Public Information Library, the Industrial Design Centre, the Institute for Acoustic and Musical Research, and workshops for children.

Rue de Rivoli. The Louvre and the Tuileries Gardens take up the south side of this street, and on the other side runs an arcade more than a mile long. Opposite the middle of the Louvre, the Place du Palais-Royal leads to the palace of Cardinal de Richelieu, which he willed to the royal family. Louis XIV lived there as a child, and during the minority of Louis XV the kingdom was ruled from there by the debauched but gifted regent Philippe II, duc d'Orléans from 1715 to 1723. Late in the 18th century Louis-Philippe d'Orléans, who was popularly renamed Philippe-Egalité during the Revolution for his radical opinions, undertook extensive building around the palace garden. It was a commercial operation, and the Prince hoped to pay his debts from the property rents. Around the garden he built a beautiful oblong of colonnaded galleries and at each end of the gallery farthest from his residence a theatre. The larger playhouse has been the home of the Comédie-Française, the state theatre company, since Napoleon's reign. The princely apartments now shelter high state bodies such as the Council of State.

Just behind the courtyard is the Bibliothèque Nationale (National Library), the national library of deposit, with an enormous collection of books and prints.

Haussmann greatly enlarged the Place du Palais-Royal in 1852, and he was careful to preserve the palace when he laid out the avenue de l'Opéra. At the top of the avenue, where the Grands Boulevards crossed an enormous new *place*, the new opera house was built from 1825 to 1898. The Paris Opera House, a splendid monument

Nancy Cohen—Black Star

to the Second Empire, was designed in the neo-Baroque style by Charles Garnier. It is known especially for its decorative embellishments, chief among them the Grand Staircase. Just behind the Opera House are various large department stores.

The next *place* along the rue de Rivoli is the Place des Pyramides. The gilded equestrian statue of Joan of Arc stands not far from where she was wounded at the Saint-Honoré Gate (Porte Saint-Honoré) in her unsuccessful attack on Paris (at that time held by the English), on Sept. 8, 1429.

Farther along toward the Place de la Concorde the rue de Castiglione leads to the Place Vendôme, an elegant octagonal *place*, little changed from the 1698 designs of Jules Hardouin-Mansart. In the centre, the Vendôme Column bears a statue of Napoleon. It was pulled down during the Commune and put back up under the Third Republic (1871–1940). The *place* and the rue de la Paix have lost none of their discreet distinction, nor have their shops.

The “Triumphal Way.” From the Arc de Triomphe du Carrousel, in the courtyard between the open arms of the Louvre, extends one of the most remarkable perspectives to be seen in any modern city. It is sometimes called la Voie Triomphale (“the Triumphal Way”). From the middle of the Carrousel arch the line of sight runs the length of the Tuileries Gardens, lines up on the obelisk in the Place de la Concorde, and goes up the Champs-Élysées to the centre of the Arc de Triomphe and beyond to the skyscrapers of La Défense, in the western suburbs.

The Louvre’s modest triumphal arch stands in the open space where costumed nobles performed in an equestrian display—*carrousel*—to celebrate the Dauphin’s birth in 1662. The design of the arch, an imitation of that of the Arch of Septimius Severus in Rome, was conceived in 1808 by Charles Percier and Pierre Fontaine. The flanks of the Carrousel arch are incised with a record of Napoleon’s victories.

The Tuileries Gardens, which fronted the Tuileries Palace (looted and burned in 1871 during the Commune), have not altered much since André Le Nôtre redesigned them in 1664. Le Nôtre was born and died in the gardener’s

cottage in the Tuileries; he succeeded his father there as master gardener. His design carried the line of the central allée beyond the gardens and out into the countryside by tracing a path straight along the wooded hill west of the palace. On this hilltop, 170 years later, the Arc de Triomphe was erected.

At the western edge of the gardens, Napoleon III erected a hothouse, known as the Orangery, and the Jeu de Paume, an indoor court for court tennis. Both eventually were adapted as museums: the Orangery had a small permanent collection, including a group of 19 of Claude Monet’s paintings of waterlilies displayed as panoramas. The Jeu de Paume housed the Louvre’s collection of paintings by the Impressionists and their forerunners. The collections of the two museums—with the exception of the Monet panoramas—were moved to the Orsay Museum, which opened in 1986, and the Jeu de Paume and the Orangery were then reserved for occasional exhibitions.

The formal exit gate from the Tuileries is flanked by two winged horses (17th century), and the entrance to the Champs-Élysées across the square is similarly adorned, only by earthbound horses (18th century), both pairs having been removed in turn from the water trough at the Château de Marly.

The Place de la Concorde was designed as a moated octagon in 1755 by Jacques-Ange Gabriel. The river end was left open, and on the inland side two matching buildings were planned. The ground floor was arcaded and the facade was nimbly adapted from the Louvre colonnade, all with a refinement typical of the era. Although Gabriel built eight giant pedestals around the periphery of his *place*, they remained untenanted until Louis-Philippe gave them statues representing provincial capitals. Viewed clockwise starting from the Navy Ministry (Ministère de la Marine), the statues are Lille, Strasbourg, Lyon, Marseille, Bordeaux, Nantes, Brest, and Rouen. Louis-Philippe also had the Luxor Obelisk, a gift from Egypt, installed in the centre and flanked by two fountains. Later, the surrounding moat was filled in.

Louis XVI was decapitated near the statue of Brest on Jan. 21, 1793. Four months later the guillotine was erected

The
Madeleine

near the gates of the Tuileries, and the executions continued there for nearly three years, accounting for a total of 1,343 deaths.

Between the twin buildings on the northeastern side of the *place*, the broad rue Royale mounts to the Church of Sainte-Marie-Madeleine, consecrated in 1842. The church is a stern oblong, fenced with columns 60 feet high. Its design, supposedly that of a Greek temple, is actually closer to the Roman notion of Greek.

The Place de la Madeleine is the western terminus of the Grands Boulevards, which imitate the arch of the river from there north and east to the Place de la République and the Bastille. The glittering chic of the Grands Boulevards, which flavoured Paris life from 1750 to the 1880s, disappeared with the *boulevardiers*, but many of the boulevards' theatres and other entertainments survive. The state-run Opéra-Comique ("Comic Opera") stands fast just off the boulevard des Italiens, the wax museum survives on the boulevard Montmartre, and, a few doors away, the Théâtre des Variétés, founded under the Second Empire by the composer Jacques Offenbach, still operates. The Théâtre de la Renaissance, where the actor Benoît-Constant Coquelin created the role of Cyrano de Bergerac in 1897, remains on the boulevard Saint-Martin, as does the Théâtre de l'Ambigu, where Frédéric Lemaître, the celebrated actor in boulevard melodrama, thrilled all Paris in the mid-19th century. Some of the movie palaces of the 1930s also remain along the boulevards.

To the west off the rue Royale runs the rue du Faubourg Saint-Honoré, which, in addition to the British Embassy and the Élysée Palace (residence of the French president), has on its shop windows some of the most prestigious names in the Paris fashion trade.

Along the first 2,500 feet of the Champs-Élysées, between Concorde and the Rond-Point des Champs-Élysées (a roundabout, or traffic circle), little has changed for a century: the avenue is bordered with chestnut trees, behind which on both sides are gardens, usually full of children at play. The pavilions in the gardens are used as tearooms, restaurants, and theatres.

From the Rond-Point up to the Arc de Triomphe, however, the avenue has changed with the times. Under the Second Empire this was a street of luxurious town houses. They were supplanted by cafés, nightclubs, luxury shops, and cinemas, but the street retained its feeling of luxury, and the tree-shaded sidewalks (wide as a normal street) offered promenades that were the pride of Paris. Since the 1950s, however, banks, automobile showrooms, airline of-

The
Champs-
Élysées
today

fices, and fast-food eateries have taken over much of the space. Automobiles park on the sidewalks and in many places one rank of the double file of trees has been felled.

At the top of the Champs-Élysées is a circular *place* from which 12 imposing avenues radiate to form a star (*étoile*). It was called Place de l'Étoile from 1753 until 1970, when it was renamed Place Charles de Gaulle. In the centre of the *place* is the Arc de Triomphe, commissioned by Napoleon in 1806. It is twice as high and as wide as the Arch of Constantine, in Rome, which inspired it. Jean Chalgrin was the architect and François Rude sculpted the frieze and the spirited group, "The Departure of the Volunteers of 1792" (called "La Marseillaise"). On Armistice Day in 1920, the Unknown Soldier was buried under the centre of the arch, and each evening the flame of remembrance is rekindled by a different patriotic group.

In the 1970s the largest concentration of tall buildings in Europe arose some two miles beyond the arch, on the far side of the suburban wedge of Neuilly. The site, called the Quartier de la Défense, was formerly just a place on the road adjoined by the suburban municipalities of Puteaux, Courbevoie, and Nanterre. Today tall office buildings, heated and air conditioned from a central plant, are the hub of the complex. The "ground level" between buildings is a raised platform reserved to pedestrians, with roads and parking below. There are shops, restaurants, cafés, a shopping centre, hotels, and apartment houses. Before the project was begun, the state had already constructed at La Défense its National Centre for Industries and Technologies, a large exhibition hall. Nanterre became the site of a campus of the University of Paris in the 1960s, and specialized schools at the university level have been installed in the new centre: the National School of Architecture, the National School of Decorative Arts, the National Conservatory of Music, and the Institute of Advanced Cinematographic Studies. The three municipalities have benefited by the acquisition of low-rise public housing in park settings, a large park, day-care centres for children, and new schools.

Modern business quarters. As a counterbalance to the westward march of office buildings and as part of the effort to limit the obliteration of residential quarters around the business centre, five "poles of attraction" were instituted in other parts of Paris, beginning in the late 1960s. Two of these are directly on the waterfront at each end of Paris: Front de Seine ("Seine Waterfront") in the southwest corner, and Austerlitz-Bercy-Lyon in the southeast corner.

The Front de Seine is located on the Left Bank, between

Fountain and the Luxor Obelisk in the Place de la Concorde.

the Eiffel Tower and the southern city limits. A neighbourhood of factories and substandard housing has been replaced by a spread of 16 towers of 32 stories and four buildings 15 stories high. One-quarter of the space is used for offices and the rest for apartments, some of which are low-cost housing.

Modern-
ization at
Bercy

The project at the opposite end of the river straddles the Seine, with office buildings around the Austerlitz (Left Bank) and the Lyon (Right Bank) railroad stations. Bercy, which lies directly on the river on the Right Bank, was until this development one of the "secret cities" of Paris. This was the village of vintages, where merchants stored and sold their stocks of wine. Fenced and guarded, its chalets lined cobbled lanes named for the great vineyard districts of France. The great oaks, it was said, flourished because their roots were soaked in wine. The Bercy area is being redeveloped on a large scale, with many large office blocks and a new sports and leisure centre.

The "Italian sector," near the Place d'Italie in the south of Paris, between the centre and Orly Airport, underwent an extensive renovation during the 1970s. Some 9,000 time-worn dwellings were demolished and replaced by 13,000 new ones capable of housing 45,000 persons. A cultural centre was built, and new green spaces and a sports ground were provided.

The planning achievement that overshadows the others is Maine-Montparnasse, where the centrepiece of the composition is a 56-story office tower on the site of the old Montparnasse railway station. A more compact station has been built one street away on the avenue du Maine, where the rails are hidden on three sides by three buildings 15 to 18 stories high. The units are joined by a raised platform that serves as a "ground level" above the street.

The ministry quarter. The government, both local and national, occupies a vast amount of Paris' office space. The seventh *arrondissement*, a district on the Left Bank that runs along the river from the Eiffel Tower to the Carrousel Bridge, is known as the ministry quarter. Most of the ministries are located there along with the headquarters of the Île-de-France Region and the National Assembly. The *arrondissement* is the old Faubourg Saint-Germain, an impeccable address since the early 18th century. As such, it was subject to heavy expropriation during the Revolution, and ministries are lodged mostly in splendid old mansions and convents. Although imposing, these are never large enough and are always difficult to adapt to the needs of modern administration. When it proves impractical to spread into adjacent buildings or to construct annexes in the garden, branches are installed wherever space can be found. Some of the ministries occupy as many as 25 separate buildings.

Quai
d'Orsay

Probably the best known of all ministries is the low-built, ornate Ministry of Foreign Affairs on the Quai d'Orsay between the Invalides Esplanade and the National Assembly. The address "Quai d'Orsay" has become a synonym for the ministry.

The National Assembly is housed in the Bourbon Palace (1722–28), which was seized during the Revolution. Succeeding regimes have added bits and pieces onto the old palace, including the Greek peristyle facing the river as ordered in 1807 by Napoleon.

The old, disused Orsay railway station near the river was renovated and in 1986 was reopened as a museum of 19th-century art and civilization. It contains, among other collections, the Impressionist and Postimpressionist paintings—by Cézanne, Manet, Monet, Renoir, van Gogh, and others—that were formerly in the Jeu de Paume.

The Latin Quarter (Quartier Latin). At the Concorde Bridge the boulevard Saint-Germain begins, curving eastward to join the river again at the Sully Bridge. A little less than halfway along the boulevard is the pre-Gothic church of Saint-Germain-des-Prés. The old church, which belonged to a Benedictine abbey founded in the 8th century, was sacked four times by Vikings and was rebuilt between 990 and 1201. Parts of the present church date from that time.

The area has long been a gathering place for practitioners of the arts. Racine died there in 1699, Delacroix had his studio in the Place Fürstemberg, publishing houses moved

in during the 19th century, and the principal cafés have been meeting places for artists, writers, and publishers ever since. From 1945 to about 1955 it was the hub of the existentialist movement and an associated revival of bohemianism. It is still a lively centre for literature, food, and conversation.

Straight north from the Saint-Germain-des-Prés crossroads is the School of Fine Arts (École des Beaux-Arts), the state school of painting and sculpture, on the Quai Malaquais. Two streets south of the crossroads is the church of Saint-Sulpice (1646–1780), the work of six successive architects. The street alongside the church is sprinkled with shops specializing in devotional statuary, much of it on the aesthetic level of tourist souvenirs and known in France as "Saint Sulpicerie." Eastward to the boulevard Saint-Michel, the area toward the river from the boulevard Saint-Germain is a tangle of narrow, animated streets, which typify the tourist's idea of a vivacious and noisy Paris.

Beyond the boulevard Saint-Michel is the university precinct, self-governing under the kings, where, in class and out, students and teachers spoke Latin until 1789. At the junction of the boulevards Saint-Germain and Saint-Michel are the remains of one of the three baths of the Roman city. These are in the grounds of the Cluny Museum, a Gothic mansion built 1485–1500, which now houses a collection of medieval works of art, including the renowned six-panel unicorn tapestry "La Dame à la licorne."

The wide, straight boulevard Saint-Michel is the main street of the student quarter. It is lined with bookshops, cafés, cafeterias, and movie houses. The buildings of the university are found on smaller streets. The university was built up of colleges, each founded and supported by a donor, often a prelate or a religious order. In about 1257 Robert de Sorbon, chaplain to Louis IX, established a college, known as the Sorbonne, that eventually became the centre of theological study in France. The oldest part of the Sorbonne is the chapel (1635–42), the gift of Richelieu, who is buried there. Designed by Lemercier, it was one of a number of new domed Jesuit-style churches of the period.

The
Sorbonne

The Sorbonne served for centuries as the administrative seat of the University of Paris. In 1968–71 the university was divided into a number of entirely separate universities, and the Sorbonne building proper continues to serve as premises for some of these. Other faculties, schools, and institutes have moved out of Paris to more spacious sites in the suburbs in an effort to ease the overcrowding of the Paris student milieu.

The independent College of France was set up a few steps from the university by Francis I in 1529 to offer a more liberal, modern curriculum than the narrow theology and Latin of the Sorbonne. Bestowing no degrees, it has always had a superb faculty of well-known specialists, especially in philosophy, literature, and the sciences.

At the top of the hill rising from the river the boulevard skirts the Luxembourg Gardens, the remains of the park of Marie de Médicis' Luxembourg Palace (1616–21), which now houses the French Senate. The gardens are planted with chestnuts and are enhanced with a pond for toy sailboats, a marionette theatre, and statuary.

Across the boulevard at the end of the rue Soufflot stands the Panthéon (1755–92), designed by Jacques-Germain Soufflot. It was commissioned by Louis XV, after his recovery from an illness, as a votive offering to St. Geneviève and was to replace the mouldering 5th-century abbey in her name. Though intended as the principal church in Paris, it was renamed the Panthéon by the Revolutionary authorities, who made it the last resting place for heroes of the Revolution. The walling up of a number of its windows and removal of much interior decoration replaced the intended effect of light interior space with a gloomy dignity. Among those buried under the inscription "Aux grands hommes, la Patrie reconnaissante" ("To great men, [from] their grateful land") are the authors Victor Hugo, Voltaire, Rousseau, and Zola and Jean Moulin, chief of the Resistance in World War II.

The
Panthéon

Behind the Panthéon is a steep street named the rue

de la Montagne Sainte-Geneviève. It was the paved road to Italy in Roman times. The hill leads down to the lively market square of Place Maubert and a tangle of ancient, picturesque riverside streets. The best known of these is the medieval rue de la Huchette, from which the rue du Chat-qui-Pêche ("Street of the Fishing Cat") leads to the Quai Saint-Michel. Two churches, Saint-Séverin (1489-94), Gothic and humble, and Saint-Julien-le-Pauvre (1165-1220), which belongs to the transitional period between the Romanesque and the Gothic, rise from the tangle of streets. The square in front of the church offers one of the finest views of Notre-Dame de Paris.

The Buttes. The river valley of Paris is almost entirely circled by high ground. Upon the heights of Passy, on the Right Bank between the western city limits and the Arc de Triomphe, perch the wealthy neighbourhoods of the 16th *arrondissement*. The Butte-Montmartre (18th *arrondissement*) and the Buttes-Chaumont (19th *arrondissement*), which rise along the northern rim of the city, are still working-class. The 18th *arrondissement* has broad avenues, but it also has winding lanes, some of which become stairways on the steeper hills. From the early 19th century until the migration in the 1920s to Montparnasse, Montmartre was the major art colony of Paris. Some sections are highly commercialized for the tourist trade; others, however, are unself-consciously picturesque. Montmartre is known for its nightclubs and entertainment.

The most noted landmark of Montmartre was built only in 1919: the Sacred Heart Basilica (Basilique du Sacré-Coeur), paid for by national subscription after the French defeat by the Prussians in 1870. The work began in 1876 but was delayed by the death of the architect, Paul Abadie, who took inspiration from the 12th-century five-domed Romanesque church of Saint-Front in Périgueux, itself inspired by either Venetian or Byzantine churches. Alongside the monumental terraced stairway of the garden-planted Square Willette below the church entrance runs the only funicular railway in Paris.

On the Buttes-Chaumont just to the east of Montmartre is the Buttes-Chaumont Park, which was created under Haussmann in 1864-67. A bare hill, half hollowed out by abandoned tunnel quarries and filled with the refuse of generations, was turned into a romantic landscape with a lake, a waterfall, a grotto, winding woodland paths, and picturesque bridges. It is the largest park within the walls of Paris.

This portion of the 19th *arrondissement* is known as Belleville, and just below on the slope toward the river is Ménilmontant, in the 20th *arrondissement*. Père-Lachaise Cemetery, on hilly ground in the 20th *arrondissement*, is the site of the Federalists' Wall (Mur des Fédérés), against which the last of the Communard fighters were shot and to which pilgrimages are still made. Chopin, Marshal Ney, Baron Haussmann, Alfred de Musset, Balzac, Delacroix, Bizet, Rossini, Sarah Bernhardt, Isadora Duncan, Colette, and Edith Piaf are among the well-known people buried there. On the northeastern edge of the city proper, at La Villette, the giant structure of the old city abattoirs, out of use since 1974, was reopened in 1986 as a science museum. Nearby are a spherical panoramic cinema building and a large leisure park and culture complex.

Parks and open spaces. The appearance of Paris as a city well-endowed with parks is fostered in part by the garden effect of the Seine's open waters and its tree-lined banks. Some 87,000 trees (mostly plane trees, with a scattering of chestnuts) line the streets as well. But in fact parks and open spaces cover only 11 percent of the area of the City of Paris. Under Mayor Jacques Chirac the municipal government initiated efforts to create new parks, but the results have been modest.

Most of the parks and gardens of the modern central city are on land that formerly was reserved for the kings on the old city's outskirts. Under Napoleon III, who had been impressed by London's parks while living in Britain, two ancient royal military preserves at the approaches to Paris were made into "English" parks—the Bois de Boulogne on the west, and the Bois de Vincennes to the east. Moreover, during his reign a large area of land was laid out in promenades and garden squares. An assortment of

municipal departments care for the public squares, street trees, riverbank trees, and various gardens.

(B.E./J.A.C.A.)

THE PEOPLE

In 1850 Paris had only 600,000 inhabitants. But it then grew rapidly, as industrial expansion attracted a constant stream of people from the provinces. By 1870 the population had surpassed 1,000,000; and by 1931 the conurbation contained some 5,000,000 people, more than half of them living in the City of Paris, the administrative city within the old gates. Since World War II this growth has continued, and Greater Paris by the late 1980s had close to 9,000,000 inhabitants. The population of the City of Paris, however, has steadily declined, from a peak of 2,900,000 in 1931 to 2,200,000 by 1982, so that more than three out of four Parisians are now suburbanites. The shift has taken place in part because massive rehousing has reduced the City's high density, though it remains well above the north European average. Many families have moved out to newer and more spacious homes in the suburbs, leaving the City of Paris with an aging population and one that is curiously solitary: almost half of the households consist of just one person.

Paris-born Parisians are outnumbered by immigrants who keep their provincial ties; hence many shops, restaurants, and neighbourhoods have a regional flavour. For example, there are said to be more Aveyronnais living in Paris than in the Aveyron *département* of central France. Most of the population is nominally Roman Catholic, though only a small percentage attend Mass regularly.

The foreign element has been increasing and now accounts for nearly one-fifth of the total population. The majority are Muslim Arabs from Algeria, Morocco, and Tunisia. In general, the North Africans are badly housed in the poorer quarters and are employed at menial jobs; in the 1980s their presence gave rise to racial tensions and conflicts. The sizable population of blacks is made up mainly of immigrants from the French Caribbean territories of Martinique and Guadeloupe: they tend to have better jobs and living conditions and are better accepted than are the Muslims. The Jewish community, which has long been settled in Paris, is centred on the Rue des Rosiers quarter of the Marais, where there are numerous synagogues, kosher stores, and Hebrew bookshops. In the 1980s encounters with Sephardic Jewish immigrants from North Africa provoked a mild revival of the anti-Semitism rife in prewar Paris.

In the earlier part of the 20th century Paris was favoured by expatriate writers and artists, including Ernest Hemingway from the United States, James Joyce from Ireland, Pablo Picasso from Spain, and Amedeo Modigliani from Italy. The foreign population from Europe and North America is now fairly small, however, consisting mainly of business people and the staffs of the large Paris-based international agencies, notably UNESCO and the Organisation for Economic Co-operation and Development.

THE ECONOMY

Paris is not only the political and cultural capital of France but also its major financial and commercial centre. Even if large French firms have their manufacturing plants in the provinces, they nearly all keep their headquarters in Paris, conveniently close to the major banks and key ministries. As an industrial centre the Paris region is less dominant in France than it was in its heyday in the 1930s, for since World War II most industrial growth has been in the provinces; but it still contains nearly a quarter of French industry. As a financial centre Paris is the base for many large international concerns in commerce and banking, and despite some pockets of poverty it is a very wealthy city, home of many vast private fortunes both French and foreign. After industry and commerce, the main activity is government administration, which employs nearly 700,000 people.

Industry. It was largely because it was already the political capital, with firms thus attracted to it, that Paris became an actively industrial city in the 19th century. Unlike other older French industrial areas, such as Lor-

Mont-
martre

Abundance
of trees

rairie and the Nord, it was not near mineral resources. But it did have some natural assets of its own, notably the Seine River, which is still used for heavy barge traffic moving downstream to the sea at Le Havre. Traditional industries were devoted mainly to handicrafts and luxury goods, but, when the growth of railways and canals in the 19th century made the northern coalfields more accessible, heavier industries such as engineering and chemicals began to develop. These soon spread beyond the city into the new industrial suburbs.

Since the 1950s the policy of successive French governments has been to limit the industrial growth of the Paris region in favour of the provinces, many of them still underdeveloped. Paris, which is in many ways overcongested, has instead been encouraged in developing commerce, finance, and services, a policy that has achieved some success. Industrial firms were forbidden to expand in the Paris area or were given various cash incentives to transfer their plants to the regions, and many did so. From 1962 to 1973 the Paris region had a net loss of 77,000 industrial jobs (about 5 percent of the total), while the rest of France gained 670,000.

The region, however, still employs well over a million people in industry. The City of Paris itself is still the home of many small-scale but typically Parisian activities: haute couture, notably in the Faubourg Saint-Honoré; the clothing industry, in the Sentier quarter; jewelry, in the Place Vendôme and rue de la Paix; furniture making, in the Faubourg Saint-Antoine. Newer and larger industries have developed in the northern and western suburbs, especially along the Seine valley toward Rouen: located there are several large automobile and aircraft factories. To the northwest, along the Seine's loop from Suresnes to Gennevilliers, are armaments factories, heavy engineering works, and chemical plants. Other firms are located to the northeast, within reach of Charles de Gaulle Airport. To the south and southwest along the valley of the Bièvre River are tanneries, cement works, breweries, tobacco factories, and other traditional concerns. Many light industries have settled in the new towns that now ring the Paris conurbation.

Commerce and finance. The major French banks, insurance companies, and other financial bodies are all centred on Paris, predominantly in the main financial quarter on the Right Bank around the Stock Exchange (Palais de la Bourse) and the state-owned Bank of France. Scores of foreign multiservice banks have branches in Paris, but the city is not a dynamic centre for specialist activities such as merchant banking and venture capital investment. The Paris Stock Exchange, though expanded and modernized in the 1980s, still handles little more than one-fifth of the volume of the London Stock Exchange.

Paris has developed greatly since World War II as a centre for international commerce, especially in the new skyscraper quarter of La Défense, where many large companies are situated. The city is one of the world's most popular sites for international business conferences, often hosting more than 200 a year. It has several major modern convention centres, notably the Palais des Congrès at the Maillot Gate.

It was the French who invented the modern department store, with the opening of the Bon Marché on the Left Bank in 1852. In the 1960s the major food and wine wholesale markets were transferred from their central locations at the Halles on the Right Bank and the Halle aux Vins (the wine market) on the Left Bank to new and more spacious homes in the suburbs.

Transportation. The Paris public transport system, operated by a body that is largely state-controlled, has been superbly modernized and extended since the early 1970s, and it is now regarded by many as the finest of any major world city. Trains on the 16 principal lines of the Métropolitain (Métro) subway system are fast and frequent. The Réseau Express Régional (RER), a high-speed express subway system, extends far into the suburbs, and at some points its lines have been integrated with the mainline railway network. The hub of the system is Châtelet-Les-Halles, said to be the world's largest and busiest underground station. By the 1980s Paris had become a com-

muter city, its Métro carrying 5,000,000 passengers daily. The cost of the Métro is subsidized by the government; passengers pay only about half of the actual cost. The city's bus system also has been modernized.

Such improvements have been part of an official campaign to ease traffic problems by discouraging the daily use of automobiles for commuting. But the campaign has not been entirely successful. The volume of traffic has swelled inexorably, and, although it often moves briskly along the many broad avenues and boulevards, it also can get clogged for hours in the honeycomb of narrow older streets. In a further attempt to decrease congestion the city has created many new underpasses and riverside expressways and has developed an extensive network of one-way streets. Underground garages have been built to provide parking space.

The city of Paris is encircled by an expressway, the boulevard Périphérique. The expressway is linked with suburban highways and with the national highway network, of which Paris is the hub. Similarly, the large Paris railway terminals serve the French railway network, first built in the 19th century. The network has been modernized and operates high-speed trains to Lyon and elsewhere. The main international airport is Charles de Gaulle, to the northeast; the older Orly Airport, to the south, is used mainly for domestic and charter flights. The Seine River carries barges and pleasure traffic; there are commercial ports both upstream and downstream from the city.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. A sharp distinction is drawn between city administration and suburban administration. The City of Paris is a single political unit—a *commune*—governed by an elected mayor and council, like any other French *commune* down to the smallest village. The suburbs consist of more than 1,200 separate *communes*, large and small, which together with the City of Paris form the administrative region of Île-de-France. The Île-de-France region, with an area of about 4,640 square miles (12,000 square kilometres), extends far beyond the Paris conurbation. The urban area of Greater Paris therefore is not a political unit, and coordination is frequently poor between Paris and its inner suburbs. Because of the fierce rivalries between left-wing and right-wing *communes*, it has never been possible to follow the pattern of other major world cities and create a federated urban district.

The Île-de-France is the most populous of France's 22 regions. The region consists of eight *départements*: Hauts-de-Seine, Seine-Saint-Denis, Val-de-Marne, Essonne, Yvelines, Val-d'Oise, Seine-et-Marne, and Paris. Under the socialist government's devolutionary reforms of 1982–86, the Île-de-France, like the other regions, was given a certain degree of autonomy. It has a directly elected assembly with a chairman and executive; it can raise its own taxes; and it has responsibility for adult education and for some aspects of culture, tourism, road building, planning, and aid for industrial development. The directly elected representatives of the eight *départements* have also been given increased responsibilities: they run the welfare and social services, involving large budgets, as well as controlling some matters concerning the infrastructure. The *communes* in turn look after their own town planning and building. Each *département* is supervised by a state-appointed prefect and the Île-de-France by a regional prefect, but the office of prefect has much less power than before the reforms.

The City of Paris itself has a curious history of local government. The Municipal Council of Paris is elected by the people every six years. From 1871 to 1977 the council had no mayor and was controlled directly by the departmental prefect, so that Paris had less autonomy than any village. The national government, worried by memories of the uprisings of 1789, 1848, and 1871, wanted to keep power from the Paris populace. A statute passed in 1975, however, permitted the councillors once again to elect their own mayor. The mayor now has the same status and powers as in other French towns. The first mayoral election was held in 1977. In 1982 a ward system was introduced, whereby each of the 20 *arrondissements* was

given its own mayor and local council. In practice, however, these have not proved very effective, and real control remains in the hands of Paris' mayor.

Services. Electricity and gas utilities in Paris are run by the state, as are the fire departments, the telephone service and, unlike all other French cities, the police, who have wider powers than in other towns. In addition to dealing with crime, traffic, and public order, the Paris police register vehicles and drivers; issue passports, identity cards, and aliens' residence permits; and conduct political surveillance. One of their main challenges has been the growing wave of crime, particularly terrorism. Special police agencies include detective and counterespionage services and the Republican Security Force, used for dispersing demonstrations. The Republican Guard, a mounted squadron of spurred, helmeted, plumed, and breast-plated guardsmen armed with sabres, are used only for ceremonial occasions such as visits by foreign heads of state.

Health. The public hospitals and hospital groups in Paris are run jointly by the city and the national Ministry of Health and are financed largely by a social welfare system. Some other hospitals are run by churches and by private organizations, and there are numerous private clinics. Of the city's many medical research bodies the best known is the Pasteur Institute, founded in 1887.

Education. As in the rest of France, schools are largely in the hands of the state and are of three main kinds: primary, junior secondary (*collèges*), and senior secondary (*lycées*). Almost one-fifth of all pupils are in private, non-state schools, most of them run by the Roman Catholic Church. Some of the best-known *lycées* in central Paris are the Lycée Henri IV, the Lycée Louis-le-Grand, and the Lycée Janson de Sailly; such schools traditionally have educated a large number of the nation's intelligentsia.

Paris has long been an important world centre of higher education. The building known as the Sorbonne housed the arts and science faculties of the University of Paris, one of Europe's oldest universities, until it was split into 13 autonomous universities (1968–71), some of which still occupy the Sorbonne. The 13 universities, overcrowded and underfunded, with some 250,000 students, have lost prestige to a number of much smaller bodies of higher education that are more specialized and more elitist. These include the engineering, technical, and business colleges known as the Grand Schools (*Grandes Écoles*), of which the two best known in the Paris area are the School of Higher Business Studies (*École des Hautes Études Commerciales*; HEC) and the Polytechnical School (*École Polytechnique*), both of them now transferred to spacious new homes in the suburbs. The Normal Superior School (*École Normale Supérieure*) serves mainly to prepare future university and *lycée* teachers. The Institute of Political Sciences (*Institut des Sciences Politiques*) nurtures many of those who go on to the influential postgraduate Normal School for Administration (*École Normale d'Administration*; ENA) to train as senior civil servants. This selective structure has served France well in many ways but has come under heavy criticism and undergone sporadic reform.

CULTURAL LIFE

Paris has for centuries been regarded as the main cultural powerhouse of the Western world, a magnet for artists and intellectuals, a place where new ideas originate and art reigns supreme. While some people feel its cultural life is now more a matter of show and dazzle than of true creativity, the cultural life is still highly active and distinctive. Parisians love novelty, they have an abounding intellectual curiosity, they know how to dress up the simplest cultural event with flair and elegance, and they are avid patrons of the arts, so that the theatres and concert halls, museums, art galleries, and art cinemas are always well-attended.

The principal state-run theatres are the Comédie-Française, the Odéon Theatre, and the National Theatre of Chaillot, which offer a repertoire of French classics, serious modern plays, and foreign imports. Lighter fare is provided by the many privately owned "boulevard" theatres, which struggle to survive. There are more than 150 smaller theatres, many of them state-supported, which present a mixed program of experimental "fringe" shows, cabaret,

and the like. In addition to many multiscreen commercial cinemas, there are scores of little "art" houses that show a wide variety of movies, many of them with subtitles. France's main film studios are in the suburbs of Paris.

While the newly remodeled Louvre is the greatest of the classic art museums, Paris has built major new museums in the past years, including the National Museum of Modern Art in the Pompidou Centre, the Orsay Museum of 19th-century art and civilization (opened in 1986), and the new science museum at La Villette. A speciality of Paris is the staging of large and lavishly mounted exhibitions, usually retrospectives of an individual artist or historical period. The city's musical life, once moribund, has become much livelier since the early 1970s, in part because the state has provided much-needed funding. The quality of the Paris Opera has been uneven and the building ill-suited to modern productions, but the city renewed its commitment to opera by opening a new opera house in 1989. Major annual festivals emphasizing music and drama are the Marais Festival, held in June and July, and the Autumn Festival, held from mid-September through December.

The main publishing houses and bookshops are located in the Latin Quarter and Saint-Germain-des-Près. The best-known daily newspaper is the evening *Le Monde*, followed by the daily *Le Figaro* and *Liberation*. While the Paris daily press is relatively weak, accounting for less than one-third of total daily circulation in France, weekly newsmagazines flourish, notably *L'Express* and *Le Point*. All of the main French national radio and television networks are centred in Paris; some are owned by the state and some are privately owned. (J.A.C.A.)

History

FOUNDATION AND MEDIEVAL GROWTH

Paris was in existence by the end of the 3rd century BC as a settlement on an island, the modern Île de la Cité, in the Seine River and was inhabited by a Gallic tribe known as the Parisii. The first recorded name for the settlement was Lutetia (Latin: "Midwater-Dwelling"). When the Romans arrived, the Parisii were sufficiently organized and wealthy to have their own gold coinage. Julius Caesar wrote in his *Commentaries* (52 BC) that the inhabitants burned their town rather than surrender it to the Romans. In the 1st century AD Lutetia grew as a Roman town and spread to the left bank of the Seine. The straight streets and the public buildings in this locale were characteristically Roman, including a forum, several baths, and an amphitheatre.

A series of barbarian invasions began in the late 2nd century. The town on the left bank was destroyed by the mid-3rd century, and the inhabitants took refuge on the island, around which they built a thick stone wall. From the early 4th century the place became known as Paris.

By this time, Christianity seems to have spread to Paris. A 10th-century sacramentary cites St. Denis (Latin Dionysius) as having been the first bishop of Paris, in about AD 250. A graveyard excavated near the Carrefour des Gobelins shows that there was a Christian community in very early times on the banks of the Bièvre (a left-bank tributary of the Seine); but it was probably under St. Marcel, the ninth bishop (c. 360–436), that the first Christian church, a wooden structure, was built on the island.

By the end of the 5th century, the Salian Franks, under Clovis, had captured Paris from the Gauls, making it their own capital. It remained the capital until the end of Chilperic's reign in 584, but succeeding Merovingians carried the crown elsewhere. Charlemagne's dynasty, the Carolingians, tended to leave the city in the charge of the counts of Paris, who in many cases had less control over administration than did the bishops. After the election of Hugh Capet, a count of Paris, to the throne in 987, Paris, as a Capetian capital, became more important.

The population and commerce of Paris increased with the gradual return of political stability and public order under the Capetian kings. The maintenance of order was entrusted to a representative of the king, the provost of Paris (*prévôt de Paris*), first mentioned in 1050. In the 11th century the first guilds were formed, among them the butchers' guild and the river-merchants' guild, or *marchan-*

dise de l'eau. In 1141 the crown sold the principal port (near the Hôtel de Ville) to the *merchandise*, whose ship-blazoned arms eventually were adopted as those of Paris. In 1171 Louis VII gave the *merchandise* a charter confirming its "ancient right" to a monopoly of river trade.

During the reign of Philip II (1179–1223), Paris was extensively improved. Streets were paved, the city wall was enlarged, and a number of new towns were enfranchised. In 1190, when Philip II went on a crusade for a year, he entrusted the city's administration not to the provost but to the guild. In 1220 the crown ceded one of its own precious rights to the townsmen—the right to collect duty on incoming goods. The merchants were also made responsible for maintaining fair weights and measures. The King's formal recognition of the University of Paris in 1200 was also a recognition of the natural division of Paris into three parts. On the Right Bank were the mercantile quarters, on the island was the *cité*, and the Left Bank contained the university and academic quarters. Numerous colleges were also founded, including the Sorbonne (about 1257).

In the 14th century the development of Paris was hindered not only by the Black Death (1348–49) but also by the Hundred Years' War (1337–1453) and by internal disturbances resulting from it. The provost of the merchants in 1356 was Étienne Marcel, who wanted a Paris as rich and free as the independent cities of the Low Countries. He gave the House of Pillars to the municipal government, and he slew the Dauphin's counselors in the palace throne room and took over the city. Marcel showed great executive skill and equally great political stupidity and allied himself with the revolting peasants (the Jacquerie), with the invading English, and with Charles the Bad, the ambitious king of Navarre. While going to open the city gates to the Navarrese in 1358, Marcel was slain by the citizens.

In 1382 a tax riot grew into a revolt called the "Maillotin uprising." The rioters, armed with mauls (*maillets*), were ruthlessly put down, and the municipal function was suspended for the next 79 years. It was not until 1533, when Francis I ordered the teetering House of Pillars replaced by a new building, that a monarch manifested an encouraging interest in municipal government.

The dynastic and political vendetta between the Burgundian and the Armagnac faction (1407–35) had continual repercussions in Paris, where the butchers and skinners, led by Simon Caboche, momentarily seized power (1413). The resumption of the Hundred Years' War by the English in 1415 made matters worse. After a revolt of the Parisians (1418), the Burgundians occupied Paris; the Anglo-Burgundian Alliance (1419) was followed by the installation of John Plantagenet, duke of Bedford, as regent of France for the English king Henry VI (1422). Whereas Charles VI had lived in his father's Hôtel Saint-Paul, Bedford lived in the Hôtel des Tournelles, on the southeastern edge of the Marais, which was to be the Paris residence of later kings until 1559. During the reign of Charles VI, construction began on the Notre-Dame Bridge (1413).

In 1429 Joan of Arc failed to capture Paris. Only in 1436 did it fall to the legitimists, who welcomed Charles VII in person in 1437. Successive disturbances had reduced the population, but the Anglo-French truce of 1444 allowed Charles to begin restoring prosperity.

In 1469, during Louis XI's reign (1461–83), the Sorbonne installed the first printing press in Paris. Otherwise this was a period of intellectual stagnation. Churches were rehabilitated and new houses were built, however; from 1480 splendid private mansions began to appear, such as the Hôtel de Sens and the Hôtel de Cluny.

FROM THE RENAISSANCE TO THE REVOLUTION

The influence of the Italian Renaissance on town architecture appeared in the new building for the accounting office and in the reconstruction of the Notre-Dame Bridge (1500–10) in Louis XII's reign. Under Francis I (1515–47) this influence grew stronger, finding notable expression in the new Hôtel de Ville. Furthermore, whereas from Charles VII's time the kings of France had preferred to reside in Touraine, Francis returned the chief seat of royalty to Paris. With this in mind he had extensive alterations

made to the Louvre from 1528 onward. The new splendour of the monarchy, which was well on its way toward absolute rule, was reflected in the way Paris developed as the capital of an increasingly centralized state. The population increased and the town expanded again. Rigorous measures were taken to stamp out Protestantism, which first appeared in Paris during Francis I's reign.

The Renaissance in Paris culminated with Henry II, who made his solemn entry into the capital in 1549. The new impulse given to building mansions for the nobility and bourgeoisie began to transform Paris from a medieval to a modern city. In 1548 the Brothers of the Passion began performing secular plays at the Hôtel de Bourgogne, in the rue Française, thus inaugurating the first theatre in Paris.

The transfer of the royal residence from the Hôtel des Tournelles to the Louvre, signaling the development of the neglected western outskirts of Paris, was completed after Henry II's death in 1559. Catherine de Médicis began to build the Tuileries Palace, the gardens of which became a meeting place for elegant society. Classical taste was brilliantly exemplified by the Pont-Neuf, begun in 1577.

In the mid-16th century the Wars of Religion broke out in France between Roman Catholics and Huguenots, which in Paris brought about the Massacre of St. Bartholomew's Day (1572); the Day of the Barricades (1588), when the Catholic League rose against Henry III; and the long resistance of the Parisians to the Protestant Henry of Navarre, who succeeded as Henry IV in 1589. Henry IV's siege in 1590 was unsuccessful, and only after his conversion to Catholicism did Paris submit to him (1594).

In Louis XIII's reign (1610–43) Paris expanded farther. On the Left Bank, outside the wall, the queen mother, Marie de Médicis, built the Luxembourg Palace, with its spacious gardens; along the Right Bank, west of the Tuileries, she laid out the Cours-la-Reine as a promenade for carriages. While the Marais north of the Place Royale was being reclaimed and developed, two uninhabited islets east of the *cité* were united to form the Île Saint-Louis. On the western fringe of the town, a quarter with straight streets was laid out north of Richelieu's new palace, the Palais-Cardinal (1624–36; later the Palais-Royal), which also had a magnificent garden; west of this there was more building and a new fortification was erected.

The war of the Fronde (1648–53) was the major event of the first two decades of Louis XIV's reign. From 1661, when Cardinal Mazarin died and Louis started his personal rule, Paris was dedicated to reflecting the glory of the monarch, even though he was early resolved to establish himself and the seat of his government outside of Paris (he chose Versailles). For the planning of the new splendours of Paris, the greatest part of the credit must go to Jean-Baptiste Colbert, the king's superintendent of buildings.

Work on the Louvre had been resumed in 1624 and was completed by Claude Perrault's magnificent colonnade (1667–74). The Tuileries Palace was altered and sumptuously decorated. Beyond its gardens to the west, outside the walls of Paris, the tree-planted avenues of the Champs-Élysées were laid out (1667); these were complemented, at the opposite end of Paris, by the Cours de Vincennes.

In 1702 the Marquis d'Argenson (Marc René de Voyer), who as lieutenant general of police succeeded the provosts of Paris, raised the number of districts from 16 to 20 (15 on the Right Bank, five on the Left). Paris had nearly 600,000 people, and from the Left Bank new suburbs were advancing toward the villages on the surrounding hills.

During the 18th century a great deal was done to improve and beautify Paris. Louis XV's temporary residence in the Tuileries during his younger days encouraged development nearby, so that the Faubourg Saint-Honoré expanded and became, like the Faubourg Saint-Germain, an aristocratic quarter. The garden of the Palais-Royal became a centre of elegant society. The Grands Boulevards began to be bordered with houses, including some fine mansions, and the eastern stretch became a fashionable promenade with little theatres and cafés. Villas built by nobles and financiers were scattered around this outlying sector. On the Left Bank the southern course of boulevards was laid out and the routes were lined with trees and houses. Some of the houses that had been built earlier

The
Wars of
Religion

on the bridges were razed in 1786–88; others remained until 1808. Water was supplied to both banks by two fire pumps, developed by Jacques-Constantin Périer and his father, Auguste-Charles. The wall of the farmers-general, built in the 1780s to facilitate the levying of duties on imports, represented the extension and the unity of Paris.

EVOLUTION OF THE MODERN CITY

The Revolution and Napoleon I. The French Revolution of 1789 destroyed those vestiges of the seigneurial systems that had remained in Paris and consolidated the status of Paris as the capital of a centralized France. The major events of the Revolution took place in Paris, including the storming of the Bastille (July 14, 1789); the conveying of the King and the National Constituent Assembly from Versailles to Paris (October 1789); the establishment of the numerous clubs in the convents of the old religious orders, Jacobins, Cordeliers, and Feuillants; the insurrection that heralded the abolition of the monarchy (Aug. 10, 1792); the execution of the King (Jan. 21, 1793) in the Place de la Révolution, not yet named Place de la Concorde; the most prolonged manifestation of the Terror (1793–94); and the series of coups d'état, from that of 9 Thermidor, year II (1794), to that of 18 Brumaire, year VIII (1799), which preceded the ascendancy of Napoleon Bonaparte.

Under the Thermidorians and the Directory the boulevard des Italiens became a resort of the fashionable and the frivolous, whereas the populace favoured the boulevard du Temple. After the inauguration of the First Empire, Napoleon in 1806 ordered the triumphal arches of the Carrousel and of the Étoile to be erected. While the Neoclassical style recalled imperial Rome, great works of public utility served to modernize Paris: the Bourse; new quays and bridges (the Arts, Jena, Austerlitz, and Saint-Louis bridges); the Ourcq and Saint-Martin canals; numerous fountains (such as the Palmier Fountain, on the site of the Châtelet); as well as slaughterhouses, marketplaces, the wine market, and the warehouses of Bercy.

The
Restoration
and the
July
Monarchy

Industrialization, in progress in the Napoleonic period, advanced rapidly under the Restoration (1814–30) and the July Monarchy (1830–48). Gas lighting was introduced; omnibus services began in 1828; and Paris got its first railway, which ran to Le Pecq, near Saint-Germain-en-Laye, in 1837. New districts grew up on the outskirts of Paris. Although the wall of the farmers-general remained the administrative boundary of Paris until 1859, it was decided in 1840 to reformat the capital with a longer military wall.

Napoleon III and Haussmann. Even by the mid-19th century, some areas of Paris had not been improved substantially for hundreds of years. Access from one centre to another and to the railway stations (which had become in effect the gateways of Paris) was difficult; moreover, overpopulation and rapid industrialization had brought squalor and misery, which account in part for the dominant role of Paris in the revolutions of both 1830 and 1848. Napoleon III, emperor from 1852 to 1870, enjoined his prefect of the Seine, Baron Haussmann, to remedy these problems.

Haussmann was the creator of modern Paris. A planner on the grand scale, he advocated straight arterial thoroughfares, symmetry, and advantageous vistas. He slashed the boulevards through the tangles of slums, began the modern sewer and water systems, gutted the Île de la Cité, rebuilt the ancient market of the Halles, and added four new Seine bridges and rebuilt three old ones. The brilliance and prosperity of Paris under Napoleon III were exemplified in the exhibitions held there in 1855 and 1867.

The Third Republic and after. The Franco-German War (1870–71), which brought the fall of the Second Empire and the siege of Paris, was followed by the Commune (1871). Under the Third Republic, Haussmann's projects were continued. Further international exhibitions (1878, 1889, 1900, and 1937) were the occasions for the building of monuments such as the Trocadéro (1878), the Eiffel Tower (1889), and the Grand Palais and Petit Palais, with the Alexandre III Bridge (1900), and for the reconstruction of the Trocadéro as the Chaillot Palace (1937). The Métro was constructed, commerce and industry annexed formerly residential districts, and the ever-expanding popu-

lation overflowed the old limits of Paris. Louis-Philippe's fortifications were abolished by a law of April 1919.

During the German occupation of Paris in World War II, the city was only slightly damaged. It was a centre for the activities of the Resistance movement, which culminated in the liberation of the city in August 1944.

The immediate postwar years were a time of eager intellectual activity but also of poverty and social tension. The housing shortage was grave, the psychological scars of the German occupation were slow to heal, and colonial wars and political instability lowered morale. Conditions gradually improved, especially after Charles de Gaulle returned to power in 1958. The city's economy improved, old buildings and neighbourhoods were cleaned up and renovated, and housing and commercial space were built.

In May 1968 Paris was rocked by a great student uprising, which swelled from scattered unrest among students in the Latin Quarter to a nationwide outbreak of labour strikes and protests. Attention was focused on Paris' economic and social problems, and the uprising was later seen as useful in hastening the modernization of French society. Paris, like many other Western cities, has come to terms with problems as diverse as high unemployment and politically motivated acts of terrorism. But these are among the few serious blemishes on a city of bright prosperity and dynamic self-confidence.

Particle Accelerators

A particle accelerator is a device that produces a beam of fast-moving, electrically charged atomic or subatomic particles. Physicists use accelerators in fundamental research on the structure of nuclei, the nature of nuclear forces, and the properties of nuclei not found in nature, such as the transuranic (heavier than uranium) elements and other unstable elements. Accelerators are also used for radioisotope production, industrial radiography, cancer therapy, sterilization of biological materials, polymerization of plastics, and in a certain form of radiocarbon dating. The largest accelerators are used in

research on the fundamental interactions of the elementary subatomic particles.

This article reviews the development of accelerators and delineates the various types and their distinguishing features. For specific information about the particles accelerated by these devices, see *ATOMS* and *SUBATOMIC PARTICLES*.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 111, 112, 127, and 723, and the *Index*.

GENERAL CONSIDERATIONS

The effectiveness of an accelerator is usually characterized by the kinetic energy, rather than the speed, of the particles. The unit of energy commonly used is the electron volt (eV), which is the energy acquired by a particle that has a charge of the same magnitude as that of the electron when it passes between electrodes that differ in potential by one volt. Related larger units are the kiloelectron volt (keV), which is 1,000 eV; the megaelectron volt (MeV; 1,000,000 eV); the gigaelectron volt (GeV; 1,000,000,000 eV); and the teraelectron volt (TeV; 1,000,000,000,000 eV). Compared with the quantities of energy encountered in everyday experience, even the TeV is a very small amount, about that of a mosquito in flight. The masses of the particles accelerated are so small, however, that kinetic energies in this range correspond to very high speeds: the particles in the smallest ion accelerators travel about 8,000 kilometres (5,000 miles) per second, about 3 percent of the speed of light.

The particles that are accelerated are electrons, positrons (positive electrons), or ionized atoms such as protons (ionized hydrogen), deuterons (ionized heavy hydrogen), alpha particles (ionized helium), or heavier ionized atoms. Sometimes the primary beam is used; in other cases, the primary beam is directed onto a target to produce a beam of secondary particles, such as X rays, neutrons, mesons, hyperons, or neutrinos. A few accelerators are operated as sources of the intense radiation, called synchrotron radiation, emitted by electrons moving at almost the speed of light along curved paths.

Every accelerator has three essential parts: a source of the particles to be accelerated, a vacuum chamber in which to accelerate them, and a source of the electric fields needed to effect the acceleration. Thermionic emission (the emission of electrons from the surface of a heated solid) provides electrons. Positrons are produced as secondary particles by an electron accelerator and then further accelerated. Positive and negative ions are produced by electric arc or glow discharges in a gas at low pressure in a chamber; a high-voltage electrode extracts the ions from the gas through a hole in the chamber. The region in which the particles are accelerated must be highly evacuated to keep the particles from being scattered out of the beam, or even stopped, by collisions with molecules of air.

Accelerators are differentiated by the arrangements of

the accelerating electric fields. In a linear accelerator, the path of the particles is a straight line, and the final energy of the particles is proportional to the sum of the voltages produced by the accelerating devices along that line. In a cyclic accelerator, the path of the particles is bent by the action of a magnetic field into a spiral or a closed curve that is approximately circular. In this case, the particles pass many times through the accelerating devices; the final energy depends on the magnitude of the voltages multiplied by the number of times the particles pass through. Because the total distance traveled by the particles in a cyclic accelerator may be more than a million kilometres, the cumulative effect of minute deviations from the desired trajectory would be dissipation of the beam. Therefore, the beam must be continually focused by the magnetic fields, which are precisely shaped by powerful magnets.

HISTORY

The motivation for most of the development of the various types of particle accelerators has been their application to research into the properties of atomic nuclei and subatomic particles. Starting with Ernest Rutherford's discovery in 1919 of a reaction between a nitrogen nucleus and an alpha particle, all research in nuclear physics until 1932 was performed with alpha particles from naturally radioactive elements. The natural alpha particles have kinetic energies as high as 8 MeV. It was not possible, however, to form natural alpha particles into a well-defined beam in which all the particles were of equal energy without reducing the number of particles so much that they were useless. Further experimentation required a beam of artificially accelerated ions, but there seemed little hope of generating laboratory voltages sufficient to accelerate ions to the desired energies. A calculation made by George Gamow (then at the University of Göttingen, in Germany) in 1928, however, indicated that considerably less energetic ions could be useful, and this stimulated attempts to build an accelerator that could provide a beam of particles suitable for nuclear research. The first successful experiments with artificially accelerated ions were performed at the University of Cambridge, England, by John Douglas Cockcroft and E.T.S. Walton in 1932. Using a voltage multiplier, they accelerated protons to energies as high as 710 keV and showed that these react with the lithium nucleus, the products being two energetic alpha particles.

Basic
compo-
nents

First
proton
accel-
erator

Other developments of that period demonstrated principles still employed in the design of particle accelerators. For example, Robert J. Van de Graaff had constructed the first belt-charged electrostatic high-voltage generator at Princeton University, in New Jersey, by 1931.

The principle of the resonance linear accelerator was demonstrated by Rolf Wideröe in 1928. At the Rhenish-Westphalian Technical University in Aachen, Ger., he had used alternating high voltage to accelerate ions of sodium and potassium to energies twice as high as those imparted by one application of the peak voltage. In 1931 Ernest O. Lawrence and his assistant David H. Sloan, at the University of California, Berkeley, employed high-frequency fields to accelerate mercury ions to more than 1.2 MeV. This work augmented Wideröe's achievement in accelerating heavy ions, but the ion beams were not useful in nuclear research.

The magnetic resonance accelerator, or cyclotron, was conceived by Lawrence as a modification of Wideröe's linear resonance accelerator. Lawrence's student M.S. Livingston demonstrated the principle of the cyclotron in 1931, producing 80-keV ions; in 1932 Lawrence and Livingston announced the acceleration of protons to more than 1 MeV. Later in the 1930s cyclotron energies reached about 25 MeV, and Van de Graaff generators, about 4 MeV. In 1940 Donald W. Kerst, applying the results of careful orbit calculations to the design of magnets, constructed the first betatron, a magnetic-induction accelerator of electrons, at the University of Illinois.

The rapid advance in the science of accelerating particles to high energies that has occurred since the end of World War II was initiated by Edwin Mattison McMillan, at Berkeley, and Vladimir Iosifovich Veksler, at Moscow, who in 1945 independently described the principle of phase stability, which removed an apparent limitation on the energy of resonance accelerators for protons (see below *Cyclotrons: Classical cyclotrons*) and made possible the construction of magnetic-resonance accelerators (called synchrotrons) for electrons. The principle was promptly demonstrated by the construction of a small synchrocyclotron at the University of California and an electron synchrotron in England. The first proton linear resonance accelerator was constructed soon thereafter. The large proton synchrotrons that have been built since then all depend on this principle.

In 1947 William W. Hansen, at Stanford University, California, constructed the first traveling-wave linear accelerator of electrons, exploiting microwave technology that had been developed for radar during World War II.

The progress in research made possible by raising the energies of protons led to the building of successively larger accelerators; the trend was ended only by the cost of fabricating the huge magnet rings required—the largest weighs approximately 40,000 tons. A means of increasing the energy without increasing the scale of the machines was provided by the demonstration, in 1952, by Livingston, Ernest D. Courant, and H.S. Snyder of the technique of alternating-gradient focusing (sometimes called strong focusing). Synchrotrons incorporating this principle needed magnets only $1/100$ the size that would be required otherwise. All recently constructed accelerators make use of alternating-gradient focusing.

In 1956 Kerst realized that, if two sets of particles could be maintained in intersecting orbits, it should be possible to observe interactions in which one particle collided with another moving in the opposite direction. Application of this idea requires the accumulation of accelerated particles in loops called storage rings (see below *Other types of accelerators*). The highest reaction energies now obtainable have been produced by the use of this technique.

CONSTANT-VOLTAGE ACCELERATORS

The simplest type of particle accelerator is constructed by mounting a particle source on one end of an insulated, evacuated tube and creating a high voltage between the ends, with the polarity such that the particles are impelled from the source toward the far end of the tube. Such an accelerator is necessarily linear, and the electrostatic field can be applied to a given particle only once (unless, as in

the tandem accelerator described below, the charge of the particle undergoes change in sign). The simplicity of concept soon gives way to complexity in execution when the electric potential exceeds 1,000,000 volts (1 megavolt, or 1 MV); these high voltages produce corona discharges and lightninglike sparks outside the accelerator, which dissipate the potential needed to accelerate the particles. Even more difficult to control are sparks within the equipment and, in positive-ion accelerators, unwanted secondary beams produced when the accelerated ions strike the end of the tube.

Because these discharges and sparks generally originate at sharply curved or pointed places on the surface of an electrode, the high-voltage electrode of a modern accelerator is made in the shape of a sphere or a cylinder with rounded ends or, in the case of a low-energy device, a box with rounded edges. The insulating columns that support the terminals are meticulously designed to suppress corona or sparking. Care also is devoted to the design of the accelerator tube to ensure the uniform distribution of the voltage along its length. The voltage that a structure will withstand is increased if the pressure of the gas surrounding it is increased, so direct-voltage accelerators commonly are mounted in tanks pressurized with mixtures of nitrogen and carbon dioxide or, in certain cases, the gas sulfur hexafluoride.

Voltage multipliers (cascade generators). The source of the high voltage for Cockcroft and Walton's pioneering experiments was a four-stage voltage multiplier assembled from four large rectifiers and high-voltage capacitors. Their circuit, in effect, combined four rectifier-type direct-voltage power supplies in series. The alternating voltage supplied by a high-voltage transformer was transmitted to the higher stages through an array of capacitors; a second group of capacitors kept the direct voltage constant. The final direct voltage would have been four times the peak voltage available from the transformer (200,000 volts) if corona discharge had not drained away considerable power. Nevertheless, the apparatus did accelerate protons to energies of 710 keV, sufficient to bring about the hoped-for result, a reaction with lithium nuclei. Their achievement, the first nuclear reaction effected by artificially accelerated particles, was recognized by the award of the Nobel Prize for Physics in 1951.

Cockcroft and Walton's system for building up high direct voltages can be extended to multiplication factors many times that originally demonstrated. Commercially available accelerators that reach 4 MeV are based on this circuitry.

Van de Graaff generators. In Van de Graaff generators, electric charge is transported to the high-voltage terminal on a rapidly moving belt of insulating material driven by a pulley mounted on the grounded end of the structure; a second pulley is enclosed within the large, spherical high-voltage terminal, as shown in Figure 1. The belt is charged by a comb of sharp needles with the points close to the belt a short distance from the place at which it moves clear of the grounded pulley. The comb is connected to a power supply that raises its potential to a few tens of kilovolts. The gas near the needle points is ionized by the intense electric field, and in the resulting corona discharge the ions are driven to the surface of the belt. The motion of the belt carries the charge into the high-voltage terminal and transfers it to another comb of needles, from which it passes to the outer surface of the terminal. A carefully designed Van de Graaff generator insulated by pressurized gas can be charged to a potential of about 20 megavolts.

In most constant-voltage accelerators, Van de Graaff generators are the source of high voltage, and most of the electrostatic proton accelerators still in use are two-stage tandem accelerators. These devices provide a beam with twice the energy that could be achieved by one application of the high voltage. Figure 2 is a diagram of a tandem accelerator. An ion source yields a beam of protons, which are accelerated to a low energy by an auxiliary high-voltage supply. This beam passes through a region containing a gas at low pressure, where some of the protons are converted to negative hydrogen ions by the addition of two electrons. As the mixture of charged particles moves through a magnetic field, those with negative charge are

deflected into the accelerator tube, and those with positive charge are deflected away. The beam of negative ions is then accelerated toward the positive high-voltage terminal. In this terminal, the particles pass through a thin carbon foil that strips off the two electrons, changing many of the negative ions back into positive ions (protons). These, now repelled by the positive terminal, are further accelerated through the second part of the tube. At the output end of the accelerator the protons are magnetically separated, as before, from other particles in the beam and directed to the target. In three- or four-stage tandem accelerators, two Van de Graaff generators are combined with the necessary additional provisions for changing the charge of the ions.

Figure 2: Two-stage tandem accelerator (see text).

Van de Graaff and Cockcroft-Walton generators also are utilized for accelerating electrons. The rates at which charge is transported in electron beams correspond to currents of several milliamperes; the beams deliver energy at rates best expressed in terms of kilowatts. These intense beams are used for sterilization, industrial radiography, cancer therapy, and polymerization of plastics.

BETATRONS

A betatron is a type of accelerator that is useful only for electrons, which sometimes are called beta particles; hence the name. The electrons in a betatron move in a circle under the influence of a magnetic field that is caused to grow stronger as the energy of the electrons is increased.

The magnet that produces the field on the electron orbit also produces a field in the interior of the orbit. The increase in the strength of this field with time produces an electric field that accelerates the electrons. If the average magnetic field inside the orbit is always twice as strong as the magnetic field on the orbit, the radius of the orbit remains constant, so that the acceleration chamber can be made in the shape of a torus, or doughnut, as shown in Figure 3. The poles of the magnet are tapered to cause the field near the orbit to weaken with increasing radius. This focuses the beam by causing any particle that strays from the orbit to be subjected to forces that restore it toward its proper path. The theory of this focusing was first worked out for the betatron; by analogy, the oscillations of particles about their equilibrium orbits in all cyclic accelerators are called betatron oscillations.

Betatron oscillations

Just after the sinusoidally varying strength of the magnetic field has passed through zero and starts increasing in the direction proper to guide the electrons in their circular orbit, a burst of electrons is sent into the doughnut, where—in a 20-MeV betatron—they gain about 100 eV per revolution and traverse the orbit about 200,000 times during the acceleration. The acceleration lasts for one-quarter of the magnet cycle until the magnetic field has reached its greatest strength, whereupon the orbit is caused to shrink, deflecting the electrons onto a target to produce a beam of intense X rays.

Figure 3: (Top) Cross section and (bottom) plan view of a betatron (see text).

The practical limit on the energy imparted by a betatron is set by the emission of electromagnetic energy by electrons moving in curved paths. The intensity of this radiation, commonly called synchrotron radiation (see below *Synchrotrons: Electron synchrotrons*), rises rapidly as the speed of the electrons increases. The largest betatron accelerates electrons to 300 MeV, sufficient to produce pions in its target; the energy loss by its electrons through radiation (a few percent) is compensated by changing the relation between the field on the orbit and the average field inside the orbit. At higher energies this compensation would not be feasible.

Betatrons are now commercially manufactured, principally for use as sources of highly energetic ("hard") X rays for industrial and medical radiography.

CYCLOTRONS

The magnetic resonance accelerator, or cyclotron, was the first cyclic accelerator and the first resonance accelerator that produced particles energetic enough to be useful for nuclear research. For many years the highest particle energies were those imparted by cyclotrons modeled upon Lawrence's archetype. In these devices, commonly called classical cyclotrons, the accelerating electric field oscillates at a fixed frequency and the guiding magnetic field has a fixed intensity.

Classical cyclotrons. The key to the operation of a cyclotron is the fact that the orbits of ions in a uniform magnetic field are isochronous; that is, the time taken by a particle of a given mass to make one complete circuit is the same at any speed or energy as long as the speed is much less than that of light. (As the speed of a particle

Iso-
chronous
ion orbits

approaches that of light, its mass undergoes the increase—predicted by the theory of relativity—that is called relativistic increase.) This isochronicity makes it possible for a high voltage, reversing in polarity at a constant frequency, to accelerate a particle many times. As shown in Figure 4, an ion source is located at the centre of an evacuated chamber that has the shape of a short cylinder, like a pillbox, between the poles of an electromagnet that creates a uniform field perpendicular to the flat faces. The accelerating voltage is applied by electrodes, called dees from their shape: each is a D-shaped half of a pillbox. The source of the voltage is an oscillator—similar to a radio transmitter—that operates at a frequency equal to the frequency of revolution of the particles in the magnetic field. The electric fields caused by this accelerating voltage are concentrated in the gap between the dees; there is no electric field inside the dees. The path of the particle inside the dees is therefore circular. Each time the particle crosses the gap between the dees it is accelerated, because in the time between these crossings the direction of the field reverses. The path of the particle is thus a spirallike series of semicircles of continually increasing radius.

Figure 4: Plan view of the classical cyclotron.

Some means of focusing is required, as otherwise a particle that starts out in a direction making a small angle with the orbital plane will spiral into the dees and be lost. While the energy of the particle is still low, this focusing is supplied by the accelerating electric fields; after the particle has gained significant energy, focusing is a consequence of a slight weakening of the magnetic field toward the peripheries of the dees as in the betatron.

The energy gained by a particle in a classical cyclotron is limited by the relativistic increase in the mass of the particle, a phenomenon that causes the orbital frequency to decrease and the particles to get out of phase with the alternating voltage. This effect can be reduced by applying higher accelerating voltages to shorten the overall acceleration time. The highest energy imparted to protons in a classical cyclotron is less than 25 MeV, and this achievement requires the imposition of hundreds of kilovolts to the dees. The beam current in a classical cyclotron operated at high voltages can be as high as five milliamperes; intensities of this magnitude are very useful in the synthesis of radioisotopes.

Synchrocyclotrons. Cyclotrons in which the frequency of the accelerating voltage is changed as the particles are accelerated are called synchrocyclotrons, frequency-modulated (FM) cyclotrons, or, in the Soviet Union, phasotrons. Because of the modulation the particles do not get out of phase with the accelerating voltage, so that the relativistic mass increase does not impose a limit on the energy. Moreover, the magnetic focusing can be made stronger, so that the magnetic field need not be so precisely shaped.

Because of the phenomenon of phase stability, it is unnecessary to program the frequency of the accelerating voltage precisely to follow the decreasing frequency of revolution of the particles as they are accelerated. To see how phase stability affects the operation of a cyclotron, consider a particle moving in an orbit. Let the frequency of the accelerating voltage match the orbital frequency of this particle. If the particle crosses the accelerating gap at the time the accelerating voltage is zero, its energy and orbital radius will remain unchanged—it is said to be in

equilibrium. There are two such times during each cycle of the accelerating voltage; only one of these (that at which the voltage is falling, rather than rising, through zero) corresponds to stable equilibrium. If a particle should arrive a short time before the voltage has fallen to zero, it is accelerated. Its speed therefore increases, but the radius of its orbit increases by an even larger proportion, so that the particle will take longer to reach the gap again and will next cross it at a time closer to that at which it would receive no acceleration. If, on the other hand, the particle reaches the gap a short time after the voltage has fallen through zero, its speed is diminished, and the radius of its orbit is diminished even more, so that it takes less time to reach the gap again, arriving—like the other particle—at a time closer to that at which it receives no acceleration. This phenomenon, by which the trajectories of errant particles are continually corrected, confers stability on the entire beam and makes it possible to accelerate the particles uniformly, by modulating the frequency, without dispersing them. The small periodic variations of the particles about the equilibrium values of phase and energy are called synchrotron oscillations.

In the operation of a synchrocyclotron, particles are accelerated from the ion source when the frequency of the accelerating voltage is equal to the orbital frequency of the particles in the central field. As the frequency of the voltage falls, the particles, on the average, encounter an accelerating field. They oscillate in phase but around a value that corresponds to the average acceleration. The particles reach the maximum energy in bunches, one for each time the accelerating frequency goes through its program. The intensity of the beam is a few microamperes, much lower than that of a classical cyclotron.

Large synchrocyclotrons have been constructed in many countries. They are used primarily for research with secondary beams of pi-mesons. The practical upper limit of the energy of a synchrocyclotron, set by the cost of the huge magnets required, is about 1 GeV.

Sector-focused cyclotrons. The sector-focused cyclotron is another modification of the classical cyclotron that also evades relativistic constraint on its maximum energy. Its advantage over the synchrocyclotron is that the beam is not pulsed and is more intense. The frequency of the accelerating voltage is constant, and the orbital frequency of the particles is kept constant as they are accelerated by causing the average magnetic field on the orbit to increase with orbit radius. This ordinarily would cause the beam to spread out in the direction of the magnetic field, but in sector-focused cyclotrons the magnetic field varies with the angular position as well as with the radius; this produces the equivalent of alternating-gradient focusing (see below *Synchrotrons*). This principle was discovered in 1938 by Llewellyn H. Thomas, then at Ohio State University, but was not applied until the alternating-gradient synchrotron was invented in 1952. Several of these devices, sometimes called azimuthally varying field (AVF) cyclotrons, have been built for use in nuclear and medical research.

LINEAR RESONANCE ACCELERATORS

The technology required to design a useful linear resonance accelerator was not developed until after 1940. These accelerators require very powerful sources of radio-frequency accelerating voltage. Further, a practical linear accelerator for heavy particles, such as protons, must make use of the principle of phase stability.

Linear accelerators fall into two distinct types: standing-wave linear accelerators (used for heavy particles) and traveling-wave linear accelerators (used to accelerate electrons). The reason for the difference is that after electrons have been accelerated to a few MeV in the first few metres of a typical accelerator, they have speeds very close to that of light. Therefore, if the accelerating wave also moves at the speed of light, the particles do not get out of phase, as their speeds do not change. Protons, on the other hand, must reach much higher energies before their speeds can be taken as constant, so that the accelerator design must allow for the prolonged increase in speed.

Linear electron accelerators. The force that acts on electrons in a traveling-wave accelerator is provided by an

electromagnetic field with a frequency near 3,000 MHz (1 MHz = 1,000,000 Hertz, or 1,000,000 cycles per second)—a microwave. The acceleration chamber is an evacuated cylindrical pipe that serves as a wave guide for the accelerating field. The phase velocity of an electromagnetic wave in a cylindrical pipe is greater than the velocity of light in free space, so the wave must be slowed down by the insertion of metal irises a few centimetres apart in the pipe, as shown in Figure 5. In the intense field, the electrons gain about 2 MeV every 30 centimetres or so. The microwaves are produced by large klystrons (high-frequency vacuum-tube amplifiers) with power outputs of 20–30 megawatts. Because sources of radio-frequency power of this magnitude must be operated intermittently (they will not survive continuous service), the beams from these accelerators are delivered in short bursts.

Pulses of electrons are injected at energies of a few hundred keV (that is, speeds about half that of light). The accelerator is so designed that, during the first part of the acceleration, the electrons are caused to gather into

Figure 5: Wave guide acceleration chamber of a linear electron accelerator showing the irises, which decrease the phase velocity of the wave (see text).

bunches, which then are accelerated nearly to the speed of light. Subsequently, the electrons move with the crest of the electromagnetic wave.

Linear electron accelerators are manufactured commercially. They are used for radiography, for cancer treatment, and as injectors for electron synchrotrons.

(Top) This national facility for research in subatomic physics has a 3.2-kilometre linear accelerator (upper centre) that produces the highest-energy electron beams in the world. (Bottom) The accelerator tube, which measures about 10 centimetres in diameter, is housed in an underground tunnel. The larger pipe beneath the tube contains optical targets and serves to confine a laser beam used to align the accelerating structure.

Stanford linear accelerator centre) is the source of very energetic beams of electrons and positrons (Figure 6). It has an output energy capacity of 50 GeV, and electron-beam currents in excess of 50 microamperes and positron-beam currents of more than 1 microampere can be obtained. The accelerator is used for research on subatomic particles and for filling the electron-positron storage ring called SPEAR (Stanford positron-electron asymmetric ring).

Linear electron accelerators constructed of superconducting materials have been developed. The advantage offered by such a device is low power consumption, allowing production of a continuous, rather than a pulsed, beam.

Linear proton accelerators. The design principle applied in linear accelerators for protons was originated by Luis Alvarez at Berkeley in 1946. It is based on the formation of standing electromagnetic waves in a long cylindrical metal tank, or cavity, as it is sometimes called. In the design that has been adopted, the electric field is parallel to the axis of the tank. Most of these accelerators operate at frequencies of about 200 MHz.

During the time required for a proton to traverse one of these tanks, the accelerating electric fields undergo many reversals of direction. In Alvarez' design, the decelerating effect of the field during the intervals when it opposes the motion of the particles is prevented by installing on the axis of the tank a number of "drift tubes," as shown in Figure 7. The electric field is zero inside the drift tubes, and if their lengths are properly chosen, the protons cross the gap between adjacent drift tubes when the direction of the field produces acceleration and are shielded by the drift tubes when the field in the tank would decelerate them. The lengths of the drift tubes are proportional to the speeds of the particles that pass through them.

Figure 7: Linear proton resonance accelerator containing n metallic drift tubes (see text).

It would appear that any error in the magnitude of the accelerating voltages would cause the particles to lose the synchronism with the fields needed for proper operation of the device, but the principle of phase stability reduces to a manageable magnitude the need for precision in construction. It also makes possible an intense beam because protons can be accelerated in a stable manner even if they do not cross the gaps at exactly the intended times. The principle is the same as that of a synchrotron, except that the gap-crossing time for stable phase oscillations coincides with the rise, rather than the fall, of the voltage wave. If a proton arrives at the accelerating gap late, it receives a larger-than-normal increment of energy, enabling it to "catch up."

A very large amount of radio-frequency power is required to produce the accelerating voltages. This makes it necessary for linear proton accelerators to be operated in a pulsed mode. They are supplied with protons accelerated to about 750 keV by a Cockcroft-Walton generator. The entering beam passes through an accelerating radio-frequency cavity a short distance upstream from the main linear accelerator, so that as the particles pass through the first drift tubes, they are already bunched.

The intense pulses of protons emerging from linear accelerators make these devices ideal as injectors for proton synchrotrons. Their high cost has precluded their construction for other uses except as meson factories. The largest linear accelerators used as injectors are located at the Brookhaven National Laboratory, Upton, N.Y., and at the Fermi National Accelerator Laboratory ("Fermilab"), Batavia, Ill. These accelerators are very similar in construction. The beam energy is 200 MeV, and the peak beam current is more than 100 milliamperes. They are needed as injectors only for a short time every few seconds; most of the beams are used for radioisotope production and medical applications.

At the Los Alamos Meson Physics Facility in New Mexico, a linear proton accelerator has been constructed for nuclear research and as a meson factory. The protons are accelerated to 100 MeV in Alvarez-type tanks and then to 800 MeV in a traveling-wave linear accelerator similar to those used for electrons but operated at a frequency of 805 MHz. The apparatus produces a beam carrying a current in excess of one milliampere, which delivers a power of more than 800 kilowatts. Its intense secondary beam of low-energy pi-mesons has been applied in experimental cancer therapy.

Heavy-ion linear accelerators. For research with ions more massive than the alpha particle, a relatively high energy per unit of atomic weight is desirable. The production of beams of heavy charged particles at a reasonable cost is practical only if the particles are highly ionized, because the energy gained by an ion is proportional to its charge. The superHILAC at Berkeley ("hilac" is an acronym from *heavy-ion linear accelerator*) consists of two Alvarez accelerators operating at 70 MHz. The ions, after acceleration by the first of these machines, have a kinetic energy of 1.2 MeV per unit of atomic weight; this energy corresponds to a speed one-twentieth of the speed of light. These ions then pass through a thin carbon foil, which strips off many electrons. After stripping, the ions (now more highly charged) are accelerated by the second machine to an energy of 8.5 MeV per unit of atomic weight, corresponding to a speed about one-seventh of the speed of light. Ions as heavy as those of uranium may be accelerated by the superHILAC. Heavy-ion beams have been used in the search for new heavy elements. For example, in 1974 a U.S. research group employed the superHILAC to synthesize the element with atomic number 106.

SYNCHROTRONS

As the particles in a synchrotron are accelerated, the strength of the magnetic field is increased to keep the radius of the orbit approximately constant. This technique has the advantage that the magnet required to form the particle orbits is much smaller than that needed in a cyclotron to produce the same particle energies. The acceleration is effected by radio-frequency voltages, while the synchronism is maintained by the principle of phase stability. The rate of increase of the energy of the particles is set by the rate of the strengthening of the magnetic field. The peak accelerating voltage is ordinarily about twice as large as the average energy gain per turn would require, to provide the margin for phase stability. Particles can be stably accelerated with a range of energies and phases with respect to the accelerating voltage, and very intense beams can be produced.

The magnetic field must be shaped so as to focus the beam of particles. In early synchrotrons the field was caused to decrease slightly with increasing radius, as in a betatron. This arrangement resulted in a weak focusing effect that was adequate for machines in which the dimensions of the magnet gap could be appreciable in comparison with the radius of the orbit. The magnitude of the magnetic fields that may be used is limited by the saturation of the iron components that shape the field and provide a path for the magnetic flux. Therefore, if the energy of accelerators is to be increased, their radius must be increased correspondingly. For relativistic particles, the radius is proportional to the kinetic energy. The magnet of a synchrotron with weak focusing, designed to have a reasonable intensity, would have a mass proportional to the cube of the radius. It is clear that increasing the energy beyond some point—in practice, about 10 GeV—would be very expensive.

The introduction of alternating-gradient focusing provided the solution to this problem and made possible the development of synchrotrons with much higher energies. The idea was promptly incorporated in the design of the 33-GeV proton synchrotron at the Brookhaven National Laboratory and the 28-GeV machine at the European Organization for Nuclear Research (CERN), near Geneva.

The magnetic fields in an alternating-gradient synchrotron vary much more strongly with radius than those used for weak focusing. A magnet with pole-tips shaped as

Alternating-gradient focusing

Use of drift tubes

Injectors for proton synchrotrons

shown in cross section *ab* in Figure 8 produces a magnetic field that sharply decreases with increasing radius. To the particle beam, this magnetic field acts like a lens with a very short focal length. In the vertical direction (the orbital plane is horizontal) it focuses the beam, but in the radial direction it is almost equally defocusing. A magnet with the pole-tip shapes shown in cross section *cd* in Figure 8 produces a field that strongly increases with increasing radius. This field is defocusing in the vertical direction and focusing in the radial direction. Although pairing such magnetic fields results in partial cancellation, the overall effect is to provide focusing in both directions. The ring of magnetic field is created by a large number of magnets, with the two types of pole-tips alternating, as shown at the top of Figure 8. The beam, in effect, passes through a succession of lenses as the particles move around the ring, producing a large beam current in a vacuum chamber of small cross section.

Figure 8: Synchrotron with alternating-gradient focusing, showing the placement of the two types of magnets. Shown at the bottom is a cross section of a typical magnet with the two different types of pole-tips used (see text).

Particles accelerated in a large synchrotron are commonly injected by a linear accelerator and are steered into the ring by a device called an inflector. They begin their acceleration in the ring when the magnetic field is small. As the field created by the ring magnets increases, the injection pulse is timed so that the field and the energy of the particles from the linear accelerator are properly matched. The radio-frequency accelerating devices, usually called cavities, operate on the same principle as a short section of a linear accelerator. The useful beam may be either the accelerated particles that have been extracted from the ring by special magnets or secondary particles ejected from a target that is introduced into the beam.

Electron synchrotrons. The invention of the syn-

chrotron immediately solved the problem of the limit on the acceleration of electrons that had been imposed by the radiation of electrons moving in circular orbits. This radiation has been named synchrotron radiation because it was first observed during the operation of a 70-MeV electron synchrotron built at the General Electric Company research laboratory, Schenectady, N.Y. A betatron can accelerate electrons to 300 MeV only if the radiation is carefully compensated, but a synchrotron needs only a modest increase in the radio-frequency accelerating voltage. As the particles lose energy by radiation, their average phase with respect to the accelerating voltage simply shifts slightly so as to increase their average energy gain per revolution.

Several similar electron synchrotrons with energies near 300 MeV were constructed in several countries, the first being the one built in 1949 at Berkeley under McMillan's direction. In these accelerators, the electrons were injected by a pulsed electron gun, and the initial acceleration from 50–100 keV to 2–3 MeV was induced as in a betatron. The magnets were specifically designed to provide the accelerating flux in the initial part of the magnet cycle; during this time, the speed of the electrons increased from about 50 percent of the speed of light to more than 95 percent. At this point, acceleration by the radio-frequency cavity supervened, and the small further change in speed was accommodated by a 5-percent change in the radius of the orbit.

Strong focusing was first applied to the electron synchrotron in the 1.2-GeV device built in 1954 at Cornell University in New York. All large electron synchrotrons now are equipped with linear accelerators as injectors. The practical limit on the energy of an electron synchrotron is set by the cost of the radio-frequency system needed to restore the energy the electrons lose by radiation. To minimize this energy loss, the acceleration time is made as short as possible (a few milliseconds) and the magnetic fields are kept weak. By 1982 superconducting radio-frequency accelerating cavities had been successfully tested in the electron synchrotron.

Proton synchrotrons. The mode of operation of a proton synchrotron is very similar to that of an electron synchrotron, but there are two important differences. First, because the speed of a proton does not approach the speed of light until its energy is well above 1 GeV, the frequency of the accelerating voltage must be modulated to keep it proportional to the speed of the particle during the initial stage of the acceleration. Second, protons do not lose a significant amount of energy by radiation at energies attainable by present-day techniques. The limit on the energy of a proton synchrotron is therefore set by the cost of the magnet ring, which increases only as the first power of the energy, or even more slowly. The highest-energy particle accelerators yet built are proton synchrotrons.

The first proton synchrotron to operate (1956) was the 3-GeV Cosmotron at Brookhaven. It, and other accelerators that soon followed, had weakly focusing magnets. The 28-GeV proton synchrotron at CERN and the 33-GeV machine at Brookhaven made use of the principle of alternating-gradient focusing but not without complications. Such focusing is so strong that the time required for a particle to complete one orbit does not depend strongly on the energy of the particle. Therefore, for the energy range (which may extend to several GeV) within which acceleration appreciably affects the speed of the particle, phase stability operates as it does in a linear accelerator: the region of stable phase is on the rising side of the time curve of the accelerating voltage. At higher energies, however, the speed of the proton is substantially constant, and the region of stable phase is on the falling side of the voltage curve, as it is in a synchrocyclotron. At the point that divides these regions, called the transition energy, there is no phase stability. At Brookhaven a model electron accelerator was built to demonstrate that the beam could be accelerated through the transition energy in a stable manner.

A large proton synchrotron called the Tevatron at Fermilab was designed to operate at 1,000 GeV or 1 TeV, the energy that gives the device its name. The intense

Synchrotron radiation

Fermilab Tevatron

Figure 9: The tunnel of the main 400-GeV accelerator at Fermilab. The magnets of the upper ring for the main accelerator are of the conventional type. Those of the lower ring for the Tevatron are superconducting (see text).

By courtesy of Fermi National Accelerator Laboratory

magnetic fields needed to guide and focus such an energetic proton beam are provided by magnets with windings made of a superconducting alloy, and the whole ring is kept at 4.5 kelvins by liquid helium. The Tevatron was built in the same tunnel as the main ring of conventional magnets of the 400-GeV accelerator that went into operation in 1972 and now serves as the injector for the Tevatron (Figure 9). The proton beam originates in a 750-keV Cockcroft-Walton generator and is accelerated to 200 MeV in a linear accelerator. The protons are then injected into a "booster" synchrotron in which they are accelerated to 8 GeV (99.4 percent of the speed of light). While the magnetic field of the main accelerator ring is held at a strength of 400 gauss, 12 pulses of protons are injected into the ring from the booster. The fields in the bending and focusing magnets are then strengthened as the protons are accelerated to 150 GeV in 1.5 seconds. The protons are then transferred to the ring of superconducting magnets for final acceleration. Figure 10 shows the sequence of processes occurring during one cycle in the operation of the main ring and the superconducting ring to produce and extract a beam of 800-GeV protons. The device completes one cycle per minute, including the extraction of the beam, which occupies about 20 seconds. Prolonging the beam extraction over this extended interval is very important for the proper interpretation of the experiments. In a typical experiment, several particles (called secondary particles) are ejected from a target when an accelerated particle (the primary particle) strikes it. The goal of the experiment is the study of either this production process or the properties of the secondary particles that result from it. These secondary particles produce signals as they pass through many detectors, and it is assumed that all the signals produced at the same time arise from particles

Ring of superconducting magnets

coming from the interaction of a single primary particle with the target. If many accelerated particles arrived at the target within too short an interval, numerous interactions would occur at practically the same time, resulting in accidental coincidences that would obscure the effects being searched for.

The two large rings at Fermilab are 1,000 metres in radius; their circumference is 6.3 kilometres. In these rings the functions of bending the beam around its orbit and focusing the beam are separated. Each ring has 774 bending magnets; the main ring has 180 focusing magnets, the superconducting ring has 216. Injection, acceleration, and extraction of the beam take place in six straight sections free from magnets. The beam from this accelerator is divided to serve many experimental areas. Figure 11 shows a plan of the accelerator and experimental areas.

An accelerator very similar to the Fermilab 400-GeV synchrotron went into operation in 1976 at CERN, where a 28-GeV proton synchrotron serves as the booster accelerator. In 1981 it was modified to permit operation as a colliding-beam storage ring (see below). Since then it has been used alternately as a collider, with beams of 315-GeV protons and antiprotons, and as a 450-GeV fixed-target accelerator.

Figure 11: The plan of the Fermi National Accelerator Laboratory accelerator and experimental areas. The angles between the branches of the beam are exaggerated for clarity.

Proton synchrotrons are in operation in laboratories in several countries; they all are used for research into the properties of subatomic particles.

OTHER TYPES OF ACCELERATORS

Storage rings. Although particles are sometimes accelerated in storage rings, the main purpose of these rings is to make possible energetic interactions between beams of particles moving in opposite directions. When a moving object strikes an identical object that is at rest, at most half of the kinetic energy of the moving object is available to produce heat or to deform the objects; the remainder is accounted for by the motions of the objects after the encounter. If, however, the two objects are in motion in opposite directions with equal speeds, then all the kinetic energy is available to produce heat or deformation at the instant of collision. If the objects stick together, the combination is at rest after the collision. For particles with speeds close to that of light, the effect is accentuated. If a 400-GeV proton strikes a proton at rest, only 27.4 GeV are available for the interaction; the remainder produces motion of the particles. On the other hand, if two 31.4-GeV protons collide, 62.3 GeV are available for the interaction (the collision is not quite "head on").

In a target of liquid or solid matter, the number of particles per unit volume accessible to an accelerated beam is large, but, when the target of one beam is another beam, the number of particles interacting is much smaller: the rate of interactions is proportional to the product of the currents in the two beams. Kerst realized in 1956 that, though the beam current in a high-energy accelerator is small, the currents circulating in the magnet rings are effectively much larger because of the high orbital frequency of the particles. Thus, if the colliding beams are circulat-

Interactions of particle beams

Colliding-beam systems

ing in such rings, useful experiments on the interactions could be carried out. In a colliding-beam apparatus, the two beams may be made up of identical particles (e.g., two beams of protons), in which case the installation consists of two separate rings of magnets. In one ring, the magnetic fields guide the particles clockwise; in the other, the fields are oriented in the opposite direction so as to guide the particles counterclockwise. The rings intersect at "interaction regions," where the beams collide. In other cases, the two beams are composed of particles of opposite charge (e.g., electrons and positrons, or protons and antiprotons). Such beams circulate in opposite directions in the same vacuum chamber, guided by the same magnets. The particles are bunched so that they collide only in the interaction regions.

The highest interaction energies are at present, and will be in the future, achieved in storage rings. This places the research with them at the very forefront of the quest for knowledge, even though many types of experiments cannot be conducted with storage rings. This is true partly because the number of interactions in a storage ring is a small fraction of that occurring in a stationary target and partly because storage beams do not produce intense beams of secondary particles.

Electron storage rings. Many storage rings have been constructed to study the interactions of electrons with positrons. The principal centres of this research are Palo Alto, Calif.; Orsay, Fr.; Hamburg, W.Ger.; Frascati, Italy; and Novosibirsk, Russian S.F.S.R.

The manner of operation of a typical electron-positron colliding-beam device is shown in Figure 12. Since the signs of their electric charges are opposite, electrons and positrons circulate in opposite directions in a magnet ring. The figure shows a linear electron accelerator for filling the ring; a synchrotron can be used instead. The deflecting magnet sends electrons to an injection point on the ring so that they circulate clockwise. Positrons are created by high-energy electrons in a target, called a converter, and then accelerated by the second stage of the linear accelerator. The deflecting magnet sends them to an injection point so that they circulate counterclockwise. Because of the radiation of energy by the particles, it is necessary to have accelerating cavities if the energy of the particles is to be kept fixed. The accelerating system causes the particles to circulate in bunches so that the collisions take place in only a few places in the ring. This sparsity of intersections simplifies the operation by minimizing the disruption of each beam caused by interactions with the other, allowing more intense beams to be collected and used in the ring. The detection equipment is positioned near the points where the beams intersect.

Figure 12: Storage ring with electron-positron colliding beams (see text).

The electrons and positrons in a storage ring emit synchrotron radiation at very great rates—more than a megawatt in some installations. From a high-energy storage ring, the wavelength of this radiation extends into the X-ray region. These storage rings now constitute the brightest sources of electromagnetic radiation available in the ultraviolet and X-ray regions. This radiation is increasingly useful for research in solid-state physics, biophysics, and chemical physics; a few electron storage rings of relatively low energy are operated solely for this purpose.

Proton storage rings. The highest interaction energies have been achieved in collisions between protons and antiprotons circulating in opposite directions in a storage ring. The high energy is possible because protons do not dissipate significant energy in the form of synchrotron

radiation, as do electrons. Creation of an intense beam of antiprotons required techniques (developed by Simon van der Meer at CERN) to reduce the amplitude of betatron oscillations and to bring all the particles to the same energy. Antiprotons have been produced at CERN by directing protons from a 27-GeV synchrotron onto a copper target. This process is very inefficient: about one million protons must strike the target to produce each antiproton. Furthermore, the antiprotons emerge from the target with random energies and directions. They are collected by magnetic fields into a diffuse beam that is injected into a small storage ring with a large cross-sectional area. As the antiprotons circulate in this ring, electronic devices sense the deviations from the desired orbit and apply corrective forces that focus the particles into a narrow beam of uniform energy. To accumulate enough antiprotons to make up a useful beam in the large storage ring at CERN takes about 24 hours. They then are accelerated to 315 GeV and allowed to collide with 315-GeV protons circulating in the opposite direction; the interaction energy is 630 GeV.

Impulse accelerators. Primarily for use in research on thermonuclear fusion of hydrogen isotopes, several high-intensity electron accelerators have been constructed. One type resembles a string of beads in which each bead is a torus of laminated iron and the string is the vacuum tube. The iron toruses constitute the cores of pulse transformers, and the beam of electrons, in effect, forms the secondary windings of all of the transformers, which are connected in series. The primaries are all connected in parallel and are powered by the discharge of a large bank of capacitors. These accelerators produce beams with energies between 1 and 9 MeV and currents between 200 and 200,000 amperes. The pulses are very brief, lasting about 50 nanoseconds. Besides their application to thermonuclear fusion, such accelerators are utilized for flash radiography, research on collective ion acceleration, microwave production, and laser excitation.

Pascal

Blaise Pascal, a mathematician, physicist, religious philosopher, and master of French prose, laid the foundation for the modern theory of probabilities, formulated what came to be known as Pascal's law of pressure, and propagated a religious doctrine that taught the experience of God through the heart rather than through reason. The establishment of his principle of intuitionism had an impact on such later philosophers as Jean-Jacques Rousseau and Henri Bergson and also on the Existentialists.

Pascal, red crayon drawing by Jean Domat, c. 1649. In the Bibliothèque Nationale, Paris.

Pascal's life to the Port-Royal years. Pascal was born on June 19, 1623, at Clermont-Ferrand, France, where his father, Étienne Pascal, was presiding judge of the tax court. His mother died in 1626, and in 1631 the family moved to Paris. Étienne, who was respected as a mathematician, devoted himself henceforth to the education of his children. While his sister Jacqueline (born in 1625) figured as an infant prodigy in literary circles, Blaise proved himself no less precocious in mathematics. In 1640 he wrote an essay on conic sections, *Essai pour les coniques*, based on his study of the now classical work of Girard Desargues on synthetic projective geometry. The young man's work, which was highly successful in the world of mathematics, aroused the envy of no less a personage than the great French Rationalist and mathematician René Descartes. Between 1642 and 1644, Pascal conceived and constructed a calculating device to help his father—who in 1639 had been appointed intendant (local administrator) at Rouen—in his tax computations. The machine was regarded by Pascal's contemporaries as his main claim to fame, and with reason, for in a sense it was the first digital calculator since it operated by counting integers. The significance of this contribution explains the youthful pride that appears in his dedication of the machine to the chancellor of France, Pierre Seguier, in 1644.

Until 1646 the Pascal family held strictly Roman Catholic principles, though they often substituted *l'honnêteté* ("polite respectability") for inward religion. An illness of his father, however, brought Blaise into contact with a more profound expression of religion, for he met two disciples

of the abbé de Saint-Cyran, who, as director of the convent of Port-Royal, had brought the austere moral and theological conceptions of Jansenism into the life and thought of the convent. Jansenism was a 17th-century form of Augustinianism in the Roman Catholic Church. It repudiated free will, accepted predestination, and taught that divine grace, rather than good works, was the key to salvation. The convent at Port-Royal had become the centre for the dissemination of the doctrine. Pascal himself was the first to feel the necessity of entirely turning away from the world to God, and he won his family over to the spiritual life in 1646. His letters indicate that for several years he was his family's spiritual adviser, but the conflict within himself—between the world and ascetic life—was not yet resolved. Absorbed again in his scientific interests, he tested the theories of Galileo and Evangelista Torricelli (an Italian physicist who discovered the principle of the barometer). To do so, he reproduced and amplified experiments on atmospheric pressure by constructing mercury barometers and measuring air pressure, both in Paris and on the top of a mountain overlooking Clermont-Ferrand. These tests paved the way for further studies in hydrodynamics and hydrostatics. While experimenting, Pascal invented the syringe and created the hydraulic press, an instrument based upon the principle that became known as Pascal's law: pressure applied to a confined liquid is transmitted undiminished through the liquid in all directions regardless of the area to which the pressure is applied. His publications on the problem of the vacuum (1647–48) added to his reputation. When he fell ill from overwork, his doctors advised him to seek distractions; but what has been described as Pascal's "worldly period" (1651–54) was, in fact, primarily a period of intense scientific work, during which he composed treatises on the equilibrium of liquid solutions, on the weight and density of air, and on the arithmetic triangle: *Traité de l'équilibre des liqueurs et de la pesanteur de la masse de l'air* (Eng. trans., *The Physical Treatises of Pascal*, 1937) and also his *Traité du triangle arithmétique*. In the last treatise, a fragment of the *De Alea Geometriae*, he laid the foundations for the calculus of probabilities. By the end of 1653, however, he had begun to feel religious scruples; and the "night of fire," an intense, perhaps mystical "conversion" that he experienced on November 23, 1654, he believed to be the beginning of a new life. He entered Port-Royal in January 1655, and though he never became one of the solitaires, he thereafter wrote only at their request and never again published in his own name. The two works for which he is chiefly known, *Les Provinciales* and the *Pensées*, date from the years of his life spent at Port-Royal.

"Les Provinciales." Written in defense of Antoine Arnauld, an opponent of the Jesuits and a defender of Jansenism who was on trial before the faculty of theology in Paris for his controversial religious works, Pascal's 18 *Lettres écrites par Louis de Montalte à un provincial* deal with divine grace and the ethical code of the Jesuits. They are better known as *Les Provinciales*. They included a blow against the relaxed morality that the Jesuits were said to teach and that was the weak point in their controversy with Port-Royal; Pascal quotes freely Jesuit dialogues and discrediting quotations from their own works, sometimes in a spirit of derision, sometimes with indignation. In the two last letters, dealing with the question of grace, Pascal proposed a conciliatory position that was later to make it possible for Port-Royal to subscribe to the "Peace of the Church," a temporary cessation of the conflict over Jansenism, in 1668.

The *Provinciales* were an immediate success, and their popularity has remained undiminished. This they owe primarily to their form, in which for the first time bombast and tedious rhetoric are replaced by variety, brevity, taut-

Contributions to physics and mathematics

Association with the Convent of Port-Royal

ness, and precision of style; as Nicolas Boileau, the founder of French literary criticism, recognized, they marked the beginning of modern French prose. Something of their popularity, moreover, in fashionable, Protestant, or skeptical circles, must be attributed to the violence of their attack on the Jesuits. In England they have been most widely read when Roman Catholicism has seemed a threat to the Church of England. Yet they have also helped Catholicism to rid itself of laxity; and, in 1678, Pope Innocent XI himself condemned half of the propositions that Pascal had denounced earlier. Thus, the *Provinciales* played a decisive part in promoting a return to inner religion and helped to secure the eventual triumph of the ideas set forth in Antoine Arnauld's treatise *De la fréquente communion* (1643), in which he protested against the idea that the profligate could atone for continued sin by frequent communion without repentance, a thesis that thereafter remained almost unchallengeable until the French church felt the repercussion of the revocation of the Edict of Nantes (which had granted religious freedom to French Protestants) in 1685. Whereas the Jesuits seemed to represent a Counter-Reformation predominantly concerned with orthodoxy and obedience to ecclesiastical authority, the *Provinciales* advocated a more spiritual approach, emphasizing the soul's union with the Mystical Body of Christ through charity.

Morality
and
spirituality

Further, by rejecting any double standard of morality and the distinction between counsel and precept, Pascal aligned himself with those who believe the ideal of evangelical perfection to be inseparable from the Christian life. Although there was nothing original in these opinions, Pascal nevertheless stamped them with the passionate conviction of a man in love with the absolute, of a man who saw no salvation apart from a heartfelt desire for the truth, together with a love of God that works continually toward destroying all self-love. For Pascal, morality cannot be separated from spirituality. Moreover, his own spiritual development can be traced in the *Provinciales*. The religious sense in them becomes progressively refined after the first letters, in which the tone of ridicule is smart rather than charitable.

"*Pensées*." Pascal finally decided to write his work of Christian apologetics, *Apologie de la religion chrétienne*, as a consequence of his meditations on miracles and other proofs of Christianity. The work remained unfinished at his death. Between the summers of 1657 and 1658, he put together most of the notes and fragments that editors have published under the inappropriate title *Pensées* ("Thoughts"; Eng. trans., *Pensées*, 1962). In the *Apologie*, Pascal shows the man without grace to be an incomprehensible mixture of greatness and abjectness, incapable of truth or of reaching the supreme good to which his nature nevertheless aspires. A religion that accounts for these contradictions, which he believed philosophy and worldliness fail to do, is for that very reason "to be venerated and loved." The indifference of the skeptic, Pascal wrote, is to be overcome by means of the "wager": if God does not exist, the skeptic loses nothing by believing in him; but if he does exist, the skeptic gains eternal life by believing in him. Pascal insists that men must be brought to God through Jesus Christ alone, because a creature could never know the infinite if Jesus had not descended to assume the proportions of man's fallen state.

The second part of the work applies the Augustinian theory of allegorical interpretation to the biblical types (*figuratifs*); reviews the rabbinical texts, the persistence of true religion, the work of Moses, and the proofs concerning Jesus Christ's God-like role; and, finally, gives a picture of the primitive church and the fulfillment of the prophecies. The *Apologie* (*Pensées*) is a treatise on spirituality. Pascal was not interested in making converts if they were not going to be saints.

Pascal's
apologetics

Pascal's apologetics, though it has stood the test of time, is primarily addressed to individuals of his own acquaintance. To convert his libertine friends, he looked for arguments in their favourite authors: in Michel de Montaigne, in the Skeptic Pierre Charron, in the Epicurean Pierre Gassendi, and in Thomas Hobbes, an English political philosopher. For Pascal, Skepticism was but a stage.

Modernist theologians in particular have tried to make use of his main contention, that "man is infinitely more than man," in isolation from his other contention, that man's wretchedness is explicable only as the effect of a Fall, about which a man can learn what he needs to know from history. In so doing, they sacrifice the second part of the *Apologie* to the first, keeping the philosophy while losing the exegesis. For Pascal as for St. Paul, Jesus Christ is the second Adam, inconceivable without the first.

Finally, too, Pascal expressly admitted that his psychological analyses were not by themselves sufficient to exclude a "philosophy of the absurd"; to do so, it is necessary to have recourse to the convergence of these analyses with the "lines of fact" concerning revelation, this convergence being too extraordinary not to appear as the work of providence to an anguished seeker after truth (*qui cherche en gémissant*).

He was next again involved in scientific work. First, the "Messieurs de Port-Royal" themselves asked for his help in composing the *Éléments de géométrie*; and second, it was suggested that he should publish what he had discovered about cycloid curves, a subject on which the greatest mathematicians of the time had been working. Once more fame aroused in him feelings of self-esteem; but from February 1659, illness brought him back to his former frame of mind, and he composed the "prayer for conversion" that the English clergymen Charles and John Wesley, who founded the Methodist Church, were later to regard so highly. Scarcely capable of regular work, he henceforth gave himself over to helping the poor and to the ascetic and devotional life. He took part intermittently, however, in the disputes to which the "Formulary"—a document condemning five propositions of Jansenism that, at the demand of the church authorities, had to be signed before a person could receive the sacraments—gave rise. Finally a difference of opinion with the theologians of Port-Royal led him to withdraw from controversy, though he did not sever his relations with them.

Pascal died on August 19, 1662, after suffering terrible pain, probably from carcinomatous meningitis following a malignant ulcer of the stomach. He was assisted by a non-Jansenist parish priest.

Assessment. At once a physicist, a mathematician, an eloquent publicist in the *Provinciales*, and an inspired artist in the *Apologie* and in his private notes, Pascal was embarrassed by the very abundance of his talents. It has been suggested that it was his too concrete turn of mind that prevented his discovering the infinitesimal calculus; and in some of the *Provinciales* the mysterious relations of human beings with God are treated as if they were a geometrical problem. But these considerations are far outweighed by the profit that he drew from the multiplicity of his gifts; his religious writings are rigorous because of his scientific training; and his love of the concrete emerges no less from the stream of quotations in the *Provinciales* than from his determination to reject the vigorous method of attack that he had used so effectively in his *Apologie*.

MAJOR WORKS

MATHEMATICS, LOGIC, AND THE FOUNDATIONS OF SCIENCE: *Essai pour les coniques* (1640); *Lettre sur le sujet de la machine inventée par le sieur B.P. pour faire toutes sortes d'opération d'arithmétique* (1645); *De l'autorité en matière de philosophie*, the first editor's title of Pascal's preface to a projected *Traité du vuide*, consisting of a general statement of the principle of scientific research (written 1647, printed 1779); *Traité du triangle arithmétique avec quelques autres petits traités sur la même matière* (written 1654, printed 1665); *De l'esprit géométrique—de l'art de persuader* (written c. 1658, first printed in two parts 1728 and 1776); *Histoire de la roulette, appelée autrement trochoïde ou cycloïde* (1658); *Lettres de A. Dettonville, contenant quelques-unes de ses inventions de géométrie* (1658–59).

PHYSICS: *Expériences nouvelles touchant le vuide* (1647); *Récit de la grande expérience de l'équilibre des liqueurs* (1648); *Traites de l'équilibre des liqueurs et de la pesanteur de la masse de l'air* (written 1651, printed 1663; *The Physical Treatises of Pascal: The Equilibrium of Liquids and the Weight of the Mass of the Air*, 1937).

RELIGIOUS PHILOSOPHY AND CONTROVERSY: *Abrégé de la vie de Jésus-Christ* (written 1654 or 1655, printed 1846); *Lettre écrite à un Provincial par un de ses amis sur le sujet des disputes présentes de la Sorbonne* (January 1656, followed by

17 more pamphlets on the same themes down to March 1657), all 18 being subsequently republished together as *Les Provinciales* (1657; augmented edition, with supplementary pamphlets, 1659); *Projet de mandement contre l'Apologie pour les casuistes* (written 1658, printed 1779); *Ecrits sur la grâce* (four treatises drafted between 1656 and 1658 and printed from 1779 onward); *Pensées de M. Pascal sur la religion et sur quelques autres sujets* (1670; the first Eng. trans. was *Monsieur Pascal's Thoughts, Meditations, and Prayers*, 1688; numerous new translations and versions have appeared since then); *Prière pur demander à Dieu le bon usages des maladies* (written 1659, printed 1666 and 1670).

OTHER WORKS: *Trois discours sur la condition des grands* (comprised 1660, printed 1670). Collected editions of Pascal's works include letters of mathematical or spiritual interest.

COLLECTED EDITIONS: Considerable editions of Pascal's *Oeuvres complètes* were undertaken by the Abbé Charles Bossut, 5 vol. (1779); and by Léon Brunschvicg, Pierre Boutroux, and Félix Gazier, 14 vol. (1908–25). The handiest edition is by LOUIS LAFUMA, *l'Intégrale* (1960). Collections in English include *The Miscellaneous Writings of Pascal* (1849); *Thoughts, Letters, Minor Works* (1910); and *Provincial Letters, Pensées, Scientific Treatises*, Encyclopædia Britannica "Great Books of the Western World" (1952).

BIBLIOGRAPHY. A standard edition of Pascal's works is that by LÉON BRUNSCHVICG, PIERRE BOUTROUX, and FÉLIX GAZIER, 14 vol. (1908–25); in part replaced by the edition of JEAN MESNARD, 2 vol. (1964–72); and by *Pensées sur la religion*, ed. by LOUIS LAFUMA, 3rd ed., 3 vol. (1960). See also the editions by HUGH F. STEWART of *Pensées* (1950), containing an English translation, and of *Provinciales* (1920, reissued 1951). Biographical and critical studies include: JEAN MESNARD, *Pascal: His Life and Works* (1952; originally published in French, 1951), an excellent biography, with bibliography, *Pascal* (1965), and *Pascal et les Roannez*, 2 vol. (1965); LUCIEN JERPHAGNON, *Le Caractère de Pascal* (1962); PHILIPPE SELLIER, *Pascal et saint Augustin* (1970); ROBERT J. NELSON, *Pascal: Adversary and Advocate* (1982), a biographical study concentrating on linguistics, theology, and personal development; ALBAN J. KRAILSHEIMER, *Pascal* (1980), an introductory biography for the general reader; JAN MIEL, *Pascal and Theology* (1970), a study of his theology of grace; HUGH M. DAVIDSON, *The Origins of Certainty* (1979), an introduction to the *Pensées*; ÉMILE CAILLIET, *The Clue to Pascal* (1943, reprinted 1973); and *Blaise Pascal, l'homme et l'oeuvre* (1956), a collection of articles and discussions from the proceedings of a congress on Pascal held at Royaumont, France, in 1954.

(J.Or./L.J./Ed.)

Pasteur

The scientific contributions of Louis Pasteur, French chemist and microbiologist, were among the most varied and valuable in the history of science and industry. It was he who proved that microorganisms cause fermentation and disease; he who originated and was the first to use vaccines for rabies, anthrax, and chicken cholera; he who saved the beer, wine, and silk industries of France and other countries; he who performed important pioneer work in stereochemistry; and he who originated the process known as pasteurization.

Pasteur.

Stereo-chemical investigations

Born December 27, 1822, at Dole in eastern France, Pasteur was the descendant of generations of tanners. His great-grandfather had been an indentured labourer who had purchased his freedom. In his youth Pasteur showed little interest in anything but drawing and produced a number of pastels, portraits of his parents and friends. After attending primary and secondary schools in Arbois, where his family had moved, and then in Besançon, Pasteur earned his *bachelier ès lettres* (bachelor of arts) in 1840 and *bachelier ès sciences* (bachelor of science) at the Royal College in Besançon in 1842. The following year he was admitted to the École Normale Supérieure, the famous teachers' college in Paris. He became *licencié ès sciences* (master of science) in 1845, and, after acquiring an advanced degree in physical sciences, he won his *docteur ès sciences* (doctor of philosophy) in 1847. On May 22, 1848, at the age of 26, he presented before the Paris Academy of Sciences a paper reporting a remarkable discovery he had just made—that certain chemical compounds were capable of splitting into a "right" component and a "left" component, one component being the mirror image of the other. His discoveries arose out of a crystallographic investigation of tartaric acid, an acid formed in grape fermentation that is widely used commercially, and racemic acid—a new, hitherto unknown acid that had been discovered in certain industrial processes in the Alsace region. Both acids not only had identical chemical compositions but also had the same structure; yet they showed marked differences in properties. The German chemist Eilhardt Mitscherlich (1794–1863) had shown that while ordinary commercial tartaric acid affects the rotation of plane polarized light, the unknown acid had no such effect. With the help of his own chemical methods Pasteur supplied the clue to this enigma by showing that the salts of the racemic acid consisted of two types of crystals that were mirror images of one another (like right- and left-hand

gloves). When separated the two types of crystals rotated plane polarized light to the same degree but in opposite directions (one to the right, or clockwise, and the other to the left, or counterclockwise). One of the two crystal forms of racemic acid proved to be identical with the tartaric acid of fermentation. As Pasteur showed further, one component of the racemic acid (that identical with the tartaric acid from fermentation) could be utilized for nutrition by micro-organisms, whereas the other, which is now termed its optical antipode, was not assimilable by living organisms. On the basis of these experiments, Pasteur elaborated his theory of molecular asymmetry, showing that the biological properties of chemical substances depend not only on the nature of the atoms constituting their molecules but also on the manner in which these atoms are arranged in space.

In 1848 Pasteur was appointed professor of physics at the Dijon Lycée (secondary school) but was shortly called to the University of Strasbourg as professor of chemistry. There, on May 29, 1849, he married the daughter of the rector of the university, Marie Laurent, by whom he was to have five children, only two of whom survived childhood.

In 1854 Pasteur became dean of the new science faculty at the University of Lille, where he initiated a highly modern educational concept: by instituting evening classes for the many young workmen of the industrial city, conducting his regular students around large factories in the area, and organizing supervised practical courses, he demonstrated the relationship that he believed should exist between theory and practice, between university and industry. At Lille, after receiving a query from an industrialist on the production of alcohol from grain and beet sugar, Pasteur began his studies on fermentation. In the course of his analysis he once again encountered—though in liquid form—new "right" and "left" compounds. From studying the fermentation of alcohol he went on to the problem of lactic fermentation, showing yeast to be an organism capable of reproducing itself, even in artificial media, without free oxygen—a concept that became known as the Pasteur effect.

In 1857 he was named Director of Scientific Studies at the École Normale Supérieure. He continued his researches and announced that fermentation was the result of the activity of minute organisms and that when fermentation failed, either the necessary organism was absent or was unable to grow properly. Before this discovery, all explanations of fermentation had lacked experimental foundation; Pasteur showed that milk could be soured by injecting a number of organisms from buttermilk or beer but could be kept unchanged if such organisms were excluded.

He was elected to the Academy of Sciences in 1862, and the following year a chair at the École des Beaux-Arts was established for him for a new and original program of instruction in geology, physics, and chemistry applied to the fine arts.

As a scholar engaged in research, Pasteur eventually found his administrative duties as Director of Scientific Studies at the École Supérieure too irksome. He gave up the post in 1867, and, thanks to the support of Emperor Napoleon III, a laboratory of physiological chemistry was created for him at the same institution. As a logical sequel to his work on fermentation, he began research on spontaneous generation (the concept that bacterial life arose spontaneously), a question which at that time divided scientists into two opposing camps. Pasteur's recognition of the fact that both lactic and alcohol fermentations were hastened by exposure to air led him to wonder whether his invisible organisms were always present in the atmosphere or whether they were spontaneously generated. By means of simple and precise experiments, including the filtration of air and the exposure of unfermented liquids to the air

Fermentation research

of the high Alps, he proved that food decomposes when placed in contact with germs present in the air, which cause its putrefaction, and that it does not undergo transformation or putrefy in such a way as to spontaneously generate new organisms within itself.

Pasteuriza-
tion

After laying the theoretical groundwork, Pasteur proceeded to apply his findings to the study of vinegar and wine, two commodities of great importance in the economy of France; his pasteurization process, the destruction of harmful germs by heat, made it possible to produce, preserve, and transport these products without their undergoing deterioration.

In 1865 he undertook a government mission to investigate the diseases of the silkworm, which were about to put an end to the production of silk at a time when it comprised a major section of France's economy. To carry out the investigation, he moved to the south of France, the centre of silkworm breeding. Three years later he announced that he had isolated the bacilli of two distinct diseases and had found methods of preventing contagion and of detecting diseased stock.

In 1870 Pasteur devoted himself to the problem of beer. Following an investigation conducted both in France and among the brewers in London, he devised, as he had done for vinegar and for wine, a procedure for manufacturing beer that would prevent its deterioration with time. British exporters, whose ships at the time had to sail entirely around the African continent, were thus able to send British beer as far as India without fear of its deteriorating.

Although Pasteur was partially paralyzed in 1868 and applied for retirement from the university, he continued his researches. In 1873 he was elected a member of the Academy of Medicine, and in 1874 the French Parliament provided him with an award that would ensure his material security while he pursued his work.

When, in 1881, he had perfected a technique for reducing the virulence of various disease-producing microorganisms, he succeeded in vaccinating a herd of sheep against the disease known as anthrax. Likewise, he was able to protect fowl from chicken cholera, for he had observed that once animals stricken with certain diseases had recovered, they were later immune to a fresh attack. Thus by isolating the germ of the disease and by cultivating an attenuated, or weakened, form of the germ and inoculating fowl with the culture, he could immunize the animals against the malady. In this he was following the example of the English physician Edward Jenner in his method for vaccinating animals against cowpox.

On April 27, 1882, Pasteur was elected a member of the Académie Française, at which point he undertook research that proved to be the most spectacular of all—the preventive treatment of rabies. After experimenting with inoculations of saliva from infected animals, he came to the conclusion that the virus was also present in the nerve centres, and he demonstrated that a portion of the medulla oblongata of a rabid dog, when injected into the body of a healthy animal, produced symptoms of rabies. By further work on the dried tissues of infected animals

and the effect of time and temperature on these tissues, he was able to obtain a weakened form of the virus that could be used for inoculation. Having detected the rabies virus by its effects on the nervous system and attenuated its virulence, he applied his procedure to man; on July 6, 1885, he saved the life of a nine-year-old boy, Joseph Meister, who had been bitten by a rabid dog. The experiment was an outstanding success, opening the road to protection from a terrible disease. In 1888 the Pasteur Institute was inaugurated in Paris for the purpose of undertaking fundamental research, prevention, and treatment of rabies. Pasteur, although in failing health, headed the institute until his death on September 28, 1895.

Louis Pasteur brought about a veritable revolution in the 19th-century scientific method. By abandoning his laboratory and by tackling the agents of disease in their natural environments, he was able through his investigations to supply the complete solution to a given question, not only identifying the agent responsible for a disease but also indicating the remedy.

A skillful experimenter, endowed with a great curiosity and a remarkable gift of observation, Pasteur devoted himself with immense enthusiasm to science and its applications to medicine, agriculture, and industry. He was prompt to defend his ideas with courage and often with considerable harshness—in writings as well as in speech—toward his opponents. It was chiefly in his work on spontaneous generation and on rabies that he encountered the strongest opposition to his ideas (which were, for the time, revolutionary) from medical circles and the press. He was happy to accept the glory and honours that came his way, for he was well aware of his own value and of his scientific successes. A great friendship developed between Pasteur and the renowned British surgeon Sir Joseph Lister (1827–1912), who was quick to apply to his own discipline the discoveries of his French colleague.

ROUX, "L'oeuvre médicale de Pasteur," in *Centième Anniversaire* (1922), written by one of Pasteur's collaborators; RENÉ VALLERY-RADOT, *M. Pasteur: Histoire d'un savant par un ignorant* (1884), written by Pasteur's son-in-law, who was also his secretary, and *The Life of Pasteur* (1900, reissued 1975; originally published in French, 1899), a fundamental work on the life of Pasteur but weak from the scientific point of view.

(J.-M.-R.N./Ed.)

Assessment

The Apostle Paul

The Apostle Paul is an outstanding figure in the history of Christianity. Converted only a few years after the death of Jesus, he became the leading Apostle (missionary) of the new movement and played a decisive part in extending it beyond the limits of Judaism to become a worldwide religion. His surviving letters are the earliest extant Christian writings. They reveal both theological skill and pastoral understanding and have had lasting importance for Christian life and thought.

Sources. There are no reliable sources for Paul's life outside the New Testament. The primary source is his own letters. Of these, Romans, I and II Corinthians, and Galatians are indisputably genuine. Most scholars also accept Philippians, I Thessalonians, and Philemon. Opinion is divided about Ephesians, Colossians, and II Thessalonians. The Pastoral Letters (I and II Timothy and Titus) are held by many scholars to have been written considerably later than the time of Paul. The story of Paul's conversion and missionary career is given in Acts, probably written many years after his death. Some sections dealing with sea journeys may be derived from the diary of a companion of Paul. Traditionally this was thought to be Luke, the evangelist and author of Acts, a view still held by a number of scholars. For further information on the sources for Paul's life, see *BIBLICAL LITERATURE AND ITS CRITICAL INTERPRETATION: New Testament literature*.

St. Paul preaching the gospel, detail of a 12th-century mosaic in the Cappella Palatina, Palermo, Sicily.

Life. *Early life.* Paul was a Jew, born, perhaps in AD 10, at Tarsus, a city in Cilicia on the main trade route between East and West, and the home of famous Stoic philosophers. Like many of the Jews there he inherited Roman citizenship, probably granted by the Romans as a reward for mercenary service in the previous century. This fact explains his two names. He used his Jewish name, Saul, within the Jewish community and his Roman surname, Paul, when speaking Greek. Though he had a

strict Jewish upbringing, he also grew up with a good command of idiomatic Greek and the experience of a cosmopolitan city, which fitted him for his special vocation to bring the gospel to the Gentiles (non-Jews). At some stage he became an enthusiastic member of the Pharisees, a Jewish sect that promoted purity and fidelity to the Law of Moses. According to Acts, he received training as a rabbi in Jerusalem under Gamaliel I. His knowledge of the Law and of rabbinic methods of interpreting it is evident in his letters. Like most rabbis he supported himself with a manual trade—tent making—probably learned from his father. It is clear that he never met Jesus while in Jerusalem, if, indeed, he was there before the Crucifixion. He learned enough about Jesus and his followers, however, to regard the Christian movement as a threat to the Pharisaic Judaism that he had embraced so eagerly. Thus he first appears on the scene of history as a persecutor of the newly founded church.

Serious persecution of Christians first arose in connection with converts among the Hellenists (Greek-speaking Jews) in Jerusalem. When one of them, Stephen, was stoned to death, the murderers “laid down their garments at the feet of a young man named Saul” (Acts 7:58). At that time Paul shared the sense of outrage aroused by the Hellenist converts. They had not only proclaimed Jesus as the Messiah and heavenly Lord, a man who had been crucified and therefore accursed by God (Deut. 21:23), but they also claimed that the temple and its sacrifices were superseded by the sacrificial death of Jesus and that therefore the Law could be disregarded (the subject of another curse, Deut. 27:26). Paul thus joined in the effort to stamp out the Christian movement. The Hellenist converts fled to the foreign cities where they had family connections, while the original Aramaic-speaking group in Jerusalem kept a low profile to avoid giving provocation.

Conversion. Paul, in Galatians, bears out the impression given in Acts that he was converted as a result of a vision on the road to Damascus, on his way to apprehend some of the scattered converts. His own account is tantalizingly brief: “he who had set me apart before I was born, and had called me through his grace, was pleased to reveal his Son to me, in order that I might preach him among the Gentiles” (Gal. 1:15–16). The longer description in Acts, given three times, dramatizes what may have been essentially an inward experience. It was certainly a moment of revelation, changing Paul from bitter enmity to lifelong dedication to the Christian cause.

Paul's conversion has often been explained psychologically as the resolution of an inner conflict. But the notion that Paul was tormented by scruples rests on a misunderstanding of Rom. 7. This chapter is concerned not with autobiography but with universal experience seen in the light of mature Christian understanding. Paul would not have spoken in these terms before his conversion. In fact, it is clear from other passages that his early life was free from such struggle. He excelled in zeal for the Law, and by its standards his life was blameless.

Paul's own account is much more in keeping with Old Testament callings of a prophet. Though it is impossible to state exactly what happened, the central feature was certainly his vision of Jesus in glory. It convinced him that Jesus was risen from the dead and exalted as Lord in heaven, as the Christians claimed. It also was proof that Jesus had been crucified wrongfully. Hence the curse did not apply, and his death could be understood as a sacrifice on behalf of others.

To Paul this had universal significance. Believing, like many Jews of his time, that God's final Day of Judgment, on which he would come to free the world from evil and to establish lasting peace and righteousness, was imminent, Paul then saw his vocation to be a missionary to people of

message

every nation to prepare them for God's coming. The new feature of this expectation was the place accorded to Jesus Christ. In agreement with the earliest apostolic preaching, Paul believed that Jesus, having died for the sins of mankind, was now reserved in heaven as God's agent for the judgment. Those that believed in him and acknowledged him as Lord would have him as their deliverer on that day. Thus faith in Christ became the foundation of Paul's preaching. Along with this he proclaimed the love of God shown in the sacrificial death of Christ, who "loved me and gave himself for me" (Gal. 2:20). All his devotion was transferred to this new centre. Formerly his energy had been directed to preparing people for God's Kingdom by imposing on them strict Pharisaic interpretation of the Law. Now all that seemed useless in the light of what God himself had done for humanity through Jesus. Henceforth his one aim was to proclaim the faith of Jesus as Lord everywhere.

Immediately after his conversion Paul spent a period of solitude in Arabia. He then took up residence in Damascus. There presumably he established contact with the Christians he had originally planned to harm and received from them information about Jesus and his teaching as well as experience of Christian fellowship. Damascus was the base for his first missionary work, but nothing is known of the effects of his mission in the region.

Paul in Antioch. After three years his work in Damascus came to an abrupt end. Somehow he had fallen foul of the ethnarch (governor) of the region of Nabataean Arabia. The ethnarch set a watch on the gates of Damascus, but Paul escaped over the wall in a basket and made his way to Jerusalem. There he met Peter, the Apostle, and James, the Lord's brother. This was an important meeting, for it established Paul as a recognized Apostle alongside the founders of the church at Jerusalem. The visit was brief, and Paul did not meet the Christian communities in the vicinity. Most likely this was due to the danger of reprisals from the Pharisees, who regarded Paul as a renegade. Therefore, after only two weeks, he set out on a new mission to Cilicia and Syria, with a base in his native city of Tarsus. About this mission, again, there is no information.

At some point Paul moved to Antioch, the capital of Syria, to assist Barnabas in his successful mission there. The converts included a large number of Gentiles. This eventually led to a serious crisis, in which Paul emerged as the champion of the Gentiles. The controversy, which lasted several years, stimulated Paul's most important contribution to Christian theology. His stand on behalf of the Gentiles ensured that Christianity became not just a Jewish sect but a universal religion. The point at issue was the relationship between Jewish and Gentile Christians. Primitive Christianity was a closely knit fellowship with the common meal and the Eucharist (thanksgiving for the sacrificial death of Christ) at the heart of it. But the Jewish purity rules made Jews reluctant to eat with Gentiles for fear of transgressing the Law. Jesus had taught that purity of heart was more important than attention to rules, but this did not lead his followers to abandon them. But at Antioch the accession of Gentile converts created a mixed congregation, in which the Jewish members were content to eat with the Gentiles for the sake of Christian fellowship. In Jerusalem, however, since the death of Stephen, the Christians had had to take great care not to offend Jewish susceptibilities, and the prospect of making headway in the mission there depended on their being seen as faithful to the Law. Thus reports of the liberal attitude of the Christians in Antioch were bound to be extremely damaging. Some of the Jerusalem Christians who were converted Pharisees even held the view that Gentile converts should be required to accept circumcision and the obligations of the Law.

Paul states in Galatians that he did not revisit Jerusalem for 14 years, and, when he finally did so, it was to deal with the problem of Gentile membership of the church. This conflicts with the information in Acts, which tells of a visit by Paul and Barnabas to bring relief during a famine at some time in AD 47-49. Acts then describes a further visit to deal with the Gentile issue. Most schol-

ars today identify the latter visit with that described in Galatians. This means that Luke, in writing Acts on the basis of various sources, either presented twice what was actually one visit or wrongly included Paul's name in the earlier relief visit.

Antioch continued to be Paul's base for further pioneering work. Acts records three itineraries, generally referred to as missionary journeys, spanning a number of years. The second visit to Jerusalem probably took place at the end of the first of these.

First missionary journey. Acts describes how Paul and Barnabas, accompanied by Barnabas' cousin John Mark, set out for Cyprus, visiting Salamis and Paphos. They then crossed to the mainland (modern Turkey), landing at Perga (near modern Murtana), but Mark left them and returned to Jerusalem. They worked in Pisidia and Pamphylia, which formed the southern part of the Roman province of Galatia, beginning in Pisidian Antioch (near modern Yalvaç). Acts records a sermon that Paul preached in the synagogue, which is a fine specimen of the presentation of the faith to a Jewish audience in New Testament times. After further stops at Iconium (modern Konya), Lystra (near modern Hatunsaray), and Derbe (unidentified), they retraced their steps to Perga and the port of Attalia (modern Antalya) and then sailed back to Antioch.

It is unclear from this account how many of the new converts were drawn from local Jewish communities and how many were Gentiles. The monotheism and strong morality of the Jews always attracted to the synagogues Gentiles who proved to be receptive to the Christian mission, especially as Paul did not require circumcision and observance of the Law for Christian fellowship. In some places the new congregations may have been entirely composed of Gentiles.

At this time Greek and Roman traditional religion was losing its hold, and a deputation had come from Jerusalem to Antioch to insist that the Gentile converts should be circumcised. This led to Paul's second visit to Jerusalem. Paul says that he and Barnabas went "by revelation," perhaps meaning as a result of a message from a prophet, not in response to a summons from Jerusalem as stated in Acts. The party from Antioch included Titus, a Gentile whom Paul had taken into his mission team.

It is almost impossible to harmonize the information in Acts 15 and Gal. 2, but it is best to regard them as accounts of the same occasion. In Jerusalem there seem to have been three main actions. First, Paul and Barnabas had a private consultation with James, Peter, and John, in which they compared the content of their mission preaching and established that they were in basic agreement. This confirmed Paul's contention that the gospel message did not require the circumcision of Gentile converts. A campaign by the hard-line party to have Titus circumcised was firmly resisted. Second, a larger conference was convened in order to inform all about the Gentile mission so that they should have no doubt that the power of the Holy Spirit had been at work. This resulted in the decision that the Gentile mission should continue without pressure to Judaize converts. Paul would carry this on from Antioch, while Peter would continue the mission among Jews from the base at Jerusalem. Paul, however, was urged to bear in mind the precarious position of the Jerusalem church. Third, a letter was sent to Antioch with minimum rules for Gentile converts: to abstain from meat used in pagan sacrifices, to use only kosher meat according to Jewish custom, and to observe Jewish restrictions on sexual relationships. Later events show that the contents of this letter were unknown to Paul, and it is conjectured that it belongs to a later attempt to regulate relationships with the numerous Jewish Christian congregations of Judaea and Syria after Paul had ceased to have close contact with Antioch.

Paul's view had been endorsed by Peter, who subsequently visited the church in Antioch. Apparently he had no difficulty in sharing in the life of the mixed congregation. Yet when some hard-liners came from Jerusalem, Peter felt compelled to withdraw from meals with Gentile members. Other Jewish members also yielded to the pressure, including even Barnabas. Paul, however, was

Gentiles

Second
visit to
Jerusalem

The missionary journeys of St. Paul.

Demands to Judaize Gentile converts

adamant in his conviction that this was fundamentally wrong. This crisis could never have arisen if the letter from Jerusalem had already been sent; it must have been due to differing views of the implications of what had been agreed. Not only Paul but also Peter and the main body in Jerusalem had assumed that the purity rules would not be allowed to interfere with table fellowship in mixed congregations. But it is clear from the trouble over Titus that the hard-liners would demand separation into two groups and then claim that the unity of the congregation would require Judaizing of the Gentile converts. Paul insisted on his own understanding of the agreement, and the visitors left.

Second missionary journey. Paul then planned to revisit the churches of south Galatia. Barnabas wished to take Mark, but Paul refused in view of his previous failure. Barnabas and Mark went to Cyprus, and nothing more is said about them in Acts. The subsequent account is entirely concentrated on Paul, who took with him Silas, also a Roman citizen (Roman name Silvanus). They went overland to Galatia. At Lystra Paul took into his team Timothy, a Gentile with a Jewish mother, who is mentioned with Silas in Paul's letters. The claim of Acts that Paul circumcised him seems improbable in view of the earlier decisions but is not impossible if the work was mainly among Jewish communities.

Because Paul hoped to establish the church in large centres of influence, he planned to go to Ephesus, the principal city of the province of Asia and a port on the Aegean coast. He was, however, prevented from doing so "by the Holy Spirit" (perhaps another reference to Christian prophecy). Instead he turned toward the large cities of Bithynia in the north. Possibly the Gentile churches of north Galatia, to which the letter to the Galatians is addressed, were founded on the way. Once more his plans were prevented, and so he moved northwest to Troas. From there, in response to a vision, he sailed to Macedonia and founded churches at Philippi, Thessalonica (modern Thessaloníki, Greece), and Berea. Philippi, a Roman colony on the Via Egnatia, the major route across Greece, produced a loyal group of Gentile converts, who frequently contributed funds to Paul in later years. Acts tells how Paul and Silas were imprisoned there but released when they revealed their Roman citizenship. At Thessalonica and Berea trouble from hostile Jews compelled Paul to move on to Athens. After a short stay there, during which

he is said to have addressed the council of the Areopagus, he went on to Corinth. The speech, as given in Acts, was an attempt to meet the needs of a philosophically trained audience. No church was founded in Athens.

The events of that time are reflected in I Thessalonians, perhaps the earliest of Paul's letters, written after Silas and Timothy had joined Paul at Corinth. The letter expressed his great anxiety for this newly founded church in Thessalonica, which he had had to leave hurriedly, having been accused of treason for proclaiming Christ as a rival emperor. It emerges from the letter that he had taught the Gentile audience to turn "to God from idols, to serve a living and true God, and to wait for his Son from heaven, whom he raised from the dead, Jesus who delivers us from the wrath to come" (1:9-10). This can be taken as a good example of Paul's basic mission preaching. Timothy had reported that the converts were anxious about their fate because some of them had already died. Paul explained that the time of Christ's coming (Parousia) for judgment was unknown, but both living and dead who had faith in him would be claimed by him as his own and saved for the everlasting kingdom. II Thessalonians is regarded by some as a supplementary letter, written shortly afterward, but there is doubt about its authenticity. It contains details of the events that are to precede the Parousia (unfortunately these details are by no means easy to understand).

Paul was in low spirits when he reached Corinth after the failure at Athens. At Corinth he met a Jewish couple, Aquila and Priscilla, tentmakers like himself, who became his lifelong friends. They had recently come from Rome, following an edict of the emperor Claudius expelling all Jews from the capital. Possibly they had already become Christians in Rome. In Corinth Paul at last was able to exercise a long and fruitful ministry in a great trading centre. Acts records an incident in which Paul was brought before the proconsul Gallio. This is important for dating Paul's career because an inscription discovered at Delphi proves that Gallio began his year of office in AD 51. Paul had probably arrived in the previous year. When he left Corinth, Aquila and Priscilla accompanied him to Ephesus, but he went on alone by sea to Caesarea for Jerusalem and from there to Antioch.

Third missionary journey. Paul had by then established churches in Asia Minor and Greece, with a major centre at Corinth, and had begun work in the equally important Ephesus. Then followed a period of consolidation.

Success in Corinth

He went overland to Ephesus, which became his base for the next three years. Acts gives little detail, but he must have founded the churches at Colossae, Hierapolis, and Laodicea in the Lycus Valley during this period. A group of followers of John the Baptist at Ephesus is mentioned, and there were probably other Christian missionaries working in the same region. References in his letters to fighting wild beasts at Ephesus and to imprisonment show that he faced great hazards.

Active
period of
correspon-
dence

This was the period of Paul's most important letters. His correspondence with Corinth shows the grave difficulties that were liable to arise. I Corinthians refers to a previous letter urging the Christians not to associate with immoral persons, but it has not survived. In I Corinthians Paul tackles a whole array of problems. Rival groups were claiming the authority of different teachers (Peter, Apollos, and Paul himself). A case of incest had gone unrebuked. Paul's teaching on freedom from the Law had been twisted to justify licentiousness. There were problems of marriage and divorce. The question of which foods a Gentile Christian might eat was causing problems of conscience. There was disorderly conduct at the Eucharist (Lord's Supper). In dealing with these matters Paul showed knowledge of Jesus' teaching on marriage, and he gave the account of the Last Supper in its oldest known form. A section on the gifts of the Holy Spirit includes his famous chapter on love (chapter 13) and regulates the practice of speaking with tongues. A long section on resurrection shows that, while teaching that Christian life was already participation in the risen Christ, Paul still thought that the Parousia was near and that the full experience of eternal life lay beyond this event.

Before long, however, there were fresh troubles at Corinth. Intruders from another church were trying to undermine Paul's authority. He dashed to Corinth but failed to restore confidence. He returned to Ephesus and wrote a severe letter (possibly partly preserved in II Cor. 10-13), which he regretted as soon as Titus had left with it. Paul had intended to work at Troas but was so anxious about Corinth that he went on to Macedonia instead in the hope of meeting Titus on his return. Titus returned with the good news that the severe letter had accomplished its purpose. With tremendous relief Paul wrote II Corinthians (perhaps only chapters 1-9), which is full of the theme of reconciliation: "God was in Christ reconciling the world to himself, not counting their trespasses against them, and entrusting to us the message of reconciliation" (5:19). Paul also gave further teaching on the resurrection of the body in terms of renewal and transformation into the state of glory.

Another theme of II Corinthians is a collection for the poor church of Jerusalem, a gift that Paul intended to symbolize the unity between the Jewish and Gentile churches. Behind this project was the continuing problem of the Judaizing party. This comes to the fore in Galatians, probably written during this period. The letter is concerned with the attempt of some Jewish Christians to persuade the Gentile Christians of Galatia to be circumcised and keep the Law. Here Paul lays out his doctrine of justification by faith, generally reckoned his most important contribution to Christian theology, which was to reach its classic expression in Romans.

Justifica-
tion by
faith

From Macedonia Paul went to Corinth, and it was during his three months there that he wrote to the Christians in Rome. The letter was written ostensibly to seek their help in his plan to evangelize the far west (Spain is mentioned) after taking the collection to Jerusalem. In fact, he clearly felt the need to win their support for his position on the Judaizing issue, and he presented the case at length. God's plan, he argued, is for universal salvation. This is God's gift available through faith in the sacrificial death of Christ. By itself the Law cannot bring salvation. It can show the nature of human sin but is powerless to make people righteous. Paul's opponents feared that without the Law the Gentile converts would be liable to libertine behaviour (as had happened at Corinth). Paul replied that faith in Christ opens the believer to the sanctifying power of the Holy Spirit. Then the opponents complained that Paul's argument left no room for the privileged position of the Jews as God's chosen people. Paul replied that,

though many Jews had failed to respond to the gospel, the success of the mission to the Gentiles would prompt them to seek salvation at the end of time, "and so all Israel [would] be saved" (Rom. 11:26). Then the universe would reach the fulfillment of its purpose, and the final transformation could begin.

Arrest and imprisonment. At the end of the letter Paul expressed his fear of danger from the Jews in Jerusalem and even hinted that the church there might not feel able to accept the collection. It seems that both these fears were realized. Acts tells that Paul was accompanied by delegates from the Gentile churches but does not mention the collection. This omission is best explained on the assumption that Luke did not wish to say that the church in Jerusalem did not dare to accept it. If so, Paul's hope that it would symbolize the gathering of the Gentiles into the one family of God was disappointed. In Jerusalem Paul was mistakenly accused of bringing one of the Gentile delegates into the inner courts of the Temple, beyond the barrier excluding Gentiles. He was arrested, partly to save his life from the mob, but given good treatment on account of his Roman citizenship. When a plot against his life came to light, he was removed to Caesarea, the Roman military headquarters. The governor Felix kept him in prison to avoid antagonizing the Jewish authorities. Two years later Felix's successor, Festus, wanted to send him to Jerusalem for trial, but Paul refused to go and appealed to Caesar.

The journey to Rome began in late autumn, but a shipwreck delayed the travelers for three months at Malta, so that they arrived in Rome in the spring of AD 60. There Paul was kept under house arrest for two years awaiting trial. At this point the narrative of Acts closes, and it is left to the reader to guess what happened. As long as the Pastoral Letters were accepted as genuine, their evidence demanded the hypothesis of acquittal, further work in Greece, Asia Minor, and even Crete, before a second arrest, return to Rome, and sentence to death. Now that these letters are recognized to be pseudonymous, there is no reason to suppose that Paul was acquitted at all.

Paul wrote several letters during captivity. These might have been written during an earlier imprisonment in Ephesus or, perhaps, while he was at Caesarea, but Rome seems most likely. Of the four captivity letters, Philippians and Philemon are generally accepted as genuine; Colossians and Ephesians are questioned. The letter to Philemon, a Christian of Colossae, concerns his runaway slave whom Paul has converted in prison and now sends back to him "no longer as a slave but more than a slave, as a beloved brother" (verse 16). This letter, with its sensitive handling of a delicate situation, is a gem among the Pauline writings. Philippians is a serene acknowledgement of the generosity of the Christians at Philippi. Colossians is concerned with trouble from false teachers at Colossae, conjectured to be an unorthodox fringe sect of Judaism. In response, Christ is presented as the true wisdom of God, embodying his whole plan of salvation. Ephesians is an eloquent, perhaps overly rhetorical, statement of the privilege of the Gentiles, who in Christ enjoy the status of God's chosen people. Through his death Christ "has made us both one, and has broken down the dividing wall of hostility" (2:14).

Letter to
Philemon

Achievement and influence. Paul's lasting monument is the worldwide Christian Church. Though he was not the first to preach to the Gentiles, his resolute stand against the Judaizing party was decisive for future progress. It can be justly claimed that it was due to Paul more than anyone else that Christianity grew from being a small sect within Judaism to become a world religion.

Paul's influence continued after his death. The Pastoral Letters to Timothy and Titus were written in Paul's name to promote fidelity to his teaching, probably around the end of the 1st century. At the same time, Paul's surviving letters were collected for general circulation. They quickly became a standard of reference for Christian teaching. In particular, theories of atonement (the reconciliation of mankind to God through the sacrificial death of Christ) have always relied heavily on Paul.

In the Western (Latin) half of Christendom Paul had a profound effect upon the history of the church through the

writings of St. Augustine. The Pelagian controversy concerning grace and free will turned on the interpretation of passages in Paul's letter to the Romans. In arguing for the necessity of divine grace for salvation, Augustine built on Paul's idea of predestination, correctly interpreting Paul's idea as a reference to God's predestined plan of universal salvation and as a concept that did not necessarily conflict with the exercise of free will.

The reformers of the 16th century were also deeply indebted to Paul. Martin Luther seized on the doctrine of justification by faith and made the distinction between faith and works the basis of his attack on the late medieval church. John Calvin drew from Paul his concept of the church as the company of the elect, using the idea of predestination and adding that predestination to salvation belongs only to the elect. Thus Paul's teaching came through the influence of Augustine to dominate the Reformation and its legacy in the Lutheran and Calvinist churches of modern Protestantism. These issues, however, never had the same prominence in the Eastern Orthodox churches.

Modern study of Paul has tried to reach behind these controversies and to see Paul in his true context of the rise of Christianity. Once the basis of Paul's thought in the context of Jewish concepts of his time is understood in the light of modern scholarship, uncompromising predestinarian views of some of Calvin's followers can be seen to be an overly rigid interpretation of Paul's meaning. Attempts to derive Paul's ideas from Greek or Gnostic influences have been largely abandoned. Paul stands out more clearly as a Christian Jew, whose conversion experience convinced him that Christ was the universal Lord under God, the agent and leader of God's kingdom. Paul thus maintained that through Christ every barrier is broken down: "There

is neither Jew nor Greek, there is neither slave nor free, there is neither male nor female; for you are all one in Christ Jesus" (Gal. 3:28).

BIBLIOGRAPHY. From the immense Pauline bibliography, which includes many commentaries on the Acts and letters, only a representative selection can be chosen. GUSTAV ADOLF DEISSMANN, *St. Paul*, trans. from the German (1912); T.R. GLOVER, *Paul of Tarsus* (1925, reissued 1938); and JAMES S. STEWART, *A Man in Christ* (1935, reissued 1975), are valuable biographical studies. H.J. SCHOEPS, *Paul* (1961, reissued 1979; originally published in German, 1959), is a modern Jewish view of Paul. MICHAEL GRANT, *Saint Paul* (1976, reissued 1982), is an introduction to his life and his writings for the general reader. GÜNTHER BORNKAMM, *Paul* (1971; originally published in German, 1969); and FREDERICK F. BRUCE, *Paul: Apostle of the Heart Set Free* (1978, reprinted 1984), are a critical and a conservative account, respectively, of both his life and thought. WAYNE A. MEEKS, *The First Urban Christians* (1983), is a reinterpretation of Pauline thought in light of new information on its social and political contexts. Other specialized studies include WILLIAM M. RAMSAY, *St. Paul the Traveller and the Roman Citizen* (1896, reissued 1982, with an essay on the author), a valuable contribution to historical geography; ROBERT JEWETT, *A Chronology of Paul's Life* (1979); JOHANNES MUNCK, *Paul and the Salvation of Mankind* (1959; originally published in German, 1954), dealing with various aspects of Paul's relationship with the other Apostles; ALBERT SCHWEITZER, *The Mysticism of Paul the Apostle* (1931, reissued 1968; originally published in German, 1930); W.D. DAVIES, *Paul and Rabbinic Judaism*, 4th ed. (1980); E.P. SANDERS, *Paul and Palestinian Judaism* (1977), and *Paul, the Law, and the Jewish People* (1983), providing a balanced discussion of modern assessments of Paul's relationship to Judaism. D.E.H. WHITELEY, *The Theology of St. Paul*, 2nd ed. (1974); and J. CHRISTIAAN BEKER, *Paul the Apostle* (1980), are both thorough works on Paul's teaching. (B.L.)

Peking

Peking (Wade-Giles romanization: *Pei-ching*, Pinyin: *Beijing*), the capital of the People's Republic of China, is one of the world's great cities. Few cities in the world have served for so long as the political headquarters and cultural centre of a country as immense as China. The city has constituted an integral part of the history of China over the past eight centuries, and there is scarcely a major building of any age in Peking that has not made its contribution toward the evolution of the country as a whole. The importance of Peking thus makes it impossible to understand China without a knowledge of this city as well.

More than 2,000 years ago, a site near present-day Peking was already an important military and trading centre for the northeastern frontier of China. In 1267, during the Yüan (Mongol) dynasty (1206–1368), a new city built on the site—called *Ta-tu*—became the administrative capital of China. During the reigns of the first two emperors of the Ming dynasty (1368–1644), Nanking was the capital, and the old Mongol capital was renamed *Pei-p'ing* ("Northern Peace"); the third Ming emperor, however, restored

it as the Imperial seat of the dynasty and gave it a new name, Peking ("Northern Capital"). Peking has remained the capital of China except for a brief period (1928–49) when the Nationalist government again made Nanking the capital (although the capital was removed to Chungking during World War II); during that time Peking once again resumed the old name *Pei-p'ing*, which is still used by the Nationalist government in Taiwan.

In spite of frequent political changes in China, the city throughout the early decades of the 20th century remained the most flourishing cultural centre in the nation; Peking's importance was fully realized, however, only when the city was chosen as the capital of the People's Republic of China in 1949, and this political status has added much vitality to it. Indeed, few cities have ever had such rapid growth in population and geographic area, as well as in industrial and other activities. Combining both historical relics of an ancient culture and new urban construction under a socialist system, Peking has become the showplace of modern China.

CHARACTER OF THE CITY

Although much of Peking's older and more picturesque character has been destroyed in the drive since 1949 to modernize and industrialize, some parts of the city are still redolent of the past. Many fine monumental buildings, old restaurants, and centres of traditional Chinese arts and crafts remain, and the central government has taken measures to prevent Peking's further industrialization. Broad new boulevards have displaced the colourful stalls and markets for which the city was once famous, but the neighbourhood life of old Peking can still be glimpsed in the narrow *hu-t'ungs* (residential alleys), with their coal-burning stoves, tiny potted-plant gardens, and enclosed courtyards—some of which are still guarded by carved stone lions at their gates.

The pace of life in Peking is slow by Western standards. People commute by bus or bicycle and on hot summer evenings sit outside their apartment blocks to catch cooling breezes and to gossip. The citizenry has a wide range of leisure pursuits, particularly those considered good for health. The ancient art of *T'ai Chi ch'üan* (Chinese boxing) is widely practiced, singly or in groups, along roadsides and in parks. Young people delight in taking day excursions to such nearby historical sites as the Summer Palace, the tombs of the Ming emperors, and the Great Wall. Older people, especially the men, like to huddle in tiny restaurants and tea shops or to sit alone at the Peking equivalent of corner taverns nursing a glass of beer or *mao-t'ai* (a strong liquor made from sorghum).

For all of the vicissitudes of its history, Peking continues to be a source of pride for its inhabitants. Their obsessions are, as they have been for centuries, food and knowledge: they eat heartily when they have the means and read voraciously in spite of the limited supply of books. Food stalls on the streets, selling a variety of cooked treats, are well-patronized, as are newspaper and magazine kiosks. The ambition of most families is to provide their offspring with a higher education or, if not that, a secure factory job. Despite the shortage of living space in the city, families still try to accommodate parents and grandparents and to be responsible for the well-being of other elderly relatives.

THE LANDSCAPE

The city site. Peking is situated at the northern apex of the triangular North China Plain and lies at an elevation of between about 100 and 130 feet (30 and 40 metres) above sea level. To the north lies the fringe of the Mongolian Plateau; to the northeast rises the mountain range of the Yen Mountains, part of which forms the eastern part of the concave arc that circles the Peking lowland from the northeast to the southwest and is known to geologists as the "Bay of Peking."

The city was built at the mouth of this embayment, which opens onto the great plain to the south and east, and between two rivers, the Yung-ting and the Ch'ao-pai, which eventually join to empty into the Po Hai (Gulf of Chihli), some 100 miles (160 kilometres) to the south-east of Peking. Peking is a natural gateway on the long-distance land communication route between the North China Plain and the northern ranges, plains, and plateaus.

To the south of the city the plain spreads out for about 400 miles until it merges into the lower valley and the delta of the Yangtze. On the east the plain is bounded by the sea, except for the break caused by the Shantung Hills; on the west it is flanked by the T'ai-hang Mountains, which constitute the eastern edge of the Loess Plateau (loess is loamy material deposited by wind).

Because Peking stands at the apex of the triangle, routes running across the great plain naturally converge on the city. In addition, since the dawn of Chinese history, the Yen range has constituted a formidable barrier between the North China Plain to the south, the Mongolian Plateau to the north, and the Liao River Plain in the southern region of the Northeast (formerly Manchuria). A few passes, however, cut through the ranges—the most important being the Nankow (Chü-Yung), Ku-pei, and Shan-hai—and are so situated that all roads leading from Mongolia and the Northeast to the North China Plain are bound to converge on Peking. For centuries, therefore, Peking has been an important terminus of the caravan routes leading to and from the vast Central Asian hinterland.

The
metropoli-
tan district

Since the early 15th century, the city of Peking and its surrounding territories have been organized as a metropolitan district of enormous size, having a governor—formerly appointed by the emperor himself—equal in rank to a provincial governor. This special district organization was continued by the Ch'ing dynasty and by the People's Republic of China. The present metropolitan boundary was established in 1959 and covers a territory of approximately 6,900 square miles (17,900 square kilometres). The metropolis consists of 10 urban and suburban *ch'u* (districts) and eight annexed *hsien* (counties) in peripheral areas. It may be divided into three concentric zones, based on urban functions. The central zone coincides with the central city; it is mainly occupied by old palaces, government buildings, commercial districts, and old residential areas and makes up roughly 1 percent of the total metropolitan area. Four of the *ch'u* lie within the central city. The second zone, the near suburb, comprises five *ch'u* immediately surrounding the old walled city; it is the site of the newer factories, schools, government buildings, and workers' dormitories. The outer fringe of this zone is intensively cultivated and supplies vegetables and fruits to the population of the central zone. The near suburb accounts for about 8 percent of the metropolitan area. The third zone, the far suburb, consists of one *ch'u* and nine annexed *hsien* and constitutes the remainder of the metropolitan area. This zone functions as the economic base—supplying coal, lumber, construction materials, vegetables and fruits, dairy products, water, and some grain crops to the urban population in the central zone and the near suburb. The far suburb of Peking is mainly under the administration of *hsinang* (country towns).

Climate. Though the distance from Peking to the Po Hai is only about 100 miles, the general air circulation in Peking is mainly from the northwest throughout the year. Maritime effects on Peking's weather are meagre. The climate is clearly of the continental monsoon type that occurs in the temperate zone. Local topography has a great effect on Peking's climate. Being located in the lowland area of the nation and shaded by mountains, the city is a little warmer in winter than other areas of China located on the same latitude; it has only five months each year in which the mean monthly temperature is lower than 50° F (10° C). Wind direction in Peking is also influenced by topography, with changes occurring from day to night. Generally, there are more southerly winds in the day but northerly or northwesterly winds at night.

Tempera-
ture and
rainfall

The annual mean temperature of the city is 53° F (12° C). The coldest month is January, when monthly mean temperatures are 24° F (−4° C), and the warmest month is July, when the monthly mean is 79° F (26° C). In an average year, there are 132 days of freezing temperature in Peking (between October and March); the mean amount of precipitation is 25 inches (635 millimetres), with most of the annual total falling from June to August. July is ordinarily the wettest month of the year, with monthly mean precipitation averaging about nine inches.

One of the characteristics of Peking's rainfall is its vari-

ability. In 1959—an extremely wet year for Peking—the total precipitation amounted to 55 inches, whereas in 1891—an extremely dry year—only seven inches of rainfall was recorded. The average number of rainy days is about 80, and the average relative humidity for the city is 57 percent.

Winter in Peking is long and usually begins in October, when northwesterly winds gradually gain strength. Until March, this seasonal wind system dominates Peking; the Siberian air that passes southward over the Mongolian Plateau and into China proper is cold and dry, bringing little snow or other precipitation. The monthly mean temperature from December to February is below freezing. Spring, the windiest season, is short and rapidly becomes warm. Mainly because of the prevailing high winds, the evaporation rate in spring averages about nine times the total spring precipitation and frequently is sufficient to cause droughts that are harmful to agriculture. In addition to being the season of torrential rains, summer is rather hot, as warm and humid air from the southeast often penetrates into North China. Autumn begins in late September and is a pleasant, though short, season when the sky is clear and the temperature comfortable.

Plant life. The mountain areas of Peking belong to the temperate deciduous forest zone, while the plains area belongs to the wooded steppe zone. Because of continuous deforestation by man for several centuries, however, only the mountain areas in the northeast and the western parts of the metropolitan area are still covered with mixed forests, composed mainly of pine, oak, and Manchurian birch. Different types of forest, divided into vertical zones, can be seen at higher elevations. On the lower slopes of many hills to the west of the city, human activities have resulted in the disappearance of forest cover so that only bushes and shrubs dot the landscape. On sunny slopes at altitudes of between about 2,300 and 5,600 feet, a variety of species occurs, including Manchurian birch (*Betula mandshurica*), Dahurian birch (*B. davurica*), trembling poplar (*Populus tremula*), Mongolian oak (*Quercus mongolica*), and Liaotung oak (*Q. liaotungensis*). Between 5,600 and 6,250 feet above sea level, the mixed forest of truncated maple (*Acer truncatum*) and trembling poplar replaces all other species. Above 6,250 feet, goat willow (*Salix caprea*) becomes the dominant tree.

The larger part of the plain areas of Peking has been either cultivated or occupied by various settlements so that it is for the most part bare of any natural vegetation. Occasionally, some small groves of planted trees may be seen near graveyards or in the vicinity of villages; these are mainly composed of mixed woods consisting of oil pine, Chinese juniper, Chinese cypress, willow, elm, and Chinese locust.

The city layout. The traditional core of Peking essentially consisted of two walled cities (the walls no longer stand), the northern inner city and the southern outer city. The inner city, also known as Tatar City, lay approximately on the site of the Mongol city of Ta-tu; it was in the form of a square, with walls nearly 15 miles in length. The outer city, also known as the Chinese City, was added during the reign of the Ming emperor Chia-ching (1521–66/67); it was in the form of an oblong adjoining the inner city, with walls that were 14 miles in length, including four miles of the southern wall of the inner city. Within the inner city was the former Imperial City, also in the form of a square, which had red plastered walls six and a half miles in length. Within the Imperial City, in turn, is the moated "Forbidden City," with walls two and a quarter miles long. The Forbidden City contains the former Imperial Palaces, which have been converted into a museum.

Peking represents, better than any other existing city, the heritage of Chinese architectural achievement. During each dynasty in which Peking was the capital, care was consistently taken to preserve tradition when the city was rebuilt or remodeled. Few cities in the world can thus rival Peking in the regularity and harmony of its city plan.

The plan was composed about a single straight line, drawn north and south through the centre of Peking, on which the internal coherence of the city hinged. All the city walls, important city gates, main avenues and streets, religious

The north-
south axis

Market (Tung-tan) is balanced by the West Market (Hsi-tan); these form the main business districts. The T'ien-t'an (Temple of Heaven) Park to the south of the inner city is counterbalanced by the Ti-t'an (Altar of the Earth) Park to the north of the city. Of the 16 city gates constructed in Ming times, seven were located on each side of the north-south line, and two were situated on the line itself. Only a few of the old gates still stand, but their names are carried by the city streets.

The main avenues of the old city, whether running north-south or east-west, connected the gates on the opposite walls and divided the whole city into a rectangular grid. Within the walls, buildings were constructed around a courtyard or series of courtyards, with every important building facing south. Buildings often stood behind one another along a north-south line, with small courtyards in between. This prevailing southern orientation of buildings has a climatic functional basis, but it also appears to have been sanctified or conventionalized early in the Bronze Age in connection with ancestral ceremonies and with the worship of heaven and earth.

Since 1949, the greatest change in the city's appearance has been the extension of its streets immediately outside the former old city walls. On the west side of the old city, an area extending about a mile from the spot where the Fu-hsing Gate stood (Fu-hsing Gate site on map) has become an extension of the avenue Hsi Ch'ang-an Ta-chieh and is used primarily for government offices. Toward the Summer Palace, to the northwest, is an area where the most important universities and research institutes of the country are located. To the north of the city, the outlying districts have been developed as a housing area adjoining the educational district in the northwest. The eastern suburb is an industrial district dominated by the manufacture of chemicals, automobiles, and agricultural machinery. Vegetable fields in the southern suburb are gradually being supplanted by industrial plants.

Housing. To cope with the rapid growth of population, a number of housing projects have been constructed for office and factory workers. During the first five-year plan (1953-57), housing projects were concentrated in the western outskirts of the city, where apartment buildings were erected near government offices outside the Fu-hsing Gate site. After 1958 the construction of a large group of multi-unit housing estates was begun in the northern outlying districts between the An-ting Gate site and Te-sheng Gate, centring on the residential neighbourhood of Ho-p'ing-li. The Ho-p'ing-li housing development contains primary and secondary schools, nurseries, hotels, and recreational facilities, as well as scores of four- or five-story apartment buildings. In addition, there are many groups of single-family houses in the northern suburbs, with associated parks, theatres, and recreational centres. All these buildings are supplied with gas and water, in contrast with the older parts of the city, where the existence of old stone paving hindered the development of modern structures and facilities.

In the area outside the Chien-kuo Gate site, to the east of the city, apartment buildings accommodate the families of office workers employed in nearby government office buildings. This area has also been selected as the diplomatic district and contains many foreign embassies, together with a number of Western-style houses for diplomatic representatives and their families.

In the older districts inside the former city walls, many dilapidated houses have been pulled down in municipal housing-renewal projects and have been replaced by multistory apartment buildings. Urban-renewal projects, however, have been unable to match the growth of population. As a consequence, many traditional house compounds—originally designed centuries ago to house the families of officials during the Ch'ing, or Manchu, dynasty (1644-1911/12)—have been repaired or renovated and subdivided to provide quarters for three or four families per compound; each family in a compound faces a public courtyard and shares a common front gate with other families.

In order to minimize commuting traffic in the metropolis, many factories in the eastern and southern outskirts

of the city have erected apartment buildings to house workers. These workers' residences constitute independent communities and are located so that they are easily accessible from the place of work yet are far enough away to be free from noise and smoke. Satellite towns have also been developed in the rural counties in an effort to disperse population and industries from the central city. Industries have been encouraged in rural areas in order to absorb surplus labourers and to supplement farmers' incomes.

Architecture. Peking's heritage of Chinese architectural achievement is exemplified by both private housing and public buildings. As the whole city was laid out upon a rectangular street pattern symmetrically arranged around the palace compound, almost every dwelling in the city is rectangular in form, with the four sides squarely facing the cardinal directions. Most houses in the inner city were designed as residences of former officials and their families, and almost every dwelling compound is surrounded by high walls, with an open courtyard in the centre flanked by houses on the eastern, western, and northern sides, usually one story high. The former residences of high-ranking officials were composed of two or three compounds, interconnected along a north-south axis.

Stepping over the high wooden gate-sill of the front gate of a large compound, the visitor will find a brick screen wall located a few feet inside the gate—a structure that was supposed to shut off the intrusion of evil spirits, as well as to prevent curious passersby from looking inside. Beyond the screen is the outer courtyard, or service courtyard, which is flanked by houses to the east and west. There, in former days, were the kitchen and living quarters for the gatekeeper, servants, and any visiting guests and relatives. A red-painted gate leads through the north wall of the outer court into the main part of the house. This is built around three sides of the main courtyard, which, usually shaded by a large tree, was the centre of the family's life. All the windows look inward to the courtyard, and a double door opens into the courtyard from each of the three wings. The windows extend from three feet above the ground up to the deep, overhanging eaves. As they face south, the rooms in the main building get the maximum possible sunshine in winter, and the eaves provide a pleasant shade in summer, when the sun is high. The wing at the northern end of the court was intended for the head of the family and his wife. It is divided into three compartments, the central one being the living or community room, and the smaller rooms at either side being the bedroom and study. The rooms facing east and west—three on each side of the court—were for married sons and their families. This is the basic plan of all the old houses in Peking. Larger families built an extra courtyard behind the main house, because the traditional ideal was that all the existing generations should live together. Since 1949, however, as mentioned above, a great many of the old-style houses have been adapted for use by several families.

While the style and architecture of private dwelling units are uniform throughout the city, the public buildings and temples are characterized by a variety of designs and structures. As the nation's political and cultural centre for more than 700 years, Peking has more buildings of historical and architectural significance than any other contemporary city in China. Since 1949 many new government and municipal buildings, combining both traditional and Western architecture, have added to the city's landscape.

The Imperial Palaces (now the Palace Museum), with their golden roofs, white marble balustrades, and red pillars, stand in the heart of Peking and are surrounded by a moat and walls with a tower on each of the four corners. The palaces consist of outer throne halls and an inner court. North of the three tunnel gates that form the front gate, called the Wu (Meridian) Gate, a great courtyard lies beyond five marble bridges. Farther north is the massive, double-tiered Hall of Supreme Harmony (T'ai-ho tien), once the throne hall. A marble terrace rises above the marble balustrades that surround it, upon which stand beautiful, ancient bronzes in the shapes of caldrons, cranes, turtles, compasses, and ancient measuring instruments. The Hall of Supreme Harmony is the largest wooden structure in China.

The
Imperial
Palaces

The Hall of Supreme Harmony (centre), one of the former Imperial Palaces, now part of the Palace Museum complex in the Forbidden City.

Xinhua News Agency

Behind it, beyond another courtyard, is the Hall of Complete Harmony (Chung-ho tien), where the emperor paused to rest before going into the Hall of Supreme Harmony. Beyond the Hall of Complete Harmony is the last hall, the Hall of Preserving Harmony (Pao-ho tien), after which comes the Inner Court (Nei-t'ing). The Inner Court was used as the emperor's personal apartment. It contains three large halls, the Palace of Heavenly Purity (Ch'ien-ch'ing kung), the Hall of Heavenly and Earthly Intercourse (Chiao-t'ai tien), and the Palace of Earthly Tranquillity (K'un-ning kung).

The Palace of Heavenly Purity is divided into three parts. The central part was used for family feasts and family audiences, audiences for foreign envoys, and funeral services; the eastern section was used for mourning rites and the west section for state business. The other two palaces, one behind the other, were Imperial family residences. The three throne halls in the Outer Court and the three main halls in the Inner Court lie along the central axis. On either side are smaller palaces, with their own courtyards and auxiliary buildings. Behind the buildings, before the north gate of the Imperial Palaces is reached, lies the Imperial Garden. Each palace, its courtyard and side halls, forms an architectural whole.

Among the historical and religious structures in Peking, the Temple of Heaven (T'ien-t'an), located in the old outer city, is unique both for its unusual geometric layout and because it represents the supreme achievement of traditional Chinese architecture. Entering from the western gate of the temple, along a path that is about 1,600 feet in length and shaded by ancient cypresses, one comes to a raised passage about 1,000 feet long. This broad walk connects the two sets of main buildings in the temple enclosure. To the north lies the Hall of Prayer for Good Harvests (Ch'i-nien tien) and to the south, the Imperial Vault of Heaven (Huang-ch'iuung yü) and the Circular Mound Altar (Huan-ch'iu t'an). The three buildings are built along a straight line. Seen from the air, the wall of the enclosure to the south is square, while the one on the north side is semicircular. This pattern symbolizes the traditional Chinese belief that heaven is round and earth square.

The Hall of Prayer for Good Harvests, built in 1420 as a place of heaven worship for the emperors, is a lofty, cone-shaped structure with triple eaves, the top of which is crowned with a gilded ball. The base of the structure is a large, triple-tiered circular stone terrace. Each ring has balustrades of carved white marble, which gives the effect of lace when seen from a distance. The roof of the hall is deep blue, resembling the colour of the sky. The entire structure, 125 feet high and about 100 feet in diameter, is supported by 28 massive wooden pillars. The four central columns, called the "dragon-well pillars," represent the four seasons; there are also two rings of 12 columns each, the inner ring symbolizing the 12 months and the outer

ring the 12 divisions of day and night, according to a traditional system. The centre of the stone-paved floor is a round marble slab that has a design of a dragon and a phoenix—traditional symbols of king and queen. The hall has no walls, only partitions of open latticework doors.

The Imperial Vault of Heaven, first erected in 1530 and rebuilt in 1752, is a smaller structure some 64 feet high and about 50 feet in diameter. The circular building has no crossbeam, and the dome is supported by complicated span work. Its decorative paintings still retain their fresh original colours.

South of the enclosure lies the Circular Mound Altar, built in 1530 and rebuilt in 1749. The triple-tiered white stone terrace is enclosed by two sets of walls that are square outside and round inside; thus, the whole structure forms an elaborate and integrated geometric pattern. The inner terrace is 16 feet above the ground and about 100 feet in diameter; the middle terrace is about 165 feet across and the lowest terrace some 230 feet across. Each terrace is encircled by nine rings of stones. Both the Imperial Vault of Heaven and the Circular Mound Altar were erected to portray the geometric structure of heaven, as conceived by the architects of the Ming dynasty. After 1949 the whole enclosure of the Temple of Heaven was repaired; it is now a public park.

To the east of T'ien-an Men Square within the People's Cultural Park is found the Working People's Cultural Palace (formerly the Temple of the Imperial Ancestors), where the tablets of the emperors were displayed. The temple, like the Imperial Palaces in style, was built in three stonework tiers, each with double eaves. On either side are two rows of verandas surrounding a vast courtyard large enough to hold 10,000 people. Exhibitions of economic and cultural achievements, both of China and of other countries, are frequently held in the three halls. Lectures by leading scholars on science, literature, and the arts are also held there.

Perhaps the most imposing structure constructed in the heart of the city since 1949 is the Great Hall of the People. The Great Hall is located on the southwestern side of T'ien-an Men Square and is an immense building with tall columns of gray marble set on red marble bases of floral design. It has a flat roof with a golden-yellow tile cornice over green eaves shaped like lotus petals. The base of the building is of pink granite, and its walls are apricot yellow. Its frontage is 1,100 feet long—about the equivalent of two city blocks. The floor space of some 6,060,000 square feet (563,000 square metres) is more than that of all the palaces in the old Forbidden City. Inside the building, the ceiling and walls are rounded. The focus of the lighting system is a red star surrounded by golden sunflower petals. The grand auditorium is where the National People's Congress holds its sessions. Other components are a banquet hall for 5,000, huge lobbies, and scores of meeting rooms and offices for the standing committee of the congress.

THE PEOPLE

Population growth

Since 1949 Peking has been one of the most rapidly growing urban centres in China. During the dynastic period, when Peking was the capital, from the 13th to the beginning of the 20th century, the population of Peking seems to have increased very slowly, but in the four decades (1901–49) after the downfall of the Ch'ing dynasty it increased at an accelerating rate. This rapid increase has been attributed to at least three factors: the rural disorder on the North China Plain during the rule of the warlords caused extensive migration to the walled city of Peking; the loss of Manchuria to Japan in 1931 made Peking a shelter for thousands of refugees from the northeastern provinces; and the establishment of numerous institutes of higher education, sponsored by the government or by foreign missionaries, stimulated the growth of the student population in a city that was a cultural as well as a political capital.

The phenomenal increase in Peking's population, however, occurred after the city had resumed its role as the national capital. In 1949 Peking was the fourth largest city in the country; some 10 years later it had become the second largest. This increase resulted primarily from the necessary migration of thousands of government workers to the new capital, the rapid rate of industrial development in the municipality during the 1950s and '60s, and the extension of the municipal boundary in 1959 to include large rural areas. The effect of these circumstances has been that in the four decades since 1949 the population of

Peking has more than doubled, with people living in rural areas of the municipality accounting for about two-fifths of the total.

The overwhelming majority of Peking's population is Han (Chinese). Hui (Chinese Muslims), Manchus, and Mongols constitute the largest minority groups. Peking residents speak a dialect that is difficult for outsiders to understand, but all educated citizens can speak Mandarin, or *p'u-t'ung hua* ("common language").

Peking has a small but growing community of foreign residents—mainly diplomats, journalists, business people, and teachers—who have become an important aspect of the city's life. Government authorities have made great efforts to meet the special demands of foreigners and to isolate them as much as possible from local people. Foreigners generally are housed in hotels or in large, enclosed apartment compounds and send their children to Western-style schools (although the children are free to attend Chinese schools); in addition, the government has provided an international club with dining and recreational facilities.

Since the late 1970s efforts have been made to restore the ancient temples, churches, and seminaries of various religions (most prominently Buddhism) that were damaged during the Cultural Revolution (1966–76). Some of the restored structures are again being used by worshippers, monks, and pupils.

THE ECONOMY

Agriculture. Although Peking has been the capital of China for hundreds of years, it is far away from the nation's traditional key economic area, the productive Yangtze Valley. In the past the task of feeding the large urban population in Peking was facilitated by using the Grand Canal and by transporting grain from the south by sea. Since the first decade of the 20th century, railways have played an important role in bringing food supplies to the capital. The city, however, has striven for a high degree of self-sufficiency in secondary food supplies, such

CLICK/Chicago

The People's Heroes Monument, in front of the Great Hall in T'ien-an Men Square.

as vegetables, fruits, fish, and poultry, and in a number of construction materials. The expansion of municipal boundaries in 1958 and 1959 was partially aimed at this goal, and the municipality has succeeded in maintaining an adequate supply of vegetables and fruits. Agricultural reforms in the early 1980s gave individual households greater freedom of production and resulted in greater and more varied food supplies in the city.

Thus, unlike in most of the world's major cities, agriculture forms a significant part of Peking's economy. Vegetables are grown in a belt that encircles the city and is covered by a network of irrigation channels. The channels are supplemented by a large number of electric pumps. These irrigation measures have made intensive farming possible in an area prone to frequent droughts. Vegetables are grown in the winter months in hothouses. This large farm belt is also one of the most highly mechanized agricultural areas in China. The municipal government has encouraged the expanded cultivation of fruit and nut trees, and large areas of wasteland to the north and east of the city have been reclaimed for fruit tree planting. The large-scale planting of fruit and other trees has also reduced considerably the wind erosion of the soil. While the hill areas produce large quantities of pears, persimmons, apples, chestnuts, and walnuts, the reclaimed lowlands are covered with vineyards and peach orchards. Part of the Peking fruit crop is shipped by train to the cities of the Northeast and Inner Mongolia.

Industry. One of the main differences between the Imperial capital of former times and present-day Peking is that the Imperial capital was a consumption rather than a production centre, receiving supplies of all kinds from other parts of the country. Since 1949, however, Peking has emerged as China's most industrial city after Shanghai in terms of total production value. Heavy industries predominate over light industries in the city. Most of the growth took place in the 1950s and 1960s, but concern for the adverse effects of industrialization on the city's environment has since led to a curtailment of industrial expansion.

Zhang Shuyuan—Xinhua News Agency

Agricultural produce market in northern Peking.

Among the large industrial establishments is the Shih-ching-shan Iron and Steel Works, located about nine miles west of the old city. The Shih-ching-shan plant was originally started in 1920, based on local ore and anthracite in the Western Hills; after the Japanese occupation of 1937, it produced a meagre amount of pig iron. Since 1958 the plant has been enlarged and is now one of the largest steel plants in China. Its high-quality steel production supplies such Peking industries as machine building, electrical engineering, and precision instrument manufacturing. A number of smaller finishing mills have also been established to produce such items as cold-drawn bearing steel and flat spring steel for tractor and automobile accessories, seamless tubes for high-pressure boilers, and magnetic steel for machine tools and radios. Peking is also an important centre of machinery manufacture, with plants for manufacturing cranes, locomotives, automobile parts, tractors, wheat harvesters, mining machinery, and printing equipment. Most of these plants were built in the suburbs east and south of the central city, where extensive tracts of level land were available and where the prevailing north-west winds would carry industrial pollutants away from the densely populated areas. With the rapid expansion of cotton cultivation in Hopeh Province in the 1950s and 1960s, Peking also became one of China's major textile centres. Peking's textile industry includes the manufacture of cotton and woolen fabrics and piece goods, serge, and several types of synthetic fabric. Peking's petrochemical industry expanded rapidly when an oil pipeline was constructed in the mid-1970s to link the city with the Tach'ing oil field in the Northeast (formerly Manchuria). The petrochemical industry is dominated by the Yen-shan Petrochemical Corporation, located southwest of the city.

As a former Imperial capital, Peking has a rich accumulation of art treasures, produced by a variety of arts and handicraft industries that were intimately connected with court life and Imperial needs. Much of the traditional handicraft industry has been reorganized and reequipped. Among the city's well-known handicraft products are rugs and carpets, porcelain and chinaware, jade and ivory sculpture, brass ware, enamel and lacquer ware, lace, and embroidery.

Commerce and finance. With the rapid growth of industry and population in the city, many service industries, operated mainly by government agencies, have also greatly expanded.

China has a nationwide and centralized system of banking, in which the state-owned People's Bank of China plays a key role. This bank, with its head office in the inner city, functions as the agent of the national treasury. All funds of state-owned industrial enterprises, as well as of national, provincial, and local governments, the People's Liberation Army, and the network of cooperatives, are deposited with the People's Bank. The bank uses the working capital at its disposal for the operations of the economy and the government. The People's Bank thus acts as cashier of the national budget and of a large part of the nation's financial operations. Through its branch offices and savings account centres, the bank also serves the daily needs of people in the city and in the suburbs. Working in cooperation with the People's Bank and under its supervision are three other banking institutions—the People's Construction Bank, which has the task of financing and supervising all basic construction projects, such as new railways; the Agricultural Bank of China, which specializes in agricultural investment; and the Bank of China, which handles all international trade and foreign exchange. In addition, several foreign-owned banks have representative offices in the city to assist foreign nationals doing business in China.

Because of the symmetrical layout of the city, Peking lacks the compact central business district that characterizes most cities in the Western world. Historically, the market areas of the city were situated at two street intersections to the southwest and southeast of the Imperial Palace, and the Tung Tan and Hsi Tan neighbourhoods are still major shopping centres. In addition, a number of multistory department stores have been erected along Wang-fu-ching Ta-chieh and in Hsi Tan, supplying a wide

Iron and
steel
manufac-
turing

Banking
institutions

Shopping
facilities

variety of goods for daily needs. The Peking Department Store, a state-owned enterprise, is one of the largest department stores in China and has branch stores in major cities throughout the country. The Friendship Store near the San-li-t'un Diplomatic Compound mainly serves foreign visitors, although some Chinese—especially those who receive foreign-currency remittances from relatives living abroad—are allowed to shop there; it specializes in foodstuffs, high-quality clothes, antiques and curios, and other items that are not easily available to most Chinese. In addition to these modern establishments, there are a dozen traditional markets that still serve an important local function. The Peking markets have evolved through a long period of history, and each has developed its own reputation for special commodities and services.

The East Wind Market, located on the busy Wang-fuching Ta-chieh, is noted for the traditional handicrafts produced in the city. The market also contains a number of restaurants and cafés serving a variety of Chinese regional foods. The West Market was established in 1932 around Hsi-tan Pei Ta-chieh. It is one of the most diverse markets in the city, composed of several different sections that each offer special commodities or services. There is also a complete department store, as well as a number of recreational establishments.

Two of Peking's more interesting shopping areas are the Liu-li-ch'ang and T'ien-ch'iao markets. The restored Liu-li-ch'ang Market is located just south of the Ho-p'ing Gate site in the old outer city. The area acquired its name (which means "the glazier's shop") from the colourful glazed tiles that were made there during the Ming dynasty, but in the later part of the 18th century it gradually became a market for curios, antiques, old books, paintings, works of ancient Chinese calligraphers, and paper. It is still the centre for traditional art shops. The T'ien-ch'iao Market is located at the south end of the old outer city, near T'ien-t'an Park. As early as the 16th century, poor people of the city began to come to T'ien-ch'iao to buy and sell secondhand goods. Open-air markets were also held there in the evenings. After 1900, when the railway station in the southern suburbs was moved to the vicinity of the Temple of Heaven, peddlers and small traders, folk artists, storytellers, and musicians began to appear in large numbers, and the place became a bustling market for fish, poultry, fruit, and vegetables, as well as a recreational area for poor people. This market has some of the best food shops in the city and remains a folk-entertainment centre for the metropolis.

Tourism Tourism has become increasingly important to the Peking economy. Tourists are drawn not only to the historical and cultural attractions of the central city but also to such sites in the rural areas as the Great Wall and the tombs of the Ming emperors to the north of the city and the Peking-man caves to the southwest. There has been a steady increase in tourist services provided in Peking. Many hotels and hostels have been built, especially in the 1980s, and old ones have been renovated and enlarged to meet the ever greater demand. The China International Travel Service, which is state-owned, especially serves foreign tourists, while the main function of the Overseas Chinese Travel Service is to take care of overseas Chinese, who constitute the majority of visitors touring China; the general offices of both organizations are located in the inner city, and each has branch offices throughout the country.

Transportation. Peking is the railroad centre of China, forming the terminus of a number of lines in the national railroad network. The major lines radiating from Peking provide connections with Shen-yang (Liaoning Province), Shanghai Municipality, Canton (Kwangtung Province), Pao-t'ou (Inner Mongolia Autonomous Region), and T'ai-yüan (Shansi Province), respectively, each city being a major national industrial and commercial centre. The local lines are of regional importance and serve outlying districts within the metropolitan area. Peking is linked by direct express with several other large urban centres, and it is also periodically connected by express train with Moscow; P'yöngyang, N. Kor.; and Ulaanbaatar, Mong.

While railroads connect Peking with distant cities, highways are the principal means of communication with

communities within a 125-mile radius. There are about a dozen major highways radiating from the city, along which regular bus services run. Several major bus depots are located in the inner city. Peking's road-transport system, however, is highly inadequate for a city of its size. There are no long-distance express highways. Three-wheeled cycle carts are widely used in the city for short-distance transport, and in the rural areas goods are still commonly hauled by carts drawn by animals or people.

Peking is also the centre of China's civil air transport. The nation's major domestic air routes radiate from Peking to regional centres at Shanghai, Canton, and Wu-lu-much'i (in Sinkiang Uighur Autonomous Region), as well as to other major cities. Peking's Capital Airport, located northeast of the central city, is the principal international air terminal of the country.

Peking's intracity commuting services are provided primarily by a network of city-owned buses and trolleys. At places to which a large number of people are carried, such as the Shih-ching-shan Iron and Steel Works, bus routes run through the plants themselves. Trolley routes run through the densely populated districts of the city, the pattern much influenced by the symmetrical arrangement of the old city plan. In the early 1970s a subway line—the first in China—was opened, running east-west through the centre of the city; this line was supplemented by a separate loop line opened in the 1980s that follows the old limits of the inner city. There are relatively few taxicabs or private automobiles. Bicycles are very popular for short-distance intracity travel, and they constitute the bulk of street traffic.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Peking is one of the three centrally administered (*i.e.*, province-level) *shih* (municipalities) in China (the others being Shanghai and Tientsin), and there is no governmental tier between it and the central government. The municipality is divided administratively into four urban and six suburban *ch'u* (districts) and the eight *hsien* (counties) in the peripheral areas. Peking's municipal government is part of the hierarchical structure of the Chinese government—and the parallel structure of the Chinese Communist Party (CCP)—that extends from the national organization, through the provincial apparatus, to the municipal and, ultimately, neighbourhood levels. The principal responsibilities of the People's Congress of Peking Municipality, the major decision-making body, include issuing administrative orders, collecting taxes, determining the budget, and implementing economic plans. A standing committee selected from its members recommends policy decisions and oversees the operation of municipal government. Executive authority rests with the Peking People's Government, the officers of which are elected by the congress; it consists of a mayor, vice mayors, and numerous bureaus in charge of public security, the judicial system, and other civil, economic, social, and cultural affairs.

As a subdivision of the municipality, each district or township has its own mayoralty. Below the urban district there are police substations and street mayoralties. Neighbourhood associations have various functions, including mediating disputes, conducting literacy campaigns, supervising sanitation and welfare, and promoting family planning.

As the national capital, Peking houses all of the most important governmental and political institutions in the nation. These include the National People's Congress, nominally the supreme organ of state power; the State Council, the highest executive organ of the state; and the various administrative departments under the jurisdiction of the State Council, including the ministries and commissions in charge of foreign affairs, internal affairs, public security, national defense, justice, finance, culture, health, education, nationality affairs (concerning minority groups in the country), agriculture, and various branches in industry. Peking is also the headquarters of the parallel CCP organizations—the National Party Congress, the Central Committee and Politburo, and the Secretariat. In addition to the above, the highest organ of state concerned with

the maintenance of law and order—the Supreme People's Court—is located in Peking.

Public utilities. Peking is not on a river, and most water for municipal consumption has to be brought from elsewhere. Some water, however, comes from shallow wells, which are common throughout much of the region. These provide some villages with drinking water and supply water for irrigation.

From the earliest history of the city, use has been made of local rivers and springs. To the east is the Pai River, which, after being joined by the Ch'ao River at the Mi-yün Reservoir, forms the Ch'ao-pai River, which then flows southward. The tumultuous Yung-ting is a large river, draining the Shansi Plateau and the northwest of Hopeh. After following a twisting course through the mountains, it reaches the Peking plain, passes under the Marco Polo Bridge, nine miles southwest of Peking, and then turns southward to meet the Grand Canal north of Tientsin. The flow of the Yung-ting is irregular; in the rainy season it rises rapidly, carrying with it large quantities of silt, which raise the level of the riverbed considerably. At Marco Polo Bridge it is 50 feet above the level of the city, thus constituting a hazard when the river is in flood but facilitating canalization and irrigation. Several springs rise at the foot of the Hsiang Hills and on Yü-ch'üan Hill, both to the northeast of the city. During the Ch'ing dynasty these springs were tapped by means of an aqueduct that conveyed water for the city moat and for the three lakes near the Imperial Palaces. The moat around the city walls became an important means of water distribution for the municipality.

In the early 1950s, large-scale water-conservation projects were begun to provide more water for the expanding urban area. Two large artificial lakes have since been made: the Mi-yün Reservoir, northeast of the city, and the Kuan-t'ing Reservoir, in the northwestern mountains beyond the Great Wall. These regulate the flow of the Pai and Yung-ting rivers upstream, storing water at times of heavy discharge and releasing it when the rivers are low. Two lesser projects have also been carried out: the construction of the Ming Tombs Reservoir, whose waters feed a hydroelectric power station and irrigate the neighbouring countryside, and a hydroelectric power station near Mo-shih-k'ou, which uses the waters of the Yung-ting and feeds them back into the river through an ancient canal. The hydroelectric station at Kuan-t'ing is the largest source of electricity for the metropolitan area of Peking.

The Peking Water Company, which was originally formed in 1908, is responsible for supplying water for the municipality. Water is obtained from the waterworks within the old city, as well as from several waterworks in the suburbs; the network of mains and pipes extends to every residential and industrial unit, including towns and villages near the Men-t'ou-kou coal mine about seven miles from the city. Public standpipes have also been installed at regular intervals throughout the city, the suburbs, and nearby rural people's communes. The Kuan-t'ing Reservoir, the largest man-made lake in the North China Plain, supplies the metropolitan area of Peking with most of its water.

Peking is one of the few cities in China equipped with a modern sewage system. An underground sewage system was installed as early as the 15th century, which extended nearly 195 miles. Later this network became clogged with effluent and silt. A new system was installed in the early 1950s, which, within the walled area, was partly based on the rehabilitation of the old system. All open sewers, characteristic of many Chinese cities, were eliminated, and new pipes were laid throughout the densely populated areas of the municipality.

The headquarters of the Peking General Post Office is located on the east side of T'ien-an Men Square. It provides more comprehensive services than do post offices in Western cities, handling mail, telegrams, long-distance telephone calls, and the distribution of newspapers and magazines. There are also more than 350 branch offices and stations in the city and the suburbs. The Peking General Post Office also maintains several service centres at certain busy traffic points, such as the Ch'ien Gate and Peking Railway Station, and Wang-fu-ching Ta-chieh.

The service centre on Wang-fu-ching Ta-chieh takes subscriptions to foreign newspapers and magazines and sells single issues.

Health. Chinese medical services employ both the traditional Chinese and the Western systems of medicine. Peking has some of the best hospitals of both systems in the nation.

The Peking Union Hospital, the earliest modern hospital to be established in China, was founded in 1921 as an affiliate of the Peking Union Medical College, which from 1915 onward was supported by the China Medical Board of the Rockefeller Foundation. The hospital, now renamed Capital Hospital, is a large polyclinic combined with an institute of gynecology and pediatrics. It is the largest hospital in Peking. Since 1949 many new hospitals, clinics, and sanitariums have been built. People's Friendship Hospital, a gift of the Soviet Union at the peak of Sino-Soviet friendship in the 1950s, is located in the T'ien-ch'iao neighbourhood in the outer city. Until 1960 the Soviet staff not only treated patients but also gave advanced training to Chinese medical personnel on the latest Soviet methods.

Many hospitals are clinical teaching hospitals attached to medical schools; these include the Fu Wai Hospital of the Chinese Academy of Medical Science, located outside the Fu-ch'eng Gate site; the First Affiliated Hospital of the Peking Medical College, near the Hsi-an Gate site; and the Affiliated Hospital of the Research Institute of Chinese Medicine, located in the western suburban town of Hsiao-yüan. The largest pediatrics hospital in China, the new Peking Children's Hospital, is situated just outside the Fuh-sing Gate site. It was designed to provide a homelike atmosphere for its young patients. In the hills to the west, a sanitarium in the traditional Chinese architectural style has been built for students from Asian countries. The most specialized hospitals are located in the old residential districts of the city and include the Stomatological Hospital (dealing with the mouth and related diseases), the Chest Surgery Hospital, the Hospital of Plastic Surgery, the old Peking Children's Hospital, the Hospital of Chinese Medicine, and the Ji-sui-tan Hospital, which specializes in traumatic (accident-related) and orthopedic surgery.

Chinese traditional medicine comprises prescribing Chinese herb drugs and employing acupuncture (a medical practice encompassing therapeutics and anesthesia that involves inserting needles into various parts of the body). Doctors in both Chinese and Western systems are trained in many universities and institutes in Peking. Students in the Western-style medical schools are taught the essentials of Chinese traditional medicine, and Chinese traditional medical students are expected to be familiar with the essentials of Western medicine. Diagnoses of difficult cases are made only after consultations with specialists of both systems.

For the rural areas of the metropolis, each county has a well-equipped hospital located in the county seat. But the basic unit of the medical service is the health centre in the commune, which is equipped with complete clinical facilities. Medical teams of doctors, nurses, and public health personnel are sent frequently from the teaching centres in the city to the communes to assist in the general medical work and to keep the local medical staff in touch with the latest medical progress and techniques.

Education. The educational system of Peking was massively disrupted by the Cultural Revolution, and throughout the 1980s it was in the process of being restored. Nevertheless, there has been no radical change in the structure of the school system in Peking since 1949; it is still largely composed of six years of primary education, which is universal, and six years of secondary education. For preschool-age children, kindergartens and nurseries are operated by factories, business enterprises, government offices, and city block cooperatives. Their main function is to permit mothers to work, and although some of these facilities are located in the residential neighbourhoods, many are located on the premises of places of employment. In the suburban or rural areas, kindergartens are often temporarily set up during such events as the harvest.

In the early 1950s, efforts were made to abolish private

Traditional
medicineThe
schools

schools and to put all education in the hands of the state. As a result, all private schools run by missionaries were taken over by the government. It was soon realized, however, that the government could not possibly provide enough schools for the millions who required education. The government then reversed its policy to some degree and decided to encourage the establishment of schools by local organizations, such as factories, business concerns, collectives, and communes. A major part of the finance for elementary education is now met by sources other than the central government, though the government does provide considerable subsidies to schools in difficult financial situations.

The curriculum in the primary school is basic. The early part of primary education is largely devoted to reading, writing, and mathematics, and, in the last two years of primary school, nature study, history, geography, and physical education are added to the curriculum. Closely related to primary education are movements for eliminating illiteracy, phoneticizing Chinese writing, and simplifying Chinese characters.

The secondary schools in Peking are mainly of three types: the general middle school, the normal school, and the vocational and technical school. The general middle school is of the academic type, with a curriculum designed to prepare students for college. The normal school trains teachers for primary schools. The vocational and technical schools, created to provide skilled workers in various fields, have developed most rapidly in the city.

Institutions
of higher
education

Peking's position as a centre of higher education in China has been further strengthened since 1949, and within the metropolitan area there are numerous institutes of higher learning. A scientific and educational district has emerged in the northwestern outskirts of the city, against the background of K'un-ming Lake, the Summer Palace, and the Western Hills. This area contains such prestigious institutions as Peking University and Ch'ing-hua University. Peking University was founded in 1898 and is one of the largest composite universities in China. In 1953 the university moved from its old site at Sha-t'an, in the inner city, to the present campus, which previously belonged to the missionary-established Yen-ch'ing University. The new campus has been expanded considerably to the east and south. Ch'ing-hua University is the most renowned technical institute in China.

Within the academic district are also found the People's

University of China, an institute of ideological training, and the Central Institute of Nationalities, which accepts students from the various autonomous regions and districts. Situated in the same area are the Peking Normal College, the Peking Medical College, and the Central Conservatory of Music. Numerous institutes of higher education are also located in this area; these include the Peking Institute of Steel and Iron, the Peking Institute of Aeronautics and Astronautics, the Peking Petroleum Institute, the Peking Institute of Geological Prospecting, the Peking Institute of Forestry, and the Peking Mechanical Institute of Agriculture. The Chinese Academy of Sciences, the most prestigious research institute in the nation, is also located in this district.

Besides technical colleges, there are a number of foreign-language institutions in Peking where foreigners are employed to teach alongside their Chinese colleagues. The Peking Foreign Language Institute, located on the northwestern outskirts of the city, is the largest institute of its kind in China. The Second Foreign Language Institute was set up in 1964 for training personnel for the New China News Agency. There are also a number of small institutes of language training run by the government and by the Peking Radio Station. The School of Foreign Languages is an institute at the secondary level, which accepts children as young as eight years of age; half of them learn English, while others study French, German, Spanish, Arabic, Russian, and Japanese.

language
institutions

CULTURAL LIFE

Peking has been the magnificent centre of traditional Chinese culture and learning since the Ming dynasty. Emperors and courtiers patronized the arts, especially painting and calligraphy. Precious objects from other parts of the empire and from foreign countries poured into the capital. This role of cultural centre was continued during the Ch'ing dynasty, although the century of political and social upheaval that began in the mid-19th century led to an overall cultural decline in Peking. This decline continued into the modern period and affected not only Peking but the whole of China. With their defeat in 1949, the Nationalists shipped a huge quantity of art treasures to Taiwan. On the mainland, subsequently, many family heirlooms were purchased by the state for very low prices and were then sold for export or used to enhance museum holdings.

Until the early 1960s traditional arts, crafts, and scholar-

Der Stern—Black Star

May Day rally in T'ien-an Men Square, Peking.

ship were encouraged by the Chinese Communist Party, but the Cultural Revolution swept all before it. Art objects that were not deliberately smashed by the Red Guards were confiscated (some were returned to their former owners during the 1980s). The Cultural Revolution also put a virtual end to traditional Chinese scholarship, as many academics were sent out to the countryside or imprisoned. Since the late 1970s, however, the government has made a concerted effort to restore damaged treasures and to revive the work of traditional artists and scholars. Since much of this activity has taken place in Peking, the capital has undergone something of a cultural renaissance.

Museums and libraries. The Palace Museum, containing the city's greatest collection of art treasures, is housed in the main buildings of the former Imperial Palaces. Many of the halls are kept as they were in dynastic times, each constituting a museum in itself; others are kept for the display of some of the priceless treasures from China's past. Of special interest are the porcelains and enamels, works in embroidery and precious metals, and the stone carvings and scrolls.

The Museum of Chinese History is located on the eastern side of T'ien-an Men Square. There are thousands of historical relics and documents on display, arranged to give a comprehensive survey of the progress of human achievement in China, beginning with the appearance of the prehistoric Peking man some 500,000 years ago, then continuing through the last 6,000 years of Chinese history. The Museum of the Chinese Revolution occupies a wing of the museum building. Its purpose is to trace the history of China since the mid-19th century, laying particular stress on the revolutionary movement and the part played by the Communist Party.

The Peking Planetarium, the first of its kind in China, is located outside the Hsi-chih Gate site. It is an educational centre for the dissemination of general knowledge in astronomy and natural science by means of exhibitions, forums, films, projector demonstrations, and telescopic observations of the heavens. The planetarium proper is situated on the south side of the building. Behind the main building stand an observatory and meteorological station.

The Peking Library, which holds the historical collections of the National Library of China, is located on the west bank of Pei Hai. The library inherited books and archives from the Imperial Wen-yüan Ko library, a famous collection that has existed for more than 500 years and that, in turn, included books and manuscripts from the Imperial Library of the Southern Sung dynasty, established some 700 years ago. Also in its holdings are other collections from Imperial libraries of the Ch'ing dynasty, Imperial colleges, and private owners. Among them are rare copies of ancient manuscripts and books of five dynastic periods from the Sung to the Ch'ing, including a vast number of manuscript volumes on different subjects, copies of Buddhist sutras dating to the 6th century, old maps, diagrams, and rubbings from ancient inscriptions on metal and stone; in addition, it possesses the *Yung-lo ta-tien* ("Yung-lo Encyclopedia") of the Ming dynasty and a copy of the *Ssu-k'u ch'üan-shu* ("Complete Library of the Four Branches of Literature"), dating from the Ch'ing dynasty. In the late 1980s the collection of modern holdings of the National Library was moved from the Peking Library to a new facility in the western outskirts of the city.

The arts. Traditional Peking opera (*ching-hsi*)—with its elaborate and stylized costumes and makeup, cacophonous music, and spectacular dance and acrobatic routines—has been revived, after an attempt during the Cultural Revolution to adapt the form to modern revolutionary themes. The opera has great appeal to older people but less for the young, who instead prefer motion pictures, television, and popular music. Musical performances of all kinds are given in Peking; the city boasts a symphony orchestra and Western-style opera and ballet companies and hosts visits by foreign orchestras and performers.

A variety of Chinese plays are staged each year, and works by Shakespeare and other Western dramatists have again been playing in Peking. The city's bookshops, almost denuded of cultural works and foreign literature during the Cultural Revolution, are now better stocked. In addition,

calligraphy and the painting of non-revolutionary subjects have again become popular pastimes.

Recreation. As the residence of the Imperial families through several dynastic periods, Peking is well known for its numerous parks and playgrounds; few cities in China have as large a proportion of land within the central city allocated for recreational uses. Among the most popular of Peking's parks are Chung-shan Park, Pei-hai Park, Ching-shan Park, the Summer Palace, and the Peking Zoological Gardens.

Chung-shan Park adjoins the west wall of T'ien-an Men Square; it is the most centrally located park in Peking and encloses the former Altar of Earth and Harvests, where the emperors made offerings to the gods of earth and agriculture. The altar consists of a square terrace in the centre of the park, to the north of which is the 550-year-old Hall of Worship, now the Sun Yat-sen Memorial Hall, which is used for public meetings. The Hall of Worship is the oldest wooden structure in Peking; its simple form, masterly design, and sturdy woodwork bear the characteristic marks of early Ming architecture.

The Water Pavilion, built out over a lotus pond on three sides to provide a gathering place for scholars and poets, is also located in the park. Scattered among the park's pools, goldfish enclosures, rocky hills, weeping willows, pines, cypresses, bamboos, and flowers are pavilions, kiosks, and towers, which are typical of Chinese garden landscape.

Pei-hai Park lies to the northwest of the Forbidden City. It covers some 176 acres (71 hectares), half of which is water. It contains Pei Hai, the most northerly of the three lakes—called "seas" (*hai*)—that lie roughly north and south within the Imperial City. Pleasure grounds, lakes, and buildings have existed on this site for 800 years. As the lakes were deepened and dredged, the excavated earth was used to build hillocks and islands of great beauty. In 1651 a Manchu emperor built the White Pagoda, the most striking landmark in the park, on the top of a hill. Many of the buildings in the park are used for serious pursuits, as well as recreation. They include an Institute of Research on the History of Chinese Classical Literature and a Natural History Museum, as well as the Peking Library. Pei Hai is crowded with rowboats in summer, and it freezes over to become a natural skating rink in winter.

Ching-shan (Prospect Hill) Park, also known as Mei-shan (Coal Hill) Park, is a man-made hill, more than a mile in circumference, located north of the Forbidden City. The hill, from the top of which a spectacular panorama of Peking can be seen, has five ridges, with a pavilion on each. The hill was the scene of a historical tragedy when, in 1644, at the end of the Ming dynasty, the defeated Ming emperor hanged himself on a locust tree on its east slope. In the northern part of the park is Peking Children's Palace, with recreational, athletic, and educational facilities.

The Summer Palace, lying close to the Western Hills, is about six miles northwest of the Hsi-chih Gate site. It is the largest park on the outskirts of Peking and is noted for its artificial landscaping, which provides an inimitable blend of woods, water, hills, and architecture. The Summer Palace covers more than 800 acres, four-fifths of which consists of K'un-ming Lake, the remainder being man-made hillocks. More than 100 buildings—halls, towers, pavilions, bridges, and pagodas—lie scattered throughout the park; a marble boat, two stories high and some 80 feet long, located at the northwest corner of the lake, is one of the major attractions. Connecting the buildings and courts along the shore of the lake are a series of richly painted covered promenades.

Peking Zoological Gardens is located on the western outskirts of the city. The zoo was established toward the end of the 19th century and was named the "Garden of Ten Thousand Animals" (Wan-sheng Yuan). Its collection is actually less than half that size, but it is the largest zoo in the country, with animals from all parts of China and the world; one of the zoo's most popular attractions is its collection of giant pandas.

Peking Workers' Stadium, located in the eastern part of the city, seats 80,000 and is the largest sports facility in China. Soccer games and field and track events are

often held there. The Capital Gymnasium in the western outskirts has facilities for a variety of indoor games; it has enough space for 24 table tennis matches to be held simultaneously. A movable floor facilitates formation of an ice rink for figure skating and ice hockey.

Cuisine

The Chinese love of good food is world-renowned, and Peking is China's culinary showcase. All of the regional cuisines are represented among the city's hundreds of restaurants, although the Peking style predominates. The best-known dish to foreigners is Peking duck, which is the specialty of several establishments.

History

THE EARLY EMPIRES

With but few interruptions, Peking has been the capital of China for some 700 years, and in the number of years as the Imperial capital it is exceeded only by Sian (Ch'ang-an) in Shensi Province and Lo-yang in Honan Province. In prehistoric times the area around Peking was inhabited by some of the earliest known human beings. Between 1918 and 1939 the fossil remains of Peking man (formerly *Sinanthropus pekinensis*; now known as *Homo erectus pekinensis*), who lived about 500,000 years ago, and of Upper Cave man, who lived about 50,000 years ago, were unearthed at Chou-k'ou-tien, a village about 30 miles southwest of Peking.

While long periods in Peking's early history necessarily remain blank, it is certain that, some 3,000 years ago, Neolithic communities settled on or near the site where Peking now stands. During the Chan-kuo (Warring States) period (475–221 BC) of the Chou dynasty (c. 1111–255 BC), one of the powerful feudal states, the kingdom of Yen, established its capital named Chi near the present city of Peking; this was the first capital city to be associated with the site. The city was destroyed by the troops of Shih Huang-ti, founder of the Ch'in dynasty (221–206 BC).

Chi—the capital of Yen

During the Ch'in dynasty, the Yen capital was incorporated into one of the 36 prefectures then established throughout the country. A new town was built during the Han dynasty (206 BC–AD 220) and was known as Yen. Throughout the Han dynasty and the turbulent centuries that followed, however, the place remained a provincial town, witnessing most of the time the fateful struggle between the Han Chinese to the south and the nomadic Hsiung-nu, or Huns, to the north.

During the period of San-kuo (Three Kingdoms; AD 220–280), the city was again called Yen. The northern border of ancient China ran close to the present city of

Peking, and northern nomadic tribes frequently broke in from across the border. Thus the area that was to become Peking became an important strategic as well as a local political centre.

For nearly 300 years (from the end of the Hsi [Western] Chin dynasty in 316/317 to the beginning of the Sui dynasty in 581), the northern territory, including the site where Peking now stands, was largely under the control of invading nomads. It was not until the T'ang dynasty (618–907) that it was recovered by the Han people and became known as Yu-chou. By the middle of the T'ang dynasty, measures were taken to prevent the nomadic Tangut tribes of Tibet, the Hsi Hsia and the Khitans (a Manchurian people), from raiding the border lands and the local capital. The position of Yu-chou consequently became increasingly important. On the fall of T'ang China, a number of states emerged in North China. One of these states was established by the Khitans; after destroying the city of Yu-chou, the Khitans established the Liao kingdom (947–1125) and built one of their capitals on approximately the same site, calling it Nanking ("Southern Capital") to distinguish it from other capitals in their Manchurian homeland. The Liao capital was bounded by a square wall, almost 14 miles in circumference and some 32 feet high. It had eight gates and enclosed a fine Imperial palace in the centre, which indicated the strong influence of Chinese city planning.

In the middle of the 12th century, when the Juchen, a Manchurian people from the Amur Valley, defeated the Liao and established the state of Chin, the Liao capital was rebuilt as the new Chin capital and renamed Chung-tu ("Central Capital"). Chung-tu under the rule of the Juchen was constructed on a larger scale, with splendidly decorated palaces and halls.

Between 1211 and 1215 the Mongols, under the leadership of Genghis Khan, one of the great conquerors of history, repeatedly attacked and finally took the city from the Chin. In the battle the palaces of Chung-tu were set on fire and blazed for more than a month. When all China fell to the Mongol hordes, Kublai Khan (1215–94), a successor to Genghis Khan and founder of the Yüan, or Mongol, dynasty (1206–1368), determined to build a new capital at Peking, abandoning the old city of Karakorum in Mongolia. In 1272 he named the new capital Ta-tu ("Great Capital"); under Mongol control it became for the first time the political centre of all China.

Ta-tu was larger than any of its forerunners and was rebuilt slightly northeast of the old site. The square of the outer wall measured about 18 miles in length and

The Mongol capital of Ta-tu

enclosed an area of more than 20 square miles. The city walls were built with pounded earth, and once a year labourers were called in to repair them with mud. The Imperial Palace, which was approximately to the west of the existing one, was situated in the southern half of the capital city. The chief palace architect at the time was an Arab, appointed by Kublai Khan. The city of Ta-tu exemplified the imposing and variegated architecture of the Mongol period. The square walls and the 12 gates were all modeled on the Chinese plan, but the inner chambers and living quarters were often in the style of Mongolia or of Central Asia. It was at this time that a canal, the T'ung-hui Canal, was dug and connected to the Grand Canal, so that boats transporting the tribute rice from the provinces south of the Yangtze could sail into one of the new lakes inside the city. Ta-tu, which had magnificent Imperial palaces and treasures drawn from every corner of the country, was the scene of stupendous feasts given by the khan (ruler) on state occasions. These characteristics and the well-organized post-stages on the roads leading to the city astounded Marco Polo, the Venetian traveler who visited Ta-tu in the 1280s.

CENTURIES OF GROWTH

The Ming and Ch'ing dynasties. In the middle of the 14th century, Chu Yüan-chang headed a peasant revolt that overthrew the Mongol dynasty and, as the Hung-wu emperor, established the Ming dynasty (1368-1644). He moved the capital to Chin-ling, near his own hometown in Anhwei Province, and called it Nanking; Ta-tu was renamed Pei-p'ing ("Northern Peace") and was placed under his son's rule. On Chu's death (1398) the throne passed to his grandson in Nanking, but his son, Chu Ti (also called the Yung-lo emperor), who ruled Pei-p'ing, usurped the throne. In consequence, in 1403 the city was renamed Peking ("Northern Capital"), and in 1421 it was officially made the capital city of the Ming dynasty.

Peking in the Ming period grew on a yet grander scale than under the Mongols. The former city walls and the extant moats, palaces, and temples were mostly built in the 15th century. The old city of Ta-tu, including the palaces, was largely demolished. The new city was situated farther south, thus leaving the northern part of the Mongol city derelict while at the same time slicing off one gate from the east and west walls, respectively. In 1553 an outer city wall was begun, to include the increasing number of inhabitants living outside the city, but, when the entire construction was subsequently found to be too costly, the plan was abandoned on the completion of the south wall, thus producing the present shape of the old city. Unlike the city wall of pounded earth of Mongol times, the walls of the Ming city were faced with a layer of bricks, in order to prevent weathering.

In 1644 Peking was taken over by Li Tzu-ch'eng, who led a peasant uprising against the Ming regime. Li's army held it for only 40 days, for the Manchus were simultaneously preparing an incursion south of the Great Wall, and—thanks to the treachery of a Ming general who opened the gate—they swept down on the city. Peking fell intact and in the same year was declared the Manchu capital by Shun-chih, the first emperor of the Ch'ing dynasty (1644-1911/12).

Peking remained superficially the same throughout Ch'ing times. The city plan was unaltered, though many palaces, temples, and pavilions were added outside the walls to the west, notably the Yüan-ming Yüan (old Summer Palace), built in the 17th century, and the I-ho Yüan (new Summer

Palace), built in the late 19th century. The old Summer Palace was completely destroyed by fire in 1860 by the allied British and French troops during the "Arrow" War (1856-60). In the same year, as a result of the treaties of Tientsin in 1858, a permanent British embassy was established in the city, and a legation quarter, situated to the southeast of the palace ground, was reserved for British and other embassies. The legation quarter was besieged for nearly two months by the Boxer rebels in 1900.

The modern city. After the revolution of 1911, Peking remained the political centre of the Republic of China until 1928, when the Nationalists moved the capital to Nanking; Peking was again called Pei-p'ing. The city came under increasing pressure from the Japanese, who established the puppet state of Manchukuo in Manchuria in 1931. In July 1937 fighting broke out between Chinese and Japanese troops near the Marco Polo Bridge, southwest of the city; Pei-p'ing was subsequently occupied by the Japanese until 1945. After World War II the city reverted to the Nationalists, who were defeated by the Communists in the ensuing civil war. In 1949, with the establishment of the People's Republic of China, Peking (with its old name restored) was chosen as the capital of the new regime. The city soon regained its position as the leading political, financial, and cultural centre of China.

BIBLIOGRAPHY

General works: ROSS TERRILL, *Flowers on an Iron Tree: Five Cities of China* (1975); FELIX GREENE, *Peking* (1978); and DAVID BONAVIA, *Peking* (1978), describe city life in Peking. A number of important works on scenic and structural aspects of Peking were completed during the 1930s; among them are L.C. ARLINGTON and WILLIAM LEWISOHN, *In Search of Old Peking* (1935, reprinted 1987); and JULIET BREDON, *Peking: A Historical and Intimate Description of Its Chief Places of Interest*, 3rd rev. ed. (1931). OSVALD SIRÉN, *The Walls and Gates of Peking* (1924), and *The Imperial Palaces of Peking* (1926, reprinted 1976), give details on architectural features of the old walled city. HEDDA MORRISON, *A Photographer in Old Peking* (1985), is a record of the city in the 1940s. NORMAN A. CHANCE, *China's Urban Villagers: Life in a Beijing Commune* (1984), provides insight into economic and political factors. For demographic information, see the annual *China Urban Statistics*.

Guidebooks: DAVID BONAVIA *et al.*, *A Guide to Beijing* (1987), is a survey from the China Guide Series. LIU JUNWEN, *Beijing: China's Ancient and Modern Capital* (1982), is a detailed guidebook. There is a chapter on history, development, and life in the city in the comprehensive work by FREDRIC M. KAPLAN, JULIAN M. SOBIN, and ARNE J. DE KEIJZER, *The China Guidebook*, 8th ed. (1987). YU ZHUOYUN (comp.), *Palaces of the Forbidden City* (1984; originally published in Chinese, 1982), is a guide to the Palace Museum.

History: Historical development is covered by RODERICK MACFARQUHAR, *The Forbidden City* (1972); NIGEL CAMERON and BRIAN BRAKE, *Peking: A Tale of Three Cities* (1965); and ZHOU SHACHEN, *Beijing Old and New: A Historical Guide to Places of Interest* (1984; originally published in Chinese, 1982). FRANK DORN, *The Forbidden City* (1970), associates the details of the Imperial Palaces with historical events. Other studies include JOHN S. BURGESS, *The Guilds of Peking* (1928, reprinted 1970); PETER FLEMING, *The Siege at Peking* (1959, reissued 1984); and GEORGE N. KATES, *The Years That Were Fat: The Last of Old China* (1952, reissued 1976), covering the period of the 1930s. Accounts of life in the city in the early decades of the 20th century are found in H.Y. LOWE, *The Adventures of Wu: The Life Cycle of a Peking Man* (1940, reprinted 1983); HAROLD ACTON, *Peonies and Ponies* (1983), a novel set in Peking's expatriate community in the 1930s; and PU YI, *From Emperor to Citizen: Autobiography of Aisin-Gioro Pu Yi*, new ed., trans. from Chinese by W.J.F. JENNER (1987), the memoir of the last Chinese emperor.

Human Perception

Perception, or perceiving, refers to the process whereby sensory stimulation is translated into organized experience. That experience, or percept, is the joint product of the stimulation and of the process itself. Relations found between various types of stimulation (*e.g.*, light waves and sound waves) and their associated percepts suggest inferences that can be made about the properties of the perceptual process; theories of perceiving then can

be developed on the basis of these inferences. Because the perceptual process is not itself public or directly observable (except to the perceiver himself, whose percepts are given directly in experience), the validity of perceptual theories can be checked only indirectly. That is, predictions derived from theory are compared with appropriate empirical data, quite often through experimental research.

General considerations

Historical
back-
ground

Historically, systematic thought about perceiving was the province of philosophy. Indeed, perceiving remains of interest to philosophers, and many issues about the process that were originally raised by philosophers are still of current concern. As a scientific enterprise, however, the investigation of perception has especially developed as part of the larger discipline of psychology.

Philosophical interest in perception stems largely from questions about the sources and validity of what is called human knowledge (see *EPISTEMOLOGY*). Epistemologists ask whether a real, physical world exists independently of human experience and, if so, how its properties can be learned and how the truth or accuracy of that experience can be determined. They also ask whether there are innate ideas or whether all experience originates through contact with the physical world, mediated by the sense organs. For the most part, psychology bypasses such questions in favour of problems that can be handled by its special methods. The remnants of such philosophical questions, however, do remain; researchers are still concerned, for example, with the relative contributions of innate and learned factors to the perceptual process.

Such fundamental philosophical assertions as the existence of a physical world, however, are taken for granted among most scientific students of perceiving. Typically, researchers in perception simply accept the apparent physical world particularly as it is described in those branches of physics concerned with electromagnetic energy, optics,

and mechanics. The problems they consider relate to the process whereby percepts are formed from the interaction of physical energy (for example, light) with the perceiving organism. Of further interest is the degree of correspondence between percepts and the physical objects to which they ordinarily relate. How accurately, for example, does the visually perceived size of an object match its physical size as measured (*e.g.*, with a yardstick)?

Questions of the latter sort imply that perceptual experiences typically have external referents and that they are meaningfully organized, most often as objects. Meaningful objects, such as trees, faces, books, tables, and dogs, are normally seen rather than separately perceived as the dots, lines, colours, and other elements of which they are composed. In the language of Gestalt psychologists, immediate human experience is of organized wholes (*Gestalten*), not of collections of elements.

A major goal of Gestalt theory in the 20th century was to specify the brain processes that might account for the organization of perception. Gestalt theorists, chief among them the German-U.S. psychologist and philosopher, the founder of Gestalt theory, Max Wertheimer and the German-U.S. psychologists Kurt Koffka and Wolfgang Köhler, rejected the earlier assumption that perceptual organization was the product of learned relationships (associations), the constituent elements of which were called simple sensations. Although Gestaltists agreed that simple sensations logically could be understood to comprise organized percepts, they argued that percepts themselves were basic to experience. One does not perceive so many dis-

crete dots (as simple sensations), for example; the percept is that of a dotted line.

Without denying that learning can play some role in perception, many theorists took the position that perceptual organization reflects innate properties of the brain itself. Indeed, perception and brain functions were held by Gestaltists to be formally identical (or isomorphic), so much so that to study perception is to study the brain. Much contemporary research in perception is directed toward inferring specific features of brain function from such behaviour as the reports (introspections) people give of their sensory experiences. More and more such inferences are gratifyingly being matched with physiological observations of the brain itself.

Many investigators relied heavily on introspective reports, treating them as though they were objective descriptions of public events. Serious doubts were raised in the 1920s about this use of introspection by the U.S. psychologist John B. Watson and others, who argued that it yielded only subjective accounts and that percepts are inevitably private experiences and lack the objectivity commonly required of scientific disciplines. In response to objections about subjectivism, there arose an approach known as behaviourism that restricts its data to objective descriptions or measurements of the overt behaviour of organisms other than the experimenter himself. Verbal reports are not excluded from consideration as long as they are treated strictly as public (objective) behaviour and are not interpreted as literal, reliable descriptions of the speaker's private (subjective, introspective) experience. The behaviouristic approach does not rule out the scientific investigation of perception; instead, it modestly relegates perceptual events to the status of inferences. Percepts of others manifestly cannot be observed, though their properties can be inferred from observable behaviour (verbal and nonverbal).

One legacy of behaviourism in contemporary research on perception is a heavy reliance on very simple responses (often nonverbal), such as the pressing of a button or a lever. One advantage of this Spartan approach is that it can be applied to organisms other than man and to human infants (who also cannot give verbal reports). This restriction does not, however, cut off the researcher from the rich supply of hypotheses about perception that derive from his own introspections. Behaviourism does not proscribe sources of hypotheses; it simply specifies that only objective data are to be used in testing those hypotheses.

Behaviouristic methods for studying perception are apt to call minimally on the complex, subjective, so-called higher mental processes that seem characteristic of adult human beings; they thus tend to dehumanize perceptual theory and research. Thus, when attention is limited to objective stimuli and responses, parallels can readily be drawn between perceiving (by living organisms) and information processing (by such devices as electronic computers). Indeed, it is from this information-processing approach that some of the more intriguing theoretical contributions (*e.g.*, abstract models of perception) are currently being made. It is expected that such practical applications as the development of artificial "eyes" for the blind may emerge from these man-machine analogies. Computer-based machines that can discriminate among visual patterns already have been constructed, such as those that "read" the code numbers on bank checks.

CLASSICAL PROBLEMS

Sensing and perceiving. Many philosophers and psychologists have commonly accepted as fundamental a distinction made on rational grounds between sensing and perceiving (or between sensations and percepts). To demonstrate empirically that sensing and perceiving are indeed different, however, is quite another matter. It is often said, for example, that sensations are simple and that percepts are complex. Yet, only if there is offered some agreed upon (*a priori*) basis for separating experiences into two categories—sensations and percepts—can experimental procedures demonstrate that the items in one category are "simpler" than those in the other. Clearly, the arbitrary basis for the initial categorization itself cannot be

subjected to empirical test. (See also SENSORY RECEPTION.)

Problems of verification aside, the simplicity–complexity distinction derives from the assumption that percepts are constructed of simple elements that have been joined through association. Presumably, the trained introspectionist can dissociate the constituent elements of a percept from one another, and in so doing, experience them as simple, raw sensations. Efforts to approach the experience of simple sensations might also be made by presenting very simple, brief, isolated stimuli; *e.g.*, flashes of light.

Another commonly offered basis for distinction is the notion that perceiving is subject to the influence of learning while sensing is not. It might be said that the sensations generated by a particular stimulus will be essentially the same from one time to the next (barring fatigue or other temporary changes in sensitivity), while the resulting percepts may vary considerably, depending on what has been learned between one occasion and the next (see below *Perceptual learning*).

Some psychologists have characterized percepts as typically related to external objects and sensations as more nearly subjective, personal, internally localized experiences. Thus, a spontaneous pain in the finger would be called a sensation; however, if the salient feature of experience is that of a painfully sharp, pointed object, such as a pin located "out there," it would be called a percept.

The above definitional criteria all relate to properties of experience; that is, they are psychological. An alternative way of distinguishing between sensing and perceiving that has become widely accepted is physiological-anatomical rather than psychological. In this case, sensations are identified with neural events occurring immediately beyond the sense organ, whereas percepts are identified with activity farther "upstream" in the nervous system, at the level of the brain. This assignment of anatomical locations to sensory and to perceptual processes seems consistent with psychological criteria. That is, the complexity and variability of percepts (both a product of learning) are attributed to the potential for physiological modification inherent in the vastly complex neural circuitry of the brain.

Temporal (time) relations. Clearly, many subjective processes (such as problem solving) take time to run their courses. This is true even for such relatively simple activities as perceptual discriminations in the size of different objects. It is not readily apparent, however, whether

Perceptual
learning

Figure 1: An ambiguous picture. Increasing viewing distance permits more precise perception (see text).

percepts themselves—which, for example, might enter as elements in problem solving—take time to form. To the naïve observer, percepts probably do seem essentially instantaneous: the moment a square is shown, a square seems to be seen. Yet, experimental evidence suggests that percepts, even of simple geometric forms, follow a measurable, developmental time course. In some instances the temporal development of percepts is relatively long (on the order of seconds), and in some it is quite brief (on the order of thousandths of a second).

Pictures that are incomplete or ambiguous provide good examples of relatively long-term temporal development of percepts. Look at Figure 1 and continue looking until you see something more than a pattern of black, gray, and white patches. Abruptly, you probably will perceive a familiar face that, on subsequent viewing, will reappear to you without difficulty. How long it takes for such a percept to develop will vary considerably from one person to another, perhaps revealing fundamental differences among individuals in their speed of perceptual processing. It might be instructive to show Figure 1 to several people, and with the aid of a stopwatch, measure the time it takes each of them to achieve the desired percept, both initially and then on some later occasion. (Figure 1 commonly is seen by most people as the face of Abraham Lincoln.)

A somewhat different way in which percepts may change with time is illustrated in the section *Illusions and hallucinations*, below. On initial viewing of this type of drawing, one will probably immediately see a meaningful picture. After continued gazing at the drawing, the initial percept may abruptly be replaced by another. Thereafter, the two percepts should alternate with the passage of time. Stimuli of this sort (which can yield more than one percept) raise such questions as, for example, what determines the initial percept; why do some people first see a vase whereas others see two profiles; why does the initial percept give way to the alternate; what determines the rate of fluctuation from one percept to the other; do differences from one person to another in the rate of fluctuation of ambiguous figures indicate fundamental differences in perceptual activity? Tentative answers to such questions continue to be proposed.

Instances of slowly developing percepts require relatively simple procedures to uncover. Those percepts with a very rapid time course may be studied with the aid of instruments known as tachistoscopes that permit the durations of visual stimuli to be precisely controlled. Sophisticated electronic tachistoscopes flash reliably for periods as brief as one millisecond (one-thousandth of a second). Such precision permits study of the short-term development (microgenesis) of such percepts as those of simple geometric figures. Thus, it has been found that perception of a small black disk is disrupted (masked) by the rapidly successive tachistoscopic presentation of a second stimulus: a black ring that fits snugly around the disk. Indeed, as far as experimental subjects can tell, the disk target simply does not appear, though when flashed without being followed by the ring, it is readily detectable. Other target and mask stimuli also have been successfully employed.

It has been theorized that it takes time for any percept to develop; that one's experience of a figure such as a disk develops from the figure's centre outward; that one's percept of the disk becomes stable only when the outer contour is appreciated; and that the ring functions in backward masking (metacounter) because in the course of its own emergence as a percept the inner contour of the ring "absorbs" the perceptually developing contour of the disk. (Unless the viewer becomes aware of its contour, the disk theoretically cannot be perceived.) This interpretation is consistent with evidence of an optimal time interval between disk and ring onsets (about 30 to 50 milliseconds) for the best masking effect. Thus, masking is most evident at the moment developing awareness of disk contour is held to coincide in space and time with the initial perceptual growth of the ring's inner contour. If the ring is presented too soon or too late, theoretically, the contour absorption on which masking presumably depends is ineffective.

While such theories are controversial, masking experi-

ments in general do clearly indicate that in human beings there is a brief period (100 to 200 milliseconds at most) during which a percept is highly vulnerable to disruption. Whatever its exact mechanism, the phenomenon of masking manifestly demonstrates that percepts do not emerge instantaneously and full-blown at the moment of sensory stimulation. Thus, assuming that percepts are synthesized from simpler elements, relatively complex percepts would be expected to take longest to develop and, hence, to be most vulnerable to masking. Yet empirical studies show just the opposite, indicating that the more complex the visual target, the more difficult it is to mask.

Perceiving as synthesizing. The organization apparent in percepts has been attributed by some to learning, as being built up through arbitrary associations of elements that have repeatedly occurred together in the person's experience. Other theorists (particularly Gestaltists) stress the view that perceptual organization is physiologically inborn, being inherent in innate aspects of brain functioning rather than depending on a synthesizing process of learning to combine simpler elements into more complex, integrated wholes. One way of resolving such theoretical disputes would be to deprive people from birth of all visual sensory experience and, hence, of all opportunity for visual perceptual learning. Then at the time normal sensory function was restored, they would need to be tested to determine what perceptual functions, if any, were intact. Such a strategy was proposed in a letter to the British philosopher John Locke by a fellow philosopher William Molyneux in 1690. Molyneux's suggestion waited until the 20th century to be taken seriously, after surgical methods had been found to restore the sight of people born blind because of cataract (clouded lens within the eye).

After removal of their cataracts, such newly sighted people are found to be normally sensitive to changes in intensity of illumination and to colour. Though they are able initially to tell when a figure is present, they cannot at first discriminate one simple shape from another, nor can they readily remember the shape of a just-exposed object. This deficiency extends to such socially important visual stimuli as people's faces. Only after a long and painstaking period of experience—perhaps of several months duration—do such seemingly primitive visual performances as discriminating a square from a triangle come easily. Until then, the person must count corners, for example, to achieve accurate discrimination.

Findings derived from cataract surgery have provided a rich source of hypotheses for further research, including posited neurophysiological mechanisms (e.g., assemblies of brain cells) that might serve as the medium for the structural changes presumed to accompany perceptual learning. This situation led to experimental attempts to show how, through repeated stimulation, the perceptual system could progress from performance of only very primitive functions to the highly complex operations (such as form identification and discrimination) that are characteristic of the mature organism.

A host of experiments using laboratory animals as subjects (e.g., pigeons, rats, cats, dogs, monkeys, and chimpanzees) have been conducted to determine, under rigorous experimental control, the extent to which learning early in life contributes to later perceptual functioning. By analogy with humans born with cataract, such animals were deprived of visual experience from as close to birth (or hatching) as possible; e.g., chimpanzees were reared in darkness. In another type of experiment, animals were reared in environments that provided more than the normal amount and variety of stimulation or were exposed to specific stimuli they might not ordinarily encounter. These research strategies are said to provide impoverished or enriched environments. Experiments of both sorts have consistently provided verification of the general hypothesis that early perceptual experience plays an important role in later perceptual (as well as intellectual and emotional) development, even producing changes in brain weight and biochemistry. This research also offers a strong scientific rationale for efforts to enrich the environments of so-called disadvantaged or culturally deprived children.

Studies of human infants indicate that their early per-

The use of cataract surgery to study perception

Backward masking, or meta-contrast

ceptual experiences are not the "blooming, buzzing confusion" postulated by the U.S. psychologist William James late in the 19th and early in the 20th century. Rather, even infants one or two days old are capable of refined visual discriminations. Recording of the infants' visual fixations as their eyes move indicates them to have reliable preference for one paired stimulus over another, giving evidence of visual discrimination. Research employing this technique shows that preferences among various visual patterns or shapes generally are related to the complexity and novelty of the stimuli, for infants and for older human subjects as well. Evidence of this sort seems out of keeping with the findings of cataract surgery, which suggest that figural discrimination is not innate for the visually naïve. It may be, however, that adults who were blind with cataracts at birth suffer more than mere lack of normal visual experience; they are not quite comparable to visually naïve, but otherwise intact, infants. It may be that visual experience is necessary, not to generate pattern perception but to maintain it; that is, the infant's built-in (innate) perceptual abilities may somehow deteriorate through disuse.

The visual cliff technique

Similar research has dealt with visual depth perception in laboratory animals and human babies. One technique (the visual cliff) depends on the evident reluctance of young animals to step off the edge of what seems to be a steep cliff. The so-called visual cliff apparatus in one of its versions consists of a narrow platform on which the subject is placed and two wide platforms on either side of it. Although both flanking platforms are equally and only slightly lower than the central platform, the subject sees visual patterns designed so that one looks much deeper than the other. Typically, the subject explores the central platform and then investigates the flanks, finally stepping down onto the shallow-appearing side. By this response, the subject indicates sensitivity to visual depth cues. To discover if prior visual experience is necessary for the typical avoidance of the flanking platform that looks deepest requires subjects able to locomote well from the start (*e.g.*, chicks) or those deprived of visual experience (*e.g.*, rats) until their locomotor ability has developed. Research with the visual cliff clearly demonstrates the presence of depth perception in visually naïve subjects.

In summary, there is evidence among cataract sufferers of the necessity of early visual experience in human visual pattern discrimination; laboratory animals reared in impoverished or enriched environments demonstrate the importance (if not necessity) of early visual stimulation for perceptual development; human infants and other visually naïve animals behave as if they are innately capable of pattern and depth perception (*i.e.*, without the need for learning). These data together suggest that some basic visual functions, including pattern perception, are built in but that visual experience serves to maintain and elaborate them.

Structuralism

In a theory called structuralism, that everyday perceptual experience is structured or synthesized from "sensations," psychologists such as the English-U.S. introspectionistic psychologist Edward Bradford Titchener even devised a formal method of introspection for experimentally analyzing (or taking apart) percepts in an effort to reveal their constituent elements. The procedure required that the introspecting experimental subjects learn to avoid reporting on their experiences as they naïvely seemed. To establish this way of treating experience required careful training. One consequence of this training is that the observer's introspective reports may be contaminated by his expectations and hence may, in all honesty, reflect little more than his theoretical biases.

But the problem remains interesting: If percepts are indeed syntheses of simpler elements, can those elements be made to appear in experience? If so, what will they turn out to be? Can this problem be investigated without recourse to the structuralist's method of introspection and reliance on the reports of strongly biased observers?

Evidence that percepts have constituent elements emerged serendipitously from research on stabilized retinal images. The image cast on the retina of the eye by a fixed object normally is continually moving because the perceiver

himself is always in motion. Even when dampened by physical restraint, some residual movement will be left, attributable largely to high-frequency tremors (nystagmus) of the eyeballs. If the perceiver functioned as if he were a camera, the normal instability of the retinal image would produce a blurred percept and a concomitant impairment of visual acuity.

It is not feasible to eliminate eye movements, but it is possible to stabilize or fix the location of the retinal image by coupling the source of the image to the eyeball itself. An optical lever system can be so adjusted that when the eye moves the image source moves with it, and potential motion in the retinal image is eliminated. As expected, visual acuity is slightly enhanced when the retinal image is kept motionless. A remarkable, unexpected finding, however, was that such stabilized images rapidly seem to disappear, the perceiver losing awareness of them. It would seem that some movement in retinal image is needed to maintain perception over extended periods of time.

The optical lever system

One limitation of the optical lever system is that it permits the use of only very simple targets, such as straight, vertical lines. With a different device (in effect, a miniature projector attached to the eyeball), stabilized images of complex patterns may be presented. Complex patterns are found to produce percepts that are relatively slow to deteriorate; furthermore, they do not disappear in toto. The manner of the fragmentation is perhaps revealing of the way in which complex percepts are synthesized. Speaking metaphorically, observing how percepts "come apart" under retinal stabilization may be very much like discovering the structure of a rock by striking it with a powerful hammer blow.

Indeed, under retinal stabilization, single lines seem to disappear and reappear in a unitary (altogether) fashion. In a figure comprised of several lines (say, a square), percepts of parallel lines are likely to disappear and reappear together; proximity also affects the joint perceptual fate of pairs of lines. Retinally stabilized segments of such geometric figures as circles and triangles can seem to disappear and reappear without implicating the entire figure. In the disappearance of percepts of triangles, lines rather than angles are the functional units. (This finding is embarrassing to earlier theorizing about the crucial role of angles in the development of the neural network underlying the percept of a triangle.)

Clearly, with stabilized images, the constituent perceptual elements of complex geometric forms are lines, straight or curved; and lines with the same orientation are likely to have similar perceptual fates, as though forming a higher-order component of complex patterns than do individual lines. These conclusions are remarkably similar to those drawn from studies of the effect of visual stimuli on the electrical activity of single neurons in the cerebral cortex. A finding of major theoretical significance is the failure of percepts of circles, squares, and triangles to act as units. Such percepts are treated in classical Gestalt theory, however, as though they are basic and unitary and not readily decomposable.

PRIMARY TENDENCIES IN PERCEPTUAL ORGANIZATION

Gestalt principles. Gestalt theory was meant to have general applicability; its main tenets, however, were induced almost exclusively from observations on visual perception. Whatever their ultimate theoretical significance, these observations have been raised to the level of general principles. It is conventional to refer to them as Gestalt principles of perceptual organization.

The overriding theme of the theory is that stimulation is perceived in organized or configurational terms (*Gestalt* in German means "configuration"). Patterns take precedence over elements and have properties that are not inherent in the elements themselves. One does not merely perceive dots; he perceives a dotted line. This notion is captured in a phrase often used to characterize Gestalt theory: "The whole is more than the sum of its parts."

Of the many principles of organization that have been enunciated by various Gestalt theorists, the most general is referred to as *Prägnanz*. In effect, according to the prin-

The notion of “good” configurations

ciple of *Prägnanz*, the particular perceptual configuration achieved, out of a myriad of potential configurations, will be as good as prevailing conditions permit. What constitutes a “good” configuration, or a poor one, is unfortunately not clearly specified, though several properties of good configurations can be listed, chief among them being simplicity, stability, regularity, symmetry, continuity, and unity. What happens when these properties of figures come into conflict is not specified, but should be possible to determine empirically.

The principle of closure often operates in the service of *Prägnanz*; for example, a circular figure with small gaps in it will be seen as a complete or closed circle. Similarly, if a portion of the image of a figure falls on the blind spot of the retina, a complete figure often will still be perceived. Some distortions from good configuration may be so large as to preclude closure; in those cases, the figures may be a source of tension for the observer.

Prägnanz may also be achieved through good continuation; this principle describes a tendency for smooth continuity of contour to be dominant over discrete, irregular, abruptly changing contours. Thus, a figure composed of the overlapping outlines of an ellipse and a rectangle will probably be seen as such rather than as three figures, each with irregular, noncontinuous borders.

Closure and good continuation represent two of the factors that are held to determine what percepts will emerge from a complex stimulus. Implicit in them (and in the general principle of *Prägnanz*) is the assumption that whenever possible some figure will be perceived; more specifically, that the visual field will be articulated into figures and patterns of figures. It is understood that such emerging patterns are not *in* the stimulus. Although they are *permitted* by the stimulus, they are created by the perceptual system; that is, by the perceiver himself.

In the illustrations in Figure 2, in the panel on the left, the vertical distance between elements is less than the horizontal distance. By virtue of this differential proximity, the elements become perceptually organized into columns. In the right-hand panel, similarity, another principle of organization, is operative. Here, by virtue of similarity in brightness, the visual field tends to be perceptually articulated into alternating sets of black and gray rows.

It is not at all obvious why organization by similarity should occur; physical stimulation allows but does not demand it. Clearly in that case the articulation of the visual

Figure 2: Examples of Gestalt principles of organization. (Left) Horizontal distance between dots is greater than vertical distance. (Right) Equal distance between horizontal and vertical.

field into columns reflects a tendency in the perceptual system itself. Organization by proximity may not seem to reveal anything more than a close correspondence between perception and stimulation. (Though as argued by the Gestalt theorist Kurt Koffka, it is not an adequate explanation to say that “things look as they do because they are what they are.”) Yet, when a proximity pattern like the one shown in Figure 2 was briefly presented and subjects were asked (under guise of another task) to reproduce what they saw, many people failed to indicate a differentiated percept of columns. Instead, they reproduced a homogeneous matrix of elements. After repeated exposures, some of those subjects began to draw proximity-based columns of elements. Organization according to the principle of

proximity seems to be neither universal nor, for those who achieve it, immediate.

In the latter experiment, people who failed to obtain the differentiated percept of columns scored significantly lower on a test of verbal intelligence than did those who succeeded at some point in the experiment. Perhaps the Gestalt principles of organization apply to perceivers (such as Gestalt theorists) whose intellectual development has reached a high degree of maturity. When organized percepts are easy to come by, gradations in intelligence do not seem to matter; when some barrier to organization is imposed (as by brief stimulus exposure), however, then the effect on perception of such differences among individuals may show up.

If people see a pattern of columns in the left panel of Figure 2 because that is how the stimulus is constructed, then why do some people not see it that way? Both achieving and failing to achieve an organized percept must be explained. Surely, part of the explanation must lie in the nature of the perceptual process itself. Thus, the experimental results indicate that perceptual organization is not universal and immediate; rather, they support the major tenet of Gestalt theory that things look as they do because of the organization imposed by the perceptual process (*i.e.*, by the perceiver).

One Gestalt principle, that of common fate, depends on movement and is quite striking when observed. According to the principle of common fate, stimulus elements are likely to be perceived as a unit if they move together. An illustration of this principle is provided by a well-camouflaged object, such as a military vehicle; when stationary, the elements of the vehicle are integrated, through proximity, similarity, and so on, into patterns of background elements, and the object is difficult to detect. But it is easy to see it once it starts moving; with all of its elements moving in unison, the vehicle is readily perceived as a unitary figure, clearly segregated from its background.

Movement is also at the heart of a set of observations of considerable significance in the historical development of Gestalt theory. These observations concern circumstances in which people perceive movement in the absence of actual physical motion of the stimulus. One familiar instance of this class of events is referred to as the phi phenomenon. In simplest form, the phi phenomenon can be demonstrated by successively turning two adjacent lights on and off. Given appropriate temporal and spatial relations between the two lights, an observer will perceive the first light as if it were moving from its location to that of the second light. The phi phenomenon is basic to the eye-catching displays used on theatre marquees and to cinematic and television presentations. The motion-picture screen, for example, presents a series of briefly flashed, still images; the movement people see is a creation of their own perceptual systems (see below *Perception of movement*).

It is the lack of one-to-one correspondence between stimulation and perception, as dramatically illustrated in the phi phenomenon, that underscores the Gestaltists' dissatisfaction with stimulus-bound models of perception and their insistence on the priority of patterns and relations. What people perceive is determined not only by what is present at the point under direct observation but also by what is occurring in the total stimulus context or display.

Context effects. One of the simplest instance of relational (or context) effects in perception is that of brightness contrast. Thus, the apparent brightness of a stimulus depends not only on its own luminance but also on that of the surrounding stimulation. The same gray square looks whiter against a dark background and blacker when placed in a bright surround. Similarly, a white or gray patch will take on an apparent hue that is complementary to the colour of the surround (*e.g.*, the patch will seem tinged with yellow when it is placed against a blue background).

Analogous context effects are evident in many commonplace experiences. A man of average height seems to be a runt when he is on a basketball court with much taller players; yet the same man looms like a giant when refereeing a game played by little boys. It is known that a typical winter's day seems delightfully balmy when temperatures rise after a week of subfreezing weather.

Gestalt views of movement

Analogous context effects

Proximity patterns

To the Gestaltist, contrast effects dramatize the relational nature of perception. They also play a significant role in a more recently developed adaptation-level theory, which also provides a general perceptual model. At the core of the model is the notion that the manner in which a stimulus is perceived depends not only on its own physical characteristics but also on those of surrounding stimuli and of stimuli previously experienced by the observer. In other words, the perceiver is said to be perceptually adapted to past sensory stimuli; his adaptation level forms a kind of zero point against which any new stimulus is perceived. An example is provided by the almost overwhelming silence one experiences when the sound of an air conditioner (to which he has adapted) suddenly ceases.

Gestalt theorists also attached significance to the observer's history of stimulation; indeed, some of them interpreted so-called figural aftereffects within a Gestaltist model of brain functioning. Figural aftereffects refer to changes in the perceived shape or location of a figure following its inspection; for example, a curved line will appear to get straighter after prolonged inspection. Or the distance between two parallel lines seems to change as an aftereffect of previous inspection.

In a typical experiment one looks at a point adjacent to a dark vertical bar (the inspection figure) on a screen. Following this inspection period, the dark bar is replaced by two identical pairs of vertical lines, one pair on either side of the region where the bar had been, the second pair alongside in a region not previously exposed to the inspection figure. The subject again fixates the same point. A figural aftereffect shows up as a greater apparent distance between the pair of lines surrounding the region of the inspection figure even though the other pair is actually identical. This distortion is not simply a generalized contrast effect because it occurs only in the small area along the borders of the inspection figure; that is, the effect is localized and restricted.

Localized
satiation in
the brain

It thus has been speculated that visual exposure to a figure induces in the brain a condition of localized satiation. The passage of electrical activity is assumed to be impeded in satiated areas of the brain. Moreover, it is postulated that the perceived distance between two borders of a figure is directly related to the time it takes for electrical currents to pass between them. Thus, it is held that one effect of satiation is to increase the apparent distance between the borders of a figure that straddles a satiated region. Whatever the merits of such physiological speculations, they have stimulated a vast amount of research on figural aftereffects. Good evidence for similar effects in other senses, such as touch, also has been obtained. Clearly, perception can be influenced not only by the context of current background but also by the residues (after-effects) of previous stimulation.

Concurrent visual stimulation may modify one's acuity in detecting auditory stimuli. Similar interactions are claimed to occur for other combinations of senses. Some dentists report success in using audioanalgesia, in which stimulation with sound waves is said to reduce the experience of pain in the mouth. The high specificity of some of the reported sensory interactions seems to preclude an explanation that concurrent stimulation works by changing the subject's general level of alertness. However these intersensory effects might be mediated, they do suggest that the brain does not function as a collection of entirely independent sensory channels. As a physical system, the brain follows physical principles; thus overlapping and spreading or waning fields of neural excitation in the brain have been theorized to underlie such phenomena as closure and audioanalgesia. Köhler referred to these models of neural analogues of perceptual phenomena as physical Gestalten; unfortunately, there is little direct physiological evidence for them.

An alternative to field effects in brain functioning is the assumption that local stimulation gives rise, in one-to-one fashion, to a mosaic of local responses. Implicit in the mosaic hypothesis is a kind of telephone switchboard model of the brain as a machine in which the electrical activity is strictly confined to separate pathways of neurons that are well insulated (isolated) from one another. The Gestaltists

rejected this model because in its early formulations it did not explain intersensory and intrasensory perceptual phenomena. A more sophisticated machine model, however, provides for fieldlike effects through the operation of complex networks of neural elements. It is held that electrical activity remains confined to discrete pathways, but that these pathways do not simply travel straight through the system; that they also interconnect, with both excitatory and inhibitory consequences. Supporting evidence comes from records of the electrical activity in single neurons in the cat brain; when the cat's eye is probed by a small spot of light, a specific area on the retina can be found that serves to excite a given brain neuron.

Further mapping of the cat retina often uncovers inhibitory areas adjacent to the one that is excitatory; that is, when light strikes those retinal areas the activity in the brain neuron being monitored is depressed. The excitatory and inhibitory areas thus comprise the brain neuron's retinal receptive field. Analogous inhibitory effects have also been found in research on the eye of the crab, *Limulus*. Such context effects as brightness contrast could be based on these simple inhibitory mechanisms. It remains to be seen, however, just how many perceptual phenomena that fit Gestalt field theory also can be handled by sophisticated variants of the machine or mosaic model.

Perceptual constancies. Even though the retinal image of a receding automobile shrinks in size, the normal, experienced person perceives the size of the object to remain constant. Indeed, one of the most impressive features of perceiving is the tendency of objects to appear stable in the face of their continually changing stimulus features. Though a dinner plate itself does not change, its image on the retina undergoes considerable changes in shape and size as the perceiver and plate move. What is noteworthy is stability in perception despite gross instability in stimulation. Such matches between the object as it is perceived and the object as it is understood to actually exist (regardless of transformations in the energy of stimulation) are called perceptual constancies.

Dimensions of visual experience that exhibit constancy include size, shape, brightness, and colour. Perceptual constancy tends to prevail for these dimensions as long as the observer has appropriate contextual cues; for example, perception of size constancy depends on cues that allow one a valid assessment of his distance from the object. With distance accurately perceived, the apparent size of an object tends to remain remarkably stable, especially for highly familiar objects that have a standard size. Thus, people's heads all tend to look the same size regardless of distance; similarly, an object identified as a lump of coal tends to look black even when intensely illuminated.

The experience of constancy may break down under extreme conditions. If distance is sufficiently great, for example, the perceived size of objects will decrease; thus, viewed from an airplane in flight, there seem to be "toy" houses, cars, and people below. To the extent that they prevail, the constancies lend the perceiver's experience and behaviour relative stability. Imagine an alternative, kaleidoscopic perceptual world in which everything seems to change, solid objects apparently swelling, shrinking, and warping with every movement. Breakdown in perceptual constancy seems to complicate the course of some psychiatric disorders in which the perceptual boundary between the sufferer and the external world is weakened. Normal constancies also can be intentionally overcome, as in paintings of flabby watches and distorted people that apparently depict the unique perceptual world of the artist.

Loss of
perceptual
constancy

INDIVIDUAL DIFFERENCES IN PERCEIVING

Theoretical assertions about perceiving are often made as though they apply indiscriminately to all organisms, or at least to all people. Perhaps perceptual principles of such great generality eventually will be uncovered. In the meantime it is evident that there are clear differences in perceptual functioning among individuals, among classes of individuals, and within the same individual from one occasion to another.

Perceptual learning. That perceptual functioning should change with the perceiver's age is expected on the grounds

Optical
illusions
among
older
persons

that psychological development stems from maturation and learning. Indeed, empirical evidence for age-related changes in perceiving is substantial. There are, for example, reliable data that perceptual constancies are enhanced with the person's increasing age, improvement leveling off at about age ten. Similarly, there is a great deal of evidence for both decreased and increased susceptibility to various optical illusions with increasing age (see *Illusions and hallucinations*). Those illusions that become less pronounced with increasing age probably depend on the subject's changes in scanning and on his increased ability to segregate parts of a pattern from one another; illusions that become more pronounced probably reflect the operation of expectancies that develop through experience. Anatomical and physiological changes in the eye itself also may account for some age-related perceptual changes. (W.N.D.)

Theories:
discovery
versus en-
richment

Historically, the perceptual role of learning was a source of controversy. Vigorous denials that perceiving is influenced by learning are found in arguments of early Gestalt psychologists (e.g., Max Wertheimer, 1880–1943, a German). By contrast, heavy reliance is placed on learning processes in the writings of the German philosopher and scientist H.L.F. von Helmholtz (1821–94). Today, there is virtually full agreement that perceiving is modified by learning. Disputes now focus on the process of perceptual learning itself. Most theoretical alternatives reflect two underlying themes: discovery and enrichment. The discovery thesis is reflected in Eleanor J. Gibson's view that perceptual learning is a process of discovering how to transform previously overlooked potentials of sensory stimulation into effective information. Enrichment theories depict perceptual learning as enriching sensory experience with specific associations and with rules for its interpretation that derive from past experience. Discovery theories propose that perceptual modification results from learning to respond to new aspects of sensory stimuli, while enrichment theories hold that such modification results from learning to respond differently to the same sensory stimuli.

Direct confrontations of these positions are rare, their advocates tending to differ in their selection of experimental procedures and learning situations. It may be that discovery and enrichment theories are compatible, simply accounting for different forms of perceptual learning.

General acceptance of the perceptual role of learning should not be taken to endorse the claim that perceiving originally depends on learning. Indeed, studies of human newborn and very young infants indicate highly organized and stable perceptual functions. Learning is to be regarded as supplementary to unlearned factors that mediate perceiving.

Detection
of stimuli

Effects of practice. The most direct examination of perceptual learning is provided by investigating the effects of practice. In so-called detection tasks the observer is required to detect the presence or absence of a selected stimulus. For example, effects of practice on visual acuity were studied by requiring observers to detect simple orientation (left or right) in a row of leaning letters; e.g., $\epsilon \ \epsilon \ \epsilon \ \epsilon$. Practice tended to lower acuity thresholds, defined as the lowest intensity of illumination at which each observer could detect the orientation. Or, observers were asked to say when they just could see that an approaching pair of parallel bars was double. With practice they continued to report seeing the narrow space between the bars at increasing distances. Such improvements suggest that sensitivity to simple (unidimensional) stimuli is not immutable, being modifiable through practice.

Improvement is not limited to simple variables. In one visual-search procedure, subjects scanned a long list of letters to find a single letter that appeared only once. Search time was reduced by a factor of 10 following extensive practice, after which 10 different letters could be detected as quickly as a single letter. Practice effects with complex targets also have been studied. In one experiment, two rows of figures were displayed on each trial, one with four simple outlines of geometrical figures, the other containing three complicated figures. Subjects were to guess or detect which one of the simple figures was concealed (embedded)

in all three of the complex figures. Again, ability to identify the correct simple figure improved with practice.

Tasks involving absolute judgment require much more of the observer than does simple or complex detection. For example, he may be asked to estimate the diameters of circular targets numerically (e.g., in inches or centimetres). In a similar study, two groups of subjects made absolute judgments of widely varying distances outdoors, both before and after interpolated activity. One group spent the interpolated period estimating a large number of other distances, none the same as in the original series. The other group spent the interval on unrelated paper-and-pencil work. In the first (extra-practice) group, judgments became more accurate and less variable than among the pencil-and-paper workers. Increased precision following practice also has been reported for absolute judgments of odour intensities, and of multidimensional visual (colour) and auditory stimuli. Improvement with practice is observed even when the subject remains uninformed of his accuracy; correcting him seems to confer slight benefit.

Many studies have failed to establish a clear basis for observed improvements in altered perceptual sensitivity or discriminability. For example, better performance on an acuity test may result from adopting a new criterion of visual doubleness or from learning how to use characteristics of blur to infer slant among leaning Es. Such uncertainties cloud the theoretical and practical significance of much available data.

U.S. psychologist William James (1842–1910) probably introduced the notion that practice in labelling stimuli can alter their discriminability. Indeed, sometimes vague visual forms that are distinctively named are easier to discriminate (acquired distinctiveness). If several such stimuli have the same verbal label, discriminability may be reduced (acquired equivalence).

Labelling effects in the laboratory have been discouragingly fragile, however, and factors that favour them are poorly understood. Perhaps labelling affects one's efforts to discover distinguishing characteristics of stimuli. Having him learn distinctive labels may encourage him to analyze sensory features more fully. Or it may be that he begins to perceive a compound stimulus that includes the visual form and its associated label. If labels differ, the presumed compound stimuli are different, and discrimination should be enhanced. These hypotheses express both the discovery and enrichment theses.

Effects of perceptual assumptions. According to one version of the enrichment thesis, exposure to recurrent regularities among stimuli prompts one to assume specific relationships between the environment and his sensory experience. For example, one learns that a continuous sequence of projective transformation (e.g., the circular profile of a dinner plate seems to become elliptical) is associated with changing positions of the object in view, or that continuous symmetrical expansion of the retinal image is associated with approach. In addition, one presumably learns to make assumptions about what is called reality; e.g., despite alterations in retinal image, one perceives the plate to stay the same size. Psychologists Adelbert Ames, Jr., and Egon Brunswik proposed that one perceives under the strong influence of his learned assumptions and inferences, these providing a context for evaluating sensory data (inputs). In keeping with enrichment theory, Brunswik and Ames contended that sensory stimuli alone inherently lack some of the information needed for mature, adaptive perceiving; enrichment was held necessary to reduce ambiguity.

Much of the evidence for the contention that all perceiving is modified by one's assumptions comes from investigations in which most of the visual, everyday stimuli are eliminated. Often, the subject may view an isolated target in total darkness or look at a motionless display while keeping his head steady. To show that learned assumptions about physical size affect perceived distance, the observer may be asked to judge how far he is from a rectangle of light displayed against total darkness. He is told at one time that the rectangle is a calling card; at another it is called a business envelope. His assumptions about these objects in relation to the size of his retinal

Figure 3: Perception modified by learned assumptions in a distorted room. The same men change places in A and B in a room modelled after C.

image are invoked as prompting him to say that the “envelope” looks more distant than does the “calling card.” Dramatic examples of this effect were invented by Ames, including his famous distorted room (see Figure 3).

Ames held that perceiving under unusual conditions (*e.g.*, in a dark room) follows the same principles that govern more ordinary experience. The special conditions are said to permit experimental scrutiny of the same processes that are so difficult to examine under ordinary, uncontrolled conditions.

An opposing view is that such perceptual assumptions and inferences operate *only* under specific experimental conditions. It is asserted that only when commonly available sources of information are eliminated is the subject forced to rely on assumptions.

In the tradition of Helmholtz, Ames and Brunswik seemed to liken perceiving to reasoning, although not as a conscious process. They held that perceptual assumptions, once established, are influenced only, slightly by logic. Although the floor and ceiling of the distorted room are sloped and all windows are of different size, it projects the same retinal pattern as a normal room; and a naïve subject will report that he sees an ordinary room. But even after he explores the room he remains likely to say it looks rectangular as before, despite his new information. Comparable observations have been reported for a variety of situations. Familiarization or instruction seems to have little effect on long-established perceptual assumptions.

(W.E.)

Psychoanalytic theory explicitly calls for motivational influences on such functions as memory, thinking, and

perceiving. In particular, the theory is concerned with unconscious motives and conflicts and with unconscious defenses (such as repression) used to control them. According to the psychoanalytic hypothesis, there should be wide perceptual variation among individuals in response to stimuli that have motivational significance. At any rate, a host of experiments have been designed to show that perceiving is indeed subject to unconscious influences.

In some studies, for example, it seemed that so-called obscene words flashed on a screen had to be exposed longer than apparently neutral (control) words before their meaning could be perceived. In the other studies, children of poor families have been found to overestimate the size of coins as compared with the judgments of children of richer families. One major problem with such research lies in finding or creating appropriate experimental and control stimuli. Considering differences in the use of language, for example, it is most unlikely that what once were widely called obscene words would currently evoke the conflicts and defenses of more than a few subjects.

Assuming suitable stimuli can be found, an even more serious problem arises around the interpretation of the subjects' behaviour; for example, do people really find it more difficult to recognize obscene words or are they simply reluctant to admit recognition? Problems of this sort have plagued researchers, and unambiguously interpretable experiments in this field are most difficult to produce. The hypothesis of such individual influences as motivation on perception remains appealing and viable, but unproved.

(W.N.D.)

Information discrepancy. Striking examples of perceptual learning are observed when one receives sensory data that contradict earlier experiences. For example, spectacles containing a wedge prism will bend light rays to displace images on the retina. An object thus will be seen as if it were somewhere other than its ordinarily perceived position. The subject's initial attempts to touch the target will be misdirected, and there is a discrepancy between its location as seen and as felt. A right-angle prism will tilt the visual scene to any desired degree, altering the customary direction in which retinal images move. Usually, images of stationary objects move parallel to the direction of head movement; now their motion is at an angle to the head's path.

However, if an observer wears such eyeglasses for an extended period, objects no longer seem displaced, nor does the scene continue to appear tilted. The observer has adapted to the prismatic distortions and comes to perceive the environment as he did pre-experimentally. Similarly adaptation to the perceptual aftereffects rapidly occurs after the prism is removed in such experiments.

Adaptation may be interpreted as perceptual learning that results from exposure to discrepancy. People who wear prism spectacles during active, self-initiated movement tend to show a greater degree of adaptation than do those who sit still or who are moved passively. Apparently conditions that heighten exposure to discrepancies facilitate adaptation. It seems likely that adaptation reflects a learning process during which the perceiver re-evaluates one or more sources of sensory information to reduce his experience of discrepancy. For example, information generated by receptors that respond to tension in skeletal muscles may be re-evaluated to resolve a discrepancy between felt and seen position.

It often is suggested that adaptation to prism eyeglasses may involve the same processes that serve perceptual development in infants. Indeed, some conditions that experimentally facilitate adaptation to prism distortion also seem necessary for everyday perceptual development (*e.g.*, active, self-initiated movement). In work reported by Richard Held (*Scientific American*, November 1965), actively moving kittens developed visually guided movements normally. When each of these was yoked to a littermate that was pulled passively over the same path, the passive partner failed to develop normal perceptual function. Yet both kittens apparently received identical visual stimuli.

The effects of learning on perceiving are varied. Most of these involve learning to respond to new stimuli or to

Psychoanalytic theory

Adaptation

Reasoning and perceiving

make new responses to old stimuli. The one case consists of differentiating previously neglected stimulus characteristics; the other is a matter of re-evaluating stimuli and learning to respond to them differently.

(W.E.)

Sex differences in perceiving. It is difficult to assess the degree to which differences related to the sex of the perceiver are biologically based or are the cultural product of traditional differences in sex role. Biological sex and sex role thus far have been hopelessly confounded in experiments with human subjects.

Sex differences in perceiving, whatever their basis, can be illustrated in research on differences in the style with which people perceive. This stylistic difference emerges in extremes of response to context. If a person perceives the world as highly differentiated, he tends to resist contextual influences and is said to be field independent; the person who perceives in an extremely diffuse style, the field-dependent individual, tends to be highly susceptible to contextual effects. Thus, field-independent people are superior in locating a simple visual figure (*e.g.*, a triangle) embedded in a complex pattern; similarly, field-independent subjects can better adjust a rod in a tilted frame to the true vertical when no other visual cues to verticality are present.

Both age and sex are found to be implicated in these differences in perceptual style. Specifically, field dependence declines with increasing age, as does the closely related susceptibility to optical illusions. In North American studies, female subjects tend to be more field dependent than are males, especially after puberty. Perhaps these results are distinctive of cultures in which females are at least implicitly trained to be passive and perceptually diffuse, and in which males are encouraged to assume an active, perceptually articulated stance. This hypothesis has received some support in studies of the parent-child interactions characteristic of the early years of the two types of subject.

Cultural influences. Beyond sex differences in perceiving that seem to be culturally imposed, there is evidence for more general cultural influences on perception. The burden of much research is to show that the type of physical environment people construct for themselves or choose to inhabit can influence their style of perceiving. There are African groups (*e.g.*, Zulu and San), for example, whose environments are virtually lacking in rectangular forms, by contrast with the carpentered, right-angled world of people in Western cultures. People in these African groups also make no use in their art work of two-dimensional representations of three-dimensional objects. Such differences in visual environments show up in tests of susceptibility to illusions. Zulu and San subjects are relatively resistant to those visual illusions that depend for their effectiveness on the subjects' treating the lines comprising the pictures as borders of three-dimensional, rectangular objects. Analogous effects with different classes of illusion have been shown for other peoples who live in a perceptually unique environment.

(W.N.D.)

Perception of movement

Most animals (including people) move in search of food that itself often moves; they move to avoid predators and to mate. Animals must perceive their own movements to balance themselves and to move effectively; without such perceptual functions the chances for survival would be sharply reduced.

VISUAL CUES TO MOVEMENT

The eye is by far the most effective organ for sensing movement. Some animals are especially sensitive to visual stimuli that move in specific ways. For instance, electrical patterns from the eye of a frog show that some elements in the organ respond only when the stimulus is about the size of a fly moving in the insect's range of speed. Generally the eyes of lower animals seem to respond selectively to what is of importance to survival. In these animals the eye's retina does much of the visual processing. This is an economical arrangement since the animal tends to respond only to essential stimuli, the brain having little to

do but relay signals to the motor system. It is an inflexible mechanism, however; higher animals process visual information in more elaborate ways, the brain being more heavily involved. Thus, some cells in the visual area of the cat's brain respond only to moving stimuli, sets of movement-detector cells functioning specifically for each direction across the field of view. Features of human visual experience also suggest that movement detectors exist in the human brain.

Each retina in most higher animals has a central (foveal) zone for detailed colour and pattern vision and a surrounding peripheral zone that effectively is sensitive only to the grosser features of the outer visual field. The peripheral retina is especially sensitive to movement (often a signal of danger), which induces a reflex turning of the eyes to project the image on the fovea and permit the moving object to be recognized.

Visual stability. Mechanisms have evolved that yield stable, clear visual input despite swaying and other blurring factors. In a reflex mechanism called optokinetic nystagmus, the eyes pursue a moving scene to keep the image stationary on the retina. When they can move no farther, they snap back and pursue the scene again in a to-and-fro alternation of slow pursuit and quick return. These eye movements are readily observed in people who are looking at a moving pattern of stripes or turning their heads, this response being inhibited only when something stationary is visually fixated.

Similar nystagmic movements are triggered by impulses arising in the inner ear when the head moves. These persist even when the eyes are closed and may be felt by pressing the eyelids lightly as one rotates the whole body.

In a related stabilizing activity the eyes scan in quick jerks (saccades) with short fixations; *e.g.*, in reading. Normally the eyes cannot move steadily over a stationary scene but make a series of stationary images (like still photographs); visual function tends to be suppressed when there is saccadic blurring. Yet the eyes can follow a steadily moving object smoothly.

When one looks from one point to another, movements of the retinal image are the same as those produced by a moving scene on a stationary eye. It might be thought that the sensory structures found in the eye muscles would provide the cues for judging whether it is the eye or the scene that has moved. Yet we see the scene as stationary only when we move our eyes voluntarily and not when they are moved passively by the finger. This suggests that motor-nerve signals inform us whether our eyes are moving, rather than the sensory structures in the eye muscles. When the eye is moved by pushing it with the finger there is no normal motor discharge to inform the brain, and changes in retinal image are perceived as movement of the scene. Indeed, people with paralyzed eye muscles experience the scene as moving when they try to move their eyes. When the motor discharge thus generated is not accompanied by the expected image motion, the person falsely perceives the scene and the eye to be moving together.

Relative visual movement. A visual field containing familiar objects provides a stable framework against which relative motion may be judged. People often report that an isolated point of light in a dark room is moving when it is not; the experience is known as autokinetic movement. It was observed in 1799 by Alexander von Humboldt while he was watching a star through a telescope, and he attributed it to movement of the star itself. Not until about 60 years later was the effect shown to be subjective, apparently arising from instability in the sense of eye position without a visual frame of reference.

Similarly, if a small object is presented in a frame with nothing else in view, movement usually is attributed to the object even when only the frame moves. This induced movement effect reflects our tendency to use the larger surround as a stable frame of reference. Recall the illusion that your train is moving when it is really the moving train alongside that, seen through the window, is falsely accepted as the frame of reference.

People cannot perceive very slow movement; below a minimum speed (about that of the minute hand on a

Eye and
brain

Nystag-
mus;
saccades

Auto-
kinesis;
induced
movement

watch) movements become imperceptible and can only be inferred (as in remembering the previous position of the hour hand). At high speeds, one perceives a blurred streak rather than a definite object in motion.

Movement aftereffect. When a parade is interrupted after some minutes, the pavement may seem to move in the opposite direction to the marchers who have passed. Phenomena similar to this movement aftereffect occur in other senses. For instance, after disembarking, a sailor feels the land to be rolling like a ship as the result of kinesthetic and vestibular aftereffects. The visual movement aftereffect probably arises when movement detectors in the brain that respond to the original direction of motion become fatigued, leaving predominant those detectors that respond to contrary movement.

Apparent movement. Motion-picture film is a strip of discrete, still pictures but produces the visual impression of continuous movement. Stationary light bulbs coming on one after the other over the theatre entrance also produce an impression of steady movement. In part, such effects of apparent movement (called the visual phi phenomenon) depend on persistence of vision: visual response outlasts a stimulus by a fraction of a second. When the interval between successive flashes of a stationary light is less than this visual-persistence time, the flicker will appear to fuse into a continuous light. The flicker frequency at which this occurs is called the perceiver's flicker-fusion frequency (or critical flicker frequency) and represents the temporal resolving power of his visual system at the time. Another process on which apparent movement depends is a tendency (called visual closure or phi) to fill in the spaces between adjacent visual objects. This means that the movement detectors of the visual system are triggered as effectively by a closely spaced pair of lights alternately going on and off as by a single light moving back and forth. It would seem that two aspects of visual function (flicker fusion and phi) make the motion-picture industry possible.

Stroboscopic effect. When a rotating electric fan is illuminated by a flashing light source (called a stroboscope) so that a flash arrives whenever a fan blade passes a fixed position, the blades will seem to stand still. This is a useful way of observing fast-moving objects such as machinery or insect wings. If the flashes occur less frequently, the object will seem to move slowly in its actual direction; when the flashes arrive more frequently, the object will seem to move backward, as stagecoach wheels may do in the cinema.

Visual movement in depth. An object moving directly away from an observer provides fewer visual cues of movement than it would be moving across the field of view. However, changes in retinal-image size are produced that give a clue to its movement. Thus a stationary, but shrinking, luminous object in the dark is seen as if it were receding. Other clues to movement in depth are changes in the convergence angle of the two eyes, in the focussing mechanism, and in the haziness and brightness of the object.

NONVISUAL CUES

Auditory. Sound waves travel well in water, and fish are accordingly able to rely heavily on acoustic cues to detect moving objects. Land animals, although typically more visually oriented, also make some use of such cues, including changes in intensity (loudness) and small differences in the time at which the wave reaches each ear. Some animals (e.g., rabbit, horse) have mobile external ears that track moving sound sources. Bats vocalize high-frequency waves and are able to detect objects by sonic reflection (a technique similar to sonar).

Kinesthetic. Kinesthesia here refers to experiences that arise during movement from sense organs in the membranes lining the joints and from the sense of effort in voluntary movement; receptors in muscles seem to have little role in the perception of bodily movements. Depending on speed of motion and the joint involved, blindfolded people can detect a passive joint movement as small as a quarter of a degree. People vary widely in the accuracy with which they can actively produce movement of a given

extent; this ability also varies with direction of movement and the opposing friction, mass, and springiness.

Kinesthetic perception may persist for a limb that has been amputated, giving rise to a hallucinatory experience known as the phantom limb. The patient may experience vividly the "movement" of the absent part; a recent amputee may attempt to stand on his missing leg or to grasp with his missing hand.

Vestibular system. Vestibular structures, enclosed in a fluid-filled cavity in the region of each inner ear, include the utricle, a small sac containing minute sensitive hairs associated with tiny sandlike granules called otoliths. The utricle functions as a linear accelerometer. When the head tilts relative to gravity or is accelerated, the relatively dense otoliths deflect the hair cells and nerve impulses are transmitted to the brain. At constant velocity the otoliths become stable, stimulation ceases, and a person must rely on other cues (e.g., by observing the passing scene) to detect his motion.

Vestibular structures for each ear also include three fluid-filled semicircular canals, each in a different plane. Each canal has a swelling (ampulla) that contains the cupula, a cluster of sensitive hairs embedded in a jellylike mound. As the head moves in the plane of a given canal, motions of the fluid deflect the cupula to produce nerve impulses. These travel through the brainstem to other brain and spinal centres that mediate equilibrium or balance and that generate nystagmic eye movements.

Taken together, the semicircular canals serve as a rotary accelerometer. If a person is rotated at constant velocity and then is suddenly stopped, the cupula is redeflected to give a feeling of rotation in the opposite direction; this also gives rise to dizziness and postrotational nystagmus. Dancers and skaters learn to overcome such effects by concentrating on some fixed, visible object; with their eyes closed they are as likely to fall as anyone.

Overstimulation of the vestibular system (e.g., on a ship or airplane) may induce motion sickness. A person with vestibular function totally destroyed is not subject to motion sickness; but if the vestibular mechanism is impaired only on one side, each movement of the head can be nauseating. Such a patient takes a long time to compensate for this imbalance.

In outer space there is no gravitation to mediate feelings of up or down, although these still may arise from visual cues. The utricles and vestibular canals still respond to movements of the head, however, and serve orientation within the spacecraft. (I.P.H.)

Space perception

Human beings have been interested in the perception of objects in space at least since the question of how a picture or image arises in the human eye was first asked. It was popularly thought in ancient Greece that objects are seen because they emit what was imagined to be a continuous series of extremely thin "membranes" in their own image, which fall upon the eye and there merge into the picture that is perceived. Only after long experimental research was a more tenable conception reached, in which space was described in terms of three dimensions or planes: height (vertical plane), width (horizontal plane), and depth (sagittal plane). These planes all intersect at right angles, and their single axis of intersection is defined as being located within perceived three-dimensional space—that is, in the "eye" of the perceiving individual. Man does not ordinarily perceive a binocular space (a separate visual world from each eye), but sees a so-called Cyclopean space, as if the images from each eye fuse to produce a visual field akin to that of Cyclops, a one-eyed giant in Greek mythology. The horizontal, vertical, and sagittal planes divide space into various sectors: something is perceived as "above" or "below" (the horizontal plane), as "in front of" or "behind" (the vertical plane), or as "to the right" or "to the left" (of the sagittal plane).

GENERAL CONSIDERATIONS

The study of space perception developed rapidly in the second half of the 19th century and still more rapidly

Phantom limb

Equilibrium

Flicker fusion; phi

Perception
and
orientation

during the 20th. Many modern psychologists who deal with perceptual function hold that the study of space perception is rapidly becoming a distinct branch of psychology in its own right. This special field of investigation within psychology concentrates on the factors contributing to the perceptual articulation (organization) of objects in space (*e.g.*, on cues to depth perception, movement, form, colour, and their interactions), or dwells on particularly interesting special problems such as that of amodal perception (*e.g.*, the question of how one perceives that there are six sides on a cube, even though only three of them can be directly visible at once). Another special problem is the effect of the so-called mirror-ego on perception. It is questioned, for example, whether, when one's skin is touched while he is looking at himself in front of a mirror, he experiences the touch as if it were in the mirror image or perceives it to be in contact with his own body as it actually appears in front of the mirror.

Space perception research also has tended to become a distinct specialty because of indisputable evidence that behaviour in this area is involved in orienting the individual to his environment. Specifically, man's orientation in space typically seems to reflect his strivings (*e.g.*, to seek food or to avoid injury). He would not be capable of effective orientation behaviour, however, unless the environmental information reaching him through the various sense organs were articulated (perceptually organized) in one way or another, permitting objects in space to be perceived at least approximately in a way that corresponds to their physical "reality" (*i.e.*, to their "actual" condition as stimuli). Such perception is called veridical perception, despite philosophical disputes about perceptual truth or verity (see EPISTEMOLOGY). Without some degree of veridicality of what is perceived to be physical space, one should be unable to efficiently seek food, flee from his enemies, or take part in social interaction. This means that, in service to one's veridical perception (direct perception of stimuli as they exist), one must also experience changing stimuli as if they were stable (invariant); that is, one experiences so-called perceptual invariances. Even though the sensory image of an approaching tiger grows larger, for example, one tends to perceive that the animal's size remains unchanged. One must be capable of perceiving objects in his environment as having relatively constant characteristics (as to size, colour, and so on) despite considerable variations in stimulus conditions.

Primary gravitational effects. Not all perception of space, however, is veridical; *i.e.*, it may fail to correspond to reality. A large number of perceptual effects have been demonstrated in which space as perceived deviates from reality in some systematic way. These are cases of nonveridical perception; for example, it has been demonstrated experimentally that the three basic spatial planes (horizontal, vertical, and sagittal) dominate the ability of the individual to localize visual objects in nearby space. Carefully controlled experiments show that objects tend to be perceived as lying closer to these basic dimensions or planes than they really are. Part of the explanation of these perceptual discrepancies in visual experience may lie in the force of gravity, which undeniably affects the individual from the moment of conception onward, pulling a man's viscera and muscles "down" toward the centre of the earth. The various perceptual phenomena indicative of nonveridical perception nevertheless do not generate chaos in one's perception of space, as might theoretically be expected; indeed, most often they serve to simplify and to articulate the perceived characteristics of surrounding space. If all of the mass of sensory information available at a given moment were perceived veridically, the flood of data might so confuse the perceiver that he would be unable to orient himself appropriately. In other words, some degree of selectivity in perception in general appears to be demanded for the survival of the individual. Ideally, information about the environment is perceived only as it is relevant to the goals, needs, or physiological state of the individual at a given moment.

Visual factors in space perception. On casual consideration, it might be concluded that the perception of space is based exclusively on vision. After closer study, however,

this so-called visual space is found to be supplemented perceptually by what are clearly identifiable as cues from auditory (sense of hearing), kinesthetic (sense of bodily movement), olfactory (sense of smell), and gustatory (sense of taste) experience. In addition to these, a number of other spatial cues, such as vestibular stimuli (sense of balance) and other modes for sensing body orientation, must be taken into account. These various (*e.g.*, visual, olfactory) "spaces" are not found to be perceptually independent of one another; powerful experimental evidence shows them to interact in producing unified perceptual experiences.

It is nevertheless undeniable that the individual ordinarily receives the largest part of his information about the environment through the sense of sight; balance or equilibrium (vestibular sense) seems to rank next in importance. It has been shown that in a state of total darkness the orientation of an individual in space is mainly dependent on sensory data deriving from vestibular stimuli. The dominance of visual stimuli in the perception of space becomes particularly understandable when it is noted that vision is a so-called distance sense; it is capable of gathering information from extremely distant points in the environment, reaching out to the stars themselves. Hearing is also considered a distance sense, as is smell, though the space they encompass is considerably more restricted than that of vision. All the other senses, such as touch and taste, are usually considered to be proximal (proximate or direct) senses—*i.e.*, conveying information about the space in direct contact with the perceiving individual's body. Strictly speaking, the latter senses may, on occasion, function over distances. The smell of rotten eggs (produced by hydrogen sulfide gas) several yards away may be associated with a taste experience if the gas dissolves in the perceiver's saliva.

The eye has often been compared to a camera; this is, of course, a very rough comparison, but it is possible to think of the retina (the back surface of the inside of the eye) as if it were the film in a camera and of the lens within the eye as analogous to the single lens of the camera (see SENSORY RECEPTION: *Human vision*). Just as in a portrait photographer's camera, the picture (image) that is projected from the environment onto the retina is upside down. While it might be expected that the perceiver therefore would experience space as turned upside down, normally this does not happen. Some sort of perceptual mechanisms within the individual enable him to see his environment right side up; the exact nature of these mechanisms is under study, yet remains poorly understood. But the process of perception seems to involve at least two inversions: one (optical) inversion of the image on the retina; another (perceptual) associated with nerve impulses in the visual tissues of the brain.

Experiments have been carried out with people who were wearing special optical devices (*e.g.*, as spectacles) that reverse the right-left or up-down dimensions of images as normally received at the surface of the retina. At first the person becomes disoriented, but when he wears such a device all the time, he gradually learns to cope with space correctly while the special glasses are on. Indeed, he reorients himself to his environment to the point that he visually begins to perceive objects as if they were right side up again. This is evidence that the individual can become visually adapted in his perception of space to a new set of stimulus cues that deviate considerably from those previously learned. The process changes direction when the optical distorting device is removed; at first the basic visual dimensions appear reversed to the subject who has adapted to the spectacles. Within a short time, however, a new adaptation occurs; the subject quickly reorients himself to the earlier, well-learned, normal visual cues and perceives his environment as normal once more.

PERCEPTION OF DEPTH AND DISTANCE

The perception of depth and distance depends on information transmitted through various sense organs. Sensory cues indicate the distance at which objects in the environment are located from the perceiving individual and from each other. Such sense modalities as seeing and hearing are known to transmit depth and distance cues and are

Selective
perception

in substantial degree independent of one another. Each modality by itself can produce consistent perception of the distances of objects. Ordinarily, however, the individual relies on the collaboration of all his senses, (so-called intermodal perception).

Gross tactual-kinesthetic cues. In his perception of the distances of objects located in nearby space, one depends on his tactile (tactual or touch) sense. In tactile experience, however, kinesthetic experience (sensations of muscle movements and of movements of the sense-organ surfaces) normally is so closely associated that investigators lump the two as tactual-kinesthetic cues.

Man's own
body as a
perceptual
standard

Tactual-kinesthetic sensations enable one to differentiate his own body from the surrounding environment. The body of the individual seems to function as a perceptual frame of reference—that is, as a standard against which the distances of objects are gauged. One's perception of his own body may vary from time to time, and so its role as a perceptual standard is not always consistent. It has been found that the way in which the environment is perceived also affects one's perception of his own body. Thus, for example, it has been shown experimentally that one experiences his own arm as growing longer when he is using it to point at some object off in the environment.

Cues from the eye muscles. When one looks at an object at a distance, the effort arouses activity in two eye-muscle systems called the ciliary muscles and the rectus muscles. The ciliary effect is called accommodation (focussing the lens for near or far vision), and the rectus effect is called convergence (moving the entire eyeball). Each of these muscle systems contracts as a perceived object approaches. The effect of accommodation in this case is to make the jellylike lens more convex, while the rectus muscles rotate the eyes to converge on the object as it comes nearer. One's experience of these muscle contractions provides him with cues to the distance of objects.

Beyond the cues of accommodation and convergence, the size of the retinal image also serves to indicate how far one is from an object. The larger the image on the retina, the closer one judges the object to be. Some workers theorize that these sensory cues activate inherited tendencies immediately to perceive such sensory attributes as size without the need for learning (the so-called nativistic theory). Modern efforts to study these cues have been especially directed toward physiological changes in the body that may be related to depth perception; whether one's perception of depth is totally inborn (nativistic), and thus independent of learning, however, remains most controversial.

Accommodations and convergence provide reliable cues when the perceived object is at a distance of less than about 30 feet (nine metres) and when it is perceived binocularly (with both eyes at once).

Visual cues. Perhaps the most important perceptual cues of distance and depth depend on so-called binocular disparity; that is, since the eyes are imbedded at different points in the skull, they receive slightly different (disparate) images of any given object. The two retinal images of the same object seem to be combined perceptually in the brain into one three-dimensional experience. The degree of disparity between the two retinal images, so-called binocular parallax, depends on the difference between the angles at which an object is fixed by the right eye and by the left eye. Thus, in looking at the indicator needle on a pressure gauge, for example, one will make slightly different readings because of parallax if he uses first the left eye alone and then the right eye. The greater the parallax difference between the two retinal images, the closer the object is perceived to be.

Binocular
disparity

The phenomenon of binocular disparity functions primarily in near space because with objects at considerable distances from the viewer the angular difference between the two retinal images diminishes. Visual disparity nevertheless can be used in estimating greater distances by simply using optical devices that magnify the parallax distance separately for each eye. Such devices include artillery range-finding devices and old-fashioned, three-dimensional picture viewers called stereoscopes.

In what is called visual movement parallax, distance cues

are obtained from retinal changes that depend on the interposition of objects in space. Thus, when the individual moves his head either from side to side, or forward and backward, the retinal image of a nearby tree moves more, while that of a distant tree moves less. Unlike binocular disparity, which functions only in binocular vision, movement parallax is especially important for judging distance when only one eye is used (monocular vision).

Another group of visual images called perspective projections provide perceptual cues that are independent of whether there is monocular or binocular vision. Although estimates of distance based on such perspective effects as the apparent distant fusing of railroad tracks in a single point are incompletely understood, they are often considered to depend heavily on learning. Such phenomena illustrate the tendency of the individual to integrate perceptions into consistent and invariant wholes. Experiences of perspective may be generated by putting appropriate lines in an oil painting (linear perspective), by gradations in the tint of the paint (colour perspective), and by viewing the surface of the earth from an airplane (aerial perspective).

Still another group of visual cues of depth and distance consists of apparent differences in object brightness. In experimental studies it is found that the brighter an object appears, the closer it seems to be. Thus, a white card against a dark background seems to recede or to move forward as the level of illumination on the card is experimentally varied. Similar effects can be induced by changing the colour (hue) of an object—e.g., from bright red to dark red.

Auditory cues. Auditory cues for depth perception include sound intensity (loudness), auditory pitch, and the time lapse between visual perception and auditory perception (for example, one hears a distant cannon after seeing the flash and smoke of the explosion).

Hearing
in depth

Changes in pitch function as depth cues because when a moving object (e.g., an automobile) is emitting sound waves (e.g., from its horn), the pitch of the sound seems to rise when the object is approaching the perceiver; to fall when it is moving away.

INTERRELATIONS AMONG THE SENSES

The development of human ability to perceive space normally depends on the interaction of the senses (modalities) of sight and touch. Toward the end of its first year, a child eagerly begins to touch and to explore objects with his hands. Compared with his visual apparatus, which begins to function more efficiently at a later time, the child's sense of touch at this stage of development is delicately and effectively sensitive. By touching objects that are placed at various heights and distances from him, the child learns excellent tactual ways of perceptually evaluating what must be a highly ambiguous world as transmitted by his relatively immature visual apparatus.

The part played by other modalities (e.g., hearing) does not appear to be as fundamental in perceptual learning among young children. By contrast, people are most seriously hampered in learning a detailed, well-articulated perceptual appreciation of space without vision or touch; most people (including those who are blind) may find it difficult to imagine how impoverished an understanding of space one would have if there were only auditory cues. It is well known that people with full sensory endowment learn to locate the sources of sounds by consulting both their visual and tactual experiences. There are subtler forms of sensory interaction as well; for example, one is more accurate in turning a pointer toward a distant source of sound (e.g., a buzzer) if the pointer is simultaneously illuminated whenever there is buzzing. Such anchoring of one sense to another as a basis for spatial perception is vividly illustrated by experiments with laboratory animals.

Young monkeys have been taught to discriminate, on the basis of tactual perception alone, differently shaped objects (balls, cubes, cones, and cylinders, all about the size of a matchbox). That is, each animal was given two of these objects at a time and was allowed to feel them with its hands without seeing them. The animal's choice of one specific shape (say, a cube) and its rejection of

Experi-
ments with
animals

another (say, a cone) were rewarded with bits of food. When this selective tactual response had been learned, the animal was given the same tasks of selection, this time to be performed visually (by looking at pictures of the same objects). Under these conditions the animal often was able to discriminate the visually presented figures correctly. This phenomenon (called cross-modal learning) may be explained as a transfer effect based on earlier visual-tactual learning.

Success in orientation, in moving about effectively and without accident in everyday pursuits, is most probable when environmental information at any given time is available through as many senses as possible. When the range of sensory stimuli that forms the usual basis for the experience of perceptual space is experimentally reduced, one's success in orientation is impaired. When visual cues are sharply reduced for sighted people, they complain of disorientation, akin to groping around in a diffuse, undifferentiated fog. Indeed, injuries are all too common even when one seeks in the dark to negotiate such familiar territory as his own bedroom.

Apparently, by learning about systematic relationships that exist among a number of simultaneously available stimuli, people can perceive distances more or less correctly. The retinal image of an object 100 yards (91 metres) away is so much smaller than the image of the same object at a distance of 10 yards (9 metres) that (if they relied solely on the sizes of retinal images) people might perceive moving objects to shrink or grow rather than to recede or approach.

Experiments have shown that the distance (in depth) between selected objects in photographs is most accurately estimated when the objects have been filmed in a richly organized environment—*e.g.*, many people standing at different distances from the camera. On the other hand, it is most difficult indeed to reliably perceive even the relative depth of two vertical rods when they are presented against a background in which other cues have been reduced or eliminated.

Factors of constancy. In general, the considerable range of sensory information offered by isolated local stimuli is typically controlled, sifted, and corrected by the perceiver. The specific nature of these "corrections to conform to reality" generally depends on the unique combination of simultaneously presented stimuli at any given moment. In this way, spatial perception tends to ensure that a person experiences the continually changing circumstances of the environment in which he moves and lives with some degree of stability or constancy.

This "realistic" perception, based on an awareness of the apparently real, physical world, serves as the basis for practical adjustment and survival and appears clearly in a group of perceptual experiences of so-called object constancy. In the experience of size constancy, for example, within a radius of a few hundred yards from the observer, the size of objects is perceived to remain roughly constant no matter where they are. Constancy of form means that an object is perceived to retain its fixed characteristic shape regardless of variation in the angle at which it is observed; for example, a pencil seen end-on only shows a small circular profile but is still perceived as a pencil. Colour constancy clearly illustrates the way in which the brightness and hue experienced over the surface of an object is determined by direct comparison with other objects; a lump of coal still is perceived as black whether the Sun is shining brightly or whether there is a dull, leaden sky.

Path recognition: navigation in space. Different animal species are equipped in various ways for the recognition of their path of movement. Earthbound species of animals often use olfactory (smell) signals in recognizing paths of varying distance; this is encountered both among social insects (*e.g.*, ants) and among many mammals (the dog sniffing from tree to tree). Certain insect larvae can retrace their path of movement by using as guides extremely fine webs or filaments spun during their advance. Many species seem to navigate by the Sun, the angle between the rays of the Sun and the organism's own path being held constant. The ability of migratory birds to orient themselves by stars in twilight or at night is most impressive (see BEHAVIOUR,

ANIMAL: *Migratory behaviour*). In addition to cues offered by the stars and other heavenly bodies, such stimuli as the effects of gravity, temperature changes, and direct visual observation of landmarks such as rivers all seem to contribute to path recognition among animals.

With the burgeoning of aviation and space technology, there has been a growing research effort to increase understanding of the sensory basis for human navigation in space. Reliable perception of the vertical and horizontal dimensions and preservation of perceptual constancy for these dimensions during flight are based on the parallel activity of vision and the vestibular sense (balance, or equilibrium). Even in flying small aircraft it has been shown that the pilot becomes disoriented unless he preserves visual control of the horizontal dimension; he cannot safely rely on the information conveyed by his sense of balance to inform him that a wing tip, for example, is dipping dangerously low. While the sense of balance ordinarily depends on the effect of gravity, the movement of an airplane produces additional (so-called centrifugal and centripetal) forces, particularly as the plane tilts or changes direction, which easily mislead a person's vestibular (balance) receptors. For this reason, in high-altitude flying the horizontal line of the surface of the Earth is simulated for the pilot by an optical display that works on the same principles as does a television screen.

Even greater demands on the human senses of vision and balance are made in space flights, since a person is effectively weightless in outer space. At one laboratory maintained by the U.S. Navy, an enormous, very slowly rotating cylindrical chamber has been constructed. Variations in the perceptual sensitivity of people remaining for variable periods (even days at a time) in this simulated "outer space" environment are studied in an effort to anticipate the short-term and long-term effects of interplanetary flight.

Social and interpersonal aspects of space perception. Many animal species that use nests, lairs, or dens and care for their young act to defend a specifically delimited territory against interlopers. This process is clearly observable in birds and among seals during breeding season. Apparently territorial behaviour depends on a rather precise perception of space, since the animal ceases its defensive manoeuvres when an interloper passes out of the territory by moving across the "border." The social distances maintained by primates (*e.g.*, human beings and apes) are theorized to be the result of territorial groupings. Modern architecture is held to be dominated by an inborn human tendency to divide groups into small, separate family territories (just as birds do), the result being such structures as apartment houses. Geographical distance may also be maintained to separate individuals who belong to different social classes or races, as is observed in the ethnic neighbourhoods or ghettos of large cities.

Theories of space perception. An early theory put forth by the Anglican bishop George Berkeley at the beginning of the 18th century was that the third dimension (depth) cannot be directly perceived in a visual way since the retinal image of any object is two-dimensional, as in a painting. He held that the ability to have visual experiences of depth is not inborn (nativistic) but can only result from logical deduction based on empirical learning through the use of other senses (*e.g.*, touch).

Although modern research fails to verify the importance Berkeley placed on reason in perception, contemporary theories still include both nativistic and empiricistic considerations. According to empiricistic theorists, spatial perception develops primarily as the result of learning; indeed, during the early stages of development, the individual gradually does seem to learn something about the significance of observable (empirical) spatial cues. It is just as difficult, however, to deny the nativistic concept that space perception is based on the innate (hereditary) structure of sense receptors and the nervous system; for example, the ability to detect differences in the size of two-dimensional figures seems to be inborn (that is, the differences seem to be immediately recognizable without training or learning).

judge
distance

Territorial
distance

Time perception

The human experience of change is complex. One primary element clearly is that of a succession of events; but distinguishable events are separated by more or less lengthy intervals that are called durations. Sequence and duration are fundamental aspects of what is perceived in change.

Manifestly, duration is relative to the events people isolate in the sequences through which they live: the duration of a kiss, of a meal, of a trip. A given interval always can be subdivided into a sequential chain delimiting briefer durations, as with the regular units that provide empirical measures of time: the second, the day, the year.

Indeed, human experience is not simply that of one single series of events, but of a plurality of overlapping changes. The duration of a radio program, for example, can combine with that of a breakfast, both being inserted within the longer period of an ocean voyage.

Man seems to be unable to live without some concept of time. Ancient philosophies sought to relate the concept of time to some objective reality to which it would correspond. René Descartes (1596–1650) inaugurated a critical era of philosophy by stressing the ancient problem of the origin of ideas, including the idea of time. Immanuel Kant (1724–1804), providing a radical answer to the epistemological problem of time, wrote that we do not appreciate time objectively as a physical thing; that it is simply a pure form of sensible intuition. Other philosophers of the 18th and 19th centuries sought to explain the notion of time as arising from association and memory of successive perceptions.

A move to empirical psychology emerged with the growth of research on the introspective data of experience. From about mid-19th century, under the influence of the psychophysical notions of Gustav Theodor Fechner, psychologists conducted experiments to study the relationship between time as perceived and time as measured in physics. Their work with adults gradually spread to the study of children and of animals. The psychologists then broadened their investigations of time to cover all forms of adaptation to sequence and duration.

SEQUENTIAL ACTIVITIES

Adaptation to successive events. One may respond to stimulation in an immediate way (as in unconditioned reflex action) without taking the element of time into account. Stimulation, however, can also signal an event to follow; then it has meaning only as part of the sequence of which it is the first term: bell announcing dinner, a road sign, or an approaching danger. People react to such stimuli with anticipatory behaviour that is adapted to a stimulus or action that has not yet occurred. The principles that govern such time-binding adaptation are none other than those of conditioning. One event becomes conditioned as the signal for another stimulus that is to be sought or avoided.

The bottle-fed infant who initially reacts to the nipple on his lips with a simple sucking reflex is gradually conditioned to stop crying when he sees the bottle (the signal for feeding). Later he may learn to react to even more secondary signals that announce the arrival of the bottle; *e.g.*, being lifted from the crib or hearing the sounds of his mother warming the milk in the kitchen. His behaviour has come to incorporate the temporal dimension of the events.

According to the principles of instrumental conditioning, one stimulus becomes the signal for an ensuing event only if the second stimulus elicits an adaptive reaction (consummatory or aversive) and only if the order of the sequence is repeated. Conditioning tends to be established most rapidly when the interval between the signal (conditioned stimulus) and the unconditioned stimulus is quite brief. Ivan P. Pavlov estimated that the optimum interval for such a sequence was 0.5 second, which corresponds approximately to the intervals characteristic of sequences that are most accurately discriminable perceptually (see below).

Aside from adapting the individual to the order of a sequence, conditioning also adapts to the duration between signal and immediately effective stimulus. Response to

signal tends to occur after about the same interval that separated the two stimuli during conditioning. Thus, an animal may be trained to delay a response for some time after the signal (delayed conditioning).

This form of adaptation is most pervasive in human behaviour, permitting people to anticipate sequences of events in their environment so that they can prepare to cope appropriately with what is yet to happen.

Adaptation to periodic change. In 1912 one of Pavlov's students (I.P. Feokritova) demonstrated that a dog accustomed to being fed every 30 minutes would begin to drool toward the end of each half-hour period. It was clear evidence of conditioning to time; the between-feedings interval itself served as a conditioned stimulus.

That discovery underscores the ever-present periodicity of daily living, especially on the biological level: rhythms of activity and sleep, rhythms of eating and lovemaking. As conditioning intervenes, anticipatory experiences of hunger, fatigue, or arousal serve our adaptation to ecological demands.

Allowance should also be made for the daily, or circadian, rhythms in metabolic activity (*e.g.*, daily cycles of temperature change). There is evidence that these fundamental biological functions can synchronize with the rhythmic phases of environmental (exogenous) change. Thus within a few days after a factory worker has been assigned to the night shift, highs and lows of his daily fluctuations of temperature will be inverted. The rhythmic changes in body temperature persists, nevertheless, suggesting an innate (endogenous) basis for circadian phenomena. Such a hypothesis would mean that the gradual establishment of human circadian rhythms of sleep or temperature results from maturation of the nervous system rather than from conditioning in the strict sense. Experiments begun in 1962, in which men lived in caves or other enclosures for months deprived of temporal cues from the environment, also demonstrated the enduring nature of rhythms in body temperature and in sleep-wakefulness. The rhythmic periods, however, sometimes expanded, the subject beginning to live on an approximately two-day cycle without being aware of it.

Through conditioning to time and by way of circadian rhythms, human physiology provides a kind of biological clock that offers points of reference for temporal orientation.

PERCEPTION OF SEQUENCE AND DURATION

The psychological present. To perceive is to become aware of stimulation. Awareness of sequence or duration may, at first glance, seem inconsistent with the definition of perceiving. In a mathematical sense, certainly, the present is only a point along the continuum of becoming, an instant when future is transformed into past. Nevertheless, there is indeed a more prolonged psychological present, a brief period during which successive events seem to form a perceptual unity and can be apprehended without calling on memory. There is a perceptual field for time just as there is a visual field. The rate or speed of a sequence determines the limits of the time field.

When a metronome ticks two or three times a second, one perceives an integral sequence, becoming aware of a rhythmic auditory series characterized by a perceptually distinct frequency. When the ticks come less often, however—at intervals of three seconds, say—the frequency or sequence no longer is perceived. Each physically discrete sound impulse remains an isolated perceptual event; each tick is no longer perceived as belonging to the same temporal field as the one that follows. Similar effects can be achieved by playing a recording of music or speech at a very slow rate. Music or spoken sentences are recognizable only when their elements (melody, rhythmic patterns, phrase) are presented at an optimal speed that permits significant perceptual unity; that is, only when they belong to the relative simultaneity of the psychological present.

The perceived field of time also depends on the number of stimulus elements presented. When a clock strikes three or four times, one knows without counting that it is three or four o'clock. At noon one must count; the first chimes no longer belong to the psychological present that includes the last. Most people also can repeat a series of letters or

Circadian rhythms in metabolic activity

Relation of perceived time to number of elements presented

Early philosophical views of time

Time-binding adaptation as conditioning

numbers they hear, so long as there are no more than seven or eight elements. This ability varies with the degree of perceptual (*e.g.*, semantic) organization among the elements. While most adults can apprehend only about eight letters, they can grasp and repeat without fault sentences of 20 to 25 syllables (see also ATTENTION).

Perception of sequence. A series of physically discrete stimuli that impinge too rapidly on a sensory structure (*e.g.*, flashes of light on the retina) may produce perceptual fusion; the flashes will be indiscriminable and will appear to be uninterrupted light. The experience of fusion yields to one of discontinuity over distinctive critical ranges of frequency for some of the senses: visual flicker appears under prescribed experimental conditions at about 60 flashes per second, auditory flutter at about 1,000 interruptions per second, and tactual vibration at about 4,000 pulses per second. These values depend on differences in the persistence of the receptor systems (*e.g.*, how long an image is seen after removal of the stimulus).

The question of perceiving sequence hardly has meaning for the senses of taste and smell. Hearing appears to be particularly adapted to temporal perception, since the pattern of auditory excitement shows little inertial lag, closely following the physical duration of successive stimuli. Tactual function can give comparable results, but hearing has the practical superiority in everyday experience of reception at a distance.

When two heterogeneous stimuli (*e.g.*, a flash and a click) are successively presented, the critical threshold for passing from perceived simultaneity to an awareness of succession is found for intervals that vary between 0.02 to 0.1 second, depending on the training of the subjects. The maximum interval for perceiving sequence is more difficult to measure. The minimum time intervals are largely determined by the immediate physiological conditions of direct perceiving, while the maximum intervals are obscured by the effects of other cognitive activities. Determining when direct perception ends and when memory takes over is difficult.

At any rate, awareness of unitary sequence ceases for pairs of auditory or visual stimuli when the interval between them increases to approximately two seconds. For perceptually organized stimuli (as in a rhythm, a melody, or a phrase) the interval may reach five seconds, as indicated by one's ability to reproduce the pattern.

Between the upper and lower limits there are optimal values that seem most likely to produce perception of sequence. In the simple case of two homogeneous stimuli the optimum interval seems to be about 0.6 to 0.8 second. This is inferred from a series of clues: the same interval defines the tempo most frequently adopted in spontaneous motor activity (*e.g.*, tapping, walking) and corresponds to the heart rate. It is the interval that is most precisely reproduced by subjects in experiments; shorter intervals tend to be overestimated and longer ones underestimated. Stimuli repeated at that rate are subjectively judged to proceed most comfortably, without appearing to rush each other as in faster tempos and with no tendency to be separately perceived as at slower frequencies.

Perceived duration. Duration, the interval between two successive events, may be distinguished as full or empty (filled or unfilled) in terms of the sensory stimulation that intervenes. An empty interval is bounded by two perceptually discrete stimuli (*e.g.*, two clicks in succession); a duration is full when there is continuous stimulation, being delimited by an onset and cessation (*e.g.*, a light stays on throughout the interval). To experience an empty duration is to perceive sequence, while full duration corresponds to the temporal length of a stimulus.

Human subjects need a minimum of about 0.1 second of visual experience or about .01 to .02 second of auditory experience to perceive duration; any shorter experiences are called instantaneous. Direct, unitary perception of duration occurs up to a maximum period of approximately 1.5 to 2 seconds from the beginning to the end of a continuous sensory stimulus.

This roughly two-second maximum for directly perceived duration seems to have a biological basis and can be considered the upper temporal limit of some sort of integrated

neural mechanism. The immediate physiological process triggered by a stimulus endures beyond the period of stimulation, and may be measured as the duration of electrical impulses (*i.e.*, in the optic nerve) evoked by simple stimulation. This initial activity appears to be integrated subjectively into a cognitive unit that embraces the rapidly ensuing perceptual processes as well. The optimum range of 0.6 to 0.8 second noted earlier seems to represent the typical duration of this integrating mechanism, as inferred from studies of sensory physiology and from reaction-time experiments.

At any rate, only within these limits can the quality and precision of direct human perception (as opposed to estimation and recall) of duration be studied. Such perception can be absolute or relative. Absolute perception corresponds to estimates expressed in subjectively qualitative terms as long or short. In making such estimates, people can discriminate four to five different durations between 0.1 and 1.0 second and six to seven between 0.5 and 5.0 seconds. In studies of relative perception, subjects attempt to reproduce intervals that are presented, or are told either to produce durations of specified length or to compare two successively presented durations. These tasks, especially comparison, give rise to constant time-order errors; that is, errors in estimation that depend on which interval is presented first.

Experimentally, the perception of empty duration is found to vary with the sense that marks the limits. With duration constant, interval estimates tend to be greater (1) when the limits are visual rather than auditory or tactual, (2) when they are of low intensity, or (3) when auditory limits are higher pitched. If the unfilled limits are defined by successive stimuli from different places, duration appears longer when the distance between the two sources is greater; this is called the S effect or kappa effect. The reverse is the tau effect, in which the distance is perceived as being wider when the interval between successive stimuli is longer.

Kappa and tau effects

The perception of filled duration also varies with the stimulus. Holding the interval constant, interrupted stimulation (*e.g.*, several successive clicks) appears to last longer than does a continuous stimulus; and auditory stimuli appear to last longer than visual. Filled durations seem longer as stimulus intensity (*e.g.*, loudness) or auditory pitch rises.

One interval can be perceived as longer or shorter than the next when the difference is about 7 to 10 percent (both full and empty durations). This relative difference threshold is lowered by practice. Such studies also reveal that apparent duration remains proportional to the objectively measured length of the interval.

Estimating duration. When an interval lasts more than a few seconds, it no longer is directly perceivable as a whole, but its length can be estimated on the basis of memory function. Since common experience shows how imprecise these estimates are, people generally calculate time from such indicators as the position of the sun or with clocks and watches. Duration then is inferred rather than perceived.

Estimates, however, often are made, including those of absolute duration in which an activity is appreciated as brief or prolonged. Lacking a watch, one may make crude estimates based on such quantitative aspects of activity as distance travelled, number of dishes washed, or number of pages read. Or one may estimate directly as in subjectively counting seconds.

Several important factors influence the subjects estimation of time:

Type of activity. The more often a task is broken up or interrupted, the longer it seems to take. As a corollary, a period of doing nothing appears longer than an equally long period when one is doing something. Similarly, relatively passive activities appear longer than do those requiring active participation; *e.g.*, time passes faster for the student who is taking notes than for one who passively listens.

Level of motivation. The more one is motivated by a given task, the shorter it appears to last. Clearly, motivation and the type of activity pursued are interdependent

Full and empty duration

Change as
a factor
in judging
time

factors. Lack of motivation tends to interrupt attention to a task; a task in which perceptual focus frequently shifts rarely corresponds to one for which there is strong motivation. The more one notices change during an interval, the longer it is judged to be. More generally, it may be said that time has subjective duration only when one notices it; e.g., in awaiting the arrival of a friend (as opposed to the actual meeting) or in hoping to finish a task (in contrast to working at it).

Personality traits. Although inadequacies in quantifying personality traits and difficulties in studying estimates of time spans exceeding a few seconds have hampered scientific study, simple observation reveals marked individual differences in the ability to estimate time. Sex differences have not been reliably established, but the influence of age is well known. Experimental data indicate that children use the same criteria as do adults, but give more variable estimates of duration. One reason for this seems to be that they are less able to compensate for differences in the nature of a task or in personal motivation; also they are inexperienced in making inferences based on the volume of work they have accomplished. Elderly people tend to find time shorter, probably since they are likely to notice long-accustomed changes less frequently.

Children are as accurate as adults in reproducing various series of metronome clicks that last about two seconds or less. But estimates of longer intervals require processes for organizing experience that develop only with age, and very young children seem to depend only on limited criteria: "It lasts because it's longer; because there's more of it; because it goes faster." According to Jean Piaget, estimates based on more or less explicit comparison with standard units of duration imply concrete cognitive operations that are developed only after about the age of seven or eight. Adolescents typically construct more sophisticated notions of time abstracted from such concrete experimental data.

Physiological effects: drugs. The precision with which time is perceived has not been found to be related to heart rate or to electroencephalographic data. It has been shown, however, that perception of time as in clapping or counting accelerates or decelerates with the rise and fall of body temperature. The precise metabolic basis for such temperature effects awaits further study.

Ethical considerations sharply limit the dosage level of drugs employed for experiments on human beings. Understanding of the interactions between drug effects and personality traits in studies of time estimation is, therefore, quite incomplete. Within the dosage ranges investigated, however, stimulating drugs (e.g., thyroxine, caffeine, amphetamines) produce overestimates of duration, while depressants and anesthetics (e.g., barbiturates, nitrous oxide) promote underestimates. Under the influence of hallucinogens (e.g., marijuana, mescaline, LSD), subjects tend to estimate absolute duration as very long. In addition, a marijuana user may underestimate the speed of a motor vehicle, increasing the chances of accident.

Sensory deprivation and hypnosis. Relatively complete sensory deprivation (such as may be experienced, for example, by persons undergoing prolonged stays in experimental isolation chambers) compresses the experience of time to the point that short or long intervals (from about a minute to a day) seem to pass about twice as fast as usual. Time spent under these unpleasant conditions paradoxically seems shorter than normal time. Thus, the 58 objective days of a subject's first stay in a cave were underestimated as 33 days.

Under hypnosis, durations ordinarily are estimated at least as precisely as ever. Time distortion, however, can be readily induced among hypnotized subjects by simple suggestion. Such a subject, for example, may be exposed to two clicks that delimit an objective, 10-second interval but be told that it lasts 10 minutes. On being asked to count objects for 10 minutes, he may report having counted several hundreds without difficulty over what the experimenter's stopwatch shows to have been 10 seconds.

(P.F.)

Illusions and hallucinations

Illusion and hallucination are terms formulated to describe subjective (perceptual) experiences that contradict objective "reality" as it is defined by general agreement among people. Such experiences are not necessarily signs of psychiatric disturbances; they are or have been regularly and consistently reported by virtually everyone. Generally, illusions comprise misinterpretations of "real" sensory stimuli (e.g., the child who perceives tree branches at night as if they are hobgoblins). Hallucinations are experiences that seem to originate when no external source of such stimulation appears (e.g., one's name is called by a voice that no one else seems to hear).

THE NATURE OF ILLUSIONS

Illusions, then, are special perceptual experiences in which information arising from "real" external stimuli leads to an incorrect perception, or false impression, of the object or event from which the stimulation comes.

Some of these false impressions may arise from factors beyond an individual's control (such as the characteristic behaviour of light waves that makes a pencil in a glass of water seem bent), from inadequate information (as under conditions of poor illumination), or from the functional and structural characteristics of the sensory apparatus (e.g., distortions in the shape of the lens in the eye). Such visual illusions are experienced by every sighted person.

Another group of illusions results from misinterpretations one makes of seemingly adequate sensory cues. In such illusions, sensory impressions seem to contradict the "facts of reality" or fail to report their "true" character. (For more profound philosophical considerations, see EPISTEMOLOGY.) In these instances the perceiver seems to be making an error in processing sensory information. The error appears to arise within the central nervous system (brain and spinal cord); this may result from competing sensory information, psychologically meaningful distorting influences, or previous expectations (mental set). The driver who sees his own headlights reflected in the window of a store, for example, may experience the illusion that another vehicle is coming toward him even though he knows there is no road there.

TYPES OF ILLUSORY EXPERIENCE

Stimulus-distortion illusions. This type of illusory sense perception, common to mankind, arises when the environment changes or warps the stimulus energy on the way to the person, who efficiently receives it in its distorted pattern (as in the case of the "bent" pencil referred to above).

Auditory illusions. A common phenomenon is the auditory impression that a blowing automobile horn changes its pitch as it passes an observer on a highway. This is known as the Doppler effect, for C. Doppler, an Austrian physicist, who in 1842 noted that the pitch of a bell or whistle on a passing railroad train is heard to drop when the train and the perceiver are moving away from each other and to grow higher when they are approaching each other. The sound heard is also affected by such factors as a wind blowing toward or away from the person.

Another auditory illusion was described in 1928 by P.T. Young, an American psychologist, who tested the process of sound localization (the direction from which sound seems to come). He constructed a pseudophone, an instrument made of two ear trumpets, one leading from the right side of the head to the left ear and the other vice versa. This created the illusory impression of reversed localization of sound. While walking along the street wearing the pseudophone he would hear footsteps to his right when they actually came from the left.

When two sources of sound in the same vicinity emit sound waves of slightly different frequencies (i.e., vibrations per second), there will come intervals when waves from both sources arrive at the ear in phase (simultaneously) and produce the experience of a combined, louder sound. These intervals of combined sound will be perceived as "beats," or periodic alternations of sound intensity. When such auditory beats occur too rapidly to

Causes of
illusions

Uses of the
pseudo-
phone

The
influence
of body
temper-
ature

be discriminated, the resulting experience may be that of a harsh, continuous noise. Another case of interference results when two tones sounded together produce a subjectively heard third tone. When this third tone is lower in pitch than the original two, it is called a difference tone; *i.e.*, its frequency is the difference between the frequencies of the two original tones. When the third tone is higher, it is called a summation tone; *i.e.*, its frequency is the sum of the frequencies of the two original tones. Piano tuners depend in part upon their ability to employ these experiences in a reliable way in tightening and loosening the strings of the instruments.

Visual illusions. Numerous optical illusions are produced by the refraction (bending) of light as it passes through one substance to another in which the speed of light is significantly different. A ray of light passing from one transparent medium (air) to another (water) is bent as it emerges. Thus, the pencil standing in water seems broken at the surface where the air and water meet; in the same way, a partially submerged log in the water of a swamp gives the illusion of being bent.

Rainbows also result from refraction. As the sun's rays pass through rain, the droplets separate (refract) the white light into its component colours (see LIGHT). As rays of white light from any source pass through a prism, they are refracted to give the appearance of a spectrum of colour as in the rainbow of a summer morning. Another illusion that depends on atmospheric conditions is the mirage, in which, for example, the vision of a pool of water is created by light passing the layers of hot air above the heated surface of a highway. In effect, cooler layers of air refract the sun's rays at different angles than do less dense strata of heated air, giving the appearance of water where there is none; nearby objects may even appear to be reflected in it. Under unusual conditions, more elaborate mirages may appear as cities, forests, "unidentified flying objects," oases, and even as the images of ships in a nearby body of water plying the sky of a desert.

Perceiver-distortion illusions. Some illusions are related to perceiver characteristics such as brain function. When an observer is confronted with a visual assortment of dots, for example, the brain may appear to group the dots that "belong together." These groupings are made on the basis of such things as observed similarity (*e.g.*, red versus black dots), proximity, common direction of movement, perceptual set (the way one is expecting to see things grouped), and extrapolation (one's estimate of what will happen based on an extension of what is now happening).

Time-induced error is an example of a Gestalt illusion that occurs over brief time intervals. Two images of the same line, for example, will appear to differ in length if they are flashed quickly one after the other.

Closure (another Gestalt term) is the illusion of seeing an incomplete stimulus as though it were whole. Thus, one unconsciously tends to complete (close) a triangle or a square with a gap in one of its sides. In watching movies, closure occurs to fill the intervals between what are really rapidly projected still pictures, giving the illusion of uninterrupted motion.

Visual illusion. The "figure and ground" illusion is commonly experienced when one gazes at the illustration of a white vase the outline of which is created by two black profiles (see Figure 4). At any moment one will be able to see either the white vase (in the centre area) as "figure" or the black profiles on each side (in which case the white is seen as "ground"). The fluctuations of figure and ground may occur even when one fails deliberately to shift attention, appearing without conscious effort. Seeing one aspect apparently excludes seeing the other.

Another example of ambiguity and object reversibility is the Necker cube (see Figure 5), which may seem to "flip-flop"; younger people tend to perceive these reversals more readily than do their elders.

The so-called Müller-Lyer illusion (also Figure 5) is based on the Gestalt principles of convergence and divergence: the lines at the sides seem to lead the eye either inward or outward to create a false impression of length. The Poggendorff illusion depends on the steepness of the intersecting lines. As obliqueness is decreased, the illusion

Figure 4: Ambiguous figure seen as either white vase or two black profiles.

becomes less compelling. In the Zöllner illusion, the cross-hatching disturbs the perception of parallel lines. A figure seen touching converging lines, as in the Ponzo illusion, creates the impression of size larger than does another figure placed between the lines where they are farther apart. In a related experience, linear perspective creates the illusion that parallel lines or contours (such as railroad tracks) converge as they recede from the viewer. If it were not for these converging lines, a figure in the distant background might appear smaller than would an identical figure in the foreground.

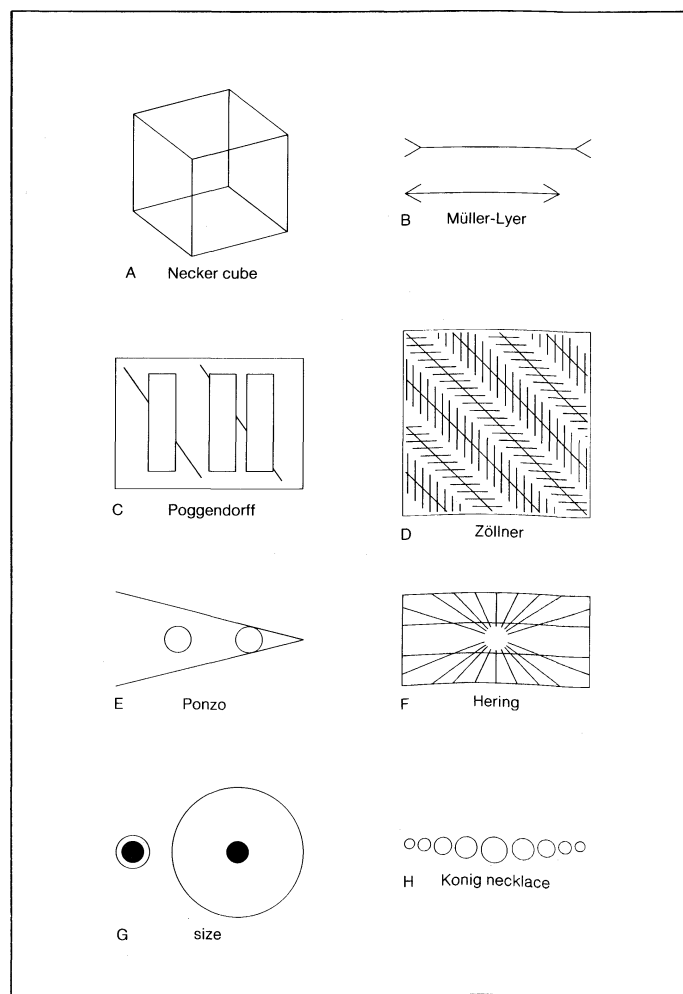

Figure 5: Examples of optical illusions. (A) Cube changes orientation. (B) Lines are equal in length. (C) Lines covered by rectangles are straight. (D) All long lines are parallel. (E) Circles are equal in size. (F) Horizontal lines are parallel. (G) Black dots are equal in size. (H) Tops of circles are on a straight line.

Colour
in visual
illusions

Visual illusions include a variety of contrast colour phenomena. A successive contrast occurs when, after one has stared at a red surface, a green surface looks much brighter. As one enters a dark room from bright sunshine, the room at first seems quite dark by contrast. A simultaneous contrast occurs when an area of brightness is seen against a less intense or a more intense background. If a gray patch of paper is placed on a black background, it looks whiter than it did before; if placed on a white background, it looks darker.

In studies of visual verticality, experimenters investigated the conditions that determine perception of the "upright." A tilted chair that could be mechanically controlled by the subject was placed in a slanted room containing visual indicators of verticals and horizontals. When various persons were asked to sit in the chair and align themselves in a vertical position, some of the subjects aligned themselves with the "true vertical" determined by gravity, while others experienced the illusion of verticality by aligning themselves with the visual directions they saw in the slanted room. Closing the eyes made "true" alignment easier.

Staring at a single bright spot in an otherwise darkened room creates the illusion that the stationary light is moving (autokinetic effect). One theory to account for this is that the impression is caused by minute eye movements of the observer. The so-called phi phenomenon is an illusion of movement that arises when stationary objects, light bulbs for example, are placed side by side and illuminated rapidly one after another. The effect is frequently used on theatre marquees to give the impression of moving lights.

There is a well-known apparent difference in the size of the moon when it is at the horizon and when it is fully risen. The horizon moon, though it is actually farther away from the observer, looks much larger than it does when it is high in the sky and closer. This phenomenon was explained by English physicist S. Tolansky:

... we are expecting, like all other objects, that its size should diminish as it nears the horizon. This does not happen. So, because it does not get smaller, as we expect, it therefore appears larger than it should be.

The
illusion of
the size of
the moon

Other explanations have attributed the moon illusion to the fact that the fully risen moon cannot be readily compared to the terrain, as it can at the horizon; to atmospheric haze, which alters the impression of distance and size; to the change in the angle of elevation of the observer's eyes; and to the idea that the moon's increase in altitude (above the horizon) creates an expectation of decrease in size. (This last point seems to be at odds with Tolansky's ideas.) The moon illusion remains a paradox since, although the retinal images (in the eye) of the high moon and the horizon moon are about the same, the perceived size differs grossly.

Other illusory experiences. *Successive-contrast illusions.* Gestalt psychologists have proposed a "fading trace" theory to explain such illusions as occur in successive weight lifting (in which the same object seems to change in weight). It is suggested that, in such contrast illusions (in all the senses), a physical trace (in the form of temporarily excited nerve cells) of the original stimulus is left in the brain even after that stimulus stops; and that this trace influences the estimate or appreciation of a subsequent stimulus.

Recently, it has been suggested that not all people are equally receptive to optical illusions. The thesis is that an aftereffect is a surviving neural "trace" left by the imprint of a visually fixated (stared at) stimulus. The strength of the aftereffect or the speed of its disappearance varies greatly in individual cases. Persons who are field dependent (that is, who tend to observe a field in its totality) are said to show weaker aftereffect traces. Conversely, field-independent subjects (those who, by selective attention, are more likely to consider a specific stimulus apart from its context) show stronger perceptual aftereffects. When experimental subjects viewed a curved line and then the Hering figure (displayed elsewhere in this article), it was found that those who exhibit potent aftereffects (and are field independent) are able to counteract optical illusions, while those who have weaker aftereffects are more prone to experience visual illusions.

Tactual illusions. The skin contains numerous "spots" that respond selectively to either cold or warmth, but generally not to both. It can happen, however, that a very warm stimulus will produce a sensation of cold when placed on a spot that responds to cold. Thus, when a warm stimulus is perceived as cold, the illusion is called that of "paradoxical cold."

"Paradoxical heat," a less frequent experience, results from stimulating warm and cold spots simultaneously. It appears to be a fusion of warm and paradoxical cold effects, producing a strange, somewhat unpleasant sensation of "heat" that seems to be attended by uneasiness resembling that of pain. The sensation is sometimes called "psychological heat."

Sudden temperature contrasts can play tricks on the senses. If hot water is run over one hand, and cold water over the other long enough for both to adjust to the temperatures and both are then plunged into lukewarm water, the resulting sensation will be that the cold hand will feel warm and the hot, cold. It would seem that in plunging the cold-adapted hand, nerve cells for perceiving cold were suddenly inhibited and those for perceiving hot were suddenly stimulated, while in the hot-adapted hand the reverse took place.

A single pencil may be felt as if it were two when it is held between crossed fingers in such a way that the skin is simultaneously stimulated at two points that would usually require two separate objects to produce such a sensation.

Anchor-effect phenomena. Sensitivity in any sense (sight, hearing, touch, and so on) may be measured as the just-perceptible intensity (threshold, or limen) of the appropriate stimulus. A light too dim to see is said to be subliminal (or below the visual threshold); a sound stimulus that is loud enough to hear is described as being above the auditory threshold (as being supraliminal). The smallest detectable stimulus is called the absolute threshold; the smallest detectable change in the intensity of a stimulus is called the difference threshold. Since such thresholds fluctuate within the same individual under different conditions, they are recognized as statistical (average) values rather than as fixed personal characteristics. At any rate, such thresholds can serve as points of reference, or anchors, against which subsequent stimuli are judged or perceived.

Other colour illusions. The normal human eye can function to detect about 130 gradations of colour in the visible spectrum (as in the rainbow), about 20 barely noticeable differences within a given colour, and about 500 of brightness. When two spots of equally bright light are observed in close succession, the first intensity may seem brighter. (This aftereffect is another example of time error.) The first light may be said to serve the function of brightness adaptation (or adjustment) in the eye, causing the second light to fall on a partly adapted and therefore less sensitive retina. In a brief time such excitement in the retina (or even in the brain) tends to subside, or fade. As a result of what theorists call "fading traces" of excitement (held to produce such aftereffect phenomena), various hues of a given colour may appear to be lighter or darker when looked at successively or in contrast to the background.

Weight illusions. The felt perception of differences in weights received experimental attention in 1899, which experiments indicated that a second weight is felt to be either heavier or lighter than an immediately preceding first one, partially as a result of the expectancy of the person doing the lifting. Having lifted the first weight, the subject is "set" for a certain effort on the next try. If the second weight is lifted quickly and easily, it will feel lighter than the first; if it comes up more slowly, it will feel heavier. Expectancy, or set, is often invoked in efforts to explain the size-weight illusion, in which a large cardboard box feels lighter than a smaller box even though both weigh the same.

Olfactory intensity. Smell (olfactory) discrimination is influenced by any odour to which the olfactory structures already have adapted. Receptors in the nose, however, adapt quickly and cease to respond to a particular stimulus producing so-called olfactory fatigue. Thus, an odour

Illusions
of hot
and cold

Weight
perception

that is strong at first will gradually become imperceptible, as happens when one becomes unaware of the smell of his own body. There may also be present the phenomenon of masking; this is a decrease in sensitivity to one odour after exposure to another (for example, a strong-smelling disinfectant).

Loudness illusions. The human ear typically serves to distinguish between about 1,500 levels of pitch. For loudness, differential-threshold studies reveal about 325 separately perceived levels in the region of greatest auditory sensitivity (about 1,000 to 4,000 cycles per second). The number of discriminable tones is in the hundred thousands. When two sounds are heard in close succession (time error once more) the intensity or loudness of the second is judged by comparing it with the first. Thus, a murmur may sound loud when compared to a whisper, or a "deafening" noise may make all other sounds inaudible. The hum of an electric fan may help to diffuse the street noises of traffic and thus improve the discrimination of sounds in the room.

Intersensory effects. Normally, the senses combine to produce a kind of common, unitary, or integrated perceptual experience. In dining, for example, the visual array on the table, the conversational tones or background music, the tactile sensations, aromas, and taste of the food, all combine to enhance the gustatory experience with each sense (e.g., sight, hearing) contributing to it. Physiologically, taste and smell appear to be particularly subject to intersensory effects (interdependent). In other situations, seeing, hearing, touching, and often smelling and tasting are all employed in an intersensory way in object identification or location.

Synesthesia. A "crossing" of the senses, analogous to a short circuit in a radio and called synesthesia, has been reported. "Colour-hearing," in which people say that specific sounds evoke in them the actual experience of certain colours, is relatively frequent. Some musicians and others report that they see particular colours whenever they hear given tones and musical passages; poets sometimes claim to hear sounds or musical tones when they see words, images, and colours. Synesthesia may be induced with drugs, and in rare psychiatric disorders the sufferer may not be able to tell whether he is seeing or hearing.

Intersensory rivalry and facilitation. Stimulation through one sense may enhance the function of another. Seeing a boat rocked by waves may activate the sense of balance in an observer on a pier to the point at which it causes seasickness. A painting of an Arctic scene of frost and snow may evoke the sensation of cold or a shiver that produces gooseflesh. An explosion or gunshots may give a bystander the illusion of being struck; and a picture of appetizing food may evoke sensations of taste and smell.

Sensory rivalry, in which one stimulus inhibits the perception of another, may result from a conflict of cues if sensory information is ambiguous or discrepant, as in the tilted-room experiment, during which the visual sense conflicts with cues from the sense of equilibrium. States of pain, panic, monotony, or fatigue may create conditions in which various senses mask or inhibit each other. A witness of a terrifying sight, for example, may become oblivious to all sounds around him. Distraction can elevate the pain threshold, as in the case of wounded soldiers whose injuries become painful only after the stress of combat subsides. In a similar way, some dentists use auditory analgesia (a "masking" of pain by sound).

Illusions of psychiatric significance. Illusions called pseudohallucinations occur at times when feelings of anxiety or fear are projected on external objects, as when a child perceives threatening faces or monsters in shadows at night or sees hobgoblins in trees. A soldier tense with apprehension may, in his fear, perceive inanimate objects as an attacking enemy or one of his own comrades as the foe. In literature, the character Don Quixote perceived windmills as enemy knights. Psychiatric patients have perceived other people as machines, or as teddy bears, or as devils.

The *déjà vu* phenomenon is a feeling that a past episode is repeating itself in the present; there is a fusion of past and present to create an illusion that one is reliving an

experience and that he therefore knows its outcome. It might be called a "hallucination" of familiarity; some theorists interpret the experience as being based on reactivation of old memory traces by stimuli resembling those experienced in the past in the way that a pressed rose discovered in a long-forgotten dance program, for example, may trigger a flood of old memories (see also MEMORY).

Emotions, compelling associations, or strong expectations frequently cause illusionary misperceptions in everyday life. The hostile listener hears someone say "wire" and thinks he is being called a "liar"; the self-consciously obese girl misinterprets the word "fate" as "weight." There is also the mistaken identification of strangers as friends in the street. It is as if John thinks Tom is Dick because he is hoping to see Dick or because he definitely wants to avoid Tom.

THE DEVELOPMENT OF MODERN UNDERSTANDING OF HALLUCINATIONS

Traditional psychiatric sources define hallucinations as "perceptions without corresponding stimuli from without" (Swiss psychiatrist E. Bleuler), or as the "apparent perception of an external object when no such object is present" (L.E. Hinsie and J. Shatzky, *Psychiatric Dictionary*, 1940). A historical survey of the subject of hallucinations clearly reflects the development of scientific thought in psychiatry, psychology, and neurobiology. By 1838 the significant relationship between the content of dreams and of hallucinations had been pointed out. In the 1840s the occurrence of hallucinations under a wide variety of conditions (including psychological and physical stress) as well as their genesis through the effects of such drugs as stramonium and hashish had been described.

A.J.F. Briere de Boismont, a French physician, in 1845 described many instances of hallucinations associated with intense concentration, or with musing, or simply occurring in the course of psychiatric disorder. In the last half of the 19th century, studies of hallucinations continued. Investigators in France were particularly oriented toward abnormal psychological function, and from this came descriptions of hallucinosis during sleepwalking and related reactions. Perhaps the most simple and yet enduring conceptions were those evolved by Sir Francis Galton in the 1880s, and English neurologist John Hughlings Jackson's formulation of the hallucination as being released or triggered by the nervous system was a milestone along the way.

During the first three decades of the 20th century, a spirited interest in hallucinations continued. Freud's concepts of conscious and unconscious activities added new significance to the content of dreams and hallucinations. It was theorized that infants normally hallucinate the objects and processes that give them gratification. Although the notion has recently been disputed, the "regression" hypothesis (i.e., that hallucinating is a regression, or return, to infantile ways) is still widely employed, especially by those who find it clinically useful. During the same period, others put forth theories that were more broadly biological than Freud's but that had more points in common with Freud than with each other.

The medical and scientific literature has continued to contain many references to hallucinatory phenomena, though for 20 years after 1932 there was a surprising decrease of interest. Attention has been revived by the recent upsurge of work on hallucinogenic drugs.

THE NATURE OF HALLUCINATIONS

The general theory of hallucinations here delineated rests upon two fundamental assumptions. One is that life experiences influence the brain in such a way as to leave in that organ enduring physical changes that have variously been called neural traces, templates, or engrams. Ideas and images are held to derive from the incorporation and activation of these engrams in complex circuits involving nerve cells. Such circuits in the cortex (outer layers) of the brain appear to subserve the neurophysiology of memory, thought, imagination, and fantasy. The emotions associated with these intellectual and perceptual functions seem to be mediated through cortex connections with the deeper parts of the brain (the limbic system or "visceral brain,"

Sounds
can evoke
visual ex-
periences

Infantile
hallucina-
tions

Déjà vu

for example), thus permitting a dynamic interplay between perception and emotion through transactions that appear to take place largely at unconscious levels.

Insofar as conscious awareness can be interpreted neurophysiologically, it is found to be regulated through a general arousal process the influence of which is mediated by the ascending midbrain reticular activating system (a network of nerve cells in the brainstem). Analyses of hallucinations reported by sufferers of neurological disorders and by neurosurgical patients in whom the brain is stimulated electrically have shown the importance of the temporal lobes (at the sides of the brain) to auditory hallucinations, for example, and of other functionally relevant parts of the brain in this process.

A second basic assumption is that the total human personality is best understood in terms of the constant interplay of forces that continually emanate from inside (as internal physiological activity) and from outside the individual (as sensory stimuli). Such transactions between the environment and the individual may be said to exert an integrating and organizing influence upon memory traces stored in the nervous system and to affect the patterns in which sensory engrams are activated to produce experiences called images, fantasies, dreams, or hallucinations, as well as the emotions associated with these patterns. If such a constantly shifting balance exists between internal and external environmental forces, both physiological considerations (*e.g.*, brain function) and cultural, experiential factors emerge as major determinants of the content and meaning of hallucinations.

The brain is bombarded constantly by sensory impulses, but most of these are excluded from consciousness in a dynamically shifting, selective fashion. The exclusion seems to be accomplished through the exercise of integrative inner mechanisms that permit the limited field of one's awareness to hold selected parts of potential experience in clear focus. (The sound of a ticking clock, for example, fades in and out of awareness.) These mechanisms somehow must simultaneously survey previously stored information within the brain, select tiny samples needed to give adaptive significance to the incoming flow of information from the environment, and bring forth only a few items for actual recall from the brain's enormous "memory banks." (L.J.W.)

Attention. Thus, the work of concentration or attention may be defined as a scanning and screening process, tending to keep out of consciousness what is not needed or wanted. Theoretically, this work involves an activity akin to information retrieval in digital computers (called "secondary process" thinking by Freud), which employs mainly the associative memory functions of the most recently evolved parts of the brain cortex. It may be contrasted with the way in which unconscious, instinctual, and emotional (analogue) information processing (Freud's "primary process" thinking) primarily involves functions of the parts of the brain that appeared much earlier in evolution. In conditions of psychological health, these primary and secondary functions seem highly integrated with each other. There is evidence that in dreams, delirium, or major psychiatric disorder (*e.g.*, schizophrenia), images, feelings, thoughts, and perceptions become dissociated from each other, and fragments of information arising within the brain itself are confused with information coming in from the external environment.

During normal wakefulness, the input of information through the sensory pathways serves a basic function in maintaining the organization of scanning and screening activity. As long as it is working well, the brain mechanism of scanning and screening seems to exclude from awareness not only information from the internal and external environments that is undesired or has low priority but also the vast bulk of information already stored within the brain in the form of neural traces, their derivations, and interrelations. Some of this information can be brought deliberately into awareness. (One readily recalls his address when asked, for example.) Many children and a few adults can screen in and scan perceptual memory traces with great clarity, thereby permitting eidetic ("photographic") or near-eidetic imagery.

Reduced sensory activity. When, as in sleep, sensory input is diminished, distorted, or impaired, its organizing effect upon the screening and scanning mechanism tends to decrease. Simultaneously, as a rule, there is a decrease in the stimulating effect of sensory input on the ascending midbrain reticular activating system (through connections from the major incoming sensory pathways, such as tactual structures, passing through the brainstem), and, as a result, arousal and awareness diminish. Under a variety of circumstances, however, great reduction or impairment of sensory input may be accompanied by a residual awareness of considerable degree. In such instances, when the usual information-input level no longer suffices completely to inhibit their emergence, ordinarily quiescent perceptual traces stored in the brain may be activated or "released" and re-experienced. Released perceptions of this sort do not ordinarily become conscious with hallucinatory vividness. In order for them to emerge even into clear awareness, there must be a sufficient general level of arousal for awareness to occur, and the particular perception-bearing brain circuits must trigger and reverberate sufficiently to command awareness.

A sustained level and variety of sensory input normally contributes to the process that inhibits the emergence of reactivated memory traces from within the brain. When effective (attention-commanding) sensory input decreases sufficiently, there may be a release into awareness of previously recorded perceptions through disinhibition of the brain circuits that represent them. If a sufficient level of cortical arousal persists or is stimulated in any one of several ways, these released perceptions can enter awareness and be experienced as fantasies, illusions, visions, dreams, or hallucinations. The greater the level of arousal, the more vivid the hallucinations will be.

INDUCTION OF HALLUCINATIONS

Direct brain stimulation. Hallucinatory experiences can be brought about through direct stimulation of the exposed brain, as in cases of local cortical arousal under the neurosurgeon's stimulating electrode. Under circumstances other than surgery or such situations as, for example, some forms of epilepsy, however, there must be a decrease in the forces that ordinarily dominate consciousness (and inhibit the release of recorded percepts) before hallucinations occur. These inhibiting forces require for their maintenance a relatively high level of sensory input of appropriate quality and frequency.

Sleep. The ways in which the reticular network of cells in the brainstem acts as a regulatory and integrating system for these relationships remain under intensive study. Since levels of brain arousal during sleep and wakefulness also are mediated via reticular formation activity, sleeping and dreaming merit consideration as hallucinatory activities. As a person falls asleep, he passes through a period of "partial sleep" in which awareness of the environment drops rapidly but in which the level of cortical arousal (which falls less rapidly) remains sufficiently high to permit some appreciation of external stimulation. Thus, the so-called hypnagogic phenomena occur.

Hypnagogic hallucinations. Common hypnagogic hallucinations may be visual (*e.g.*, scenes from the previous few hours appear) or auditory (*e.g.*, one seems to hear his name called). A frequently occurring hypnagogic hallucination is the sensation of loss of support or balance, perhaps accompanied by a fragmentary "dream" of falling, followed immediately by a jerking reflex recovery movement (the myoclonic jerk) that may jolt the sleeper back into wakefulness.

Dreams. The first stages of sleep appear to be dream free, the sleeper producing large, slow brain waves that may be recorded with a device called the electroencephalograph (EEG.) Sensory stimuli from without (*e.g.*, noise, cold) or stimuli from within the body (*e.g.*, dyspepsia, anxiety), plus a somewhat regular spontaneous fluctuation in the depth of sleep, periodically (perhaps every 90 minutes or so) bring the sleeper into a state that favours perceptual release, in which case dreaming tends to take place. This state (with specific EEG signs and rapid movements of the closed eyes) probably occurs several times every night, so

Dreams
and hal-
lucinations

that more than 20 percent of an average person's sleep is taken up with several dreams, each of about 10 to 15 minutes' duration. At the time of awakening, the typical sleeper again passes through a period of perceptual release, often experiencing dreams that increase in intensity, and perhaps may have the hallucinations of "partial sleep," these now being called hypnopompic experiences.

A simplified but perhaps helpful way of characterizing these conditions might be to imagine a person standing at a window opposite a fireplace, looking out at a garden in the sunset. He is so absorbed by the view of the outside world that he fails to visualize the interior of the room at all. As it becomes darker outside, images of the objects in the room behind him are reflected dimly in the window glass. For a time he may see either the garden (if he gazes into the distance) or the reflection of the room's interior (if he focusses on the glass). Night falls, but the fire still illuminates the room. The watcher now sees in the glass a reflection of the interior of the room behind him, which appears to be outside the window. This illusion becomes dimmer as the fire dies down, and, finally, when it is dark both outside and within, nothing more is seen. If the fire flares up from time to time, the visions in the glass reappear.

In an analogous way, hallucinatory experiences such as those of normal dreams occur when the "daylight" (sensory input) is reduced while the "interior illumination" (general level of brain arousal) remains "bright," and images originating within the "rooms" of our brains may be perceived (hallucinated) as though they came from outside the "windows" of our senses.

Another analogy might be that dreams, like the stars, are shining all the time. Though the stars are not often seen by day, since the sun shines too brightly, if, during the day, there is an eclipse of the sun, or if a viewer chooses to be watchful awhile after sunset or awhile before sunrise, or if he is awakened from time to time on a clear night to look at the sky, then the stars, like dreams, though often forgotten, may always be seen.

A more brain-related concept is that of a continuous information-processing activity (a kind of "preconscious stream") that is influenced continually by both conscious and unconscious forces and that constitutes the potential supply of dream content. The dream is an experience during which, for a few minutes, the individual has some awareness of the stream of data being processed. Hallucinations in the waking state also would involve the same phenomenon, produced by a somewhat different set of psychological or physiological circumstances.

Excessive excitation. It is valuable to consider the probable relationship between the level of physiological arousal in the brain and information processing during the waking state. The functions of consciousness apparently reach an optimal point in relation to level of arousal, beyond which they disorganize progressively as arousal increases. The presence of marked arousal (produced, for example, by extreme anxiety or by chemical stimulation of the brain) is accompanied by marked disturbance of concentration. Again, contact with external stimuli is impaired, this time by excessive input that "jams the circuits," in which case spontaneous dissociative experiences may occur. As arousal increases further, the hallucinations of full-blown delirium or psychotic excitement may appear with frightening vividness, intensity, and emotional accompaniment. Greater brain arousal might result in generalized seizure phenomena, as in epilepsy.

Sensory deprivation. When people are kept in isolation (sensory deprivation), information input via the senses (e.g., hearing and sight) is depatterned or reduced. If such a person remains alert, he is likely to experience vivid fantasies and perhaps hallucinations. A slight amount of stimulation of the hallucinated sense may enhance the likelihood of the hallucination's appearance. If stimuli are markedly reduced and the level of arousal is high, the hallucinations can be especially vivid and emotionally charged.

Loss of sleep. Progressive sleep loss appears to decrease one's capacity for integrating perceptions of the external environment. Hallucinations probably will occur in any-

one if wakefulness is sufficiently prolonged; anxiety is likely to hasten or to enhance hallucinatory production. The disorganizing effect of excessive wakefulness has been exploited in extorting confessions from prisoners. Observations suggest that fleeting hallucinations typically begin after two or three days without sleep, and that after 100 to 200 sleepless hours a progressive personality disorganization will develop, marked by periods of hallucinosis or, in some cases, by the reappearance of a previously existing psychiatric disorder.

Hypnosis and trance states. The mystic achieves hallucinations by gaining control of his own dissociative mechanisms; perhaps this is a form of self-hypnosis. Such individuals can accomplish an astonishing withdrawal from the environment by prolonged intense concentration (e.g., by gazing at some object). The hallucinations may be of the type in which the person perceives his "inner self" to leave his body to view himself (autoscopic hallucination) or to be transported to new surroundings. Alternatively, the hallucinations may take the form of unique visual imagery; for example, the *yantra* is a visual hallucination of a coloured, geometrical image that appears at a level of trance of the sort experienced by practitioners of Yoga. The recurrence of certain designs and patterns in human hallucinatory experience is probably related to structural aspects of the visual system.

Ordinary experimental hypnotic and posthypnotic suggestions of hallucinations are well known. The hypnotic subject (who can be described as a person in a controlled dissociative state) may on occasion also experience spontaneous hallucinations in the absence of specific suggestions.

Prolonged monotony or fixation of attention may lead to diminished responsiveness to the environment with a general effect similar to that of absolute reduction of stimulation or of hypnotic trance. Under these conditions such dissociative phenomena as "highway hypnosis" among drivers of motor vehicles may occur. Similar phenomena that occur among aviators have been called fascination or fixation. During prolonged, monotonous flight, pilots may experience visual, auditory, and bodily (kinesthetic) hallucinations; for example, one may suddenly feel that his plane is in a spin or a dive or that it is upside down, even though it is flying level. A kinesthetic hallucination such as this can be so vivid that the pilot will attempt "corrective" manoeuvring of the aircraft, with potentially tragic results.

Sensory defects. Many other examples of hallucinations related to decrease or impairment of sensory input are known in clinical medicine. Visual hallucinations may occur in cases of cataract (opaque lens in the eye) and have been compared with phantom limb experiences (e.g., "pain" in the toes of a missing foot), since there is an absence of normal stimuli from the environment in both cases. Individuals who suffer a progressive loss of hearing may experience auditory hallucinations. A case of combined visual and auditory hallucinations in a patient with progressive blindness (from cataracts) and with deafness from ear disease (otosclerosis) has been observed. Hallucinations of the phantom limb probably arise as the projection of an experientially established set of brain engrams in the absence of long-accustomed sensory input from the missing part. Differences in nerve impulses from those once produced by a missing limb may cause the phantom to be perceived as being distorted in proportion or in size.

Psychological factors. Although the role of expectation (mental set) continues to be studied in relation to perception, there can be no doubt of the significance of psychological factors in determining the nature of hallucinated objects. It may be that the psychophysiological basis for recognition requires the unconscious preparation of a perceptual engram (the physically stored memory of a previously seen object, for example) against which to match incoming sensory information for identification, significance, and meaning in terms of past experience. If some external object is present but inadequately recognized, an incorrect perceptual engram may be activated to be experienced as an illusion; in the absence of an external stimulus, such an engram is perceived as a hallucination. This may account for the specificity of collective visions

The *yantra*

Hallucination of a phantom limb

(i.e., those shared by more than one person). Among lifeboat survivors at sea, for example, several people who share similar expectancies (mental sets) may see a nonexistent ship projected against the blank screen of empty sea and sky. Such an experience may persist in some of the people even after a logical belief in its impossibility has been communicated to all.

Multiple factors undoubtedly combine in bringing about the psychiatric symptoms of the psychoses; these symptoms often resemble the waking dreams in which hallucinations (usually auditory) may figure prominently. Such additive effects can also be demonstrated among "normal" people in the laboratory; for example, one may readily produce signs of hallucinations among sleep-deprived subjects or among subjects in a state of sensory isolation by administering otherwise subhallucinatory doses of drugs such as LSD or mescaline. In hospital cases of acute psychotic reactions with hallucinosis, combinations of factors clearly can be inferred to be at work: hereditary and cultural predispositions; excessive arousal in anxiety or panic; auto-intoxication (self-poisoning via deranged body physiology) through stress, exhaustion, sleep loss, and dehydration (water loss); and dissociative mechanisms that impair or distort the reception of information from a frightening or threatening social environment.

Chemical factors. Hallucinations may be produced by chemical changes deriving from internal metabolic disturbances that are otherwise engendered inside of the body, or that originate from outside of the body. Some chemicals that produce hallucinatory experiences seem to act by reducing sensory input; for example, dramatic hallucinatory recall of intense experiences from the recent past can be brought about by injections of anesthetic drugs such as sodium amobarbital, which favours the conditions for perceptual release. Hallucinations during induction of (and emergence from) general surgical anesthesia induced by a variety of other chemicals are well-known and can be explained on the same basis.

Such hallucinogenic chemicals seem to impair sensory input by decreasing the transmission of nerve impulses by raising the resistance of the nervous system to their passage. Other hallucinogens increase nerve transmission, disrupting the orderly input of information and "jamming the circuits." Many botanically derived hallucinogens seem to function this way—e.g., LSD (lysergic acid diethylamide) and the ergot (a fungus) that grows on rye, psilocybin from mushrooms, mescaline from the peyote cactus, and tetrahydrocannabinol (THC) from marijuana. Hallucinations also can be induced by jamming the circuits through input overload produced mechanically, bombarding several sensory systems with intense stimuli simultaneously (e.g., with bright flashing lights and loud noises).

Hallucinogenic drugs are substances that, administered in pharmacological doses (not toxic overdoses), create gross distortions in perception without causing loss of consciousness. These distortions frequently include hallucinations. Such compounds also are likely to exert profound effects on mood, thought, and observable behaviour. These resemble (or mimic) the disturbances generated in spontaneously occurring psychoses; indeed some hallucinogens have been termed "psychotomimetic" or "psychotogenic" on this account.

Research scientists and clinicians such as psychiatrists have sometimes deliberately taken these compounds in efforts to understand how it feels to be a severely psychiatric patient. It has been hoped that the study of such chemically induced "model psychoses" would lead to improved methods of treatment. In addition, some psychiatric workers speak of "psychedelic" (mind-manifesting) substances, controversially held to expand perceptual horizons and insight among a variety of people under treatment for such disorders as alcoholism, rigid personality patterns, and sexual frigidity.

The potentially dangerous psychological changes produced by psychedelic chemicals have sometimes been interpreted as "loosening ego structures," "dissolving ego boundaries," or "disrupting ego defenses." Such changes

may include the experiencing of thoughts, feelings, and perceptions that are usually outside the individual's awareness ("unconscious" or "repressed"). Persons who take such drugs (e.g., LSD) may become hypersuggestible, emotionally labile (unstable), and unusually aware of their own reactions and those of others. Feelings of transcendence of ordinary experience, distortions in time perception (e.g., time may seem to slow down), and hallucinations have also been reported.

It appears that all human behaviour and experience (normal as well as abnormal) is well attended by illusory and hallucinatory phenomena. While the relationship of these phenomena to mental illness has been well documented, their role in everyday life has perhaps not been considered enough. Greater understanding of illusions and hallucinations among normal people may provide explanations for experiences otherwise relegated to the uncanny, "extrasensory," or supernatural. Such understanding may also illuminate the remarkable certainty that individuals express in their contrary interpretations of the same basic information. "Reality," like beauty, lies in the eye of the beholder.

BIBLIOGRAPHY. For a clear presentation of Gestalt theory and its case against structuralism and behaviourism, see W. KOHLER, *Gestalt Psychology* (1959). A comprehensive historical overview is available in E.G. BORING, *Sensation and Perception in the History of Experimental Psychology* (1942). Illustrations and discussions of Gestalt principles of organization along with material on illusions, context effects, and related phenomena are provided in W.N. DEMBER, *The Psychology of Perception* (1960); J.J. GIBSON, *The Perception of the Visual World* (1950); and J.E. HOCHBERG, *Perception* (1964). Implications of research on early experience for perceptual and intellectual development are spelled out in J.M. HUNT, *Intelligence and Experience* (1961). Two excellent collections of technical articles on perception, covering a wide range of topics, have been compiled and edited by R.N. HABER: *Contemporary Theory and Research in Visual Perception* (1968), and *Information-Processing Approaches to Visual Perception* (1969). For a scholarly discussion of depth perception and a lucid description of an elegant series of experiments, see B. JULESZ, *Foundations of Cyclopean Perception* (1971). The potential contributions of neurophysiological research to an understanding of perception are suggested in N. WEISSTEIN, "What the Frog's Eye Tells the Human Brain: Single Cell Analyzers in the Human Visual System," *Psychol. Bull.* 72:157-176 (1969).

P. FRAISSE, *Psychologie du temps* (1957; Eng. trans., *The Psychology of Time*, 1963), provides the most complete synthesis of the psychological works on time. A comparison with M. STURT, *The Psychology of Time* (1925), shows how this problem has developed and evolved. The collective works edited by J.T. FRASER, *The Voices of Time* (1966); and R. FISHER, "Interdisciplinary Perspectives of Time," *Ann. N.Y. Acad. Sci.*, vol. 138, article 2 (1967), present the most varied aspects of the problem of time, ranging from religious conceptions to scientific data from physics and biology. E. BUNNING, *The Physiological Clock* (1964), provides a very sound study of the problems of the temporal regulation of organisms. The point of view of genetic epistemology is developed by JEAN PIAGET, *Le développement de la notion de temps chez l'enfant* (1946; Eng. trans., *The Child's Conception of Time*, 1969).

Descriptive reviews of the literature on perceptual learning have appeared at intervals in the *Annual Review of Psychology*, particularly the articles by J.D. DREVER (1960); E.J. GIBSON (1963); and J.F. WOHLWILL (1966). A more extensive review and evaluation of the diverse phenomena and theoretical formulations may be found in W. EPSTEIN, *Varieties of Perceptual Learning* (1967). A major publication is E.J. GIBSON, *Principles of Perceptual Learning and Development* (1969), an examination of the field from the viewpoint of the discovery theory of perceptual learning.

Works on the psychology of illusion and hallucination include A. BRIERRE DE BOISMONT, *Des hallucinations* . . . , 2nd ed. (1852; Eng. trans., *Hallucinations: Or, the Rational History of Apparitions, Dreams, Ecstasy, Magnetism, and Somnambulism* (1853), an early classic; S. TOLANSKY, *Optical Illusions* (1964), most of the known visual illusions illustrated, in one of the few modern books on this subject; W. GREY WALTER, *The Neurophysiological Aspects of Hallucinations and Illusory Experience* (1960), visual phenomena viewed by a brain researcher; and L.J. WEST (ed.), *Hallucinations* (1962), an analysis of the subject by contributors from several scientific disciplines.

Personality

The term personality has been defined in many ways, but as a psychological concept two main meanings have evolved. The first pertains to the consistent differences that exist between people: in this sense, the study of personality focuses on classifying and explaining relatively stable human psychological characteristics. The second meaning emphasizes those qualities that make all people alike and that distinguish psychological man from other species; it directs the personality theorist to search for those regularities among all people that define the nature of man as well as the factors that influence the course of lives. This duality may help explain the two directions that personality studies have taken: on the one hand, the study of ever more specific qualities in people, and, on the other, the search for the organized totality of psychological functions that emphasizes the interplay between organic and psychological events within people and those social and biological events that surround them. The dual definition of personality is interwoven in most of the topics discussed below. It should be emphasized, however, that no definition of personality has found universal acceptance within the field.

The study of personality can be said to have its origins in the fundamental idea that people are distinguished by their characteristic individual patterns of behaviour—the distinctive ways in which they walk, talk, furnish their living quarters, or express their urges. Whatever the behaviour, personologists—as those who systematically study personality are called—examine how people differ in the ways they express themselves and attempt to determine the causes of these differences. Although other fields of psychology examine many of the same functions and processes, such as attention, thinking, or motivation, the personologist places emphasis on how these different processes fit together and become integrated so as to give each person a distinctive identity, or personality. The systematic psychological study of personality has emerged from a number of different sources, including psychiatric case studies that focused on lives in distress, from philosophy, which explores the nature of man, and from physiology, anthropology, and social psychology.

Personality theories

The systematic study of personality as a recognizable and separate discipline within psychology may be said to have begun in the 1930s with the publication in the United States of two textbooks, *Psychology of Personality* (1937) by Ross Stagner and *Personality: A Psychological Interpretation* (1937) by Gordon W. Allport, followed by Henry A. Murray's *Explorations in Personality* (1938), which contained a set of experimental and clinical studies, and by Gardner Murphy's integrative and comprehensive text, *Personality: A Biosocial Approach to Origins and Structure* (1947). Yet personology can trace its ancestry to the ancient Greeks, who proposed a kind of biochemical theory of personality.

PHYSIOLOGICAL TYPE THEORIES

The idea that people fall into certain personality type categories in relation to bodily characteristics has intrigued numerous modern psychologists as well as their counterparts among the ancients. The idea that people must fall into one or another rigid personality class, however, has been largely dismissed. Two general sets of theories are considered here, the humoral and the morphological.

Humoral theories. Perhaps the oldest personality theory known is contained in the cosmological writings of the Greek philosopher and physiologist Empedocles and in related speculations of the physician Hippocrates. Empedocles' cosmic elements—air (with its associated qualities,

warm and moist), earth (cold and dry), fire (warm and dry), and water (cold and moist)—were related to health and corresponded (in the above order) to Hippocrates' physical humours, which were associated with variations in temperament: blood (sanguine temperament), black bile (melancholic), yellow bile (choleric), and phlegm (phlegmatic). This theory, with its view that body chemistry determines temperament, has survived in some form for more than 2,500 years. According to these early theorists, emotional stability as well as general health depend on an appropriate balance among the four bodily humours; an excess of one may produce a particular bodily illness or an exaggerated personality trait. Thus, a person with an excess of blood would be expected to have a sanguine temperament—that is, to be optimistic, enthusiastic, and excitable. Too much black bile (dark blood perhaps mixed with other secretions) was believed to produce a melancholic temperament. An oversupply of yellow bile (secreted by the liver) would result in anger, irritability, and a "jaundiced" view of life. An abundance of phlegm (secreted in the respiratory passages) was alleged to make people stolid, apathetic, and undemonstrative. As biological science has progressed, these primitive ideas about body chemistry have been replaced by more complex ideas and by contemporary studies of hormones, neurotransmitters, and substances produced within the central nervous system, such as endorphins.

Morphological (body type) theories. Related to the biochemical theories are those that distinguish types of per-

Hippocrates' physical humours

sonalities on the basis of body shape (somatotype). Such a morphological theory was developed by the German psychiatrist Ernst Kretschmer. In his book *Physique and Character*, first published in 1921, he wrote that among his patients a frail, rather weak (asthenic) body build as well as a muscular (athletic) physique were frequently characteristic of schizophrenic patients, while a short, rotund (pyknic) build was often found among manic-depressive patients. Kretschmer extended his findings and assertions in a theory that related body build and personality in all people and wrote that slim and delicate physiques are associated with introversion, while those with rounded heavier and shorter bodies tend to be cyclothymic—that is, moody but often extroverted and jovial.

Despite early hopes that body types might be useful in classifying personality characteristics or in identifying psychiatric syndromes, the relations observed by Kretschmer were not found to be strongly supported by empirical studies. In the 1930s more elaborate studies by William H. Sheldon in the United States developed a system for assigning a three-digit somatotype number to people, each digit with a range from 1 to 7. Each of the three digits applies to one of Sheldon's three components of body build: the first to the soft, round endomorph, the second to the square, muscular mesomorph; and the third to the linear, fine-boned ectomorph. Thus, an extreme endomorph would be 711, an extreme ectomorph 117, and an average person 444. Sheldon then developed a 20-item list of traits that differentiated three separate categories of behaviours or temperaments. The three-digit temperament scale appeared to be significantly related to the somatotype profile, an association that failed to excite personologists.

Also during the 1930s, personality studies began to consider the broader social context in which a person lived. The American anthropologist Margaret Mead studied the patterns of cooperation and competition in 13 primitive societies and was able to document wide variations in those behaviours in different societies. In her book *Sex and Temperament in Three Primitive Societies* (1935), she showed that masculinity is not necessarily expressed through aggressiveness and that femininity is not necessarily expressed through passivity and acquiescence. These demonstrated variations raised questions about the relative roles of biology, learning, and cultural pressures in personality characteristics.

PSYCHOANALYTIC THEORIES

Freud. Perhaps the most influential integrative theory of personality is that of psychoanalysis, which was largely promulgated during the first four decades of the 20th century by the Austrian neurologist Sigmund Freud. Although its beginnings were based in studies of psychopathology, psychoanalysis became a more general perspective on normal personality development and functioning. The field of investigation began with case studies of so-called neurotic conditions, which included hysteria, obsessive-compulsive disorders, and phobic conditions. Patients with hysterical symptoms complained of acute shortness of breath, paralyses, and contractures of limbs for which no physical cause could be found. In the course of interviews, Freud and his early coworker and mentor, the Austrian physician Josef Breuer, noted that many of their patients were unsure of how or when their symptoms developed and even seemed indifferent to the enormous inconvenience the symptoms caused them. It was as if the ideas associated with the symptoms were quarantined from the consciousness and lay neglected by normal curiosity. To explain this strange pattern Breuer and Freud made two assumptions. The first was based on the general scientific position of determinism, which was quite prevalent in 19th-century science: although no apparent physical causes could be implicated, these neurotic symptoms were nevertheless caused, or determined, perhaps not by one but by multiple factors, some of which were psychologically motivated. The second assumption entailed unconscious psychological processes; that is, ideas continue to be active, to change, and to influence behaviour even when they are outside of awareness. One source for this assumption was the observation of posthypnotic suggestion, which seemed to imply

that past experiences, surviving outside of consciousness as latent memories, could be activated by a signal from the environment and could then influence behaviour even though the hypnotized person was unaware of the reasons for his behaviour.

Breuer and Freud believed that the specific motivation for these neurotic symptoms lay in the patient's desire to obliterate from memory profoundly distressing events that were incompatible with the patient's moral standards and therefore in conflict with them. These events were considered to have been sexual in nature, and further exploration convinced Freud that his patients had had even earlier troublesome sexual experiences—usually seductions—the memories of which had lain dormant until awakened by a more recent sexual encounter. Freud reasoned that the earlier seduction experience imparted to the later one its pathogenic force. Freud at first accepted many of the experiences reported by his young, impressionable patients as actual seductions. He later came to believe that many, though not all, of the narrations were fantasies. Based upon this conviction Freud formulated a theory indicating that personality is shaped by such experiences as well as by other traumatic or frustrating events. He postulated that the fantasies about sexual traumas were expressions of a sexual drive. Thereafter in Freud's therapeutic method, the search for actual sexual trauma was replaced by an exploration of the ways in which patients' sexual inclinations, already present in childhood, were expressed in behaviour. Neurosis and personality in general came to be viewed as outcomes of conflict between sexual motivations and defenses against them, the conflict being rooted in early child development.

Freud assumed that his patients were motivated to ward off those fantasies that had an exciting as well as a repelling quality about them. Freud described various psychological devices (defense mechanisms) by which people tried to make the fantasies bearable. For example, in the obsessive-compulsive condition, which refers to persistent unwelcome ideas or recurrent irresistible urges to perform certain acts, such as incessant hand washing, the defense maneuvers are called isolation and displacement. They consist in separating (isolating) a fantasy from its corresponding emotion, and then attaching (displacing) the emotion to another, previously trivial idea; for instance, to the hand washer it is the hands that are dirty rather than the desires. Freud also noted that people who rely on isolation and displacement are otherwise characterized by non-pathological personality qualities such as perfectionism, indecisiveness, and formality in interpersonal contacts. To Freud the fantasies were the mental representations of basic drives, among which sex, aggression, and self-preservation were paramount. These drives, moreover, required taming as the child matured into an adult, and the taming process involved blocking out of consciousness some of the ideas associated with the expression of those drives. Other methods of defense include repression, a kind of withholding of conflicting ideas from recall; projection, the attribution to others of one's own rejected tendencies; and reaction formation, turning into its opposite a tendency rejected in oneself—as in excessive generosity as a defense against avarice. The basic conflict between drives and control processes, which Freud believed to be the basis of several neuroses, was also invoked to explain both dream content and the "psychopathology of everyday life"—the ordinary slips of the tongue (sometimes called Freudian slips) and errors such as forgetting intentions or misplacing objects.

These primary human drives, moreover, were seen to undergo transformations as part of psychological and physical growth. This formulation widened the realm of sexuality beyond reproduction, by proposing that genital activity does not encompass all of sexuality, because sexual activity can be observed long before biological maturity and can occur without leading to reproduction. The theory further proposed that sexual maturation develops in a sequence of stages as parts of the body successively yield sensual pleasure to the child, beginning with the mouth, followed by the anus, and then the genitals. Social demands for inhibition and control of the drives centre about the functions

processes

of these zones, and it is from this process of socialization that personality is said to emerge. For example, the extent to which the personality expresses power, responsibility, compliance, and defiance seems to coincide with anal expressions of the sexual drive and is related to the process of obtaining control over anal functions.

The conflict between the drives—conceptualized as a wholly unconscious structure called the id—and the drive control processes—conceptualized as a largely unconscious structure called the ego—results in the creation of a characteristic style for mediating conflicts, which is assumed to be formed prior to adolescence. While learning and experience are recognized as conspicuous factors in the shaping of these behaviours, the theory also gives prominence to possibly inborn differences in the strength of drives and of the control processes.

Among the controlling functions of the ego are identifications and defenses. Children are inclined to behave like the significant adult models in their environment, Freud postulated. These identifications give identity and individuality to the maturing child. Moreover, the process of self-criticism is part of the ego controls (Freud called it the superego) and acts as an internal and often unconscious conscience that influences moral values.

Jung. The Swiss psychiatrist Carl Gustav Jung, an early adherent of Freud's theories, questioned the degree of emphasis that Freud gave to sexual motivations in personality development. Jung accepted the significant effect of the unconscious processes, but unlike Freud he preferred to emphasize that behaviour is motivated more by abstract, even spiritual, processes than by sexual drives. Jung also focused more on individual differences; in particular he developed a typology of reaction styles, distinguishing between two basic means of modulating basic drives, introversion and extroversion. Introversion was defined as preoccupation with one's inner world at the expense of social interactions and extroversion as a preference for social interplay for living out inner drives (collectively termed libido). The existence of these two types receives empirical support from most studies of traits (see below).

Adler. The Austrian psychiatrist Alfred Adler, another of Freud's early followers, also disputed the importance of sexual motives. Adler described a coping strategy that he called compensation, which he felt was an important influence on behaviour. In his view people compensated for a behavioral deficiency by exaggerating some other behaviour: a process analogous to organic processes called hypertrophy, in which, for example, if one eye is injured, the other eye may compensate by becoming more acute. In Adler's view, a person with a feeling of inferiority related to a physical or mental inadequacy would also develop compensating behaviours or symptoms. Shortness of stature, for example, could lead to the development of domineering, controlling behaviours. Adler assigned a prominent place to family dynamics in personality development. Children's position in their family—their birth order—was seen as determining significant character traits.

Erikson. Freud's emphasis on the developmental unfolding of the sexual, aggressive, and self-preservative motives in personality was modified by the American psychoanalyst Erik H. Erikson, who integrated psychological, social, and biological factors. Erikson's scheme proposed eight stages of the development of drives, which continue past Freud's five stages of childhood (oral, anal, phallic, latency, and genital) and through three stages of adulthood. The stages proceed in leaps according to what is called an epigenetic process. The term epigenesis, borrowed from embryology, refers to the predetermined developmental sequence of parts of an organism. Each part has a special time for its emergence and for its progressive integration within the functioning whole. Each phase of emergence depends upon the successful completion of the preceding phase. According to Erikson, environmental forces exercise their greatest effect on development at the earliest stages of growth, because anything that disturbs one stage affects all of the following stages. As if controlled by a biological timetable, each given stage must be superseded by a new one, receding in significance as the new stage assumes dominance. A constant interleaving at critical

periods—in which some parts emerge while others are suppressed—must proceed smoothly if personality problems are to be avoided.

The Freudian theory of development with Erikson's modifications provides for a succession of drive-control (inner and environmental) interactions. These can be fit into a schema of polar attitudes that develop in progressive stages of a person's life, creating a conflict at each stage which should be resolved to avoid extremes of personality development. Erikson thus evolved his eight stages of development, which he described as: (1) infancy: trust versus mistrust; (2) early childhood: autonomy versus shame and doubt; (3) preschool: initiative versus guilt; (4) school age: industry versus inferiority; (5) puberty: identity versus identity confusion; (6) young adulthood: intimacy versus isolation; (7) middle adulthood: generativity versus stagnation; and (8) late adulthood: integrity versus despair.

The impact of psychoanalysis. There is little doubt that psychoanalysis had a profound influence on personality theory during the 20th century. It turned attention from mere description of types of people to an interest in how people become what they are. Psychoanalytic theory emphasizes that the human organism is constantly, though slowly, changing through perpetual interactions, and that, therefore, the human personality can be conceived of as a locus of change with fragile and indefinite boundaries. It suggests that research should focus not only on studies of traits, attitudes, and motives but also on studies that reflect the psychoanalytic view that personality never ceases to develop and that even the rate of personality modification changes during the course of a life. Although the theory holds that conflict and such basic drives as sex and aggression figure prominently in personality development and functioning, their presence may be neither recognizable nor comprehensible to persons untrained to look for those motives. However, personality characteristics are relatively stable over time and across situations, so that a person remains recognizable despite change. Another feature of psychoanalytic theory is the insistence that personality is affected by both biological and psychosocial forces that operate principally within the family, with the major foundations being laid early in life.

The data on which psychoanalytic theory rests came from the psychoanalysts' consulting rooms, where patients in conflict told their life stories to their analysts. No provision is made in that setting for experimental manipulation, for independent observation, or for testing the generality of the formulations. As a consequence, although much of the theory has found its way into accepted doctrine, psychoanalysis cannot claim a body of experimentally tested evidence. Nevertheless, psychoanalytic theory provides at least a preliminary framework for much of personality research involving motives and development.

TRAIT THEORIES

Contemporary personality studies are generally empirical and based on experiments. While they are more precise, and thus may be more valid than much of psychoanalytic theory, experiments perforce have a narrower scope than the grand sweep of psychoanalysis. In the 1940s many investigators focused on intensive studies of individual traits and of combinations of traits that seemed to define personality types, such as the "authoritarian personality." Others, like the American psychologists David C. McClelland and John W. Atkinson, studied the characteristic presence of certain needs identified by Murray, such as the need for achievement or affiliation. The method used to measure these needs was to examine the fantasy productions of Murray's Thematic Apperception Test (TAT) and to relate the motive score to other behavioral indexes such as personal history, occupational choice, speed of learning, and persistence of behaviour following failure.

Stability of traits. Traits such as sociability, impulsiveness, meticulousness, truthfulness, and deceit are assumed to be more or less stable over time and across situations. Traits refer not to single instances of a behaviour, such as lying, but to persistent although not unvarying behaviour that, according to some personologists, implies a disposition to respond in a particular, identifiable way. According

development

The basis
of psycho-
analytic
theory

to Allport's 1937 textbook, traits represent structures or habits within a person and are not the construction of observers; they are the product of both genetic predispositions and experience. It can be generally stated that traits are merely names for observed regularities in behaviour, but do not explain them. Nevertheless, the study of how traits arise and are integrated within a person forms a major area of personality studies.

In the English language there are several thousand words representing traits, many of them close in meaning to others (for example, meticulous, careful, conscientious). Most of the measurement studies employ self-report (personality) inventories that require people to describe themselves by checking relevant adjectives or answering questions about typical behaviours that they are conscious of displaying. In some measurements, observers rate the behaviour of others. Psychologists such as Hans J. Eysenck in the United Kingdom and Raymond B. Cattell in the United States have attempted to reduce the list to what they could consider to be the smallest possible number of trait clusters. The statistical technique of factor analysis has been favoured for this task, since it explores the correlations among all of the trait names and identifies clusters of correlations among traits that appear to be independent of (uncorrelated with) each other. Common to almost all the trait systems are variables related to emotional stability, energy level, dominance, and sociability, although different investigators choose different names for these factors. Eysenck, for example, has reduced the trait names to but three higher-order factors—introversion—extroversion, neuroticism, and psychoticism—and has attempted to explore the biological roots of each factor.

Deviation from trait theory. The idea that traits represent relatively stable behaviours has received criticism from psychologists who point out that behavioral consistency across situations and across time is not the rule. For example, in a study of children's moral development, the American psychologists Hugh Hartshorne and Mark A. May in 1928 placed 10- to 13-year-old children in situations that gave them the opportunity to lie, steal, or cheat; to spend money on themselves or on other children; and to yield to or resist distractions. The predictive power of personal and educational background was low, and children were not found consistently honest or dishonest, distractible, or altruistic. The most powerful predictor of children's behaviour was what other children around them were doing.

In the 1960s and '70s some psychologists, including Walter Mischel and Albert Bandura in the United States, recalled the Hartshorne and May study and variations of it to support their view that behaviour is controlled not by hypothetical traits but according to the degree of regularity of external stimuli. That is, they believe that personality traits are only consistent if the situation is consistent and that they vary once the situation changes. In their view, behavioral consistency does not reflect stable personality traits. Rather, it is the environment that evokes and shapes the illusion of such traits. This would be in keeping with the view of social learning theorists that personality, like other elements of a person's psychological makeup, is largely a learning phenomenon related to such factors as the imitation of role models. Social learning theory would also contend that personality is more susceptible to change than would trait theory.

Although it has been demonstrated that behaviour is seldom entirely consistent, it also has been shown that it reflects considerable consistency. Even in the Hartshorne and May study some children showed consistently honest or dishonest behaviour, and behavioral consistency was found to increase with age.

Support for personal consistency is bolstered by studies of what has been called the fundamental attribution error. The investigators, most of them social psychologists, report that, in observing the behaviour of others, people exaggerate the role of internal causes and invoke traits as a primary cause (e.g., "John acted the way he did because he is honest"). In assigning cause to their own behaviour, however, people more often cite external causes such as the particular situation. These tendencies are accompanied

by another discovered regularity: in seeking sources for their own behaviour, people are likely to favour internal causes (and thus agree with an observer's judgment) when they consider a behaviour to be desirable (e.g., success, as in "I was successful because I am skillful"), and they invoke external, situational causes in judging a behaviour they deem undesirable (e.g., failure, as in "I failed because the test was unfair"). There are, of course, limits to the regularity with which these generalizations hold. Because people tend to know their own characteristics better than observers do, they are generally more aware than observers are of any divergences from their usual behaviour.

Although people may assume the existence of traits in themselves, they do not, in analyzing a specific situation, see themselves as a mere collection of trait names. Consequently, they are not for the most part perplexed by, and often do not recognize, cross-situational inconsistency in their own behaviour. But in observing another person's behaviour, most people attribute high consistency to that person, as if many positive traits could be inferred from the attribution or observation of one positive trait. For example, the American social psychologist Solomon Asch has shown that a physically attractive person will tend to be judged as having many other desirable qualities. Asch also demonstrated that, in forming impressions of the personal characteristics of others, observers are most influenced by their first impression. The reason first impressions seem to be almost indelible is that they carry an excessive amount of new information, which has a high degree of unpredictability. That is, the more new information contained in an event, the more attention it attracts. Since impressions about a person tend to be integrated into a single characterization, an observer may be jarred by recognizing an undesirable fact about an attractive person and may try either to ignore that fact or to mitigate (rationalize) it. These propensities make up a "common sense psychology," in the words of Fritz Heider, an American psychologist. This "naïve" psychology, as he called it, consists of a set of rules that guide most people's impressions of other people and of social situations. These rules are used constantly to interpret one's own and other people's behaviour and to predict behaviour under certain conditions. The psychoanalytic view, however, seriously challenges this common sense psychology. Psychoanalysis has no problem explaining that those who put to death countless people in the Nazi death chambers, for example, could also be devoted parents, whereas common sense psychology would have difficulty with this. For the psychoanalyst, a personality may be integrated, but it is rarely seamless and regular. People generally make two types of errors in judging personality: they impute more personality consistency to others than the actors themselves would allow, and they often ignore the operation of unconscious psychological processes that can explain at least some of the inconsistencies.

Much work on trait structure and impression formation has concerned adjectival words that describe traits, and the fact that these studies have been carried out principally in the United States and western Europe has led some anthropologists, such as the American Robert LeVine, to remark that modern personality trait theory is ethnocentric. For example, the folk-psychological concepts and the trait matrices derived from factor analyses include culture-specific assumptions about personal experiences, such as the distinctions between mind and body, natural and supernatural, and intellect and morality, which do not exist in the folk traditions of many non-Western peoples. Unlike most other cultures, Western thought assumes that a high degree of personal autonomy is desirable and that the most important emotional and personal relations are with a marital partner. For some psychologists these cultural differences point to the need for a less culture-bound approach to personality trait theory.

MODERN TRENDS IN PERSONALITY STUDIES

Sex differences. Despite the physical differences between males and females the finding of behavioral differences between the sexes is controversial. Behaviours associated with sex roles depend heavily on the social

Variations in trait identification

Eysenck's three basic traits

Ethnocentric trait theory

and cultural context, and studies of stereotypic male and female roles are therefore understandably ambiguous. Yet some findings indicate small but consistent differences. While there are no differences in measured IQ, itself regarded as a culture-bound assessment, females do better than males on verbal tasks. Girls generally begin to speak earlier than boys and have fewer language problems in school and in the course of maturation. Males generally exhibit greater skill in understanding spatial relations and in solving problems that involve mathematical reasoning. Beginning at the toddler stage, the activity level of males is generally higher than that of females. A related finding is that boys are more likely to be irritable and aggressive than girls and more often behave like bullies. Men usually outscore women in antisocial personality disorders, which consist of persistent lying, stealing, vandalism, and fighting, although these differences do not appear until after about the age of three. A study by the American anthropologists Beatrice B. Whiting and Carolyn P. Edwards found that males were consistently more aggressive than females in seven cultures, suggesting that there is a predisposition in males to respond aggressively to provocative situations, although how and whether the attacking response occurs depends on the social and cultural setting.

The tendency of man to kill his own kind

Aggression. Humans are perhaps the only species of animal that does not have an internal inhibition against slaughtering other members of the species. It has been theorized that man, like other animals, is motivated by an aggressive drive, which has significant survival value, but lacks internal inhibitions against killing his fellow men. Inhibitions, therefore, must be imposed externally by society. Social learning theorists emphasize the decisive effects of situations in triggering and controlling aggression. They account for the poor predictability of aggressive behaviour in man by noting that the environmental context is generally unpredictable. Yet research has shown that an aggressive act is most likely to be produced by a person with a history of aggressive behaviour.

Genetic aspects. While social learning theorists emphasize the active shaping of personality by external social influences, experimental evidence has accumulated that genetic factors play a prominent role, if not in the transmission of specific behaviour patterns, then in the readiness of people to respond to environmental pressures in particular ways. In observations of animals, it is commonplace to find in different breeds of dogs wide divergences in behaviour that are attributed to genetic differences: some are friendly, others aggressive; some are timid, others bold (of course there may also be wide variations within a given breed). Among human infants observed in a neonatal nursery, there are also clearly observable differences in activity, passivity, fussiness, cuddliness, and responsiveness. These patterns, which some authorities say may be genetically influenced, shape the ways in which the infant will interact with the environment and can be considered an expression of personality.

Personality studies of twins

In systematic studies of humans, studies of twins and adopted children have been used to try to evaluate environmental and genetic factors as determinants of a number of behaviour patterns. These studies have shown that genetic factors account for about 50 percent of the range of differences found in a given population. Most of the remaining differences are attributable not to the environment that is common to members of a family but to the environment that is unique to each member of the family or that results from interactions of family members with one another. In the United States, behaviour geneticists such as Robert Plomin report that, in behaviours describable as sociability, impulsiveness, altruism, aggression, and emotional sensitivity, the similarities among monozygotic (identical) twins is twice that among dizygotic (fraternal) twins, with the common environment contributing practically nothing to the similarities. Similar findings are reported for twins reared together or separately.

The study of the genetic aspects of personality is a relatively new undertaking. Almost all populations studied have been from industrialized Western nations whose rearing environments are more nearly alike than different. It is known that the more homogeneous the environment,

the stronger the genetic contribution will appear. As with the psychology of traits, cross-cultural studies are required to test the validity of the claims of behaviour genetics.

Cognitive controls and styles. Psychologists have long been aware that people differ in the consistent way in which they receive and respond to information. Some make careful distinctions between stimuli, whereas others blur distinctions, and some may typically prefer to make broad categories, whereas others prefer narrow ones for grouping objects. These consistencies in an individual seem to be fairly stable across time and even across situations. They have been referred to as cognitive controls. Combinations of several cognitive controls within a person have been referred to as cognitive style, of which there can be numerous variations.

Cognitive control studies explore constraints within a person that limit the influence of both environment and motivation, and as such they are expressions of personality. In the 1940s and '50s several studies explored the extent to which personal needs or drives determine what one perceives. In one study, children from rich and poor families were asked to adjust a circle of light to the size of several coins of increasing value and to the size of cardboard disks. All of the children overestimated the size of the coins, although not of the neutral disks, but the poor children overestimated the sizes more than did the rich children. The assumption that need influences such judgments has been widely held. Even Shakespeare, in *A Midsummer Night's Dream*, noted, "Or in the night, imagining some fear, / how easy is a bush supposed a bear." But there are limits to the distorting power of drives, and the experimental demonstration of the influence of motives has been difficult to confirm, perhaps because the formal components of cognition—the workings, for example, of attention, judgment, or perception—and individual difference in their expression have been neglected by personologists. Investigators of cognitive controls examine the psychological limits on the distorting effects of needs and of external reality. For example, in estimating the size of a disk, some people are more exact than others, and the extent to which a need can distort size judgments will consequently be limited by the perceiver's preference for strict or relaxed standards of comparison.

The American psychologists George S. Klein and Herman Witkin in the 1940s and '50s were able to show that several cognitive controls were relatively stable over a class of situations and intentions. For example, the psychologists found a stable tendency in some people to blur distinctions between successively appearing stimuli so that elements tended to lose their individuality (leveling) and an equally stable tendency in other individuals to highlight differences (sharpening). This organizing principle is apparent in judgments of the size of a series of objects, as well as in memory, where it may manifest itself in a blurring of elements in the recall of a story.

Another much studied cognitive control is called field dependence-field independence. It pertains to the extent to which people are influenced by inner (field-independent) or environmental (field-dependent) cues in orienting themselves in space and the extent to which they make fine differentiations in the environment. The more field-independent people are, the greater is their ability to articulate a field. There are no general intellectual capacity differences between field-dependent and field-independent people, but there is a tendency for field-dependent people to favour careers that include working with other people, such as teaching or social work. Field-independent people are more often found in careers that involve abstract issues such as mathematics. Cultural differences have also been found. Some Eskimo live and hunt in an environment with little variation, and a high degree of articulation of the field (field independence) would favour survival; some farmers of Sierra Leone, however, who inhabit an area of lush vegetation and many varieties of shape, require less differentiation of the field.

Limits of psychological drive distortion

Characteristics of field dependence-field independence

ORIGINS OF PERSONALITY STUDY

In general, information about human personality has come from three different sources of study. The first is biologi-

ical, conceived to have genetic as well as environmental origins. The second is that of the social realm, including the impact of social forces on the growing child that shape such personal responses as motives, traits, behaviours, and attitudes. The third is the examination of clinical contacts with people who have suffered adaptive and adjustive failures. Some authorities have suggested that a greater degree of integration of all three sources of information and the methods derived from them would accelerate the growth of valid information about personality. (P.S.H.)

Personality assessment

The measurement of personal characteristics is the subject matter of the field of psychology today called personality assessment. Assessment is an end result of gathering information intended to advance psychological theory and research and to increase the probability that wise decisions will be made in applied settings (*e.g.*, in selecting the most promising people from a group of job applicants). The approach taken by the specialist in personality assessment is based on the assumption that much of the observable variability in behaviour from one person to another results from differences in the extent to which individuals possess particular underlying personal characteristics (traits). The assessment specialist seeks to define these traits, to measure them objectively, and to relate them to socially significant aspects of behaviour.

A distinctive feature of the scientific approach to personality measurement is the effort, wherever possible, to describe human characteristics in quantitative terms. How much of a trait manifests itself in an individual? How many traits are present? Quantitative personality measurement is especially useful in comparing groups of people as well as individuals. Do groups of people from different cultural and economic backgrounds differ when considered in the light of their particular personality attributes or traits? How large are the group differences?

Overt behaviour is a reflection of interactions among a wide range of underlying factors, including the bodily state of the individual and the effects of that person's past personal experiences. Hence, a narrowly focused approach is inadequate to do justice to the complex human behaviour that occurs under the constantly changing set of challenges, pleasures, demands, and stresses of everyday life. The sophisticated measurement of human personality inescapably depends on the use of a variety of concepts to provide trait definitions and entails the application of various methods of observation and evaluation. Personality theorists and researchers seek to define and to understand the diversity of human traits, the many ways people have of thinking and perceiving and learning and emoting. Such nonmaterial human dimensions, types, and attributes are constructs—in this case, inferences drawn from observed behaviour. Widely studied personality constructs include anxiety, hostility, emotionality, motivation, and introversion-extroversion. Anxiety, for example, is a concept, or construct, inferred in people from what they say, their facial expressions, and their body movements.

Personality is interactional in two senses. As indicated above, personal characteristics can be thought of as products of interactions among underlying psychological factors; for example, an individual may experience tension because he or she is both shy and desirous of social success. These products, in turn, interact with the types of situations people confront in their daily lives. A person who is anxious about being evaluated might show debilitated performance in evaluative situations (for example, taking tests), but function well in other situations in which an evaluative emphasis is not present. Personality makeup can be either an asset or a liability depending on the situation. For example, some people approach evaluative situations with fear and foreboding, while others seem to be motivated in a desirable direction by competitive pressures associated with performance.

MEASURING CONSTRUCTS

Efforts to measure personality constructs stem from a variety of sources. Frequently they grow out of theories of

personality; anxiety and repression (the forgetting of unpleasant experiences), for example, are among the central concepts of the theory of psychoanalysis. It is understandable that efforts would be made to quantify one's degree of anxiety, for example, and to use the score thus obtained in the assessment of and in the prediction of future behaviour. Among the major issues in the study of personality measurement is the question of which of the many personality constructs that have been quantified are basic or fundamental and which can be expected to involve wasted effort in their measurement because they represent poorly defined combinations of more elemental constructs; which measurement techniques are most effective and convenient for the purpose of assessment; and whether it is better to interview people in measuring personality, or to ask them to say, for example, what an inkblot or a cloud in the sky reminds them of.

Efforts to measure any given personality construct can fail as a result of inadequacies in formulating or defining the trait to be measured and weaknesses in the assessment methods employed. An investigator might desire to specify quantitatively the degree to which individuals are submissive in social and competitive situations. His effectiveness will depend on the particular theory of submissiveness he brings to bear on the problem; on the actual procedures he selects or devises to measure submissiveness; and on the adequacy of the research he performs to demonstrate the usefulness of the measure. Each of these tasks must be considered carefully in evaluating efforts to measure personality attributes.

The methods used in personality description and measurement fall into several categories that differ with regard to the type of information gathered and the methods by which it is obtained. While all should rely on data that come from direct observations of human behaviour if they are to have at least the semblance of scientific value, all may vary with regard to underlying assumptions, validity, and reliability (consistency, in this case).

ASSESSMENT METHODS

Personality tests provide measures of such characteristics as feelings and emotional states, preoccupations, motivations, attitudes, and approaches to interpersonal relations. There is a diversity of approaches to personality assessment, and controversy surrounds many aspects of the widely used methods and techniques. These include such assessments as the interview, rating scales, self-reports, personality inventories, projective techniques, and behavioral observation.

The interview. In an interview the individual under assessment must be given considerable latitude in "telling his story." Interviews have both verbal and nonverbal (*e.g.*, gestural) components. The aim of the interview is to gather information, and the adequacy of the data gathered depends in large part on the questions asked by the interviewer. In an employment interview the focus of the interviewer is generally on the job candidate's work experiences, general and specific attitudes, and occupational goals. In a diagnostic medical or psychiatric interview considerable attention would be paid to the patient's physical health and to any symptoms of behavioral disorder that may have occurred over the years.

Two broad types of interview may be delineated. In the interview designed for use in research, face-to-face contact between an interviewer and interviewee is directed toward eliciting information that may be relevant to particular practical applications under general study or to those personality theories (or hypotheses) being investigated. Another type, the clinical interview, is focused on assessing the status of a particular individual (*e.g.*, a psychiatric patient); such an interview is action-oriented (*i.e.*, it may indicate appropriate treatment). Both research and clinical interviews frequently may be conducted to obtain an individual's life history and biographical information (*e.g.*, identifying facts, family relationships), but they differ in the uses to which the information is put.

Although it is not feasible to quantify all of the events occurring in an interview, personality researchers have devised ways of categorizing many aspects of the content of

Problems
in
measuring
personality
constructs

Personality
constructs

The
clinical
interview

what a person has said. In this approach, called content analysis, the particular categories used depend upon the researchers' interests and ingenuity, but the method of content analysis is quite general and involves the construction of a system of categories that, it is hoped, can be used reliably by an analyst or scorer. The categories may be straightforward (e.g., the number of words uttered by the interviewee during designated time periods), or they may rest on inferences (e.g., the degree of personal unhappiness the interviewee appears to express). The value of content analysis is that it provides the possibility of using frequencies of uttered response to describe verbal behaviour and defines behavioral variables for more-or-less precise study in experimental research. Content analysis has been used, for example, to gauge changes in attitude as they occur within a person with the passage of time. Changes in the frequency of hostile reference a neurotic makes toward his parents during a sequence of psychotherapeutic interviews, for example, may be detected and assessed, as may the changing self-evaluations of psychiatric hospital inmates in relation to the length of their hospitalization.

Sources of erroneous conclusions that may be drawn from face-to-face encounters stem from the complexity of the interview situation, the attitudes, fears, and expectations of the interviewee, and the interviewer's manner and training. Research has been conducted to identify, control, and, if possible, eliminate these sources of interview invalidity and unreliability. By conducting more than one interview with the same interviewee and by using more than one interviewer to evaluate the subject's behaviour, light can be shed on the reliability of the information derived and may reveal differences in influence among individual interviewers. Standardization of interview format tends to increase the reliability of the information gathered; for example, all interviewers may use the same set of questions. Such standardization, however, may restrict the scope of information elicited, and even a perfectly reliable (consistent) interview technique can lead to incorrect inferences.

Rating scales. The rating scale is one of the oldest and most versatile of assessment techniques. Rating scales present users with an item and ask them to select from a number of choices. The rating scale is similar in some respects to a multiple choice test, but its options represent degrees of a particular characteristic.

Rating scales are used by observers and also by individuals for self-reporting (see below). They permit convenient characterization of other people and their behaviour. Some observations do not lend themselves to quantification as readily as do simple counts of motor behaviour (such as the number of times a worker leaves his lathe to go to the restroom). It is difficult, for example, to quantify how charming an office receptionist is. In such cases, one may fall back on relatively subjective judgments, inferences, and relatively imprecise estimates, as in deciding how disrespectful a child is. The rating scale is one approach to securing such judgments. Rating scales present an observer with scalar dimensions along which those who are observed are to be placed. A teacher, for example, might be asked to rate students on the degree to which the behaviour of each reflects leadership capacity, shyness, or creativity. Peers might rate each other along dimensions such as friendliness, trustworthiness, and social skills. Several standardized, printed rating scales are available for describing the behaviour of psychiatric hospital patients. Relatively objective rating scales have also been devised for use with other groups. Rating scales often take a graphic form:

To what degree is John shy?

not at all	slightly	moderately	very	extremely

A number of requirements should be met to maximize the usefulness of rating scales. One is that they be reliable: the ratings of the same person by different observers should be consistent. Other requirements are reduction of sources of inaccuracy in personality measurement; the so-called halo effect results in an observer's rating someone favourably on a specific characteristic because the observer

has a generally favourable reaction to the person being rated. One's tendency to say only nice things about others or one's proneness to think of all people as average (to use the midrange of scales) represents other methodological problems that arise when rating scales are used.

Self-report tests. The success that attended the use of convenient intelligence tests in providing reliable, quantitative (numerical) indexes of individual ability has stimulated interest in the possibility of devising similar tests for measuring personality. Procedures now available vary in the degree to which they achieve score reliability and convenience. These desirable attributes can be partly achieved by restricting in designated ways the kinds of responses a subject is free to make. Self-report instruments follow this strategy. For example, a test that restricts the subject to true-false answers is likely to be convenient to give and easy to score. So-called personality inventories (see below) tend to have these characteristics, in that they are relatively restrictive, can be scored objectively, and are convenient to administer. Other techniques (such as inkblot tests) for evaluating personality possess these characteristics to a lesser degree.

Self-report personality tests are used in clinical settings in making diagnoses, in deciding whether treatment is required, and in planning the treatment to be used. A second major use is as an aid in selecting employees, and a third is in psychological research. An example of the latter case would be where scores on a measure of test anxiety—that is, the feeling of tenseness and worry that people experience before an exam—might be used to divide people into groups according to how upset they get while taking exams. Researchers have investigated whether the more test-anxious students behave differently than the less anxious ones in an experimental situation.

Personality inventories. Among the most common of self-report tests are personality inventories. Their origins lie in the early history of personality measurement, when most tests were constructed on the basis of so-called face validity; that is, they simply appeared to be valid. Items were included simply because, in the fallible judgment of the person who constructed or devised the test, they were indicative of certain personality attributes. In other words, face validity need not be defined by careful, quantitative study; rather, it typically reflects one's more-or-less imprecise, possibly erroneous, impressions. Personal judgment, even that of an expert, is no guarantee that a particular collection of test items will prove to be reliable and meaningful in actual practice.

A widely used early self-report inventory, the so-called Woodworth Personal Data Sheet, was developed during World War I to detect soldiers who were emotionally unfit for combat. Among its ostensibly face-valid items were these: Does the sight of blood make you sick or dizzy? Are you happy most of the time? Do you sometimes wish you had never been born? Recruits who answered these kinds of questions in a way that could be taken to mean that they suffered psychiatric disturbance were detained for further questioning and evaluation. Clearly, however, symptoms revealed by such answers are exhibited by many people who are relatively free of emotional disorder.

Rather than testing general knowledge or specific skills, personality inventories ask people questions about themselves. These questions may take a variety of forms. When taking such a test, the subject might have to decide whether each of a series of statements is accurate as a self-description or respond to a series of true-false questions about personal beliefs.

Several inventories require that each of a series of statements be placed on a rating scale in terms of the frequency or adequacy with which the statements are judged by the individual to reflect his tendencies and attitudes. Regardless of the way in which the subject responds, most inventories yield several scores, each intended to identify a distinctive aspect of personality.

One of these, the Minnesota Multiphasic Personality Inventory (MMPI), is probably the personality inventory in widest use in the English-speaking world. Also available in other languages, it consists in one version of 550 items (e.g., "I like tall women") to which subjects are to respond

rating
scales

"true," "false," or "cannot say." Work on this inventory began in the 1930s, when its construction was motivated by the need for a practical, economical means of describing and predicting the behaviour of psychiatric patients. In its development efforts were made to achieve convenience in administration and scoring and to overcome many of the known defects of earlier personality inventories. Varied types of items were included and emphasis was placed on making these printed statements (presented either on small cards or in a booklet) intelligible even to persons with limited reading ability.

Most earlier inventories lacked subtlety; many people were able to fake or bias their answers since the items presented were easily seen to reflect gross disturbances; indeed, in many of these inventories maladaptive tendencies would be reflected in either all true or all false answers. Perhaps the most significant methodological advance to be found in the MMPI was the attempt on the part of its developers to measure tendencies to respond, rather than actual behaviour, and to rely but little on assumptions of face validity. The true-false item "I hear strange voices all the time" has face validity for most people in that to answer "true" to it seems to provide a strong indication of abnormal hallucinatory experiences. But some psychiatric patients who "hear strange voices" can still appreciate the socially undesirable implications of a "true" answer and may therefore try to conceal their abnormality by answering "false." A major difficulty in placing great reliance on face validity in test construction is that the subject may be as aware of the significance of certain responses as is the test constructor and thus may be able to mislead the tester. Nevertheless, the person who hears strange voices and yet answers the item "false" clearly is responding to something—the answer still is a reflection of personality, even though it may not be the aspect of personality to which the item seems to refer; thus, careful study of responses beyond their mere face validity often proves to be profitable.

Much study has been given to the ways in which response sets and test-taking attitudes influence behaviour on the MMPI and other personality measures. The response set called acquiescence, for example, refers to one's tendency to respond with "true" or "yes" answers to questionnaire items regardless of what the item content is. It is conceivable that two people might be quite similar in all respects except for their tendency toward acquiescence. This difference in response set can lead to misleadingly different scores on personality tests. One person might be a "yea-sayer" (someone who tends to answer true to test items); another might be a "nay-sayer"; a third individual might not have a pronounced acquiescence tendency in either direction.

Acquiescence is not the only response set; there are other test-taking attitudes that are capable of influencing personality profiles. One of these, already suggested by the example of the person who hears strange voices, is social desirability. A person who has convulsions might say "false" to the item "I have convulsions" because he believes that others will think less of him if they know he has convulsions. The intrusive potentially deceiving effects of the subjects' response sets and test-taking attitudes on scores derived from personality measures can sometimes be circumvented by varying the content and wording of test items. Nevertheless, users of questionnaires have not yet completely solved problems of bias such as those arising from response sets. Indeed, many of these problems first received widespread attention in research on the MMPI, and research on this and similar inventories has significantly advanced understanding of the whole discipline of personality testing.

The MMPI as originally published consists of nine clinical scales (or sets of items), each scale having been found in practice to discriminate a particular clinical group, such as people suffering from schizophrenia, depression, or paranoia (see MENTAL DISORDERS). Each of these scales (or others produced later) was developed by determining patterns of response to the inventory that were observed to be distinctive of groups of individuals who had been psychiatrically classified by other means (e.g., by long-

term observation). The responses of apparently normal subjects were compared with those of hospital patients with a particular psychiatric diagnosis—for example, with symptoms of schizophrenia. Items to which the greatest percentage of "normals" gave answers that differed from those more typically given by patients came to constitute each clinical scale.

In addition to the nine clinical scales and many specially developed scales, there are four so-called control scales on the inventory. One of these is simply the number of items placed by the subject in the "cannot say" category. The L (or lie) scale was devised to measure the tendency of the test taker to attribute socially desirable attributes to himself. In response to "I get angry sometimes" he should tend to mark false; extreme L scorers in the other direction appear to be too good, too virtuous. Another so-called F scale was included to provide a reflection of the subjects' carelessness and confusion in taking the inventory (e.g., "Everything tastes the same" tends to be answered true by careless or confused people). More subtle than either the L or F scales is what is called the K scale. Its construction was based on the observation that some persons tend to exaggerate their symptoms because of excessive openness and frankness and may obtain high scores on the clinical scales; others may exhibit unusually low scores because of defensiveness. On the K-scale item "I think nearly anyone would tell a lie to keep out of trouble," the defensive person is apt to answer false, giving the same response to "I certainly feel useless at times." The K scale was designed to reduce these biasing factors; by weighting clinical-scale scores with K scores, the distorting effect of test-taking defensiveness may be reduced.

In general, it has been found that the greater the number and magnitude of one's unusually high scores on the MMPI, the more likely it is that one is in need of psychiatric attention. Most professionals who use the device refuse to make assumptions about the factualness of the subject's answers and about his personal interpretations of the meanings of the items. Their approach does not depend heavily on theoretical predilections and hypotheses. For this reason the inventory has proved particularly popular with those who have strong doubts about the eventual validity that many theoretical formulations will show in connection with personality measurement after they have been tested through painstaking research. The MMPI also appeals to those who demand firm experimental evidence that any personality assessment method can make valid discriminations among individuals.

In recent years there has been growing interest in actuarial personality description—that is, in personality description based on traits shared in common by groups of people. Actuarial description studies yield rules by which persons may be classified according to their personal attributes as revealed by their behaviour (on tests, for example). Computer programs are now available for diagnosing such disorders as hysteria, schizophrenia, and paranoia on the basis of typical group profiles of MMPI responses. Computerized methods for integrating large amounts of personal data are not limited to this inventory and are applicable to other inventories, personality tests (e.g., inkblots), and life-history information. Computerized classification of MMPI profiles, however, has been explored most intensively.

The MMPI has been considered in some detail here because of its wide usage and because it illustrates a number of important problems confronting those who attempt to assess personality characteristics. Many other omnibus personality inventories are also used in applied settings and in research. The California Psychological Inventory (CPI), for example, is keyed for several personality variables that include sociability, self-control, flexibility, and tolerance. Unlike the MMPI, it was developed specifically for use with "normal" groups of people. Whereas the judgments of experts (usually psychiatric workers) were used in categorizing subjects given the MMPI during the early item-writing phase of its development, nominations by peers (such as respondents or friends) of the subjects were relied upon in work with the CPI. Its technical development has been evaluated by test authorities to be of high

order, in part because its developers profited from lessons learned in the construction and use of the MMPI. It also provides measures of response sets and has been subjected to considerable research study.

From time to time, most personality inventories are revised for a variety of reasons, including the need to take account of cultural and social changes and to improve them. For example, a revision of the CPI was published in 1987. In the revision, the inventory itself was modified to improve clarity, update content, and delete items that might be objectionable to some respondents. Because the item pool remained largely unchanged, data from the original samples were used in computing norms and in evaluating reliability and validity for new scales and new composite scores. The descriptions of high and low scorers on each scale have been refined and sharpened, and correlations of scale scores with other personality tests have been reported.

Other self-report techniques. Beyond personality inventories, there are other self-report approaches to personality measurement available for research and applied purposes. Mention was made earlier of the use of rating scales. The rating-scale technique permits quantification of an individual's reactions to himself, to others, and, in fact, to any object or concept in terms of a standard set of semantic (word) polarities such as "hot-cold" or "good-bad." It is a general method for assessing the meanings of these semantic concepts to individuals.

Another method of self-report called the Q-sort is devised for problems similar to those for which rating scales are used. In a Q-sort a person is given a set of sentences, phrases, or words (usually presented individually on cards) and is asked to use them to describe himself (as he thinks he is or as he would like to be) or someone else. This description is carried out by having the subject sort the items on the cards in terms of their degree of relevance so that they can be distributed along what amounts to a rating scale. Examples of descriptive items that might be included in a Q-sort are "worries a lot," "works hard," and "is cheerful."

Typical paper-and-pencil instruments such as personality inventories involve verbal stimuli (words) intended to call forth designated types of responses from the individual. There are clearly stated ground rules under which he makes his responses. Paper-and-pencil devices are relatively easy and economical to administer and can be scored accurately and reliably by relatively inexperienced clerical workers. They are generally regarded by professional personality evaluators as especially valuable assessment tools in screening large numbers of people, as in military or industrial personnel selection. Assessment specialists do not assume that self-reports are accurate indicators of personality traits. They are accepted, rather, as samples of behaviour for which validity in predicting one's everyday activities or traits must be established empirically (*i.e.*, by direct observation or experiment). Paper-and-pencil techniques have moved from their early stage of assumed (face) validity to more advanced notions in which improvements in conceptualization and methodology are clearly recognized as basic to the determination of empirical validity.

Projective techniques. One group of assessment specialists believes that the more freedom people have in picking their responses, the more meaningful the description and classification that can be obtained. Because personality inventories do not permit much freedom of choice, some researchers and clinicians prefer to use projective techniques, in which a person is shown ambiguous stimuli (such as shapes or pictures) and asked to interpret them in some way. (Such stimuli allow relative freedom in projecting one's own interests and feelings into them, reacting in any way that seems appropriate.) Projective techniques are believed to be sensitive to unconscious dimensions of personality. Defense mechanisms, latent impulses, and anxieties have all been inferred from data gathered in projective situations.

Personality inventories and projective techniques do have some elements in common; inkblots, for example, are ambiguous, but so also are many of the statements on inven-

tories such as the MMPI. These techniques differ in that the subject is given substantially free rein in responding to projective stimuli rather than merely answering true or false, for example. Another similarity between projective and questionnaire or inventory approaches is that all involve the use of relatively standardized testing situations.

While projective techniques are often lumped together as one general methodology, in actual practice there are several approaches to assessment from a projective point of view. Although projective techniques share the common characteristic that they permit the subject wide latitude in responding, they still may be distinguished broadly as follows: (1) associative techniques, in which the subject is asked to react to words, to inkblots, or to other stimuli with the first associated thoughts that come to mind; (2) construction techniques, in which the subject is asked to create something—for example, make up a story or draw a self-portrait; (3) completion techniques, in which the subject is asked to finish a partially developed stimulus, such as adding the last words to an incomplete sentence; (4) choice or ordering techniques, in which the subject is asked to choose from among or to give some orderly sequence to stimuli—for example, to choose from or arrange a set of pictures or inkblots; (5) expressive techniques, in which the subject is asked to use free expression in some manner, such as in finger painting.

Hidden personality defense mechanisms, latent emotional impulses, and inner anxieties all have been attributed to test takers by making theoretical inferences from data gathered as they responded in projective situations. While projective stimuli are ambiguous, they are usually administered under fairly standardized conditions. Quantitative (numerical) measures can be derived from subjects' responses to them. These include the number of responses one makes to a series of inkblots and the number of responses to the blots in which the subject perceives what seem to him to be moving animals.

The Rorschach Inkblot Test. The Rorschach inkblots were developed by a Swiss psychiatrist, Hermann Rorschach, in an effort to reduce the time required in psychiatric diagnosis. His test consists of 10 cards, half of which are in colour and half in black and white. The test is administered by showing the subject the 10 blots one at a time; the subject's task is to describe what he sees in the blots or what they remind him of. The subject is usually told that the inkblots are not a test of the kind he took in school and that there are no right or wrong answers.

Rorschach's work was stimulated by his interest in the relationship between perception and personality. He held that a person's perceptual responses to inkblots could serve as clues to basic personality tendencies. Despite Rorschach's original claims for the validity of his test, subsequent negative research findings have led many users of projective techniques to become dubious about the role assigned the inkblots in delineating relationships between perception and personality. In recent years, emphasis has tended to shift to the analysis of nuances of the subject's social behaviour during the test and to the content of his verbal responses to the examiner—whether, for example, he seeks to obtain the assistance of the examiner in "solving" the inkblots presented to him, sees "angry lions" or "meek lambs" in the inkblots, or is apologetic or combative about his responses.

Over the years, considerable research has been carried out on Rorschach's inkblots; important statistical problems in analyzing data gathered with projective techniques have been identified, and researchers have continued in their largely unsuccessful efforts to overcome them. There is a vast experimental literature to suggest that the Rorschach technique lacks empirical validity. Recently, researchers have sought to put the Rorschach on a sounder psychometric (mental testing) basis. New comprehensive scoring systems have been developed, and there have been improvements in standardization and norms. These developments have injected new life into the Rorschach as a psychometric instrument.

A similar method, the Holtzman Inkblot Test, has been developed in an effort to eliminate some of the statistical problems that beset the Rorschach test. It involves the

Inkblot
techniques

The
Holtzman
Inkblot
Test

Evaluation
of
self-reports

administration of a series of 45 inkblots, the subject being permitted to make only one response per card. The Holtzman has the desirable feature that it provides an alternate series of 45 additional cards for use in retesting the same person.

Research with the Rorschach and Holtzman has proceeded in a number of directions; many studies have compared psychiatric patients and other groups of special interest (delinquents, underachieving students) with ostensibly normal people. Some investigators have sought to derive indexes or predictions of future behaviour from responses to inkblots and have checked, for example, to see if anxiety and hostility (as inferred from content analyses of verbal responses) are related to favourable or unfavourable response to psychotherapy. A sizable area of exploration concerns the effects of special conditions (e.g., experimentally induced anxiety or hostility) on the inkblot perceptions reported by the subject and the content of his speech.

Thematic Apperception Test (TAT). There are other personality assessment devices, which, like the Rorschach, are based on the idea that an individual will project something of himself into his description of an ambiguous stimulus.

The TAT, for example, presents the subject with pictures of persons engaged in a variety of activities (e.g., someone with a violin). While the pictures leave much to one's imagination, they are more highly specific, organized visual stimuli than are inkblots. The test consists of 30 black and white pictures and one blank card (to test imagination under very limited stimulation). The cards are presented to the subject one at a time, and he is asked to make up a story that describes each picture and that indicates the events that led to the scene and the events that will grow out of it. He is also asked to describe the thoughts and feelings of the persons in his story.

Although some content-analysis scoring systems have been developed for the TAT, attempts to score it in a standardized quantitative fashion tend to be limited to research and have been fewer than has been the case for the Rorschach. This is especially the state of affairs in applied settings in which the test is often used as a basis for conducting a kind of clinical interview; the pictures are used to elicit a sample of verbal behaviour on the basis of which inferences are drawn by the clinician.

In one popular approach, interpretation of a TAT story usually begins with an effort to determine who is the hero (i.e., to identify the character with whom the subject seems to have identified himself). The content of the stories is often analyzed in terms of a so-called need-press system. Needs are defined as the internal motivations of the hero. Press refers to environmental forces that may facilitate or interfere with the satisfaction of needs (e.g., in the story the hero may be physically attacked, frustrated by poverty, or suffer the effects of rumours being spread about him). In assessing the importance or strength of a particular inferred need or press for the individual who takes the test, special attention is given to signs of its pervasiveness and consistency in different stories. Analysis of the test may depend considerably on the subjective, personal characteristics of the evaluator, who usually seeks to interpret the subjects' behaviour in the testing situation; the characteristics of his utterances; the emotional tone of the stories; the kinds of fantasies he offers; the outcomes of the stories; and the conscious and unconscious needs speculatively inferred from the stories.

Word-association techniques. The list of projective approaches to personality assessment is long, one of the most venerable being the so-called word-association test. Jung used associations to groups of related words as a basis for inferring personality traits (e.g., the inferiority "complex"). Administering a word-association test is relatively uncomplicated; a list of words is presented one at a time to the subject who is asked to respond with the first word or idea that comes to mind. Many of the stimulus words may appear to be emotionally neutral (e.g., building, first, tree); of special interest are words that tend to elicit personalized reactions (e.g., mother, hit, love). The amount of time the subject takes before beginning each response

and the response itself are used in efforts to analyze a word association test. The idiosyncratic, or unusual, nature of one's word-association responses may be gauged by comparing them to standard published tables of the specific associations given by large groups of other people.

Sentence-completion techniques. The sentence-completion technique may be considered a logical extension of word-association methods. In administering a sentence-completion test, the evaluator presents the subject with a series of partial sentences that he is asked to finish in his own words (e.g., "I feel upset when . . ."; "What burns me up is . . ."). Users of sentence-completion methods in assessing personality typically analyze them in terms of what they judge to be recurring attitudes, conflicts, and motives reflected in them. Such analyses, like those of TAT, contain a subjective element.

Behavioral assessment. Objective observation of a subject's behaviour is a technique that falls in the category of behavioral assessment. A variety of assessments could be considered, for example, in the case of a seven-year-old boy who, according to his teacher, is doing poorly in his schoolwork and, according to his parents, is difficult to manage at home and does not get along with other children. The following types of assessment might be considered: (1) a measure of the boy's general intelligence, which might help explain his poor schoolwork; (2) an interview with him to provide insights into his view of his problem; (3) personality tests, which might reveal trends that are related to his inadequate social relationships; (4) observations of his activities and response patterns in school; (5) observations of his behaviour in a specially created situation, such as a playroom with many interesting toys and games; (6) an interview with his parents, since the boy's poor behaviour in school may be symptomatic of problems at home; and (7) direct observation of his behaviour at home.

Making all of these assessments would be a major undertaking. Because of the variety of data that are potentially available, the assessor must decide which types of information are most feasible and desirable under a given set of circumstances. In most cases, the clinician is interested in both subjective and objective information. Subjective information includes what clients think about, the emotions they experience, and their worries and preoccupations. Interviews, personality inventories, and projective techniques provide indications of subjective experience, although considerable clinical judgment is needed to infer what is going on within the client from test responses. Objective information includes the person's observable behaviour and usually does not require the assessor to draw complex inferences about such topics as attitudes toward parents, unconscious wishes, and deep-seated conflicts. Such objective information is measured by behavioral assessment. It is often used to identify behavioral problems, which are then treated in some appropriate way. Behavioral observations are used to get information that cannot be obtained by other means. Examples of such observations include the frequency of a particular type of response, such as physical attacks on others or observations by ward attendants of certain behaviours of psychiatric patients. In either case, observational data must meet the same standards of reliability as data obtained by more formal measures.

The value of behavioral assessment depends on the behaviours selected for observation. For example, if the goal of assessment is to detect a tendency toward depression, the responses recorded should be those that are relevant to that tendency, such as degrees of smiling, motor activity, and talking.

A type of behavioral assessment called baseline observations is becoming increasingly popular. These are recordings of response frequencies in particular situations before any treatment or intervention has been made. They can be used in several ways. Observations might be made simply to describe a person's response repertoire at a given time. For example, the number of aggressive responses made by children of different ages might be recorded. Such observations also provide a baseline for judging the effectiveness of behaviour modification techniques. A similar

Types of
assessment

Word
stimulus
responses

Baseline
observa-
tions

set of observations, made after behaviour modification procedures have been used, could be compared with the baseline measurement as a way of determining how well the therapy worked.

Behavioral observations can be treated in different ways. One of these is to keep track of the frequency with which people make designated responses during a given period of time (*e.g.*, the number of times a psychiatric patient makes his own bed or the number of times a child asks for help in a novel situation). Another approach involves asking raters to support their judgments of others by citing specific behaviour (critical incidents); a shop foreman, for example, may rate a worker as depressed by citing incidents when the worker burst into tears. Critical incidents not only add validity to ordinary ratings, but they also suggest behavioral details that might be promising predictors of success on the job, response to psychiatric treatment, or level of academic achievement.

Behavioral observations are widely made in interviews and in a variety of workaday settings. Employers, supervisors, and teachers—either formally or informally—make use of behavioral observations in making decisions about people for whom they have responsibility. Unfortunately the subject may know he is being studied or evaluated and, therefore, may behave atypically (*e.g.*, by working harder than usual or by growing tense). The observer may be a source of error by being biased in favour of or against the subject. Disinterested observers clearly are to be preferred (other things being equal) for research and clinical purposes. The greater the care taken to control such contributions to error, the greater the likelihood that observations will prove to be reliable.

Cognitive assessment. The types of thoughts experienced by individuals are reflective of their personalities. Just as it is important to know what people do and how their behaviour affects others, it is also necessary to assess the thoughts that may lie behind the behaviour. Cognitive assessment provides information about thoughts that precede, accompany, and follow maladaptive behaviour. It also provides information about the effects of procedures that are intended to modify both how subjects think about a problem and how they behave.

Cognitive assessment can be carried out in a variety of ways. For example, questionnaires have been developed to sample people's thoughts after an upsetting event. Beepers (electronic pagers) have been used to signal subjects to record their thoughts at certain times of the day. There are also questionnaires to assess the directions people give themselves while working on a task and their theories about why things happen as they do.

The assessment of thoughts and ideas is a relatively new development. It has received impetus from the growing evidence that thought processes and the content of thoughts are related to emotions and behaviour. Cognitive assessment provides information about adaptive and maladaptive aspects of people's thoughts and the role their thoughts play in the processes of planning, making decisions, and interpreting reality.

Bodily assessment. Bodily responses may reveal a person's feelings and motivations, and clinicians pay particular attention to these nonverbal messages. Bodily functions may also reflect motivations and concerns, and some clinicians also pay attention to these. Sophisticated devices have been developed to measure such physiological changes as pupil dilation, blood pressure, and electrical skin responses under specific conditions. These changes are related to periodic ratings of mood and to other physiological states that provide measures of stability and change within the individual. Technological advances are making it possible to monitor an individual's physiological state on a continuous basis. Sweat, heartbeat, blood volume, substances in the bloodstream, and blood pressure can all be recorded and correlated with the presence or absence of certain psychological conditions such as stress.

Personal facts. One type of information that is sometimes overlooked because of its very simplicity consists of the subject's life history and present status. Much of this information may be gathered through direct interviews with a subject or with an informant through questionnaires and

through searches of records and archives. The information might also be gathered by examining the subject's personal documents (*e.g.*, letters, autobiographies) and medical, educational, or psychiatric case histories. The information might concern the individual's social and occupational history, his cultural background, his present economic status, and his past and present physical characteristics. Life-history data can provide clues to the precursors and correlates of present behaviour. This information may help the investigator avoid needlessly speculative or complex hypotheses about the causation of personality traits when simple explanations might be superior. Failure on the part of a personality evaluator to be aware of the fact that someone had spent two years during World War II in a concentration camp could result in misleading inferences and conjectures about the subject's present behaviour.

RELIABILITY AND VALIDITY OF ASSESSMENT METHODS

Assessment, whether it is carried out with interviews, behavioral observations, physiological measures, or tests, is intended to permit the evaluator to make meaningful, valid, and reliable statements about individuals. What makes John Doe tick? What makes Mary Doe the unique individual that she is? Whether these questions can be answered depends upon the reliability and validity of the assessment methods used. The fact that a test is intended to measure a particular attribute is in no way a guarantee that it really accomplishes this goal. Assessment techniques must themselves be assessed.

Evaluation techniques. Personality instruments measure samples of behaviour. Their evaluation involves primarily the determination of reliability and validity. Reliability often refers to consistency of scores obtained by the same persons when retested. Validity provides a check on how well the test fulfills its function. The determination of validity usually requires independent, external criteria of whatever the test is designed to measure. An objective of research in personality measurement is to delineate the conditions under which the methods do or do not make trustworthy descriptive and predictive contributions. One approach to this problem is to compare groups of people known through careful observation to differ in a particular way. It is helpful to consider, for example, whether the MMPI or TAT discriminates significantly between those who show progress in psychotherapy and those who do not, whether they distinguish between law violators of record and apparent nonviolators. Experimental investigations that systematically vary the conditions under which subjects perform also make contributions.

Although much progress has been made in efforts to measure personality, all available instruments and methods have defects and limitations that must be borne in mind when using them; responses to tests or interview questions, for example, often are easily controlled or manipulated by the subject and thus are readily "fakeable." Some tests, while useful as group screening devices, exhibit only limited predictive value in individual cases, yielding frequent (sometimes tragic) errors. These caveats are especially poignant when significant decisions about people are made on the basis of their personality measures. Institutionalization or discharge, and hiring or firing, are weighty personal matters and can wreak great injustice when based on faulty assessment. In addition, many personality assessment techniques require the probing of private areas of the individual's thought and action. Those who seek to measure personality for descriptive and predictive reasons must concern themselves with the ethical and legal implications of their work.

A major methodological stumbling block in the way of establishing the validity of any method of personality measurement is that there always is an element of subjective judgment in selecting or formulating criteria against which measures may be validated. This is not so serious a problem when popular, socially valued, fairly obvious criteria are available that permit ready comparisons between such groups as convicted criminals and ostensible non-criminals, or psychiatric hospital patients and noninstitutionalized individuals. Many personality characteristics, however, cannot be validated in such directly observable

Methods of recording people's thoughts

Techniques for gathering personal information

Limitations in personality measurement methods

ways (e.g., inner, private experiences such as anxiety or depression). When such straightforward empirical validation of an untested measure hopefully designed to measure any personality attribute is not possible, efforts at establishing a less impressive kind of validity (so-called construct validity) may be pursued. A construct is a theoretical statement concerning some underlying, unobservable aspect of an individual's characteristics or of his internal state. ("Intelligence," for example, is a construct; one cannot hold "it" in one's hand, or weigh "it," or put "it" in a bag, or even look at "it.") Constructs thus refer to private events inferred or imagined to contribute to the shaping of specific public events (observed behaviour). The explanatory value of any construct has been considered by some theorists to represent its validity. Construct validity, therefore, refers to evidence that endorses the usefulness of a theoretical conception of personality. A test designed to measure an unobservable construct (such as "intelligence" or "need to achieve") is said to accrue construct validity if it usefully predicts the kinds of empirical criteria one would expect it to—e.g., achievement in academic subjects.

Predictive-
ness of
personality
measures

The degree to which a measure of personality is empirically related to or predictive of any aspect of behaviour observed independently of that measure contributes to its validity in general. A most desirable step in establishing the usefulness of a measure is called cross-validation. The mere fact that one research study yields positive evidence of validity is no guarantee that the measure will work as well the next time; indeed, often it does not. It is thus important to conduct additional, cross-validation studies to establish the stability of the results obtained in the first investigation. Failure to cross-validate is viewed by most testing authorities as a serious omission in the validation process. Evidence for the validity of a full test should not be sought from the same sample of people that was used for the initial selection of individual test items. Clearly this will tend to exaggerate the effect of traits that are unique to that particular sample of people and can lead to spuriously high (unrealistic) estimates of validity that will not be borne out when other people are studied. Cross-validation studies permit assessment of the amount of "shrinkage" in empirical effectiveness when a new sample of subjects is employed. When evidence of validity holds up under cross-validation, confidence in the general usefulness of test norms and research findings is enhanced. Establishment of reliability, validity, and cross-validation are major steps in determining the usefulness of any psychological test (including personality measures).

Clinical versus statistical prediction. Another measure of assessment research has to do with the role of the assessor himself as an evaluator and predictor of the behaviour of others. In most applied settings he subjectively (even intuitively) weighs, evaluates, and interprets the various assessment data that are available. How successful he is in carrying out his interpretive task is critical, as is knowledge of the kinds of conditions under which he is effective in processing such diverse data as impressions gathered in an interview, test scores, and life-history data. The typical clinician usually does not use a statistical formula that weighs and combines test scores and other data at his disposal. Rather, he integrates the data using impressions and hunches based on his past clinical experience and on his understanding of psychological theory and research. The result of this interpretive process usually includes some form of personality description of the person under study and specific predictions or advice for that person.

Evaluating
the
evaluator

The degree of success an assessor has when he responds to the diverse information that may be available about a particular person is the subject of research that has been carried out on the issue of clinical versus statistical prediction. It is reasonable to ask whether a clinician will do as good a job in predicting behaviour as does a statistical formula or "cookbook"—i.e., a manual that provides the empirical, statistically predictive aspects of test responses or scores based on the study of large numbers of people.

An example would be a book or table of typical intelligence test norms (typical scores) used to predict how well children perform in school. Another book might offer

specific personality diagnoses (e.g., neurotic or psychotic) based on scores such as those yielded by the different scales of the MMPI. Many issues must be settled before the deceptively simple question of clinical versus statistical prediction can be answered definitively.

When statistical prediction formulas (well-supported by research) are available for combining clinical information, however, experimental evidence clearly indicates that they will be more valid and less time-consuming than will a clinician (who may be subject to human error in trying to simultaneously consider and weigh all of the factors in a given case). The clinician's chief contributions to diagnosis and prediction are in situations for which satisfactory formulas and quantified information (e.g., test scores) are not available. A clinician's work is especially important when evaluations are required for rare and idiosyncratic personality characteristics that have escaped rigorous, systematic empirical study. The greatest confidence results when both statistical and subjective clinical methods simultaneously converge (agree) in the solution of specific clinical problems. (I.G.S.)

BIBLIOGRAPHY. Definitions of personality as a psychological concept, with treatment of related issues, are found in the following reference works: ROM HARRÉ and ROGER LAMB (eds.), *The Dictionary of Personality and Social Psychology* (1986); RICHARD L. GREGORY (ed.), *The Oxford Companion to the Mind* (1987); RAYMOND J. CORSINI et al. (eds.), *Concise Encyclopedia of Psychology* (1987); and JONATHAN L. FREEDMAN, *Introductory Psychology*, 2nd ed. (1982).

Major theories of personality are surveyed in CALVIN S. HALL and GARDNER LINDZEY, *Theories of Personality*, 3rd ed. (1978); and in NATHAN BRODY, *Personality: In Search of Individuality* (1988). ROGER BROWN, *Social Psychology, the Second Edition* (1986); and IRWIN G. SARASON, *Personality: An Objective Approach*, 2nd ed. (1972), review and evaluate contemporary personality studies and research methods. The best presentation of psychoanalytic ideas remains Freud's own, available in many translated selections. The following two, edited and translated by JAMES STRACHEY, can be recommended: SIGMUND FREUD, *Introductory Lectures on Psychoanalysis* (1977; originally published in German, 1916–17), and *New Introductory Lectures on Psychoanalysis* (1974; originally published in German, 1933). GARDNER MURPHY, *Personality: A Biosocial Approach to Origins and Structure* (1947, reissued 1966), integrates views and data that reach across historical epochs and many intellectual disciplines. The theory of cognitive controls and styles is carefully analyzed in GEORGE S. KLEIN, *Perception, Motives, and Personality* (1970).

Discussions of the variety of currently held views on personality, demonstrating a broad interdisciplinary approach, include JAMES F. MASTERTON, *The Search for the Real Self: Unmasking the Personality Disorders of Our Age* (1988); and ARTHUR PEACOCKE and GRANT GILLET (eds.), *Persons and Personality: Contemporary Inquiry* (1987). Adaptation of personality in social interaction is explored in JOEL ARONOFF and JOHN P. WILSON, *Personality in the Social Process* (1985); ALAN S. WATERMAN, *The Psychology of Individualism* (1984); ROBERT A. LEVINE, *Culture, Behavior, and Personality: An Introduction to the Comparative Study of Psychosocial Adaptation*, 2nd ed. (1982); NANCY CANTOR and JOHN F. KIHLSSTROM, *Personality, Cognition, and Social Interaction* (1981); and NANCY CANTOR and JOHN F. KIHLSSTROM (eds.), *Personality and Social Intelligence* (1987). Issues of personality development from childhood through adulthood are interpreted in ROBERT L. LEAHY (ed.), *The Development of the Self* (1985); LAURENCE R. SIMON, *Cognition and Affect: A Developmental Psychology of the Individual* (1986); LAWRENCE S. WRIGHTSMAN, *Personality Development in Adulthood* (1988); and ERIK H. ERIKSON, *Childhood and Society*, new anniversary ed. (1985).

General approaches to personality assessment are surveyed in ANNE ANASTASI, *Psychological Testing*, 6th ed. (1988); and LEE J. CRONBACH, *Essentials of Psychological Testing*, 4th ed. (1984). JAMES V. MITCHELL, JR. (ed.), *The Ninth Mental Measurement Yearbook*, 2 vol. (1985), describes numerous psychometric tests, including personality assessment instruments. DOUGLAS N. JACKSON and SAMUEL MESSICK (eds.), *Problems in Human Assessment* (1967, reprinted 1978), deals with selected aspects of personality assessment. E. JERRY PHARES, *Introduction to Personality*, 2nd ed. (1988), reviews the personality field with a focus on assessment; and IRWIN G. SARASON and BARBARA R. SARASON, *Abnormal Psychology: The Problem of Maladaptive Behavior*, 6th ed. (1989), provides examples of personality assessment of individuals who display deviant behaviour.

(P.S.H./I.G.S.)

Peru

A country that borders the Pacific Ocean, straddles the great Andes Mountain Ranges, and contains the headwaters of the Amazon River, Peru is the third largest nation in South America after Brazil and Argentina. Officially it is called the Republic of Peru (República del Perú). Its name is derived from a Quechua Indian word implying land of abundance, a reference to the economic wealth produced by the highly organized Inca civilization that ruled the region for centuries. The nation's vast mineral, agricultural, and marine resources long have served as the economic foundation of the country.

Except for the Lake Titicaca basin in the southeast, Peru's borders run through sparsely populated zones. The boundaries with Ecuador to the northwest, Bolivia to the southeast, and Chile to the south run across the high Andes, whereas the borders with Colombia to the northeast and Brazil to the east traverse lower ranges or tropical forests. Peru's land area of 496,225 square miles (1,285,-

216 square kilometres) is supplemented by territorial waters, reaching 200 miles (320 kilometres) into the Pacific, that are claimed by Peru.

Peru is essentially a tropical country, with its northern tip nearly touching the Equator. Despite its tropical location, a great diversity of climate, of way of life, and of economic activity is brought about by the country's extremes of altitude and by the southwest winds that sweep in across the cold Peru, or Humboldt, Current, which flows along its Pacific shoreline. The immense difficulties of travel posed by the Andes have long impeded national unity. Iquitos, on the upper Amazon, lies only about 600 miles northeast of Lima, the capital, but before the airplane, travelers between the cities often chose a 7,000-mile trip via the Amazon, the Atlantic and Caribbean, the Isthmus of Panama, and the Pacific, rather than the shorter mountain route.

Physical and human geography

THE LAND

Relief. Peru is traditionally described in terms of three broad, longitudinal regions: the arid Costa on the west; the rugged Sierra, or Andes, system in the centre; and, on the east, the wet and forested Montaña of the tropical Amazon Basin.

The Costa. The coastal plain can be readily divided into three parts—north, central, and south—based on the amount of level land and the distance between the Andean ranges and the sea. Generally speaking, the amount of level coastal land diminishes from north to south. In the northern region, from Ecuador to Chimbote, the plain is typically some 20 to 30 miles wide, with a maximum width of more than 90 miles in the Sechura Desert south of Piura. The central coastal region, which stretches from Chimbote to Nazca, is narrower than the northern region and is characterized by areas of rough hills that extend from the Andes to the shores of the ocean. From Nazca southward to the Chilean border the coast is for the most part lined by low mountains; the southern valleys are narrow and only in scattered spots are level lands found near the ocean.

The Sierra, or Andean, region. Along the western edge

of South America, the Andes Mountains were created by tectonic activity in which the South American Plate overrode the Nazca Plate. The Peruvian Andes are typical of mountain regions of the Pacific Rim: they are young in geologic terms, and their continuing uplift is manifested by frequent earthquakes and much instability. Three main backbones protrude from the Peruvian Andes; they are commonly called the cordilleras Occidental, Central, and Oriental, although these designations are not used within Peru.

Slopes are relatively gentle in northern Peru, and maximum elevations seldom exceed 16,000 feet (about 5,000 metres). The Andes in central Peru are higher and more rugged. The ranges of the central zone form particularly difficult barriers to movement. The main pass east of Lima, for instance, is at an elevation of more than 15,000 feet—higher than many of the peaks in the north. Many of the mountains of central Peru are snowcapped and are a popular attraction for climbers and tourists. Of particular fame is the Cordillera Blanca, with the country's highest peak, Mount Huascarán, at 22,205 feet. In southern Peru the character of the Andes changes to that of a high plateau region; this is the Puna, with vast tablelands and elevations between 13,000 and 16,000 feet. Scattered peaks, with elevations of up to about 21,000 feet, protrude

Mount
Huascarán

above the broad southern plateaus. Beginning with Misti Volcano, near Arequipa, many of the southern peaks form a volcanic chain that stretches into northern Chile.

The Montaña. The lower slopes of the western Andes merge with the heavily forested tropical lowlands of the Amazon Basin to form the Montaña, which occupies more than three-fifths of the area of Peru. The term *selva* is also used to refer to this area. The physiography of the region is characterized by rolling hills and level plains that extend eastward to the borders with Colombia, Brazil, and Bolivia. Elevations are uniformly low, ranging from about 1,300 feet at the eastern edge of the Andes to about 300 feet above sea level along the Amazon River at the Peru-Brazil border.

Drainage. Distinctive drainage patterns dissect the Costa, Sierra, and Montaña. Of the more than 50 rivers that flow west from the Andes across the Costa, most are short (usually less than 200 miles long) and precipitous, with highly seasonal rates of flow. Most have a period of peak flow (usually during the December to March rainy season) followed by a long dry period; only the largest of the Costa rivers, such as the Santa, have dependable year-round flows.

The Sierra not only contains the headwaters of the streams that flow to both the Pacific and the Amazon but also has a large area of internal drainage. In the south several rivers cross the altiplano in Peru to empty into Lake Titicaca, which is shared with Bolivia and is—at an altitude of 12,500 feet—the world's highest navigable body of water.

The Montaña region is characterized by great rivers. The Amazon, with the largest volume of flow of any river in the world, has headwaters that rise in several places in the Peruvian Andes; one of the main branches, the Ucayali, originates in southern Peru some 1,700 miles from its juncture with the main branch. The Amazon is navigable, but such large tributaries as the Marañón, Huallaga, and Ucayali can be navigated only for relatively short distances west of the port of Iquitos. These rivers flow northward in long deep valleys before turning east to join the Amazon, forming mostly hindrances to transportation rather than important trade routes.

Soils. Peru has little fertile soil. In the Costa region most of the river valleys have rich soils, derived from silts carried to the coastal plain by rivers flowing out of the Andes. In some areas, however, improper use of the land has led to deposition of salts, thus reducing soil fertility. The soils between valleys, derived largely from windblown sands, are also poorly developed. Sierra soils are fertile in some of the highland basins, but soils on the mountain slopes are often thin and of poor quality. Soils of low fertility covered by heavy forest growth typify the Montaña; they quickly erode when the forests are cut.

Climate. Three broad climatic regions can be readily distinguished in Peru paralleling the three main topographic regions: the Costa, the Sierra, and the Montaña.

The coastal desert. From the Peruvian-Ecuadorian border south to northern Chile, the west coast of South America has one of the Earth's driest climates. This region is dry for three reasons: (1) The Andes block rain-bearing winds from the Amazon Basin, (2) air masses moving toward the coast out of the South Pacific high pressure system produce little rainfall, and (3) northward-flowing cold water off the coast (the Peru, or Humboldt, Current) contributes little moisture to surface air masses. This is not a hot desert, however; average temperatures of the Costa range from 66° F (19° C) in winter to 72° F (22° C) in summer. Despite its dryness some parts of the Costa receive sufficient moisture from winter fogs (locally known as *garúa*) to support some vegetation.

The mountain climates. Within the Sierra are a wide range of climates that vary according to such factors as latitude, altitude, local winds, and rain shadow effects. In general, temperatures decrease as elevation increases and rainfall decreases from north to south and from east to west. During the December-March rainy season, the heaviest precipitation is in the north and along the eastern flanks of the Andes. Temperatures vary little seasonally, but there is a tremendous diurnal range (between daily

highs and lows). In Cuzco at 11,152 feet of altitude, for example, the January average temperature is 52° F (11° C), and the July average 47° F (8° C). The diurnal range, however, is frequently more than 40° F (22° C) between the midday maximum and the predawn minimum. Snow falls in the Sierra at higher altitudes, and many peaks have permanent snow.

The tropical forest climates. Hot humid conditions characterize the Montaña climate of eastern Peru. Rainfall throughout the region is high (Iquitos averages more than 90 inches [2,286 millimetres] annually), with precipitation common throughout the year, although it is somewhat heavier from December to March. There is little seasonal variation of temperatures, but the diurnal range again is relatively large. Daytime highs at Iquitos sometimes extend into the mid-90°s F (mid-30°s C), whereas at night temperatures may fall into the 60°s F (below 15° C).

El Niño. The most severe variation in Peruvian weather patterns occurs irregularly, at intervals of about a decade or so. This change, usually called El Niño ("The Child," because it usually begins around Christmas time), is but a small part of what is known as the Southern Oscillation, a pan-Pacific reversal of atmospheric and sea conditions. Although the causes of this phenomenon are not completely understood, the effects in Peru are quite clear: (1) warm water replaces the cold water of the Peru Current, (2) heavy rains fall in the coastal desert, and (3) drought occurs in the southern highlands. Severe occurrences of the El Niño phenomenon, such as those that took place in 1925 and 1983, cause ecological disasters, including widespread loss of bird and fish life and great economic damage.

Plant and animal life. Peruvian plant and animal life can be classified according to the three main physiographic regions: the Costa, the Sierra, and the Montaña.

The Costa. Evidence of plant life is relatively rare in the barren desert of coastal Peru. Where coastal fog is heavy, *lomas* (a mix of grasses and other herbaceous species) are common. In the north coast region, some parts of the desert are covered by epiphytes or by stands of sapote or algarroba (mesquite). The most important feature of the coast, however, is the enormous amount of bird, marine mammal, and fish life that abounds in the coastal waters. The biomass includes such small fish as anchovies and such larger types as corbina (sea bass), tuna, swordfish, and marlin. Sea lions thrive in isolated parts of the coast. Bird life is heavy on islands off the coast. Among the most important bird species are pelicans, cormorants, gannets, and various gulls. Humboldt penguins, an endangered species, are found as far north as the Ballestas Islands near the Paracas Peninsula.

The Sierra. Two plant communities characterize the Peruvian highlands: puna grasslands at elevations from about 13,000 to 16,000 feet, and, at lower elevations, a mixture of native and introduced species. The Puna has an abundance of forage grasses and is home to the llama, alpaca, vicuña, and guanaco, which are native to the region. At lower elevations grow such domesticates as potatoes, quinoa, and corn (maize). Several species of eucalyptus have replaced native tree species.

The Montaña. The eastern slopes of the Andes and the Amazon plains are covered by a heavy growth of tropical forest. In its woods and waters live thousands of plant and animal species. Interesting mammals of this region include the jaguar, capybara, tapir, and several species of monkey. Of special note is the wide and colourful variety of bird and fish life. Reptiles and insects abound. The forests have a broad assortment of hardwood and softwood species that produce a variety of forest products. Scattered in isolated fields in the eastern foothills of the Andes, too, are plantations of coca, the plant from which cocaine is illegally produced.

Settlement patterns. The nature of Peruvian life, whether urban or rural, varies by physiographic region. Modern patterns of settlement also reflect three major influences: (1) pan-Andean cultures of pre-Hispanic Peru; (2) colonial settlement of the Costa and the Sierra; and (3) migration to the cities and colonization of the Montaña.

Pre-Hispanic patterns. Diverse groups of indigenous In-

The Amazon River

Coastal aridity

Amazonian wildlife

The early migrants

dians occupied Peru during the pre-Hispanic period. When the first migrants arrived in the Andean area, probably more than 13,000 years ago, they were at a hunting and gathering stage of cultural development. Over a long period of time, however, varied and more sophisticated ways of life were developed. Along the coast, groups became specialized in fishing and shellfish collecting. In the Puna, hunting of vicuña and guanaco was replaced by herding of their related species, the llama and alpaca. Finally, in many parts of Peru agriculture was developed—including the domestication of numerous species of plants, such as beans, quinoa, and potatoes.

At the time of the Spanish arrival, the population of Peru was largely resident in rural areas, with society organized around villages (called by the Incas *ayllus*). The most densely settled areas were the coastal river valleys and some fertile basins in the highlands—for example, those of Cajamarca, the Mantaro Valley near Huancayo, and Cusco, as well as the region around Lake Titicaca. Some urban centres had developed as the capitals of kingdoms or empires—such as the Chimú's Chan Chan near Trujillo

and the Inca's Cuzco—or as religious centres—such as the pre-Incan Pachacamac, south of Lima.

Colonial patterns. The Spanish conquest of the Incas in 1532 was accompanied by several dramatic changes in Andean settlement patterns. First, the Spanish were oriented toward their mother country in Europe. Thus, Spanish cities such as Piura (1532), Lima (1535), and Trujillo (1534) were established near ports that were the sea links to Spain. Second, Spanish settlements focused on the extraction of resources, leading to the establishment of mining centres in Huancavelica and at Potosí, in modern Bolivia. Third, after a period of rapid population decline caused mainly by the introduction of European diseases, the Spanish established new towns that brought together the remnants of the surviving rural population. Finally, the Spanish divided the country into *encomiendas*, which later formed the basis for *haciendas* and kept the best agricultural land in the hands of a few wealthy owners. They established feudal systems based on peasant labour that lasted until the sweeping land reforms of the mid-20th century.

The Spanish influence on settlement

Recent migrations. In Peru, as in most Latin-American countries, there has been a mass migration to the cities during the 20th century, especially since the end of World War II. Lima has been the principal destination during this rural exodus, but Trujillo in the north and Arequipa in the south have also received large numbers of migrants. The lack of opportunity in rural regions is usually cited as the reason for movement to the cities, where migrants hope they will find better health care and educational opportunities, as well as jobs. Some do improve their lot, but others end up in city slums or in squatter settlements at the edges of the cities, where conditions may be little improved over those in the rural areas.

A second focus of migration in Peru has been eastward, to the *Montaña*. At the end of the 19th century the world rubber boom caused many people to move into the Amazon Basin; more recently the Peruvian government has developed a program to improve the economy of the *Montaña*, a main purpose of which is to divert migrants away from the already crowded coastal urban centres. The completion of roads from Chiclayo on the north coast to Tarapoto in the northern *Montaña* and from Lima to Pucallpa in the central *Montaña* region have stimulated this eastward movement. Further development along the eastern side of the Andes is designed to open new settlements in this region. Nevertheless, the *Montaña* remains the least populated of the three regions.

Urban Peru. The massive 20th-century migration from the countryside has brought rapid growth to Peruvian urban centres. Lima has become the urban giant, more than 10 times larger than the next largest city, but other cities, particularly Trujillo and Chimbote in the north and Arequipa in the south, have also grown rapidly. Since World War II Peru has changed from a country with a predominantly rural population to one that has more than two-thirds of its people living in cities; more than one-fourth of the nation's population lives within the greater Lima metropolitan area.

Ornate colonial architecture contrasts with modern high-rise buildings in Lima, which is the heart of Peru's commerce and industry. Large factories are located in the city, but much of the industrial production takes place in the small workshops of the squatter settlements that surround the city. A difficult problem in Lima has been that of matching the urban infrastructure to the city's growth rate. Lima has only one freeway and lacks an up-to-date mass transit system. Basic public services are, in many neighbourhoods, rudimentary at best. (See LIMA.)

Arequipa in the Sierra and Trujillo in the Costa are other major urban centres. Arequipa is the largest city in southern Peru. Founded in 1540, it is often called the White City because most of its buildings are constructed out of white volcanic rock. Agriculture around Arequipa has improved with the completion of several important irrigation projects, and the area has become a major wool-processing and milk-producing region. Trujillo is a major centre in northern Peru but does not dominate the north as Arequipa does the south. That is because other cities, notably Chiclayo, Chimbote, and Piura, share power in the north, whereas Arequipa is rivaled only by Cuzco, which is in the mountains to the east. Trujillo is the historic power centre in northern Peru, however, and it has become an important commercial centre. Its industries include tractor and diesel motor factories as well as food-processing plants. Chimbote, Peru's best harbour, has a steel mill and numerous fish-processing plants. Chiclayo and Piura mainly serve as regional political and commercial centres.

Most highland cities are small. In the north the principal city, Cajamarca, is noted chiefly as the place where the Spanish conquistador Francisco Pizarro captured the Inca emperor Atahualpa. Huaraz, 200 miles north of Lima, is a rapidly growing city that was connected to Lima by a paved road in the mid-1970s. To the south, Cerro de Pasco, the nation's largest mining centre, is, at more than 14,200 feet, one of the world's highest cities. Huancayo, about 100 miles due east of Lima, is a farming centre famous for its colourful Sunday market, where Indians sell such handicrafts as llama-wool blankets, ponchos, and

Chachani volcano (highest peak) overlooking terraced fields near Arequipa in the southern Sierra region, Peru.
Chip and Rosa Maria de la Cueva Peterson

sweaters. The best-known Andean centre is the ancient city of Cuzco, once the Inca capital. Tourists from all parts of the world visit Inca remains in Cuzco and its environs, as well as its many colonial churches. The Inca past is apparent in many places. Inca walls topped by Spanish-style structures stand along many streets around Cuzco's main plaza. The most monumental Inca ruins are those of the fortress/sanctuary of Sacsahuamán, built on a hill overlooking the city. The bygone world of Spanish colonial power is evident in the tile-roofed houses and churches of Cuzco. Among the most impressive is the cathedral, dating from around 1550.

The major cities of eastern Peru are Iquitos and Pucallpa. Iquitos, on the upper Amazon, was a small jungle outpost until the rubber boom of the 1880s. When the boom ended, lumber became the major product of the area. More recently oil and tourism have contributed to its growth. Pucallpa, on the Ucayali River, is connected to Lima by road and to Iquitos by river vessels. The area around Pucallpa is a major colonization zone.

THE PEOPLE

Pre-Hispanic groups. Throughout the pre-Hispanic period, the peoples of Peru were largely isolated from one another by the rugged topography of the country. At least three times, however, a unifying culture spread across the Andes. Beginning c. 1000 BC, the Chavín culture permeated the region, emanating possibly from the northern ceremonial site of Chavín de Huántar. After AD 600, the Huari civilization, based at a site of the same name near modern Ayacucho, dominated most of the central Andean region. Finally, the Inca Empire developed, eventually to control all of the territory from northern Ecuador to central Chile. The Inca spread their language, Quechua, across the highlands and along the coast, although some groups near Lake Titicaca spoke Aymara at the time of the Spanish conquest. Quechua and Aymara are still prevalent and have official usage, with Spanish, in regions where they are heavily spoken. Tropical forest areas were outside Incan influence, and the numerous languages and dialects now spoken in the Amazon region reflect the diverse linguistic heritage of the tropical forest peoples.

Ethnic diversity. The Spanish conquerors dominated Peruvian society, including politics, religion, and economics. They brought their European culture and trans-

Growth of cities

Andean cities

Spanish
cultural
influence

mitted their racial characteristics, Spanish language, and Roman Catholic religion to their descendants. The Spaniards introduced a few African slaves, but their number did not become significant. Following independence and the prohibition of slavery, Chinese immigrants were imported as farm labourers, and new groups of Spaniards, northern Europeans, and Japanese were among other arrivals. These diverse racial and ethnic groups have tended to intermarry and produce a mix of racial types, which in modern Peru constitute a complex racial mosaic.

Differences in life-styles and attitudes are pronounced. Peruvians of Spanish descent and the mestizos (racially mixed people) live mainly along the coast and control most of the nation's wealth. Typically, a small group of white people hold the main power in government and industry. Mestizo culture is a blend of Indian and European ways known as *criollo*. The Spanish-speaking mestizos make up the middle class of Peruvian society. They hold managerial, administrative, and professional jobs, but some are also small landowners and labourers. The Indians of the Sierra, who make up about one-third of the population, live in extreme poverty in a harsh environment; they remain both indifferent to, and outside of, the mainstream affairs of the country. Land reforms have brought some improvement, but many highland Indians shepherd llama herds and work tiny plots of land to eke out a living. Like their Inca ancestors, the overwhelming number of Indians read neither their own nor another language. The lowland Indians of the Montaña occupy a social position similar to that of the highland Indians.

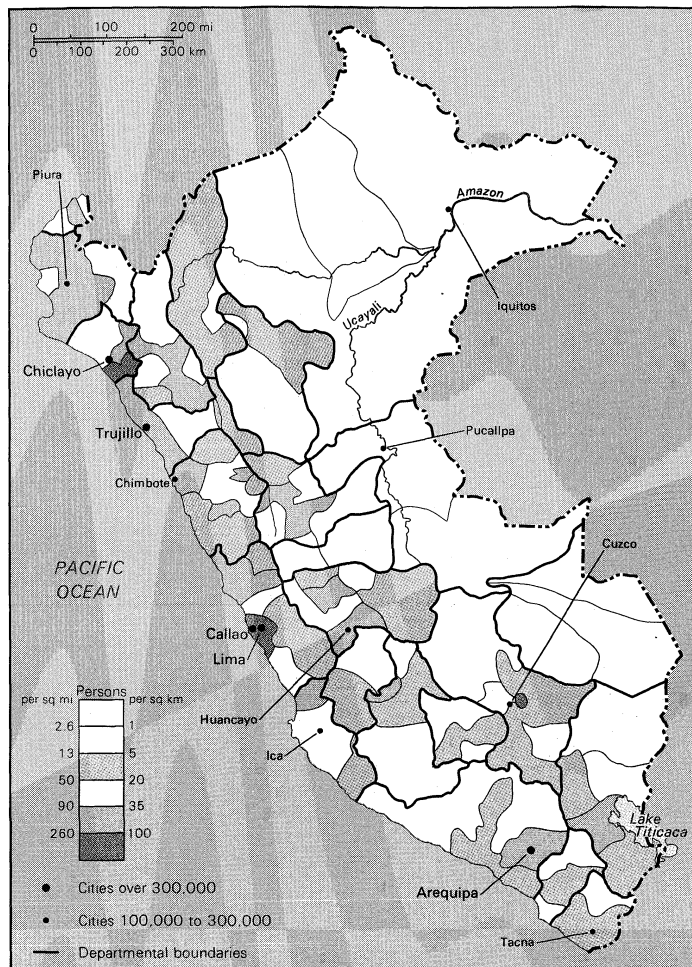

Religion. Ancient Peru had various polytheistic and pantheistic religions. The most important gods were Viracocha (lord, creator, and father of men) and Pacha Mama (Earth mother). The Sun, Moon, and such phenomena as lightning and mountains were also worshiped. Each culture raised temples to honour its local divinity.

The Hispanic conquest of the Incas brought new religious traditions to the Andean area. The Spanish indoctrinated the Indians and spread Roman Catholicism, built hundreds of churches, and held fiestas for patron saints in each village. The people were not strict in their practices, however. Protestant sects have proliferated during the 20th century, and the Indians have mixed many pagan beliefs into the Roman Catholic rituals to produce a syncretic religion rich in traditions. Although most Peruvians are Roman Catholic, the constitution provides for freedom of religion.

Demography. The population of the Inca Empire at the time of the Spanish conquest in 1532 is commonly estimated to have been around 12,000,000, although estimates vary. Not all of these people, of course, lived within the boundaries of modern Peru, but it is clear that Peru was the most densely settled area in pre-Hispanic South America. During the first century of Spanish domination, the Indian population declined by almost 80 percent—due to overwork, malnutrition, and the introduction of such diseases as smallpox and measles. The country's first accurate census (1791) showed the impact of Hispanic dominance of the Inca: the population had declined to slightly more than 1,000,000 (which included Europeans, people of mixed ancestry, and black slaves). After independence the population gradually increased, mainly as a result of high birth rates. By the mid-1960s the population of Peru was about the same as that of the Inca society at its height—in other words, it had taken more than 300 years to replace the population lost in the first century of Spanish domination.

Since World War II, the population of Peru has grown rapidly and has become predominantly urban. There has been a sharp decline in death rates, caused mainly by improvements in sanitation practices and health care, while at the same time birth rates have remained very high. As a result, there has been a surplus of population in many areas, particularly in the Andean region. Overpopulation of the rural areas has been the root cause of the mass migration to the cities that has occurred in Peru since the 1950s. The high rate of population growth has also placed great pressure on Peru's educational and health care systems.

Catholic
dominance

Population density of Peru.

THE ECONOMY

Peru is a developing country whose economy has long been dependent upon the export of raw materials to the more developed nations of the Northern Hemisphere. It is one of the world's leading fishing countries and ranks among the largest producers of bismuth, silver, and copper. In recent decades, the country has struggled to modernize its economy by developing nontraditional export industries as well as the manufacture of consumer items to meet local needs. Serious economic problems persist, however, in several areas. A shortage of investment capital is paralleled by a loss of university-trained technicians to offers of higher salaries abroad. Extensive destruction of transportation and agricultural systems occurs periodically from earthquakes, landslides, and other natural disasters. The limited agricultural areas do not meet the needs of the rapidly expanding population, resulting in continually rising imports of foodstuffs and difficult attempts to alter the nation's farming and eating habits. To remedy these and other economic deficiencies the government nationalized the petroleum and other industries in the late 1960s and early 1970s and made extensive efforts at agrarian reform. Nationalization, however, created additional economic problems, including massive government debt and a large trade deficit. This caused successive Peruvian governments to reassess the role of the state in the economy and to reopen some economic sectors to private entrepreneurs.

Resources. *Minerals and mining.* Peru has a wealth of mineral resources. Copper, iron, lead, zinc, bismuth, phosphates, and manganese exist in great quantities of high-yield ores. Gold and silver are found extensively, as are other rare metals, and petroleum fields are located along the far north coast. Oil exploration in the eastern tropical forests indicates substantial reserves.

In spite of this potential mineral wealth, exploitation

Major
economic
problems

Hydro-
electric
develop-
ment

has lagged for a number of reasons, including diminished foreign investment, world price fluctuations, lack of transportation facilities, a scarcity of processing plants, and the depletion of deposits. Difficulties of geography have also hindered development, because some of the most promising resources are located at elevations above 12,000 feet or in the Amazonian forests.

Power. The hydroelectric potential of Peru is great, especially on the rivers that flow eastward out of the Andes Mountains to the Amazon Basin. Large power plants have been built on the Santa and Mantaro rivers, and other locations have been selected for future development. Most existing plants, both thermal and hydroelectric, have been connected to a coordinated national electric grid. More than three-fourths of the nation's electrical energy is produced from hydroelectric sources. Much of the nation's production and demand are in the Lima metropolitan area, where there is a heavy concentration of industry.

Agriculture. The primary economic activity in Peru has long been farming, although since World War II the importance of this sector of the national economy has declined sharply. More than one-third of the work force, however, is still employed in agriculture. Despite the number of farm labourers, harvests have not kept pace with the country's rapid population growth, and since the 1960s the per capita production of food has been declining. Peru must import large amounts of grain (particularly wheat, rice, and corn), vegetable oils, dairy products, and meat to feed its population. Although ambitious development plans have been designed to improve output, the scarcity of arable land is an extremely limiting factor in Peru.

The most productive agricultural areas are the irrigated valleys of the coastal region, where yields are uniformly high. Principal crops include sugarcane, cotton, rice, corn, grapes, olives, and vegetables. In the Sierra, cropland is limited and soil fertility low. The main crops in the Sierra region are potatoes and grains, especially wheat, corn, and quinoa, an extremely high-protein cereal. There is little beyond subsistence agriculture in the Amazon region of Peru, although the Montaña Indians have traditionally harvested the coca leaves for local use and for trade with the Sierra Indians.

Fishing and forestry. In the 1950s and 1960s Peru's fishing industry expanded rapidly, based on the harvest of enormous schools of anchovy. These fish were converted into fish meal and oil for export as animal feed. By 1963 Peru was the world's leading fishing nation, measured in terms of tonnage caught. The anchovy catch peaked at more than 12,000,000 tons in 1970. Overfishing, combined with a severe occurrence of the El Niño current in 1971-72, sent the fishing industry into decline. Recovery took place during the late 1970s and early 1980s, although the catch did not approach earlier record levels. Increasing emphasis is put on fish for human consumption in the domestic and export markets. Forestry has been mainly concentrated in the Montaña. Many commercial woods are available, but they are often inaccessible and exploitation has been hampered by fears of ecological damage.

Decline of
the fishing
industry

Industry. Although the Peruvian government has tried to disperse industrial production, most Peruvian factories are located within the greater Lima area. Many products are imported as partially assembled kits, such as automobiles and appliances, with completion done in local factories using Peruvian labour and some Peruvian components. Much of the production of consumer goods is done in small workshops, outside government regulation and taxation—a disturbing factor for economic planners.

The government has emphasized plans that call for industry to increase its share of the gross national product, and manufacturing has become the fastest growing segment of the economy. To better utilize the nation's natural resources to achieve self-sustained growth, a strong push has been given to industries such as those producing petroleum, textiles, processed food, steel, cement, fertilizer, and chemicals. Many of these industries either were nationalized or benefited from special tax incentives and trade protectionist policies during the 1970s. In general, though, the government's efforts to promote industrial development have not met expected goals.

Finance. The main institutions dealing with finance in Peru are the large state-owned banks, which control such areas as credit, currency regulation, bank regulation, and foreign exchange. Government financial policies are focused on dealing with inflation and foreign debt, which have become serious problems since the mid-20th century. Major financial institutions include the Central Reserve Bank of Peru, the National Bank, and the Development Finance Corporation.

Trade. Foreign trade has been a mainstay of the Peruvian economy since colonial times. The country has been historically dependent on imported manufactured products, a situation that has prompted the government to subsidize import substitution industries. The need for imported materials remains, however. Since the 1950s, Peru's imports have consisted primarily of foodstuffs, consumer goods, and component parts for Peruvian industries. Petroleum products formed an expensive share of Peru's imports in the early 1970s, but increased domestic production, particularly from the Amazon area, turned Peru into a net exporter of oil by 1980. Other important exports have been such primary commodities as ores and minerals (copper, silver, lead, and zinc, for example) and such agricultural products as cotton, sugar, and coffee. Fish meal, too, has been a leading export since the 1960s.

The United States is Peru's major trading partner, usually accounting for as much as one-third of imports and exports. Western European countries and Japan are the source for most other manufactured goods, and those countries also buy a large percentage of what Peru exports. Other recipients of Peru's exports include the Soviet Union (particularly for minerals and agricultural commodities) and neighbouring South American countries such as Colombia and Brazil. In 1969 Peru became a charter member of the Andean Common Market (Andean Group), but economic problems have hampered implementation of trade policies.

Major
trading
partners

Transportation. Peru's transportation system faces the challenge of the Andes and of the complex Amazon River system. The only truly integrated networks are the roads and the airlines; the country's two railroad systems have not been interconnected, and maritime traffic is primarily dependent on calls from world shipping lines. River traffic in the Amazonian region is unimportant because of the vast distances and low population density of that area. Roadways cross the country from north to south, or they form penetration roads that run east-west over the Andes. The most important road is the Pan American Highway, which parallels the coast from Ecuador to Chile. Another main road connects Lima to Chile through the Andes.

The major Peruvian railroad, the Central Railway, rises from the coast at Callao near Lima to cross the continental divide at about 15,700 feet. It connects with a branch line to Cerro de Pasco, making it of great importance to the mining industry of the central Andes. A longer line, the Southern Railway, serves Cuzco, Arequipa, and other cities; some of its traffic originates in Bolivia. Callao, on the Pacific Ocean, is the largest of Peru's numerous ports. Iquitos, located on the Amazon some 2,300 miles from the river's mouth, is the major river port of eastern Peru.

The rough terrain of Peru compels the use of the airplane, but it also complicates flight. Air transport is especially important in hard-to-reach places of the heavily forested east. Commercial aviation began in 1928, and domestic lines operate in addition to numerous foreign airlines. The Jorge Chávez International Airport in Callao, which services Lima, is the most important of Peru's airports.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Peru has a long history of unstable political life that has been punctuated by numerous military coups and changes of constitution. The 1979 Peruvian constitution decrees a government headed by a popularly elected president who serves as the chief of state and commander of the armed forces. The prime minister, appointed by the president, presides over the Council of Ministers (Cabinet), also appointed by the president. The council approves all presidential law decrees and draft bills sent to the legislature. The bicameral legislature consists of

The
legislature

a Senate and Chamber of Deputies. Members of the legislature are elected to five-year terms, running concurrently with the term of the president. All judges are appointed by the president from lists of nominees submitted by the National Justice Council. Appointments are confirmed by the Senate, and, once confirmed, judges may serve until age 70. The Supreme Court has nationwide jurisdiction and hears appeals from lower-court decisions; it also investigates the conduct of lower-court judges.

The country has been politically divided into 24 departments and one constitutional province, Callao; the departments are further divided into provinces and districts. The 1979 constitution calls for each department to be governed by a regional assembly. Considerable powers were given to local governments by the 1979 constitution. In 1987 legislation was passed that provided for the reorganization of departments into 12 regions. A wide spectrum of political parties, ranging from right-wing conservative to left-wing socialist and communist, participate in the political process.

Education. Peru's educational problems are complicated by the steadily increasing percentage of young people in its population. Thus the state must spend a disproportionate share of its resources on education, which is free and compulsory for all children between six and 15. Compulsory education is difficult to enforce, however, especially outside urban centres. Because of extremely large class sizes, inadequate facilities, and poorly trained teachers, the quality of education received by children in public schools is regarded as low. As a result, most middle- and upper-class parents send their children to private schools. Universities in Peru include such large, high-calibre institutions as the Pontifical Catholic University of Peru, the University of Lima, and the National University of San Marcos, which was founded in 1551 and claims to be the oldest university in South America. There are also a number of provincial universities.

Shortage of
health care

Health and welfare. Numerous public agencies in Peru are involved with national health and social security. Nevertheless there is a shortage of doctors, nurses, and health care facilities, particularly outside the Lima urban area, and the nation faces a difficult path to adequate health service for its population. Infant and young-child mortality long has been a major problem, and it is one of the major concerns of the government. Peru has a serious shortage of housing units, especially in the urban squatter settlements, but also in the countryside. Sanitation is another major problem, with most cities lacking adequate sewerage as well as street lighting and paving.

CULTURAL LIFE

The complex ethnic and cultural mixture of Peru presents an entwining of aboriginal pantheism, Spanish mysticism, and African religious practices manifested in the nation's music, literature, textiles, handicrafts, gold and silver work, and bounteous cuisine.

Machu
Picchu

Heritage. Peru's cultural past is best known in such Inca remains as Machu Picchu, a "lost city" discovered in 1911 on an 8,000-foot-high mountain northwest of Cuzco. Surrounded by lush, green, forested hills and snow-capped peaks, Machu Picchu comprises hundreds of well-built agricultural terraces, a multitude of small stone houses, and several ceremonial temples constructed of carved rock. Research suggests that Machu Picchu was a royal estate of the Inca emperor Pachacuti. Hundreds of archaeological ruins dot the Peruvian countryside, but they are especially impressive around Cuzco, in the region known as the Sacred Valley. Archaeologists have uncovered thousands of decorated jugs and bowls and embroidered textiles; the weavings of the Paracas culture and the ceramics of the Mochica are especially distinguished. The dryness of the coast has preserved many pre-Incan remains.

The arts. *Folk culture.* Peruvian folk culture is deeply tinged with inheritances from the ancestral races. In both town and countryside notable examples of pre-Hispanic and mestizo lore abound in myths, song, superstitions, and dances. Handicrafts, popular with tourists and collectors, provide a close link with such pre-Hispanic crafts as weaving, ceramics, and metalworking.

Westernized arts. The arts have long occupied positions of esteem among Peru's educated minority. Since the late 19th century, most writers have felt a ceaseless duty to analyze their society. Ricardo Palma was among the first to utilize Peruvian themes. *Aves sin nido* (1889; *Birds Without a Nest*), by Clorinda Matto de Turner, was the first of many books whose authors exposed the conditions of Indian life. César Vallejo is often regarded as Peru's finest poet, and José María Arguedas and Mario Vargas Llosa have received high critical acclaim in the post-World War II era. José María Valle-Riestra's opera *Ollanta* and Vicente Stea's *Sinfonía autóctona* (*Aboriginal Symphony*) were the major musical works of 19th-century Peru. Later, Luis Duncker Lavalle incorporated Peruvian motifs into Western forms.

Literature

Painting reached its zenith with the famous Cuzco school during the 17th and 18th centuries. Most of the thousands of paintings and sculptures are anonymous, and the works show resemblances both to Byzantine and to Asian forms. Modern Peruvian art has followed an abstract course, notably in the work of the painter Fernando de Szyszlo and the sculptor Joaquin Roca Rey.

The ancient Peruvians were great builders of houses, temples, palaces, and fortresses, adapting their architecture to the landscape. The oldest colonial work is the cathedral of Lima, and the most important architectural jewel is the convent and church of San Francisco in Lima. Contemporary architecture has been characterized by the so-called neo-Peruvian, or Peruvian Baroque, and by the introduction of modern concrete and steel structures.

The theatre is a popular institution in Peru with a strong tradition dating to colonial times. National professional companies perform in major productions at the Municipal Theatre, which was built in Lima at the site of a colonial theatre dating to 1604. The concerts of the National Symphony Orchestra are also presented there, as are the performances of the main national and touring ballet and folk dance companies. Filmmaking in Peru is not well-developed; most films produced there are short, the full-length features being mostly imports.

Cultural institutions. Much of the country's cultural development is overseen by the National Institute of Culture, which seeks to make cultural activities available to all. The Peruvian museums are especially rich in their archaeological collections representing Peru's pre-Hispanic past. The most noteworthy of these are in Lima and include such institutions as the National Museum of Art, the Museum of Anthropology and Archaeology, and the Gold Museum. The main library collection is housed in the National Library in Lima and in the major university libraries.

Museums
and
libraries

Recreation. Recreational activities vary as widely in Peru as do the social classes, but for everyone there are the fiestas, which are held by numerous communities across the country. These colourful events often celebrate religious themes, but some are held for secular holidays and other events. The most popular spectator sports, as in most other Latin-American nations, are soccer and bullfighting, the latter drawing huge crowds to the renowned Plaza de Acho bullring in Lima. Basketball, horse racing, and cockfighting are among other well-attended events. Sporting and recreational facilities are most prevalent in the large metropolitan areas of the Costa.

Press and broadcasting. Although freedom of the press is guaranteed by the Peruvian constitution, the media has been periodically subjected to government control. The major dailies generally have a tradition of taking strong political stands in support of political parties of their choice. Most of the leading dailies, such as *El Comercio*, *Expreso*, and *Ojo*, are in Lima; others are published in Arequipa and Chiclayo. Lima's *El Peruano*, one of the oldest dailies in the Americas, was founded in 1825. Electronic media have also been subjected to control, which became especially severe in the early 1970s when the administration assumed 51 percent of the ownership of all television stations and 25 percent of all radio stations. Lima has several television channels, and there are stations in all of the major cities of the Costa.

For statistical data on the land and people of Peru, see

the *Britannica World Data* section in the *BRITANNICA WORLD DATA ANNUAL*. (J.P.-V./J.S.K.)

History

Humans have probably lived in Peru for more than 13,000 years. Beginning about 1250 BC, several advanced cultures, such as the Chavín, Chimú, Nazca, and Tiahuanaco, developed in different parts of Peru; however, the area was not unified politically until AD 1438, when the Inca set out from their base in Cuzco on a career of conquest that, during the next 50 years, brought under their control the area of present-day Peru, Bolivia, northern Argentina, Chile, and Ecuador. Within this area, the Inca established a totalitarian state that enabled the tribal ruler and a small minority of nobles to dominate an inert population.

(R.N.Bu./T.M.D.)

THE INCA

Like the Aztec, the Inca came late upon the historical scene; even their legends do not predate AD 1200, with the first emperor. For, like Old World peoples, and unlike other aboriginal Americans, the Inca recounted their history by kingly reigns. Most of the accounts agree on 13 emperors (see *PRE-COLOMBIAN CIVILIZATIONS*). The first seven emperors were legendary, local, and of slight importance; their traditions are full of impossible or improbable events, especially those of the quasi-mythological founder, Manco Capac. In this period the Inca were a small tribe, one of many, whose domain did not extend many miles around their capital, Cuzco. They were almost constantly at war with neighbouring tribes.

Pachacuti

The incredibly rapid expansion of the Inca Empire began with Viracocha's son Pachacuti, one of the great conquerors, and one of the great men, in the history of the Americas. Also with his accession in 1438 reliable history began, almost all the chroniclers being in practical agreement. Pachacuti was called by the British geographer-historian Sir Clements Markham "the greatest man that the aboriginal race of America has produced." He and his son Topa Inca may be aptly compared to Philip and Alexander of Macedon. Pachacuti was evidently a great civic planner as well; tradition ascribes to him the city plan of Cuzco as well as the erection of many of the massive masonry buildings that still awe visitors to this ancient capital.

The sudden great expansion of the Inca Empire was one of the most extraordinary events of history. It covered a little less than a century, from the accession of Pachacuti in 1438 to the conquest by Francisco Pizarro in 1532, and most of it was apparently accomplished by Pachacuti and Topa Inca in the 30 years between 1463 and 1493. At its maximum the empire extended from the present Colombia-Ecuador border to central Chile, a coastal distance of more than 2,500 miles, encompassing approximately 380,000 square miles, about equal in area to France, Belgium, The Netherlands, Luxembourg, Switzerland, and Italy combined.

First the Aymara-speaking rivals in the region of Lake Titicaca, the Colla and Lupaca, were defeated, and then the Chanca to the west; the latter attacked and nearly captured Cuzco. After that there was little effective resistance. First the peoples to the north were subjugated as far as Quito, Ecuador, including the powerful and cultured "kingdom" of Chimú on the northern coast of Peru. Topa Inca then took over his father's role and turned southward, conquering all of northern Chile as far as the Maule River, the southernmost limit of the empire. His son, Huayna Capac, continued conquests in Ecuador to the Ancasmayo River, the present border between Ecuador and Colombia.

(J.A.Mn./T.M.D.)

DISCOVERY AND EXPLORATION BY EUROPEANS

Spanish interest in the west coast of South America grew after Vasco Núñez de Balboa discovered the Pacific in 1513, but it was not until 1524 that Francisco Pizarro, aided by another soldier, Diego de Almagro, and a priest, Hernando de Luque, undertook explorations that led to the conquest of Peru. By 1527 they were convinced of the

wealth of the Inca Empire. Failing to win further cooperation from Panama's governor, Pizarro returned to Spain, where he received authorization from Charles I to conquer and govern the area extending 600 miles south from Panama. When Pizarro, accompanied by his brothers, returned to Panama, Almagro was outraged by the vast powers Pizarro had acquired for himself. Nevertheless, he continued to collaborate. Pizarro embarked for Peru in late 1530 or early 1531 with 180 men. Establishing a base at San Miguel on the north coast of Peru, Pizarro crossed the mountains to make contact with the Inca Atahualpa, who had recently been victorious in civil war against his half-brother Huascar, and who was then residing near Cajamarca with an army of about 30,000. Atahualpa, scornful of the tiny band of invaders, accepted Pizarro's invitation to meet in Cajamarca. There, after Atahualpa had refused to accept Spanish suzerainty, he was taken prisoner. After his agents had collected a large ransom for his promised release, Atahualpa was executed for his presumed responsibility for the murder of Huascar. As a means of controlling the Indians, Pizarro then recognized Manco Capac, Huascar's brother, as emperor. In November 1533 the Spaniards occupied Cuzco, the Inca capital.

Pizarro's
base at
San Miguel

COLONIAL PERIOD

The consolidation of Spanish control proceeded. The city of Quito was subdued and Diego de Almagro left to conquer his domain of Chile. Pizarro organized a Spanish-type municipal government for Cuzco and in 1535 established a new city, Lima, on the coast, to facilitate communications with Panama. Lands were allotted to the conquerors, who were provided with a labour force by grants of *encomiendas*, which enabled them to collect tribute from the Indians.

Serious trouble then erupted. An unsuccessful Indian rebellion led by Manco Capac in 1536 was followed by open conflict among the conquerors over the division of the spoils. Almagro, disillusioned by Chile's poverty, sought to seize Cuzco from the Pizarros. Almagro was defeated and executed in 1538, but his adherents continued to conspire with his son, and they succeeded in assassinating Francisco Pizarro in 1541. However, an agent of the Spanish crown, sent to establish order, refused to recognize the younger Almagro, who was captured and executed in 1542.

Difficulties persisted nonetheless. The King of Spain, impelled by humanitarianism and by fear that the *encomienda* system might promote feudalism, promulgated in 1542 the New Laws. These laws threatened the existence of the *encomiendas*, which were so important to the conquerors. When Viceroy Blasco Núñez Vela arrived in Peru in 1544 to enforce the New Laws, the conquerors, led by Gonzalo Pizarro, revolted and executed the Viceroy. Pizarro maintained control for two years until Pedro de la Gasca, a Spanish agent, undermined his power.

The New
Laws

It was nearly a decade before unruly conquerors were controlled under Viceroy Andrés Hurtado de Mendoza (1555-61), and not until the viceregal administration of Francisco de Toledo (1569-81) was systematic control of the huge Indian population attempted. Toledo adapted Indian institutions to the purposes of Spanish authority. Indian chieftains administered local Indian affairs according to custom but were responsible for collecting tribute and providing forced labour. Spanish agents (*corregidores*) were appointed to protect the interests of both crown and Indian in the Indian communities. Fearing that Manco Capac's son, Tupac Amaru, might prove dangerous to Spanish authority, Toledo ordered him executed in 1571.

By the end of Toledo's administration, the viceroyalty of Peru had assumed the form that it retained into the 18th century. Its territory included all of South America except Venezuela and Portuguese Brazil. Although ranching, agriculture, and commerce were carried on, the mining of precious metals, particularly silver, was the basic industry, making the colony the most important in the Spanish empire. The discovery of the fabulous Potosí mines in 1545 had been followed in 1563 by the opening of the Huancavelica mines, which produced the mercury essential to efficient processing of silver. Because the viceroyalty's mineral resources, except for the gold of New Granada

(Colombia), were in Peru proper and Upper Peru (Bolivia), these areas became the most highly developed and richest.

The centre of wealth and power for the entire region was the viceregal capital of Lima. There, during the 16th and 17th centuries, a series of viceroys ruled over most of Spanish South America. The elaborate viceregal court was the apex of a highly stratified society based upon forced Indian labour. It attracted not only the politically oriented but also the wealthy, the artistic, and the intellectual.

Lima was also important as seat of the *audiencia*, which administered royal justice, and as a religious, cultural, and commercial centre. The archbishop of Lima was head of the church in Peru. Many religious orders established monasteries and convents there, and the tribunal of the Inquisition worked to extirpate religious heresy. In Lima also was the capstone of the educational system—the University of San Marcos. Adding to the wealth and importance of Lima was the privileged position that its merchants enjoyed under the monopolistic Spanish trade system. Lima, with its port of Callao, was the entrepôt for trade between Europe and the commercial centres of South America, ranging from Quito to Chile on the Pacific coast and to Buenos Aires on the Atlantic. Under the Spanish system the bulk of legitimate trade to and from these areas had to pass through merchants in Lima.

During the later 17th century Peru experienced difficulties. Some of these, such as increasing contraband trade with non-Spanish merchants, attacks by pirates, and the growth of venality among government officials, reflected the internal decay of Spain and the decline of its international power. Contributing to Peruvian difficulties was the decline of its production of precious metals.

A series of governmental reforms complicated Peru's problems in the 18th century. The Bourbon dynasty, which in 1700 had replaced the Habsburgs as rulers of Spain, undertook a program of reform during the 18th century, seeking to promote the economic development of their colonies, improve colonial defenses, and provide more efficient government. The first to seriously affect Peru was the establishment of the new Viceroyalty of New Granada, ending Peru's control over northern South America and resulting in its loss to New Granada of the thriving port of Guayaquil (now in Ecuador). For the next few decades Bourbon reforms, together with overall expansion of the economy, improved conditions in Peru. In 1777–78, however, the Spanish government established another viceroyalty, that of Río de la Plata, this time depriving the Peruvian viceroy of authority over Upper Peru and the areas of present-day Argentina, Paraguay, and Uruguay. Chile was reconstituted as a virtually autonomous captaincy general. Following the disastrous loss of the silver mines of Upper Peru, the viceroyalty of Peru was still more weakened by reforms in the trade system, which permitted merchants in ports on the Atlantic and Pacific to trade directly with Spain.

Internal strife created further complications. The Indians, who had from the time of the conquest suffered oppressive taxation and enforced labour, revolted in 1780 under Tupac Amaru II, a descendant of the last Inca emperor and a man of wealth and education. The revolt spread throughout Peru and into Upper Peru and Ecuador. Although Tupac Amaru II was captured and executed in 1781, the Indians continued to fight the Spaniards until 1783, causing considerable disruption.

Nevertheless, in the late 18th and 19th centuries, Peru experienced a period of intellectual development that was the result of the influence of the utilitarian ideas of the European Enlightenment, brought to Peru in books and by European participants in scientific expeditions in 1778 and 1793. Its chief manifestation was the establishment of a literary and scientific club in Lima, the Society of the Lovers of the Country.

ACHIEVEMENT OF INDEPENDENCE

The Napoleonic invasion of Spain in 1808 sparked the Creoles (those of European descent born in America) in other Spanish colonies to struggle for independence between 1810 and 1821. But Peru remained loyal because of the conservative attitude of the Peruvian aristocracy,

the presence of many Spaniards in Peru, the concentration of Spanish military power in Lima, and the effective suppression of Indian uprisings. Peru's independence was, consequently, achieved primarily by outsiders.

Among them was General José de San Martín of Argentina, whose aims were to secure Argentine control of Upper Peru's silver from the Spanish forces that had occupied Upper Peru and to assure Argentina's independence by destroying the remaining Spanish power in South America. Because Argentine forces had previously been defeated in Upper Peru, San Martín determined to surround the Spaniards by liberating Chile and using it as a base for a seaborne attack on Peru. Chile was freed in 1818 and a fleet was readied, which enabled San Martín to occupy the Peruvian port of Pisco in September 1820. When the viceroy withdrew his forces into the interior, San Martín entered Lima. Peruvian independence was declared on July 28, 1821.

Lacking power to attack the strong Spanish forces in the interior, San Martín sought aid from Simón Bolívar, who had liberated northern South America, but Bolívar declined, refusing to share leadership. San Martín then withdrew, and Bolívar assumed power in Peru to carry on the struggle for liberation. At the battles of Junín (Aug. 6, 1824) and Ayacucho (Dec. 9, 1824) Spanish power was broken and Peru's independence assured.

(R.N.Bu./T.M.D.)

PERU FROM 1824 TO 1884

The end of Spanish rule did not, however, provide a solution to the many political, social, and economic problems facing the country. The transition from a colonial dependency to a modern state proved difficult.

Struggle for power. At the outset of Peru's national existence, military leaders (*caudillos*) who had gained prominence in the struggle for independence sought to seize power. The departure of Simón Bolívar in 1826 removed a stabilizing influence. The aims of the *caudillos* were furthered by the absence of a tradition of self-government, by the prevalence of a feudal society of Creoles and Indians, and by the reluctance of civilians to assume political responsibility. Despite military influences, a liberal constitution was adopted in 1828. This did not prevent General Agustín Gamarra from taking government power by illegal means. He was succeeded in 1835 by another self-seeking *caudillo*, General Felipe Salaverry.

The ambitions of Gamarra and Salaverry were thwarted by Andrés de Santa Cruz, a military commander of Spanish-Indian descent who proposed a confederation of Peru and Bolivia. For three years Santa Cruz, though born in La Paz, was backed by influential groups in Peru and maintained the political union. But his hopes were shattered at the Battle of Yungay in 1839 by a joint force of nationalist-minded Peruvians and of Chileans fearing a threat to the balance of power in the Pacific.

Establishment of order. During the initial period of statehood in Peru, liberal and conservative parties with ill-defined programs emerged. Their rivalry enhanced the political instability of the country.

General Ramón Castilla assumed the presidency in 1845. Castilla dominated the political scene from 1845 to 1851 and from 1855 to 1862, in spite of his mestizo background. His greatest accomplishment for the promotion of national wealth was the exploitation of the guano deposits along the coast and offshore islands. Taxes on this industry, which was controlled by foreign corporations, furnished the principal source of government revenue for several decades. Castilla appealed to liberals by abolishing the payment of tribute by Indians and by emancipating the black slaves. Landowners on the coastal plantations, however, were permitted to import thousands of Chinese coolies in order to have a sufficient labour supply. As an additional concession to the liberals, Castilla established a system of state education at the primary and secondary levels. Through his influence, an assembly in 1860 adopted a constitution that lasted into the 1900s.

In the second half of the 19th century, Peru's history was characterized by many setbacks. In 1864 Spain dispatched a naval force to the Pacific, ostensibly to protect the

José de
San Martín

The
caudillos

Loss of
Upper
Peru

rights of Basque immigrants but in reality to reestablish domination over its former colony. In 1869, after meeting with the determined opposition of Peru and Chile, Spain withdrew and recognized Peru's independence for the first time, but the conflict was a heavy drain on Peru's treasury.

Dissatisfaction with military rule resulted in 1871 in the formation of the Civilian Party, representing an oligarchy of landowners and merchants. This party, headed by Manuel Pardo (president, 1872–76), approved a costly program of internal development, which included the construction of railroads across the Andes. Corruption on the part of government officials and contractors characterized the work, which decreased the isolation of the Peruvian interior but increased enormously the national debt.

The War of the Pacific (1879–83). Another untoward event was the War of the Pacific with Chile, caused mainly by rivalry over the exploitation of rich nitrate beds in the Atacama Desert (then in Peru, now in Chile). Chile's superior resources and military discipline brought overwhelming defeat to Peru and its ally Bolivia.

At the Battle of Iquique (then in Peru, now in Chile), on May 21, 1879, the Peruvians suffered the loss of one of their best warships, the *Independencia*; the *Huáscar* was then sunk on October 8, and this eventual surrender of control of the sea permitted a Chilean army to land on the Peruvian coast. On Jan. 17, 1881, Chilean forces captured the capital, Lima. Looting and pillaging followed and the National Library was destroyed. According to the terms of the Treaty of Ancón (Oct. 20, 1883), Peru turned over to Chile full possession of the province of Tarapacá and the administration for 10 years of the provinces of Tacna and Arica, after which a plebiscite was to determine their future sovereignty.

PERU FROM 1884 TO 1930

Economic
recovery
program

Expenditures for the war, and the consequent loss of revenue from the nitrate fields, created the possibility of imminent bankruptcy. To avert this disaster, the Civilian regime accepted in 1889 a plan proposed by the bondholders for handling the debt. The Peruvian Corporation, representing the creditors, with headquarters in London, was to control the railroads for 66 years, to mine up to 3,000,000 tons of guano, and to receive 33 annual payments of £80,000 each. The plan worked satisfactorily but was hated by the Peruvian people.

Social reforms and economic development. The decline in national prestige created an atmosphere conducive to political change. The Democratic Party was formed, and in 1895, under the leadership of Nicolás de Piérola, it won the presidential election. Having a broad, popular base, it championed direct suffrage and the restoration of municipal elections. Public education was fostered, but schools for the children of the poor were lacking.

An orderly political scene, marked by rivalry between the Democratic and Civilian groups, accelerated economic development. There was an increase in the production of minerals, notably copper, and of such agricultural commodities as cotton, sugar, and wool. In the mining of copper, U.S. capital acquired important interests.

Augusto
Leguía y
Salcedo

Augusto Leguía y Salcedo, chief spokesman for the Civilians, assumed the presidency in 1908. His first term in office (1908–12) was marked by the expansion of sugar and cotton production and the settlement of the boundary dispute with Brazil. During Leguía's second term (1919–30), he embarked upon expensive public works projects, financed by loans from U.S. banks. Rights to the oil fields of La Brea-Pariñas were given to the U.S.-owned International Petroleum Company, which built a refinery to supply the nation with gasoline and oil.

Leguía supported the adoption of a new constitution in 1920. Among its progressive provisions was Article 58, which protected the communal lands of the Indians from sale and seizure. Failure to implement this provision, however, gave rise to a significant development of Indianism. While most intellectuals urged gradual reforms, more radical measures were advocated by the Peruvian Communist Party and others.

Formation of the Aprista movement. The American Popular Revolutionary Alliance (APRA), known as the

"Aprista movement," was formed in 1924 in Mexico City by Víctor Raúl Haya de la Torre, an intellectual then in exile. Internationally, it expressed the ideals of the unity of American Indians and the elimination of U.S. imperialism. Internally, it proclaimed the need to end the exploitation of the Peruvian masses through the institution of a planned economy and the nationalization of foreign-owned enterprises. Its anticapitalist and anti-imperialist stand appealed to intellectuals, to the Indians, and to the lower middle class.

By 1930 Leguía had experienced a definite loss in popularity. Final settlement of the long-standing Tacna-Arica dispute with Chile, by which Peru ceded the province of Arica, angered the extreme nationalists, while world depression cost Leguía the support of business groups.

PERU FROM 1930 TO 1968

In 1930 a military junta headed by Colonel Luis Sánchez Cerro overthrew Leguía, and Sánchez Cerro defeated Haya de la Torre, the APRA candidate, in the presidential elections of 1931. APRA claimed that the elections were fraudulent and instigated a campaign to discredit the regime. The threat from the left led to the emergence of a Fascist group, whose chief exponent was the historian José de la Riva Agüero. In July 1932 Apristas organized an uprising in Trujillo, on the northern coast, and Sánchez Cerro was assassinated by an Aprista in 1933. These incidents created an enduring enmity between the military establishment and APRA.

Troubled democracy. Sánchez Cerro's successor (1933–39) was General Oscar Benavides, who restored confidence in the economy. He also settled a dangerous boundary controversy with Colombia over the port of Leticia on the upper Amazon and a finger of land giving access to the river, both of which had been ceded to Colombia in a treaty of 1922. To avoid war Benavides returned the territory to Colombia. Benavides reduced the strength of APRA by declaring the party illegal, by a relentless persecution of its leaders, and by the adoption of social assistance projects. In the presidential election of 1939 the Apristas supported Manuel Prado, a banker and member of an aristocratic family of Lima.

During World War II Peru cooperated with the United States, authorized Allied use of airfields and ports, and arranged to sell the Allies petroleum, cotton, and minerals. In 1942 Peru severed diplomatic relations with the Axis powers, and in 1945 it declared war on them. During the war Peru succeeded, with U.S. support, in getting a favourable settlement of a boundary dispute with Ecuador, which it had invaded.

World War II not only brought economic prosperity but also hope for real democracy. Prado, swayed by public opinion, approved the presidential candidacy in 1945 of José Luis Bustamante y Rivero, a lawyer from Arequipa with liberal leanings, who represented a coalition of middle- and upper-class elements. APRA, again a legal party, obtained a majority of seats in the lower house and half the seats in the Senate. Bustamante generally followed an independent course, and the Apristas withdrew their support. After Apristas staged an abortive insurrection in Callao, near Lima, the President outlawed the party.

The dictatorship of Manuel Odría. In October 1948 General Manuel Odría seized power, protesting the President's lack of firmness in dealing with the radicals, and extreme measures were taken to suppress the Apristas. Haya de la Torre found refuge in the Colombian embassy, where he stayed for five years before leaving Peru.

Odría led an authoritarian regime in which political stability allowed the revival of prosperity. The Korean conflict of the early 1950s benefited foreign trade because of heavy U.S. demand for Peruvian minerals, and a friendly policy toward foreign capital prompted large-scale investments.

Return to elected government. In the election of 1956, Manuel Prado, who was supported by Odría, won a second term, defeating Fernando Belaúnde Terry. A surprising feature of the election was the decline of APRA, some of whose members joined Belaúnde's National Front Party.

Prado countered the financial crisis inherited from Odría by appointing as minister of the treasury Pedro Beltrán,

Alignment
with the
United
States

whose policies contributed to a 4½ percent annual increase in the gross national product. The fishing industry based on the Peru Current expanded. Beltrán's measures did not, however, lessen the pressure from the landless Indians and the underpaid urban proletariat.

(J.P.M./T.M.D.)

With political tension at a high level in 1962, none of the presidential candidates received the one-third vote necessary for election; the decision went to the congress, but the military forces seized the government. A new election called in 1963 by the junta permitted Belaúnde's party, now called Popular Action, to be victorious.

Reforms
under
Belaúnde

Belaúnde promised solutions to the country's economic and social problems. An agrarian act of 1964 provided for expropriation of unused or misused agricultural properties; by 1966 more than 500,000 acres had been distributed. Community development projects and irrigation schemes were instituted, and a network of roads was planned. Indians were encouraged to colonize land in the foothills east of the Andes. Education was promoted with the establishment of new universities and with attacks on illiteracy.

MILITARY RULE (1968–80)

On Oct. 3, 1968, the military forced the resignation of Belaúnde. The junta, headed by Juan Velasco Alvarado, imprisoned opposing politicians and suspended constitutional liberties. On October 9 the government expropriated the holdings of the International Petroleum Company, straining relations with the United States.

Economic nationalism. In 1969 the junta embarked on a program of economic nationalism that would affect U.S. capital investments totaling \$600,000,000. In 13 months three basic reform measures were enacted: the Agrarian Law (June 24, 1969), the Mining Law (April 14, 1970), and the Industrial Law (July 30, 1970). Accordingly, on Aug. 22, 1969, the government seized the Paramonga chemical and paper plant, which belonged to one of the largest U.S. interests in Peru. It sought also to control essential industries and public services through outright ownership and by "Peruvianization"—insistence that a majority of the stock of a foreign company be held by nationals. The occurrence on May 31, 1970, of a major earthquake in northern Peru partly jeopardized the financial stability of the regime.

Agrarian
and fishing
reforms

The junta appealed to the peasants by expropriating landed estates, which were operated by government-directed collectives or by individuals or Indian communes. The opening up of arid lands being part of the new agricultural program, the junta signed a contract in July 1971 with a Yugoslav company for the construction of a canal in the Piura Valley to irrigate 330,000 additional acres, and two more projects were subsequently initiated. Fishing was to be encouraged, but the disappearance of the anchovies in 1972 because of El Niño brought about a suspension of fish exports and dealt a serious blow to the economy. In 1973 the government moved to nationalize the fish meal industry, valued at \$500,000,000. With the organization of Petroperú, a state-owned company, the petroleum industry expanded.

An education reform bill, promulgated in March 1972, was to put in force "a system of learning from the cradle to the grave." Major features were recognition of the equality of women, the establishment of rural schools, the granting of autonomy to the universities, and the use of the Indian languages Quechua or Aymara in the schools in the Andes and east of the Sierra.

To prevent criticism of its tight dictatorship, the junta censored the press, closed some radio stations and newspapers, and acquired control of privately owned television stations. In foreign relations the junta initiated a two-China policy, hoping to arrange the sale of minerals and fish meal to Peking. As part of an innovative trans-Pacific policy, Japanese investments and contacts were invited to Peru. Friendship with the Soviet Union led to the exchange of ambassadors with Communist-bloc nations.

New junta. Economic factors fostered resentment among many groups toward the Velasco regime. The decline in fish meal exports and in copper prices ended the economic boom, while loans obtained abroad for agrarian

reform and huge copper and petroleum projects increased the foreign debt. On Aug. 29, 1975, a new junta was formed, headed by General Francisco Morales Bermúdez, former minister of finance and economy, and Peruvian policies were constantly altered as repeated changes in the Cabinet took place. Morales shifted toward more moderate right-wing policies. The National Agrarian Confederation was dissolved in 1978; the state fishing enterprise was denationalized; mining projects were opened to private investors; and more foreign investment was encouraged.

RETURN TO CIVILIAN RULE

The Morales government committed itself to reestablishing constitutional rule, and a popularly elected Constituent Assembly was summoned in June 1978 to draft a new constitution. The Apristas formed the largest bloc of the assembly, and Haya de la Torre was elected president. The new constitution was signed on July 12, 1979.

Elections were held in May 1980, and Fernando Belaúnde Terry was returned to the presidency. His party, Popular Action, headed a majority coalition in the legislature. Belaúnde immediately returned to their previous owners newspapers that had been confiscated by the military junta. The legislature issued a package of decrees designed to reorganize the economy with a view toward reducing government involvement and encouraging private enterprise, but these were insufficient to ameliorate the growing economic and political crisis. The economy was hurt by an increase in imports due to Belaúnde's free-market policies, lower world prices for Peru's major export commodities, high international interest rates on the nation's burgeoning foreign debt, and a devastating El Niño in 1982–83. Aggravating the economic problems was the rise of the guerrilla movement, led by the neo-Maoist Sendero Luminoso (Shining Path) and the Tupac Amaru Revolutionary Movement, which forced the government to commit ever-increasing resources to combating the guerrillas and to repairing the damages inflicted in the conflict. When the inflation rate rose a staggering 3,240 percent between July 1980 and June 1985, the economy almost collapsed. Moreover, the sol lost so much of its value that a new currency, the inti, was created in 1986.

In the 1985 elections APRA, capitalizing on the nation's plight, had its presidential candidate elected for the first time in its history. He was the young and charismatic Alan García Pérez. The new leader shocked the international community when he announced that Peru would pay no more than 10 percent of its export earnings toward a nearly \$14,000,000,000 foreign debt. Adopting a populist stance domestically, García attempted to reactivate the economy, end human rights abuses in the war against the guerrillas, gain control over the drug traffickers, and rally the population. The International Monetary Fund added a blow to the country's condition when it declared Peru to be ineligible for future loans and credits until García adopted more orthodox economic and debt repayment measures. Facing a deteriorating economic situation, the president moved to nationalize the banks in 1987, an act that eroded his personal popularity. The end of García's term was marked by runaway inflation, a series of crippling general strikes, and even rejection by his own party, which abolished his post as president.

With inflation, guerrilla war, and the drug trade major concerns, the 1990 presidential elections resulted in a runoff between Mario Vargas Llosa of the Democratic Front Movement, or Fredemo, and Alberto Fujimori of the Change 90 Movement. Vargas Llosa, a novelist, advocated a drastic anti-inflation program that alarmed many of Peru's poor. His support among the European-descended coastal elite was not enough to defeat Fujimori, an agricultural engineer and the son of Japanese immigrants, who drew his support from Peru's poor neighborhoods and the rural interior.

Physical and human geography: An overview of Peru is provided by RICHARD F. NYROP (ed.), *Peru, A Country Study*, 3rd ed. (1981). An analysis of the geography is *Gran geografía del Perú: naturaleza y hombre*, 8 vol. (1986). Other useful studies include DAVID A. ROBINSON, *Peru in Four Dimensions* (1964, reprinted 1971); CARLOS PEÑAHERRERA DEL AGUILA, *Geografía general del Perú: síntesis*, vol. 1, *Aspectos físicos* (1969); and CLAUDE COLLIN DELAUAUD, *Les Régions côtières du Pérou septentrional: occupation du sol, aménagement régional* (1968), available also in Spanish, *Las regiones costeras del Perú septentrional* (1984). Peru's natural regions and vegetation are discussed in JAVIER PULGAR VIDAL, *Geografía del Perú: las ocho regiones naturales del Perú*, 8th ed. (1981).

Notable works on the topic of Indians and peasants include HILDEBRANDO CASTRO POZO, *Nuestra comunidad indígena*, 2nd ed. (1979); and MOISÉS SÁENZ, *Sobre el indio peruano y su incorporación al medio nacional* (1933), both early classics; THOMAS M. DAVIES, JR., *Indian Integration in Peru: A Half Century of Experience, 1900-1948* (1974); PAUL L. DOUGHTY, *Huaylas: An Andean District in Search of Progress* (1968), an anthropological study; WILFREDO KAPSOLI E., *Los movimientos campesinos en el Perú, 1879-1965*, 2nd ed. (1982), the best study of peasant uprisings; and PIERRE L. VAN DEN BERGHE and GEORGE P. PRIMOV, *Inequality in the Peruvian Andes: Class and Ethnicity in Cuzco* (1977), a study of Indian domination by the "urban mestizo elite." Good ethnographies include STEPHEN B. BRUSH, *Mountain, Field, and Family: The Economy and Human Ecology of an Andean Valley* (1977); and SUSAN C. BOURQUE and KAY BARBARA WARREN, *Women of the Andes: Patriarchy and Social Change in Two Peruvian Towns* (1981).

General economic studies include ROSEMARY THORP and GEOFFREY BERTRAM, *Peru, 1890-1977: Growth and Policy in an Open Economy* (1978); and E.V.K. FITZGERALD, *The Political Economy of Peru, 1956-78: Economic Development and the Restructuring of Capital* (1979). The economic geography of Peru is discussed in EMILIO ROMERO, *Geografía económica del Perú*, 5th ed. (1966). Labour studies include DAVID CHAPLIN, *The Peruvian Industrial Labor Force* (1967); and DENIS SULTON, *Historia del movimiento obrero en el Perú, de 1890 a 1977* (1977). Studies on agriculture and fishing include BALTAZAR CARAVEDO MOLINARI, *Estado, pesca y burguesía, 1939-1973: teoría y realidad* (1979); and ARTHUR J. COUTU and RICHARD A. KING, *The Agricultural Development of Peru* (1969).

Samplings and discussions of Peruvian literature can be found in LUIS ALBERTO SÁNCHEZ, *La literatura peruana: derrotero para una historia cultural del Perú*, 5th ed., 5 vol. (1981); and LYNN A. DARROCH (ed.), *Between Fire and Love: Contemporary Peruvian Writing* (1980). On the political role of the Roman Catholic Church and popular religiosity, see JEFFREY L. KLAIBER, *Religion and Revolution in Peru, 1824-1976* (1977). (J.S.K./T.M.D.)

History: JORGE BASADRE, *Historia de la república del Perú, 1822-1933*, 6th rev. ed., 17 vol. (1968-70), is the basic point of departure for any study of Peru. HENRY F. DOBYNS and PAUL L. DOUGHTY, *Peru: A Cultural History* (1976), is a sensitive treatment of Peru's historical tradition, with particular emphasis on race relations and ecological adaptation. FREDRICK B. PIKE, *The Modern History of Peru* (1967, reprinted 1969), is competent and comprehensive, while his *United States and the Andean Republics: Peru, Bolivia, and Ecuador* (1977), is a brilliant synthesis of the incompatibility of Hispanic and Anglo cultures. DAVID SCOTT PALMER, *Peru: The Authoritarian Tradition* (1980), treats Peruvian history within the context of Latin-American development.

The best accounts of Peru's pre-conquest peoples are EDWARD P. LANNING, *Peru Before the Incas* (1967); LUIS G. LUMBRERAS, *The Peoples and Cultures of Ancient Peru* (1974; originally published in Spanish, 1969); JOHN V. MURRA, *Formaciones económicas y políticas del mundo andino* (1975); and FRANKLIN PEASE G.Y., *Del Tawantinsuyu a la historia del Perú* (1978), which emphasizes the indigenous origins of modern Peruvian culture. Superb ethnohistorical accounts of the impact of conquest and of the early colonial period are NATHAN WACHTEL, *The Vision of the Vanquished: The Spanish Conquest of Peru*

Through Indian Eyes, 1530-1570 (1977; originally published in French, 1971); KAREN SPALDING, *Huarochoir: An Andean Society Under Inca and Spanish Rule* (1984); and STEVE J. STERN, *Peru's Indian Peoples and the Challenge of Spanish Conquest: Huamanga to 1640* (1982). See also JAMES LOCKHART, *Spanish Peru, 1532-1560: A Colonial Society* (1968); and NOBLE DAVID COOK, *Demographic Collapse: Indian Peru, 1520-1620* (1981), which treats the devastating loss of Indian life due to European contact.

Treatments of Spanish colonial institutions and economy include J.R. FISHER, *Government and Society in Colonial Peru: The Intendant System, 1784-1814* (1970), and *Silver Mines and Silver Miners in Colonial Peru, 1776-1824* (1977); ROBERT G. KEITH, *Conquest and Agrarian Change: The Emergence of the Hacienda System on the Peruvian Coast* (1976); and NICHOLAS P. CUSHNER, *Lords of the Land: Sugar, Wine, and Jesuit Estates of Coastal Peru, 1600-1767* (1980). LEON G. CAMPBELL, *The Military and Society in Colonial Peru, 1750-1810* (1978), studies the origins of Peruvian civil-military relations. TIMOTHY E. ANNA, *The Fall of the Royal Government in Peru* (1979), views independence as an accidental occurrence; while HERACLIO BONILLA et al., *La independencia en el Perú*, 2nd ed. (1981), argues that Peru had to be conquered. HERACLIO BONILLA, *Guano y burguesía en el Perú*, 2nd ed. (1984), analyzes the rise of the guano industry and its impact on capitalist development. FLORENCIA E. MALLON, *The Defense of Community in Peru's Central Highlands: Peasant Struggle and Capitalist Transition, 1860-1940* (1983), treats nascent Peruvian capitalism from a rural perspective. ROBERT N. BURR, *By Reason or Force: Chile and the Balancing of Power in South America, 1830-1905* (1965, reprinted 1974), remains the best diplomatic history of the War of the Pacific.

Excellent political analyses of the 20th century include FRANÇOIS BOURRICAUD, *Power and Society in Contemporary Peru* (1970; originally published in French, 1967); CARLOS A. ASTIZ, *Pressure Groups and Power Elites in Peruvian Politics* (1969); and JULIO COTLER, *Clases, estado y nación en el Perú*, 2nd ed. (1982). The best studies of the crucial period 1919-40 are STEVE STEIN, *Populism in Peru: The Emergence of the Masses and the Politics of Social Control* (1980); and BALTAZAR CARAVEDO MOLINARI, *Clases, lucha política y gobierno en el Perú, 1919-1933* (1977). APRA, one of the most important political movements in Latin America, is the subject of ROBERT J. ALEXANDER (ed. and trans.), *Aprismo: The Ideas and Doctrines of Víctor Raúl Haya de la Torre* (1973); PETER F. KLARÉN, *Modernization, Dislocation, and Aprismo: Origins of the Peruvian Aprista Party, 1870-1932* (1973); and FREDRICK B. PIKE, *The Politics of the Miraculous in Peru: Haya de la Torre and the Spiritualist Tradition* (1986). Economic analyses of Belaúnde's first term include PEDRO-PABLO KUCZYNSKI, *Peruvian Democracy Under Economic Stress: An Account of the Belaúnde Administration, 1963-1968* (1977); and RICHARD C. WEBB, *Government Policy and the Distribution of Income in Peru, 1963-1973* (1977). Guerrilla movements are discussed by members of the movements in HUGO BLANCO, *Land or Death: The Peasant Struggle in Peru* (1972); and HECTOR BÉJAR, *Peru 1965: Notes on a Guerrilla Experience* (1970; originally published in Spanish, 1969).

Civil-military relations are treated in VÍCTOR VILLANUEVA, *Ejército peruano: del caudillaje anárquico al militarismo reformista* (1973), and his seminal study of the Center for High Military Studies, *El CAEM y la revolución de la fuerza armada* (1972); and in BRIAN LOVEMAN and THOMAS M. DAVIES, JR. (eds.), *The Politics of Antipolitics: The Military in Latin America* (1978). The most important literature on the 1968-80 military government includes ABRAHAM F. LOWENTHAL (ed.), *The Peruvian Experiment: Continuity and Change Under Military Rule* (1975), an overly optimistic account; CYNTHIA MCCLINTOCK and ABRAHAM F. LOWENTHAL (eds.), *The Peruvian Experiment Reconsidered* (1983), a scathing postmortem; CYNTHIA MCCLINTOCK, *Peasant Cooperatives and Political Change in Peru* (1981); ALFRED STEPAN, *The State and Society: Peru in Comparative Perspective* (1978), a study of authoritarian rule; GEORGE D.E. PHILIP, *The Rise and Fall of the Peruvian Military Radicals 1968-1976* (1978), an analysis of the reforms undertaken by Velasco; and STEPHEN M. GORMAN (ed.), *Post-Revolutionary Peru: The Politics of Transformation* (1982), an analysis of the successes, failures, and legacy of the military government.

(T.M.D.)

Peter I the Great, of Russia

Peter I the Great (Russian Pyotr I Velikiy, in full Pyotr Alekseyevich), tsar of Russia from 1682 and emperor from 1721, was one of his country's greatest statesmen, organizers, and reformers. He was born in Moscow on June 9 (May 30, old style), 1672, the son of Tsar Alexis by his second wife, Natalya Kirillovna Naryshkina. Unlike his half-brothers, sons of his father's first wife, Mariya Ilinichna Miloslavskaya, Peter proved a healthy child, lively and inquisitive. It is probably significant to his development that his mother's former guardian, Artamon Sergeyevich Matveyev, had raised her in an atmosphere open to progressive influences from the West.

Youth and accession. When Alexis died in 1676 Peter was only four years old. His elder half-brother, a sickly youth, then succeeded to the throne as Fyodor III; but, in fact, power fell into the hands of the Miloslavskys, relatives of Fyodor's mother, who deliberately pushed Peter and the Naryshkin circle aside. When Fyodor died childless in 1682, a fierce struggle for power ensued between the Miloslavskys and the Naryshkins: the former wanted to put Fyodor's brother, the delicate and feeble-minded Ivan V, on the throne; the Naryshkins stood for the healthy and intelligent Peter. Representatives of the various orders of society, assembled in the Kremlin, declared themselves for Peter, who was then proclaimed tsar; but the Miloslavsky faction exploited a revolt of the Moscow *streltsy*, or musketeers of the sovereign's bodyguard, who killed some of Peter's adherents, including Matveyev. Ivan and Peter were then proclaimed joint tsars; and eventually, because of Ivan's precarious health and Peter's youth, Ivan's 25-year-old sister Sophia was made regent. Clever and influential, Sophia took control of the government; excluded from public affairs, Peter lived with his mother in the village of Preobrazhenskoye, near Moscow, often fearing for his safety. All this left an ineradicable impression on the young tsar and determined his negative attitude toward the *streltsy*.

One result of Sophia's overt exclusion of Peter from the government was that he did not receive the usual education of a Russian tsar; he grew up in a free atmosphere instead of being confined within the narrow bounds of a palace. While his first tutor, the former church clerk Nikita Zotov, could give little to satisfy Peter's curiosity, the boy enjoyed noisy outdoor games and took especial interest

in military matters, his favourite toys being arms of one sort or another. He also occupied himself with carpentry, joinery, blacksmith's work, and printing.

Near Preobrazhenskoye there was a *nemetskaya sloboda* ("German colony") where foreigners were allowed to reside. Acquaintance with its inhabitants aroused Peter's interest in the life of other nations, and an English sailboat, found derelict in a shed, whetted his passion for seafaring. Mathematics, fortification, and navigation were the sciences that appealed most strongly to Peter. A model fortress was built for his amusement, and he organized his first "play" troops, from which, in 1687, the Preobrazhensky and Semyonovsky Guards regiments were formed—to become the nucleus of a new Russian Army.

Early in 1689 Natalya Naryshkina arranged Peter's marriage to the beautiful Eudoxia (Yevdokiya Fyodorovna Lopukhina). This was obviously a political act, intended to demonstrate the fact that the 17-year-old Peter was now a grown man, with a right to rule in his own name. The marriage did not last long: Peter soon began to ignore his wife, and in 1698 he relegated her to a convent.

In August 1689 a new revolt of the *streltsy* took place. Sophia and her faction tried to use it to their own advantage for another coup d'état, but events this time turned decisively in Peter's favour. He removed Sophia from power and banished her to the Novodevichy convent; she was forced to become a nun after a *streltsy* rebellion in 1698. Though Ivan V remained nominally joint tsar with Peter, the administration was now largely given over to Peter's kinsmen, the Naryshkins, until Ivan's death in 1696. Peter, meanwhile continuing his military and nautical amusements, sailed the first seaworthy ships to be built in Russia. His games proved to be good training for the tasks ahead.

External events. At the beginning of Peter's reign, Russia was territorially a huge power, but with no access to the Black Sea, the Caspian, or to the Baltic, and to win such an outlet became the main goal of Peter's foreign policy.

The Azov campaigns (1695–96). The first steps taken in this direction were the campaigns of 1695 and 1696, with the object of capturing Azov from the Crimean Tatar vassals of Turkey. On the one hand, these Azov campaigns could be seen as fulfilling Russia's commitments, undertaken during Sophia's regency, to the anti-Turkish "Holy League" of 1684 (Austria, Poland, and Venice); on the other they were intended to secure the southern frontier against Tatar raids, as well as to approach the Black Sea. The first campaign ended in failure (1695), but this did not discourage Peter: he promptly built a fleet at Voronezh to sail down the Don River and in 1696 Azov was captured. To consolidate this success Taganrog was founded on the northern shore of the Don Estuary, and the building of a large navy was started.

The Grand Embassy (1697–98). Having already sent some young nobles abroad to study nautical matters, Peter, in 1697, went with the so-called Grand Embassy to western Europe. The embassy comprised about 250 people, with the "grand ambassadors" Franz Lefort, F.A. Golovin, and P.B. Voznitsyn at its head. Its chief purposes were to examine the international situation and to strengthen the anti-Turkish coalition, but it was also intended to gather information on the economic and cultural life of Europe. Travelling incognito under the name of Sgt. Pyotr Mikhaylov, Peter familiarized himself with conditions in the advanced countries of the West. For four months he studied shipbuilding, working as a ship's carpenter in the yard of the Dutch East India Company at Saardam; after that he went to Great Britain, where he continued his study of shipbuilding, working in the Royal Navy's dockyard at Deptford, and he also visited factories, arsenals, schools, and museums and even attended a session

of Parliament. Meanwhile, the services of foreign experts were engaged for work in Russia.

On the diplomatic side of the Grand Embassy, Peter conducted negotiations with the Dutch and British governments for alliances against Turkey; but the Maritime Powers did not wish to involve themselves with him because they were preoccupied with the problems that were soon to come to a crisis, for them, in the War of the Spanish Succession.

The destruction of the streltsy (1698). From England, Peter went on to Austria; but while he was negotiating in Vienna for a continuance of the anti-Turkish alliance, he received news of a fresh revolt of the *streltsy* in Moscow. In the summer of 1698 he was back in Moscow, where he suppressed the revolt. Hundreds of the *streltsy* were executed, the rest of the rebels were exiled to distant towns, and the corps of the *streltsy* was disbanded.

The Northern War (1700–21). When it became clear that Austria, no less than the Maritime Powers, was preparing to fight for the Spanish Succession and to make peace with Turkey, Peter saw that Russia could not contemplate a war without allies against the Turks, and he abandoned his plans for pushing forward from the Sea of Azov to the Black Sea. By the Russo-Turkish Peace of Constantinople (Istanbul, 1700) he retained possession of Azov. He was now turning his attention to the Baltic instead, following the tradition of his predecessors.

The Swedes occupied Karelia, Ingria, Estonia, and Livonia and blocked Russia's way to the Baltic coast. To dislodge them, Peter took an active part in forming the great alliance, comprising Russia, Saxony, and Denmark-Norway, which started the Northern War in 1700. This war lasted for 21 years and was Peter's main military enterprise. In planning it and in sustaining it he displayed iron willpower, extraordinary energy, and outstanding gifts of statesmanship, generalship, and diplomacy. Mobilizing all the resources of Russia for the triumph of his cause, constantly keeping himself abreast of events, and actively concerning himself with all important undertakings, often at his personal risk, he could be seen sometimes in a sailor's jacket on a warship, sometimes in an officer's uniform on the battlefield, and sometimes in a labourer's apron and gloves with an axe in a shipyard.

The defeat of the Russians at Narva (1700), very early in the war, did not deter Peter and, in fact, he later described it as a blessing: "Necessity drove away sloth and forced me to work night and day." He subsequently took part in the siege that led to the Russian capture of Narva (1704) and in the battles of Lesnaya (1708) and of Poltava (1709). At Poltava, where Charles XII of Sweden suffered a catastrophic defeat, the plan of operations was Peter's own: it was his idea to transform the battlefield by works of his military engineers—the redoubts erected in the path of the Swedish troops to break their combat order, to split them into little groups, and to halt their onslaught. Peter also took part in the naval battle of Gangut (Hanko, or Hangö) in 1714, the first major Russian victory at sea.

The treaties concluded by Russia in the course of the war were made under Peter's personal direction. He also travelled abroad again for diplomatic reasons—e.g., to Pomerania in 1712 and to Denmark, northern Germany, Holland, and France in 1716–17.

In 1703, on the banks of the Neva River, where it flows into the Gulf of Finland, Peter began construction of the city of St. Petersburg (now Leningrad) and established it as the new capital of Russia in 1712. By the Treaty of Nystad (September 10 [August 30, O.S.], 1721) the eastern shores of the Baltic were at last ceded to Russia, Sweden was reduced to a secondary power, and the way was opened for Russian domination over Poland.

In celebration of his triumph, the Senate on November 2 (October 22, O.S.), 1721, changed Peter's title from tsar to that of emperor (imperator) of all the Russias.

The popular revolts (1705–08). The peasant serfs and the poorer urban workers had to bear the greatest hardships in wartime and moreover were intensively exploited in the course of Peter's great work for the modernization and development of Russia (see below *Internal reforms*). Their sufferings, combined with onerous taxation, pro-

voked a number of revolts, the most important of which were that of Astrakhan (1705–06) and that led by Kondraty Afanasyevich Bulavin in the Don Basin (1707–08). These revolts were cruelly put down.

The Turkish War (1710–13). In the middle of the Northern War, when Peter might have pressed further the advantage won at Poltava, Turkey declared war on Russia. In the summer of 1711 Peter marched against the Turks through Bessarabia into Moldavia, but he was surrounded, with all his forces, on the Prut River. Obligated to sue for peace, he was fortunate to obtain very light terms from the inept Turkish negotiators, who allowed him to retire with no greater sacrifice than the retrocession of Azov. The Turkish government soon decided to renew hostilities; but the Peace of Adrianople (Edirne) was concluded in 1713, leaving Azov to the Turks. From that time on Peter's military effort was concentrated on winning his war against Sweden.

The Tsarevich Alexis and Catherine (to 1718). Peter had a son, the tsarevich Alexis, by his discarded wife Eudoxia. Alexis was his natural heir, but he grew up antipathetic to Peter and receptive to reactionary influences working against Peter's reforms. Peter, meanwhile, had formed a lasting liaison with a low-born woman, the future empress Catherine I, who bore him other children and whom he married in 1712. Pressed finally to mend his ways or to become a monk in renunciation of his hereditary rights (1716), Alexis took refuge in the dominions of the Holy Roman emperor Charles VI, but he was induced to return to Russia in 1718. Thereupon proceedings were brought against him on charges of high treason, and after torture he was condemned to death. He died in prison, presumably by violence, before the formal execution of the sentence.

The Persian campaign (1722–23). Even during the second half of the Northern War, Peter had sent exploratory missions to the East—to the Central Asian steppes in 1714, to the Caspian region in 1715, and to Khiva in 1717. The end of the war left him free to resume a more active policy on his southeastern frontier. In 1722, hearing that the Ottoman Turks would take advantage of Persia's weakness and invade the Caspian region, Peter himself invaded Persian territory. In 1723 Persia ceded the western and southern shores of the Caspian to Russia in return for military aid.

Death. The campaign along the parched shores of the Caspian obviously put a great strain on Peter's health, already undermined by enormous exertions and also by the excesses in which he occasionally indulged himself. In the autumn of 1724, seeing some soldiers in danger of drowning from a ship aground on a sandbank in the Gulf of Finland, he characteristically plunged himself into the icy water to help them. Catching a chill, he became seriously ill in the winter but even so continued to work; indeed, it was at this time that he drew up the instructions for the expedition of Vitus Bering to Kamchatka.

Peter died in St. Petersburg on February 8 (January 28, O.S.), 1725, leaving an empire that stretched from Arkhangelsk (Archangel) on the White Sea to Mazanderan on the Caspian and from the Baltic Sea to the Pacific Ocean. Though he had in 1722 issued a decree reserving to himself the right to nominate his successor, he did not in fact nominate anyone. His widow Catherine, whom he had crowned as empress in 1724, succeeded him to the temporary exclusion of his grandson, the future Peter II.

Internal reforms. At the beginning of Peter's reign, Russia was backward by comparison with the countries of western Europe. This backwardness inhibited foreign policy and even put Russia's national independence in danger. Peter's aim, therefore, was to overtake the developed countries of western Europe as soon as possible, in order both to promote the national economy and to ensure victory in his wars for access to the seas. Breaking the resistance of the boyars, or members of the ancient landed aristocracy, and of the clergy and severely punishing all other opposition to his projects, he initiated a series of reforms that affected, in the course of 25 years, every field of the national life—administration, industry, commerce, technology, and culture.

The towns. At the beginning of Peter's reign there was

Peter's

War

already some degree of economic differentiation between the various regions of Russia; and in the towns artisans were establishing small businesses, small-scale production was expanding, and industrial plants and factories were growing up, with both hired workers and serfs employed. There was thus a nascent bourgeoisie, which benefitted considerably from Peter's plans for the development of the national industry and trade. The reform of the urban administration was particularly significant.

By a decree of 1699, townspeople (artisans and tradesmen) were released from subjection to the military governors of the provinces and were authorized to elect municipalities of their own, which would be subordinated to the Moscow municipality, or *ratusha*—the council of the great merchant community of the capital. This reform was carried further in 1720, with the establishment of a chief magistracy in St. Petersburg, to which the local town magistracies and the elected municipal officers of the towns (mayors, or *burmistry*; and councillors, or *ratmany*) were subordinated.

All townspeople, meanwhile, were divided between "regulars" and "commons" (inferiors). The regulars were subdivided between two guilds—the first comprising rich merchants and members of the liberal professions (doctors, actors, and artists); the second, artisans (classified according to their vocations) and small tradesmen. A merchant belonged to the first or to the second guild according to the amount of his capital; and those who were also manufacturers had special privileges, coming under the jurisdiction of the College of Manufactures and being exempt from the billeting of troops, from elective *rotas* of duty, and from military service. The commons were hired labourers, without the privileges of regulars.

Thanks to the reforms, the economic activity and the population of the towns increased. Anyone engaged in trade was legally permitted to settle in a town and to register himself in the appropriate category, and there was a right of "free commerce for people of every rank."

The provinces and the districts. In order to create a more flexible system of control by the central power, Russia was territorially divided in 1708 into eight *guberny*, or governments, each under a governor appointed by the tsar and vested with administrative, military, and judicial authority. In 1719 these *guberny* were dissolved into 50 *provintsy*, or provinces, which in turn were subdivided into districts. The census of 1722, however, was followed by the substitution of a poll tax for the previous hearth tax; and this provoked a wave of popular discontent, against which Peter decided to distribute the army regiments (released from active service by the Peace of Nystad) in garrisons throughout the country and to make their maintenance obligatory on the local populations. Thus came into being the "regimental districts," which did not coincide with the administrative. The regimental commanders, with their own sphere of jurisdiction and their own requirements, added another layer to the already complex system of local authority.

The central government. In the course of Peter's reign, medieval and obsolescent forms of government gave place to effective autocracy. In 1711 he abolished the *boyarskaya дума*, or boyar council, and established by decree the Senate as the supreme organ of state—to coordinate the action of the various central and local organs, to supervise the collection and expenditure of revenue, and to draft legislation in accordance with his edicts. Martial discipline was extended to civil institutions, and an officer of the guards was always on duty in the Senate. From 1722, moreover, there was a procurator general keeping watch over the daily work of the Senate and its chancellery and acting as "the eye of the sovereign."

When Peter came to power the central departments of state were the *prikazy*, or offices, of which there were about 80, functioning in a confused and fragmented way. To replace most of this outmoded system, Peter in 1718 instituted 9 "colleges" (*kollegy*), or boards, the number of which was by 1722 expanded to 13. Their activities were controlled, on the one hand, by the General Regulation and, on the other, by particular regulations for individual colleges, and indeed there were strict regulations for every

branch of the state administration. Crimes against the state came under the jurisdiction of the Preobrazhensky Office, responsible immediately to the tsar.

Industry. A secondary purpose of Peter's Grand Embassy to western Europe in 1697 (see above *The Grand Embassy*) had been to obtain firsthand acquaintance with advanced industrial techniques, and the exigencies of his great war against Sweden, from 1700, made industrial development an urgent matter. In order to provide armaments and to build his navy (Russia had virtually no warships at all), metallurgical and manufacturing industries on a grand scale had to be created; and Peter devoted himself tirelessly to meeting these needs. Large capital investments were made, and numerous privileges were accorded to businessmen and industrialists. These privileges included the right to buy peasant serfs for labour in workshops, with the result that a class of "enlisted" serfs came into existence, living in specified areas and bound to the factories. The methods of other countries were further studied, and foreign experts were invited to Russia. The overall result was satisfactory: the army and the navy were supplied with their material needs; a great number of manufacturing establishments were founded (mainly with serf labour); the metallurgical industry was so far advanced that by the middle of the 18th century Russia led Europe in this field; and the foreign-trade turnover was increased sevenfold in the course of the reign.
