The armed forces. Peter established a regular army on completely modern lines for Russia in the place of the unreliable *streltsy* and the militia of the gentry. While he drew his officers from the nobility, he conscripted peasants and townspeople into the other ranks. Service was for life. The troops were equipped with flintlock firearms and bayonets of Russian make; uniforms were provided; and regular drilling was introduced. For the artillery, obsolete cannons were replaced with new mortars and guns designed by Russian specialists or even by Peter himself (he drew up projects of his own for multicannon warships, fortresses, and ordnance). The Army Regulations of 1716 were particularly important; they required officers to teach their men "how to act in battle," "to know the soldier's business from first principles and not to cling blindly to rules," and to show initiative in the face of the enemy. For the navy, Peter's reign saw the construction, within a few years, of 52 battleships and hundreds of galleys and other craft; thus a powerful Baltic fleet was brought into being. Several special schools prepared their pupils for military or naval service and finally enabled Peter to dispense with foreign experts.

Cultural and educational measures. From January 1, 1700, Peter introduced a new chronology, making the Russian calendar conform to European usage with regard to the year, which in Russia had hitherto been numbered "from the Creation of the World" and had begun on September 1 (he adhered however to the Julian Old Style as opposed to the Gregorian New Style for the days of the month). In 1710 the Old Church Slavonic alphabet was modernized into a secular script.

Peter was the first ruler of Russia to sponsor education on secular lines and to bring an element of state control into that field. Various secular schools were opened; and since too few pupils came from the nobility, the children of soldiers, officials, and churchmen were admitted to them. In many cases, compulsory service to the state was preceded by compulsory education for it. Russians were also permitted to go abroad for their education and indeed were often compelled to do so (at the state's expense). The translation of books from western European languages was actively promoted. The first Russian newspaper, *Vedomosti* ("Records"), appeared in 1703. The Russian Academy of Sciences was instituted in 1724.

Beside his useful measures, Peter often enforced superficial Europeanization rather brutally; for example, when he decreed that beards should be shorn off and Western dress worn. He personally cut the beards of his boyars and the skirts of their long coats (*kaftany*). The Raskolniki (Old Believers) and merchants who insisted on keeping their beards had to pay a special tax, but peasants and the Orthodox clergy were allowed to remain bearded.

Control
over
church
and
nobility

The church. In 1721, in order to subject the Orthodox Church of Russia to the state, Peter abolished the Patriarchate of Moscow. Thenceforward the patriarch's place as head of the church was taken by a spiritual college, namely the Holy Synod, consisting of representatives of the hierarchy obedient to the tsar's will. A secular official—the *ober-prokuror*, or chief procurator—was appointed by the tsar to supervise the Holy Synod's activities. The Holy Synod ferociously persecuted all dissenters and conducted a censorship of all publications.

Priests officiating in churches were obliged by Peter to deliver sermons and exhortations to make the peasantry "listen to reason" and to teach such prayers to children that everyone would grow up "in fear of God" and in awe of the tsar. The regular clergy were forbidden to allow men under 30 years old or serfs to take vows as monks.

The church was thus transformed into a pillar of the absolutist regime. Partly in the interests of the nobility, the extent of land owned by the church was restricted; Peter disposed of ecclesiastical and monastic property and revenues at his own discretion, for state purposes.

The nobility. Peter's internal policy served to protect the interest of Russia's ruling class—the landowners and the nascent bourgeoisie. The material position of the landed nobility was strengthened considerably under Peter. Almost 100,000 acres of land and 175,000 serfs were allotted to it in the first half of the reign alone. Moreover, a decree of 1714 that instituted succession by primogeniture and so prevented the breaking up of large properties also removed the old distinction between *pomestya* (lands granted by the tsar to the nobility in return for service) and *votchiny* (patrimonial or allodial lands) so that all such property became hereditary.

Moreover, the status of the nobility was modified by Peter's Table of Ranks (1722). This replaced the old system of promotion in the state services, which had been according to ancestry, by one of promotion according to services actually rendered. It classified all functionaries—military, naval, and civilian alike—in 14 categories, the 14th being the lowest and the 1st the highest; and admission to the 8th category conferred hereditary nobility. Factory owners and others who had risen to officer's rank could accede to the nobility, which thus received new blood. The predominance of the boyars ended.

Personality and achievement. Peter was of enormous height, more than six and one-half feet (two metres) tall; he was handsome and of unusual physical strength. Unlike all earlier Russian tsars, whose Byzantine splendours he repudiated, he was very simple in his manners; for example, he enjoyed conversation over a mug of beer with shipwrights and sailors from the foreign ships visiting St. Petersburg. Restless, energetic, and impulsive, he did not like splendid clothes that hindered his movements; often he appeared in worn-out shoes and an old hat, still more often in military or naval uniform. He was fond of merrymaking and knew how to conduct it, though his jokes were frequently crude; and he sometimes drank heavily and forced his guests to do so too. A just man who did not tolerate dishonesty, he was terrible in his anger and could be cruel when he encountered opposition: in such moments only his intimates could soothe him—best of all his beloved second wife, Catherine, whom people frequently asked to intercede with him for them. Sometimes Peter would beat his high officials with his stick, from which even Prince A.D. Menshikov, his closest friend, received many a stroke. One of Peter's great gifts of statesmanship was the ability to pick talented collaborators for the high-

est appointments, whether from the foremost families of the nobility or from far lower levels of society.

As a ruler, Peter often used the methods of a despotic landlord—the whip and arbitrary rule. He always acted as an autocrat, convinced of the wonder-working power of compulsion by the state. Yet with his insatiable capacity for work he saw himself as the state's servant, and whenever he put himself in a subordinate position he would perform his duties with the same conscientiousness that he demanded of others. He began his own army service in the lowest rank and required others likewise to master their profession from its elements upward and to expect promotion only for services of real value.

Peter's personality left its imprint on the whole history of Russia. A man of original and shrewd intellect, exuberant, courageous, industrious, and iron-willed, he could soberly appraise complex and changeable situations so as to uphold consistently the general interests of Russia and his own particular designs. He did not completely bridge the gulf between Russia and the Western countries, but achieved considerable progress in development of the national economy and trade, education, science and culture, and foreign policy. Russia became a great power, without whose concurrence no important European problem could thenceforth be settled. His internal reforms achieved progress to an extent that no earlier innovator could have envisaged.

Peter's
influence
on Russia

BIBLIOGRAPHY. There are numerous studies in Russian on Peter I and his age. *Письма и бумаги Императора Петра Великого*, 11 vol. (1887–1964), contains valuable documents on Russian history up to 1711. Other works particularly recommended include: МИХАИЛ М. ВОГОСЛОВСКИЙ, *Петр I*, 5 vol. (1940–48, reprinted 1969), a detailed biography of Peter I until 1700; СЕРГЕЙ М. СОЛОВЬЕВ, *Публичные чтения о Петре Великом* (1872), a famous Russian historian on the role of Peter I; ИВАН И. ГОЛИКОВ, *Деяния Петра Великого*, 30 vol. (1788–97), on his reforms; and ЛЕОНИД А. НИКИФОРОВ, *Русско-английские отношения при Петре I* (1950). Peter's military campaigns and his role as the founder of the new Russian army are explored in the works of a prominent Soviet historian, ЕВГЕНИЙ В. ТАРЛЕ, *Русский флот и внешняя политика Петра I* (1949), and *Северная война и шведское нашествие на Россию* (1958). Works in English include BENEDICT H. SUMNER, *Peter the Great and the Ottoman Empire* (1949, reprinted 1965), and *Peter the Great and the Emergence of Russia* (1950, reprinted 1972); and IAN GREY, *Peter the Great, Emperor of All Russia* (1960). Peter's reforms aimed at modernizing Russian society are analyzed in JAMES CRACRAFT, *The Church Reform of Peter the Great* (1971); and ALEXANDER V. MULLER (ed. and trans.), *The Spiritual Regulation of Peter the Great* (1972). See also REINHARD WITTRAM, *Peter der Grosse: Der Eintritt Russlands in die Neuzeit* (1954), and *Peter I, Czar und Kaiser*, 2 vol. (1964). Other biographies include, MATTHEW S. ANDERSON, *Peter the Great* (1978); ALEX DE JONGE, *Fire and Water: A Life of Peter the Great* (1979); and ROBERT K. MASSIE, *Peter the Great: His Life and Work* (1980). XENIA GASIOROWSKA, *The Image of Peter the Great in Russian Fiction* (1979), is a study of some 60 historical novels written since Pushkin's time. Works that put Peter the Great and his reign into their historical perspective include MARTHA E. ALMEDINGEN, *The Romanovs: Three Centuries of an Ill-Fated Dynasty* (1966); JOHN D. BERGAMINI, *The Tragic Dynasty: A History of the Romanovs* (1969); IAN GREY, *The Romanovs: The Rise and Fall of a Dynasty* (1970); VASIL KLYUCHEVSKY, *The Rise of the Romanovs*, trans. and ed. by LILIANA ARCHIBALD (1970), originally part of Klyuchevsky's comprehensive five-volume history of Russia, published in 1912; J.G. GARRARD (ed.), *The Eighteenth Century in Russia* (1973); and W. BRUCE LINCOLN, *The Romanovs: Autocrats of All the Russias* (1981).

(L.A.N./Ed.)

Philadelphia

Philadelphia has been described either as the elegant but rather jaded great lady or as the overage and sickly spinster of American cities. A more realistic look at Philadelphia, however, shows it to be a very modern and vigorous city, arising in gracious counterpoint to the deep serenity of an older city that has provided gentle but firm intellectual, economic, and humanitarian direction to the nation at whose birth it played midwife.

Philadelphia, which is the fourth largest city in the United States and the largest in Pennsylvania, displays many characteristics of a small town. Its many trees, parks, and other open spaces and its quiet pace of life reflect in various ways the genteel Quaker heritage bestowed on the city by its founder, William Penn. Nearly everywhere are dignified reminders of the colonial and Revolutionary city and of Benjamin Franklin, a Philadelphian by adoption, who left his imprint on innumerable ongoing

institutions, both cultural and commercial, in the city.

Beneath this facade, however, Philadelphia represents an urban cluster of national and international stature. Its harbour, one of the largest freshwater ports in the world, is the major element in the official agglomeration of Delaware River ports known as Ameriport, collectively one of the busiest shipping centres in the world. The enormous industrial production of the city and the surrounding metropolitan area represents a continuation of Philadelphia's early leadership in the Industrial Revolution and in American commerce and finance generally. Lying in the midst of the vast urban community stretching down the Atlantic Seaboard, Philadelphia is an integral part of the turbulent fabric of contemporary social and economic life as well as a tranquil oasis joining together the spirit of America, past and present.

THE LANDSCAPE

The city site. Philadelphia spreads over about 129 square miles (334 square kilometres) from the Delaware on the east across the Schuylkill and beyond. The coextensive boundaries of Philadelphia city and county remain essentially as defined by the Consolidation Act of 1854.

The city layout. The gridiron of streets in central Philadelphia, the first U.S. city to be so arranged, follows the original plans of William Penn. Midway between the two rivers, Penn Square, occupied by City Hall, is the centre of the plan. Four shady, fountained squares—Logan, Franklin, Washington, and Rittenhouse—dot the quadrants. Westward from Penn Square along John F. Kennedy Boulevard is Penn Center, a prime symbol of rejuvenated Philadelphia since the 1950s. The multilevel complex comprises high-rise offices and hotels, with interior courts and malls and underground walkways lined with shops and restaurants.

Benjamin Franklin Parkway provides a splendid vista as it cuts diagonally northwestward from Penn Square through the grid, encircling Logan Square and leading into Fairmount Park. The nation's largest landscaped park within city limits and the centre of the Centennial Exposition of 1876, Fairmount is one of the most frequent foregrounds for photographs of Philadelphia's skyline, adding to the city's reputation for shaded, sculpted elegance. Once a section of outlying estates of the wealthy, the park contains many fine old mansions maintained by the city as museums. Through it winds the narrow valley of Wissahickon Creek, whose rugged beauty has inspired generations of poets and painters.

The oldest sections of Philadelphia—Southwark, Society Hill, and the Independence Hall area—lie to the east, along and inland from the Delaware. Southwark is the oldest, having been settled by Swedes in 1643. Those of its ancient and dilapidated houses that have escaped bulldozing for riverfront expressways resemble the edifices

of Society Hill before its restoration in the 1950s. This latter area contains some of the city's finest old houses, taverns, and churches, though some high-rise apartment buildings strike a dissonant note in the hearts of many Philadelphians.

Independence National Historical Park, established in 1956 and designated a World Heritage Site in 1979, contains Independence Hall, with the nearby Liberty Bell Pavilion, and many other buildings used by the Revolutionary and early federal governments. Nearby, Elfreth's Alley, dating from 1690, contains 33 houses that make up the oldest continuously inhabited street in the country. Included in the complex are Carpenters' Hall, site of the meeting of the First Continental Congress, and Philosophical Hall, home of the American Philosophical Society.

Throughout these areas and elsewhere, domestic architecture is characterized primarily by two- and three-story red-brick structures fronting directly on the sidewalks and containing impressive examples of colonial design both outside and inside. The Philadelphia Historical Commission has certified about 7,500 buildings and structures, ranging from 17th-century houses to a bridge constructed in 1950. Restoration of the old but habitable has been more characteristic than wholesale demolition and rebuilding throughout most of the city. Even in its downtown section, Philadelphia continues to be a city of shops rather than of huge merchandising outlets. It has nothing approaching New York City's Fifth Avenue as a street of large stores. Chestnut Street is an attractive street of shops but has only one department store, John Wanamaker's. Pine and other streets are noted for such specialties as antique shops. Major features of the skyline are the massive contours of the city's many banking and financial institutions.

The long stretches of Philadelphia north, south, and west of the intersection of Broad and Chestnut streets, a "city hub" of sorts just below Penn Square, contain numerous distinctive sections, often identified for generations with various ethnic groups that have filled the city during its long history. Among the more interesting is the German-

Historic
preservations and
restorations

town section of North Philadelphia, settled in Penn's time by Germans and the home in the 18th century of wealthy Philadelphians fleeing the periodic yellow-fever epidemics of the riverside city. Much of North Philadelphia comprises a massive black and Puerto Rican community. South Philadelphia contains notable Italian and other sections settled by European immigrants mainly in the 19th century.

THE PEOPLE

Though Philadelphia has had most of the characteristics of an ethnic and racial pot nearly from its start, it lacks the steaming hurly-burly visible everywhere in its behemoth neighbour, New York City, about 90 miles (150 kilometres) northeast. The Philadelphians by and large are not a street people, and their orientation has been so traditionally toward the home that the city became known as a "city of homes." Philadelphians are also great joiners, giving the city more social and other clubs than any other in America. Many of these are based in ethnic neighbourhoods, others are city wide, and still others serve the affluent "Main Liners" who reside in the plush suburbs that grew up in past centuries along the main line of the Pennsylvania Railroad (now Amtrak).

Quaker tradition and ethnic mix

Much of this tradition dates from Philadelphia's early years, from the beliefs and attitudes not only of the Quakers but also of such German pietist sects as the Mennonites, who stressed personal religious experience rather than institutionalized formulations. A basic sobriety underlying these tenets led to many stringent laws that remain in both the city and state. On the other hand, these groups strove for tolerance in all matters. Pennsylvania was among the few colonies admitting Roman Catholics and Jews, and the Quakers long were leaders in seeking justice and the alleviation of inhumanity in racial and other human relations. Philadelphia still has innumerable small, endowed charities of Quaker origin to provide the poor with coal or food—as well as one of the oldest and strongest municipal commissions on human relations.

During the 1800s the Protestant sects were joined by Roman Catholics, initially Irish and German and later Italian, Polish, and Slavic. Eastern European Jews also immigrated, eventually comprising a significant portion of the city's population. Cultural conflicts and competition for housing and jobs created tensions between the oldstock groups and the new arrivals. A series of anti-Catholic nativist riots rocked Philadelphia in the Jacksonian period, with an especially violent riot in 1844. Although immigrants came to Philadelphia in the hundreds of thousands in the late 19th and early 20th centuries, the city had a relatively low proportion of foreign-born when compared with other major cities at that time. Some Irish, Italian, Polish, and Jewish newcomers did find opportunities for considerable economic advancement in Philadelphia; for many, however, hopes never materialized and the urban experience proved rough and oftentimes shattering. The slow progress of these ethnic groups toward full acceptance is represented by the fact that Philadelphia did not elect its first Irish mayor until 1963 and its first Italian mayor until 1971.

Philadelphia has been the focal point of one of the historically most important black communities in the nation. During the early national and antebellum periods, many black leaders came from or centred their activities in Philadelphia, and the free black community there was intensely involved in many efforts to abolish slavery, assist fugitive slaves, and advance the general social and economic well-being of blacks. Between 1829 and 1860, however, the Philadelphia black community was victimized by several antiblack mob actions. At the beginning of the 20th century Philadelphia was the site of the largest black community of any northern city. The migration of Southern-born blacks to the city continued to augment the city's black population throughout the first half of the 20th century. Discrimination in housing resulted in the creation of overcrowded black districts. By the late 20th century about 40 percent of all Philadelphians and well over 50 percent of the public school population were black. The suburbs, by contrast, were about 95 percent white.

During the late 1960s Philadelphia, like other major American cities, was shaken by race riots. This led, in 1971, to a backlash in the election as mayor of Frank Rizzo, a tough former police commissioner oriented toward "law and order." In 1979, however, Philadelphians turned toward more moderate rule by rejecting the attempt of Rizzo to alter the city charter and thereby win permission to seek a third term. In 1983 the city elected its first black mayor, W. Wilson Goode.

Problems of substandard and insufficient housing, delinquency, public health, crime, drug abuse, and other ills, by no means confined to the ghettos, have somewhat dimmed the city's image. Efforts at public housing date back to 1937. Other municipal and federal bodies have continued efforts at urban renewal for both blacks and poor whites, usually following the pattern of rehabilitating neighbourhoods rather than razing them. Unusual is the fact that about two-fifths of the black families own their homes.

THE ECONOMY

Industry. Many of Philadelphia's business enterprises were established in the 1700s, but the city's economy has changed greatly. Such old and once-dominant industries as textile mills met stiff competition from the South. Industry was given a boost by World War II but began to decline later; thousands of jobs were lost in the 1960s. Nonmanufacturing and service industries, however, continue to increase employment. Although such old industries as textiles have declined, new industries, such as electrical products and appliances, have grown. The area is a centre for phonograph and record production, along with radio and television manufacturers. Apparel, food and food products, printing and publishing, and electrical machinery are leaders in manufacturing. A decline has been evident in the migration of both people and business from the city to the suburbs. The Valley Forge area has become a nest of business and industrial locations. Much of this relocation is under the sponsorship of the public Philadelphia Industrial Development Corporation.

Research. George Washington approved the first U.S. patent in 1790, to a Philadelphian named Samuel Hopkins for a better way of making potash. In today's economy research and invention are keys to progress. In West Philadelphia is located the University City Science Center and Institute, a nonprofit project of more than 20 universities and colleges with a multimillion-dollar commitment to research. General Electric, E.I. du Pont de Nemours, Westinghouse, Monsanto, Rohm and Haas, and the Philadelphia Electric Company are other large concerns with extensive research programs within the metropolitan area. U.S. Steel's Fairless Works, on the Delaware at Morrisville, is a fully integrated plant and the largest steel plant in the Delaware River Valley. The area is a centre for research on and refining of petroleum. The computer age was born out of experiments at the University of Pennsylvania, where the first electronic computer was operated in 1945. A unit of the Boeing Company at Eddystone is one of the world's most advanced plants for helicopter research and design.

The unique Food Distribution Center, a nonprofit corporation managed by a board of directors representing city government and private enterprise, is a prime example of how Philadelphia has joined the work of the private and public sectors to serve the best interests of both. Covering more than 400 acres (160 hectares), it is a food-industry park handling in a unified operation every food-marketing facility from ripening bananas to smoking fish; it is composed of more than 100 stores plus warehousing and processing plants.

Finance. From its early days until the 1850s, Philadelphia was the financial capital of the United States, but it then lost this position to New York City. It was the birthplace of American banking, and the first building and loan association was founded there. The city continues to be a major centre of banking, with its financial institutions remaining the oldest and among the most prosperous in the nation. Philadelphia also supplies the stock and exchange services demanded by modern business. The Philadelphia Commercial Exchange was set up in 1868 as

An economic overview

an outgrowth of the older Corn Exchange Association of 1863 to regulate the then-flourishing grain and flour trade. The Philadelphia Bourse was organized in 1891, and the Maritime Exchange was founded in 1875. Philadelphia has the oldest stock exchange (founded in 1790) in the United States. The Philadelphia-Baltimore-Washington Stock Exchange was joined by Pittsburgh in 1969 and in 1976 was renamed the Philadelphia Stock Exchange.

Transportation. A complex system of public and private trolley and bus lines was consolidated in 1963 by the state legislature's creation of the Southeastern Pennsylvania Transportation Authority (SEPTA) to plan, develop, and coordinate a regional transportation system and to fund projects by the sale of bonds. Express buses provide rapid service between the inner and outer city.

A joint New Jersey-Pennsylvania bridge commission operates six toll and 13 tax-supported bridges over the Delaware. Two of these are solely for pedestrian use. The Schuylkill is bridged at a number of points and has a subway tunnel. The New Jersey-Pennsylvania-Delaware port authority administers Ameriport and the Benjamin Franklin and Walt Whitman bridges over the Delaware. The authority has also carried out major improvement and expansion programs throughout the entire port area. Philadelphia International Airport, less than seven miles (11 kilometres) from the city centre, provides nationwide and international flights.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. The city-county consolidation in 1854 was a result of the inability of a colonial-type government by committees to adapt to the needs of a growing city for new public services; *e.g.*, better streets, police, transportation, sanitation, and schools. Ironically, Philadelphia had, in fact, led most cities in providing urban improvements, but they were too few and too slow, and the breakdown of law and order in the 1840s forced changes. Until the early 1950s the standard type of U.S. city government prevailed in Philadelphia, comprising an elected mayor and a city council elected from among candidates presented by the political parties in the political divisions, or wards. As in other large cities, this form was subject to pressures for special favours, such as street-railway franchises and public-works contracts; bribery and corruption were both inevitable and rampant.

The reform movement that began in 1939 was joined in 1948 by top business and financial leaders, who organized the Greater Philadelphia Movement, and together they took up the battle for an entirely new city charter. This document effectively removed the city council from its administrative role and increased the staff and powers of the mayor. A strong civil-service commission improved

professional employment. The council, seven of whose members were elected by all the voters and 10 by districts, was to review and approve taxes and budgets and enact ordinances. Philadelphia thus had the first modern big-city charter in the United States; its approval by a two-to-one popular vote made it an expression of the desire of Philadelphians for better, more efficient, and honest city government.

The first mayors under the new charter were Joseph S. Clark and Richardson Dilworth, men devoted to making it work. From wealthy Republican families, both were lawyers who revolted against the corruption and inefficiency of city government and became Democrats. Men of the highest qualifications were selected for key positions, planning was made a virtue, and a \$150,000,000 plan was launched at once for improvements in sewerage and sanitation, playgrounds, lighting and streets, police and fire protection, and other basic services long neglected. The ambitious plan for a Penn Center involved removal of the old Pennsylvania Railroad "Chinese Wall" of overhead tracks, which ran into the heart of the city at Broad Street, and replacing it and the Broad Street Station.

Renewal planning gave close attention to the need for better housing. The Philadelphia Housing Authority and the Philadelphia Redevelopment Authority, with federal and private aid, approached Philadelphia's housing in terms of improving neighbourhoods rather than total clearance followed by new high-rise apartments. Affected areas included the Independence Hall area, neighbouring Society Hill, and the historic waterfront.

Much of the work of the city government is carried out through housing redevelopment, parking, and other authorities. The Old Philadelphia Development Corporation was organized in 1956 as a quasi-public and private body to aid the new development plans.

Public services. Though the Philadelphia metropolitan area has a per capita income that is the highest of any such area in the state, a large percentage of Philadelphians live below the poverty level. City, state, and federal agencies administer a full range of ameliorative social-service programs. A department of public health operates a variety of services through a number of health districts. With its Quaker tradition, Philadelphia is known for its humanitarian concern and has a great variety of privately supported child-care, hospital, and other social services.

Education. Philadelphia's public school system is an independent governmental unit operating under a board of education appointed by the mayor on the recommendation of a citizens' nominating panel. The city's institutions of higher learning are headed by the privately endowed University of Pennsylvania, which was founded in 1740, opened the nation's first medical school (1765),

Institutions
of higher
education

and was the first designated "university" in the United States (1779). Temple University (1884) has acquired the reputation of "the people's college" and is known for work in the arts and social sciences. Roman Catholic colleges include LaSalle and St. Joseph's. Philadelphia is also a centre for medical education, with several general schools and specialized schools in pharmacy, podiatry, optometry, and osteopathy. The Curtis Institute of Music (1924) is a leading music school, while the Pennsylvania Academy of Fine Arts (1805) is the oldest art school in the United States.

CULTURAL LIFE

Much of the essence of Philadelphia lies in the features described previously—its small-town atmosphere, its parks and tree-shaded downtown squares and streets, and its innumerable memorials to the American past, as well as its teeming riverside and factories and its diverse business institutions. There are other factors as well that contribute in their way to an understanding of Philadelphia's culture, considered in its broadest implications to comprise the life-styles of its people.

Recreational
facilities

In addition to Fairmount Park, Philadelphia has Pennypack Park in the northeast, a semiwilderness setting with bridle paths, bird-watching trails, and an abundance of deer and other wildlife. More than 100 other parks are located throughout the city.

Philadelphians have always been a sports-loving group, whether passive or participatory, though professional teams have always been the object, like the city itself, of a good-natured depreciation that is tolerated in residents but not in strangers. City baseball fans enjoyed a long-awaited triumph in 1980 when the Philadelphia Phillies won the World Series. Fox hunting in the surrounding countryside is of old Quaker origins, while the Schuylkill is a major rowing site for collegiate and other individuals and crews, and Germantown harbours remnants of a once-lively city-wide enthusiasm for cricket.

In colonial days Philadelphia was known as the "Athens of America," and it retains a high place in the artistic achievement of the nation. The Academy of Music, opened in 1857, is the home of the Philadelphia Orchestra, which is among the finest orchestras of the world and was among the first to broadcast and make recordings. At Fairmount Park are two facilities—the Fredric R. Mann Music Center, which presents classical music, and the Robin Hood Dell, which presents popular music.

Philadelphia was the nation's theatrical centre until well after the Revolution, its stages having hosted the greatest players of Europe and America. The Walnut Street Theatre, opened in 1809, is the oldest playhouse in active use in the English-speaking world. The Playhouse in the Park opened in 1952 as the first city-owned and city-operated theatre of its kind.

Museums
and
galleries

Philadelphia was a pioneer in museums of all kinds. Charles Willson Peale's museum was housed in Independence Hall in the 1800s, but the art museums are now led by the Philadelphia Museum of Art. One of the world's great museums, it houses priceless collections of art from the Western Middle Ages onward and from the Orient. Others include the Rodin Museum, featuring the largest collection of sculptures by Auguste Rodin outside of Paris. The Historical Society of Pennsylvania has some 700 portraits by Benjamin West, James Copley, Gilbert Stuart, the four Peales, and other early American painters. The output of visual artists in Philadelphia and vicinity has been by and large conservative, though Thomas Eakins gained fame for work beyond his American contemporaries, and Mary Cassatt was among the few women in the Impressionist school of the late 19th century.

Other museums include the Museum of the Philadelphia Civic Center, originally organized in 1894 as the Commercial Museum to promote trade exhibitions. The Academy of Natural Sciences is the oldest of its kind in the United States. The Franklin Institute Science Museum and Planetarium is full of marvellous things that move and can be moved, while the University Museum is a major feature of the University of Pennsylvania. Among the newer museums in Philadelphia are the Afro-American Historical

and Cultural Museum and the New Year's Shooters and Mummery Museum, both established in 1976, and the Port of History Museum at Penn's Landing. There also are many small museums housed in restored buildings throughout the city.

History

FOUNDATION AND EARLY SETTLEMENT

William Penn acquired the province of Pennsylvania in 1681 from King Charles II of England as a place where his fellow Quakers could enjoy freedom of worship and a chance to govern themselves and develop their own way of life. The King made the grant, signed on March 4, 1681, and proclaimed it a few weeks later, on April 2, partly to settle a debt owed to Penn's father, Adm. Sir William Penn, upon his death and also to complete the settlement of the Middle Atlantic region with Englishmen. Penn sent his cousin William Markham to take charge of affairs of government and also to lay out the city Penn named Philadelphia, city of "brotherly love," the name symbolizing his idealistic concepts. From England, Penn wrote in 1681 asking that "the Rivers and Creeks be sounded on my side of the Delaware River . . . in order to settle a great Towne, and be sure to make your choice where it is most navigable, high, dry, and healthy." He wanted every house to be placed in the middle of its own plot to provide ground about it "that it may be a greene Country Towne, which will never be burnt, and always be wholesome."

Penn arrived in 1682 but had little chance to enjoy his city. He was forced to travel to England in 1684 and was unable to return until 1699. By then, Philadelphia was a flourishing town with many shops and trading houses, as well as several hundred dwellings and about 10,000 people clustered close to the riverfront. Penn's governor declared the city already was the equal of New York "in trade and riches." Penn's policies throughout the colony of religious toleration and the right of the people to take part in the government, in addition to growing prosperity, soon began to attract thousands of English, German, and Scots-Irish settlers, and most came by way of Philadelphia.

Philadelphia by the 1770s had grown to at least 30,000 persons in the central city, and it was the third most important business centre in the British Empire, overshadowed only by Liverpool and London. This position was due in large measure to the city's site at the confluence of the Delaware and Schuylkill rivers, which provided the city access to inland farm regions and to the coal and ore resources that supplied the early iron industry.

A visitor in 1756 wrote that "Everybody in Philadelphia deals more or less in trade," a tribute not merely to Philadelphia's location but also to the shrewd business talents of the Quaker merchants. A large and profitable system of triangular trade involved foodstuffs and wood products, such as lumber and barrel staves, that went from Philadelphia to the West Indies and there were exchanged for sugar, rum, and other West Indian products. These were carried to English ports, where they in turn were exchanged for English manufactures to be brought back to Philadelphia. The prosperous farm country of interior Pennsylvania supplied the Philadelphia merchant with goods for the West Indies, and a profitable coastal trade existed with other colonies and directly with England. By the 1750s Philadelphians had invested heavily in the flourishing charcoal-iron industry. Anthracite coal became an important mineral resource of Pennsylvania 100 years later, and the Philadelphia capital played a leading part in this industry as well as in the mining of bituminous coal farther to the west. Philadelphia continued its leadership in foreign commerce until about 1810, when New York City, with an even more advantageous location, took over this position. Philadelphia surrendered its position as financial capital of the nation in the 1850s.

Shipyards had flourished along the Delaware since colonial days. Most of what came to the city was raw material for manufacture, and Philadelphia became a major centre of the early Industrial Revolution in the United States. In 1785 Oliver Evans invented the first gristmill operated

Penn's

commerce
and culture

entirely by mechanical power. The city was a pioneer in textile manufacturing and took the raw iron from inland furnaces and made it into tools and implements, such as saws, huge iron castings for cotton-mill machinery, and the first American-built steam locomotives. By 1860 the value of Philadelphia's manufactures ran into several hundred million dollars, about 30 percent of the national total. Textiles, ships, iron products, leather, refined sugar, and boots and shoes were leaders, giving important aid to the Union in the Civil War.

THE GROWTH OF THE CITY

Cultural dominion. Prosperity was translated into personal and community wealth, and with these social and economic advantages Philadelphia assumed early leadership in the arts, in science, and in culture. Benjamin Franklin, who as a young man had migrated from Boston to Philadelphia, became an American leader in scientific and intellectual affairs. Philadelphia had the nation's first free library, its first hospital, and its first learned society, the American Philosophical Society—all founded by Franklin. Along with Franklin, there were men such as Benjamin Rush, the great physician, and David Rittenhouse, an astronomer, mathematician, inventor, and early Philadelphia aristocrat, and many others. The city excelled in printing and publishing: by 1776 there were 23 printers and newspapers with circulations of from 500 to 3,000 copies. Fine private and public buildings were erected. One of them was Andrew Hamilton's Independence Hall, originally—and still—better known by Philadelphians as “the statehouse.” Led by Benjamin West, Charles Willson Peale, and Gilbert Stuart, oil painting flourished in the colonial and Federal periods.

The city's strategic location near the midpoint of colonial settlement and its important status as a vital political, economic, and cultural centre—as well as concern that Pennsylvania might not favour the Revolution—brought to Philadelphia the delegates who formed the First Continental Congress in 1774 and a year later the Second Continental Congress, which proclaimed the Declaration of Independence and governed throughout the Revolution. The Constitutional Convention met in Philadelphia in 1787 and framed the federal Constitution, and the city served as the capital of the United States from 1790 to 1800. The nation celebrated its centennial in Philadelphia in 1876.

Political evolution. In the decades just before and following the Civil War, Pennsylvania fell into the hands of Philadelphia-based Republican political machines that, like their counterparts (usually Democratic) in other cities, were becoming increasingly sophisticated in methods of manipulating the political processes, especially through the newer immigrant groups, and profiting from the economic life of the state and city. They were instrumental in electing governors and U.S. senators, and, in the Depression years of the 1930s, the hard-hit city refused aid from the Democratic administration in Washington, D.C. Powerful bankers and industrial and business leaders, living for the most part outside the city, favoured this form of government because it kept taxes low, imposed little or no regulation on business, and maintained an aura of social calm through benign neglect or quiet but forceful repression.

The 20th century. In about 1900 Philadelphia had been described as “corrupt but content,” a status quo that

Philadelphians were indeed content with until 1939, when a group known as the Young Turks and influenced by the nationwide New Deal of the Democratic Party began to agitate for charter reform and a city planning commission. Women and blacks were brought into the city's political life for the first time. In spite of continued machine domination of the city, the group began to realize its goals—with a “Better Philadelphia Exhibition” in 1947, a coalition of top business and financial leaders the following year, and a new charter in 1951. The election in 1952 of Joseph S. Clark as mayor signalled the moment for a new Philadelphia to leap off the drawing boards.

Philippines

The Republic of the Philippines (Pilipino: Republika ng Pilipinas) is an archipelago consisting of some 7,100 islands and islets lying about 500 miles off the southeast coast of Asia. The total land area of the Philippines is 115,800 square miles (300,000 square kilometres). It is bounded by the Philippine Sea to the east, the Celebes Sea to the south, and the South China Sea to the west and north. The Philippines takes its name from Philip II, who was king of Spain during the Spanish colonization of the islands in the 16th century. Manila is the biggest city and the national capital. It is located on Luzon, the largest island, which has a land area of 40,420 square miles.

The archipelago spreads out in the form of a triangle, with the islands south of Palawan, the Sulu Archipelago, and the island of Mindanao forming (west-east) its southern base and the Batan Islands, in the north, its apex. The islands stretch for about 1,150 miles (1,850 kilometres) from north to south and for about 700 miles from east to west at their widest extent. Only about two-fifths of the islands and islets have names, and only some 350 have areas of one square mile or more. The large islands fall

into three groups: (1) the Luzon group in the north and west, consisting of Luzon, Mindoro, and Palawan; (2) the Visayan group in the centre, consisting of Bohol, Cebu, Leyte, Masbate, Negros, Panay, and Samar; and (3) Mindanao in the south.

Because it was under Spanish rule for 333 years and under U.S. tutelage for a further 48 years, the Philippines has many cultural affinities with the West. It is, for example, the fourth most populous country in which English is an official language and the only predominantly Roman Catholic country in Southeast Asia. Its peoples, however, are Asian in consciousness and in aspiration. In many ways Filipino society is composed of paradoxes, perhaps the most apparent being the great extremes of wealth and poverty in the nation. The Philippines is a country of rich resources, but it is in the process of developing its full potentialities. It is primarily agricultural, although a high degree of domestic and foreign investment has spurred the rapid development of its industrial potential. Educationally, it is among the most advanced of Asian countries, having a high literacy rate.

Physical and human geography

THE LAND

Relief and drainage. The irregular configuration of the archipelago, the coastline of more than 21,500 miles, the great extent of mountainous country, the narrow and interrupted coastal plains, the generally northward trend of the river systems, and the lakes are the outstanding physical features of the Philippines. The islands are composed of volcanic, coral, and all principal rock formations. The mountain ranges for the most part run in the same general direction as the islands themselves, approximately north to south. The Cordillera Central, the central mountain chain of Luzon, running north to the Luzon Strait from the northern boundary of the central plain, is the most prominent range. It consists of two and in places three parallel ranges, each of which averages 5,900 feet (1,800 metres) in height. The Sierra Madre, extending along the Pacific coast from northern to central Luzon, is the longest mountain range in the country. This range and the Cordillera Central merge in north-central Luzon to form the Caraballo Mountains. To the north of the latter, and between the two ranges, is the fertile Cagayan Valley. The narrow Ilocos, or Malayan, range, lying close along the west coast of northern Luzon, rises in places to

more than 5,000 feet and is seldom less than 3,500 feet in height; it is largely volcanic. In the southwestern part of northern Luzon are the rugged Zambales Mountains, consisting of more or less isolated old volcanic stocks (rock formed under great heat and pressure deep beneath the Earth's surface).

The central plain of Luzon, about 150 by 50 miles, is only about 100 feet above sea level except near its centre. The greater part of southern Luzon is occupied by isolated volcanoes and irregular masses of hills and mountains. The highest peak is Mayon Volcano (8,077 feet) near Legazpi in Albay province.

Through the island of Palawan, about 25 miles wide and more than 250 miles long, there extends a range with an average height of from 4,000 to 5,000 feet. Each of the Visayan Islands except Samar and Bohol is traversed longitudinally by a single range with occasional spurs. Several peaks in Panay reach an altitude of 6,000 feet or more. Canlaon Volcano, on Negros, is 8,087 feet high, and other peaks reach altitudes of more than 6,000 feet.

There are several important ranges on Mindanao, the Diuata (Diwata) Mountains along the eastern coast being the most prominent. West of this lies the fertile valley of the Agusan River, 20 to 30 miles wide. Farther west and southwest is the Cotabato Valley of the Mindanao River

Mountains
of Luzon

Relief of
Mindanao

(Río Grande de Mindanao), and between its lower course and the southern coast lies a range trending northwest-southeast. On the southeastern border of the basin of the Mindanao River is Mount Apo, at 9,692 feet (2,954 metres) the highest peak in the Philippines. Around Lake Lanao are a number of volcanic peaks, and a low cordillera extends through the Zamboanga Peninsula in the far west.

The plains lying amid the mountains—for example, the central plain of Luzon and the central plain of Panay—have the greatest density of population in the islands, except Cebu, where the people live mostly on the coastal plain because the interior is high and rugged. The most important rivers are the Cagayan, Agno, Pampanga, Pasig,

and Bicol on Luzon and the Mindanao and Agusan on Mindanao. The Pasig, which flows through the city of Manila, is commercially important. The largest lake in the archipelago is Laguna de Bay, located south of Manila.

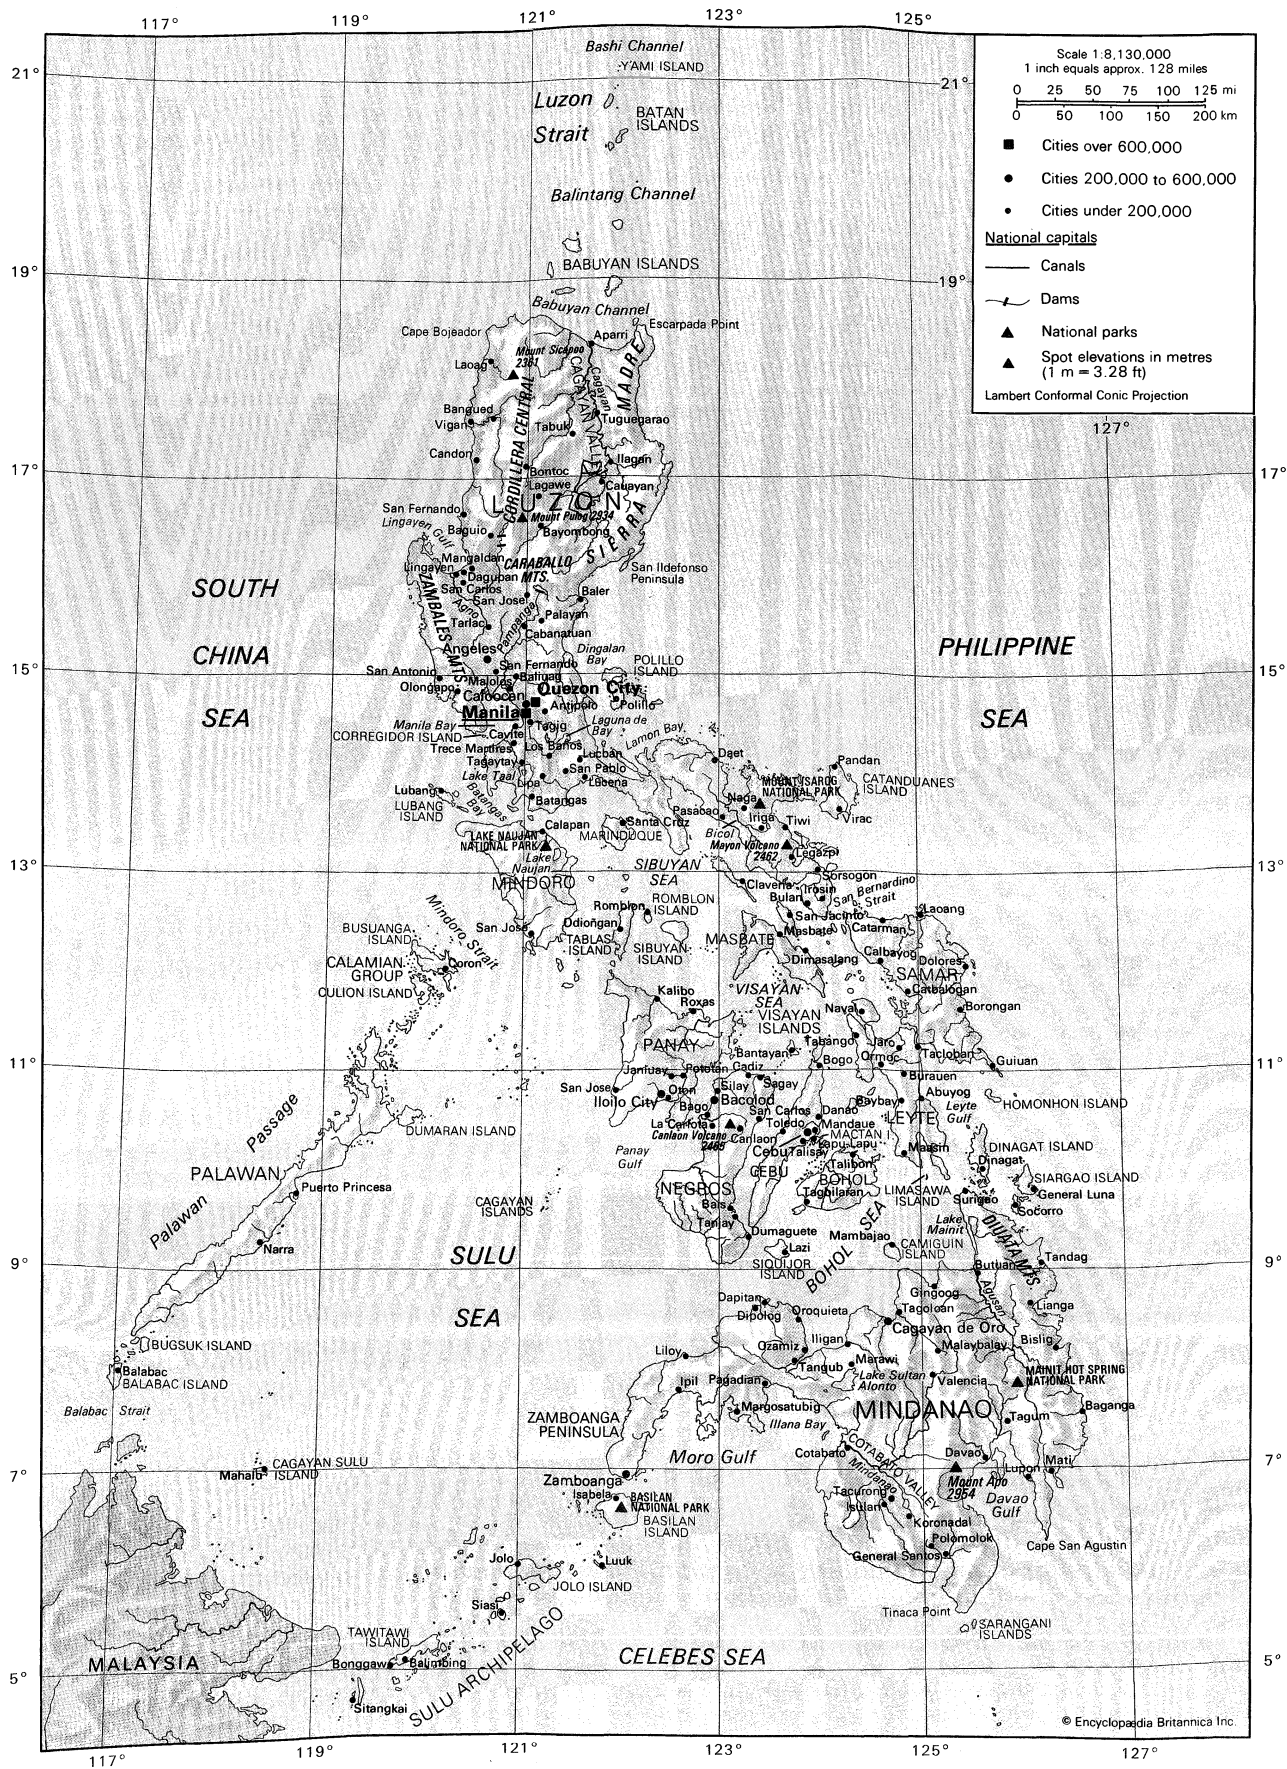

Volcanoes are a conspicuous feature of the landscape, but there is relatively little volcanic activity. There are altogether about 50 volcanoes, of which more than 10 are known to be active. All gradations of volcanoes can be seen, from the almost perfect cone of Mayon, which has been compared to Mount Fuji in Japan, to old, worn-down volcanic stocks, the present forms of which give little indication of their origin. The several distinct volcanic areas are in south-central and southern Luzon and

on the islands of Negros, Mindanao, Jolo, and elsewhere. Tremors and earthquakes are common.

Climate. The climate of the Philippines is tropical and is strongly affected by monsoon (rain-bearing) winds, which blow from the southwest from approximately May to October and from the northeast from November to February. Thus, temperatures remain relatively constant from north to south during the year, and seasons consist of periods of wet and dry. Throughout the country, however, there are considerable variations in the frequency and amount of precipitation. The western shores facing the South China Sea have marked dry and wet seasons. The dry season generally begins in December and ends in May, the first three months being cool and the second three hot; the rest of the year consists of the wet season. The dry season shortens progressively to the east until it ceases to occur. During the wet season, rainfall is heavy in all parts of the archipelago except for an area extending southward through the centre of the Visayan group to central Mindanao and then southwestward through the Sulu Archipelago; rain is heaviest along the eastern shores facing the Pacific Ocean.

From June to December typhoons often strike the archipelago. Most of these storms come from the southeast, their frequency generally increasing from south to north; in some years the number of typhoons reaches 25 or more. Typhoons are heaviest in Samar, Leyte, eastern Quezon province, and the Batan Islands, and when accompanied by floods or high winds they may cause great loss of life and property. Mindanao is generally free from typhoons.

November through February constitutes the most agreeable season; the air is cool and invigorating at night, and the days are pleasant and sunny. During the hot part of the dry season in most places, and especially in the cities of Cebu, Davao, and Manila, the temperature sometimes rises as high as 100° F (38° C). Overall temperatures decline with altitude, however, and cities and towns located at higher elevations—such as Baguio in northern Luzon, Majayjay and Lucban south of Manila, and Malaybalay in central Mindanao—experience a pleasant climate throughout the year; at times the temperature in these places dips as low as 43° F (6° C).

Plant and animal life. Much of the land area of the islands is covered with forest, and many of the mountains are densely forested. In northern Luzon the principal mountain tree is pine. In many places where the forests have been burned away their place has been taken by tall, coarse cogon grass (genus *Imperata*) or similar grasses. There are about 10,000 known species of flowering plants and ferns. Much of the vegetation resembles that found in Malaysia, and the vegetation of the coastal areas, including the mangrove swamps, is practically identical with that of similar areas throughout the Malay Archipelago. Himalayan elements occur in the mountains of northern Luzon, while a few Australian types are found at various altitudes. A majority of the plant species are indigenous, including the dominant forest species. Lauan (Philippine mahogany) often composes a high percentage of the forest. There are many other valuable hardwoods as well as many softwoods. About 800 species of orchids, some very rare, are found.

There are about 220 species of mammals, among which are carabaos (water buffalo), goats, horses, hogs, cats, dogs, monkeys, squirrels, lemurs, mice, pangolins (scaly anteaters), chevrotains (mouse deer), mongooses, civet cats, and red and brown deer. The tamarau, a very small species of carabao, is found only on Mindoro. There are at least 56 species of bats, many peculiar to the Philippines. Fossil remains show that there were once elephants on the islands.

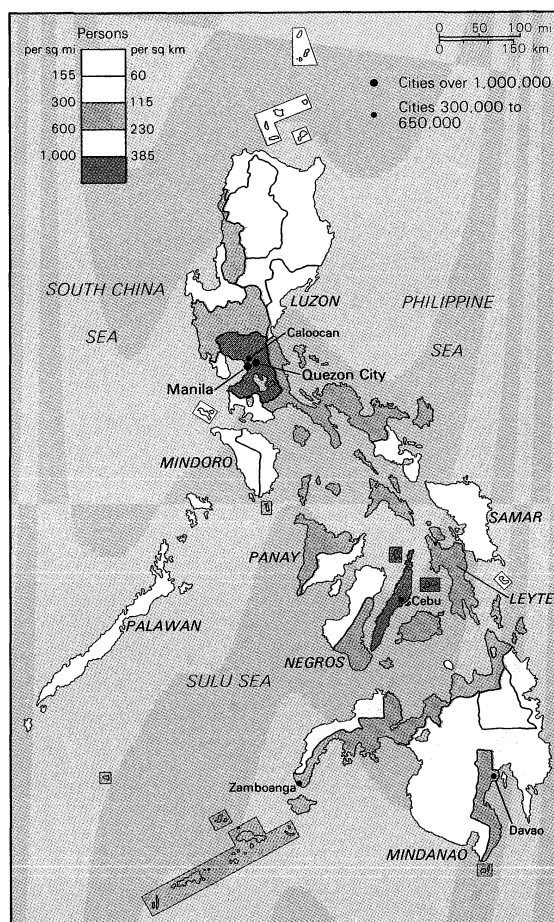

There are some 500 species of birds, many of which are migrants. Birdlife includes jungle fowl, pigeons, peacocks, pheasants, doves, parrots, hornbills, kingfishers, sunbirds, tailorbirds, weaverbirds, herons, and quails. Many species of birds are unique to the island of Palawan. The rare and endangered monkey-eating eagle is restricted mainly to isolated areas on Mindanao and in the Sierra Madre on Luzon.

Settlement patterns. Before the arrival of the Spanish in the 16th century, the people lived in small independent villages called barangays, each ruled by a petty king called a *datu*. Rural settlement today is centred upon poblaciones, or small towns, originally founded by the Spanish. Roads or trails were built from the poblacion in four to six directions, like the spokes of a wheel, and along the roadsides barrios, or villages, grew up, subdivided into smaller units called sitios. More people now live in the barrios than in the poblaciones. A large barrio may be composed of as many as 1,000 households and have a population of 4,000 or more. The cultivation of rice or corn (maize) and fishing provide the basic subsistence.

Manila, Cebu, Jaro, Vigan, and Nueva Caceres (now called Naga) were granted city charters by the Spanish. More chartered cities were founded under U.S. administration and since independence in 1946. Quezon City was

The
barangay

Chartered
cities

chartered in 1939 and became the capital of the Philippines in 1948. In 1975 Manila, Pasay City, Caloocan, and Quezon City and 13 adjoining municipalities were placed under one administrative unit known as Metropolitan, or Metro, Manila. The city proper of Manila was again made the national capital in 1976; Metropolitan Manila is designated the National Capital Region. In addition to the cities there are a great many municipalities and a number of municipal districts.

THE PEOPLE

Ethnic composition. The people of the Philippines are called Filipinos. Their ancestors, who were of Malay stock, came from the southeastern Asian mainland as well as from what is now Indonesia. From the 10th century, contacts with China resulted in a group of mixed Filipino-Chinese descent, who account for a minority of the population. A small percentage of Chinese nationals also live in the country. Spanish-Filipinos and Filipino-Americans may be distinguished by their fairer complexion,

The
Filipinos

taller stature, and aquiline nose structure. The relatively small numbers of emigrants from the Indian subcontinent added to the population's racial mixture. There are small numbers of resident U.S. nationals (excluding military personnel) and Spaniards. The aboriginal inhabitants of the islands were the Negritos, or Pygmies, also called Aetas or Balugas; they now constitute only a small percentage of the total population.

Linguistic groups. Estimates of the total number of native languages and dialects spoken in the Philippines differ, but scholarly studies suggest that there are some 70 of them. These languages are all closely related, belonging to the Austronesian (Malayo-Polynesian) family of languages. Traditionally, eight major linguistic groups are identified. These are (1) the Tagalog group, concentrated in Manila, central and south central Luzon, and the islands of Mindoro and Marinduque; (2) Cebuano, in Cebu, Bohol, eastern Negros, western Leyte, and parts of Mindanao; (3) Ilocano, dominant in many parts of northern Luzon; (4) Hiligaynon (Ilongo), spoken in parts of Panay and western Negros; (5) Bicol, spoken in southern Luzon and on the island of Catanduanes; (6) Waray-Waray, spoken in Samar and Leyte; (7) Pampango, spoken in parts of central Luzon; and (8) Pangasinan, spoken in central Luzon. Other notable languages are Magindanao and Maranao, spoken in parts of Mindanao, and Aklanon, spoken in Panay.

The
Pilipino
language

The national, and most widely spoken, language of the Philippines is Pilipino (also called Filipino), based on Tagalog. Pilipino and English are the two official languages and mediums of instruction. Tagalog is the richest of all Philippine languages and has the most extensive written literature.

Religion. The great majority of Filipinos are Roman Catholic; adherents of the Philippine Independent Church (the Aglipayans), Muslims, and Protestants are the largest religious minorities, including a Protestant sect called Iglesia ni Kristo. There are also some Buddhists and animists. Roman Catholicism has been strengthened by an increase in the number of Filipinos in the church hierarchy, the building of seminaries, and the increased involvement of the church in the political and social life of the country.

Demography. The population density of the Philippines is high—some 500 people per square mile (193 per square kilometre) on the average—although the distribution of the population is uneven. Population density in urban areas is extremely high—that of the National Capital Region is about 30,000 per square mile—while density in such outlying areas as the Batan Islands and northeastern Mindanao is considerably lower than the national average. Because it is largely a Roman Catholic country and because most of its population is rural, the country has a high birth rate. Efforts since the mid-20th century at reducing the overall growth rate have had some success, but reductions in the birth rate have been partially offset by reductions in the death rate.

Demo-
graphic
trends

Especially since World War II, population has tended to move from rural areas to towns and cities. At the beginning of the 20th century more than 80 percent of the population was rural, but by the late 1980s the number had dropped to less than 60 percent. There is also a considerable amount of Filipino emigration, particularly of manual labourers and professionals. Many emigrants have gone to the United States, Okinawa, Guam, and Canada; in addition, a large number of skilled and semiskilled workers have taken temporary overseas assignments, mainly in the Middle East.

THE ECONOMY

Resources. The Philippines is rich in mineral resources. There are major deposits of gold in northern and southern Luzon; iron ore in northern Mindanao and on nearby islands and in central Luzon; copper in west-central Luzon; lead and zinc in western Mindanao; and high-grade chromium ore (chromite) in west-central and southern Luzon, northern Mindanao, and central Palawan. Deposits of silver, nickel, mercury, molybdenum, cadmium, and manganese occur in several other places. Nonmetallic minerals include limestone for cement, found on Cebu,

Luzon, and Romblon; salt and asbestos on Luzon; marble on Romblon and Panay; asphalt on Leyte; mineral waters on Luzon; gypsum on Luzon; sulfur on Luzon, Leyte, and Mindanao; guano and phosphate rock on Cebu and Bohol; coal and silica on Cebu and Palawan; and petroleum off the northwest shore of Palawan.

At one time about half of the Philippines' total land area was covered with forests. Of this, a large part abounded with trees of commercial value, especially lauan, narra (species of *Pterocarpus*, used in cabinetmaking), ipil (*Intsia bijuga*), molave (*Vitex littoralis*), and kamagong (*Diospyros discolor*). Heavy logging and inadequate reforestation measures, however, have reduced considerably the amount of forested land.

No fewer than 2,000 varieties of fish are in the seas surrounding the islands and in lakes, rivers, estuaries, and fish ponds. The most important commercial fishes are milkfish (a herringlike fish), anchovy, herring, sardine, mackerel, grouper, snapper, cavalla, mullet, barracuda, mudfish, and caesio. Fish are raised in ponds in some provinces of Luzon and Panay. There are pearl beds in the Sulu Archipelago to the south, and mother-of-pearl used for making buttons is exported to China, Hong Kong, and elsewhere. Tortoiseshells and shells used for windows are exported to Singapore, Malaysia, and other countries.

Hydroelectric power in the past has supplied only a small proportion of the country's electrical output, with thermal plants, most of which burn imported oil, supplying the major proportion. But the completion of several dam projects on Luzon and the expansion of another project on Mindanao have increased the percentage of power generated by hydroelectric installations; irrigation and flood control are additional benefits of some of the projects. Dependence on foreign oil has also been reduced by the construction of geothermal and conventional coal-fired thermal plants.

Hydro-
electric
projects

Agriculture. The Philippines is chiefly an agricultural country. Its soil is rich and fertile, and crops grow abundantly throughout the year. The principal farm products are rice, corn (maize), coconut, sugarcane, abaca (Manila hemp), tobacco, maguey (used for making such products as rope), and pineapple. Many tropical fruits are also raised, the most important being banana, mango, lanseh, or lanzon (*Lansium domesticum*), citrus, and papaya. A wide variety of vegetables are raised for domestic consumption.

Rice, the principal staple crop, is grown everywhere, but especially in central and north-central Luzon, south-central Mindanao; western Negros and eastern and cen-

Rice
production

Shostal Associates

tral Panay. Much of the total farmland is used for rice growing. Since the early 1970s rice production in the Philippines has improved considerably, and in some years the country has had surplus rice available for export. Factors contributing to this increase in output include the development and use of higher-yielding strains of rice, the construction of feeder roads and irrigation canals, and the use of chemical fertilizers and insecticides. Use of scientific farming techniques in the Philippines, however, has had its drawbacks. The newer strains of rice have required the application of chemicals that are expensive and that generally must be imported.

Coconut production

The Philippines is one of the world's largest producers of coconuts and a major exporter of coconut products. The area devoted to coconut production is second only to that used for rice and corn. The Philippines also produces more than one-third of the world's copra.

Sugar is one of the country's top exports and earns a substantial amount of foreign exchange. Sugarcane is grown extensively in central and north-central Luzon, western Negros, and on Panay. Much of the sugar crop is exported to the United States. Abaca, or Manila hemp, the source of a useful plant fibre, is also an important export. It is grown extensively in eastern Mindanao, southeastern Luzon, and on Leyte and Samar.

High-quality timber and veneer products traditionally have been leading exports, although their importance has declined. Other forest products include dyewoods, rattan, tanbarks, gutta-percha, beeswax, and rubber. Fishing is also one of the most important of Filipino industries. Canned tuna is the principal fish exported, and fish provides an important proportion of the protein in the Filipino diet. Commercial fishing is carried on primarily off Palawan, Negros, Mindanao, and Panay.

Industry. The principal minerals mined include gold, silver, iron, copper, manganese, zinc, lead, coal, and chromite; some petroleum is also extracted. Many of these minerals—notably copper—are produced for export and thus are vulnerable to fluctuations in world demand. Much industrial growth has taken place in the Philippines, particularly in the 1950s and the 1970s, but the manufacturing sector is still in an early stage of development. Many factories are licensees of foreign companies or act as subcontractors for foreign firms, turning out finished products for export from imported semifinished goods. Major manufactured goods include processed foods and beverages, petroleum products, textiles and wearing apparel, and chemicals.

Finance and trade. In addition to the Central Bank of the Philippines, there are commercial banks, thrift banks, and rural banks. Banking operations are also conducted by such other institutions as the Philippine National Bank and the Development Bank, of the Philippines. The principal exports are electronic equipment, coconuts and coconut products, minerals (copper, gold, iron ore), sugar, and garments. The principal imports are fuel, machinery, transport equipment, and electrical equipment. Major trading partners are the United States, Japan, The Netherlands, West Germany, and Hong Kong.

Administration of the economy. The economy of the Philippines is based on free enterprise; individuals and nongovernmental entities are free to participate in its development and management, sometimes with the aid of government credit.

The public sector. The government has assisted the private sector of the economy by exempting certain new industries from taxation for a certain period. Only nominal taxes are imposed on selected industries, and loans on favourable terms are available to others. Government banks, such as the Central Bank of the Philippines, the Philippine National Bank, and the Development Bank, were established to encourage business, agriculture, and industry. Much of the original capital investment of many private rural banks was provided by the government. Private development banks have likewise received government assistance. The National Economic and Development Authority (NEDA) and the Board of Investments were created to help both public and private sectors in planning further economic development.

The government plans national economic development through the NEDA, the National Planning Commission, and other agencies. In so doing, it has sought to increase economic independence; while there have been advantages in the preferential trade relations between the United States and the Philippines, this trade has resulted in the development of industries that would primarily benefit the American rather than the Filipino economy. Although the United States and Japan have continued to be the Philippines' top trading partners, a number of new markets, including those in Communist countries, have been explored. The government has also been engaged in business in its own right. It owns such enterprises as the National Development Corporation, the Philippine Ports Authority, and the Philippine National Railways.

Labour relations. The trade-union movement is well-established in Manila and in most other towns and cities. Farmers and tenants are also organized, as are teachers and government employees. The right of all workers to organize unions has been recognized in the constitution promulgated in 1987. Management, for its part, has organized company unions. Relations between trade unions and the employers' union have been generally untroubled. The Bureau of Labor Relations has been effective in settling disputes between labour and management.

Taxation. The government derives its revenue from three major sources: taxation, earnings and other credits, and extraordinary income, including the transfer from special funds (*i.e.*, funds derived mainly from unexpended balances in the budget that are deposited as savings accounts). Revenue is collected primarily through the Bureau of Internal Revenue and the Bureau of Customs. Excise taxes constitute the largest portion of government income; import duties, corporate and individual income taxes, and sales taxes provide much of the remainder. Local governments have only limited taxing powers.

Transportation. Thousands of miles of roads, gravel, asphalt, and concrete, link the towns on the archipelago's many islands, with expressways running north and south from Manila. Elsewhere on Luzon, most of the road from Manila to Laoag, in the far north of the island, and the greater part of the road to Sorsogon in the extreme south, are hard-surfaced, as are roads branching out from Manila to the city of Baguio and to the heavily populated provinces to the north and south. Thousands of miles of roads of various types have also been constructed on Mindanao, Mindoro, and Palawan and in the Visayas. A major achievement in road construction in the country is the Pan-Philippine Highway (also called the Maharlika Highway), a system of hard-surface roads, bridges, and ferries that connects the islands of Luzon, Samar, Leyte, and Mindanao.

Two principal railroads operate on Luzon and Panay. The Luzon main line extends from San Fernando in the north to the city of Legazpi in the south. The railroad in Panay connects Iloilo City with Roxas.

The most important port is Manila. Manila North Harbor handles domestic trade, while Manila South Harbor handles shipping from abroad. Other international ports are Cebu (next in importance to Manila), Iloilo City, Davao, Zamboanga, Cagayan de Oro, and Legazpi.

The international airport at Manila, like those at Hong Kong and Singapore, is a focal point for air routes. A separate terminal is used by domestic airlines. The Mactan airport, on Mactan Island near Cebu, also handles international flights. There are a number of other airports for domestic flights, all of which have service to and from Manila.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Constitutional framework. The Philippines has been governed under three constitutions, the first of which was promulgated in 1935, during the period of U.S. administration. It was closely modeled on the U.S. Constitution and included provisions for a bicameral legislative branch, an executive branch headed by a president, and an independent judiciary. During the period of martial law (1972–81) under President Ferdinand E. Marcos, the old constitution was abolished and

Government
businesses

Highway

Exports
and
imports

replaced by a new constitution (adopted in January 1973) that changed the Philippine government from a U.S.-style presidential system to a parliamentary form; the president became head of state, and executive power was vested in a prime minister and Cabinet. President Marcos, however, also served (until 1981) as prime minister and ruled by decree. Subsequent amendments and modifications of this constitution replaced the former bicameral legislature with a unicameral body and gave the president even more powers, including the ability to dissolve the legislature and (from 1981) to appoint a prime minister from among members of the legislature.

Constitution of 1987

After the downfall of Marcos in 1986, a new constitution, similar to the 1935 document, was drafted and was ratified in a popular referendum held in February 1987. Its key provision was a return to a bicameral legislature, called the Congress of the Philippines, consisting of a 250-member House of Representatives and a 24-member Senate. House members are elected from districts, although a number of them are appointed; they can serve no more than three consecutive three-year terms. Senators, elected at large, can serve a maximum of two six-year terms. The first legislative election under the new constitution was held in May 1987. The president, the head of state, can be elected to only a single six-year term, and the vice president to two consecutive six-year terms. The president appoints the Cabinet, which consists of the heads of the various ministries responsible for running the day-to-day business of the government. Most presidential appointments are subject to the approval of a Commission of Appointments, which consists of equal numbers of senators and representatives.

Local government. The country is divided administratively into 73 provinces, which are grouped into 12 regions; the National Capital Region has special status. Each province is headed by an elected governor. Local political subdivisions that also have elected officials include cities and municipalities; during the Marcos regime the ancient barangay was reinstated as the smallest unit of government.

Political parties. Partisan political activity was vigorous before 1972, the principal rivals being the Nacionalista and Liberal parties. Martial-law restrictions all but eliminated partisan politics. Marcos' organization, the New Society Movement (Kilusang Bagong Lipunan; KBL), was created from elements of the Nacionalista Party and other supporters and became predominant. Organized political opposition was revived for legislative elections held in 1978; and since the downfall of Marcos, partisan politics has returned to its pre-1972 level, with a large number of political parties emerging. Certain outlawed political organizations also operate within the country, the two principal ones being the Moro National Liberation Front (MNLF), a group seeking autonomy for Muslim Filipinos (Moros), and the National Democratic Front (NDF), a Communist-led insurgency movement.

Justice. Justices and judges enjoy fixed tenure and reasonably high compensation. The judiciary has consequently been less criticized than other branches of the government; and since 1900 the Supreme Court has retained the trust of the people, although trust in the entire judiciary diminished considerably during the Marcos regime. Judicial independence was reaffirmed by the constitution of 1987.

The extra-judicial lupon

In order to reduce the load of the lower courts, local committees of citizens called Pacification Committees (Lupon Tagapayapa) have been organized to effect extra-judicial settlement of minor cases between barangay residents. In each *lupon* there is a Conciliation Body (Pangkat Tagapagkasundo), the main function of which is to bring opposing parties together and effect amicable settlement of differences. The committee cannot impose punishment, but otherwise its decision is binding.

Armed forces. The Department of National Defense is divided into four services: the army, the navy, the air force, and the constabulary (the national police force), each with a commanding officer whose rank is at least that of brigadier general or, in the navy, commodore. Several army battalions served in the Korean and Viet-

nam wars, though in the latter the men performed civic instead of combat duties. The armed forces are responsible for containing the antigovernment military actions of the NDF and the MNLF; for controlling smuggling; and for maintaining order. The armed forces also engages in nonmilitary activities, such as providing disaster relief, constructing civilian housing, and participating in literacy campaigns. The commander in chief of the armed forces (the president of the Philippines) is a civilian.

Under a series of agreements reached in 1947, the United States maintains several bases in the Philippines and provides the Philippines with military equipment and training. Since the treaty dealing with the bases was revised in 1978, Philippine sovereignty over them has been recognized; all U.S. bases in the country have been placed under the overall command of a Filipino, and the Philippine flag flies over them.

U.S. military bases

The constabulary is divided into commands in the 12 administrative regions and the National Capital Region. Each province, including the cities within its territorial jurisdiction, is assigned a constabulary unit under a provincial commander. The police throughout the country are integrated under the supervision of the National Police Commission.

Education. The largest governmental ministry is that which administers education as well as such cultural institutions as the Institute of National Language (Surian ng Wikang Pambansa), the National Library, the National Museum of the Philippines, and the National Historical Institute.

Elementary education lasts for six years, secondary education for four, and college courses for four to nine years. Vocational schools offer specialized training for one to two years. Relatively few students finish high school. In view of this, greater emphasis has been placed on non-formal educational opportunities for adults and out-of-school youths. A Bureau of Continuing Education supervises programs in adult literacy, vocational and technical training, health, and family planning.

There are some four dozen state-run universities and colleges, about one-third of them in Metropolitan Manila, as well as a number of private institutions. The University of Santo Tomas was founded as early as 1611. There are also many technical institutions and community colleges in the provinces, but the tendency of the students is to go to Manila, despite discouragement by the government.

Pilipino is the medium of instruction in all elementary school subjects except science, mathematics, and the English language, which are taught in English. A chronic shortage of supplies and facilities has been partially remedied by a textbook program begun in the mid-1970s and the large-scale manufacture of prefabricated classrooms. A small number of foreign students (mainly from the Middle East, Southeast Asia, and the United States) study annually in the Philippines.

Health and welfare. Health and welfare are the responsibility of the departments of health and social services. The national government maintains a general hospital, a mental hospital, an orthopedic hospital, and a hospital for war veterans and their families. There are also government and private hospitals, as well as rural health units. Incorporated into the Department of Social Services is the Philippine National Red Cross, and a number of private social welfare agencies cooperate with the department.

The rate of mortality has been considerably reduced, particularly among infants and mothers, and there has been a steady increase in average life expectancy. The improvement in health is credited to better prenatal care and the services of more trained midwives, doctors, and nurses, improved housing and sanitation, the provision of health services to government employees and Social Security members, the increasing number of medical and nursing school graduates, and the requirement that a medical graduate render rural service. Nonetheless, the demand for health care continues to outstrip available resources; a large number of trained medical professionals emigrate, particularly to the United States, and many of the poorest people still rely on the services of practitioners of traditional medicine and unlicensed midwives.

Housing

There is a serious housing shortage everywhere, although it is especially acute in Manila. In many places people live in their own dwellings, but the houses are often substandard and lack elementary facilities for health and sanitation. To help meet this problem the government has relocated thousands of squatters from Manila to resettlement areas in nearby provinces. The Marcos regime instituted housing projects in which model communities were built that provided the residents with hygienic dwellings, a number of amenities, and facilities for raising livestock and for pursuing cottage industries and other means of making a living. This program met with some success.

CULTURAL LIFE

Philippine society is an incongruous blend of diversity and homogeneity. Geographically the country is part of the East, but in culture it is strongly Western. Forces of assimilation have constantly worked to overcome differences caused by the relative physical isolation of various groups of people throughout the archipelago who had come over time from disparate ethnic and cultural backgrounds. Nearly four centuries of Western rule, however, left the most indelible imprint on the country, serving as a conduit for the introduction of Western culture and as the catalyst for the emergence of a sense of Philippine political and cultural unity. The Christian churches built by the Spaniards and the mosques in the Muslim areas provided a spiritual anchor, while the educational system established by the United States and expanded by the Filipinos became a strong factor for socioeconomic progress. Nonetheless, traditionally strong family ties and other Asian moorings have remained. The revival of the *barangay* as the smallest unit of government has contributed to the revival of ancient traditions; and Asian and African history and literature—neglected in the past—have received more attention. Thus, the Philippines has been strengthening its Asian ties without abandoning its Western cultural acquisitions.

Early Spanish chroniclers testified that the Filipinos carved the images of their *anitos* (gods and goddesses) and ancestors in wood. They also played a variety of musical instruments, including flutes, nose flutes, and guitars. They performed appropriate songs and dances to celebrate courtship, marriage, the harvest, and other occasions. Many of these songs and dances, accompanied by the same musical instruments, have been preserved or reinterpreted and are presented by dance and song groups. Some of these groups—among them the Bayanihan, *Filipinescas*, *Barangay*, and *Hariraya* groups, as well as the *Karilagan Ensemble* and the groups associated with the guilds of the Manila and Fort Santiago theatres—have also performed abroad. Many Filipino musicians have risen to prominence, such as the composer and conductor Antonio J. Molina, the composer Felipe P. de Leon, known for his nationalistic themes, and the opera singer Jovita Fuentes. The Cultural Center of the Philippines, the Folk Arts Theatre, and the restored Manila Metropolitan Theatre (all in Manila) provide homes for the performing arts, featuring local and foreign opera and ballet. To encourage the development of arts the government gives awards of recognition and has established an Arts Center in Los Baños south of Manila.

Filipino painters have included Juan Luna; Fernando Amorsolo, who is known for his traditional rural scenes; the muralists Carlos V. Francisco and Vicente Manansala; and the modernists Victorio Edades and Arturo Rogelio Luz. Among the sculptors, Guillermo Tolentino and Napoleon Abueva are prominent. Tribesmen from mountainous regions in northern Luzon and craftsmen living northwest of Manila and in Paete on the eastern shore of Laguna de Bay are known for wood carving. Romblon and other nearby islands are noted for their marble sculptures. Among Filipino architects, the most notable include Juan F. Nakpil, Otilio Arellano, Fernando Ocampo, Leandro Locsin, Juan Arellano, Carlos Arguelles, and Tomas Mapua.

Folk traditions. Filipinos have a rich folklore tradition. Myths and legends deal with such subjects as the origin of the world, the first man and woman on Earth, why

the sky is high, why the sea is salty, and why there are different races. Other tales are associated with the Spanish conquest. Muslim Filipinos have an epic called *Darangen*, and the Ilocanos of northern Luzon have another entitled *Biag ni Lamang*. Most folktales and popular cultural traits are still to be found in remote barrios and *sitios*. Dean S. Fansler, Maximo Ramos, and Armando and Carolina Malay have compiled collections of Philippine folktales.

Museums. The Bureau of Science and the National Museum, both in Manila, have gathered artifacts connected with many of the folktales and popular beliefs. Several provinces—including Cagayan, Bulacan, Aklan, and Iloilo—have built their own museums. A few universities, such as the University of Santo Tomas, Silliman University in eastern Negros, and Mindanao State University in Lanao del Sur, likewise have added museums to their campuses. Nongovernmental organizations such as the Conservation Society and some historical groups have also sought to preserve the folklore heritage. The Cultural Centre of the Philippines opened in 1970 to encourage interest in the nation's heritage.

The media. A highly independent press developed in the Philippines when it was under U.S. administration, but many newspapers ceased publication during the period of martial law. Limited press freedom was granted in the early 1980s, with full freedoms returning after the change of government in 1986. Newspapers are published in English, Pilipino, and many of the country's vernacular dialects. The major English-language dailies—all published in Manila—include the *Bulletin Today*, *Times Journal*, and *Manila Times*; the *New Philippines Daily Express* has English and Pilipino editions. Among the major weeklies is *Veritas Weekly*, published by the Roman Catholic Church. The operators of radio and television stations belong to a national organization called the Association of Broadcasters in the Philippines.

For statistical data on the land and people of the Philippines, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (Eu.M.A./G.C.B.)

History

In ancient times, the inhabitants of the Philippines were a diverse agglomeration of peoples who arrived in various waves of immigration from the Asian mainland and who maintained little contact with each other. The Philippines is the only nation in Southeast Asia that became subject to Western colonialism before it had had the opportunity to develop either a centralized government ruling over a large territory or an advanced elite culture. Chinese traders were known to have been resident from about AD 1000, and some cultural influences from South Asia, such as a Sanskrit-based writing system, were carried to the islands by the Indonesian empires of Srivijaya and Majapahit; but in comparison with other parts of the region, the influence of both China and India on the Philippines was of little importance. The peoples of the Philippine archipelago, unlike most of the other peoples of Southeast Asia, never adopted Hinduism or Buddhism.

PRE-SPANISH HISTORY

According to what can be inferred from somewhat later accounts, the Filipinos of the 15th century must have been primarily shifting cultivators, hunters, and fishers. Sedentary cultivation was the exception. Only in the mountains of northern Luzon, where elaborate rice terraces were built in the early centuries AD, were livelihood and social organization linked to a fixed territory. The lowland peoples lived in extended kinship groups known as *barangays* under the leadership of a *datu*, or chieftain. The *barangay*, which ordinarily numbered no more than a few hundred individuals, was usually the largest stable economic and political unit.

Within the *barangay*, the status system, though not rigid, appears to have consisted of three broad classes: the *datu* and his family and the nobility, freeholders, and "dependents." This third category consisted of three levels—sharecroppers, debt peons, and war captives—with the last two levels being termed slaves by Spanish observers. The

Philippine
epics

dance
groups

Barangay
society

slave status was inherited but, through manumission and interclass marriage, seldom extended over more than two generations. The fluidity of the social system was, in part, the consequence of a bilateral kinship system in which lineage was reckoned equally through the male and female line. Marriage was apparently stable, though divorce was socially acceptable under certain circumstances.

Animism was the religion of the early Filipino, a mixture of monotheism and polytheism in which the latter dominated. The propitiation of evil spirits required numerous rituals, but there was no religious hierarchy. In religion, as in social structure and economic activity, there was considerable variation between—and even within—*islands*.

This pattern, however, began to change in the 15th century, when Islām was introduced to Mindanao and the Sulu islands through Brunei. Along with changes in religious beliefs and practices came new political and social institutions. By the mid-16th century two sultanates had been established, bringing under their sway a number of *barangays*. A powerful *datu* as far north as Manila embraced Islām. It was in the midst of this wave of Islāmic proselytism that the Spaniards arrived. Had they come a century later or had their motives been strictly commercial, Filipinos today might be a predominantly Muslim people.

THE SPANISH PERIOD

Spanish colonialist motives were not, however, strictly commercial. The Spanish at first viewed the Philippines as a stepping-stone to the riches of the Spice Islands, but, even after the Portuguese and Dutch had foreclosed that possibility, the Spaniards still maintained their presence in the archipelago.

The Portuguese navigator and explorer Ferdinand Magellan headed the first Spanish foray to the Philippines when he made landfall on Cebu in March 1521; a short time later he met an untimely death on the nearby island of Mactan. After three further expeditions had ended in disaster, Philip II, "the most Catholic of kings," for whom the islands are named, sent out Miguel López de Legazpi, who established the first permanent Spanish settlement, in Cebu, in 1565. The Spanish city of Manila was founded in 1571, and by the end of the 16th century most of the coastal and lowland areas from Luzon to northern Mindanao were under Spanish control. Friars marched with soldiers and soon accomplished the nominal conversion to Roman Catholicism of all the natives under Spanish administration. But the Muslims of Mindanao and Sulu, whom the Spanish called Moros, were never completely subdued by Spain; it took a 20th-century U.S. army to accomplish that task.

Spanish rule for the first 100 years was exercised in most areas through a type of tax farming imported from the Americas known as the *encomienda*. But abusive treatment of the native tribute payers and neglect of religious instruction by *encomenderos*, as well as frequent withholding of revenues from the crown, led to the abandonment of the system by the end of the 17th century. The governor general, himself appointed by the king, began to appoint his own civil and military governors to rule directly.

Central government in Manila retained a medieval cast until the 19th century, and the governor general was so powerful that he was often likened to an independent monarch. He dominated the Audiencia, or high court, was captain general of the armed forces, and enjoyed the privilege of engaging in commerce for private profit.

Manila dominated the islands not only as the political capital. The galleon trade with Acapulco, Mex., assured Manila's commercial primacy as well. This exchange of Chinese silks for Mexican silver kept in Manila those Spaniards seeking quick profit, and it also attracted a large Chinese community. The Chinese, despite periodic massacres at the hands of suspicious Spaniards, persisted and soon established a dominance of commerce that they have never relinquished.

Manila was also the ecclesiastical capital of the Philippines. The governor general was civil head of the church in the islands, but the archbishop vied with him for political

supremacy. In the late 17th and 18th centuries, buttressed with the legal status of lieutenant governor, the archbishop frequently won. Augmenting their political power, religious orders, Roman Catholic hospitals and schools, and bishops acquired great wealth, mostly in land. Royal grants and devises formed the core of their holdings, but many arbitrary extensions were made beyond the boundaries of the original grants.

The power of the church derived not simply from wealth and official status. The priests and friars had a command of native languages rare among lay Spaniards, and in the provinces they outnumbered civil officials. Thus, they were an invaluable source of information to the colonial government. The cultural goal of the Spanish clergy was nothing less than the full Christianization and Hispanization of the Filipino. In the first decades of missionary work, native animism was vigorously suppressed; old practices were not tolerated. But as the Christian laity grew in number and the zeal of the clergy waned, it became more and more difficult to prevent the preservation of ancient beliefs and customs under Roman Catholic garb. Thus, even in the area of religion, pre-Spanish Filipino culture was not entirely destroyed.

Economic and political institutions were also altered under Spanish impact but perhaps less thoroughly than in the religious realm. The priests tried to move all the people into *pueblos*, or villages, surrounding the great stone churches. But the dispersed demographic patterns of the old *barangays* largely persisted. Nevertheless, the *datu's* once hereditary position became subject to Spanish appointment.

Agricultural technology changed very slowly until the late 18th century, as shifting cultivation gradually gave way to more intensive sedentary farming, partly under the guidance of the friars. The socioeconomic consequences of the Spanish policies that accompanied this shift reinforced class differences. The *datos* and other representatives of the old noble class took advantage of the introduction of the Western concept of absolute ownership of land to claim, as their own, fields cultivated by their various retainers, even though traditional land rights had been limited to usufruct. These heirs of pre-Spanish nobility were known as the *principalia* and played an important role in the friar-dominated local government.

THE 19TH CENTURY

By the late 18th century, political and economic changes in Europe were finally beginning to affect Spain and, thus, the Philippines. Important as a stimulus to trade was the gradual elimination of the monopoly enjoyed by the galleon to Acapulco. The last galleon arrived in Manila in 1815, and by the mid-1830s Manila was open to foreign merchants almost without restriction. The demand for Philippine sugar and abaca, or hemp, grew apace, and the volume of exports to Europe expanded even further after the completion of the Suez Canal in 1869.

The growth of commercial agriculture resulted in the appearance of a new class. Alongside the landholdings of the church and the rice estates of the pre-Spanish nobility there arose haciendas of coffee, hemp, and sugar, often the property of enterprising Chinese-Filipino mestizos. Some of the families that gained prominence in the 19th century still play an important part in Philippine economics and politics.

Not until 1863 was there public education in the Philippines, and even then the church controlled the curriculum. Less than 20 percent of those who went to school could read and write Spanish, and far fewer could speak it properly. The limited higher education in the colony was entirely under clerical direction, but by the 1880s many sons of the wealthy were sent to Europe to study. There, nationalism and a passion for reform blossomed in the liberal atmosphere. Out of this talented group of overseas Filipino students arose the so-called Propaganda Movement. Magazines, poetry, and pamphleteering flourished. José Rizal, this movement's most brilliant figure, produced two political novels—*Noli me tangere* (1886; *The Social Cancer*) and *El filibusterismo* (1891; *The Reign of Greed*)—which had a wide impact in the Philippines.

The
encomienda

In 1892 Rizal returned home and formed the Liga Filipina, a modest reform-minded society, loyal to Spain, that breathed no word of independence. But Rizal was quickly arrested by the overly fearful Spaniards, exiled to a remote island in the south, and finally executed in 1896. Meanwhile, within the Philippines there had developed a firm commitment to independence among a somewhat less privileged class.

The Katipunan Shocked by the arrest of Rizal in 1892, these activists quickly formed the Katipunan under the leadership of Andres Bonifacio, a self-educated warehouseman. The Katipunan was dedicated to the expulsion of the Spaniards from the islands, and preparations were made for armed revolt. Filipino rebels had been numerous in the history of Spanish rule, but now for the first time they were inspired by nationalist ambitions and possessed the education that made success a real possibility.

THE PHILIPPINE REVOLUTION

In August 1896, Spanish friars uncovered evidence of the Katipunan's plans, and its leaders were forced into premature action. Revolts broke out in several provinces around Manila. After months of fighting, severe Spanish retaliation forced the revolutionary armies to retreat to the hills. In December 1897 a truce was concluded with the Spaniards. Emilio Aguinaldo, a municipal mayor and commander of the rebel forces, was paid a large sum and was allowed to go to Hong Kong with other leaders; the Spaniards promised reforms as well. But reforms were very slow in coming, and small bands of rebels, distrustful of Spanish promises, kept their arms; clashes grew more frequent.

Meanwhile, war had broken out between Spain and the United States. After the U.S. naval victory at Manila Bay in May 1898, Aguinaldo and his entourage returned to the Philippines with the help of Admiral George Dewey. Confident of U.S. support, he reorganized his forces and soon liberated several towns south of Manila. Independence was declared on June 12, which is now celebrated as Independence Day. In September a constitutional congress met in Malolos, north of Manila, drawing up a fundamental law derived from European and Latin-American precedents. A government was formed on the basis of that constitution in January 1899, with Aguinaldo as president.

Meanwhile, U.S. troops had landed and, with important Filipino help, forced the capitulation in August 1898 of the Spanish commander in Manila. The Americans, however, would not let Filipino forces enter the city. It was soon apparent to Aguinaldo and his advisers that earlier expressions of sympathy for Filipino independence by Dewey and U.S. consular officials had little significance. They felt betrayed.

U.S. commissioners to the peace negotiations in Paris had been instructed to demand the cession of the Philippines to the United States; such cession was confirmed with the signing of the peace treaty on Dec. 10, 1898. Ratification followed in the U.S. Senate in February 1899, but with only one vote more than the required two-thirds. Arguments of "manifest destiny" could not overwhelm a determined anti-imperialist minority.

By the time the treaty was ratified, hostilities had already broken out between American and Filipino forces. Since Filipino leaders did not recognize U.S. sovereignty over the islands and U.S. commanders gave no weight to Filipino claims of independence, the conflict was inevitable. It took two years of counterinsurgency warfare and some wise conciliatory moves in the political arena to break the back of the nationalist resistance. Aguinaldo was captured in March 1901 and shortly thereafter appealed to his countrymen to accept U.S. rule.

The Filipino revolutionary movement had had two goals, national and social. The first goal, independence, though realized briefly, was frustrated by the American decision to continue administering the islands. The goal of fundamental social change, manifest in the nationalization of friar lands by the Malolos Republic, was ultimately frustrated by the power and resilience of entrenched institutions. Share tenants who had rallied to Aguinaldo's cause, partly for economic reasons, merely exchanged one landlord for

another. In any case, the proclamation of a republic in 1898 had marked the Filipinos as the first Asian people to try to throw off European colonialism.

THE PERIOD OF U.S. INFLUENCE

The juxtaposition of U.S. democracy and imperial rule over a subject people was sufficiently jarring to most Americans that, from the beginning, the training of Filipinos for self-government and ultimate independence—the Malolos Republic was conveniently ignored—was an essential rationalization for U.S. hegemony in the islands. Differences between Democratic and Republican policies focused on the speed with which self-government should be extended and the date on which independence should be granted.

In 1899 President William McKinley sent Cornell University president Jacob G. Schurman at the head of a five-man fact-finding commission to the Philippines. Schurman reported back that Filipinos wanted ultimate independence, but this had no immediate impact on policy. McKinley sent out the Second Philippine Commission in 1900, under William Howard Taft; by July 1901 it had established civil government.

In 1907 the Philippine Commission, which had been acting as both legislature and governor general's Cabinet, became the upper house of a bicameral body. The new 80-member Philippine Assembly was directly elected by a somewhat restricted electorate from single-member districts, making it the first elective legislative body in Southeast Asia. When Governor General Francis B. Harrison appointed a Filipino majority to the Commission in 1913, the American voice in the legislative process was further reduced.

Harrison was the only governor general appointed by a Democratic president in the first 35 years of U.S. rule. He had been sent by Woodrow Wilson with specific instructions to prepare the Philippines for ultimate independence, a goal that he enthusiastically supported. During Harrison's term, a Democratic Congress in Washington hastened to fulfill long-standing campaign promises to the same end. The Jones Act, passed in 1916, would have fixed a definite date for the granting of independence if the Senate had had its way, but the House prevented such a move. In its final form the act merely stated that it was the "purpose of the people of the United States" to recognize Philippine independence "as soon as a stable government can be established therein." Its greater importance was as a milestone in the development of Philippine autonomy. Under Jones Act provisions, the Commission was abolished and was replaced by a 24-member Senate, almost wholly elected. The electorate was expanded to include all literate males.

Some substantial restrictions on Philippine autonomy remained, however. Defense and foreign affairs remained exclusive U.S. prerogatives. American direction of Philippine domestic affairs was exercised primarily through the governor general and the executive branch of insular government. There was little more than one decade of thoroughly U.S. administration in the islands, however—too short a time in which to establish lasting patterns. Whereas Americans formed 51 percent of the civil service in 1903, they were only 29 percent in 1913 and 6 percent in 1923. By 1916 Filipino dominance in both the legislative and judicial branches of government also served to restrict the U.S. executive and administrative roles.

By 1925 the only American left in the governor general's Cabinet was the secretary of public instruction, who was also the lieutenant governor general. This is one indication of the high priority given education in U.S. policy. In the first few years of U.S. rule, hundreds of schoolteachers came from the United States. But Filipino teachers were trained so rapidly that by 1927 they constituted nearly all of the 26,200 in public schools. The school population expanded fivefold in a generation; education consumed one-half of governmental expenditures at all levels, and educational opportunity in the Philippines was greater than in any other colony in Asia.

As a consequence of this pedagogical explosion, literacy doubled to nearly 50 percent in the 1930s, and educated

War against the United States

U.S. education-policy

Filipinos acquired a common language and a linguistic key to Western civilization. By 1939, 27 percent of the population could speak English, a larger percentage than for any of the native dialects. Perhaps more important was the new avenue of upward social mobility that education offered. In educational policy was found the only successful U.S. effort to establish a socio-cultural basis for political democracy.

American attempts to create equality of economic opportunity were more modest and less successful. In a predominantly agricultural country the pattern of landownership is crucial. The trend toward greater concentration, which began in the 19th century, continued during the American period, despite some legal barriers. Vast American-owned plantations were forestalled, but legal restrictions had little effect on those politically well-connected Filipinos who were intent on amassing fortunes. The percentage of farmers under share tenancy doubled between 1900 and 1935; and the frustration of the tenants erupted in three small rebellions in central Luzon during the 1920s and 1930s.

Nor was U.S. trade policy conducive to the diffusion of economic power. From 1909 the Payne-Aldrich Tariff Act allowed free entry of Philippine products into the U.S. market; at the same time U.S. products, mostly manufactured, were exempted from tariff in the Philippines. The free flow of U.S. imports was a powerful deterrent to industrial growth. Export agriculture, especially sugar, prospered in the protected U.S. market. Owners of mills and large plantations profited most, thus reinforcing the political dominance of the landed elite.

American preparation of the Philippines for democratic self-government suffered from an inherent contradiction, perhaps not recognized at the time. Transferring governmental responsibility to those capable of undertaking it was not consistent with building a social and economic base for political democracy. Self-government meant, of necessity, assumption of power by those Filipinos who were already in positions of leadership in society. But these men came for the most part from the landed elite; preservation of their political and economic position was incompatible with equalization of opportunity. Even the expansion of an educated middle class did not necessarily result in a transformation of the pattern of power. Most middle-class aspirants for political leadership adjusted to the values and the practices of the existing power elite.

Formation
of political
parties

Filipino leaders quickly and skillfully utilized the opportunities for self-government that the Americans opened to them. The Filipino political genius was best reflected in an extralegal institution—the political party. The first party, the Federal Party, was U.S.-backed and stressed cooperation with the overlords, even to the point of statehood for the Philippines. But, when openly nationalist appeals were allowed in the 1907 election, the Nacionalista Party, advocating independence, won overwhelmingly. The Federalists survived with a new name, Progressives, and a new platform, ultimate independence after social reform. But neither the Progressives nor their successors in the 1920s, the Democrats, ever gained more than one-third of the seats in the legislature. The Nacionalista Party under the leadership of Sergio Osmeña and Manuel Quezon dominated Philippine politics from 1907 until independence.

More significant than the competition between the Nacionalistas and their opposition was the continuing rivalry between Osmeña and Quezon. In fact, understanding this personality conflict provides more insight into the realities of prewar Philippine politics than any examination of policy or ideology.

In 1933 the U.S. Congress passed the Hare-Hawes-Cutting Act, which set a date for Philippine independence. The act was a fulfillment of the vague pledge in the Jones Act; it was also responsive to the demands of a series of “independence missions” sent to Washington by the Philippine legislature. But this unprecedented transfer of sovereignty was decided upon in the dark days of the Great Depression—and with the help of some incongruous allies. The Depression had caused American farm interests to look desperately for relief, and those who suffered real or imaginary hurt from the competition of Philippine products sought to exclude those products. They had al-

ready failed in a direct attempt to amend the tariff on Philippine imports but found that the respectable cloak of the advocacy of independence increased the effectiveness of their efforts. Tied to independence was the end of free entry into American markets of Philippine sugar, coconut oil, rope, and other less important items. That these economic interests were able to accomplish what they did is partly explainable by the fact that their political clout was great compared to that of the small group of American traders and investors in the Philippines.

The Philippine legislature rejected the Hare-Hawes-Cutting Act, apparently as a result of the Osmeña-Quezon feud, much to the displeasure of American officialdom. But, when Quezon came to Washington the following year to work for a new bill, the same alliance of forces in the U.S. Congress obliged by producing the almost identical Tydings-McDuffie Act. It was endorsed by Quezon and accepted with alacrity by the Manila legislature. It provided for a 10-year commonwealth during which the U.S. would retain jurisdiction over defense and foreign affairs. Filipinos were to draft their own constitution, subject to the approval of the U.S. president.

A constitutional convention was quickly elected, a constitution framed (which bore a strong resemblance to its U.S. model), and the document approved by plebiscite and by President Franklin D. Roosevelt. The last governor general, Frank Murphy, became the first high commissioner, with more of a diplomatic than a governing role. The commonwealth was inaugurated on Nov. 15, 1935. The Nacionalista Party patched up its internal quarrels and nominated Quezon for president and Osmeña for vice president. They were elected overwhelmingly.

The commonwealth period was intended to be devoted to preparation for economic and political independence and perfection of democratic institutions. But even before the tragic events of 1941 the transition did not run smooth.

The
Common-
wealth

WORLD WAR II

Japanese aggression in China prompted much attention to military preparedness. Nearly one-fourth of the national budget was devoted to defense. General Douglas MacArthur, retiring as army chief of staff in Washington, was called by President Quezon to direct plans and preparations. Meanwhile, agrarian unrest festered, and leftist political activity grew. Quezon pushed significant reform legislation through the National Assembly, but implementation was feeble, despite the rapid accumulation of power in his hands.

The Japanese attack of Dec. 8, 1941, came at a time when the U.S. military buildup had hardly begun. Before Christmas, Manila was declared an “open city,” while Quezon and Osmeña were evacuated to MacArthur’s headquarters on Corregidor. Despite a desire, at one point, to return to Manila in order to surrender, Quezon was persuaded to leave the Philippines in March on a U.S. submarine; he was never to return. Osmeña also went. Filipino and American forces, under General Jonathan M. Wainwright, surrendered in May 1942. An Executive Commission, made up of more than 30 members of the old Filipino political elite, had been cooperating with Japanese military authorities in Manila since January.

The Executive Commission lasted until September 1943, when it was superseded by an “independent Philippine Republic.” The president, chosen by the Japanese, was José Laurel, former associate justice of the Commonwealth Supreme Court and the only Filipino to hold an honorary degree from Tokyo Imperial University. More than half of the Commonwealth Senate and more than one-third of the House served at one time in the Japanese-sponsored regime. Yet collaboration with Japan was neither as willing nor as widespread as elsewhere in Southeast Asia.

Even before the fall of Bataan Peninsula in April 1942, guerrilla units were formed throughout the Philippines. Most were led by middle-class officers and were enthusiastically pro-United States; in central Luzon, however, a major force was the Hukbalahap, which, under Communist leadership, capitalized on earlier agrarian unrest. Though in a number of instances collaborators secretly assisted guerrillas, many guerrillas in the hills were bitter

The
“independ-
ent
Philippine
Republic”
under the
Japanese

against those who appeared to benefit from the occupation. The differences between the two groups became an important factor in early postwar politics.

Soon after the U.S. landings on Leyte in October 1944, commanded by MacArthur, civil government was returned to the Commonwealth, at least in name. Sergio Osmeña, who had become president in exile on the death of Quezon in August, had few resources to deal with the problems at hand, however. Osmeña's role was complicated by the fact that MacArthur chose to lionize a leading collaborator who had also been in contact with U.S. military intelligence, Manuel A. Roxas. As president of the Senate, Roxas became, in effect, MacArthur's candidate for president. Roxas was nominated in January 1946 in a separate convention of the "liberal wing" of the Nacionalista Party, as it was first called. Thus was born the Philippines' second major political party, the Liberals.

Osmeña, though he had the advantages of incumbency, was old and tired and did not fully use the political tools he possessed. In April, Roxas was elected by a narrow margin. The following month he was inaugurated as the last chief executive of the Commonwealth, and on July 4, when the Republic of the Philippines was proclaimed, he became its first president.

THE EARLY REPUBLIC

Roxas, as expected, extended amnesty to all major collaborators with Japan. In the campaign for the election of 1949 there was an attempt to raise the collaboration issue against José Laurel, the Nacionalista presidential candidate, but it was not effective. In the fluidity of Philippine politics, "guerrillas" and "collaborators" were by that time to be found on both sides of all political fences.

The Philippines had gained independence in the "ashes of victory." Intense fighting, especially around Manila in the last days of the Japanese retreat, had nearly destroyed the capital. The economy generally was in disarray. Rehabilitation aid was obviously needed, and President Roxas was willing to accept some onerous conditions placed implicitly and explicitly by the U.S. Congress. The Bell Act in the United States extended free trade with the Philippines for eight years, to be followed by 20 years of gradually increasing tariffs. The United States demanded and received a 99-year lease on a number of Philippine military and naval bases in which U.S. authorities had virtual territorial rights. And finally, as a specific requirement for release of U.S. war-damage payments, the Philippines had to amend its constitution to give U.S. citizens equal rights with Filipinos in the exploitation of natural resources—the so-called Parity Amendment.

The changing character of Philippine-U.S. relations has been a major theme in postwar Philippine history. The trend has been toward weakening of the link, achieved partly by diversification of Philippine external ties and partly by more articulate anti-American feeling. Economic nationalism, though first directed against the local Chinese community's dominance of retail trade, by the 1950s was focused on the special status of American business firms.

At independence, the military ties with the United States were as strong as the economic ones. Filipino troops fought against Communist forces in Korea, and noncombatant engineers augmented U.S. forces in the Vietnam War. Crucial to U.S. military action in Vietnam were bases in the Philippines. The Military Bases Agreement has been the greatest single cause of friction in relations between the United States and the Philippines. Since 1965, however, a series of agreements between the two countries have reduced the size and number of the U.S. bases and shortened base leases. In 1979 formal jurisdiction over the base areas passed to the Philippine government; and the constitution of 1987 formalized the process by which the bases agreement could be extended beyond the expiration in 1991 of base leases.

The nature and effectiveness of Filipino political institutions since independence has been a special concern of the former colonial power that helped establish them. For Filipinos, those institutions have determined the ability or inability to maintain domestic social order. Clumsy repression of dissent and the fraudulent election of the nation's

second president, Elpidio Quirino, in 1949 set the stage for an intensification of the Communist-led Hukbalahap (Huk) Rebellion, which had begun in 1946. The rebellion also reflected a growing sense of social injustice among tenant farmers, especially in central Luzon. Suppression of the rebellion five years later, however, was attributable to American military aid as well as to the opening of the political process to greater mass participation, particularly during the campaign of Ramon Magsaysay, a uniquely charismatic figure in Filipino politics who was elected president in 1953. Magsaysay's attempts at social and economic reform failed largely because of the conservative outlook of the legislature and the bureaucracy. When Magsaysay died in a plane crash in 1957, leadership of the country fell to his vice president, Carlos P. Garcia. During Garcia's presidential term, and that of his reform-minded successor, Diosdado Macapagal (1961–65), unrest was usually channeled through the electoral process and peaceful protest.

THE MARCOS REGIME AND AFTER

In November 1965, Ferdinand E. Marcos was elected to the presidency. His administration faced grave economic problems that were exacerbated by corruption, tax evasion, and smuggling.

In 1969 Marcos became the first elected president of the Philippines to win reelection. His campaign platform included the renegotiation of major treaties with the United States and trade with Communist countries. These promises reflected a change in the self-concept of the nation during the 1960s. The idea of the Philippines as an Asian outpost of Christianity was increasingly rejected in favour of the development of Asian cultural identity. Artists, musicians, and writers began to look to pre-Spanish themes for inspiration. More important was the trend toward seeking cultural identity through the national language, Pilipino. English remained the language of business, of most government documents, and of the greater part of university education. Demands that the government meet the social and economic needs of its citizenry continued.

A short-lived sign that the Filipino political system was again attempting to respond constructively to those needs was the choosing in 1970 of a widely representative Constitutional Convention in one of the most honest and peaceful elections in Philippine history. Large student demonstrations urged the convention to undertake a fundamental restructuring of political power.

Marcos, who was approaching the end of his constitutionally delimited eight years in office, had narrower goals: he pressed for the adoption of the parliamentary style of government, which would allow him to remain in power. He feared that the new constitution would not come into force before he lost the advantages of incumbency. At the same time, foreign investors, predominantly American, felt increased pressure from economic nationalists in the legislature.

Martial law. In September 1972 Marcos declared martial law, claiming that it was the last defense against the rising disorder caused by increasingly violent student demonstrations. One of his first actions was to arrest opposition politicians in Congress and the Constitutional Convention. Under martial law the regime was able to reduce violent urban crime, collect unregistered firearms, and suppress Communist insurgency in some areas. At the same time, a series of important new concessions were given to foreign investors, including a prohibition on strikes by organized labour, and a land-reform program was launched. In January 1973 Marcos proclaimed the ratification of a new constitution based on the parliamentary system, with himself as both president and prime minister. He did not, however, convene the interim legislature that was called for in the constitution.

Initial public reaction to martial law was mostly favourable except in Muslim areas of the south, where a separatist rebellion, led by the Moro National Liberation Front, broke out in 1973. Despite half-hearted attempts to negotiate a cease-fire, the rebellion continued to claim thousands of military and civilian casualties. Communist insurgency spread to new areas.

Rebellion

Situation
at inde-
pendence

General disillusionment with martial law and with the consolidation of political and economic control by Marcos, his family, and close associates grew during the 1970s. Despite growth in the gross national product, workers' real income dropped, few farmers benefited from land reform, and the sugar industry was in confusion. The precipitous drop in sugar prices in the early 1980s, coupled with lower prices and demand for coconuts and coconut products—traditionally the most important export commodity—added to the country's economic woes; the government was forced to borrow large sums from the international banking community. Reports of widespread corruption began to surface with increasing frequency.

Elections for an interim National Assembly were finally held in 1978. The opposition—of which the primary group was led by the jailed former senator Benigno S. Aquino, Jr.—produced such a bold and popular campaign that the official results, which gave Marcos' opposition virtually no seats, were widely believed to have been illegally altered. In 1980 Aquino went into exile in the United States, and the following year, after announcing the suspension of martial law, Marcos won a virtually uncontested election for a new six-year term.

The downfall of Marcos and return of democratic government. The assassination of Aquino as he returned to Manila in August 1983 was generally thought to have been the work of the military; it became the focal point of a renewed and more heavily supported opposition to Marcos' rule. By late 1985 Marcos, under mounting pressure both inside and outside the Philippines, called a snap presidential election for February 1986. Corazon C. Aquino, Benigno's widow, became the candidate of a coalition of opposition parties. Marcos was declared the official winner; but strong public outcry over the election results precipitated a revolt that by the end of the month had driven Marcos from power. Aquino then assumed the presidency.

Euphoria over the ouster of Marcos proved to be short-lived. The new government was faced with an enormous external debt, a severely depleted economy, and a growing threat from Moro and Communist insurgents. The Aquino administration also had to weather considerable internal dissension and repeated coup attempts during its early years in power. Aquino's great personal popularity and widespread international support were instrumental in establishing the new government. Shortly after taking office she abolished the constitution of 1973 and began ruling by decree. A new constitution was drafted and was ratified in February 1987 in a general referendum; legislative elections in May and the convening of a new bicameral congress in July marked the return of the form of government that had been present before the imposition of martial law in 1972.

The resumption of active partisan politics, however, was the beginning of the end of the coalition that had brought Aquino to power. Pro-Aquino candidates had won a sweeping victory in the 1987 legislative elections, but there was less support for her among those elected to provincial and local offices in early 1988.

Philosophical Anthropology

The word anthropology was first used in the philosophical faculties of German universities at the end of the 16th century to refer to the systematic study of man as a physical and moral being. Philosophical anthropology is thus, literally, the systematic study of man conducted within philosophy or by the reflective methods characteristic of philosophy; it might in particular be thought of as being concerned with questions of the status of man in the universe, of the purpose or meaning of human life, and, indeed, with the issues of whether there is any such meaning and of whether man can be made an object of systematic study. What actually falls under the term philosophical anthropology, however, varies with conceptions of the nature and scope of philosophy. The fact that such disciplines as physics, chemistry, and biology—which are now classified as natural sciences—were until the 19th century all branches of natural philosophy serves as a reminder that conceptions of philosophy have changed.

Twentieth-century readings of philosophical anthropology are much narrower than those of previous centuries. Four possible meanings are now accepted: (1) the account of man that is contained in any comprehensive philosophy; (2) a particular philosophical orientation known as humanism (see HUMANISM), in which the study of man

provides the foundation for all else—a position that has been prominent since the Renaissance; (3) a distinctive, 20th-century form of humanism that on occasion has claimed the label of “philosophical anthropology” for itself and that has taken the human condition, the personal being-in-the-world, as its starting point; and (4) any study of man that is regarded as unscientific. Philosophical anthropology has been used in the last sense by 20th-century antihumanists for whom it has become a term of abuse; antihumanists have insisted that if anthropology is to be possible at all it is possible only on the condition that it rejects the concept of the individual human subject. Humanism, in their eyes, yields only a prescientific, and hence a philosophical (or ideological), nonscientific anthropology.

By tracing the development of the philosophy of man, it will thus be possible to deal, in turn, with the four meanings of philosophical anthropology. First, however, it is necessary to discuss the concept of human nature, which is central to any anthropology and to philosophical debates about the sense in which and the extent to which man can be made an object of systematic, scientific study.

THE CONCEPT OF HUMAN NATURE

The concept of human nature is a common part of everyday thought. The ordinary person feels that he comes to know human nature through the character and conduct of the people he meets. Behind what they do he recognizes qualities that often do not surprise him: he forms expectations as to the sort of qualities possessed by other human beings and about the ways they differ from, for example, dogs or horses. People are proud, sensitive, eager for recognition or admiration, often ambitious, hopeful or despondent, and selfish or capable of self-sacrifice. They take satisfaction in their achievements, have within them something called a conscience, and are loyal or disloyal. Experience in dealing with and observing people gives rise to a conception of a predictable range of conduct; conduct falling outside the range that is considered not to be worthy of a human is frequently regarded as inhuman or bestial whereas that which is exceptional—in that it lives up to standards which most people recognize but few achieve—is regarded as superhuman or saintly.

The common conception of human nature thus implicitly locates man on a scale of perfection, placing him somewhere above most animals but below saints, prophets, or angels. This idea was embodied in the theme, Hellenic in origin, of the Great Chain of Being—a hierarchical order ascending from the most simple and inert to the most complex and active: mineral, vegetable, animal, man, and finally divine beings superior to man. In the Middle Ages these divine beings constituted the various orders of angels, with God as the single, supremely perfect and omnipotent, ever-active being. There was a tendency in this theory to take for granted the commonality among all human be-

ings, something by virtue of which they could be classified as fully human, which differentiates them from all other animals, and which gives them their place in the order of things. Yet, as with many notions that are habitually employed, the request for a precise definition of “human nature” proves highly problematic.

The Greeks—most notably Plato and Aristotle—introduced the notion of form, nature, or essence as an explanatory, metaphysical concept. Variations on this concept were central to Western thought until the 17th century. Observation of the natural world raised the question of why creatures reproduced after their kind and could not be interbred at will and of why, for example, acorns grew into oaks and not into roses. To explain such phenomena it was postulated that the seeds, whether plant or animal, must each already contain within them the form, nature, or essence of the species from which they were derived and into which they would subsequently develop. This pattern of explanation is preserved in the modern biological concept of a genetic code that is embodied in the DNA molecular structure of each cell. There are important differences, however, between the modern concept of a genetic code and the older, Greek-derived concept of form or essence.

First, biologists are now able to locate, isolate, experimentally analyze, and manipulate DNA molecules in what has become known as genetic engineering. Being the structures responsible for physical development, DNA molecules represent the terms by which man can be biologically characterized. Forms or essences, on the other hand, were not observable; if they were granted any independent existence, it was as immaterial entities. The form, nature, or

essence of man or of any other kind of being was posited as a principle present in the thing, determining its kind by producing in it an innate tendency to strive to develop into a perfect example of itself—to fulfill its nature and to realize its full potential as a thing of a given kind. This gave rise to a teleological, or purposive, view of the natural world in which developments were explained by reference to the goal toward which each natural thing, by its nature, strives; *i.e.*, by reference to the ideal form it seeks to realize. By contrast, the genetic structure present in each cell is now invoked to explain the subsequent development of an organism in a “mechanistic” and nonpurposive way, in which development is shown to be dependent upon and determined by preexisting structures and conditions.

Second, genetic mutability forms an essential part of modern evolutionary biology. Not only are there genetic differences between individuals of a given species to account for differences between them in features, such as coloration, but random genetic mutation in the presence of changing environmental conditions may result in alterations to the genetic constitution of the species as a whole. Thus, in evolutionary biological theory species are not stable; natural kinds do not have the fixed, immutable forms or essences characteristic of biology before the advent of evolutionary theory.

Within either framework, if human nature is understood simply as man’s special form of that which is biologically inherited in all species, there remains the delicate problem of discovering, in any given case, exactly what role environment plays in determining the actual characteristics of mature members of the species. Even in the case of purely physiological characteristics this may be far from straightforward: for example, the extent to which diet, exercise, and conditions of work determine such things as susceptibility to heart disease and cancer remains the subject of intensive scientific investigation. In the case of behavioral and psychological characteristics, such as intelligence, the problems are multiplied to the point where they are no longer problems that can be answered by purely empirical investigation. There is room for much conceptual debate about what is meant by intelligence and over what tests, if any, can be supposed to yield a direct measure of this capacity, and thus provide evidence that an individual’s level of intelligence is determined at birth (by nature) rather than by subsequent exposure to the environment (nurture) that conditions the development of all his capacities.

This debate—whether the variation in intelligence levels is a product of the conditions into which people all having the same initial potential are born, or whether it is a reflection of variations in the capacities with which they are born—is very closely related to the question of whether there is such a thing as human nature common to all human beings, or whether there are intrinsic differences among those whom we recognize as belonging to the biological species *Homo sapiens*. This is because, as the name *Homo sapiens* suggests, man is traditionally thought to be distinguished from and privileged above other animals by virtue of his possession of reason, or intellect. When the intellect is positively valued as that which is distinctively human and which confers superiority on man, the thought that different races of people differ by nature in their intellectual capacities has been used as a justification for a variety of racist attitudes and policies. Those of another race, of supposedly lesser intellectual development, are classified as less than fully human and therefore as needing to be accorded less than full human rights. Similarly, the thought that women are by nature intellectually inferior to men has been used as a justification for their domination by men, for refusing them education, and even for according them the legal status of property owned by men. On the other hand, if differences in adult intellectual capacity are regarded as a product of the circumstances in which potentially similar people are brought up, the attitude is to consider all as equally human but some as having been more privileged when growing up than others.

More radically, the evidence for variations in intelligence levels may be questioned by challenging the objectivity of the standards relative to which these levels are assessed. It may be argued that conceptions of what constitutes a ra-

tional or intelligent response to a situation or to a problem are themselves culturally conditioned, a product of the way in which the members of the group devising the tests and making the judgments have themselves been taught to think. Such an argument has the effect of undermining claims by any one human group to intellectual superiority over others, whether these others be their contemporaries or their own forebears. Hence, they may also be used to discredit any idea of a progressive development of human intellectual capacities.

These debates about intelligence and rationality provide an example of the complexity of the impact of evolutionary biology on conceptions of human nature, for the dominant traditions in Western thought about human nature have tended to concentrate attention more on what distinguishes man from other animals than on the strictly biological constitution that he largely shares with them. Possession of reason or intellect is far from being the only candidate considered for such a distinguishing characteristic. Man has been characterized as essentially a tool user, or fabricator (*Homo faber*), as essentially social, as essentially a language user, and so on. These represent differing views concerning the fundamental feature that gives rise to all the other qualities regarded as distinctively human and which serve to mark man off from other animals. These characteristics all centre on mental, intellectual, psychological—*i.e.*, nonphysiological—characteristics and thus leave scope for debate about the relation between mind and body. So long as this question remains open, and so long as mental or intellectual constitution remains the central consideration in discussions of human nature, the question of changes in—and of the possible evolution of—human nature will remain relatively independent of those devoted to physiological change and hence of strictly biological evolution.

Until the 15th century the standard assumption was that man had a fixed nature, one that determined both his place in the universe and his destiny. The Renaissance humanists, however, proclaimed that what distinguishes man from all other creatures is that he has no nature. This was a way of asserting that man’s actions are not bound by laws of nature in the way that those of other creatures are. Man is capable of taking responsibility for his own actions because he has the freedom to exercise his will. This view received two subsequent interpretations.

First, the human character is indefinitely plastic; each individual is given determinate form by the environment in which he is born, brought up, and lives. In this case, changes or developments in human beings will be regarded as the product of social or cultural changes, changes that themselves are often more rapid than biological evolution. It is thus to disciplines such as history, politics, and sociology, rather than to biology, that one should look for an understanding of these processes. But if disciplines such as these must constitute the primary study of man, then the question of the extent to which this can be a strictly scientific study arises. The methods of history are not, and cannot be, those of the natural sciences. And the legitimacy of the claims of the so-called social or human sciences to genuine scientific status has frequently been called into question and remains a focus for debate.

Second, each individual is autonomous and must “make” himself. Assertion of the autonomy of man involves rejection of the possibility of discovering laws of human behaviour or of the course of history, for freedom is precisely not being bound by law, by nature. In this case, the study of man can never be parallel to the natural sciences with their theoretical structures based on the discovery of laws of nature.

(M.E.T.)

HISTORICAL BACKGROUND OF THE PHILOSOPHY OF MAN

In the tradition of Western thought up to the 20th century, the study of man has been regarded as a part of philosophy. Two sayings that have been adopted as mottoes by those who see themselves as engaged in philosophical anthropology date from the 5th century B.C. These are: “Man is the measure of all things” (Protagoras) and “Know thyself” (a saying from the Delphic oracle, echoed by Heraclitus and Socrates, among others). Both reflect

Human
nature

Intelligence

the specific orientation of philosophical anthropology as humanism, which takes man as its starting point and treats man and the study of man as the centre, or origin, on which all other disciplines ultimately depend.

Man, the world, and God have constituted three important foci of Western thought from the beginnings of its recorded history; the relative significance of these three themes, however, has varied from one epoch to another. Western thought has laid greater stress on the existence of the individual human being than have the great speculative systems of the East; in Brahmanism, for example, personal identity dissolves in the All. But even so it was not until the Renaissance that man became the primary focus of philosophical attention and that the study of human nature began to displace theology and metaphysics as "first philosophy"—the branch of philosophy that is regarded as forming the foundation for all subsequent philosophy and that provides the framework for all scientific investigation.

Ancient Greece. From late antiquity onward differing views of man were worked out within a framework that was laid down and given initial development by Plato and later by Aristotle. Plato and Aristotle concurred in according to metaphysics the status of first philosophy. Their differing views of man were a consequence of their differing metaphysical views.

Plato's metaphysics was dualistic: the everyday physical world of changeable things, which man comes to know by the use of his senses, is not the primary reality but is a world of appearances, or phenomenal manifestations, of an underlying timeless and unchanging reality, an immaterial realm of Forms that is knowable only by use of the intellect. This is the view expressed in the *Republic* in his celebrated metaphor of the cave, where the changeable physical world is likened to shadows cast on the wall of a cave by graven images. To know the real world the occupants of the cave must first turn around and face the graven images in the light that casts the shadows (*i.e.*, use their judgment instead of mere fantasy) and, second, must leave the cave to study the originals of the graven images in the light of day (stop treating their senses as the primary source of knowledge and start using their intellects). Similarly, human bodily existence is merely an appearance of the true reality of human being. The identity of a human being does not derive from the body but from the character of his or her soul, which is an immaterial (and therefore nonsexual) entity, capable of being reincarnated in different human bodies. There is thus a divorce between the rational/spiritual and the material aspects of human existence, one in which the material is devalued.

Aristotle, however, rejected Plato's dualism. He insisted that the physical, changeable world made up of concrete individual substances (people, horses, plants, stones, etc.) is the primary reality. Each individual substance may be considered to be a composite of matter and form, but these components are not separable, for the forms of changeable things have no independent existence. They exist only when materially instantiated. This general metaphysical view, then, undercut Plato's body-soul dualism. Aristotle dismissed the question of whether soul and body are one and the same as being as meaningless as the question of whether a piece of wax and the shape given to it by a seal are one. The soul is the form of the body, giving life and structure to the specific matter of a human being. According to Aristotle, all human beings are the same in respect to form (that which constitutes them as human), and their individual differences are to be accounted for by reference to the matter in which this common form is variously instantiated (just as the different properties of golf and squash balls are derived from the materials of which they are made, while their common geometrical properties are related to their similar size and shape). This being so, it is impossible for an individual human soul to have any existence separate from the body. Reincarnation is thus ruled out as a metaphysical impossibility. Further, the physical differences between men and women become philosophically significant, the sex of a person becoming a crucial part of his or her identity.

Although Plato and Aristotle gave a different metaphys-

ical status to forms, their role in promoting and giving point to investigations of human nature was very similar. They both agreed that it is necessary to have knowledge of human nature in order to determine when and how human life flourishes. It is through knowledge of shared human nature that we become aware of the ideals at which we should aim, achieved by learning what constitutes fulfillment of our distinctively human potential and the conditions under which this becomes possible. These ideals are objectively determined by our nature. But we are privileged in being endowed with the intellectual capacities that make it possible for us to have knowledge of this nature. Development of our intellectual capacities is thus a necessary part and precondition of a fulfilled human existence.

Medieval period. Western medieval culture was dominated by the Christian Church. This influence was naturally reflected in the philosophy of the period. Theology, rather than metaphysics, tended to be given primacy, even though many of the structures of Greek philosophy, including its metaphysics, were preserved. The metaphysics of form and matter was readily assimilable into Christian thought, where forms became ideas in the mind of God, the patterns according to which he created and continues to sustain the universe. Christian theology, however, modified the positions, requiring some sort of compromise between Platonic and Aristotelian views. The creation story in the book of Genesis made man a creature among other creatures, but not a creature like other creatures; man was the product of the final act of divine initiative, was given responsibility for the Garden of Eden, and had the benefit of a direct relationship with his creator. The Fall and redemption, the categories of sin and grace, thus concern only the descendants of Adam, who were given a nature radically different from that of the animals and plants over which they were given dominion. Man alone can, after a life in this world, hope to participate in an eternal life that is far more important than the temporal life that he will leave. Thus, belief in a life after death makes it impossible to regard man as wholly a natural being and entails that the physical world now inhabited by man is not the sole, or even the primary, reality. Yet, the characteristically Christian doctrine of the resurrection of the body also entails that the human body cannot be regarded as being of significance only in the mortal, physical world.

Against the background of these constraints, Christian philosophy first, through the writings of St. Augustine, gave prominence to Platonic views. But this emphasis was superseded in the 12th century by the Aristotelianism of St. Thomas Aquinas. Augustine's God is a wholly immaterial, supremely rational, transcendent creator of the universe. The twofold task of the Christian philosopher, a lover of wisdom, is to seek knowledge of the nature of God and of his own soul, the human self. For Augustine the soul is not the entire man but his better part. There remains a Platonic tendency to regard the body as a prison for the soul and a mark of man's fallen state. One of the important consequences of Augustine's own pursuit of these two endeavours was the emphasis he came to place on the significance of free will. He argued that since the seat of the will was reason, when people exercise their will, they are acting in the image of God, the supreme rational being. Thomas Aquinas, while placing less emphasis on the will, also regarded man as acting in the image of God to the extent that he exercises and seeks to fulfill his intelligent nature. But he rejected the Platonic tendency to devalue the body, insisting that it is part of the concept of man that he have flesh and bone, as well as a soul.

But whatever the exact balance struck in the relation between the mind and body, the view of man was first and foremost as a creature of God; man was privileged by having been created in the image of God and given the gift of reason in virtue of which he also has free will and must take the burden of moral responsibility for his own actions. In order to fulfill his distinctively human nature man must thus order his thoughts and actions in such a way as to reflect the supremacy of religious values.

In popular medieval culture there was also, however, a strong undercurrent of thoroughly fatalistic thought. This

Man as a creature of God

was reflected in the popularity of astrology and alchemy, both of which appealed to the idea that events on Earth are governed by the influence of the heavenly bodies.

Renaissance. It was in the cultural context of the Renaissance, and in particular with the Italian humanists and their imitators, that the centre of gravity of reflective thought descended from heaven to earth, with man, his nature, and his capacities and limitations becoming a primary focus of philosophical attention. This gave rise to the humanism that constitutes philosophical anthropology in the second sense. Man did not thereby cease to view himself within the context of the world, nor did he deny the existence of God; he did, however, disengage himself sufficiently from the bonds of cosmic determination and divine authority to become a centre of interest in his own eyes. In ancient literature the educated people of the West rediscovered a clear conscience instead of the guilty conscience of Christianity; at the same time, the great inventions and discoveries suggested that man could take pride in his accomplishments and regard himself with admiration. The themes of the dignity and excellence of man were prominent in Italian humanist thought and can be found clearly expressed in Giovanni Pico della Mirandola's influential *De hominis dignitate oratio* (Oration on the Dignity of Man), written in 1486. In this work Pico expresses a view of man that breaks radically with Greek and Christian tradition: what distinguishes man from the rest of creation is that he has been created without form and with the ability to make of himself what he will. Being without form or nature he is not constrained, fated, or determined to any particular destiny. Thus, he must choose what he will become. (In the words of the 20th-century existentialists, man is distinguished by the fact that for him existence precedes essence.) In this way man's distinctive characteristic becomes his freedom; he is free to make himself in the image of God or in the image of beasts.

This essentially optimistic view of man was a product of the revival of Neoplatonist thought. Its optimism is based on a view of man as at least potentially a nonnatural, godlike being. But this status is now one that must be earned; man must win his right to dominion over nature and in so doing earn his place beside God in the life hereafter. He must learn both about himself and about the natural world in order to be able to achieve this. This was, however, only one of two streams of humanist thought. The other (more Aristotelian) was essentially more pessimistic and skeptical, stressing the limitations on man's intellectual capacities. There is an insistence on the need to be reconciled to the fact of man's humanity rather than to persist in taking seriously his superhuman pretensions and aspirations. These two differently motivated movements to focus attention on man himself, on his nature, his abilities, his earthly condition, and his relation to his material environment became more clearly articulated in the 16th and 17th centuries in the opposition between the rationalist and empiricist approaches to philosophy.

THE 16TH AND 17TH CENTURIES: THE RISE OF SCIENTIFIC THOUGHT

Rationalism versus skepticism. The thought of Michel de Montaigne, the 16th-century French skeptical author of the *Essays* (1580–95; *Essays*), represented one of the first attempts at anthropological reflection (i.e., reflection centred on man, which explores his different aspects in a spirit of empirical investigation that is freed from all ties to dogma). Skepticism, the adoption of an empirical approach, and liberation from dogmatic authority are linked themes stemming from the more pessimistic views of man's capacity for knowledge. The emphasis on man's humanity—on the limited nature of his capacities—leads to a denial that he can, even by the use of reason, transcend the realm of appearances; the only form of knowledge available to him is experimental knowledge, gained in the first instance by the use of the senses. The effect of this skeptical move was twofold. The first effect was a liberation from the dogmatic authority of claims to knowledge of a reality behind appearances and of moral codes based on them; skeptical arguments were to the effect that human beings are so constituted that such knowledge must

always be unavailable to them. The second effect was a renewal of attention to and interest in the everyday world of appearances, which now becomes the only possible object of human knowledge and concern. The project of seeking knowledge of a reality behind appearances must be abandoned because it is beyond the scope of human understanding. And this applies as much to man himself as to the rest of the natural world; he can be known only experientially, as he appears to himself.

The anthropology of Montaigne began with a turning in upon himself; it gave priority to that reality which was within. Montaigne, however, was also witness to a renewal of knowledge brought about by numerous discoveries that made the horizons of the traditional universe expand greatly. For him, self-awareness already reflected an awareness of the surrounding world; it wondered about the "savages" of America and about the cannibals that were so different from him and yet so near; it compared the intelligence of man with that of beasts and accepted the idea of a relationship between animal existence and human existence. The idea that moral codes are the work of man, rather than reflective of an objective order, opened up the possibility of recognizing the legitimate existence of a plurality of codes and thus of the empirical study—rather than an immediate condemnation and rejection—of the customs of others.

Work of Descartes. By contrast, the work of the 17th-century French philosopher René Descartes represented a continuation of the theme of optimism about man's capacities for knowledge. Descartes explicitly set out, in his *Meditations* (first published in 1641), to beat the skeptics at their own game. He used their methods and arguments in order to vindicate claims to be able to have nonexperiential knowledge of a reality behind appearances. The *Meditations* thus also begins with a turning in of Descartes upon himself but with the aim of finding there something that would lead beyond the confines of his own mind.

Cartesianism occupies a key position in the history of modern Western philosophy; Descartes is treated as a founding father by most of its now diverse traditions. His work is characteristic of the philosophical effort of the 17th century, which was engaged in a struggle to achieve a synthesis between old established orders and the newly proclaimed freedoms that were based on a skeptical rejection of the older orders. There are undeniable tensions in the philosophy of this period that are the product of various unsuccessful attempts to reconcile two very different views of man in relation to God and the world.

The first, the authoritarian view, was that inherited from medieval philosophy and from Thomist theology. It derived its ideal of human freedom from the Stoic conception of the wise man, who, in the 17th century was called a man of *honestas* (the French concept of *honnêteté*). The man of *honestas* seeks freedom in the discovery of and obedience to the order and law on which the world is grounded. He believes that there is such a law, that he has a "place" in the scheme of things, and that he is bound to his fellow human beings by that nature through which he participates in this higher order. He tends to look to the authorities—whether these be church, state, or classical texts—for knowledge of this order, for it is not to be found at the level of experience; it is a "higher" order. His worldview is derived from a mixture of Platonic and Aristotelian (realist) metaphysics.

The second, the libertarian view, was that of the skeptical humanists—individualists and freethinkers, skeptical of any preestablished order, or at least of man's ability to know what it is or might be. The skeptical humanist is therefore untrammelled by it. He deploys skeptical arguments to release the individual from the constraints and demands of outer authorities. He is free to do what he wills or desires and to make his own destiny, for there can be no knowledge of objective norms. Human knowledge is limited to experience, to what is sensed, and people must therefore make their own order within experience. His view is descended from the *via moderna* of the medieval philosopher William of Ockham and the nominalists.

The synthesis sought was a position that would incorporate recognition of the individual and of his freedom under

of man in
relation
to God

Rise of
humanism

The
thought of
Montaigne

universal principles of order, a reconciliation of will with reason. This was sought via a nonauthoritarian conception of objective knowledge, which was the same conception that gave rise to modern science. This required, on the one hand, arguments to combat those of the skeptical freethinkers—arguments that demonstrated that there was an objective order external to human thought and that humans have the capacity not merely to know of its existence but also to discover something of its nature. On the other hand, it was necessary to establish, against the authorities, that each individual, insofar as he is rational, has the capacity to acquire knowledge for himself, by the proper use of his reason. It is this second requirement that produced numerous treatises on the scope and limits of human understanding and on the method of acquiring knowledge. The focus was now firmly fixed on the nature of human thought and on the procedures available to it.

Descartes utilized the skeptic's own arguments to urge a meditative turning inward. This inward journey was designed to show that each human being can come to knowledge of his intellectual self and that as he does so he will find within himself the idea of God, the mark of his creator, the mark that assures him of the existence of an objective order and of the objective validity of his rational faculties. The foundation and starting point of Cartesian knowledge is, for each individual, within himself, in his experience of the certainty that he must have of his own existence and in the idea of a perfect, infinite being, in other words, an idea that he finds within himself, of a being whose essence entails God's existence, and of whose existence man can thus be assured on the basis of his idea of God.

Descartes thus preserved and built on Montaigne's emphasis on self-consciousness, and this is what marks the changed orientation in philosophy that constitutes philosophical anthropology in the stricter, second sense. As the French scientist and religious philosopher Blaise Pascal realized, the question had now become one of whether man finds within himself the basis of loyalty to a universal order of reason and law with which his own thought and will is continuous, or whether he finds, by inner examination, that order, at least insofar as it can be known, is relative to his feeling, desire, and will.

Failure of
Descartes's
proofs
of the
existence
of God

The attempt to regain an objective order by looking inward apparently fails with the failure of Descartes's proofs of the existence of God, proofs that his contemporaries (even those who, like Gottfried Wilhelm Leibniz, were sympathetic to many aspects of the project) were quick to criticize. Reaction to this failure was twofold. In the work of rationalist philosophers, such as Spinoza, Leibniz, and Malebranche, there is a return to the classical Greek approach to philosophy through metaphysics. Empiricists, such as Locke, Condillac, and Hume, on the other hand, retain the Cartesian, introspective basis seeking what Hume calls a mitigated skepticism. This is a position that recognizes essential limitations placed on human cognitive capacities by assuming that experience is the only source of knowledge, but that affirms the value of the knowledge so gained and seeks to define the project of natural science as a quest for objective order within this domain.

Work of Locke. John Locke, for instance, argued that while man cannot prove that the material world exists, his senses give him evidence affording all the certainty that he needs. Locke's position is, however, essentially dualist: mind and body remain distinct even though pretensions to intellectual transcendence are given up. Moreover, Locke regarded it as in principle impossible for humans to have any understanding of the relation between mind and body. All perceptions of one's own body, as of the rest of the material world, are ideas in one's mind. It is impossible to adopt any vantage point outside oneself from which to observe the correlation between a condition of one's body and one's perception of this condition. Where other people are concerned, their bodies and behaviour can be observed but an observer can have no direct perception of what is going on in their minds. There is thus a bifurcation in the study of man. The mind and its contents are known to each person by introspection; it is presumed that the minds of all people work in basically the same way so that

introspection provides evidence for human psychology. Other people, their bodies, and their behaviour are known by observation in exactly the same way that knowledge of any other natural object is obtained. One infers from their behaviour that they have minds like one's own and on this basis attributes psychological states to them.

In keeping with this bifurcation Locke distinguished between the terms "man" and "person," reserving "man" for the animal species, an object of study for natural historians. "Person" is used to denote the moral subject, the being who can be held responsible for his actions and thus praised, blamed, or punished. According to Locke, what constitutes a person is a characteristic continuity of consciousness, which is not merely rational thought but the full range of mental states accessible to introspection. Just as a tree is a characteristic organization of life functions sustained by exchanges of matter, so a person is a characteristic organization of mental functions continuing through changes in ideas (the matter of thought). A person can be held responsible for an action only if he acknowledges that action as one which he performed; *i.e.*, one of which he is conscious and remembers having performed.

The empiricist position thus opens up the possibility of empirical studies both of man as a natural and as a moral being and puts these studies on a par with the natural sciences. But it does so in such a way that the resulting picture lacks any integral unity, for man is an incomprehensible union of body and mind.

Development of anthropological studies. A renewed study of the natural history of man was stimulated by European encounters with the great anthropoid apes of Africa (Angola) and Asia (the Sunda Islands) at the beginning of the 16th century. Until then Europe had known only the smaller monkeys, which were too far removed from the human species to present any confusion. The discovery of the chimpanzee and the orangutan (meaning "man of the woods" in Malay) raised such questions as whether the anthropoid, who resembles man, is an animal or a man, and why it should be considered an ape and not a man. In the climate of opinion—typified by Locke and fostered by the Royal Society of London, with its enthusiasm for empirical observation—these questions prompted the detailed observational studies of a leading member of the society, Edward Tyson.

Discovery
of the
anthropoid
apes

Work of Tyson. Tyson had the opportunity to study the remains of a young chimpanzee (named Pygmie) from Angola that had died in London several months after its arrival. His research was published by the Royal Society in 1699 under the title *Orang-Outang, sive Homo Sylvestris: or, The Anatomy of a Pygmie Compared with That of a Monkey, an Ape, and a Man*. This treatise, a landmark in anthropology and comparative anatomy, is remarkable for the empirical approach used in the investigation. Tyson's precise measurements, his complete exploration of the external and internal structures of the animal, and his minutely detailed sketches permitted him to pose what is perhaps the central problem of physical anthropology: whether it is possible to find among the anatomical or physiological characteristics of the ape the justification for asserting a radical difference between ape and man, notwithstanding all their similarities. He analyzed in great detail the similarities and dissimilarities between a chimpanzee and a man. He emphasized the fact that the ape is a quadruped (having four hands) rather than a quadruped (having four feet); unlike the human foot, its foot has an opposable, and thus thumblike, big toe. The arrangement of the internal organs allows the erect posture that makes the ape similar to man. But on an analysis of the form and mass of the brain and speech apparatus, Tyson concluded that he was unable to determine, from a strictly anatomical point of view, why the ape is incapable of thinking and speaking.

Integral to the empiricism that forms the philosophical background to Tyson's work was a rejection of the whole notion of forms or essences as objectively determining fixed and strict demarcations within the natural world. Classification was the work of man imposed upon a natural continuum, which replaced the older ladderlike conception of the Chain of Being. This encouraged a quest for

"missing links," examples of intermediary forms between those already recognized. For example, zoophytes (invertebrate animals resembling plants, such as sponges) were said to form the link between the vegetable order and the animal order. For Tyson, the chimpanzee was the missing link between animal and man.

Emergence of cultural anthropology. If physical anthropology was born out of Western man's encounter with the anthropoid apes, cultural anthropology was made necessary by his encounter with people in the rest of the world during the great voyages of discovery begun in the 15th century. Cultural anthropology became the product of the confrontation between the classical values of the West and the opposing values and customs of newly discovered civilizations.

The "savage" appeared to manifest a style of humanity that was a contradiction of the certainties that had sustained Europeans for centuries. The shock was such that the naked Indian and the cannibal were at first assumed not to belong to the human race; this approach enabled Europeans to avoid the problem. This solution was, however, rejected by Pope Paul III in 1537 in his bull, or decree, *Sublimus Deus* ("The Transcendent God"), according to which Indian savages were human beings; they had souls and, as such, could be initiated into the Christian religion. This left the problem of how to reconcile the increasingly manifest human diversity with the theological requirement of human unity. One solution was to account for diversity in terms of environment, including cultural environment, and to regard the "savage" as a "primitive," as a "man of nature," who remained close to an initial state from which a privileged part of humanity had been able to remove itself by a continued effort at community and individual advancement. A study of the history of man endeavoured to bring to light the successive stages through which the human species had passed along the way to the present civilized societies. The themes of "civilization" and "progress" were among the principal preoccupations of the Enlightenment.

THE 18TH-CENTURY ENLIGHTENMENT

What has come to be known as the Enlightenment is characterized by an optimistic faith in the ability of man to develop progressively by using reason. By coming to know both himself and the natural world better he is able to develop morally and materially, increasingly dominating both his own animal instincts and the natural world that forms his environment. However, the divergence between rationalist and empiricist traditions continues, giving rise to rather different interpretations of this theme.

The natural history of man. The writings of the Scottish philosopher David Hume give a clear statement of the implications of empiricist epistemology for the study of man. Hume argued first that scientific knowledge of the natural world can consist only of conjectures as to the laws, or regularities, to be found in the sequence of natural phenomena. Not only must the causes of the phenomenal regularities remain unknown but the whole idea of a reality behind and productive of experience must be discounted as making no sense, for experience can afford nothing on the basis of which to understand such talk. Given that this is so, and given that man also observes regularities in human behaviour, the sciences of man are possible and can be put on exactly the same footing as the natural sciences. The observed regularities of human conduct can be systematically recorded and classified, and this is all that any science can or should aim to achieve. Explanation of these regularities (by reference to the essence of man) is not required in the sciences of man any more than explanation of regularities is required in the natural sciences.

Man thus becomes an object of study by natural history in the widest possible sense. All observations—whether of physiology, behaviour, or culture—contribute to the empirical knowledge of man. There is no need, beyond one of convenience, to compartmentalize these observations, since the method of study is the same whether marital customs or skin colour is the topic of investigation; the aim is to record observations in a systematic fashion making

generalizations where possible. Such investigations into the natural history of man were undertaken by Linnaeus, Buffon, and Blumenbach, among others.

In his *Systema Naturae* (1735), the Swedish naturalist Carolus Linnaeus (Carl von Linné) gave a very precise description of man, placing him among the mammals in the order of primates, alongside the apes and the bat. But the distinguishing characteristic of man remains his use of reason; something that is not dependent on any physiological characteristics. Moreover, the variations that are to be found within the genus *Homo sapiens* are the product of culture and climate. In later editions of *Systema Naturae*, Linnaeus presented a summary of the diverse varieties of the human species. The Asian, for example, is "yellowish, melancholy, endowed with black hair and brown eyes," and has a character that is "severe, conceited, and stingy. He puts on loose clothing. He is governed by opinion." The African is recognizable by the colour of his skin, by his kinky hair, and by the structure of his face. "He is sly, lazy, and neglectful. He rubs his body with oil or grease. He is governed by the arbitrary will of his masters." As for the white European, "he is changeable, clever, and inventive. He puts on tight clothing. He is governed by laws." Here mentality, clothes, political order, and physiology are all taken into account.

The French naturalist Georges Leclerc, comte de Buffon, devoted two of the 44 volumes of his *Histoire naturelle, générale et particulière* (1749–1804) to man as a zoological species. Buffon criticized Linnaeus' system and all other systems of classification that depended only on external characteristics; to force individual objects into a rational set of categories was to impose an artificial construct on nature. He was echoing arguments that Locke had used, arguments based on the conception of the Great Chain of Being as a continuum, not as a sequence of discrete steps. An artificial taxonomy came from the mind, not from nature, and achieved precision at the expense of verisimilitude. Buffon's answer was to determine species not by characteristics but by their reproductive history. Two individual animals or plants are of the same species if they can produce fertile offspring. Species as so defined necessarily have a temporal dimension: a species is known only through the history of its propagation. This means that it is absurd to use the same principles for classifying living and nonliving things. Rocks do not mate and have offspring, so the taxonomy of the mineral kingdom cannot be based on the same principles as that of the animal and vegetable kingdom. Similarly, according to Buffon, there is "an infinite distance" between animal and man, for "man is a being with reason, and the animal is one without reason." Thus, "the most stupid of men can command the most intelligent of animals . . . because he has a reasoned plan, an order of actions, and a series of means by which he can force the animal to obey him." The ape, even if in its external characteristics it is similar to man, is deprived of thought and all that is distinctive of man. Ape and man differ in temperament, in gestation period, in the rearing and growth of the body, in length of life, and in all the habits that Buffon regarded as constituting the nature of a particular being. Most important, apes and other animals lack the ability to speak. This is significant in that Buffon saw the rise of human intelligence as a product of development of an articulated language. But this linguistic ability is the primary manifestation of the presence of reason and is not merely dependent on physiology. Animals lack speech not because they cannot produce articulated sound sequences, but because, lacking minds, they have no ideas to give meaning to these sounds.

The German scholar Johann Friedrich Blumenbach is recognized as the father of physical anthropology for his work *De Generis Humani Varietate Nativa* ("On the Natural Variety of Mankind"), published in 1775 or 1776. He also regarded language as an important distinguishing characteristic of man, but added that it is only man who is capable of laughing and crying. Perhaps most important is the suggestion, also made by the American statesman Benjamin Franklin, that it is only man who has hands that make him capable of fashioning tools. This was a suggestion that broke new ground in that it opened up the

of Kant

possibility of speculating on a physiological origin for the development of intellectual capacities.

Man the rational subject. The great German philosopher Immanuel Kant credited Hume with having wakened him from his dogmatic slumbers. But while Kant concurred with Hume in rejecting the possibility of taking metaphysics as a philosophical starting point (dogmatic metaphysics), he did not follow him in dismissing the need for metaphysics altogether. Instead he returned to the Cartesian project of seeking to find in the structure of consciousness itself something that would point beyond it.

Thus, Kant started from the same point as the empiricists, but with Cartesian consciousness—the experience of the individual considered as a sequence of mental states. But instead of asking the empiricists' question of how it is that man acquires such concepts as number, space, or colour, he enquired into the conditions under which the conscious awareness of mental states—as states of mind and as classifiable states distinguished by what they purport to represent—is possible. The empiricist simply takes the character of the human mind—consciousness and self-consciousness—for granted as a given of human nature and then proceeds to ask questions concerning how experience, presumed to come in the form of sense perceptions, gives rise to all of man's various ideas and ways of thinking. The methods proposed for this investigation are observational, and thus the study is continuous with natural history. The enterprise overlaps with what would now be called cognitive psychology but includes introspection regarded simply as self-observation. But this clearly begs a number of questions, in particular, how the empiricist can claim knowledge of the human mind and of the character of the experience that is the supposed origin of all ideas.

Even Hume was forced to admit that self-observation, or introspection, given the supposed model of experience as a sequence of ideas and impressions, can yield nothing more than an impression of current or immediately preceding mental states. Experiential self-knowledge, on this model, is impossible. The knowing subject, by his effort to know himself, is already changing himself so that he can only know what he was, not what he is. Thus, any empirical study, whether it be of man or of the natural world, must be based on foundations that can only be provided by a nonempirical, philosophical investigation into the conditions of the possibility of the form of knowledge sought. Without this foundation an empirical study cannot achieve any unified conception of its object and never will be able to attain that systematic, theoretically organized character that is demanded of science.

The method of such philosophical investigation is that of critical reflection—employing reason critically—not that of introspection or inner observation. It is here that the origin of what has come to be regarded as philosophical anthropology in the stricter, third sense (*i.e.*, 20th-century humanism) can be identified, since there is an insistence that studies of the knowing and moral subject must be founded in a philosophical study. But there remain questions about the humanity of Kant's subject. Kant's position was still firmly dualist; the conscious subject constitutes itself through the opposition between experience of itself as free and active (in inner sense) and of the thoroughly deterministic, mechanistic, and material world (in the passive receptivity of outer sense). The subject with which philosophy is thus concerned is finite and rational, limited by the constraint that the content of its knowledge is given in the form of sense experience rather than pure intellectual intuition. This is not a differentiated individual subject but a form of which individual minds are instantiations. The ideals regulating this subject are purely rational ideals. This tendency is even more marked in the philosophies of Fichte, Schelling, and Hegel.

Humanist thought is anthropocentric in that it places man at the centre and treats him as the point of origin. There are different ways of doing this, however, two of which are illustrated in the works of Locke and Kant, respectively. The first, realist, position assumes at the outset a contrast between an external, independently existing world and the conscious human subject. In this view man is presented as standing "outside" of the physical world

that he observes. This conception endorses an instrumental view of the relation between man and the nonhuman, natural world and is therefore most frequently found to be implicit in the thought of those enthusiastic about modern technological science. Nature, from this viewpoint, exists for man, who by making increasingly accurate conjectures as to the laws governing the regular succession of natural events is able to increase his ability to predict them and so to control his environment.

The second, idealist position, argues that the world exists only in being an object of human thought; it exists only by virtue of man's conceptualization of it. In the form in which Kant expressed this position the thought that constitutes the material, physical world, is that of a transcendent mind, of which the actual minds of humans are merely vehicles.

There is also a third, dialectical, form of anthropocentrism, which, although it did not emerge fully until the 19th century, was prefigured in the works of Vico and Herder. From this standpoint the relation between man and nature is regarded as an integral part to the dynamic whole of which it is a part. The world is what it is as a result of being lived in and transformed by human beings, while people, in turn, acquire their character from their existence in a particular situation within the world. Any thought about the world is concerned with a world as lived through a subject, who is also part of the world about which he thinks. There is no possibility of transcendence in thought to some external, non-worldly standpoint. Such a position wants both to grant the independent existence of the world and to stress the active and creative role of human beings within it. It is within this relatively late form of humanism—which arose from a synthesis of elements of the Kantian position, with the insights of the Italian Giambattista Vico and the German Johann Gottfried von Herder—that philosophical anthropology in the third sense can be located.

Vico's *Scienza nuova* (1725; *The New Science of Giambattista Vico*) announced not so much a new science as the need to recognize a new form of scientific knowledge. He argued (against empiricists) that the study of man must differ in its method and goals from that of the natural world. This is because the nature of man is not static and unalterable; a person's own efforts to understand the world and adapt it to his needs, physical and spiritual, continuously transform that world and himself. Each individual is both the product and the support of a collective consciousness that defines a particular moment in the history of the human spirit. Each epoch interprets the sum of its traditions, norms, and values in such a way as to impose a model for behaviour on daily life as well as on the more specialized domains of morals and religion and art. Given that those who make or create something can understand it in a way in which mere observers of it cannot, it follows that if, in some sense, people make their own history, they can understand history in a way in which they cannot understand the natural world, which is only observed by them. The natural world must remain unintelligible to man; only God, as its creator, fully understands it. History, however, being concerned with human actions, is intelligible to humans. This means, moreover, that the succession of phases in the culture of a given society or people cannot be regarded as governed by mechanistic, causal laws. To be intelligible these successions must be explicable solely in terms of human, goal-directed activity. Such understanding is the product neither of sense perception nor of rational deduction but of imaginative reconstruction. Here Vico asserted that, even though a person's style of thought is a product of the phase of culture in which he participates, it is nonetheless possible for him to understand another culture and the transitions between cultural phases. He assumed that there is some underlying commonality of the needs, goals, and requirement for social organization that makes this possible.

Herder denied the existence of any such absolute and universally recognized goals. This denial carried the disturbing implication that the specific values and goals pursued by various human cultures may not only differ but also may not all be mutually compatible. Hence, not

Vico's
*Scienza
nuova*

Use of
critical
reflection

only may cultural transitions not all be intelligible, but conflict may not be an attribute of the human condition that can be eliminated. If this is so, then the notion of a single code of precepts for the harmonious, ideal way of life, which underlies mainstream Western thought and to which—whether they know it or not—all human beings aspire, could not be sustained. There will be many ways of living, thinking, and feeling, each self-validating but not mutually compatible or comparable nor capable of being integrated into a harmonious pluralistic society.

THE 19TH CENTURY

Declining
influence
of religion

The 19th century was a time of greatly increased activity in the sciences of man. There was a correspondingly rapid development of various disciplines, but this was accompanied by increasing specialization within disciplines. Perhaps the most significant theme, common to all branches of science, was the declining influence of religion. The philosophers of the Enlightenment had concurred in thinking that the transcendence of God doomed to failure any attempt to encompass him within the framework of human discourse. Theological discourse was thus only human discourse. Herder had stated, "It is necessary to read the Bible in a human manner, for it is a book written by men for men." Even so, he insisted, "The fact that religion is integrally human is a profound sign in recognition of its truth." But with human truth the only available truth, such a line was hard to maintain, and by the late 19th century the German philosopher Friedrich Nietzsche had announced that God was dead.

But the death of God also meant that the essence of God in every man was dead—that which was common to all and that in virtue of which the individual transcended the natural, material world and his purely biological nature. Also dead was the part of a person that recognized universal God-given ideals of reason and truth, goodness and beauty. There thus emerged views of man that, while integrating him more thoroughly with the natural world—treating his incarnation as an essential aspect of his condition—had to come to terms with the consequences for science, morality, and the study of man himself of the removal of a transcendent support for belief in absolute standards or ideals.

The presumption of a fixed human nature was undercut at the level of natural history by the emergence and eventual acceptance of evolutionary biology. This added a historical, developmental dimension to the natural history of man, which complimented developmental views of culture and of man as a culturally constituted being. But more importantly, evolutionary biology made man a direct descendant of nonhuman primates and suggested that the gift of reason, which so many had seen as establishing a gulf between man and animal, might too have developed gradually and might indeed have a physiological basis.

Even though Buffon had tied classification to the ability to reproduce, and had thus introduced a temporal dimension into the characterization of species, he had retained the idea of stable species. But a static classification could not explain the dynamic relations between isolated species. A primitive time line of natural history thus developed. The relationship of families led to the idea of filiation between them according to an order of succession. The interpretation of fossils aroused impassioned debates. From them have arisen concepts of mutation (the process by which the genetic material of a cell is altered), transformism (the theory that one species is changed into another), and evolution. These concepts, already being formulated in the 18th century, were clarified in the work of Lamarck and Darwin.

The evolutionary theory of Charles Darwin's *Origin of Species* (1859) differed from that of Jean-Baptiste de Lamarck in that it proposed a mechanistic, nonpurposive account of evolution as the product of the natural selection of randomly produced genetic mutations (survival of the fittest). Advantageous characteristics acquired by an individual were not, as Lamarck had thought, inherited and therefore could not play a role in evolutionary development.

The theme of continuity with the rest of the natural world

was one that was also to be found in the very different, antiscientific thought of Romanticism, which was one of the reactions to the rise of the doctrine of mechanism and to the Industrial Revolution for which it was held responsible. The experience of the Industrial Revolution was crucial to most 19th-century thought about man. Reactions to this experience can be put into three broad categories. There were those who saw in industrialization the progressive triumph of reason over nature, making possible the march of civilization and the moral triumph of reason over animal instinct. This was a view that continued the spirit of the Enlightenment, with its confidence in reason and the ability to advance through science. Into this category can be put the English philosopher John Stuart Mill, a stout defender of liberal individualism. Mill's philosophy was in many respects a continuation of that of Hume but with the addition of Jeremy Bentham's utilitarian view that the foundation of all morality is the principle that one should always act so as to produce the greatest happiness of the greatest number. This ethical principle gives a prominent place to the sciences of man (which are conceived as being parallel in method to the natural sciences), their study deemed necessary for an empirical determination of the social and material conditions that produce the greatest general happiness. This is a non-dialectical, naturalistic humanism, which gives primacy to the individual and stresses the importance of his freedom. For Mill, all social phenomena, and therefore ultimately all social changes, are products of the actions of individuals.

The humanist opponents of capitalist industrialization fall into two groups, both presuming some form of dialectical humanism: those who, like Marx, retained a faith in the scientific application of reason and those who, like Goethe and Schiller, fundamentally questioned the humanity of mechanistic science and the technology it spawned.

The Romantics questioned the instrumental conception of the relation between man and nature, which is fundamental to the thinking behind much technological science. They insisted on an organic relation between man and the rest of nature. It is not man's place outside of nature that is emphasized but his situation within it. Equally central to this view was a recognition of the historicity of human culture and a rejection of any conception of a fixed, determined human nature on which a science of man parallel in structure to the natural sciences (*i.e.*, a science with laws, whether empirical or rational, that determine the actions and the historical development of mankind) could be based. There was a continued commitment to the perspective of the individual, and his creative relation with the world, an orientation that was carried over into the philosophical anthropology of 20th-century phenomenologists and existentialists, with their critiques of modern industrial science.

The Marxist opposition to capitalist industrialization is not to industrialization as such but to capitalist forms of it. This opposition is founded on socialism, which stresses the role of social structures; it is at the level of society—its structures and its economic base of production—that the course of history can be understood. Marx emphasized the importance of labour and work in man's relation both to the natural and to the social worlds in which he finds himself and which condition his ability to realize himself through these relationships. He deplored the loss of humanity associated with capitalist industrialization, which was manifest in the alienating conditions under which members of the working class were treated as objects and thus deprived of their full status as human subjects by their industrial masters. Nonetheless, he retained a faith in scientific knowledge and in the possibility of a scientific understanding of history by integrating its economic, social, and political aspects. Marx argued, however, that it was not reason but revolution that would cause the overthrow of the capitalist system.

Common to all of these reactions is that whether they privileged reason or not they did not seek to validate the claims of reason—and hence the claims of science—by reference to a rational God. But with this transcendent guarantor removed, the question of the objectivity of rational standards and of the commonality of human

capitalism

thought structures became pressing. The Cartesian starting point focused attention on thought as a sequence of ideas, knowable only to the individual concerned. Animals, even if capable of uttering structured sound sequences, were denied linguistic abilities on the ground that these sound sequences could not be the expressions of thoughts and could not have meaning; lacking minds, animals also lack ideas, the thoughts that give words their meaning. According to this view, words are simply conventionally established vehicles for the communication of thoughts that exist prior to, and independent of, their linguistic expression. However, if it is not assumed that human minds are all instantiations of a single transcendent mind, or that although individual they were created from a common pattern, this account of linguistic communication must appear inadequate. Since according to Cartesianism introspection is the only route to awareness of ideas, each person can only ever be aware of his own ideas, never of those of another. He could never know that his attempts to communicate succeed in calling up in another person's mind ideas similar to those in his own. Some new way of looking at linguistic communication was required, and this could be nothing short of a new starting point, a new way of thinking about thought itself.

THE 20TH CENTURY:

EMERGENCE OF PHILOSOPHICAL ANTHROPOLOGY

The mood of the late 19th century, which has also dominated 20th-century philosophy, can be characterized as anti-psychologistic—a rejection of introspective, idea-oriented ways of thinking about thought, which presume that thought is prior to language. This fundamental re-orientation had implications for every other aspect of the study of man. The writers of the late 19th and early 20th centuries who most influenced subsequent philosophical thought about man were Gottlob Frege, Edmund Husserl, Ferdinand de Saussure, and Sigmund Freud. Each helped to transform one of the three reactions to the Industrial Revolution outlined above, to bring it into accord with the new, anti-psychologistic orientation: Frege influenced the empiricist, scientific reaction; Husserl the Romantic; and Saussure and Freud the scientific Socialist.

Frege and empiricist anthropology. Frege argued that if language is to be a vehicle for the expression of objective, scientific knowledge of the world, then the meaning (cognitive content) of a linguistic expression must be the same for all users of the language to which it belongs and must be determined independently of the psychological states of any individual. A word may call up a variety of ideas in the mind of an individual user, but these are not part of its meaning. Such associations may be important to the poet but are irrelevant to the scientist. The function of language in the expression of scientific knowledge is to represent an independently existing world. The meanings of linguistic expressions must thus derive from their relation to the world, not from their relation to the minds of language users. Similarly, logic—embodying the principles of reasoning and the standards of rationality—must be concerned not with laws of human thought, but with laws of truth. The principles of correct reasoning must be justified by reference to the function of language in representing the world correctly or incorrectly rather than by reference to human psychology.

It is for his work on formal logic, which stemmed from these ideas, that Frege is renowned, because it opened the way for the mechanical reproduction of reasoning processes, which was crucial to the development of information processing by computers and for devices capable of artificial intelligence. Frege argued that the principles of deductive reasoning are purely formal principles, which means that their correct application does not depend on an ability to understand the sentences involved, so long as they have been put into the correct logical form. To give an account of the meaning of a sentence requires that it be analyzed so as to reveal its logical form. The logical analysis of everyday and scientific language thus becomes a primary focus of philosophical activity, hence the name “analytic philosophy” for the tradition, predominating in Great Britain, North America, and Australasia that can be

regarded as post-Fregean philosophy. In this tradition the focus is on the analysis of rational, human thought, where it is presumed that the only correct way to do this is to analyze the logical structure of language.

Thus language has replaced God as the locus of rationality and of principles of reason; and the language-world relation has taken over many of the roles previously played by the God-world relation. The individual participates in a rationality that is independent of him to the extent that he is a language user. The position assumes that standards of rationality are absolute, since they are seen as necessarily governing the meaning structures of all languages. The linguist Noam Chomsky proposed a thesis that was regarded as being complimentary to this philosophical position, namely that of a universal grammar—a formal structure that underlies all languages, no matter how diverse their grammatical forms seem on the surface. Moreover, he suggested that all humans have the same innate capacity to learn language, which explains why it is that they all structure their languages, and hence their thought, in the same way.

A further assumption (christened the “principle of charity” by the American philosopher Donald Davidson) is that all humans are rational and that the majority of human behaviour is to be explained as rational, given the beliefs and desires of the person concerned. This, together with the view that language is the locus of rationality and the embodiment of thought, leads to the view that the primary objective of the sciences of man is to interpret the language of a community under study so as to attribute beliefs and desires to its members on the basis of what they say, and so give some explanation of their behaviour. The interpretation is deemed incorrect if the attributed beliefs and desires result in too much behaviour being portrayed as irrational. There will then be a mutual adjustment between language interpretation and the explanation of behaviour in which there can be no final separation of the two and no such thing as a uniquely correct interpretation. There is thus no hope of finding laws linking psychological states of belief or desire to physiological states, even though, by maintaining that each mental event is just a physical event under a different description, a dualism of mind and body is denied. What remains is an irreducible dualism between physiological and psychosocial studies of man. The situation is frequently explained by utilizing a computer analogy (for the computer is, in this view, man creating a machine in his own image). The relation between the structures of thought and the body is likened to the relation between computer software and hardware; the same hardware may be used to run different software, and the same software may be run on different hardware. The two descriptions of computer functioning are thus relatively independent.

In this account the consciousness of the individual plays little explicit role, but a model of man is nevertheless implicit in the whole approach. It is still basically the model employed by Hume, with experience consisting of sensory stimuli. Experience of other people is thus limited to observation of their physical and behavioral characteristics. It is on the basis of such observations that we have to make conjectures about their mental states. What has changed is the method of making such attributions. It is not sufficient to argue by analogy from introspection; any attribute of rational or mental faculties must go via an analytic interpretation of the language spoken. But with the assumption that all languages must share a common logical structure in virtue of their function in representing the world, there is also an inbuilt presumption of a uniformity in the rational structure of all human thought.

Husserl and philosophical anthropology. Husserl is regarded as the founder of phenomenology. He, like Frege, wished to avoid the so-called psychologism of idea-based discussions of thought and rejected naturalistic approaches to the study of the mind and of what passes for rational thought. He, too, believed that laws of reasoning needed to be validated by reference to the objects of thought, but he did not agree that logic could be made purely formal and independent of the particular subject matter in hand, nor did he agree that the primary focus should be on language.

Frege's

formal
logic

Husserl's
phenom-
enology

Indeed, he rejected the position from which Frege started, namely, the assumption that there is a clear separation between the knowing subject and an independently existing reality that is the object of his knowledge. This assumption, Husserl argued, reveals a blindness to the conditions, or presuppositions, involved in all knowledge and already analyzed in part by Kant. Husserl adopted Kant's strategy but in a more radical form that was designed to restore the in-the-worldness of the human subject.

The program of phenomenology aimed at rigorous understanding of the life-world. Kant had explored the conditions of the possibility of experience, and in so doing he had presumed that this experience was always that of an "I," a subject. Husserl also asked after the conditions for the possibility of a consciousness that is always potentially self-conscious. He claimed that all consciousness is intentional; *i.e.*, is consciousness of something. The method pursued was a phenomenal investigation of the "contents of consciousness." This required the investigator to "bracket off" all theories, presuppositions, and evidence of existence, including his own existence. There could be no dogmas. The implication was still that the individual can, in principle, abstract from every influence of culture and environment by abstracting also from that element of consciousness that involves awareness of self. It was presumed that consciousness as such had structures that would then be revealed. It is only self-conscious thought that is culturally constituted; for Husserl, each human individual is by necessity socially and historically conditioned by his environment. But even so it has to be doubted whether the required abstraction from self is possible in the sort of consciousness—*i.e.*, reflective rational thought—that is required of a rigorous phenomenological analysis.

Descartes and his successors had taken the self, the individual subject, for granted and in the process inevitably had assigned to the knowing subject a position outside, beyond, or transcending the world of which he sought knowledge. Husserl, by putting the individual subject into the field of philosophical investigation, paved the way for investigations of the human condition that start with the concrete, with man's being-in-the world. In this respect he can also be regarded as the founder of philosophical anthropology in the narrowest sense of the term: the personal unity of the human being becomes both the point of departure and the goal of philosophical reflection. The use of philosophical anthropology to characterize this approach emerged in the first half of the 20th century with the tendency both in Germany and in France to treat the problems of anthropology as the centre of all philosophical studies. Its emergence at this time may be seen as a reaction to the totalitarian systems of the 20th century: Italian Fascism, Soviet Communism under Stalin, and German Nazism were powerful ideologies calling for the annihilation of the individual character of the person. The philosophical protests of the German phenomenologist Max Scheler, of the Russian existentialist Nikolay Berdyayev, of the Jewish philosophical theologian Martin Buber, and of the French personalist Emmanuel Mounier offered answers to this challenge; the philosophies of the person and of existence present to each individual the means to centre himself upon himself.

Work of Heidegger. Husserl's work not only gave rise to phenomenology but also to the existentialist ideas of Martin Heidegger and Jean-Paul Sartre. Heidegger adopted the method of phenomenology but rejected Husserl's refusal to allow existence to feature in the phenomenological starting point. Heidegger argued for a philosophy in which man's being-in-the-world is registered, and where this being (existence) precedes any determination of what man is (his essence).

In his *Brief über den "Humanismus"* (1947; *Brief Letter on Humanism*), Heidegger wrote:

Are we really on the right track toward the essence of man as long as we set him off as one living creature among others in contrast to plants, beasts and God? ... when we do this we abandon man to the essential realm of *animalitas* but attribute a specific difference to him. In principle we are still thinking of *homo animalitas*—even when *anima* (soul) is posited as *animus sive mens*, and this in turn is later posited as subject,

person, or spirit (*geist*). Such positing is in the manner of metaphysics.

Naturalistic definitions of man fail, because like all traditional metaphysical definitions they naively assume that we know what we mean when we say of something that it is; *i.e.*, when we ascribe being to it.

Humanity and the world form a whole in which neither is privileged. The focus shifts from intentional objects of consciousness to the world itself, a world of objects that appear (and hence exist as individualized objects) only insofar as they have meaning and significance for human beings, by virtue of the way in which they relate to human projects. A fallen tree branch is noticed as firewood only by one who is in search of fuel. Similarly, events are noticed and recorded and so become historical events but only in the light of the meaning that they have for the historian. This means that neither history nor the study of man can be objective and purely factual history. History is always a story about the past from someone who has a specific vantage point within history.

Work of Sartre and other existentialists. Sartre, in *L'Être et le néant* (1943; *Being and Nothingness*), tried to tread a middle line between Husserl and Heidegger, retaining the concrete in-the-worldness of Heidegger while restoring a place for intentional consciousness. He hoped to provide an account of, as he put it, intentional-consciousness-in-the-world-as-it-is-lived. Sartre's driving belief was in human freedom, the ability to choose not only a course of action but also what one would become. Neither Husserl, with his already structured and regulated consciousness, nor Heidegger, with his world that is already given meaning, left enough room for freedom.

Sartre insisted on the dualism of being (thingness) and consciousness (no-thingness) and of the individual in itself and for itself. The disjunction between these is absolute: no state of the world can determine human action, even to the extent of providing a motive, or reason, for action. If man is truly free, the world, whether material or social, can place no constraints on him, not even to the extent of determining what would or would not be good reasons for following a given course of action. He must create his own values and his own morality and take responsibility for his choices. Sartre's critics pointed out, however, that this total freedom dissolves into arbitrariness and randomness. An action that is selected at whim, chosen without (or beyond) reason, and that recognizes no rational constraints, is more an abandonment to fate than an assertion of freedom; where there is no basis for decision there is simply the necessity to choose.

In his later writings, and in particular the *Critique de la raison dialectique* (1960; *Critique of Dialectical Reason*), which attempts a reconciliation between existentialism and Marxism, Sartre came to recognize that there are constraints on the exercise of human freedom. He first acknowledged that man is a creature with biological needs, who must eat, drink, shelter, and clothe himself as a condition of being able to engage in other kinds of activity; and, second, he saw the struggle against need as conditioned by the fact that it takes place in conditions of scarcity. This means that there is competition for resources and thus the ever-present likelihood that the realization of an individual's freedom will limit that of another. Each individual in these conditions experiences others as possible threats to his own freedom (*i.e.*, he experiences alienation).

Individuals whose freedom is in this way conditioned, not just by naturally occurring material conditions but by the materiality of human practice, are (as Marx had said) both "subjects" and "objects" of history. But Sartre insisted that history is only intelligible because it records a process brought into being by human action. This rules out an understanding of history based on a "dialectic of nature," adopted by some Marxists whom Sartre criticized as being dogmatists. Sartre thus rejected the idea that there could be any naturalistic science of humanity—a science that proceeds by discovering laws without reference to the consciousness of individuals. History is neither a mere process (without a subject) nor the product of some form of social, collective "subject." But this does not mean that individuals can be treated as wholly independent units

ideologies

that can be understood without taking into account the formative and conditioning role of their material and social situation. It is in this work that Sartre was still facing up to, and grappling with, the problem of the reconciliation of the demands of freedom and reason, but in an altogether more practical and concrete way than was done by his 17th-century predecessors.

Sartre's abandonment of the radical freedom of *Being and Nothingness* owed much to the French phenomenologist Maurice Merleau-Ponty's criticism of it—in *Sens et non-sens* (1948; *Sense and Non-Sense*)—as being still a dualist philosophy of consciousness and for failing to put man truly in the world. In *Sense and Non-Sense* he also expressed his view of the relation between existentialism and Marxism:

Marx gives us an objective definition of class in terms of the effective position of individuals in the production cycle, but he tells us elsewhere that class cannot become a decisive historical force and revolutionary factor unless individuals become aware of it, adding that this awareness itself has social motives, and so on. As a historical factor, class is therefore neither a simple objective fact, nor is it, on the other hand, a simple value arbitrarily chosen by solitary consciousnesses.

In Merleau-Ponty's writing there is also a clear statement of the human presupposition that forms the basis of philosophical anthropology in this third sense:

I am not the result or the intersection of multiple causalities that determine my body or my "psychism"; I cannot conceive of myself as nothing but a part of the world, as the simple object of biology, psychology, and sociology, nor close over myself the universe of science. Everything that I know of the world, even through science, I know from a viewpoint that is my own . . .

One effect of the insistence that it is concrete, lived experience that must form the starting point of philosophical anthropology is that not only must class and its experience enter into such accounts, but so too must sex and gender. Once the human subject, as a focus of philosophical attention, is no longer a mind whose relation to a body is at best obscure, is no longer a pure consciousness, but is essentially embodied and immersed in human culture, the biological differences between the sexes and the socially constituted role differentiation between male and female must play a part in the account of humanity.

In Simone de Beauvoir's *Deuxième Sexe* (1949; *The Second Sex*), she used the categories provided by Sartre to argue that to be a woman—as distinct from a man—is to be robbed of one's subjectivity, to be treated as an object by men, and to have one's conception of oneself as female defined by men. To assert her subjectivity a woman must thus negate her femininity, to reject the status of object for men that constitutes the feminine. A woman is thus placed in a condition of self-alienation, with which a man does not have to contend. In this way de Beauvoir revealed the need for a philosophy of "man" that is also a philosophy of "woman," a viewpoint that generally has been acknowledged only by female writers.

Philosophical anthropology and theology. Just as class and gender determine the way in which one lives in the world and is related to the world, so too may religion. Even for those not brought up in any religion, Western culture is still one in which religion is significant. Philosophical anthropology must thus take the phenomenon of religious experience seriously, in a way that empiricist anthropology does not. But its starting point is with the constitution of a religious consciousness, and with the conditions of the possibility of the forms of religion encountered; it does not start with theology. There is room once again for dispute over the possibility of any kind of transcendence. The 19th-century Danish philosopher Søren Kierkegaard thought that man's existence has meaning only in the experience of grace, which inexplicably raises man up from his worthlessness. The anguish and loneliness of mortal existence, the "wretchedness of man without God," is only overcome by a form of experience that confers faith in the existence of God and hence the ultimate possibility of human transcendence.

Philosophical anthropology in its narrowest (third) sense is founded on an insistence that the only knowledge avail-

able to man is knowledge from his human perspective, conditioned, as he himself is, by his situation in the world. God cannot be invoked as a source of absolute standards of truth or of absolute values nor to give content to the supposition that there are any. If God exists, then the thought that there are such standards and values, even if we cannot know of them, remains possible. This possibility was denied with Nietzsche's proclamation of the death of God; the attempt to come to terms with this view defines the scope of most philosophical anthropology. The view of religion that reflects the inversion which takes place was expressed by Ludwig Feuerbach in *Das Wesen des Christentums* (1841; *The Essence of Christianity*), when he declared that "man is not a shadow of God; it is God who is the shadow of man, an illusory phantasm that man nourishes out of his own substance."

Saussure, Freud, and antihumanism. There were also those, however, who saw the death of God as heralding the death of man as the focus and starting point for philosophy. Saussure, in his *Cours de linguistique générale* (1915; *Course in General Linguistics*), held, like Frege, that the meaning of a linguistic sign, that which gives it a value for the purposes of communication, could not be an idea in the mind of an individual. But unlike Frege he did not concentrate on the relation between language and an external world. Rather, he argued that the meaning of any one linguistic sign is dependent on its relation to other signs in the language to which it belongs; thus, the meaning of one sign is determined by its place in the overall structure that constitutes a language. A consequence of this view is that language becomes a closed, autonomous system. Linguistic signs do not depend for their meaning on anything external to language. Moreover, Saussure argued that the present meaning of a word could not be revealed by tracing its etymology. It is only by reference to present language structures that current meanings are determined. The language structures that become the focus of attention are thus to be treated as autonomous from their history (*i.e.*, as if they had no history).

With this focus on structures and the method of studying them, Saussure can be considered to be one of the founding figures of structuralism. This view of meaning came to be extended from linguistic signs to all kinds of human actions to which a conventional meaning, or significance, is attributed. It has been used as the framework for anthropological investigations of cultures, their customs, etc., as, for example, in the work of Claude Lévi-Strauss or in the interpretation of dreams and the structures of the unconscious in the works of Jacques Lacan.

It is significant that, again, meaning is studied without reference to the consciousness of individual language speakers. Man is treated as essentially not just a language speaker but as a user and interpreter of signs, and the significance of these signs is determined without reference to any relation to the individual. A language, or sign-system, takes over the role of providing the framework of reason in which significance is given, but this framework transcends the individual. Such systems of codification regulate all human experience and activity and yet lie beyond the control of either individual or social groups. Indeed, since there is no meaning or understanding outside of a given sign-system, it is only from the meaning of the signs he "uses" that the individual comes to learn what it is that he means by his action, and hence what he thinks. This is why such views of language can readily be grafted onto Freud's theory of the unconscious.

Freud treated the realm of the mind as one that is as law-governed as is the natural world; nothing that a person does or says is haphazard or accidental, for everything can in principle be traced to causes that are somehow in the person's mind, although many of these are not accessible to consciousness. Freud's view of the human mind is thus very different from Descartes's. For Freud, the part of the mind that is accessible to consciousness is but the tip of a large iceberg; the hidden remainder, which influences the conscious, is the unconscious. Thus, for instance, there are unconscious desires that can cause someone to do things that he cannot explain rationally to others, or even to himself. In this there is a parallel between Freud and

Thought of
Saussure

*Deuxième
Sexe* of de
Beauvoir

Freud's
theory of
the uncon-
scious

Marx, for both hold views on which human consciousness, far from being perfectly free and rational, is really determined by causes of which man is not aware; but whereas Marx says that these causes are social and economic in nature, Freud claims that they are individual and mental. In both cases the implications for the study of man are anti-psychologistic in that they turn attention away from the individual consciousness. On both views a scientific understanding of man is only to be gained by examining the factors that determine consciousness rather than the level of the individual subject of consciousness.

The id,
ego, and
superego

In his later expositions (those given in the 1920s) Freud assigned to the mind a tripartite structure: the id, which contains all the instinctual drives seeking immediate satisfaction; the ego, which deals with the world outside the person, mediating between it and the id; and the superego, a special part of the ego that contains the conscience, the social norms acquired in childhood. Whatever can become conscious is in the ego, although even in it there may be things that remain unconscious, whereas everything in the id is permanently unconscious. The instincts or drives contained in the id are the motivating forces in the mental apparatus, and all of the energy of the mind comes from them. Freud included a sexual instinct as one of the basic instincts and thus gave sexuality a much wider scope in psychology and in the study of man than had previously been the case. Freud's account of individual human character is also developmental. He held that particular "traumatic" experiences, although apparently forgotten, could continue to exercise a harmful influence on a person's mental health. The fully fledged theory of psychoanalysis generalizes from this and asserts the crucial importance, for the adult character, of the experiences of infancy and early childhood. Freud also held that the first five or so years of life are the time in which the basis of an individual's personality is laid down; one cannot fully understand a person, therefore, until he comes to know the psychologically crucial facts about that person's early childhood. Freud produced detailed theories of the stages of development that are concerned specifically with the development of sexuality, in which this concept is widened to include any kind of pleasure obtained from parts of the body. Freud's view was that individual well-being, or mental health, depends on a harmonious relationship between the various parts of the mind and between the person and the real world in which he must live. Neurosis results from the frustration of basic instincts, either because of external obstacles or because of internal mental imbalance. The work of the analyst is to interpret the behaviour and speech of a patient in such a way as to give insight into the unconscious, to be able to explain what is inexplicable at the conscious level, and in this way to try to give the patient an understanding of himself. Here there is a need for a theory of signs and of interpretation in which its notion of meaning, or significance, does not rest on either reference to the physical world or on ideas in an individual consciousness; structuralist theories provide one such possibility.

From the point of view of either Freudian theory or of the non-existentialist reading of Marx, any attempt to provide a study of man—of human behaviour and history—that starts from the individual consciousness must seem misguided. This will include the empiricist approaches, which assume that all human behaviour is to be explained in terms of the conscious mental states (*i.e.*, beliefs and desires) of individuals. Such approaches seem to fail to acknowledge that the causes of human actions include factors of which they are not consciously aware. A scientific account, one that is concerned with providing causal explanations, must not be confined to the subjectivity of the individual consciousness but must adopt an objective standpoint, a standpoint from which these factors can be recognized and studied. Equally as important, however, the sort of arguments used by phenomenologists and existentialists to query the availability of objective viewpoints can be reapplied here. Thus, structuralism gives place to the post-structuralism of Derrida and Deleuze, according to which neither a scientific nor a philosophical anthropology is possible.

BIBLIOGRAPHY. General works include LESLIE STEVENSON, *Seven Theories of Human Nature* (1974), which gives short introductory sketches of the views of Plato, Christian philosophers, Marx, Freud, Skinner, Sartre, and Lorenz; BERNARD GROETHUYSEN, *Anthropologie philosophique* (1953, reprinted 1980), a series of historical sketches of human personality from antiquity to the Renaissance; MICHAEL LANDMANN, *De Homine: Man in the Mirror of His Thought* (1979; originally published in German, 1962), philosophical rather than anthropological; J.S. SLOTKIN (ed.), *Readings in Early Anthropology* (1965), a good selection of important historical texts, mainly of Anglo-Saxon thinkers; GEORGES GUSDORF, *Les Sciences humaines et la pensée occidentale* (1966–), a general history of the sciences of man on the basis of an anthropological philosophy—12 of 13 vol. had appeared to 1986; ERNST CASSIRER, *An Essay on Man: An Introduction to the Philosophy of Human Culture* (1944, reprinted 1974), a useful and accurate sketch; and A.L. KROEBER (ed.), *Anthropology Today: An Encyclopedic Inventory* (1953, reissued 1965).

On the history of the philosophy of man in the Western tradition, see PRUDENCE ALLEN, *The Concept of Woman: The Aristotelian Revolution, 750 BC–AD 1250* (1985), which contains an excellent bibliography and numerous quotations from historical sources on human nature and the relation between male and female. Insights into the spirit of Renaissance thinking about man are given by ERNST CASSIRER, *The Individual and the Cosmos in Renaissance Philosophy*, trans. by MARIO DOMANDI (1963, reissued 1972; originally published in German, 1927); and DOROTHY KOENIGSBERGER, *Renaissance Man and Creative Thinking: A History of Concepts of Harmony, 1400–1700* (1979). The problems faced by 17th-century philosophers are outlined in LEROY E. LOEMKER, *Struggle for Synthesis: The Seventeenth Century Background of Leibniz's Synthesis of Order and Freedom* (1972). ERNST CASSIRER, *The Philosophy of the Enlightenment*, trans. by FRITZ C.A. KOELLN and JAMES P. PETTEGROVE (1951, reissued 1979; originally published in German, 1932), provides a general discussion of the Enlightenment. On Hegel's philosophy and its impact, see CHARLES TAYLOR, *Hegel and Modern Society* (1979). A useful comparison of two very different 19th-century views of man and society is provided by GRAEME DUNCAN, *Marx and Mill* (1973, reprinted 1977). CHARLES COULSTON GILLISPIE, *Genesis and Geology: A Study in the Relations of Scientific Thought, Natural Theology, and Social Opinion in Great Britain, 1790–1850* (1951, reissued 1959), discusses the impact of science on religious conceptions of man and his place in the order of nature in the decades before Darwin; and MARY MIDGLEY, *Beast and Man: The Roots of Human Nature* (1978, reissued 1980).

Post-Fregean, analytic philosophical thinking about man is conveyed in SAMUEL GUTTENPLAN (ed.), *Mind and Language* (1975, reprinted 1977); AMÉLIE OKSENBERG RORTY (ed.), *The Identities of Persons* (1976); JOHN SEARLE, *Minds, Brains, and Science* (1984); and DONALD DAVIDSON, *Essays on Actions and Events* (1980). The controversy over whether linguistic ability is a distinctively human trait is discussed in EUGENE LINDEN, *Apes, Men and Language* (1975, reprinted 1981); and NOAM CHOMSKY's *Language and Mind*, enl. ed. (1972).

Post-Hegelian philosophy that constitutes philosophical anthropology in the strict, third sense, together with reactions against it, is discussed in KATE SOPER, *Humanism and Anti-Humanism* (1986); and MARK POSTER, *Existential Marxism in Postwar France* (1975, reprinted 1977). Works with the orientation characteristic of philosophical anthropology in this sense include HANNAH ARENDT, *The Human Condition* (1958, reprinted 1974); EDMUND HUSSERL, *Ideas: General Introduction to Pure Phenomenology*, trans. by W.R. BOYCE GIBSON (1931, reissued 1972; originally published in German, 1913); MARTIN HEIDEGGER, *Being and Time*, trans. by JOHN MACQUARRIE and EDWARD ROBINSON (1962, reissued 1973; originally published in German, 7th ed., 1953); JEAN-PAUL SARTRE, *Being and Nothingness*, trans. by HAZEL E. BARNES (1956, reissued 1978; originally published in French, 1943), and *Critique of Dialectical Reason*, trans. by ALAN SHERIDAN-SMITH (1976, reissued 1982; originally published in French, 1960); M. MERLEAU-PONTY, *Phenomenology of Perception*, trans. by COLIN SMITH (1962, reprinted 1981; originally published in French, 1945); and SIMONE DE BEAUVOIR, *The Second Sex*, trans. by H.M. PARSHLEY (1953, reprinted 1983; originally published in French, 2 vol., 1949).

Opposition to this orientation can be found in, among others, CLAUDE LÉVI-STRAUSS, *The Savage Mind* (1966, reissued 1972; originally published in French, 1962), and *Structural Anthropology*, 2 vol. (1963–76; originally published in French, 1958–73); LOUIS ALTHUSSER, *For Marx*, trans. by BEN BREWSTER (1969, reissued 1979; originally published in French, 1965); and JACQUES LACAN, *The Four Fundamental Concepts of Psychoanalysis*, trans. by ALAN SHERIDAN (1977, reissued 1981; originally published in French, 1973).

Western Philosophical Schools and Doctrines

It is the purpose of this article to examine in detail major schools of Western philosophy, ancient, medieval, and modern. Several of the ancient schools presented here developed around the philosophical systems of eponymous "founders." In the cases of Platonism and Aristotelianism, the treatments herein exclude the doctrines of Plato and Aristotle themselves, focussing rather on the survival and metamorphosis of these doctrines in subsequent thought; the original Platonic and Aristotelian systems are treated in full, along with the lives of the respective philosophers, in the *Macropædia* articles PLATONISM and ARISTOTELIANISM. While the philosophy of Thomas Aquinas is treated briefly below in the context of medieval Scholasticism, full treatment appears with the biography of Aquinas in the article THOMISM. The central systems of the major modern philosophers are likewise treated in conjunction

with *Macropædia* biographies (namely, CARTESIANISM; HEGELIANISM; KANTIANISM; MARKISM), and the discussion of their philosophies is, therefore, excluded from the present section on modern schools of thought.

It should be noted that several of the schools and doctrines here classified as ancient underwent revivals or reformulations in later periods (*e.g.*, Platonism, Skepticism); further, it could be argued that no philosophical school regarded as modern is without its precedent in the ancient tradition. The present material, therefore, is drawn together to facilitate comparing and contrasting what might be called the careers of these ideas. For chronological, narrative treatment of the development of Western philosophy, see the *Macropædia* article PHILOSOPHY, THE HISTORY OF WESTERN. (Ed.)

This article is divided into the following sections:

ANCIENT AND MEDIEVAL SCHOOLS

Aristotelianism

Aristotle's work, constituting the ancient world's greatest encyclopaedia, has exerted an immense influence over the succeeding centuries. It is proposed in the context of the present section to trace the course of the several streams of thought which had their source in Aristotle.

THE HELLENISTIC AGE AND NEOPLATONISM

The school founded by Aristotle in the Lyceum in Athens in 335 BC long survived his death. Its members became known as the Peripatetics. Aristotle's immediate disciples, Theophrastus of Eresus and Eudemus of Rhodes, devoted themselves to maintaining and to developing his teaching without altering either its content or its spirit; but after them the school fell rapidly into a decline as far as philosophy was concerned, and thenceforward until the middle or later decades of the 1st century BC no one taught as Aristotle had done. Then at last Andronicus of Rhodes made it his business to bring to light the long-sequestered treatises of Aristotle, to classify them according to their subject matter, and to publish them. His edition started a revival of interest in Aristotelian philosophy, and numerous commentaries on these texts were produced in the last centuries of the Hellenistic Age.

Andronicus
of Rhodes

Andronicus himself interpreted a series of Aristotle's treatises, especially those of the *Organon*, and his example was followed. One of the most important commentators was Alexander of Aphrodisias, who taught in Athens from AD 198 to AD 211 and was known as the Second Aristotle because of the clarity of his exposition. Commentaries by him on part of the *Organon*, on *Metaphysics* I–IV, on the *Meteorologica*, and on the treatise *On Sensation and the Sensible* are extant; and in an original work of his, *On the Soul*, he gives a materialist interpretation of Aristotle's psychology of man, at the same time identifying the "active intellect" with God.

After Alexander, the Peripatetic school was absorbed by Neoplatonism, under which Platonic doctrines were resuscitated amid strong currents of Aristotelian influence. The last Greeks of the ancient world to write commentaries on Aristotle were all Neoplatonists, as follows:

Porphyry (234–c. 305), a pupil of Plotinus, wrote a very important *Isagoge*, or introduction, to the *Categories*, as well as a commentary on that treatise.

Themistius (c. 320–390), who taught in Constantinople, left commentaries on several works of Aristotle's, notably on the treatise *On the Soul*.

Ammonius Hermiae, who after studying under Proclus in Athens was head of the school of Alexandria toward the end of the 5th century, lectured on several of Aristotle's treatises: transcripts are extant of notes taken down at his lectures on the *Categories*, on the treatise *On Interpretation*, on the *Prior Analytics*, and also on Porphyry's *Isagoge*.

Simplicius, who was a pupil of Ammonius in Alexandria, wrote ample commentaries on the *Categories*, on the *Physics*, and on the treatise *On the Heavens*.

Finally John Philoponus, another pupil of Ammonius but a member of the Christian community in Alexandria, wrote against certain doctrinal errors that he detected in Aristotle: fragments of his treatise *Against Aristotle* are extant; so is most of his book *De aeternitate mundi*, which attacks the thesis of the eternity of the world as elaborated by the pagan Neoplatonist Proclus; and a series of Aristotelian commentaries is ascribed to him, some of which consist, however, of notes taken down at Ammonius' lectures and simply filled out by John Philoponus.

To sum up, Aristotle's philosophy can hardly be said to have been maintained in its entirety among the Greeks of the ancient world after the first generation of his disciples. Andronicus launched a revival in the 1st century BC, but from the 4th century AD onward Aristotelianism was submerged in Neoplatonism, which accommodated to its own peculiar view of the universe whatever Aristotelian doctrine it cared to take up.

ARISTOTELIANISM IN ARABIC PHILOSOPHY

Aristotelianism was to have a highly distinguished history in the world of Islām; but the Arabic philosophers, who owed their first acquaintance with it to the Neoplatonists' commentaries, never presented it in its purity or disengaged it from the Neoplatonic context in which it had been transmitted to them. This is readily understandable: whereas Aristotle's own metaphysics was too imperfect to satisfy Islāmic monotheism, the Neoplatonist metaphysics of Plotinus supplied an invaluable complement, to which Muslim thinkers always, to a greater or lesser extent, had recourse. The tendency to combine Aristotelianism proper with Neoplatonism was moreover strengthened by the diffusion of a work known as the *Theology of Aristotle*: this, originally compiled in Syriac by a Christian monk availing himself of extracts from the *Enneads* of Plotinus, was translated into Arabic c. 840 and was commonly ascribed to Aristotle himself, with the result that the latter came to be credited with metaphysical doctrines characteristic of Plotinus. Much later, probably in the 12th century, another pseudo-Aristotelian work—of Arabic origin this time—was circulated in Spain, namely the work well known from its prompt translation into Latin as the *Liber de causis* ("On Causes"): a commentary on propositions selected from Proclus' *Elements of Theology*, it was monotheistic in inspiration and served further to confirm the habit of attributing to Aristotle creationist doctrines wholly foreign to him.

The combination of Aristotelianism with Neoplatonism is already realized in the writings of the first Arabic philosopher, al-Kindī, who flourished in 9th-century Baghdad. A century later, al-Fārābī (died c. 950), who likewise taught mainly in Baghdad, similarly linked Aristotle's doctrines with the metaphysics of the last Alexandrian Neoplatonists, stressing however the independence of philosophy from religion.

The first major thinker of Islām was the Iranian philosopher and physician Avicenna (properly Ibn Sīnā, 980–1037). Besides his personal writings, many of which are lost, he produced a great encyclopaedia of philosophy, *Kitāb ash-shifā* ("Book of Healing"), which consists largely of a paraphrase of Aristotelian writings but is capped with an emanationist metaphysics derived from the so-called *Theology of Aristotle* and from other Neoplatonic sources.

Avicenna

Aristotle's influence in the Arabic world reached its zenith with the work of Averroës (properly Ibn Rushd, 1126–98), of Córdoba in Andalusia, who professed a boundless admiration for the Greek master and regarded him as sent by God to teach men true philosophy. Often in reaction against Avicenna, Averroës meant to restore Aristotelianism in its integrity and composed three series of commentaries on Aristotle's treatises: (1) the "little commentaries," short compendiums or epitomes providing a brief analysis of the treatises; (2) the "middle commentaries," explaining the texts literally; and (3) the "great commentaries," a more advanced and more profound literal exegesis. While he is faithful, on the whole, to Aristotle's thought, Averroës nonetheless, perhaps unwittingly, gives it an undue extension by endowing the Aristotelian "prime mover" with the characteristics of the Plotinian and Islāmic transcendent God, the universal First Cause. Furthermore, he often enough supplements Aristotle by advancing his own interpretation of obscure passages or by developing doctrines that Aristotle scarcely considered at all. The typical instance is where he propounds his own "monopsychism": forcing Aristotle to follow his metaphysical principles to their logical conclusion, Averroës maintains that the two human intellects, namely the passive or receptive intellect and the active intellect, being immaterial, cannot be multiplied in individuals; that consequently both are single substances, entering by their own operation into relation with human individuals, as the passive intellect thinks by means of the ideas that the active intellect abstracts from images in the human brain; and that the human individual is only a superior

kind of animal, altogether mortal. If Averroës won few followers among the Arabs, his interpretation of Aristotle and, particularly, his monopsychism were taken up with great interest by Jewish and even more so by Christian thinkers.

ARISTOTELIANISM IN JEWISH PHILOSOPHY

Jewish speculative thought in the Muslim world was long dominated by Neoplatonism, but all Jewish philosophers from the time of Isaac Israeli (9th–10th century) to the end of the Middle Ages were subject, more or less, to the Aristotelian influence. A firmer orientation toward Aristotelianism is discernible in the famous *Guide of the Perplexed* of Moses Maimonides (1135–1204), a contemporary of Averroës and, like him, a native of Córdoba. But here again there is no occasion to speak of pure Aristotelianism: Maimonides adopts a large measure of Neoplatonic theology (emanation and the *via negativa* or “negative way” to knowledge of God), adopts also much of the Plotinian system of ethics, and furthermore differs from Aristotle on the question of the eternity of the world. Jewish philosophy in Spain, in France, and in Italy was influenced by Maimonides throughout the remainder of the Middle Ages and even longer.

A Jewish opposition to Aristotelianism had already manifested itself most distinctly in the first decades of the 12th century, when Judah ha-Levi denounced the current philosophy. After Maimonides this anti-Aristotelian reaction persisted, notably among the Kabbalists.

THE CHRISTIAN EAST

During the patristic period, some Aristotelian doctrines infiltrated Eastern Christianity through Neoplatonic channels: they can be shown to have affected St. Gregory of Nyssa and Nemesius of Emesa in the 4th century; Pseudo-Dionysius the Areopagite and John Philoponus (whose work as a commentator has already been mentioned) in the 6th; and St. John of Damascus in the 8th. In the 9th century the Byzantine patriarch Photius and his disciple Arethas took an interest in Aristotelian logic, and from the 11th century onward there was a major revival of Aristotelian studies in Constantinople, exemplified particularly by Michael of Ephesus (late 11th century) and by Eustratius of Nicaea (c. 1050–1120), who both wrote commentaries on parts of the *Organon* and on the *Nicomachean Ethics*. Further commentaries appeared in the 13th and 14th centuries. In the 15th century Cardinal Bessarion argued for the ultimate concordance of Aristotelianism with Platonism.

THE CHRISTIAN WEST

Aristotle's influence during the patristic period was even more restricted in Western Christianity than in Eastern: St. Augustine of Hippo, for instance, was acquainted with nothing Aristotelian except the *Categories*.

The fountainhead of Aristotelianism in the Christian West was the Roman philosopher Boethius (c. 480–524). With the intention of demonstrating the profound harmony between Plato and Aristotle, he set himself to translate the works of those two great masters into Latin. He is known to have succeeded at least in translating all the treatises of the *Organon* except the *Analytica posteriora*, together with Porphyry's *Isagoge*; and he also produced commentaries on the *Categories*, on the treatise *On Interpretation*, and on the *Isagoge*. Though his achievement fell short of his project, his work was of capital importance for the transmission of Greek philosophical thought and of Aristotelian logic to Latin Christendom: the *Categories*, the treatise *On Interpretation*, and the *Isagoge* constituted the principal textbooks of logic for the early Middle Ages and so came, later, to be known as the *Ars vetus* or *Logica vetus* (“old technique” or “old logic”) when the other parts of the *Organon*, known as the *Ars nova* or *Logica nova*, had been rediscovered and published in Latin versions. Boethius therefore well deserves to be remembered as “the Teacher of the West,” particularly because of the essential role played by Aristotelian logic in the intellectual formation of the new peoples who arrived in western Europe as barbarian invaders and remained there to develop a

civilization replacing that of the Roman Empire. With his works on logic Boethius paved the way for the elaboration of the scholastic method, and in his commentary on Porphyry's *Isagoge* he posed the problem of universals, which was to figure so prominently in the controversies of a later age.

Charlemagne's educational policy confirmed the status of Aristotelian logic in the scholastic curriculum during the literary and scientific revival of the Carolingian Renaissance: “dialectic,” or logic, was in fact the only philosophical discipline to be admitted among the seven “liberal arts” that represented secular, or “profane,” learning in the program of teaching authorized by Charlemagne's capitulary of the year 778. Subsequently, between the 9th and the 12th centuries, more and more work on logic was undertaken; Aristotle's influence grew continuously as the nature of knowledge was discussed; and with Peter Abelard (1079–1142) the moderate realism of the Aristotelians was vindicated against the extreme realism of the Platonists. With Abelard likewise, and especially in his book *Sic et non*, the scholastic method was perfected. The scholastic method, a product of Aristotelian logic, contributed much not only to the development of speculative theology but also to the progress of the deductive sciences and to the grammatical organization of the European languages.

The triumph of Aristotelianism in the epistemology and in the logic of the 12th-century scholastics prepared the ground for the Aristotelian domination of the universities in the 13th century. The middle of the 12th century had seen the start of a massive penetration of Aristotle's works into western Europe, in Latin translations first from Arabic versions, then from Greek texts. Most of Aristotle's treatises were known by the beginning of the 13th century, but it was only gradually, in the course of the next 100 years, that the consequences of this flood of pagan philosophy became clear (Aristotle's works were accompanied by those of other pre-Christian Greeks, as well as by the commentaries of the Muslims). In the universities the “faculties” of arts (successors of the earlier schools of the liberal arts) enlarged their curricula from the start of the 13th century, and Aristotelianism became more and more firmly implanted, both at Paris and at Oxford, despite opposition from some of the ecclesiastical authorities. The Paris faculty of arts decided on March 19, 1255, that its students should attend lectures on every known treatise of Aristotle's, and indeed by that time every faculty of arts was turning into a faculty of philosophy teaching Aristotelianism. Already, moreover, in the 1220s, Aristotelianism had broken into the faculties of theology; and thenceforward until the end of the Middle Ages (or even later in some establishments) it was to remain fundamental to the structure of scholasticism, both philosophically and theologically. Of all the Aristotelian revivals, the most dynamic was that which the 13th century witnessed in the Christian West.

The revived Aristotelianism of the Christian Middle Ages was no purer, however, than that of the Arabs or that of the Jews had been: various complementary or corrective elements were always present, whether religious or philosophical. Philosophically the main influence was derived, once again, from Neoplatonism.

Up to 1250, Latin Aristotelianism remained very eclectic and, for the most part, Avicennian, so that Aristotle's doctrine, albeit preponderant, was compounded with secondary importations. Avicenna's paraphrases were found useful for the interpretation of difficult texts; the Jewish Neoplatonist Ibn Gabirol (Avicbron) was highly esteemed; Proclus was also available; and in the 1230s the work of Averroës became known to Christian Europe. For theology, Aristotelianism was combined with traditional doctrines (derived mainly from St. Augustine and from the Pseudo-Dionysius) or with the teaching of the 12th-century masters.

After 1250, the Aristotelian influence becomes perceptibly stronger, though at the same time it branches out in various directions. The several schools of thought can be distinguished from one another by the differences in their attitude toward Aristotle, but all remain basically Aristotelian (the Augustinian school in the strict sense of

Aristotelianism in the medieval universities

Maimonides' Guide

Boethius

the name did not come into existence until c. 1270, as a reaction against heterodox Aristotelianism and Thomism). Thus the Aristotelianism of St. Bonaventura is of an Augustinian tendency; that of St. Albertus Magnus is more Neoplatonic, being strongly affected by Proclus, by the Pseudo-Dionysius, and by Avicenna; that of St. Thomas Aquinas is so profoundly recogitated as to be converted into a distinct system, Thomism; and that of Siger of Brabant is heterodox, as it accepts doctrines incompatible with Christianity.

The great doctrinal controversies of the 13th century were largely disputes between champions of the various sorts of Aristotelianism. Thus, when St. Thomas Aquinas held his ground against the majority of the Paris theologians (c. 1270), the conflict was not so much between Aristotelianism and Augustinianism as between the eclectic Aristotelianism for which Alexander of Hales and William of Auvergne had stood and the more consistent and vigorous Aristotelianism which Thomas was maintaining. Similarly the conflict between Thomas and Siger can be regarded as one between the Christian and the heterodox or pagan varieties of Aristotelianism.

From the end of the 13th century Aristotelianism in philosophy was upheld chiefly by the logicians, metaphysicians, psychologists, and ethical theorists teaching in the faculties of arts and was usually "moderate"; *i.e.*, orthodox with respect to Christian doctrines. Thomism became the established system of the Dominicans and even won adherents outside their order. The Neo-Augustinianism that had come into being in the reaction against the nascent Thomism found its definitive expression in Scotism, which in fact was marked by a reversion to Aristotelianism in certain fields and remained in many respects dependent on Aristotle. Finally an Averroist Aristotelianism was launched in Paris by John of Jandun in the first quarter of the 14th century and was taken up in Italy by Taddeo da Parma and by Angelo d'Arezzo. This Latin Averroism was still flourishing in Italy in the 16th century, though it was opposed alike by the Platonism of the humanist Renaissance and by the rival Aristotelianism of the Alexandrists, who revived the doctrines of Alexander of Aphrodisias to interpret Aristotle's psychology.

The 14th century, however, saw also new currents of thought running counter to the influence of Aristotelianism. On the one hand, the Aristotelian system of physics was challenged both at Paris and at Oxford; on the other hand, moderate realism was battered successively by Nominalism, by phenomenalism, by Skepticism, and by agnosticism, which, to a greater or lesser degree, questioned the validity of knowledge and, in particular, the possibility of metaphysics. Failing to disengage itself soon enough from the obsolete physics, Scholasticism was brought farther and farther into disrepute by the successes of the new. One of the reproaches that the men of the humanist Renaissance cast most frequently at the Scholastics was that of being excessively obsequious to Aristotle. Nevertheless, Aristotelianism was still the standard doctrine of some universities down to the end of the 18th century and even longer. In the 19th and 20th centuries there was a great revival of Aristotelian studies, most notably in England (Oxford), in Germany, in France, and in Belgium (Louvain). For some scholars, the interest was chiefly historical: they saw Aristotle as one of the most brilliant products of Greek culture and, indeed, of human culture in general. For the promoters of the Thomist revival, on the other hand, the interest in Aristotelianism was essentially doctrinal, St. Thomas Aquinas having taken him as the main source of his philosophy.

CONCLUSION

Very different judgments have been passed on Aristotelianism in the course of history, and its value as a philosophy or as an instrument of theological speculation is still debated. Defenders of religion, whether Jewish, Muslim, or Christian, have often denounced Aristotelianism as tending toward empiricism, as defective in its metaphysics, and as limited to earthly life in its ethic, and they have accused its followers of being naturalists or rationalists. Platonists and idealists also object to Aristotelianism on the grounds

that it is empiricist, that it gives a central place to natural philosophy in its scheme of things, and that it makes excessive use of discursive reason and of abstract concepts. Finally, many modern thinkers regard the majority of Aristotle's philosophical categories as out of date. On the contrary side, Thomists maintain that many of the notions advanced by Aristotle, not only in metaphysics but also in physics, in psychology, and in ethics, are still really valuable, quite independently of the evident fact that his "science" is now altogether obsolete.

(F.V.Sn.)

Atomism

In the broadest sense the term Atomism refers to any doctrine that explains complex phenomena in terms of aggregates of fixed particles or units. This philosophy has found its most successful application in natural science: according to the atomistic view, the material universe is composed of minute particles, which are considered to be relatively simple and immutable and too small to be visible. The multiplicity of visible forms in nature, then, is based upon differences in these particles and in their configurations; hence any observable changes must be reduced to changes in these configurations.

THE BASIC NATURE OF ATOMISM

Atomism is in essence an analytical doctrine. It regards observable forms in nature not as intrinsic wholes but as aggregates. In contrast to holistic theories, which explain the parts in terms of qualities displayed by the whole, Atomism explains the observable properties of the whole by those of its components and of their configurations.

In order to understand the historical development of Atomism and, especially, its relation to modern atomic theory, it is necessary to distinguish between Atomism in the strict sense and other forms of Atomism. Atomism in the strict sense is characterized by three points: the atoms are absolutely indivisible, qualitatively identical (*i.e.*, distinct only in shape, size, and motion), and combinable with each other only by juxtaposition. Other forms of Atomism are less strict on these points.

Atomism is usually associated with a "realistic" and mechanistic view of the world. It is realistic in that atoms are not considered as subjective constructs of the mind employed for the sake of getting a better grip upon the phenomena to be explained; instead, atoms exist in actual reality. By the same token, the mechanistic view of things, which holds that all observable changes can be reduced to changes of configuration, is not merely a matter of employing a useful explanatory model; the mechanistic thesis holds, instead, that all observable changes are caused by motions of the atoms. Finally, as an analytic doctrine Atomism is opposed to organismic doctrines, which teach that the nature of a whole cannot be discovered by dividing it into its component parts and studying each part by itself.

VARIOUS SENSES OF ATOMISM

The term Atomism is derived from the Greek word *atoma*—"things that cannot be cut or divided."

Two basic types of Atomism. The history of Atomism can be divided into two more or less distinct periods, one philosophical and the other scientific, with a transition period between them (from the 17th to the 19th century). This historical fact justifies the distinction between philosophical and scientific Atomism.

Philosophical Atomism. In philosophical Atomism, which is as old as Greek philosophy, attention was focussed not on the detailed explanation of all kinds of concrete phenomena but on some basic general aspects of these phenomena and on the general lines according to which a rational explanation of these aspects was possible. These basic aspects were the existence in nature of a manifold of different forms and of continuous change. In what way could these features be explained? Philosophical Atomism offered a general answer to that question. It did not, however, strictly confine itself to the general problem of explaining the possibility of change and multiplicity—not even in

Core concepts

Forces and change

Modern revivals

ancient Greek Atomism, for in Greek thought philosophy and science still formed a unity. Consequently, Atomists also tried to give more detailed explanations of concrete phenomena, such as evaporation, though these explanations were meant more to endorse the general doctrine of Atomism than to establish a physical theory in the modern sense of the word. Such a theory was not yet possible, because a physical theory must be based upon indirect or direct information about the concrete properties of the atoms involved, and such information was not then available.

Modern atomic theory. With the development of a scientific atomic theory, the general philosophical problems gradually disappear into the background. All attention is focussed on the explanation of concrete phenomena. The properties of the atoms are determined in direct relationship with the phenomena to be explained. For this reason the chemical atomic theory of the 19th century supposes that each identified chemical element has its own specific atoms and that each chemical compound has its own molecules (fixed combinations of atoms). What particles act as unchanged and undivided units depends upon what kind of process is involved. Some phenomena, such as evaporation, are explained by a process in which the molecules remain unchanged and identical. In chemical reactions, however, the molecules lose their identity. Their structures are broken up, and the composing atoms, while retaining their own identity, are rearranged into new molecules. With nuclear reactions a new level is reached, on which the atoms themselves are no longer considered as indivisible: more elementary particles than the atoms appear in the explanations of nuclear reactions.

Extensions to other fields. Whereas classical Atomism spoke mainly of material atoms (*i.e.*, of particles of matter), the success of the atomic doctrine encouraged the extension of the general principles of Atomism to other phenomena, more or less removed from the original field of application. Rather plausible, for example, was the extension of Atomism to the phenomena of electricity. There were reasons to suppose the existence of an elementary charge of electricity associated with an elementary material particle, the electron (19th century). A second fruitful extension concerned energetic processes (20th century). Some experimental data suggested the hypothesis that energy can exist only in amounts that are whole multiples of an elementary quantity of energy. Extensions of the idea of an atomic structure to amounts of gravitation and even to time have been attempted but have not been sufficiently confirmed.

More removed from the original field of application of Atomism is a theory known as Logical Atomism (developed by the eminent philosopher and logician Bertrand Russell and by the philosopher of language Ludwig Wittgenstein), which supposes that a perfect isomorphism exists between an "atom" of language (*i.e.*, an atomic proposition) and an atomic fact; *i.e.*, that for each atomic fact there is a corresponding atomic proposition. An atomic proposition is one that asserts that a certain thing has a certain quality; *e.g.*, "this is red." An atomic fact is the simplest kind of fact and consists in the possession of a quality by some individual thing.

Another application of Atomism (albeit in a moot sense) lies in the monadology of the philosopher-scientist G.W. Leibniz. According to Leibniz the atoms of Democritus, who provides the paradigm case of ancient Greek Atomism, were not true unities; possessing size and shape, they still were divisible in principle. The ultimate constituents of things must, therefore, be points, said Leibniz—not mathematical but metaphysical points; *i.e.*, points of real existence. They are indeed a kind of soul, which he came to call "monads."

In psychology, Atomism is a doctrine about perception. It holds that what man perceives is a mosaic of atomic sensations, each independent and unconnected with any other sensation. According to the early modern Empiricist David Hume and the pre-World War I father of experimental psychology Wilhelm Wundt, the fact that man nevertheless experiences an ordered whole formed from the unordered "atoms" of perception is caused by the mind's capacity to combine them by "association."

DIVERSE PHILOSOPHICAL CHARACTERIZATIONS OF ATOMISM

The intrinsic nature of the atoms. In 1927 the Belgian astronomer Georges Lemaître formulated the hypothesis that the present high degree of differentiation of matter in space and the complexity of forms displayed by the various astronomical objects must have resulted from a violent explosion and subsequent dispersal of an originally highly compressed homogeneous material, a kind of "primitive atom," containing all of the matter that exists. From the philosophical viewpoint this hypothesis is interesting. By its attempt to reduce the manifold to unity it recalls the beginning of Greek philosophy, which was also inspired by a thesis of the unity of being, propounded by the Eleatic Parmenides. Even apart from their respective contexts, there is, of course, a great difference between Lemaître's and Parmenides' conceptions of the unity of being, for the latter combined the thesis of the unity of being with that of the immutability of being.

Although it would be wrong to classify Parmenides among the Atomists, it is nonetheless appropriate that in an introduction to the diverse forms of Atomism, his conception of reality as just one being should be mentioned. Parmenides' thesis is not only historically but also logically the cornerstone of atomistic thought. Any atomic theory can be interpreted as an attempt to reconcile the thesis of the unity and immutability of being with the fact that the senses observe multiplicity and change. The different ways in which the unity and immutability are understood characterize the different forms of Atomism.

Atoms as lumps of corpuscles. As corpuscles (minute particles), atoms can either be endowed with intrinsic qualities or be inherently qualityless.

The most striking basic differences in the material world, which lead to a first classification of substances in nature, are those between solids, liquids, gases, and fire. These differences are an observed datum that must be accounted for by every scientific theory of nature. It is, therefore, only natural that one of the first attempts to explain the phenomena of nature was based upon these differences and proclaimed that there are four qualitatively different primitive constituents of everything, namely, the four elements: earth, water, air, and fire (Empedocles, 5th century BC)—a theory that dominated physics and chemistry until the 17th century.

Although the theory of the four elements is not necessarily an atomistic theory, it obviously lends itself to interpretation in atomistic terms, namely, when the elements are conceived as smallest parts that are immutable. In this case, all observable changes are reduced to the separation and commingling of the primitive elementary substances. Thus Parmenides' thesis that being is immutable is maintained, whereas the absolute unity of being is abandoned. Yet, the fact that the infinite variety of forms and changes in nature is reduced to just one type of process between only four elementary kinds of atoms shows its affinity with the thesis of the unity of all being.

Notwithstanding the great disparity between the theory of the four elements and modern chemistry, it is clear that modern chemistry with its approximately 100 qualitatively different atoms falls into the same class of atomic theories as that of Empedocles. There are differences, of course, but these will be deferred for later discussion.

More removed from the original thesis of Parmenides was the theory of his contemporary Anaxagoras of Clazomenae, which assumed as many qualitatively different "atoms" as there are different qualified substances in nature. Inasmuch as these atoms, which Anaxagoras called "seeds," were eternal and incorruptible, this theory still contains an idea borrowed from Parmenides. A special feature of Anaxagoras' theory was that every substance contains all possible kinds of seeds and is named after the kind of seed that predominates in it. Since the substance contains also other kinds of seed, it can change into something else by the separation of its seeds.

Another interesting form of Atomism with inherently qualified atoms, also based on the doctrine of the four elements, was proposed by Plato. On mathematical grounds he determined the exact forms that the smallest parts of

One being:
Lemaître
and Parmenides

Inherently
qualified
atoms

Logical
Atomism,
monad-
ology,
associa-
tionism

the elements must have. Fire has the form of a tetrahedron, air of an octahedron, water of an icosahedron, and earth of a cube. Inasmuch as he characterized the atoms of the four elements by different mathematical forms, Plato's conception can be considered as a transition between the qualitative and quantitative types of Atomism.

Qualityless
atoms

The most significant system of Atomism in ancient philosophy was that of Democritus (5th century BC). Democritus agreed with Parmenides on the impossibility of qualitative change but did not agree with him on that of quantitative change. This type of change, he maintained, is subject to mathematical reasoning and therefore possible. By the same token, Democritus also denied the qualitative multiplicity of visible forms but accepted a multiplicity based on purely quantitative differences. In order to reduce the observable qualitative differences to quantitative differences, Democritus postulated the existence of invisible atoms, characterized only by quantitative properties: size, shape, and motion. Observed qualitative changes are based upon changes in the combination of the atoms, which themselves remain intrinsically unchanged. Thus Democritus arrived at a position that was defined above as Atomism in the strict sense. In order to make the motion of atoms possible, this Atomism had to accept the existence of the void (empty space) as a real entity in which the atoms could move and rearrange themselves. By accepting the void and by admitting a plurality of beings, even an infinite number of them, Democritus seemed to abandon—even more than Empedocles did—the unity of being. Nevertheless, there are sound reasons to maintain that, in spite of this doctrine of the void, Democritus' theory remained close to Parmenides' thesis of the unity of being. For Democritus' atoms were conceived in such a way that almost no differences can be assigned to them. First of all, there are no qualitative differences; the atoms differ only in shape and size. Secondly, the latter difference is characterized by *continuity*; there are no privileged shapes and no privileged sizes. All shapes and sizes exist, but they could be placed in a row in such a manner that there would be no observable difference between successive shapes and sizes. Thus not even the differences in shape and size seem to offer any ground explaining why atoms should be different. By accepting an infinite number of atoms, Democritus retained as much as possible the principle that being is *one*. With respect to the acceptance of the void, it must be stressed that the void in the eyes of Democritus is more nonbeing than being. Thus even this acceptance does not seriously contradict the unity of being.

Atoms as sheer extension. Democritus had declared quantitative differences to be intelligible, because they were subject to mathematical reasoning. Precisely this relationship between quantitative differences and mathematics made it impossible for Descartes (17th century) to think along the atomistic lines of Democritus. If the only thing that is clearly understandable in matter is mathematical proportions, then matter and spatial extension are the same—a conclusion that Descartes did not hesitate to draw. Consequently, he rejected not only the idea of indivisible atoms but also that of the void. In his eyes the concept "void" is a contradiction in terms. Where there is space, there is by definition extension and, therefore, matter.

Descartes's
vortices

Yet, however strange it may seem in view of his identification of matter with extension, Descartes offered nonetheless a fully developed theory of smallest particles. To the questions that arise immediately as to how these particles are separated and distinct from each other, Descartes answered that a body or a piece of matter is all of that which moves together. In the beginning of the world all matter was divided into particles of equal size. These particles were in constant motion and filled all of space. As, however, there was no empty space for moving particles to move into, they could only move by taking the places vacated by other particles that, however, were themselves in motion. Thus the motion of a single particle involved the motion of an entire closed chain of particles, called a vortex. As a result of the original motion, some particles were gradually ground into a spherical form, and the re-

sulting intermediary space became filled with the surplus splinters or "grindings." Ultimately, three main types of particles were formed: (1) the splinter materials, which form the finest matter and possess the greatest velocity; (2) the spherical particles, which are less fine and have a smaller velocity; and (3) the biggest particles, which originated from those original particles that were not subject to grinding and became united into larger parts.

Thus Descartes could construct an atomic theory without atoms in the classical sense. Although this theory as such has not been of great value for the scientific atomic theory of modern times, its general tendency was not without importance. However arbitrarily and speculatively Descartes may have proceeded in the derivation of the different kind of corpuscles, he finally arrived at corpuscles characterized by differences in mass, velocity, amount of motion, etc.—properties that could be treated mathematically.

Atoms as centres of force: dynamic particles. Most systems of Atomism depict the action between atoms in terms of collision—i.e., as actual contact. In Newton's theory of gravitation, however, action between bodies is supposed to be action at a distance—which means that the body in question acts everywhere in space. As its action is the expression of its existence, it is difficult to confine its existence to the limited space that it is supposed to occupy according to its precise shape and size. There is, therefore, no reason for a sharp distinction between occupied and empty space. Consequently, the mind finds it natural to consider the atoms not as extended particles but as point-centres of force. This conception was worked out by the Dalmatian scientist R.G. Boscovich (1711–87), who attempted to account for all known physical effects in terms of action at a distance between point-particles, dynamic centres of force.

Boscovich's
point-centres and
Leibniz's
monads

Atoms as psychophysical monads. The idea of applying the atomistic conceptions not only to material but also to psychical phenomena is as old as Atomism itself. Democritus had spoken of the atoms of the soul. According to the principles of his doctrine these atoms could differ only quantitatively from those of the body: they were smoother, rounder, and finer. This made it easy for them to move into all parts of the body. Basically, however, the atoms of the soul were no less material than other atoms.

In Leibniz's monadology the situation was quite different. Leibniz did not first conceive of material atoms and then only later interpret the soul in terms of these atoms; from the beginning he conceived his "atoms," the monads, in terms of an analogy with the soul. A monad is much more a spiritual than a material substance. Monads have no extension; they are centres of action but not, first of all, in the physical sense. Each of the monads is gifted with some degree of perception; each mirrors the universe in its own way. Monads differ from each other, however, in the degree of perception of which they are capable.

The immutability of atoms. By their nature all atomic theories accept a certain degree of immutability of the atoms. For without any fixed units no rational analysis of complex phenomena is possible. At least with respect to the stable factors in the analysis involved, the atoms have to be considered as immutable. According to Atomism in the strict sense, this immutability had to be interpreted in an absolute way.

Absolute
vs. relative

The same absolute interpretation appeared in classical chemistry, although its atomic theory deviated from Atomism in the strict sense by assuming qualitatively different atoms and by assuming molecules (rather stable aggregates of atoms). The decisive point, however, is that molecules were formed by mere juxtaposition of atoms without any intrinsic change of the qualities of the atoms. Modern atomic theory, in contrast, gives a less rigid interpretation of the immutability of elementary particles: the particles that build up an atom do not retain their identity in an absolute way.

In some philosophical atomistic theories, the immutability of the atoms has been understood in a highly relative sense. This interpretation arose mainly in the circles of those Aristotelian philosophers who tried to combine atomistic principles with the principle of Aristotle that elements changed their nature when entering a chemical

compound. The combination of both principles led to the doctrine known as the *minima naturalia* theory, which holds that each kind of substance has its specific *minima naturalia*, or smallest entities in nature. *Minima naturalia* are not absolutely indivisible: they can be divided but then become *minima naturalia* of another substance; they change their nature. In a chemical reaction the *minima* of the reagents change into the *minima* of the substances that result from the reaction.

Other differences. Atomisms also differ regarding the number of atoms, whether they occupy a void, and how they relate to one another.

Number of atoms. As has already been mentioned, Democritus introduced the hypothesis that the atoms are infinite in number. Although one may question whether the term infinite has to be taken in its strict sense, there is no doubt that by using this term Democritus wanted not merely to express the triviality that, on account of their smallness, there had to be an enormous quantity of atoms. Democritus also had a strong rational argument for postulating a strictly infinite quantity of atoms: only thus could he exclude the existence of atoms that specifically differed from each other.

When in modern science the problem of the number of atoms arises, the situation is quite different from that of the Greek Atomists. There is now much more detailed information about the properties of the atoms and of the elementary particles, and there is also in astrophysical cosmology some information about the universe as a whole. Consequently, the attempt to calculate the total number of atoms that exist is not entirely impossible, although it remains a highly speculative matter. In a time (around 1930) when all chemical atoms were supposed to be composed of electrons and protons, the pioneering joint-relativity-quantum astrophysicist A.S. Eddington calculated the number of these elementary particles to be $2 \times 136 \times 2^{256}$, or approximately 10^{79} , arguing that, since matter curves space, this is just the number of particles required barely to close the universe up into a hypersphere and to fill up all possible existence states.

The existence of the void. To Democritus the existence of the void was a necessary element in atomistic theory. Without the void the atoms could not be separated from each other and they could not move. In the 17th century Descartes rejected the existence of the void, whereas Newton's conception of action at a distance was in perfect harmony with the acceptance of the void and the drawing of a sharp distinction between occupied and nonoccupied space.

The success of the Newtonian law of gravitation was one of the reasons that atomic theories came to prevail in the 18th century. Even with respect to the phenomena of light, the corpuscular and hence atomic theory of Newton, which held that light is made of tiny particles, was adopted almost universally, in spite of Huygens' brilliant development of the wave hypothesis.

When in the beginning of the 19th century the corpuscular theory of light in its turn was abandoned in favour of the wave theory, the case for the existence of the void had to be reopened, for the proponents of the wave theory did not think in terms of action at a distance; the propagation of waves seemed to presuppose, instead, a medium with not only geometrical properties but with physical ones as well. At first the physical properties of the medium, the ether, were described in the language of mechanics; later they were described in that of the electromagnetic field theory of J.C. Maxwell. Yet, to a certain extent the old dichotomy between occupied and nonoccupied space continued to exist. For, according to the ether theory, the atoms moved without difficulty in the ether, whereas the ether pervaded all physical bodies.

In contemporary science this dichotomy has lost its sharpness, owing to the fact that the distinction between material phenomena, which were supposed to be discontinuous, and the phenomena of light, which were supposed to be continuous, appears to be only a relative one. In conclusion it can be claimed that although modern theories still speak of space and even of "empty" space, this "emptiness" is not absolute: space has come to be regarded

as the seat of the electromagnetic field, and it certainly is not the void in the sense in which the term was used by Democritus.

Atoms in external aggregation versus in internal relationship. In most forms of Atomism it is a matter of principle that any combination of atoms into a greater unity can only be an aggregate of these atoms. The atoms remain intrinsically unchanged and retain their identity. The classical atomic theory of chemistry was based upon the same principle: the union of the atoms into the molecules of a compound was conceived as a simple juxtaposition. Each chemical formula (e.g., H_2O , H_2SO_4 , $NaCl$, etc.) reflects this principle through the tacit implication that each atom is still an H, O, or S, etc., even when in combination to form a molecule.

Chemistry had a twofold reason for adopting this principle. One reason was an observational, the other a philosophical one. The fact that some of the properties of a chemical compound could, by simple juxtaposition, be derived from those of the elements (the molecular weight, for example, equals the simple sum of the respective atomic weights) was a strong factual argument in favour of the principle. Many properties of the components, however, could not be determined in this way. In fact, most chemical properties of compounds differed considerably from those of the composing elements. Consequently, the principle of juxtaposition could not be based on factual data alone. It was in need of a more general support. This support was offered by the philosophical idea that inspired all Atomism, viz., that if complex phenomena cannot be explained in terms of aggregates of more elementary factors, they cannot be explained at all.

For the evaluation of this idea, the development of the scientific atomic theory is highly interesting, especially with respect to the interpretation of the concept of an aggregate. Is the only interpretation of this concept that of an assemblage in which the components preserve their individuality—like, for instance, a heap of stones?

Modern atomic theory offers an answer to this question. This theory still adheres to the basic principle that a complex structure has to be explained in terms of aggregates of more elementary factors, but it interprets the term "aggregate" in such a way that it is not limited to a mere juxtaposition of the components. In modern theories atomic and molecular structures are characterized as associations of many interacting entities that *lose* their own identity. The resulting aggregate originates from the converging contributions of all of its components. Yet, it forms a new entity, which in its turn controls the behaviour of its components. Instead of mere juxtaposition of components, there is an internal relationship between them. Or, expressed in another way: in order to know the properties of the components, one has to study not only the isolated components but also the structures into which they enter. To a certain extent modern atomic theory has bridged the gap between atomistic and holistic thought.

Holistic tendencies

HISTORY AND MAJOR REPRESENTATIVES OF THE VARIOUS ATOMISMS

Philosophical Atomism. From the ancient Greeks through the 16th century, Atomism remained mainly philosophical.

Ancient Greek Atomism. It is characteristic of the importance of Greek philosophy that, already in the foregoing exposition of the different aspects of Atomism, several Greek philosophers had to be introduced. Not only the general idea of Atomism but also the whole spectrum of its different forms originated in ancient Greece. As early as the 5th century BC Atomism in the strict sense (Leucippus and Democritus) is found, along with various qualitative forms of Atomism: that of Empedocles, based on the doctrine of the four elements, and that of Anaxagoras, with as many qualitatively different atoms as there are different substances.

Yet, in spite of its successful start, Atomism did not gain preeminence in Greek thought. This is mainly because Plato and Aristotle were not satisfied with the atomistic solution of the problems of change as a *general* solution. They refused to reduce the whole of reality, including

Criticisms by Plato and Aristotle

Eddington's
cosmical
number

man, to a system that knew nothing but moving atoms. Even with respect to the problems of the material world, Atomism seemed to offer no sufficient explanation. It did not explain the observable fact that, notwithstanding continual changes, a total order of specific forms continued to exist. For this reason Aristotle, with Plato, was more interested in the principle of order than in that of the material elements. In his own analysis of change, which resulted in the matter-form doctrine, Aristotle explicitly rejected the thesis of Democritus that in a chemical reaction the component parts retain their identity. According to Aristotle, the elements that entered into a composite with each other did not remain what they were but became a compound. Although there is some indication that in Aristotle's chemical theory smallest particles played a role, it was certainly not a very important one.

Meanwhile, atomistic ideas remained known in Greek thought. Their opponents paid much attention to them, and there were also a few adherents of Democritean Atomism in later times, such as the Greek hedonist Epicurus (c. 341–279 bc) and the Roman poet Lucretius Carus (c. 95–55 bc) who, through his famous didactic poem *De rerum natura* ("On the Nature of Things"), introduced Atomism into the Latin world.

The elachista of the early Aristotelian commentators. Empedocles had suggested an Atomism with qualitatively different atoms, based upon the doctrine of the four elements. Aristotle adopted the latter doctrine but without its atomistic suggestion. Certain Greek commentators on the works of Aristotle, however, viz., Alexander of Aphrodisias (2nd century AD), Themistius (4th century AD), and Philoponus (6th century AD), combined the Aristotelian theory of chemical reactions with atomistic conceptions. In their systems the atoms were called *elachista* ("very small" or "smallest"). The choice of this term is connected with the Aristotelian rejection of the infinite divisibility of matter. Each substance had its own minimum of magnitude below which it could not exist. If such a minimum particle were to be divided, then it would become a minimum of another substance.

The minima naturalia of the Averroists. The Latin commentators on Aristotle translated the term *elachista* into its Latin equivalent *minima* or also into *minima naturalia*; i.e., *minima* determined by the nature of each substance. In fact, for most medieval Aristotelians the *minima* acquired little more reality than the theoretical limit of divisibility of a substance; and in their descriptions of physical and chemical processes, they paid no attention to the *minima*. With the Averroists—followers of the Arab Aristotelian Averroës (1126–98)—an interesting development occurred. Agostino Nifo (1473–1538), for example, explicitly stated that in a substance the *minima naturalia* are present as *parts*; they are physical entities that actually play a role in certain physical and chemical processes. Because the *minima* had acquired more physical reality, it then became necessary to know how the properties of the *minima* could be connected with the sensible properties of a substance. Speculations in this direction were developed by the Italian physician, philosopher, and litterateur Julius Caesar Scaliger (1484–1558).

Modern scientific Atomism: early pioneering work. Modern Atomism arose with the flowering of science in the present sense of the word.

The 17th century. In the history of Atomism the 17th century occupies a special place for two reasons: it saw the revival of Democritean Atomism, and it saw the beginning of a *scientific* atomic theory.

The revival of Democritean Atomism was the work of the ambiguous Epicureo-Christian thinker Pierre Gassendi (1592–1655), who made his contemporaries not only better acquainted with Atomism but also succeeded in divesting it of the materialistic interpretation with which it was hereditarily infected. This reintroduction of Democritus was well timed. Because of its quantitative character Democritus' Atomism invited for its elucidation the application of mathematics and mechanics, which in the 17th century were sufficiently developed to answer this invitation. In point of fact, the 17th century was more interested in the possibilities that Atomism offered for a

physical theory than it was in the philosophical differences between the different atomistic systems. For this reason it saw, for example, hardly any difference between the systems of Gassendi and Descartes, although the latter explicitly rejected some of the fundamentals of Democritus, such as the existence of the void and the indivisibility of the atoms, as noted above (see *Atoms as sheer extension*).

In the case of scientists mainly interested in the chemical aspects, the same shift of emphasis from philosophical to scientific considerations can be discerned. According to the physician and philosopher of nature Daniel Sennert (1572–1637), Democritus' Atomism and the *minima* theory really amounted to the same thing. As far as philosophy was concerned, Sennert was only interested in the general idea of Atomism; the precise content of an atomic doctrine in his view ought to be a matter of chemical experimentation. His own experience as a chemist taught him the specific differences existing between the atoms. In this respect Sennert continued the *minima* tradition. His own contribution to the chemical atomic theory lay in the clear distinction that he made between elementary atoms and the *prima mista*, or atoms of chemical compounds.

The early modern experimentalist Robert Boyle (1627–91) followed the same line of thought as Sennert, but he was much more aware of the discrepancy between Democritus' Atomism and an atomic theory suitable for chemical purposes. Boyle's solution to this problem was the thesis that the atoms of Democritus were normally associated into primary concretions, which did not easily dissociate and which acted as elementary atoms in the chemical sense. These primary concretions can combine to form compounds of a higher order, which may be compared to Sennert's *prima mista* and to the molecules of modern chemistry.

Founding of modern Atomism. The 17th century had laid the theoretical foundations for a scientific atomic theory. For its further development it was in need of better chemical insights, especially concerning the problem of what substances should be considered as chemical elements. Boyle had shown conclusively that the traditional four "elements" were certainly not elementary substances, but at the same time he confessed that he did not yet see any satisfactory method to determine which substances were true elements. This method was provided by another of the principal founders of modern chemistry A.-L. Lavoisier (1743–94): a chemical element is a substance that cannot be further analyzed by known chemical methods.

John Dalton (1766–1844), usually regarded as the father of modern atomic theory, applied the results of Lavoisier's chemical work to atomistic conceptions. When Dalton spoke of elementary atoms, he did not have a merely theoretical idea in mind but the chemical elements as determined by Lavoisier. Dalton held that there are as many different kinds of elementary atoms as there are chemical elements. The atoms of a certain element are perfectly alike in weight, figure, etc.; and the same point applies to the atoms of a certain compound. As weight was the decisive characteristic in Lavoisier's theory, Dalton stressed the importance of ascertaining the relative weights of atoms and the number of elementary atoms that constituted one compound "atom." As to the question of the way in which the atoms are combined in a compound, Dalton conceived this combination as a simple juxtaposition with each atom under the influence of Newtonian forces of attraction. The atoms retain their identity through a chemical reaction. In this one point the founder of the chemical atomic theory did not differ from Democritus.

Recent and contemporary scientific Atomism. Until its development in the third decade of the 20th century, the scientific atomic theory did not differ philosophically very much from that of Dalton, although at first sight the difference may appear large. Dalton's atoms were no longer considered to be immutable and indivisible; new elementary particles sometimes appeared on the scene; and molecules were no longer seen as a mere juxtaposition of atoms—when entering into a compound atoms became ions. Yet, these differences were only accidental; the atoms revealed themselves as composed of more elementary particles—protons, neutrons, and electrons—

Lavoisier
and Dalton

Gassendi,
Sennert,
and Boyle

but these particles themselves were considered then as immutable. Thus the general picture remained the same. The material world was still thought to be composed of smallest particles, which differed in nature and which in certain definite ways could form relatively stable structures (atoms). These structures were able to form new combinations (molecules) by exchanging certain component parts (electrons). The whole process was ruled by well-known mechanical and electrodynamic laws.

In contemporary atomic theory the differences from Dalton are much more fundamental. The hypothesis of the existence of immutable elementary particles has been abandoned: elementary particles can be transformed into radiation and vice versa. And when they combine into greater units, the particles do not necessarily preserve their identity; they can be absorbed into a greater whole.

Atomism in the thought of India. It is interesting to note that atomistic conceptions are not restricted to Western philosophy and science. Examples of qualitative Atomism, based upon the doctrine of the four elements, are also found in Indian philosophy. In some Indian systems the atoms are not absolutely indivisible but only relatively so. In certain aspects Indian Atomism is, therefore, more related to the *minima* doctrine than to the Atomism of Democritus. Indian Atomism has, however, not developed into a scientific theory.

FOUNDATIONAL ISSUES POSED BY ATOMISM

Atomism as a metaphysical system. In discussing Atomism, one particular system, that of Democritus, has been here distinguished as Atomism in the strict sense because of the fact that in no other system have the foundational issues of Atomism been so clearly expressed. Atomism in the strict sense is not merely one of the historical forms of Atomism, one of the many possible scientific attempts at explaining certain physical phenomena; it is, first of all, a metaphysical system: it has been presented as the only possible explanation of change and multiplicity. And as a metaphysic it is rationalistic, mechanistic, and realistic.

It is *rationalistic* because it has so much confidence in reason that, in order to explain observed phenomena, it does not hesitate to postulate the existence of unobservable atoms: *i.e.*, of things that are in principle unobservable by the human senses and can be known only by a process of reasoning. Atomists go even further, for they not only are convinced of the existence of atoms but they also think it possible to deduce in a rational way their fundamental properties. Moreover, the description of these properties in *mechanistic* terms is not just a matter of convenience; it is supposed to be the adequate expression of *reality*.

This rationalistic and mechanistic metaphysics is not only characteristic of Democritus' Atomism but also of the early forms of scientific Atomism. The clearest expression of this metaphysics is found in Descartes. For Democritus mechanistic concepts are clear and distinct ideas, so that any further experimental investigation is superfluous. It should be stressed that the atomistic assumption that the human mind, by mere reasoning, can know the properties of the atoms is a necessary consequence of the idea that atoms are not subject to internal change; for the changeless can never be a subject of experimentation. The great weakness of the mechanistic concept of immutable atoms was that it forced the analyzing experiments to stop at the atoms; but this weakness could reveal itself only after, in the course of the further development of science, the fundamentally experimental character of human knowledge had become evident.

This weakness, in fact, was precisely one of the reasons why Aristotle rejected the Atomism of Democritus, *viz.*, that the latter had postulated atoms that were not subject to change. For Aristotle the very essence of matter was its being subject to change; to him the concept of immutable atoms was a contradiction in terms.

Aristotle's criticism of Atomism was clearly directed against its mechanistic metaphysics, not against its realism. This latter characteristic was the target, however, of an attack launched by the incomparable 18th-century epistemologist Immanuel Kant. In a famous argument, known as the antinomy of the continuum, Kant tried to

prove that the acceptance of the reality of spatial extension, the cornerstone of Atomism, led to contradictions. His argument can be summarized as follows: It is possible to prove that any compound must be composed of simple things (for if not, there would be nothing but composition). On the other hand, it also is possible to prove that no material thing can be simple, for the very reason that a part of an extended being is always extended and is thus open to division. Hence, every allegedly simple part is at once simple and nonsimple. Consequently, spatial extension cannot be real. Extension is therefore not a property of the material world itself; it is a form imposed upon reality by man's perception.

By his argument Kant did not intend to reject atomic theories as such; he rejected only their realistic pretensions. Kant was deeply convinced that man had to *think* of nature by way of analogy with a mechanism, but he denied that knowledge construed in such a fashion could reach reality itself.

In the 19th century, scientists were, as a rule, hardly impressed by Kant's attack on the realistic pretensions of human knowledge. Scientists had already learned to go their own way and no longer worried about philosophical considerations. Only when an internal crisis in science itself arose were they prepared to reflect upon their presuppositions. Such a crisis occurred in the 20th century when science was forced to accept the relativity of both classical models: the wave and the particle models.

To a certain extent, the problem of whether a scientific model is nothing but a subjective construct in which the scientist unites his experience is the same as the problem that Kant had in mind. One of the differences, however, is that in Kant's time science was still rather exclusively *theory*. Its close connection with praxis (practice, doing) had not yet been discovered. For this reason the Kantian epistemological (or human knowledge) problem could centre on such a question as: what guarantee does the *knowing* subject have that his "models" of reality reflect reality itself? Inasmuch as, in an exclusively theoretical science, the only contact that one has with reality is afforded by means of one's knowledge, the problem seems to be insoluble.

The development of science from a theoretical to an experimental discipline forces philosophy to view the epistemological problem in a new way. For in an experimental science man is in a twofold contact with reality, *viz.*, by his knowledge and by his experimental praxis. Modern atomic theory is one of the best examples to illustrate this point. It was this theory that was most directly confronted with the problem of the realistic value of its models. It could take up this challenge because of the theory's effectiveness for experimental praxis, which is the final judge of the realistic value of the theoretical models. It has confirmed the audacious rational speculations of ancient Atomism; but at the same time it has revealed that, in order to be really effective, reason is in need of experimental assistance.

Ancient Greek Atomism versus contemporary scientific Atomism. In comparing Greek Atomism and modern atomic theories, it should be recalled that in Greek thought philosophy and science still formed a unity. Greek Atomism was inspired as much by the desire to find a solution for the problems of mutability and plurality in nature as by the desire to provide scientific explanations for specific phenomena. While it is true that some of the Greek Atomists' ideas can rightly be considered as precursors of later physics, the main importance of the old atomistic doctrines for modern science does not lie in these primitive anticipations. Much more important is the attempt to take seriously the variety and mutability discerned by sense experience and yet to reconcile it with the thesis of Parmenides about the unity and the immutability of matter. In its search for universal and unchangeable laws, modern science is to a great extent inspired by the same idea as Parmenides, since universal laws presuppose a certain unity in the material world and unchangeable laws cannot be established without the presupposition that something unchangeable must be hidden behind all changes. By the same token, without this latter presupposition experiments would not make any sense at all. For if the diversity of reactions occurring under different conditions is to re-

ides
and the
modern
quest for
laws

veal anything, these reactions must be the expression of an immutable nature. The differences have to indicate something about that which remains the same. The great achievement of the Greek philosophers was, therefore, that they took a general view of nature as a whole that made a scientific attitude possible. To this, both the quantitative and the qualitative forms of Atomism contributed, the former drawing attention to the mathematical aspects of the problem, the latter to the observational.

A comparison of ancient Greek Atomism with scientific Atomism merely on the basis of their respective scientific contents would therefore do a great injustice to Greek Atomism; it would in fact misjudge its main value. Such a comparison would, however, also take too narrow a view of modern scientific Atomism. It would imply the philosophical irrelevance of the latter. It has here been shown, however, that the later development of the scientific atomic theory has clarified many philosophical problems that, as basic issues, divided Atomism in the strict sense from other forms of Atomism. To mention only a few examples: the development of the scientific atomic theory has deepened man's insights into the relationship between a whole and its components, into the relative character of ultimate particles, and into certain fundamental epistemological problems.

Evaluation of Atomism. The success of the atomic theory shows the value of the idea of Atomism: the explanation of the complex in terms of aggregates of fixed particles or units. Its history also shows, however, the inherent danger of this idea, namely, that of absolutism. History has corrected this absolutism: the unitary factors have to be conceived as ultimate only with respect to the complex under consideration, and their union into aggregates need not occur only by way of juxtaposition. (A.G.M.v.M.)

Eleaticism

Radical
monism

One of the principal schools of ancient Pre-Socratic philosophy was Eleaticism, so called from its seat in the Greek colony of Elea (or Velia) in southern Italy. This school, which flourished in the 5th century BC, was distinguished by its radical monism; *i.e.*, its doctrine of the One, according to which all that exists (or is really true) is a static plenum of Being as such, and nothing exists that stands either in contrast or in contradiction to Being. Thus, all differentiation, motion, and change must be illusory. This monism is also reflected in its view that existence, thought, and expression coalesce into one.

The sources for the study of Eleaticism are both archaeological and literary. Archaeologists have ascertained that, at the time of Parmenides, the Rationalist who founded the school, Elea was a large town with many temples, a harbour, and a girdle of walls several miles long. They have also unearthed a site presumed to be that of the medical school that Parmenides founded and an inscription bearing Parmenides' name.

The literary sources consist of fragments preserved by later classical authors—19 from Parmenides, four from his pupil Zeno, renowned for his paradoxes of motion, and 10 from another pupil, Melissus, an admiral of Samos—of which all but three from Parmenides and two from Melissus are 10 lines or less in length. The interpretation is also affected by the weight of scholarly opinion that now holds (as against Karl Reinhardt, an early 20th-century philologist and historian of philosophy) that Parmenides reacted to Heraclitus and not vice versa. Moreover, the biases of the citing authors must be weighed. Heraclitans and Parmenideans of the second generation, for example, saw their masters, simplistically, only as the prophets of movement and immobility; and the ancient Skeptic Sextus Empiricus distorted Parmenides' thinking into problems of epistemology (theory of knowledge), because this is what his Skeptical eye saw in his writings.

THE ELEATIC SCHOOL VIS-À-VIS RIVAL MOVEMENTS

Each member of the Eleatic school espoused a distinctive variety of Eleaticism: Parmenides pursued a direct and logical course of thought and viewed Being as finite and timeless; Zeno concurred in Parmenides' doctrines but

employed the indirect methods of *reductio ad absurdum* and infinite regress (see below); and Melissus modified the doctrines, viewing Being as infinitely extensive and eternally temporal. A fourth thinker, the Sicilian Sophist Gorgias of Leontini, though not an adherent to Eleaticism, employed the methods of the Eleatic Zeno to defend its opposite—a nihilism that affirmed Non-Being instead of Being.

Eleaticism represents a reaction against several tendencies of thought. Methodologically, it spurned the empirical (observational) approach taken by earlier cosmologists, such as the 6th-century Milesians Thales and Anaximenes, who discerned ultimate reality in water and in air (or breath), respectively, for these substances are materializations of Being—analogueous to the materialization that occurs in Pythagoreanism in passing from an abstract line or plane or three-dimensional form to a solid perceptible body—rather than Being itself; or, at best (as some scholars hold), the substances are mythological representations of Being. The Eleatics, on the contrary, ignoring perceptual appearances, pursued a rationalistic—*i.e.*, a strictly abstract and logical—approach and thus found reality in the all-encompassing, static unity and fullness of Being and in this alone. Thus Parmenides was the father of pure ontology.

Ontologically—in its view of the nature of Being—the Eleatic school, holding to what Parmenides called the “way of truth” (“what is”), stood opposed to two other “ways of research” that were then current: first, to the “way of opinion” (or seeming; later developed at length by Plato in the *Sophist*), which held that a being comprises or is defined not only by what it is but also by what it is not—*i.e.*, by its contrast with other things; and, second, to a way recognizable as that of Heraclitus, a caustic and often cryptic philosopher then living in Ephesus, who maintained—still more radically—that the essence of a being lies in part in its involvement in, or even its identity with, its opposite. Finally, as an aspect of Parmenides' opposition to the way of opinion, he was in reaction also against Anaximander, another Milesian scientist and philosopher. Though Anaximander's basic principle, the *apeiron* (“boundless”), was duly abstract and not a part of the world itself (as were water and air), his philosophy depended, nonetheless, upon the world's contrast with the infinite *apeiron*, from which all things come and to which they return “in accordance with the ordinance of Time.” This contrast—which, in a Pythagorean version, envisioned the world as breathing in voidness from the infinite outer breath in order to keep things apart or discrete—thus spawned a “many” that contradicts the Eleatic One.

THE RIGOROUS ONTOLOGISM OF PARMENIDES AND MELISSUS

For a long time Xenophanes of Colophon, a religious thinker and rhapsode of the 6th–5th century BC, was considered the founder of the Eleatic school and Parmenides' mentor. This ancient claim, however, has been successfully criticized by Reinhardt. It is even possible that, on the contrary, Xenophanes was an older pupil of Parmenides. In any case, his monistic view of a cosmic God, whom he may have equated pantheistically with Being itself, was Eleatic in its contention that God is one and ungenerated, that his seeing, thinking, and hearing are equally all-pervading (*i.e.*, he is not a composite), and that he “always remains in the same place, not moving at all.”

Parmenides' poem *Peri physeōs* (“On Nature”) is divided into three parts: (1) a proem (preface), in which his chariot ride through the heavens to the very seat of the goddess Alētheia (Truth) is described and their initial conversation is related, in which she announces that he is “to learn all things, both the unshaken heart of well-rounded truth and also what seems to mortals, in which is no true conviction”; (2) the “Way of Truth,” the main part, in which the real and unique Being is depicted; and (3) the “Way of Opinion” (or Seeming), in which the empirical world—*i.e.*, the single things as they appear every day to every man—is presented.

Logical and linguistic approach. Thus, at the very heart of Parmenides' philosophy lies the distinction made by the goddess (in Fragment 2) between the two “ways of

Contrasts
with other
movements

Parmenides' poem
and the
two ways
of research

research.” As noted earlier, the first is the antinomy (or paradox) of those who think and say that everything is Being and who shun all assertions of Non-Being; and the second is that of those who think and say that something is in a way and is not in another way—that a book is a book, for example, and not a table. There is, however, also a third way that is far more erroneous and fallacious than the second: that of Heraclitus, who acknowledged, just as Parmenides did, the ontological antinomy of is and is not but reversed it, holding that the real way of understanding things is to grasp their essential contradiction, their intrinsic opposition to everything else. In this view, one must say that to be a table is also not to be just a table and that to be a chair is not to be just a chair but to be also a table, because not only opposite things but also things that are merely different are bound to each other. Thus, life is death to Heraclitus, death is life, and justice would be meaningless if it had no injustice to defeat.

In essence, then, the possible ways are three: (1) that of renouncing all contradictions whatsoever (truth); (2) that of contradicting oneself relatively (seeming); and (3) that of contradicting oneself completely and absolutely (Heraclitus). And Eleaticism chose the first, the absolutely noncontradictory way that says that only what is, Being, is really true.

Not-Being, in fact, can neither be recognized nor expressed, for, as Parmenides then added, “for the same thing can be thought and can exist.” And—if one may guess at the words (now lost) that probably followed—what-is-not you can neither know nor say; thus, to think is indeed the same as to say that what you think is. To this coalescence of existing reality and the intellectual grasping of it, Parmenides also added the linguistic communication of such knowledge. Each way of research, in fact, is at the same time a way of speculation and a way of diction; *i.e.*, both a way of searching for truth with one’s mental eyes and of expressing it in words. The primal source of the Eleatic philosophy thus lies in the archaic sense of language, according to which one cannot pronounce “yes” and “no” without deciding about the reality or unreality of the objects of the statements. Thus, “yes,” or “is,” becomes the name of the truth; and “no,” or “it is not,” becomes that of its opposite.

This Eleatic principle may be illustrated by a passage from Aeschylus, a leading Greek dramatist, who, in his *Hepta epi Thēbais* (Eng. trans., *Seven Against Thebes*), judged it very appropriate that Helen would have destroyed Troy, because her name—naïvely derived from *helein* (“destroy”) and *naus* (“ship”)—marked her as a destroyer of ships. Here *nomen est omen*: the language is not merely a symbol; it corresponds to reality in its very structure. Thus, the Eleatic could not imagine a truth that is only expressible but not thinkable nor one that is only thinkable but not expressible.

Monistic theory of Being. From the premise of the essential coalescence of language and reality follows Parmenides’ theory of Being, which comprises the heart of his philosophy. The only true reality is Eōn—pure, eternal, immutable, and indestructible Being, without any other qualification. Its characterizations can be only negative, expressions of exclusions, with no pretense of attributing some special quality to the reality of which one speaks.

In Fragment 8, verse 5, Parmenides said that the absolute Being “neither was nor will be, because it is in its wholeness now, and only now.” Thus, its presence lasts untouched by any variation in time; for no one can find a genesis for it, either from another being (for it is itself already the totality of Being) or from a Not-Being (for this does not exist at all).

Obviously, this Parmenidean conception of the eternal presence of the Being conflicts with Melissus’ idea of the perpetual continuation of the Being in the past, in the present, and in the future. Thus, if Eleaticism had been founded by Melissus, no one could have really understood its actual doctrine. One could suspect in it only an aspiration to have things capable of being really enduring. But even then the theory would hardly be understandable, because what one wants is not stable things in general; one wants good things to be firm and stable and bad things

to be ephemeral. The perpetual continuity of existence as espoused by Melissus was despised by Parmenides just because “will be” and “has been” are not the same as “is.” Only “is” is the word of the reality—just because it is the right name for the right thinking of the right Being.

Among the consequences of this Eleatic conception is the rejection of every change (birth, movement, growth, death) as pertaining only to the second-rate reality, which is known and expressed through the second “way of research.” Thus, the true and noncontradictory reality is extraneous to all of those happenings, great or small, that make the constant stuff of all history.

Secondly, the real Being has no difference, no lack, no variety whatsoever in itself. Melissus is here the true pupil of Parmenides, who said that the Eōn is so closely connected in itself that “all Being is neighbour of all Being”: for Melissus developed this theory by the negation of every form of *kenon* (“void”): the Being is an absolute plenum just because every lack in its plentifulness would amount to a presence of some Not-Being.

THE PARADOXES OF ZENO

The position of the other great pupil of Parmenides, Zeno of Elea, was clearly stated in the first part of Plato’s dialogue *Parmenides*. There Zeno himself accepted the definition of Socrates, according to which he did not really propose a philosophy different from that of Parmenides but only tried to support it by the demonstration that the difficulties resulting from the pluralistic presupposition of the *polla* (the multiple beings of man’s daily experience) were far more severe than those that seemed to be produced by the Parmenidean reduction of all reality to the single and universal Being.

The arguments by which Zeno upheld his master’s theory of the unique real Being were aimed at discrediting the opposite beliefs in plurality and motion. There are several arguments against plurality. First, if things are really many, everything must be infinitely small and infinitely great—infinitely small because its least parts must be indivisible and therefore without extension and infinitely great because any part having extension, in order to be separated from any other part, needs the intervention of a third part; but this happens to such a third part, too, and so on ad infinitum.

Very similar is the second argument against plurality: if things are more than one, they must be numerically both finite and infinite—numerically finite because they are as many things as they are, neither more nor less, and numerically infinite because, for any two things to be separate, the intervention of a third thing is necessary, ad infinitum. In other words, in order to be two, things must be three, and, in order to be three, they must be five, and so on. The third argument says: if all-that-is is in space, then space itself must be in space, and so on ad infinitum. And the fourth argument says: if a bushel of corn emptied upon the floor makes a noise, each grain must likewise make a noise, but in fact this does not happen.

Zeno also developed four arguments against the reality of motion. These arguments may also be understood (probably more correctly) as proofs *per absurdum* of the inconsistency of any presupposed multiplicity of things, insofar as these things may be proved to be both in motion and not in motion. The first argument states that a body in motion can reach a given point only after having traversed half of the distance. But, before traversing half, it must traverse half of this half, and so on ad infinitum. Consequently, the goal can never be reached.

The second argument is that of “Achilles and the tortoise.” If in a race the tortoise has a start on Achilles, Achilles can never reach the tortoise; for, while Achilles traverses the distance from his starting point to that of the tortoise, the tortoise will have gone a certain distance, and, while Achilles traverses this distance, the tortoise goes still further, ad infinitum. Consequently, Achilles may run indefinitely without overtaking the tortoise. This argument is fundamentally identical to the previous one, with the only difference being that here two bodies instead of one are moving.

The third argument is the strongest of them all. It says

Coalescence of Being, thought, and expression

Paradoxes of plurality

Paradoxes of motion

Conflict with Melissus on the eternity of Being

the following: So long as anything is in a space equal to itself, it is at rest. Now, an arrow is in a space equal to itself at every moment of its flight; therefore, even the flying arrow is at rest all of the time. And the final argument says: Two bodies moving at equal speed traverse equal spaces in an equal time. But, when two bodies move at equal speed in opposite directions, one passes the other in half of the time that a moving body needs to pass a body that is at rest.

The difficulty with all these arguments is that of really understanding them in their historical frame, which neither Aristotle—who was mainly concerned to confute Zeno—nor many modern scholars—who are concerned with developing new theories for the calculation of infinitesimal quantities—really tried to do. Moreover, the role of the author of the paradoxes in the history of Greek philosophy is itself paradoxical, for many of the same arguments by which Zeno proved the self-contradictory nature of the unity considered as the smallest element of a pluralistic reality (the Many) were later similarly used by Gorgias and Plato to demolish the Parmenidean One-Totality itself.

THE DECLINE OF ELEATICISM

This problem is also connected with that of the correct interpretation of the second part of Plato's *Parmenides*. Here the discussion to which Zeno submits the young Socrates is meant as a serious exemplification of the logical training that Socrates still needs if he wants to make progress in philosophy. But the result is simply comic—a “fatiguing joke,” according to Plato's *Parmenides*—because Zeno always starts from the mere principles of the pure Being or the One and arrives at absurd conclusions: everything is shown to be true as well as false and deducible and not deducible from everything else.

Such dialectical futility had been anticipated by the nihilism of Gorgias, presented in a work ironically entitled *Peri tou mē ontos ē peri physeōs* (“On That Which Is Not, or On Nature”), in which he said (1) that nothing exists; (2) that if anything exists, it is incomprehensible; and (3) that if it is comprehensible, it is incommunicable—and in so doing he applied Parmenides' coalescence of Being and thought and expression to Non-Being instead of to Being and thus signalled the decline of Eleaticism.

The serious discussion and criticism of the Eleatic philosophy, however, and the positive interpretation of every Non-Being as a *heteron* (i.e., as a being characterized only by its difference from “another” being) is neither in Gorgias nor in the *Parmenides* but in the *Sophist* of Plato. There Plato argued that the antinomy between *On* and *Mē-On* (Being and Non-Being) does not really exist, the only real antinomy being that of *Tauton* and *Heteron*; i.e., only that of a single object of consciousness in its present determination and all other things from which it is distinguished.

The real story of ancient Eleaticism thus ends with Plato and with Democritus, who said that Being exists no more than Non-Being, the thing no more than the no-thing. But many thinkers, and great thinkers at that—from Aristotle to Kant and from Hegel to Marx—have continued to work or to fight with the antinomy of Being and Non-Being.

(G.C./L.H.St.)

Epicureanism

In a strict sense, Epicureanism is the philosophy taught by Epicurus (341–270 BC); in a broad sense, it is a system of ethics embracing every conception or form of life that can be traced to the principles of his philosophy. In ancient polemics, as often since, the term was employed with an even more generic (and clearly erroneous) meaning as the equivalent of hedonism, the doctrine that pleasure or happiness is the chief good. In popular parlance, Epicureanism thus means devotion to pleasure, comfort, and high living, with a certain nicety of style.

THE NATURE OF EPICUREANISM

Several fundamental concepts characterize the philosophy of Epicurus. In physics, these are Atomism, a mechanical

conception of causality, limited, however, by the idea of a spontaneous motion, or “swerve,” of the atoms, which interrupts the necessary effect of a cause; the infinity of the universe and the equilibrium of all forces that circularly enclose its phenomena; the existence of gods conceived as beatified and immortal natures completely extraneous to happenings in the world. In ethics, the basic concepts are the identification of good with pleasure and of the supreme good and ultimate end with the absence of pain from the body and the soul—a limit beyond which pleasure does not grow but changes; the reduction of every human relation to the principle of utility, which finds its highest expression in friendship, in which it is at the same time surmounted; and, in accordance with this end, the limitation of all desire and the practice of the virtues, from which pleasure is inseparable, and a withdrawn and quiet life.

In principle, Epicurus' ethic of pleasure is the exact opposite of the Stoic's ethic of duty. The consequences, however, are the same: in the end, the Epicurean is forced to live with the same temperance and justice as the Stoic. Of utmost importance, however, is one point of divergence: the walls of the Stoic's city are those of the world, and its law is that of reason; the limits of the Epicurean's city are those of a garden, and the law is that of friendship. Though this garden can also reach the boundaries of earth, its centre is always a man.

HISTORY OF EPICUREANISM

Epicurus' predecessors were in physics Leucippus and Democritus and in ethics Antiphon Sophista, Aristippus of Cyrene, and Eudoxus of Cnidus, a geometer and astronomer. Epicurus differed from all of these in his systematic spirit and in the unity that he tried to give to every part of philosophy. In this respect, he was greatly influenced by the philosophy and teachings of Aristotle—taking over the essentials of his doctrines and pursuing the problems that he posed.

Epicurus' own life and teachings. In 306 BC, Epicurus established his school at Athens in his garden, from which it came to be known as The Garden.

His works. In accordance with the goal that he assigned to philosophy, Epicurus' teaching had a dogmatic character, in substance if not in form. He called his treatises *dialogismoi*, or “conversations.” Since the utility of the doctrines lay in their application, he summarized them in *stoicheia*, or “elementary propositions,” to be memorized. In this respect, Epicurus was the inventor of the catechetical method. The number of works produced by Epicurus and his disciples reveals an impressive theoretical activity. But no less important was the practical action in living by the virtues taught by him and in honouring the obligations of reciprocal help in the name of friendship. In these endeavours, continuous assistance was rendered by Epicurus himself, who, even when old and ill, was occupied in writing letters of admonishment, guidance, and comfort—everywhere announcing his gospel of peace and, under the name of pleasure, inviting to love.

Doctrine of Epicurus. Philosophy was, for Epicurus, the art of living, and it aimed at the same time both to assure happiness and to supply means to achieve it. As for science, Epicurus was concerned only with the practical end in view. If possible, he would have done without it. “If we were not troubled by our suspicions of the phenomena of the sky and about death,” he wrote, “and also by our failure to grasp the limits of pain and desires, we should have no need of natural science.” But this science requires a principle that guarantees its possibilities and its certainty and a method of constructing it. This principle and this method are the object of the “Canon,” which Epicurus substituted for Logic. Since he made the “Canon” an integral introduction to the “Physics,” however, his philosophy falls into two parts, the “Physics” and the “Ethics.”

The name canon, which means “rule,” is derived from a special work entitled “On the Criterion, or Canon.” It held that all sensations and representations are true and serve as criteria. The same holds for pleasure and pain, the basic feelings to which all others can be traced. Also

Atomism;

His
“Canon”

true, and included among the criteria, are what may be called concepts (*prolepsis*), which consist of “a recollection of what has often been presented from without . . .” Man, therefore, must always cling to that “which was originally thought” in relation to every single “term” and which constitutes its background. Since the truth attested by each of the criteria is reflected in the *phainomena*, man must cling to these, employing them as “signs,” and must “conjecture” whatever “does not appear.” With the use of signs and conjecture, however, the level of judgment is reached, and thought is well advanced into that sphere in which error is possible, a state that begins as soon as single terms are tied into a proposition. Error, which consists of what “our judgment adds” to the evidence, can be of two types, one relative to what is not an object of experience, the other relative to what is such an object but for which the evidence is dubious. Each type has its own method of proof. Following the principles and methods of the “Canon,” Epicurus arrived at an Atomism that, like that of the ancient naturalist Democritus, taught that the atoms, the void space in which they move, and the worlds are all infinite. But in contrast to Democritus, who had followed the deductive route of the intellect, considering the knowledge of the senses to be spurious, Epicurus, following an inductive route, assigned truth to sensation and reduced the intellect to it. On the basis of the totality of problems as Aristotle posed them in his “Physics,” Epicurus modified entirely the mechanical theory of causes and of motion found in Democritus and added the concept of a natural necessity, which he called nature, and that of free causality, which alone could explain the freedom of motion of man and animals. For this purpose he distinguished three forms of motion in the atoms: a natural one of falling in a straight line, owing to their weight; a forced one due to impacts; and a free motion of declination, or swerving from a straight line. Secondly, he made finite the number of forms of the atoms in order to limit the number of sensible qualities, since each form begets a distinctive quality, and he taught a mathematical as well as a physical Atomism. Lest an infinity of sensible qualities be generated, however, by an infinity of aggregations (if not of atomic kinds), Epicurus developed, from just this concept of infinity, the law of universal equilibrium of all the forces, or “isonomy.” Upon it, enclosing the events in a circle, he founded a theory of cyclic returns.

As part of his “Physics,” Epicurus’ psychology held that the soul must be a body. It is made of very thin atoms of four different species—motile, quiescent, igneous, and ethereal—the last, thinnest and the most mobile of all, serving to explain sensitivity and thought. Thus constituted, the soul is, from another perspective, bipartite: in part distributed throughout the entire body and in part collected in the chest. The first part is the locus of sensations and of the physical affects of pain and pleasure; the second (entirely dissociated from the first) is the *psychē* par excellence—the seat of thought, emotions, and will. Thought is due not to the transmission of sense motion but to the perception of images constituted by films that continuously issue from all bodies and, retaining their form, arrive at the *psychē* through the pores. The full autonomy and freedom of the *psychē* is assured, as, with an act of apprehension, it seizes at every moment the images it needs, meanwhile remaining master of its own feelings.

The object of ethics is to determine the end and the means necessary to reach it. Taking his cue from experience, Epicurus looked to the animal kingdom for his answer. He concluded from this cue that the chief end is pleasure. He distinguished two kinds—a “kinetic” pleasure of sense and a “static” pleasure, consisting in the absence of pain—and taught that the pleasure of sense is good, though it is not good merely as motion but rather as a motion favourable to the nature of the receiving sense organ. In essence, pleasure is the equilibrium of the being with itself, existing wherever there is no pain.

Epicurus concluded that “freedom from pain in the body and from trouble in the mind” is the ultimate aim of a happy life. The damages and the advantages following the realization of any desire must be measured in a calculus

in which even pain must be faced with courage if the consequent pleasure will be of longer duration.

Having thus given order to his life, however, the wise man must also provide himself with security. This he achieves in two ways—by reducing his needs to a minimum and withdrawing, far from human competition and from the noise of the world, to “live hidden”; and by adding the private compact of friendship to the public compact from which laws arise. To be sure, friendship stems from utility; but, once born, it is desirable in itself. Epicurus then added that “for love of friendship one has even to put in jeopardy love itself”; for every existence, being alone, needs the other. “To eat and drink without a friend,” he wrote, “is to devour like the lion and the wolf.” Thus, the utility sublimates itself and changes into love. But as every love is intrepid, the wise man, “if his friend is put to torture, suffers as if he himself were there” and, if necessary, “will die for his friend.” Thus, into the bloody world of his time, Epicurus could launch the cry: “Friendship runs dancing through the world bringing to us all the summons to wake and sing its praises.”

If man’s unhappiness stemmed only from his own vain desires and from worldly dangers, this wisdom, founded upon prudence alone, would suffice. But besides these sources of unhappiness there are two great fears, fear of death and fear of the gods. If science, however, is effective in revealing the bounds of desire and (as already seen) in quelling the fear of the gods, it can also allay the fear of death. Regarding the soul as a body within another body, science envisions it as dissolving when the body dissolves. Death, then, “is nothing to us, so long as we exist, death is not with us; but when death comes, then we do not exist.” But death is feared not only for what may be awaiting man in the beyond but also for itself. “I am not afraid of being dead,” said the comic Epicharmus of Cos: “I just do not want to die.” The very idea of not existing instills a fear that Epicurus considered to be the cause of all the passions that pain the soul and disorder men’s lives. Against it Epicurus argued that if pleasure is perfect within each instant and “infinite time contains no greater pleasure than limited time, if one measures by reason the limits of pleasure,” then all desire of immortality is vain. Thus, Epicurus’ most distinguished pupil, Metrodorus of Lampsacus, could exclaim, “*bebōtai*” (“I have lived”), and this would be quite enough. He who has conquered the fear of death can also despise pain, which “if it is long lasting is light, and if it is intense is short” and brings death nearer. The wise man has only to replace the image of pain present in the flesh with that of blessings enjoyed, and he can be happy even “inside the bull of Phalaris.” The most beautiful example was set by Epicurus at the moment of his death:

A happy day is this on which I write to you . . . The pains which I feel . . . could not be greater. But all of this is opposed by the happiness which the soul experiences, remembering our conversations of a bygone time.

The ultimate concentration of all his wisdom is the *Tetrapharmakon*, preserved by Philodemus: “The gods are not to be feared. Death is not a thing that one must fear. Good is easy to obtain. Evil is easy to tolerate.”

The Epicurean school. Epicurus’ successor in the direction of the Garden was Hermarchus of Mitylene, and he was succeeded in turn by Polystratus, who was the last survivor to have heard Epicurus. Superior to both, however, were Metrodorus and Colotes, against whom a small work by Plutarch was directed. Among the Epicureans of the 2nd century BC, mention must be made of Demetrius of Lacon, of whose works some fragments remain, and Apollodorus, who wrote more than 400 books. Much was also written by his disciple Zeno of Sidon, who was heard by Cicero in 79 BC in Athens. After Zeno, there were Phaedrus, also a teacher of Cicero, who was in Rome in 90 BC, and Patro, the head of the school until 51 BC. Already famous as an epigram writer was Philodemus of Gadara (born 110 BC). In the papyri of Herculaneum, comprising the effects of Philodemus’ library, there are sizable remains of almost all of his numerous works. Epicureanism had already been introduced in Rome, in the 2nd century BC. The first person to spread its doctrines in Latin prose was

*De rerum
natura*

a certain Amfinius. At the time of Cicero, Epicureanism was in fact the philosophy in vogue; and the number of Romans subscribing to it was, according to Cicero, very large. Among the greatest was Titus Lucretius Carus (c. 95–55 BC), who, in the poem *De rerum natura* ("On the Nature of Things"), left an almost complete and amazingly precise exposition of Epicurus' "Physics." The extent to which Epicurus was still popular in the 1st century after Christ is demonstrated by Seneca, who cited and defended him. To the 2nd century AD belongs Diogenes of Oenoanda, who carved Epicurus' works on a portico wall. In the same century should perhaps be mentioned Diogenianus, fragments of whose polemic against the Stoic Chrysippus are found in the church historian Eusebius. Also Epicurean, between the 4th and 5th centuries, was the epigrammatist Palladas.

On account of its dogmatic character and its practical end, the philosophy of Epicurus was not subject to development, except in the polemic and in its application to themes that Epicurus either had treated briefly or had never dealt with at all. To be aware of this, it is sufficient to run through what remains of the representatives of his school and particularly of the works of Philodemus of Gadara. Epicurus' philosophy remained essentially unchanged. Once truth has been found, it requires no more discussion, particularly when it completely satisfies the end toward which man's nature tends. The main thing is to see this end; all of the rest comes by itself, and there is no longer anything to do but follow Epicurus, "liberator" and "saviour," and to memorize his "oracular words."

Epicureanism and egoism in modern philosophy. In the Middle Ages Epicurus was known through Cicero and the polemics of the fathers. To be an Epicurean at the time of Dante meant to be one who denied Providence and the immortality of the soul. In the 15th century, the notable humanist Lorenzo Valla—following brief hints by Petrarch—wrote, in the dialogue *De voluptate* (1431; "On Pleasure"), the first modern defense of the ethics of Epicurus, maintaining that the true good is pleasure and not virtue but concluding that the supreme pleasure is that which awaits man in heaven, which even the Bible calls *paradisum voluptatis*. In the 16th century, in terms of attitude and direction of thought, the first two great Epicureans were Michel de Montaigne in France and Francesco Guicciardini in Italy. Epicurean in everything, as man and as poet, was the early 16th-century classicist Ludovico Ariosto. But not until the 17th-century Provençal abbot Pierre Gassendi was the system of Epicurus to rise again in its entirety—this time, however, by approaching truth through faith. Gassendi in 1649 wrote a commentary on a book by the 3rd-century (AD) biographer Diogenes Laërtius. This comment, called the *Syntagma philosophiae Epicuri* ("Treatise on Epicurean Philosophy"), was issued posthumously at The Hague 10 years later. At the same time, in England, Thomas Hobbes, a friend of Gassendi, took up again the theory of pleasure and interpreted it in a dynamic sense, which was therefore closer to the doctrine of the ancient Cyrenaics. Starting from the premise that, in the natural state, "man is a wolf to man," he concluded that peace, without which there is no happiness, cannot be guaranteed by anything but force, and that this force must be relinquished, by common agreement, to the power of only one.

During the 17th and 18th centuries, the European nation in which Epicureanism was most active was France, where its representatives were called libertines, among them moralists such as François, duc de La Rochefoucauld, and Charles de Saint-Évremonde; scientists such as Julien de La Mettrie, who believed that man could be explained as a machine, Claude-Adrien Helvetius, who reduced the ethic of the useful to a form of experimental science but who put public above private well-being, and Paul Henri Dietrich, baron d'Holbach, who gave particular importance to the physics of the atoms. The purely sensistic conception of knowledge had its most thoroughgoing theoretician in Étienne de Condillac. In England, Adam Smith, developing the ethical concepts of Hume (founded on sympathy), surmounted the egoism that is the basis of every act by using the principle of the impartial observer invoked to

sympathize with one or another of the antagonists. After him, the jurist Jeremy Bentham, eliminating sympathy, reduced ethics to the pure calculus of the useful, which—in an entirely Epicurean formula—he defined as a "moral arithmetic." In the Epicurean stream lay also the Utilitarianism of the 19th century, of which the greatest representative was John Stuart Mill.

Epicureanism in contemporary philosophy. In contemporary times, the interpretation of pleasure as a psychic principle of action was initiated by Gustav Fechner, the founder of psychophysics, and developed toward the end of the century by Freud on the psychoanalytic level of the unconscious.

Epicureanism and egocentric hedonism have few faithful representatives among 20th-century philosophers, though the viewpoint remains as a residue in some strains of popular thinking.

CRITICISM AND EVALUATION

In the first half of the 17th century, at a time when Pierre Gassendi was reviving atomistic Epicureanism, René Descartes, often called the founder of modern philosophy, offered arguments that tended to undercut Atomism. Reality is a plenum, he held, a complete fullness; there can be no such thing as a vacuous region, or the void of Atomism. Since matter is nothing but spatial extension, its only true properties are geometrical and dynamic. Because extension is everywhere, motion occurs not as a passage through emptiness, as Epicurus supposed, but as vortices, or "whirlpools," in which every motion sets up a broad area of movement extending indefinitely around itself—a view that has tended to be confirmed in contemporary gravitational and field theory.

Close to the heart of Epicureanism is the principle, which occurred also in Democritus, that denies that something can come from or be rooted in nothing. In a poem composed by an ancient monist, Parmenides of Elea (born c. 515 BC), this principle had been expressed in the two formulas: "Being cannot be Non-Being," and "Non-Being must be Non-Being." Though Epicurus had faithfully adhered to this principle almost throughout his system, he has been criticized for abandoning it at one point—in the swerves that he attributed to occasional atoms that take them aside from their normal paths. Epicurus abandoned the principle at this point in order to avoid espousing a physics that was inconsistent with the autonomy that he observed in the physical behaviour of men and animals. But to his Stoic critics, the swerves of the atoms were a scandal, since they implied that an event can occur without a cause. It has seldom been noted, however, that the swerve is merely a special case—a transposition into atomistic terms—of Aristotle's theory of accidents (*i.e.*, of properties that are not essential to the substances in which they occur), inasmuch as an accident, too, as Aristotle himself had stated (*Met.* I 3), is without a cause. Moreover, a similar view has been seriously advanced in modern times under the name of tychism by Charles Sanders Peirce, a philosopher of science.

To the Stoic charge that Epicurus lacked a doctrine of Providence (since he viewed the gods as being lazy), Epicurus answered that "mythical gods are preferable to the fate" posited by the Stoics. It has been suggested that he might equally well have added that the "immobile Prime Mover" of Aristotle's theology was hardly less lazy than Epicurus' gods. Epicurus' way of phrasing this issue, however, must not obscure the fact that the problem of Providence and its secularization has been a crucial one in the philosophy of history ever since ancient times.

The effort of Epicurus to reduce the good to pleasure reflects the only criterion to which he would entrust himself, the "evidence of those passions immediately present," which give man the word of Nature. In the argument of psychological hedonism, here implied, the Epicurean holds that men as a matter of fact do take satisfaction in pleasure and decry pain, and he argues then to an egoistic ethical hedonism that identifies the (objective) good with pleasure. Most moralists, however, have felt that a thoroughgoing psychological hedonism cannot be defended; that desire is often, as a matter of fact, directed toward

Pleasure
as a life-
style

Gassendi's

Epicu-
reanism

Critique
of egoistic
hedonism

an object with no thought at all about the pleasure that it will bring; that a mother's impulse to save her young from danger is more fundamental than any pleasure involved (which usually comes only afterward); that the tendency of a child to imitate his parents can be, in fact, quite painful; and that, as a 19th-century Utilitarian, Henry Sidgwick, has argued, in what he called the "hedonistic paradox," one of the most ineffective ways to achieve pleasure is to deliberately seek it out.

Some scholars have even argued that an Epicurean egoistic hedonism, however foresighted it may be, must logically be self-defeating. If the view is universalized, the egoist must advocate the maximization of his enemy's pleasure as well as of his own, which can lead to actions painful to himself. In consequence, the entire branch of ethics that covers the advising or judging of other agents is banned from consideration, and it may be questioned whether such a view can comprise an ethic at all.

On the other hand, it has been argued that man is subject to antinomies, or contradictions, that no system can escape; there are dimensions in his nature that transcend the rational level. Thus, whatever its rational credentials may be, Epicureanism, as an attitude toward life that was theorized in its purest form by Epicurus, nonetheless remains one of the important forms that human behaviour has often assumed; and, at its best, it has achieved a type of asceticism that, even in retirement and solitude, does not negate company but welcomes it, finding the purest joys of life in the unique richness of human encounters.

(C.D.)

Platonism

Since Plato refused to write any formal exposition of his own metaphysics, our knowledge of its final shape has to be derived from the statements of Aristotle, which are confirmed by scanty remains of the earliest Platonists preserved in the Neoplatonist commentaries on Aristotle. These statements can, unfortunately, only be interpreted conjecturally.

ARISTOTLE'S ACCOUNT OF PLATONISM

According to Aristotle (*Metaphysics* i, 987 b 18–25) Plato's doctrine of forms was, in its general character, not different from Pythagoreanism, the forms being actually called numbers. The two points on which Aristotle regards Plato as disagreeing with the Pythagoreans are (1) that, whereas the Pythagoreans said that numbers have as their constituents the unlimited and the limit, Plato taught that the forms have as constituents the one and the great and small; and (2) that, whereas the Pythagoreans had said that things are numbers, Plato intercalated between his forms (or numbers) and sensible things an intermediate class of mathematical. It is curious that in connection with the former difference Aristotle dwells mainly on the substitution of the "duality of the great and small" for the "unlimited," not on the much more significant point that the one, which the Pythagoreans regarded as the simplest complex of unlimited and limit, is treated by Plato as itself the element of limit. He further adds that the "great and small" is, in his own technical terminology, the matter, the one, the formal constituent, in a number.

If we could be sure how much of the polemic against number-forms in *Metaphysics* xiii–xiv is aimed directly at Plato, we might add considerably to this bald statement of his doctrine, but unluckily it is certain that much of the polemic is concerned with the teaching of Speusippus and Xenocrates. It is not safe, therefore, to ascribe to Plato statements other than those with which Aristotle explicitly credits him. We have then to interpret, if we can, two main statements: (1) the statement that the forms are numbers; and (2) the statement that the constituents of a number are the great and small and the one.

Light is thrown on the first statement if we recall the corpuscular physics of the *Timaeus* and the mixture of the *Philebus*. In the *Timaeus*, in particular, the behaviour of bodies is explained by the geometrical structure of their corpuscles, and the corpuscles themselves are analyzed into complexes built up out of two types of elementary

triangle, which are the simplest elements of the narrative of *Timaeus*. Now a triangle, being determined in everything but absolute magnitude by the numbers that express the ratio of its sides, may be regarded as a triplet of numbers. If we remember then, that the triangles determine the character of bodies and are themselves determined by numbers, we may see why the ultimate forms on which the character of nature depends should be said to be numbers and also what is meant by the mathematical intermediate between the forms and sensible things. According to Aristotle, these mathematical differ from forms because they are many, whereas the form is one, from sensible things in being unchanging. This is exactly how the geometer's figure differs at once from the type it embodies and from a visible thing. There is, for example, only one type of triangle whose sides have the ratios 3:4:5, but there may be as many pure instances of the type as there are triplets of numbers exhibiting these ratios; and again, the geometrical triangles that are such pure instances of the type, unlike sensible three-sided figures, embody the type exactly and unchangingly. A mathematical physicist may thus readily be led to what seems to be Plato's view that the relations of numbers are the key to the whole mystery of nature, as is actually said in the *Epinomis* (990 e).

We can now, perhaps, see the motive for the further departure from Pythagoreanism. It is clear that the Pythagorean parallelism between geometry and arithmetic rested upon the thought that the point is to spatial magnitude what the number 1 is to number. Numbers were thought of as collections of units, and volumes, in like fashion, as collections of points; that is, the point was conceived as a minimum volume. As the criticisms of Zeno showed, this conception was fatal to the specially Pythagorean science of geometry itself, since it makes it impossible to assert the continuity of spatial magnitude. (This, no doubt, is why Plato, as Aristotle tells us, rejected the notion of a point as a fiction.)

There is also a difficulty about the notion of a number as a collection of units, which must have been forced on Plato's attention by the interest in irrationals that is shown by repeated allusions in the dialogues, as well as by the later anecdotes that represent him as busied with the problem of doubling the cube or finding two mean proportionals. Irrational square and cube roots cannot possibly be reached by any process of forming collections of units, and yet it is a problem in mathematics to determine them, and their determination is required for physics (*Epinomis* 990 c–991 b).

This is sufficient to explain why it is necessary to regard the numbers that are the physicist's determinants as themselves determinations of a continuum (a great and small) by a limit and why at the same time the one can no longer be regarded as a blend of unlimited and limit but must be itself the factor of limit. (If it were the first result of the blending, it would reappear in all the further blends; all numbers would be collections of one and there would be no place for the irrationals.) There is no doubt that Plato's thought proceeded on these general lines. Aristotle tells us that he said that numbers are not really addable (*Metaphysics* xiii, 1083 a 34), that is, that the integer series is not really made by successive additions of 1; and the *Epinomis* is emphatic on the point that, contrary to the accepted opinion, surds are just as much numbers as integers. The underlying thought is that numbers are to be thought of as generated in a way that will permit the inclusion of rationals and irrationals in the same series. In point of fact there are logical difficulties that make it impossible to solve the problem precisely on these lines. It is true that mathematics requires a sound logical theory of irrational numbers and, again, that an integer is not a collection of units; it is not true that rational integers and real numbers form a single series.

The Platonic number theory was inspired by thoughts that have since borne fruit abundantly but was itself premature. We learn partly from Aristotle, partly from notices preserved by his commentators, that, in the derivation of the integer series, the even numbers were supposed to be generated by the dyad that doubles whatever it lays hold of, the odd numbers in some way by the one that limits

Further

from
Pythagoreanism

Platonic
number
theory

or equalizes, but the interpretation of these statements is, at best, conjectural. In the statement about the dyad there seems to be some confusion between the number 2 and the indeterminate dyad, another name for the continuum also called the great and small, and it is not clear whether this confusion was inherent in the theory itself or has been caused by Aristotle's misapprehension.

Nor, again, is it at all certain exactly what is meant by the operation of equalizing ascribed to the one. It would be improper here to propound conjectures that our space will not allow us to discuss. A collection and examination of the available evidence is given by L. Robin in his *Théorie platonicienne des idées et des nombres d'après Aristotle* (1908), and an admirable exposition of the significance of the problem of the irrational for Plato's philosophy by G. Milhaud in *Les Philosophes-géomètres de la Grèce, Platon et ses prédécesseurs*, new ed. (1934). For a conjectural interpretation see A.E. Taylor, "Forms and Numbers," in *Mind*, new series, vol. 35 and 36 (1926, 1927).

THE ACADEMY AFTER PLATO: THE RISE OF NEOPLATONISM

Plato's Academy continued to exist as a corporate body down to AD 529, when the emperor Justinian, in his zeal for Christian orthodoxy, closed the schools of Athens and appropriated their emoluments. Plato's greatest scholar, Aristotle, had finally gone his own way and organized a school of his own in the Lyceum, claiming that he was preserving the essential spirit of Platonism while rejecting the difficult doctrine of the forms. The place of official head of the Academy was filled first by Speusippus, Plato's nephew (c. 347–339 BC), then by Xenocrates (c. 339–314 BC). Under Arcesilaus (c. 276–241 BC) the Academy began its long-continued polemic against the sensationalist dogmatism of the Stoics, which accounts both for the tradition of later antiquity that dates the rise of a New (some said Middle) and purely skeptical Academy from Arcesilaus and for the 18th-century associations of the phrase "academic philosophy."

In the 1st century BC the most interesting episode in the history of the school is the quarrel between its president, Philo of Larissa, and his scholar Antiochus of Ascalon, of which Cicero's *Academica* is the literary record. Antiochus, who had embraced Stoic tenets, alleged that Plato had really held views indistinguishable from those of Zeno of Citium and that Arcesilaus had corrupted the doctrine of the Academy in a skeptical sense. Philo denied this. The gradual rapprochement between Stoicism and the Academy is illustrated from the other side by the work of Stoic scholars such as Panaetius of Rhodes and Poseidonius of Apamea, who commented on Platonic dialogues and modified the doctrines of their school in a Platonic sense.

The history of the Academy after Philo is obscure, but since the late 1st century AD we meet with a popular literary Platonism of which the writings of Plutarch are the best example. This popular Platonism insists on the value of religion, in opposition to Epicureanism, and on the freedom of the will and the reality of human initiative, in opposition to the Stoic determinism; a further characteristic feature, wholly incompatible with the genuine doctrine of Plato, is the notion that matter is inherently evil and the source of moral evil.

Genuine Platonism was revived in the 3rd century AD, in Rome, and independently of the Academy, by Plotinus. His Neoplatonism represents a real effort to do justice to the whole thought of Plato. Two aspects of Plato's thought, however, in the changed conditions inevitably fell into the background: the mathematical physics, and the politics. The 3rd century AD had no understanding for the former, and the Roman Empire under a succession of military chiefs no place for the latter. The doctrine of Plotinus is Platonism seen through the personal temperament of a saintly mystic and with the *Symposium* and the teaching of the *Republic* about the form of good always in the foreground. Plotinus lived in an atmosphere too pure for sectarian polemic, but in the hands of his successors Neoplatonism was developed in conscious opposition to Christianity. Porphyry, his disciple and biographer, was the most formidable of the anti-Christian controversialists;

in the next century, "Platonists" were among the allies and counsellors of the emperor Julian in his attempts to invent a Hellenic counterpart to Christianity.

Early in the 5th century, Neoplatonism flourished for a short time in Alexandria (which disgraced itself by the murder of Hypatia in 415) and captured the Athenian Academy itself, where its last great representative was the acute Proclus (AD 410–485). The latest members of the Academy, under Justinian, occupied themselves chiefly with learned commentaries on Aristotle, of which those of Simplicius are the most valuable. The doctrine of the school itself ends with Damascius in mystical agnosticism.

INFLUENCE OF PLATONISM ON CHRISTIAN THOUGHT

Traces of Plato are probably to be detected in the Alexandrian *Wisdom of Solomon*; the thought of the Alexandrian Jewish philosopher and theologian Philo, in the 1st century AD, is at least as much Platonic as Stoic. There are, perhaps, no certain marks of Platonic influence in the New Testament, but the earliest apologists (Justin, Athenagoras) appealed to the witness of Plato against the puerilities and indecencies of mythology. In the 3rd century Clement of Alexandria and after him Origen made Platonism the metaphysical foundation of what was intended to be a definitely Christian philosophy. The church could not, in the end, conciliate Platonist eschatology with the dogmas of the resurrection of the flesh and the Last Judgment, but in a less extreme form the platonizing tendency was continued in the next century by the Cappadocians, notably St. Gregory of Nyssa, and passed from them to St. Ambrose of Milan. The main sources of the Platonism that dominated the philosophy of Western Christian theologians through the earlier Middle Ages, were, however, Augustine, the greatest thinker among the western Fathers, who had been profoundly influenced by Plotinus read in a Latin version before his conversion to Christianity; and Boethius, whose wholly Platonist vindication of the ways of Providence in his *De Consolatione Philosophiae* was the favourite serious book of the Middle Ages.

A further powerful influence was exerted by the writings of the Pseudo-Dionysius the Areopagite. These works are, in fact, an imperfectly Christianized version of the speculations of Proclus and cannot date before the end of the 5th century AD at the earliest, but they enjoyed an immense authority based on their attribution to an immediate convert of St. Paul. After their translation into Latin in the 9th century by John Scotus Erigena, they became popular in the West.

Apart from this theological influence, Plato dominated the thought of the earlier Renaissance that dates from the time of Charlemagne in another way. Since the West possessed the philosophical writings of Cicero, with the Neoplatonic comment of Macrobius on the *Somnium Scipionis*, as well as the Latin translation of the first two-thirds of the *Timaeus* by Chalcidius, with his commentary on the text, and versions, also, at least of the *Phaedo* and of the *Meno*, whereas nothing was known of the works of Aristotle except Latin versions of some of the logical treatises, the Middle Ages, between Charlemagne and the beginning of the 13th century, when the recovery of Aristotle's physics and metaphysics from Moors, Persians, and Jews began, was much better informed about Plato than about Aristotle; in particular, in the various encyclopaedias of this period, it is the *Timaeus* that forms the regular background.

The 13th century saw a change. Aristotle came to displace Plato as the philosopher, partly in consequence of the immediately perceived value of his strictly scientific works as a storehouse of well-digested natural facts, partly from the brilliant success of the enterprise carried through by St. Thomas Aquinas, the reconstruction of philosophical theology on an Aristotelian basis. Plato is, however, by no means supplanted in the Thomist system; the impress of Augustine on Western thought has been far too deep for that. Augustine's "exemplarism," that is, the doctrine of forms in the version, ultimately derived from Philo of Alexandria, which makes the forms creative thoughts of God, is an integral part of the Thomist metaphysics, though it is now denied that the exemplars are themselves

Augustine
and
Boethius

The
Neo-
platonism
of
Plotinus

cognizable by the human intellect, which has to collect its forms, as best it can, from the data of sense.

Directly or through Augustine, the influence of Plato, not only on strictly philosophic thought but also on popular ethics and religion, has repeatedly come to the front in ages of general spiritual requickening and shows no signs of being on the wane.

Two revivals in particular are famous. The first is that of the 16th century, marked by the Latin translation of Marsilio Ficino and the foundation of Lorenzo de' Medici's fantastic Florentine Academy. What was revived then was not so much the spirit of Plato as that of the least sober of the Neoplatonists; the influence of the revival was felt more in literature than in philosophy or morals, but in literature its importance may be measured by the mere mention of such names as Michelangelo, Sir Philip Sidney, and Edmund Spenser.

In the 17th century, Plato, seen chiefly through the medium of Plotinus, supplied the inspiration of a group of noble thinkers who were vindicating a more inward morality and religion against the unspiritual secularism and Erastianism of Hobbes: namely the so-called Cambridge Platonists, Benjamin Whichcote, Henry More, Ralph Cudworth, and John Smith. In the 20th century, on the one hand A.N. Whitehead tried to work out a philosophy of the sciences that confessedly connected itself with the ideas of the *Timaeus*; and on the other the rise of totalitarian governments produced a number of publications confronting Plato with the theories (Communist, Fascist, etc.) inherent in their policies. Neo-Kantianism, Existentialism, and analytical philosophy produced their own interpretations of Plato. (A.E.Ta./Pp.M.)

Pythagoreanism

The philosophical school and religious brotherhood known as Pythagoreanism is believed to have been founded by Pythagoras of Samos, who settled in Croton in southern Italy about 525 BC.

GENERAL FEATURES OF PYTHAGOREANISM

The character of the original Pythagoreanism is controversial, and the conglomeration of disparate features that it displayed is intrinsically confusing. Its fame rests, however, on some very influential ideas, not always correctly understood, that have been ascribed to it since antiquity. These ideas include those of (1) the metaphysics of number and the conception that reality, including music and astronomy, is, at its deepest level, mathematical in nature; (2) the use of philosophy as a means of spiritual purification; (3) the heavenly destiny of the soul and the possibility of its rising to union with the divine; (4) the appeal to certain symbols, sometimes mystical, such as the *tetraktys*, the golden section, and the harmony of the spheres (to be discussed below); (5) the Pythagorean theorem; and (6) the demand that members of the order shall observe a strict loyalty and secrecy.

By laying stress on certain inner experiences and intuitive truths revealed only to the initiated, Pythagoreanism seems to have represented a soul-directed subjectivism alien to the mainstream of Pre-Socratic Greek thought centring on the Ionian coast of Asia Minor (Thales, Anaximander, Anaxagoras, and others), which was preoccupied with determining what the basic cosmic substance is.

In contrast with such Ionian naturalism, Pythagoreanism was akin to trends seen in mystery religions and emotional movements, such as Orphism, which often claimed to achieve through intoxication a spiritual insight into the divine origin and nature of the soul. Yet there are also aspects of it that appear to have owed much to the more sober, "Homeric" philosophy of the Ionians. The Pythagoreans, for example, displayed an interest in metaphysics (the nature of Being), as did their naturalistic predecessors, though they claimed to find its key in mathematical form rather than in any substance. They accepted the essentially Ionian doctrines that the world is composed of opposites (wet-dry, hot-cold, etc.) and generated from something unlimited; but they added the idea of the imposition of limit upon the unlimited and the

sense of a musical harmony in the universe. Again, like the Ionians, they devoted themselves to astronomical and geometrical speculation. Combining, as it does, a rationalistic theory of number with a mystic numerology and a speculative cosmology with a theory of the deeper, more enigmatic reaches of the soul, Pythagoreanism interweaves Rationalism and irrationalism more inseparably than does any other movement in ancient Greek thought.

MAJOR CONCERNS AND TEACHINGS

The problem of describing Pythagoreanism is complicated by the fact that the surviving picture is far from complete, being based chiefly on a small number of fragments from the time before Plato and on various discussions in authors who wrote much later—most of whom were either Aristotelians or Neoplatonists (see below *History of Pythagoreanism*). In spite of the historical uncertainties, however, that have plagued searching scholars, the contribution of Pythagoreanism to Western culture has been significant and therefore justifies the effort, however inadequate, to depict what its teachings may have been. Moreover, the heterogeneousness of Pythagorean doctrines has been well documented ever since Heraclitus, a classic early 5th-century Greek philosopher who, scoffing at Pythagoras' wide-ranging knowledge, said that it "does not teach one to have intelligence." There probably never existed a strictly uniform system of Pythagorean philosophy and religious beliefs, even if the school did have a certain internal organization. Pythagoras appears to have taught by pregnant, cryptic *akousmata* ("something heard") or *symbola*. His pupils handed these on, formed them partly into *Hieroi Logoi* ("Sacred Discourses"), of which different versions were current from the 4th century on, and interpreted them according to their convictions.

Religion and ethics. The belief in the transmigration of souls provided a basis for the Pythagorean way of life. Some Pythagoreans deduced from this belief the principle of "the kinship of all beings," the ethical implications of which were later stressed in 4th-century speculation. Pythagoras himself seems to have claimed a semidivine status in close association with the superior god Apollo; he believed that he was able to remember his earlier incarnations and, hence, to know more than others knew. Recent research has emphasized shamanistic traits deriving from the ecstatic cult practices of Thracian medicine men in the early Pythagorean outlook. The rules for the religious life that Pythagoras taught were largely ritualistic: refrain from speaking about the holy, wear white clothes, observe sexual purity, do not touch beans, and so forth. He seems also to have taught purification of the soul by means of music and mental activity (later called philosophy) in order to reach higher incarnations. "To be like your Master" and so "to come nearer to the gods" was the challenge that he imposed on his pupils. Salvation, and perhaps ultimate union with the divine cosmos through the study of the cosmic order, became one of the leading ideas in his school.

The advanced ethics and political theories sometimes ascribed to Pythagoreanism may to some extent reflect ideas later developed in the circle of Archytas, the leading 4th-century Pythagorean. But a picture current among the Peripatetics (the school founded by Aristotle) of Pythagoras as the educator of the Greeks, who publicly preached a gospel of humanity, is clearly anachronistic. Several of the Peripatetic writers, Aristoxenus, Dicaearchus, and Timaeus, seem to have interpreted some principles—properly laid down only for esoteric use in the brotherhood—as though these applied to all mankind: the internal loyalty, modesty, self-discipline, piety, and abstinence required by the secret doctrinal system; the higher view of womanhood reflected in the admission of women to the school; a certain community of property; and perhaps the drawing of a parallelism between the macrocosm (the universe) and the microcosm (man), in which (for instance) the Pythagorean idea that the cosmos is an organism was applied to the state, which should thus mix monarchy, oligarchy, and democracy into a harmonic whole—these were all universalized.

Metaphysics and number theory. According to Aristot-

Significance of belief in transmigration of souls

The
"Cam-
bridge
Platonists"

le, number speculation is the most characteristic feature of Pythagoreanism. Things “are” number, or “resemble” number. To many Pythagoreans this concept meant that things are measurable and commensurable or proportional in terms of number—an idea of considerable significance for Western civilization. But there were also attempts to arrange a certain minimum number of pebbles so as to represent the shape of a thing—as, for instance, stars in a constellation that seem to represent an animal. For the Pythagoreans even abstracted things “have” their number: “justice” is associated with the number four and with a square, “marriage” with the number five, and so on. The psychological associations at work here have not been clarified.

The harmony of the cosmos. The sacred decad in particular has a cosmic significance in Pythagoreanism: its mystical name, *tetraktys* (meaning approximately “fourness”), implies $1 + 2 + 3 + 4 = 10$; but it can also be thought of as a “perfect triangle,” as in Figure 1.

Speculation on number and proportion led to an intuitive feeling of the *harmonia* (“fitting together”) of the *kosmos* (“the beautiful order of things”); and the application of the *tetraktys* to the theory of music (see below *Music*) revealed a hidden order in the range of sound. Pythagoras may have referred, vaguely, to the “music of the heavens,” which he alone seemed able to hear; and later Pythagoreans seem to have assumed that the distances of the heavenly bodies from the Earth somehow correspond to musical intervals—a theory that, under the influence of Platonic conceptions, resulted in the famous idea of the “harmony of the spheres.” Though number to the early Pythagoreans was still a kind of cosmic matter, like the water or air proposed by the Ionians, their stress upon numerical proportions, harmony, and order comprised a decisive step toward a metaphysics in which form is the basic reality.

The doctrine of opposites. From the Ionians, the Pythagoreans adopted the idea of cosmic opposites, which they—perhaps secondarily—applied to their number speculation. The principal pair of opposites is the limit and the unlimited; the limit (or limiting), represented by the odd (3, 5, 7, . . .), is an active force effecting order, harmony, “cosmos,” in the unlimited, represented by the even. All kinds of opposites somehow “fit together” within the cosmos, as they do, microcosmically, in an individual man and in the Pythagorean society. There was also a Pythagorean “table of ten opposites,” to which Aristotle has referred—limit-unlimited, odd-even, one-many, right-left, male-female, rest-motion, straight-curved, light-darkness, good-evil, and square-oblong. The arrangement of this table reflects a dualistic conception, which was apparently not original with the school, however, or accepted by all of its members.

The Pythagorean number metaphysics was also reflected in its cosmology. The unit (1), being the starting point of the number series and its principle of construction, is not itself strictly a number; for, to be a number is to be even or odd, whereas, in the Pythagorean view, “one” is seen as *both* even and odd. This ambivalence applies, similarly, to the total universe, conceived as the One. There was also a cosmogonical theory (of cosmic origins) that explained the generation of numbers and number-things from the limiting-odd and the unlimited-even—a theory that, by stages unknown to scholars, was ultimately incorporated into Plato’s philosophy in his doctrine of the derivation of sensed realities from mathematical principles.

Mathematics and science. Pythagorean thought was scientific as well as metaphysical and included specific developments in arithmetic and geometry, in the science of musical tones and harmonies, and in astronomy.

Arithmetic. Early Pythagorean achievements in mathematics are unclear and largely disputable, and the following is, therefore, a compromise between the widely divergent views of modern scholars.

In the speculation on odd and even numbers, the early Pythagoreans used so-called *gnōmones* (Greek: “carpenter’s squares”). Judging from Aristotle’s account, gnomon numbers, represented by dots or pebbles, were arranged in the manner shown in Figure 2. If a series of odd numbers

Use of the *gnōmones*

Figure 2: Gnomons of Pythagorean number theory (see text).

is put around the unit as gnomons, they always produce squares; thus, the members of the series 4, 9, 16, 25, . . . are “square” numbers. If even numbers are depicted in a similar way, the resulting figures (which offer infinite variations) represent “oblong” numbers, such as those of the series 2, 6, 12, 20, On the other hand, a triangle represented by three dots (as in the upper part of the *tetraktys*) can be extended by a series of natural numbers to form the “triangular” numbers 6, 10 (the *tetraktys*), 15, 21, This procedure, which was, so far, Pythagorean, led later, perhaps in the Platonic Academy, to a speculation on “polygonal” numbers.

Probably the square numbers of the gnomons were early associated with the Pythagorean theorem (likely to have been used in practice in Greece, however, before Pythagoras), which holds that for a right triangle a square drawn on the hypotenuse is equal in area to the sum of the squares drawn on its sides; in the gnomons it can easily be seen, in the case of a 3,4,5-triangle for example (see Figure 3), that the addition of a square gnomon number

Figure 3: Gnomon for Pythagorean theorem. The marked off “carpenter’s square”—comprising 3 groups of 3 dots each (3×3)—thus represents 3^2 , which when added to 4^2 yields 5^2 (the total gnomon).

to a square makes a new square: $3^2 + 4^2 = 5^2$, and this gives a method for finding two square numbers the sum of which is also a square.

Some 5th-century Pythagoreans seem to have been puzzled by apparent arithmetical anomalies: the mutual relationships of triangular and square numbers; the anomalous properties of the regular pentagon; the fact that the length of the diagonal of a square is incommensurable with its sides—*i.e.*, that no fraction composed of integers can express this ratio exactly (the resulting decimal is thus defined as irrational); and the irrationality of the mathematical proportions in musical scales. The discovery of such irrationality was disquieting because it had fatal consequences for the naive view that the universe is expressible in whole numbers; the Pythagorean Hippasus is said to have been expelled from the brotherhood, according to some sources even drowned, because he made a point of the irrationality.

In the 4th century, Pythagorizing mathematicians made a significant advance in the theory of irrational numbers, such as the-square-root-of- n (\sqrt{n}), n being any rational number, when they developed a method for finding progressive approximations to $\sqrt{2}$ by forming sets of so-called diagonal numbers.

Geometry. In geometry, the Pythagoreans cannot be credited with any proofs in the Euclidean sense. They were evidently concerned, however, with some speculation on geometrical figures, as in the case of the Pythagorean theorem, and the concept that the point, line, triangle, and tetrahedron correspond to the elements of the *tetraktys*, since they are determined by one, two, three, and four points, respectively. They possibly knew practical methods of constructing the five regular solids, but the theoretical basis for such constructions was given by non-Pythagoreans in the 4th century.

It is notable that the properties of the circle seem not to have interested the early Pythagoreans. But perhaps the tradition that Pythagoras himself discovered that the sum of the three angles of any triangle is equal to two right angles may be trusted. The idea of geometric proportions is probably Pythagorean in origin; but the so-called golden section—which divides a line at a point such

The problem of irrational numbers

that the smaller part is to the greater as the greater is to the whole—is hardly an early Pythagorean contribution. Some advance in geometry was made at a later date, by 4th-century Pythagoreans; e.g., Archytas offered an interesting solution to the problem of the duplication of the cube—in which a cube twice the volume of a given cube is constructed—by an essentially geometrical construction in three dimensions; and the conception of geometry as a “flow” of points into lines, of lines into surfaces, and so on, may have been contributed by Archytas; but on the whole the numerous achievements of non-Pythagorean mathematicians were in fact more conspicuous than those of the Pythagoreans.

Music. The achievements of the early Pythagoreans in musical theory are somewhat less controversial. The scientific approach to music, in which musical intervals are expressed as numerical proportions, originated with them, as did also the more specific idea of harmonic “means.” At an early date they discovered empirically that the basic intervals of Greek music include the elements of the *tetraktys*, since they have the proportions 1:2 (octave), 3:2 (fifth), and 4:3 (fourth). The discovery could have been made, for instance, in pipes or flutes or stringed instruments: the tone of a plucked string held at its middle is an octave higher than that of the whole string; the tone of a string held at the $\frac{2}{3}$ point is a fifth higher; and that of one held at the $\frac{3}{4}$ point is a fourth higher. Moreover, they noticed that the subtraction of intervals is accomplished by dividing these ratios by one another. In the course of the 5th century they calculated the intervals for the usual diatonic scale, the tone being represented by 9:8 (fifth minus fourth); i.e., $3/2 \div 4/3$, and the semitone by 256:243 (fourth minus two tones); i.e., $4/3 \div (9/8 \times 9/8)$. Archytas made some modification to this doctrine and also worked out the relationships of the notes in the chromatic (12-tone) scale and the enharmonic scale (involving such minute differences as that between A flat and G sharp, which on a piano are played by the same key).

Astronomy. In their cosmological views the earliest Pythagoreans probably differed little from their Ionian predecessors. They made a point of studying the stellar heavens; but—with the possible exception of the theory of musical intervals in the cosmos—no new contributions to astronomy can be ascribed to them with any degree of probability. Late in the 5th century, or possibly in the 4th century, a Pythagorean boldly abandoned the geocentric view and posited a cosmological model in which the Earth, Sun, and stars circle about an (unseen) central fire—a view traditionally attributed to the 5th-century Pythagorean Philolaus of Croton.

HISTORY OF PYTHAGOREANISM

The life of Pythagoras and the origins of Pythagoreanism appear only dimly through a thick veil of legend and semihistorical tradition. The literary sources for the teachings of the Pythagoreans present extremely complicated problems. Special difficulties arise from the oral and esoteric transmission of the early doctrines, the profuse accumulation of tendentious legends, and the considerable amount of confusion that was caused by the split in the school in the 5th century BC. In the 4th century, Plato's inclination toward Pythagoreanism created a tendency—manifest already in the middle of the century in the works of his pupils—to interpret Platonic concepts as originally Pythagorean. But the radical skepticism as to the reliability of the sources shown by some modern scholars has on the whole been abandoned in recent research. It now seems possible to extract bits of reliable evidence from a wide range of ancient authors, such as Porphyry and Iamblichus (see below *Neo-Pythagoreanism*).

Most of these literary sources hark back ultimately to the environment of Plato and Aristotle; and here the importance of one of Aristotle's students has become obvious, viz., the musicologist and philosopher Aristoxenus, who in spite of his bias possessed firsthand information independent of the point of view of Plato's Academy. The role played by Dicaearchus, another of Aristotle's pupils, and by the Sicilian historian Timaeus, of the early 3rd century BC, is less clear. Recently, the reliability of Aristot-

le's account of Pythagoreanism has also been emphasized against the doubts that had been expressed by some modern scholars; but Aristotle's sources, in turn, hardly lead farther back than to the late 5th century (perhaps to Philolaus; see below *Two Pythagorean sects*). In addition, there are scattered hints in various early authors and in some not very substantial remains of 4th-century Pythagorean literature. The mosaic of reconstruction thus has to be to some extent subjective.

Early Pythagoreanism. Within the ancient Pythagorean movement four chief periods can be distinguished: early Pythagoreanism, dating from the late 6th century BC and extending to about 400 BC; 4th-century Pythagoreanism; the Hellenistic trends; and Neo-Pythagoreanism, a revival that occurred in the mid-1st century AD and lasted for two and a half centuries.

Background. The background of Pythagoreanism is complex, but two main groups of sources can be distinguished. The Ionian philosophers (Thales, Anaximander, Anaximenes, and others) provided Pythagoras with the problem of a single cosmic principle, the doctrine of opposites, and whatever reflections of Oriental mathematics there are in Pythagoreanism; and from the technicians of his birthplace, the Isle of Samos, he learned to understand the importance of number, measurements, and proportions. Popular cults and beliefs current in the 6th century and reflected in the tenets of Orphism introduced him to the notions of occultism and ritualism and to the doctrine of individual immortality. In view of the shamanistic traits of Pythagoreanism, reminiscent of Thracian cults, it is interesting to note that Pythagoras seems to have had a Thracian slave.

Pythagorean communities. The school apparently founded by Pythagoras at Croton in southern Italy seems to have been primarily a religious brotherhood centred around Pythagoras and the cults of Apollo and of the Muses, ancient patron goddesses of poetry and culture. It became perhaps successively institutionalized and received different classes of esoteric members and exoteric sympathizers. The rigorism of the ritual and ethical observances demanded of the members is unparalleled in early Greece; in addition to the rules of life mentioned above, it is fairly well attested that secrecy and a long silence during the novitiate were required. The exoteric associates, however, were politically active and established a Crotonian hegemony in southern Italy. About 500 BC a coup by a rival party caused Pythagoras to take refuge in Metapontum, where he died.

During the early 5th century, Pythagorean communities, inspired by the original school at Croton, existed in many southern Italian cities, a fact that led to some doctrinal differentiation and diffusion. In the course of time the politics of the Pythagorean parties became decidedly antidemocratic. About the middle of the century a violent democratic revolution swept over southern Italy; in its wake, many Pythagoreans were killed, and only a few escaped, among them Lysis of Tarentum and Philolaus of Croton, who went to Greece and formed small Pythagorean circles in Thebes and Phlius.

Two Pythagorean sects. Little is known about Pythagorean activity during the latter part of the 5th century. The differentiation of the school into two main sects, later called *akousmatikoi* (Greek: *akousma*, “something heard,” viz., the esoteric teachings) and *mathēmatikoi* (Greek: *mathēmatikos*, “scientific”), may have occurred at that time. The acousmatics devoted themselves to the observance of rituals and rules and to the interpretation of the sayings of the master; the “mathematics” were concerned with the scientific aspects of Pythagoreanism. Philolaus, who was rather a mathematic, probably published a summary of Pythagorean philosophy and science in the late 5th century.

4th-century Pythagoreanism. In the first half of the 4th century, Tarentum, in southern Italy, rose into considerable significance. Under the political and spiritual leadership of the mathematic Archytas, a friend of Plato, Tarentum became a new centre of Pythagoreanism, from which acousmatics—so-called Pythagorists who did not sympathize with Archytas—went out travelling as mendicant

Four chief periods

Mathematical ratios of tones

Literary sources, especially Aristotelian

Archytas and his school

ascetics all around the Greek-speaking world. The acoustics seem to have preserved some early Pythagorean *Hieroi Logoi* and ritual practices. Archytas himself, on the other hand, concentrated on scientific problems, and the organization of his Pythagorean brotherhood was evidently less rigorous than that of the early school. After the 380s there was a give-and-take between the school of Archytas and the Academy of Plato, a relationship that makes it almost impossible to disentangle the original achievements of Archytas from joint involvements (but see above, *Geometry and Music*).

The Hellenistic Age. Whereas the school of Archytas apparently sank into inactivity after the death of its founder (probably after 350 BC), the Academics of the next generation continued "Pythagorizing" Platonic doctrines, such as that of the supreme One, the indefinite dyad (a metaphysical principle), and the tripartite soul. At the same time, various Peripatetics of the school of Aristotle, including Aristoxenus, collected Pythagorean legends and applied contemporary ethical notions to them. In the Hellenistic Age, the Academic and Peripatetic views gave rise to a rather fanciful antiquarian literature on Pythagoreanism. There also appeared a large and yet more heterogeneous mass of apocryphal writings falsely attributed to different Pythagoreans, as if attempts were being made to revive the school. The texts fathered on Archytas display Academic and Peripatetic philosophies mixed with some notions that were originally Pythagorean. Other texts were fathered on Pythagoras himself or on his immediate pupils, imagined or real. Some show, for instance, that Pythagoreanism had become confused with Orphism; others suggest that Pythagoras was considered a magician and an astrologist; there are also indications of Pythagoras "the athlete" and "the Dorian nationalist." But the anonymous authors of this pseudo-Pythagorean literature did not succeed in reestablishing the school, and the "Pythagorean" congregations formed in early imperial Rome seem to have had little in common with the original school of Pythagoreanism established in the late 6th century BC; they were ritualistic sects that adopted, eclectically, various occult practices.

Neo-Pythagoreanism. With the ascetic sage Apollonius of Tyana, about the middle of the 1st century AD, a distinct Neo-Pythagorean trend appeared. Apollonius studied the Pythagorean legends of the previous centuries, created and propagated the ideal of a Pythagorean life—of occult wisdom, purity, universal tolerance, and approximation to the divine—and felt himself to be a reincarnation of Pythagoras. Through the activities of Neo-Pythagorean Platonists, such as Moderatus of Gades, a pagan trinitarian, and the arithmetician Nicomachus of Gerasa, both of the 1st century AD, and, in the 2nd or 3rd century, Numenius of Apamea, forerunner of Plotinus (an epoch-making elaborator of Platonism), Neo-Pythagoreanism gradually became a part of the expression of Platonism known as Neoplatonism; and it did so without having achieved a scholastic system of its own. The founder of a Syrian school of Neoplatonism, Iamblichus, a pupil of Porphyry (who in turn had been a pupil of Plotinus), thought of himself as a Pythagorean sage and about AD 300 wrote the last great synthesis of Pythagoreanism, in which most of the disparate post-classical traditions are reflected. It is characteristic of the Neo-Pythagoreans that they were chiefly interested in the Pythagorean way of life and in the pseudoscience of number mysticism. On a more popular level, Pythagoras and Archytas were remembered as magicians. Moreover, it has been suggested that Pythagorean legends were also influential in guiding the Christian monastic tradition.

Medieval and modern trends. In the Middle Ages the popular conception of Pythagoras the magician was combined with that of Pythagoras "the father of the quadrivium"; i.e., of the more specialized liberal arts of the curriculum. From the Italian Renaissance onward, some "Pythagorean" ideas, such as the tetrad, the golden section, and harmonic proportions, became applied to aesthetics. To many Humanists, moreover, Pythagoras was the father of the exact sciences. In the early 16th century, Nicolaus Copernicus, who developed the view that the Earth re-

volves around the Sun, considered his system to be essentially Pythagorean or "Philolaic," and Galileo was called a Pythagorean. The 17th-century Rationalist G.W. Leibniz appears to have been the last great philosopher and scientist who felt himself to be in the Pythagorean tradition.

It is doubtful whether advanced modern philosophy has ever drawn from sources thought to be distinctly Pythagorean. Yet Platonic-Neoplatonic notions, such as the mathematical conception of reality or the philosopher's union with the universe and various mystical beliefs are still likely to be stamped as Pythagorean in origin. Even today a relatively uncritical admiration of Pythagoreanism is common.

EVALUATION

The history of the projection of Pythagoreanism into subsequent thought indicates how fertile some of its core concepts were. Plato is here the great catalyst; but it is possible to perceive behind him, however dimly, a series of Pythagorean ideas of paramount potential significance: the combination of religious esoterism (or exclusivism) with the germs of a new philosophy of mind, present in the belief in the progress of the soul toward the actualization of its divine nature and toward knowledge; stress upon harmony and order, and upon limit as the good; the primacy of form, proportion, and numerical expression; and in ethics, and emphasis upon such virtues as friendship and modesty. The fact that Pythagoras, to later ages, also became alternatively conceived of as a Dorian nationalist, a sportsman, an educator of the people, or a great magician is a more curious consequence of the productivity of his teaching.

(H.T.)

Realism

Understood in its broadest philosophical sense, Realism connotes any viewpoint that accords to the objects of man's knowledge an existence that is independent of whether he is perceiving or thinking about them. Though it may seem strange to the unphilosophical layman that the independent existence of objects "out there" should be questioned, the philosopher, faced with the many profound challenges that Idealists have posed against the independence of objects, knows that the problem of the existence of objects—whether in thought or in concrete form—is far from trivial.

Clearly, Idealists have argued, musical tones such as middle C do not have existence as tones in the air; they appear, instead, to be qualities that the mind itself generates when the appropriate hair cells in the organ of Corti are stimulated. Nor does the colour purple have existence as a quality in the world outside of the mind; there can be, in fact, no such thing as a beam of pure (monochromatic) purple light inasmuch as purple is a unique kind of colour that is perceived when vibrations at the opposite extremes of the visual spectrum (red and violet) are mixed together in the same beam. At least in this one case, the colour seems created by the mind. But if this is so of purple, the Idealists ask, is it not true, also, of all colours? Similarly, under certain circumstances heat is felt as cold and rotation as oscillation. It is not surprising, therefore, that philosophers have asked what, if any, residual properties an object might have in and of itself after due allowance has been made for those qualities that the mind and perspective of the observer have imposed upon it; nor is it surprising that they have asked what, if anything, it would mean to insist on the objective existence of an object of which all of the qualities were mental. Realists, on the other hand, have held that, in spite of the foregoing considerations as proposed by the Idealists, there still remains a sense in which objects can have an existence that is independent of minds.

Realism exists, however, in several strikingly different versions: its objects may be, for example, either individual things (such as "the Moon"), or merely particular qualities of things (such as "roundness," "yellowness"), or species and genera of things (such as "moons," "planetary bodies"). In one way or another, however, whether it regards

Amalgamation with Neoplatonism

The Idealist challenge

things from the viewpoint of the things themselves or from that of the human activities related to them, Realism tends to stress some definite function of the independent existence of objects.

NATURE AND SCOPE OF REALISM

Realism and the problem of knowledge. One of the major problems confronting Realism involves the distinction between private, public, and so-called ontological objects. A private object is a sheer datum (such as a perceived patch of yellow) taken purely as an uninterpreted item in the knower's own inner experience; a public object is one that the mind has projected into an objective conceptual frame of space and time shared in common with other minds, an object that the mind has constituted as a percept (such as the perceived Moon)—though it is still acknowledged to be in part mental (e.g., its yellowness; or its visual size, which is larger when it is near the horizon); and an ontological object is the Kantian “thing-in-itself” (the Moon as it really is), which may as well consist of monads, of God's thoughts, of will, or of action, as of force and matter. Though Realists and Idealists both acknowledge that the knower transcends the private object, they make different assumptions about the relationship between the public and the ontological object: on the one hand, the Realist holds that the physical sphericity, yellowness, and hardness perceived (or perceivable) in the public object are in some degree actual properties of the ontological thing-in-itself; the Idealist, on the other hand, holds that the public object is merely a phenomenon, from which little can be inferred about the underlying *onta* (realities), least of all of their basic qualities, which are probably quite different from the roundness and hardness of the perceived object. The Idealist may, in fact surmise that the nature of the *onta* is conveyed more faithfully in the fundamental mental tone of the public object—in the colours, feelings, and durations (which are of the nature of mind)—than in its specific material properties. (A third contender, that philosopher known as the metaphysical solipsist, would hold to the viewpoint that the ontological object does not exist at all.)

Similarly, if a particular thing regarded in its particularity (such as the Moon) is distinguished from a universal—i.e., an entity comprising the essence of the thing (moonness)—that which it shares with all the other things of the same species or genus (as with the moons of Jupiter)—then a form of Realism can be defined as asserting the independent reality of universals, which it may even exalt above that of particulars.

Accordingly, Realism may be variously opposed to the tenets of other philosophical positions. As opposed to Nominalism, which denies that essences (or the specific and generic natures of things) have any reality at all (except as names), and conceptualism, which grants such universals reality only as concepts within the mind, Realism allows to the specific or generic nature of the thing a distinct existence in reality outside the mind. Against Idealism (see above), it asserts that the existence of sense objects (such as the perceived Moon) and that of their qualities is external to thought. In opposition to phenomenalism and sensationalism, which regard objects as comprising mere private volleys or families of disconnected sense fragments, Realism grounds objects in real unified and enduring substances. Unlike conventionalism, a philosophy of science that regards scientific laws and theories as freely chosen constructs that are simply devised by the scientist for the purpose of describing reality, Realism holds that laws and theories have determined and real counterparts in things.

The term Realism first appeared early in the 19th century, though the adjective Realist dates from the late 16th century. These terms have been applied, however—often retroactively—to various systems that have arisen throughout history.

In its broadest scope, the term Realism has application in a number of distinct areas. In literature, art, and aesthetics, in law, and in philosophy, it emphasizes real existence or relation to it. The present article is concerned solely with Realism in the philosophical area.

Philosophical senses of Realism. Even within philosophy Realism has a wide range of applications. Though a definitely modern term, Realism is freely used today for tenets of the Greek and medieval epochs, as well as for the modern period.

Basic kinds of Realism. Among philosophical Realisms, two fundamentally different kinds can be distinguished: the Realism of natures and the Realism of things. In the Realism of natures, that which is viewed as having an existence external to the mind is an entity that, in some sense, is set apart in the world of things—an entity that is variously understood as the Form or Idea in which a thing participates, such as “manness” or “bedness” (Platonic Realism), as the essence or *to ti ên einai*, “the ‘what it is’ of a thing” (Aristotelian Realism), or as its nature, either absolute, specific, or generic (medieval Realism or the Realism of universals), or, finally, as laws or theoretical models abstracted from scientific observations. In the Realism of things, on the other hand, that which is viewed as having an existence external to the mind is the total, concrete, and individual object of experience, which the Realist regards as retaining its chief properties at all times, even when left unseen. This Realism, too, can be variously conceived: the externality of the world, for example, can be regarded as simply and obviously given (commonsense Realism); the object itself, though external, can be viewed as the sole entity standing before the mind and grasped by it (neo-Realism); or the object can be conceived as, in some sense, duplicated, so that the mind directly encounters only a counterpart of the external object and not the object itself (critical Realism), a counterpart which was sometimes regarded as a representation of it (representational Realism).

Distinctions among the Realisms. As previously noted, the term Realism has been applied retroactively to the transcendence of the Platonic Forms or Ideas, to the extent that for Plato the natures of things have, in the ideas of them, an existence more real than that of sensible, individual things. Yet from its emphasis on ideal as opposed to concrete existence, this Platonic doctrine would be classed as an Idealism instead of a Realism. In the parallel issue in Aristotelianism, the stand that the universals, or specific and generic natures, exist only in the mind but are nonetheless grounded in the real forms of things has been called a moderate Realism. Aristotle himself, however, vigorously denied that the universals have any substantiality (*Metaphysics*, Z: 13–14; 1038^b8–1039^b19), which clearly suggests that, for him, the universals have no existence independently of cognition; this tends, in this first context, to invalidate the designation Realism for the Aristotelian doctrine.

Correspondingly, Realism is used to describe medieval views that allowed species and genera some kind of distinct existence outside of their conception by the mind. There it meant that not only individual men and individual animals and so on exist outside cognition but also that the specific nature of man and the generic nature of animal and the like have an existence of their own in the outside world. For Realism, objects “fall into” such categories as humanness, mountaininess, etc., *naturally*. For its opponents, however, this is not always the case: thus, in terms of a modern illustration, graniteness—that which all the granite rocks share in common—does not exist except as an artificial category set up by the mind (conceptualism) because it merges by imperceptible gradations into diorite or felsite as its mineral composition and texture gradually change.

Yet in actual fact the various medieval doctrines do not fit neatly under these divisions. In the philosophies of several medieval Scholastics, for instance, both the particular thing and the universal are distinguished in one way or another from a third entity, the specific or generic nature *taken absolutely* in itself. This so-called absolute nature is given a “being of its own” by the influential Persian Avicenna, an early 11th-century philosopher and physician; and—in the 13th century—by Henry of Ghent, an eclectic Christian Scholastic, and by the voluntarist Duns Scotus, the greatest medieval British Scholastic, who gave the absolute nature a reality that was distinct in form from

Private,
public, and
ontolog-
ical objects

Realism
of
natures

Contrast
with other
views

the individual thing, but unitively contained in it. Thomas Aquinas gave it no being at all. Though these views reflect radically different metaphysical settings, they all variously bar the natures from real existence when separated in any way from the individual.

In its conventional applications to Greek and medieval thought, accordingly, Realism turns out to be an elusive and even confusing notion. It seems to be an inept way of emphasizing difficulties that are significantly present in the philosophies of these epochs, which require understanding and solution. But the granting of extramental existence to the generic and specific natures has raised more difficulties than it has solved.

All of these ancient and medieval doctrines—whether Realistic, conceptualistic, or nominalistic—accept the external existence of individual sensible things. From this viewpoint, they would all be Realisms in the second main sense of the term, that of the Realism of ordinary things, which is the sense in which Realism is predominantly employed in the modern era. Here it means the epistemological (or theory-of-knowledge) view that things taken as individual wholes have an existence that is outside of human cognition.

HISTORY OF WESTERN REALISM

In these and other related ways, modern writers have seen the philosophic attitude called Realism continually surfacing in the stream of Western thought, suggesting that it is a perennial feature.

Ancient Realism. In pre-Socratic thought, even in Parmenides (late 6th century), known for reducing reality to the One, the relevant reality of the objects of cognition was everywhere assumed. In Plato (5th and 4th centuries BC), the separate and more excellent existence of the natures, or Forms, was strongly asserted at times, though quite often the immanence of the form in individuals was just as surely implied without any satisfactory reconciliation of the contradiction. With Philo of Alexandria, a Hellenistic Jewish philosopher in the 1st century AD, the existence of the Platonic Forms was located within the mind of God, a view also found in the early 5th century in Augustine of Hippo (*De diversis quaestionibus*, “On Diverse Questions”). In the medieval Augustinian tradition, for instance in the writings of Anselm of Canterbury, the influence of this interpretation persisted. In the early 6th century, on the other hand, Boethius, perhaps the intellectual founder of the Middle Ages, in transmitting Aristotelian logic to the West, presented the universal notions with a strong cast of Platonic Realism, while acknowledging that the Aristotelian view was different. Among medieval thinkers in the early 12th century, such as William of Champeaux, the Parisian logician and theologian, the Platonizing tradition of Boethius was dominant, though it was brought under fire by such men as Roscelin, founder of nominalism, who saw universals as mere words. With the stormy controversialist Peter Abelard, who was the foremost dialectician of his time, the Boethian Realism was attacked. But according to Abelard, more than mere words were required to justify universality; in his view, universals were concepts signifying real things and had their ultimate basis in the divine ideas, as in the Augustinian tradition.

Medieval Realism. The approach of the early medieval thinkers to the problem of universals was made from the side of logic. But it soon involved theological issues, which, when added to the much deeper study of its metaphysical backgrounds made by Boethius, led the scholars to place the relevant questions in a different setting. The natures or common essences of things came to be scrutinized from a threefold viewpoint: as existent in sensible things, as existent in the mind, and as absolutely existent in themselves. This subjected the problem to metaphysical investigation. In that setting, Aquinas allowed neither being nor unity to be attributed to the nature taken absolutely. Duns Scotus, however, accorded it a lesser unity than that of the individual and gave it a kind of being proportionate to this real specific unity, but which required unitive containment of the nature by the individual. In these different ways the nature, so taken, provided the ground for the universal

that existed only in the mind. Views incorporating this feature have been called moderate Realisms, though the designation is open to the same objection as it is in its application to Aristotle (see above, *Distinctions among the Realisms*). In later Scholastic tradition the currents became badly confused, and unending controversy raged on the various kinds of universals and the respective status of each type.

Modern Realism. In the familiar formula *cogito ergo sum* (“I think; therefore, I am”) proffered by the first notable modern philosopher, René Descartes, methodical thinking was rooted in thought itself, thus raising the problem of how any material world outside of thought could be reached philosophically. In Descartes and a half century later in the British Empiricist John Locke, an external origin for sensations was accepted, though without any thoroughly philosophical justification. Rather, the denial of an external world was regarded as too absurd to be countenanced. In this perspective Locke’s philosophy displayed a commonsense Realism. According to one of Locke’s contemporaries, the Cartesian Nicolas Malebranche (known for his claim that God’s will is the true cause of motion), religious faith guaranteed the external world. The Cambridge Platonists, a sober group of 17th-century moral and religious Rationalists, in a similar atmosphere of faith and with a Cartesian understanding of sensation, acquiesced in the external existence of sensible things while, against a Neoplatonic background, they accorded a respectively greater reality to the objects of intellectual cognition. For Berkeley, an early 18th-century Empiricist and Idealist, the scriptural guarantee was lacking because matter was nowhere mentioned in the revealed descriptions of the sensible universe; accordingly, in his view, no sensible world outside cognition was left. But in David Hume, whose teachings marked the climax of the Empiricist movement, even the cognitive subject, or soul, vanished.

Facing the impossibility of a genuine philosophical justification for arguing to an external world from the starting point of mind or idea, Claude Buffier, an early 18th-century French Jesuit, and, shortly later, the Scottish Realists leaned explicitly on common sense as the motive for accepting the world’s external existence. The most prominent exponent of this school was Thomas Reid, an opponent of paradox and skepticism. And John Witherspoon, who was called from Scotland to the presidency of Princeton University, held that “the impression itself implies and supposes something external that communicates it, and cannot be separated from that supposition.” Consequently, the attempt of the viewpoint of Berkeleyan immaterialism “to unsettle the principles of common sense by metaphysical reasoning” could, in his view, never produce conviction.

20th-century Realism. Around the turn of the 20th century, a strong revolt against Kantian subjectivism and the dominant Idealisms appeared in such thinkers as William James, a psychologist and Pragmatist; Bertrand Russell, perhaps the most influential logician and philosopher of his time; and G.E. Moore, a meticulous pioneering Analyst. Thus it was that very early in the century philosophers came to use Realism, as opposed to Idealism, for their own ways of thinking. In 1904, James signalled the resurrection of natural Realism. In 1910, W.P. Montague of Columbia University and Ralph Barton Perry of Harvard University and several others signed an article entitled “The Program and First Platform of Six Realists,” and followed it with a cooperative volume, *The New Realism* (1912). New Realism, or neo-Realism, in defending the independence of known things, explained that in cognition “the content of knowledge, that which lies in or before the mind when knowledge takes place, is numerically identical with the thing known.” To other Realists this epistemological monism, as Perry called his theory of knowledge, failed to extricate itself from the egocentric predicament (*i.e.*, from the incapacity of the mind to transcend its private experience) that they all professed to see in the logic of Idealism. Nor could it give a satisfactory explanation of the mind’s proneness to error, or even of cognition itself as being significantly different from the things known. Another

type of Realism was advanced against neo-Realism in a similarly cooperative volume entitled *Essays in Critical Realism* (1920), by the naturalist George Santayana and several others. To the monism of the neo-Realists such writers opposed an epistemological dualism, in which the object in cognition and the object in reality are numerically two at the time of perception. They divided, however, into a majority group and a minority group on the status of the immediately given object. For the majority group this datum was not an existent but merely an essence; for the others it was an existent—a mental or psychic existent for some and a physical (brain) existent for others. Here agreement failed, and the cooperative effort of the critical Realists soon fell apart.

These and the ensuing discussions left a recognized distinction between the schools of representative Realism and direct Realism: for representative Realism the immediate confrontation of cognition occurred over against a mental representation of the external object; for direct Realism the confrontation was immediately with the thing existent outside of cognition. The critical Realists themselves, in claiming that the datum was not an object as such but only the means of perceiving it, disavowed any representationalism; but in others, who proposed that the sense-datum was the image directly apprehended and was markedly different from the physical object, representative Realism was definitely present. Representationalism may also be seen in the Realism of the Belgian Neoscholastic Désiré Mercier, who founded the school of Louvain, and in the physiological Idealisms of contemporary neurophysiologists. In essence, representationalism was the inferential procedure employed by Descartes and Locke for reaching the external world. Direct Realism, on the other hand—as defended by recent writers—acknowledged no intermediate object between cognition and the external thing perceived.

Naive
and tacit
Realisms

Within the ambit of contemporary discussions, naive Realism was the label for any unquestioning belief that things in reality correspond exactly to human cognition of them. Expressly meant as a prephilosophical attitude, naive Realism can hardly be included under philosophical procedures. Yet its appropriateness to the man in the street has also been widely challenged; for the ordinary man is keenly interested in distinguishing critically between reality and figments of cognition and is continually doing so in ordinary life. He does not proceed, however, as did the aforementioned Realisms: he does not first regard the object in terms of its status in cognition and then explore its relation to reality. But to come under the notion as introduced by the Realists, naive Realism must be explained in terms of the cognitional relation—e.g., as one of the “three typical theories of the knowledge relation.” It is, accordingly, a philosophical category, though historians and controversialists shun the listing of recognized philosophers under such a title.

Further, a number of philosophies that neither bore the name of Realism nor defined reality in terms of its relation to cognition are frequently regarded as Realisms today. Aristotelianism, for example, explained the reality of things through their substantiality, Thomism through their existence in themselves, Scotism through the metaphysical priority of a nature possessed in common, and contemporary linguistic philosophy, as in John Austin, an important mid-20th-century Oxford Analyst, through a completely ostensive view of language; yet all have been seen as Realisms. The process philosophies of the Pragmatist John Dewey and of Alfred North Whitehead, an influential cosmologist and metaphysician, and—still more controversially—the philosophy of Charles Sanders Peirce, an individualistic American logician and Pragmatist, may also be taken as Realisms, even though they did not stress the basic relation to cognition; for these thinkers agreed that things as a fact do have, or may have, existence outside cognition, even though this existence was not reached from cognition nor defined through its relation to cognition. With them the cognitional relation was only an inessential afterthought. Serious interest in explaining as Realism the traditional tenets of pre-Cartesian philosophies may be seen in the writings of many contem-

Meta-
physical
Realisms

poraries. Yet for Aristotle and Aquinas, what was meant by the reality of sensible things is already established metaphysically, through their substantiality or ontal (real) existence, before they are compared with cognition; hence to bring in the further notion of Realism for this purpose seems meaningless. The notion is therefore extraneous to the philosophical procedures of thinkers who locate the starting point of their philosophy in some actuality of the real thing itself; for relation to cognition does not play an operative role in their basic procedures. Only by means of entirely extrinsic bonds can they be grouped with the genuine Realisms.

MAJOR ISSUES AND EVALUATION OF REALISM

From the foregoing survey of the historical development of Realistic thought, the major issues upon which Realism focusses attention stand out clearly. For both speculative and practical reasons, men wish to distinguish sharply between what they call reality and what they recognize or suspect to be merely products of their own cognition. Accordingly, the ancient Platonic concentration on specific and generic natures and, in Aristotle, the essential role played by the universal in reasoning led to a close scrutiny of the way in which these natures exist. Undoubtedly, they exist in human thought. For the Realistically inclined thinker, however, their crucial role tends to demand counterparts if human thinking is to bear on what really exists. Still more drastic are the post-Cartesian philosophies in which the existence of external things themselves does not enter human cognition in direct confrontation. Finally, the mathematical and scientific constructs, which have been so fruitful in man's struggle for mastery over nature, seem to require for the Realistically minded thinker some counterpart in the things themselves in order to provide an adequate philosophical explanation of their success.

When the issues are faced in the foregoing manner, some lines of a procedure common to the various explicit Realisms emerge upon which it may be possible to base an evaluation. Universals, sensations and perceptions, scientific formulas and laws are all found to be existent in cognition. From that sure starting point, attempts are made to show that objects either corresponding to them or identical with them exist outside the mind. That pattern seems to be the general procedure followed in any way of thinking that has spontaneously given rise to the notion of an epistemological Realism and that can, with historical and philosophical significance, be labelled such. As is likewise apparent from the foregoing survey, this way of thinking follows a dubious procedure: Realism is not primarily a doctrine of the existence of things but rather a doctrine of cognition. In Realism, cognition is regarded as the object most present to itself; i.e., a man knows his own thought processes more intimately than anything else. But the genuine Realist seems unwittingly to take the material thing as his model in conceiving cognition. No external object can be more present to a material thing than that material thing itself. If cognition is conceived after this analogy, it will be what is most present to itself, and will have to be the starting point from which the Realist reasons. This starting point seems to offer no exit. The objects reached from it can be only internal products or occurrences in the mind, for it offers nothing more basic from which to reason than the cognition itself. Any philosophically genuine Realism seems, in consequence, prone to failure in its basic objective.

Accordingly, Realism, in the senses responsible for the epistemological use of the term, has long since ceased to inspire vigorous debate. In a Platonic tradition that continues in modern thought, however, Realism in respect to the natures of things is by no means dead. In regard to the Cartesian problem of the world's external existence, representative Realism seems to have shared the fate of the sense-datum and to be quite inoperative outside of the wake of neurophysiological writings. But attempts at direct Realism are still made. In the scientific field the opposition to conventionalism and to retaining a merely instrumental status for laws or theories has remained a lively issue. Moreover, modern means, such as the electron

Problems
and cur-
rent status

microscope (which shows molecules in real existence) and the hope of being able to see atoms foretold a greater correspondence of scientific constructs with the structure of reality than had previously been demonstrated. But this verification process consists in a comparison of reality with thought rather than in any attempt to reach reality from cognition alone. (J.O./L.H.St.)

Scholasticism

From the time of the Renaissance until at least the beginning of the 19th century, the term Scholasticism, not unlike the name Middle Ages, was used as an expression of blame and contempt. The medieval period was widely viewed as an insignificant intermezzo between Greco-Roman antiquity and modern times, and Scholasticism was normally taken to describe a philosophy busied with sterile subtleties, written in bad Latin, and above all subservient to the theology of popery. Even the German Idealist Hegel, in his *Vorlesungen über die Geschichte der Philosophie* (1833–36; *Lectures on the History of Philosophy*, 1892–96), declared that he would “put on seven-league boots” in order to skip over the thousand years between the 6th and 17th centuries and, having at last arrived at Descartes, said that now he could “cry land like the sailor.” In those same first decades of the 19th century, on the other hand, the Romantics swung the pendulum sharply to the opposite side, to an indiscriminate overestimation of everything medieval.

Today, scholars seem better able to confront the medieval epoch, as well as Scholasticism—i.e., its philosophy (and theology)—without prejudgments. One reason for this state of affairs is the voluminous research which has been devoted to this era and which has revealed its true nature, not only as a respectable continuation of the genuinely philosophical tradition but also as a period of exemplary personalities quite able to stand comparison with any of the great philosophers of antiquity or of modern times.

NATURE AND SIGNIFICANCE

Scholasticism is so much a many-sided phenomenon that, in spite of intensive research, scholars still differ considerably in their definition of the term and in the emphases that they place on individual aspects of the phenomenon. Some historians, seeming almost to capitulate to the complexity of the subject, confine themselves to the general point that Scholasticism can only be defined denotatively as that kind of philosophy that during the European Middle Ages was taught in the Christian schools. The question of its connotation, however, remains, viz., What kind of philosophy was it?

The answer that Scholasticism was “school” philosophy and, in fact, “Christian” school philosophy can be understood only by examining the historical exigencies that created the need for schools. The search thus leads the inquirer back to the transition from antiquity to the Middle Ages—a point which, according to Hegel, was marked by the symbolic date AD 529, when a decree of the Christian emperor Justinian closed the Platonic Academy in Athens and sealed “the downfall of the physical establishments of pagan philosophy.” In that same year, however, still another event occurred, which points much less to the past than to the coming age and, especially, to the rise of Scholasticism, viz., the foundation of Monte Cassino, the first Benedictine abbey, above one of the highways of the great folk migrations. This highly symbolic fact not only suggests the initial shift of the scene of the intellectual life from places like the Platonic Academy to the cloisters of Christian monasteries, but it marks even more a change in the dramatis personae. New nations were about to overrun the Roman Empire and its Hellenistic culture with long-range effects: when, centuries later, for example, one of the great Scholastics, Thomas Aquinas, was born, though he was rightly a southern Italian, his mother was of Norman stock, and his Sicilian birthplace was under central European (Hohenstaufen) control.

It was a decisive and astonishing fact that the so-called barbarian peoples who penetrated from the north into the ancient world often became Christians and set out to

master the body of tradition that they found, including the rich harvest of patristic theology as well as the philosophical ideas of the Greeks and the political wisdom of the Romans. This learning could be accomplished only in the conquered empire’s language (i.e., in Latin), which therefore had to be learned first. In fact, the incorporation of both a foreign vocabulary and a different mode of thinking and the assimilation of a tremendous amount of predeveloped thought was the chief problem that confronted medieval philosophy at its beginnings. And it is only in the light of this fact that one of the decisive traits of medieval Scholasticism becomes understandable: Scholasticism above all was an unprecedented process of learning, literally a vast “scholastic” enterprise that continued for several centuries. Since the existing material had to be ordered and made accessible to learning and teaching, the very prosaic labour and “schoolwork” of organizing, sorting, and classifying materials inevitably acquired an unprecedented importance. Consequently, the writings of medieval Scholasticism quite naturally lack the magic of personal immediacy, for schoolbooks leave little room for originality. It is therefore misleading, though understandable, that certain polemicists have wrongly characterized Scholasticism as involving no more than the use of special didactic methods or a narrow adherence to traditional teachings.

First of all, if the major historical task of that epoch was really to learn, to acquire, and to preserve the riches of tradition, a certain degree of “scholasticity” was not only inevitable but essential. It is not at all certain that today’s historians would have direct intellectual access to Plato, Aristotle, and Augustine had the Scholastics not done their patient spadework. Besides, the progress from the stage of mere collection of given sentences and their interpretation (*expositio, catena, lectio*), to the systematic discussion of texts and problems (*quaestio, disputatio*), and finally to the grand attempts to give a comprehensive view of the whole of attainable truth (*Summa*) was necessarily at the same time a clear progression toward intellectual autonomy and independence, which in order to culminate, as it did in the 13th century, in the great works of Scholasticism’s Golden Age, required in addition the powers of genius, of men like Albertus Magnus and Thomas Aquinas.

On the other hand, the moment had to come when the prevalent preoccupation with existing knowledge would give way to new questions, which demanded consideration and answers that could emerge only from direct experience. By the later Middle Ages, procedures for exploiting and discussing antecedent stocks of insight had been largely institutionalized, and it was an obvious temptation to perpetuate the dominion of those procedures—which could lead only to total sterility. It is widely agreed that this is almost exactly what did happen in the 14th century in what is called the “decline” and disintegration of Scholasticism.

HISTORY AND ISSUES

Roots of Scholasticism. From the beginning of medieval Scholasticism the natural aim of all philosophical endeavour to achieve the “whole of attainable truth” was clearly meant to include also the teachings of Christian faith, an inclusion which, in the very concept of Scholasticism, was perhaps its most characteristic and distinguishing element. Although the idea of including faith was expressed already by Augustine and the early Church Fathers, the principle was explicitly formulated by the pivotal, early 6th-century scholar Boethius. Born in Rome and educated in Athens, Boethius was one of the great mediators and translators, living on the narrow no-man’s-land that divided the epochs. His famous book, *The Consolation of Philosophy*, was written while he, indicted for treachery and imprisoned by King Theodoric the Goth, awaited his own execution. It is true that the book is said to be, aside from the Bible, one of the most translated, most commented upon, and most printed books in world history; and that Boethius made (unfinished) plans to translate and to comment upon, as he said, “every book of Aristotle and all the dialogues of Plato.” But the epithet that he won as “one of the founders of Scholasticism” refers to

Boethius
and
Cassiodorus

quite another side of his work. Strictly speaking, it refers to the last sentence of a very short tractate on the Holy Trinity, which reads, "As far as you are able, join faith to reason"—an injunction which in fact was to become, for centuries, the formal foundation of Scholasticism. Instead of "faith," such concepts as revelation, authority, or tradition could be (and, indeed, have been) cited; and "reason," though unambiguously meant to designate the natural powers of human cognition, could also be granted (and, in fact, has been granted) very different meanings. In any case, the connection between faith and reason postulated in this principle was from the beginning and by its very nature a highly explosive compound.

Boethius himself already carried out his program in a rather extraordinary way: though his *Opuscula sacra* ("Sacred Works") dealt almost exclusively with theological subjects, there was not a single Bible quotation in them: logic and analysis was all.

Though called the "first Scholastic," Boethius was at the same time destined to be for almost a millennium the last layman in the field of European philosophy. His friend Cassiodorus, author of the *Institutiones*, an unoriginal catalog of definitions and subdivisions, which (in spite of their dryness) became a source book and mine of information for the following centuries, who, like Boethius, occupied a position of high influence at the court of Theodoric and was also deeply concerned with the preservation of the intellectual heritage, decided in his later years to quit his political career and to live with his enormous library in a monastery. This fact again is highly characteristic of the development of medieval Scholasticism: intellectual life needs not only teachers and students and not only a stock of knowledge to be handed down; there is needed a certain guaranteed free area within human society as well, a kind of sheltered enclosure, within which the concern for "nothing but truth" can exist and unfold. The Platonic Academy, as well as (for a limited time) the court of Theodoric, had been enclosures of this kind; but in the politically unsettled epoch to come "no plant would thrive except one that germinated and grew in the cloister."

The principle of the conjunction of faith and reason, which Boethius had proclaimed, and the way in which he himself carried it out were both based on a profound and explicit confidence in man's natural intellectual capacity—a confidence that could possibly lead one day to the rationalistic conviction that there cannot be anything that exceeds the power of human reason to comprehend, not even the mysteries of divine revelation. To be sure, the great thinkers of Scholasticism, in spite of their emphatic affirmation of faith and reason, consistently rejected any such rationalistic claim. But it must nonetheless be admitted that Scholasticism on the whole, and by virtue of its basic approach, contained within itself the danger of an overestimation of rationality, which recurrently emerged throughout its history.

On the other hand, there had been built in, from the beginning, a corrective and warning, which in fact kept the internal peril of Rationalism within bounds, viz., the corrective exercised by the "negative theology" of the so-called Pseudo-Dionysius, around whose writings revolved some of the strangest events in the history of Western culture. The true name of this protagonist is, in spite of intensive research, unknown. Probably it will remain forever an enigma why the author of several Greek writings (among them *On the Divine Names*, "On the Celestial Hierarchy," and *The Mystical Theology*) called himself "Dionysius the Presbyter" and, to say the least, suggested that he was actually Denis the Areopagite, a disciple of Paul the Apostle (Acts). In reality, almost all historians agree that Pseudo-Dionysius, as he came to be called, was probably a Syrian Neoplatonist, a contemporary of Boethius. Whatever the truth of the matter may be, his writings exerted an inestimable influence for more than 1,000 years by virtue of the some-what surreptitious quasi-canonical authority of their author, whose books were venerated, as has been said, "almost like the Bible itself." A 7th-century Greek theologian, Maximus the Confessor, wrote the first commentaries on these writings, which were followed over the centuries by a long succession of com-

mentators, among them Albertus Magnus and Thomas Aquinas. The main fact is that the unparalleled influence of the Areopagite writings preserved in the Latin West an idea, which otherwise could have been repressed and lost (since it cannot easily be coordinated with rationality)—that of a negative theology or philosophy that could act as a counter-poise against Rationalism. It could be called an Eastern idea present and effective in the Occident. But after the Great Schism, which erected a wall between East and West that lasted for centuries, Denis the Areopagite, having become himself (through translations and commentaries) a Westerner "by adoption," was the only one among all of the important Greco-Byzantine thinkers who penetrated into the schools of Western Christendom. Thus negative theology was brought to medieval Scholasticism, as it were, through the back door.

The most important book of Denis, which dealt with the names that can be applied to God, exemplified his negative theology. It maintained first of all the decidedly biblical thesis that no appropriate name can be given to God at all unless he himself reveals it. But then Denis showed that even the revealed names, since they must be comprehensible to man's finite understanding, cannot possibly reach or express the nature of God; and that in consequence, every affirmative statement about God requires at once the corrective of the coordinate negation. The theologian cannot even call God "real" or "being," because he derives these concepts from the things to which God has given reality; and the Creator cannot possibly be of the same nature as that which he has created. Thus, *The Mystical Theology* concluded by finally relativizing also the negations, because God surpasses anything that man may possibly say of him, whether it be affirmative or negative.

Scholasticism certainly could have learned all of this also from Augustine, who repeatedly warned that "Whatever you understand cannot be God." But probably an authority of even greater weight than Augustine was needed to counteract a reason that was tending to overrate its own powers; and this authority was attributed, although falsely, to the works of Denis the Areopagite. This impact could, of course, not be restricted to the idea of God; it necessarily concerned and changed man's whole conception of the world and of existence. The influence of Denis is reflected in the noteworthy fact that Thomas Aquinas, for instance, not only employed more than 1,700 quotations from Denis the Areopagite but also appealed almost regularly to his work whenever he spoke, as he often did (and in astonishingly strong terms), of the inexhaustible mystery of being. Thomas Aquinas, however, who also wrote a remarkable commentary on Denis' book *On the Divine Names*, is mentioned here only as an example, albeit a most telling example.

At the very end of the medieval era of Scholasticism, the Areopagite emerged once more in the work of a 15th-century cardinal, Nicholas of Cusa, also known as a mathematician and advocate of experimental knowledge, in whose library there are preserved several translations of the Areopagite writings—replete, moreover, with marginal notes in the Cardinal's handwriting. But even without this concrete evidence, it would be quite plain that Cusanus' doctrine of "knowing nonknowing" is closely linked to the Areopagite's conviction that all of reality is unfathomable.

The translation into Latin of the *Corpus Areopagiticum*, which was made in the 9th century—i.e., some 400 years after the death of its author—by John Scotus Erigena, is itself worthy of mention, especially because the translator was one of the most remarkable figures of early medieval philosophy. After generations of brave and efficient collectors, organizers, and schoolmasters had come and gone, Erigena, in his *De divisione natura* ("On the Division of Nature"), developed the Dionysian Neoplatonism on his own and tried to construct a systematic conception of the universe, a more or less pantheistic world view, which (as Gilson says) for a moment offered the Latin West the opportunity—or the temptation—to choose the way of the East once and for all. The church, though not until centuries later, condemned the book, apparently convinced that any counterpoise to its own position can become dangerous in itself.

translation

The
Pseudo-
Dionysius

Anselm's
belief in
human
reason

Early Scholastic period. If there was any philosophical-theological thinker of importance during the Middle Ages who remained untouched by the spirit of the Areopagite, it was the 11th-century Benedictine Anselm of Canterbury, a highly cultivated Franco-Italian theologian who for years was prior and abbot of the abbey Le Bec in Normandy and then became, somewhat violently, the archbishop of Canterbury. In Anselm's entire work there is not a single quotation from Denis; not even the name is mentioned. Consequently, Anselm's thinking, thus freed from the corrective embodied in the Areopagite's negative theology, displayed a practically unlimited confidence in the power of human reason to illuminate even the mysteries of Christian faith; he thus frequently approached a kind of Rationalism, which did not shrink from the attempt to demonstrate, on compelling rational grounds, that salvation (for example) through God incarnate was philosophically necessary. To be sure, a theologian such as Anselm certainly would never have subscribed to the extreme thesis that nothing exists that is beyond the power of human reason to comprehend: the two famous phrases, coined by him and expressing again, in a grandiose formulation, the principle of Boethius, "faith seeking to be understood" and "I believe in order to understand," clearly proclaim his faith in the mysteries of revelation as comprising the very basis of all reasoning. Nevertheless, in the case of Anselm, the very peculiar conjunction of faith and reason was accomplished not so much through any clear intellectual coordination as through the religious energy and saintliness of an unusual personality. It was accomplished, so to speak, rather as an act of violence, which could not possibly last. The conjunction was bound to break up, with the emphasis falling either on some kind of Rationalism or on a hazardous irrationalization of faith.

That this split did actually happen can be read to some extent in the fate of the "Anselmic argument," which Kant, 700 years later, was to reject as the "ontological proof of God"—connecting it, however, not with the name of Anselm but with that of Descartes, the earliest modern philosopher. It is, in fact, significant that Descartes, in his proof of the existence of God, imagined that he was saying the same thing as Anselm, and that, on the other hand, Anselm would scarcely have recognized his own argument had he encountered it in the context of Descartes's *Discours de la méthode* (1637; *Discourse on Method*, 1950), which claims to be "pure" philosophy based upon an explicit severance from the concept of God held by faith. But given Anselm's merely theoretical starting point, that severance was not only to be expected; it was almost inevitable.

But, also within the framework of medieval Scholasticism, a dispute was always brewing between the dialecticians, who emphasized or overemphasized reason, and those who stressed the suprarational purity of faith. Berengar of Tours, an 11th-century logician, metaphysician, and theologian, who was fond of surprising formulations, maintained the preeminence of thinking over any authority holding, in particular, that the real Presence of Christ in the Eucharist was logically impossible. His contemporary the Italian hermit-monk and cardinal Peter Damian, however—who was apparently the first to use the ill-famed characterization of philosophy as the "handmaid of theology"—replied that, if God's omnipotence acts against the principle of contradiction, then so much the worse for the science of logic. Quite analogous to the foregoing controversy, though pitched on a much higher intellectual level, was the bitter fight that broke out almost one century later between a Cistercian reformer, Bernard of Clairvaux, and a logician and theologian, Peter Abelard. Bernard, a vigorous and ambivalent personality, was in the first place a man of religious practice and mystical contemplation, who, at the end of his dramatic life, characterized his odyssey as that of *anima quaerens Verbum*, "a soul in search of the Word." Although he by no means rejected philosophy on principle, he looked with deep suspicion upon the primarily logical approach to theology espoused by Abelard. "This man," said Bernard, "presumes to be able to comprehend by human reason the entirety of God."

Bernard
and
Abelard

Logic was at that time, as a matter of fact, the main battleground of all Scholastic disputations. "Of all philosophy, logic most appealed to me," said Abelard, who by "logic" understood primarily a discipline not unlike certain present-day approaches, the "critical analysis of thought on the basis of linguistic expression." From this viewpoint (of linguistic logic), Abelard also discussed with penetrating sharpness the so-called "problem of universals," which asks, Is there an "outside" and objective reality standing, for example, not only for the name "Socrates" but also for such common names as "man," "canineness," and the like? Or do common concepts ("universals") possess only the reality of subjective thought or perhaps merely that of the sound of the word? As is well known, it has been asserted that this was the principal, or even the only, subject of concern in medieval Scholasticism—a charge that is misleading, although the problem did greatly occupy philosophers from the time of Boethius. Their main concern from the beginning was the whole of reality and existence.

The advance of medieval thought to a highly creative level was foreshadowed, in those very same years before Peter Abelard died, by Hugh of Saint-Victor (an Augustinian monk of German descent), when he wrote *De sacramentis Christianae fidei* ("On the Sacraments of the Christian Faith"), the first book in the Middle Ages that could rightly be called a *summa*; in its introduction, in fact, the term itself is used as meaning a comprehensive view of all that exists (*brevis quaedam summa omnium*). To be sure, its author stands wholly in the tradition of Augustine and the Areopagite; yet he is also the first medieval theologian who proclaims an explicit openness toward the natural world. Knowledge of reality is, in his understanding, the prerequisite for contemplation; each of the seven liberal arts aims "to restore God's image in us." "Learn everything," he urged; "later you will see that nothing is superfluous."

It was on this basic that the university—which was not the least of the achievements of medieval Scholasticism—was to take shape. And it was the University of Paris, in particular, that for some centuries was to be the most representative university of the West. Though there are usually a variety of reasons and causes for such a development, in this case the importance of the university—unlike that of Bologna and also of Oxford—lay mainly in the fact that it was founded in the most radical way upon those branches of knowledge that are "universal" by their very nature: upon theology and philosophy. It is, thus, remarkable, though not altogether surprising, that there seems to have existed not a single *summa* of the Middle Ages that did not, in some way or other, derive from the University of Paris.

Strangely enough, the classical theological-philosophical textbook used in the following centuries at the universities of the West was not the first *summa*, composed by Hugh of Saint-Victor, but was instead a work by Peter Lombard, a theologian who probably attended Abelard's lectures and who became *magister* at the cathedral school of Notre-Dame and, two decades later, bishop of Paris. Lombard's famous *Four Books of Sentences*, which, though written one or two decades later than Hugh's *summa*, belonged to an earlier historical species, contained about 1,000 texts from the works of Augustine, which comprise nearly four-fifths of the whole. Much more important than the book itself, however, were the nearly 250 commentaries on it, by which—into the 16th century—every master of theology had to begin his career as a teacher. In view of this wide usage, it is not astonishing that Lombard's book underwent some transformations, at the hands, for instance, of its most ingenious commentator, Thomas Aquinas, but also (and even more so) at the hands of Duns Scotus in his *Opus Oxoniense*, which, in spite of being a work of extremely personal cast, was outwardly framed as a commentary on the "Master of Sentences."

Maturity of Scholasticism. Clearly, the world view of Western Christendom, on the whole Augustinian and Platonic in inspiration and founded upon Lombard's "Augustine breviary," was beginning to be rounded out into a system and to be institutionalized in the universities.

Hugh's
summa and
Lombard's
Sentences

The re-
nascence of
Aristotle

At the very moment of its consolidation, however, an upheaval was brewing that would shake this novel conception to its foundations: the main works of Aristotle, hitherto unknown in the West, were being translated into Latin—among them his *Metaphysics*, the *Physics*, the *Nicomachean Ethics*, and the books *On the Soul*. These writings were not merely an addition of something new to the existing stock; they involved an enormous challenge. Suddenly, a new, rounded, coherent view of the world was pitted against another more-or-less coherent traditional view; and because this challenge bore the name of Aristotle, it could not possibly be ignored, for Aristotle's books on logic, translated and equipped with commentaries by Boethius, had for centuries been accepted as one of the foundations of all culture. During the lifetime of Abelard the full challenge of the Aristotelian work had not yet been presented, though it had been developing quietly along several paths, some of which were indeed rather fantastic. For instance, most of the medieval Latin translations of Aristotle stem not from the original Greek but from earlier Arabic translations.

Within the Western Christendom of the 2nd millennium, a wholly new readiness to open the mind to the concrete reality of the world had arisen, a view of the universe and life that resembled the Aristotelian viewpoint. The tremendous eagerness with which this new philosophy was embraced was balanced, however, by a deep concern lest the continuity of tradition and the totality of truth be shattered by the violence of its assimilation. And this danger was enhanced by the fact that Aristotle's works did not come alone; they came, in fact, accompanied by the work of Arabic commentators and their heterodox interpretations.

The most influential Arabic commentators were an 11th-century polymath, Avicenna, a Persian by birth, and a 12th-century philosopher, Averroës, born in Spain. Avicenna, personal physician to sovereigns, but also a philosopher and theologian, read—according to his own account—Aristotle's *Metaphysics* 40 times without understanding it, until he learned the text by heart. F.C. Copleston has called him "the real creator of a Scholastic system in the Islâmic world." In the view of Averroës, who was not only a philosopher but also a jurist and a doctor, Aristotle's philosophy represented simply the perfection of human knowledge; and to the West, he himself was to become the commentator. A third great commentator was a 12th-century orthodox Jewish philosopher, Moses Maimonides, also born in Spain, who wrote his main works in Arabic. Maimonides was at the same time a vigorous adherent of the Aristotelian world view and was, thus, confronted by the same unending task that preoccupied the great teachers of medieval Christendom. At first sight it appears strange that none of these three thinkers had any appreciable influence within his own world (neither Islâm nor Judaism knew of any such thing as a "discovery" of Aristotle), whereas on almost every page of the 13th-century Christian *summae* the names of Avicenna, Averroës, and Maimonides are found.

The first theologian of the Middle Ages who boldly accepted the challenge of the new Aristotelianism was a 13th-century Dominican, Albertus Magnus, an encyclopedic scholar. Although he knew no Greek, he conceived a plan of making accessible to the Latin West the complete works of Aristotle, by way of commentaries and paraphrases; and, unlike Boethius, he did carry out this resolve. He also penetrated and commented upon the works of the Areopagite; he was likewise acquainted with those of the Arabs, especially Avicenna; and he knew Augustine. Nevertheless, he was in no wise primarily a man of bookish scholarship; his strongest point, in fact, was the direct observation of nature and experimentation. After having taught for some years at the University of Paris, he travelled, as a Dominican superior, through almost all of Europe. Not only was he continually asking questions of fishermen, hunters, beekeepers, and birdcatchers but he himself also bent his sight to the things of the visible world. But amidst the most palpable descriptions of bees, spiders, and apples, recorded in two voluminous books on plants and animals, Albertus formulated completely

new, and even revolutionary, methodological principles: for instance, "There can be no philosophy about concrete things," or, "in such matters only experience can provide certainty."

With Albertus, the problem of the conjunction of faith and reason had suddenly become much more difficult, because reason itself had acquired a somewhat new meaning. "Reason" implied, in his view, not only the capacity for formally correct thinking, for finding adequate creaturely analogies to the truths of revelation, but it implied, above all, the capacity to grasp the reality that man encounters. Henceforth, the Boethian principle of "joining faith with reason" would entail the never-ending task of bringing belief into a meaningful coordination with the incessantly multiplying stock of natural knowledge of man and the universe. Since Albertus' nature, however, was given more to conquest than to the establishment of order, the business of integrating all of these new and naturally divergent elements into a somewhat consistent intellectual structure waited for another man, for his pupil Thomas Aquinas.

To epitomize the intellectual task that Aquinas set for himself, the image of Odysseus' bow, which was so difficult to bend that an almost superhuman strength was needed, is fitting. As a young student at the University of Naples, he had met in the purest possible form both extremes, which, though they seemed inevitably to be pulling away from one another, it was nevertheless his life's task to join: one of these extremes was the dynamic, voluntary poverty movement whose key word was "the Bible"; and the second phenomenon was the Aristotelian writings and outlook, which at that time could have been encountered nowhere else in so intensive a form. And "Aristotle" meant to Thomas not so much an individual author as a specific world view, viz., the affirmation of natural reality as a whole, including man's body and his natural cognitive powers. To be sure, the resulting *Summa theologiae* (which Thomas himself chose to leave incomplete) was a magnificent intellectual structure; but it was never intended to be a closed system of definitive knowledge. Thomas could no longer possess the magnificent naïveté of Boethius, who had considered it possible to discuss the Trinitarian God without resorting to the Bible, nor could he share Anselm's conviction that Christian faith so completely concurred with natural reason that it could be proved on compelling rational grounds.

In the meanwhile, the poles of the controversy—the biblical impulses, on the one hand, and the philosophical and secular ones, on the other—had begun to move vigorously apart, and partisans moving in both directions found some encouragement in Thomas himself. But in his later years he realized that the essential compatibility as well as the relative autonomy of these polar positions and the necessity for their conjunction had to be clarified anew by going back to a deeper root of both; that is, to a more consistent understanding of the concepts of creation and createdness. At Paris, he had to defend his own idea of "a theologically based worldliness and a theology open to the world" not only against the secularistic "philosophism" of Siger of Brabant, a stormy member of the faculty of arts, and against an aggressive group of heterodox Aristotelians around him, but also (and even more) against the traditional (Augustinian) objection that by advocating the rights of all natural things Thomas would encroach upon the rights of God, and that, besides, the theologian needs to know only that part of creation that is pertinent to his theological subject. The latter idea was supported also by the Italian mystical theologian Bonaventura, who, in his earlier days as a colleague of Thomas at the university, had likewise been enamoured of Aristotle, but later, alarmed by the secularism that was growing in the midst of Christendom, became more mistrustful of the capacities of natural reason. Thomas answered this objection in somewhat the following way: The benefit that the theologian may derive from an investigation of natural reality cannot be determined in advance, but, in general, faith presupposes and therefore needs natural knowledge of the world; at times, an error concerning the creation leads men astray also from the truth of faith. This may sound like an optimistic Rationalism; but the corrective

Thomas
Aquinas

Albertus
Magnus
and
Aristote-
lianism

of negative theology and philosophy was always present in the mind of Thomas, as well. Not only, as he argued in his treatise on God, does man not know what God is, but he does not know the essences of things either.

Late Scholastic period. Thomas did not succeed in bridging the faith–reason gulf. When he left Paris (1272) and after his death (1274), the gulf became much more radical; and on March 7, 1277, the Archbishop of Paris, in fact, formally condemned a list of sentences, some of them close to what Thomas himself had allegedly or really taught. This ecclesiastical act, questionable though it may have been in its methods and personal motivations, was not only understandable; it was unavoidable, since it was directed against what, after all, amounted in principle to an antitheological, rationalistic secularism. Quite another matter, however, were the factual effects of the edict, which were rather disastrous. Above all, two of the effects were pernicious: instead of free disputes among individuals, organized blocks (or “schools”) now began to form; and the cooperative dialogue between theology and philosophy turned into mutual indifference or distrust. Nonetheless, the basic principle itself (“join faith with reason”) had not yet been explicitly repudiated. This was to happen in the next generation.

Duns
Scotus and
William of
Ockham

The negative element, as formulated in the theology of the Areopagite, proved to be insufficient as a corrective to counter the overemphasis of reason, for reason seemed to imply the idea of necessity; Anselm’s asserted “compelling grounds” for revealed truths, for example, were akin to such a necessitarianism. A second corrective was therefore demanded and this took the name of “freedom”—which indeed was the battle cry of an important Franciscan, Duns Scotus, known as the “subtle doctor,” who lived at the turn of the 14th century. Scotus used “freedom” primarily with reference to God; consequently, since redemption, grace, and salvation as well as all of creation were the work of God’s groundless, absolute freedom, there could be no “necessary reasons,” if indeed any reasons at all, for anything. It was therefore futile to attempt to coordinate faith with speculative reason. Clearly, Scotus’ theological starting point made the conjunction of what man believes with what he knows every bit as difficult as it had been in Siger of Brabant’s secularistic “philosophism.” From both positions there was only one step to the doctrine of a “double truth”—a step that in fact was taken in the 14th century by the Nominalist William of Ockham, also a Franciscan, to whom singular facts alone are “real,” and their coherence is not; this mere factuality, he held, can neither be calculated nor deduced, but only experienced; reason therefore means nothing but the power to encounter concrete reality. And upon such soil only a consistently “positive” theology could thrive. Any collaboration with speculative reason must be rejected as untheological. Faith is one thing and knowledge an altogether different matter; and a conjunction of the two is neither meaningfully possible nor even desirable. Inexorably, and justified by reasons on both sides, a divorce was taking place between faith and reason—to the connection of which the energies of almost a thousand years had been devoted. What was occurring was the demise of medieval Scholasticism.

ENDURING FEATURES

But not all of Scholasticism is specifically medieval and therefore definitively belonging to the dead past; there are perennial elements that are meant for every age, the present one included, three of which may be here distinguished. First, not only has Scholasticism held true to the normal historical rule that ideas, once thought and expressed, remain present and significant in the following time; but the medieval intellectual accomplishments have surpassed the rule and exerted, though more or less anonymously, a quite exceptional influence even on philosophers who consciously revolted against Scholasticism. New historical investigations clearly show that the classical modern philosophers Descartes, Locke, Spinoza, and Leibniz owe much to medieval ideas. Of Descartes, for instance, it has been said, contrary to the usual view, that he could quite well have been “included with the later Scholastics”; and even Charles Sanders Peirce, the

originator of 20th-century American Pragmatism, refers not too rarely to Scholastic maxims. Secondly, there have been explicit attempts to go back to Scholastic thinkers and inspire a renaissance of their basic ideas. Two chief movements of this kind were the Scholasticism of the Renaissance (called *Barockscholastik*) and the Neoscholasticism of the 19th and 20th centuries, both of which were primarily interested in the work of Thomas Aquinas.

Renaissance and
Neoscholasticism

Renaissance Scholasticism received its first impulses from the Reformation. One of its leading figures, a Dominican, Cardinal Thomas de Vio (16th century), commonly known as Cajetan, had some famous disputations with Martin Luther. Cajetan’s great commentary on Thomas Aquinas, published again in a late edition of the *Summa theologiae* (1888–1906), exerted for at least three centuries an enormous influence on the formation of Catholic theology. He was much more than a commentator, however; his original treatise on the “Analogy of names,” for example, can even pass as a prelude to modern linguistic philosophy. The so-called Silver Age of Scholastic thought, which occurred in the 16th century, is represented by two Spaniards: Francisco de Vitoria of the first half and Francisco Suárez of the last half of the century were both deeply engaged in what has been called the “Counter-Reformation.” Though likewise commentators on the works of Thomas Aquinas, the Renaissance Scholastics were much less concerned with looking back to the past than with the problems of their own epoch, such as those of international law, colonialism, resistance to an unjust government, and world community. Though Suárez was for more than a hundred years among the most esteemed authors, even in Protestant universities, Renaissance Scholasticism was eradicated by Enlightenment philosophy and German Idealism. This, in turn, gave rise in due time to the Neoscholasticism of the 19th century, one of the most effective promoters of which was a German Jesuit, Joseph Kleutgen, who published a voluminous scholarly apology of patristic and Scholastic theology and philosophy and was also responsible for the outline of the papal encyclical *Aeterni Patris* of Leo XIII (1879), which explicitly proclaimed the “instauration of Christian philosophy according to St. Thomas.” The result, fed of course from many different sources, was that all over the world new centres of Scholastic research and higher learning (universities) arose—some more traditionalistic, some from the start engaged in the dialogue with modern philosophy and science, and some primarily devoted to historical studies and the preparation of critical editions of the great medieval Scholastics—and that a multitude of periodicals and systematic textbooks were produced. It is too early for a competent judgment on this enterprise to be made. Its immeasurable educational benefit for several generations of students, however, is as undeniable as the unique contributions of some Neoscholastic thinkers to current intellectual life. A weak point, on the other hand, seems to be a somewhat “unhistorical” approach to reality and existence. In any case, it is scarcely a matter of mere chance that, after World War II, the impact of Existentialism and Marxism caused a noticeable decline in Neoscholasticism and that the positions of “Scholastic” authors active in the 1970s were already beyond Neoscholasticism.

The third and most important aspect of the enduring significance of the Scholastic movement implies the acceptance of the following fundamental tenets: that there exist truths that man knows, and also revealed truths of faith; that these two kinds of truth are not simply reducible to one another; that faith and theology do not, by means of symbols and sensuous images, merely say the same as what reason and science say more clearly by conceptual argumentation (Averroës, Hegel); that, on the other hand, reason is not a “prostitute” (Luther), but is man’s natural capacity to grasp the real world; that since reality and truth, though essentially inexhaustible, are basically one, faith and reason cannot ultimately contradict one another. Those who hold these convictions appear quite unable to refrain from trying to coordinate what they know with what they believe. Any epoch that addresses itself to this interminable task can ill afford to ignore the demand-

Perennial
tenets of
Scholasticism

ing and multiform paradigm of Scholasticism; but to the problems posed it will have to find its own answer.

(Jf.Pi.)

Skepticism

As a philosophical attitude, skepticism is the doubting of knowledge claims set forth in various areas. Sceptics have challenged the adequacy or reliability of these claims by asking what they are based upon or what they actually establish. They have raised the question whether such claims about the world are either indubitable or necessarily true, and they have challenged the alleged grounds of accepted assumptions. Practically everyone is skeptical about some knowledge claims; but the Sceptics have raised doubts about any knowledge beyond the contents of directly felt experience. The original Greek meaning of *skeptikos* was "an inquirer," someone who was unsatisfied and still looking for truth.

Skepticism
in history

From ancient times onward Sceptics have developed arguments to undermine the contentions of dogmatic philosophers, scientists, and theologians. The Skeptical arguments and their employment against various forms of dogmatism have played an important role in shaping both the problems and the solutions offered in the course of Western philosophy. As ancient philosophy and science developed, doubts arose about basic accepted views of the world. In ancient times Sceptics challenged the claims of Platonism, Aristotelianism, and Stoicism, and in the Renaissance those of Scholasticism and Calvinism. After Descartes, Sceptics attacked Cartesianism and other theories justifying the "new science." Later, a Skeptical offensive was levelled against Kantianism and then against Hegelianism. Each Skeptical challenge led to new attempts to resolve the difficulties. Skepticism, especially since the Enlightenment, has come to mean disbelief—primarily religious disbelief—and the Skeptic has often been likened to the village atheist.

VARIOUS SENSES AND APPLICATIONS

Skepticism developed with regard to various disciplines in which men claimed to have knowledge. It was questioned, for example, whether one could gain any certain knowledge in metaphysics (the study of the nature and significance of being as such) or in the sciences. In ancient times a chief form was medical Skepticism, which questioned whether one could know with certainty either the causes or cures of diseases. In the area of ethics doubts were raised about accepting various mores and customs and about claiming any objective basis for making value distinctions. Scepticisms about religion have questioned the doctrines of different traditions. Certain philosophies, like those of Hume and Kant, have seemed to show that no knowledge can be gained beyond the world of experience and that one cannot discover the causes of phenomena. Any attempt to do so, as Kant argued, leads to antinomies, contradictory knowledge claims. A dominant form of Skepticism, the subject of this article, concerns knowledge in general, questioning whether anything actually can be known with complete or adequate certainty. This type is called epistemological Skepticism.

Epistemo-
logical
Skepticism

Kinds of epistemological Skepticism can be distinguished in terms of the areas in which doubts are raised; that is, whether they be directed toward reason, toward the senses, or toward knowledge of things-in-themselves. They can also be distinguished in terms of the motivation of the Skeptic—whether he is challenging views for ideological reasons or for pragmatic or practical ones to attain certain psychological goals. Among the chief ideological motives have been religious or antireligious concerns. Some Sceptics have challenged knowledge claims so that religious ones could be substituted—on faith. Others have challenged religious knowledge claims in order to overthrow some orthodoxy. Kinds of Skepticism also can be distinguished in terms of how restricted or how thoroughgoing they are—whether they apply only to certain areas and to certain kinds of knowledge claims or whether they are more general and universal.

ANCIENT SKEPTICISM

Historically, skeptical philosophical attitudes began to appear in pre-Socratic thought. In the 5th century BC, the Eleatic philosophers, known for reducing reality to a static One, questioned the reality of the sensory world, of change and plurality, and denied that reality could be described in the categories of ordinary experience. On the other hand, the Ephesian philosopher of change Heraclitus and his pupil Cratylus thought that the world was in such a state of flux that no permanent, unchangeable truth about it could be found; and Xenophanes, a wandering poet and philosopher, doubted whether man could distinguish true from false knowledge.

A more developed Skepticism appeared in some of Socrates' views and in a couple of the Sophists (see below). Socrates, in the early Platonic dialogues, was always questioning the knowledge claims of others; and in the *Apology*, he said that all that he really knew was that he knew nothing. Socrates' enemy, the Sophist Protagoras, contended that man is the measure of all things. This thesis was taken as a kind of skeptical relativism: no views are ultimately true, but each is merely one man's opinion. Another Sophist, Gorgias, advanced the skeptical-nihilist thesis that nothing exists; and if something did exist, it could not be known; and if it could be known, it could not be communicated.

The putative father of Greek Skepticism is Pyrrhon of Elis (c. 360–c. 272 BC), who tried to be a living Skeptic. He avoided committing himself to any views about what was actually going on and acted only according to appearances. In this way he sought happiness or at least mental peace.

The first school of Skeptical philosophy developed in Plato's Academy (see above *Platonism*) in the 3rd century BC and was thus called "Academic" Skepticism. Starting from the skeptical side of Socrates, its leaders, Arcesilaus (316/315–c. 241 BC) and Carneades (214/213–129/128 BC), set forth a series of epistemological arguments to show that nothing could be known, challenging primarily the two foremost schools, those of the Stoics and Epicureans. They denied that any criteria could be found for distinguishing the true from the false; instead, only reasonable or probable standards could be established for knowledge. This limited or probabilistic Skepticism was the view of the Academy until the 1st century BC, when Cicero was a student there. His *Academica* and *De natura deorum* are the main sources for knowledge of this movement. (St. Augustine's *Contra academicos* is an answer to Cicero's views.)

Academic
and
Pyrrhonian
schools

The other major form of ancient Skepticism was Pyrrhonism, apparently developed by medical Sceptics in Alexandria. Beginning with Aenesidemus (1st century BC), this movement, named after Pyrrhon, criticized the Academic Sceptics because they claimed to know too much, namely, that nothing could be known and that some things are more probable than others. The Pyrrhonians advanced a series of tropes, or ways of opposing various kinds of knowledge claims, in order to bring about *epochē* (suspense of judgment). The Pyrrhonian attitude is preserved in the writings of one of its last leaders, Sextus Empiricus (2nd or 3rd century AD). In his *Outlines of Pyrrhonism* and *Adversus mathematicos*, Sextus presented the tropes developed by previous Pyrrhonists. The 10 tropes attributed to Aenesidemus showed the difficulties to be encountered in ascertaining the truth or reliability of judgments based on sense information, owing to the variability and differences of human and animal perceptions. Other arguments raised difficulties in determining whether there are any reliable criteria or standards—logical, rational, or otherwise—for judging whether anything is true or false. To settle any disagreement, a criterion seems to be required. Any purported criterion, however, would appear to be based on another criterion, thus requiring an infinite regress of criteria, or else it would be based upon itself, which would be circular. Sextus offered arguments to challenge any claims of dogmatic philosophers to know more than what is evident; and in so doing he presented in one form or another practically all of the skeptical arguments that have ever appeared in subsequent philosophy.

Sextus said that his arguments were aimed at leading people to a state of *ataraxia* (unperturbability). People who thought that they could know reality were constantly disturbed and frustrated. If they could be led to suspend judgment, however, they would find peace of mind. In this state of suspension they would neither affirm nor deny the possibility of knowledge but would remain peaceful, still waiting to see what might develop. The Pyrrhonist did not become inactive in this state of suspense but lived undogmatically according to appearances, customs, and natural inclinations.

MEDIEVAL SKEPTICISM

Fideistic
views

Pyrrhonism ended as a philosophical movement in the late Roman Empire, as religious concerns became paramount. In the Christian Middle Ages the main surviving form of Skepticism was the Academic, described in St. Augustine's *Contra academicos*. Augustine, before his conversion, had found Cicero's views attractive and had overcome them only through revelation. With faith, he could seek understanding. Augustine's account of Skepticism and his answer to it provided the basis for medieval discussions.

In Islāmic Spain, where there was more contact with ancient learning, a form of antirational Skepticism developed among Muslim and Jewish theologians. Al-Ghazālī, an Arab theologian of the 11th and early 12th centuries, and his Jewish contemporary Judah ha-Levi (c. 1075/c. 1085–c. 1141), who was a poet and physician as well as a philosopher, offered skeptical challenges (much like those later employed by the occasionalist Nicolas Malebranche and by David Hume) against the contemporary Aristotelians in order to lead people to accept religious truths in mystical faith. This kind of fideism also appears in the late Middle Ages in the German cardinal and philosopher Nicolaus of Cusa's advocacy of learned ignorance as the way to religious knowledge.

MODERN SKEPTICISM

Modern Skepticism emerged in the 16th century, not from medieval views but from the intellectual crises of the Renaissance and Reformation and from the rediscovery of the Skeptical classics. The voyages of exploration; the humanistic rediscovery of the learning of ancient Greece, Rome, and Palestine; and the new science—all combined to undermine confidence in man's accepted picture of the world. The religious controversy between the Protestants and Catholics raised fundamental epistemological issues about the bases and criteria of religious knowledge. At the same time the texts of Cicero and Sextus became available again. (Sextus' *Outlines of Pyrrhonism* [*Hypotyposesis*] was published in Latin in 1562, his *Adversus mathematicos* in 1569, and the Greek texts of both in 1621.)

Christian
Skepticism

In the Reformation. The fundamental skeptical issues raised by the Reformation appeared in the debate between the outstanding humanist scholar Erasmus and Luther. Erasmus, using Academic skeptical materials, insisted that the issues in dispute could not be resolved, that one should therefore suspend judgment and remain with the church. Luther insisted, on the other hand, that true and certain religious knowledge could and must be gained through conscience. Erasmus' view developed into a Christian Skepticism, accepting traditional Christianity on faith after seeing that no adequate evidence existed. Luther's view, and later that of Calvin, proposed a new criterion—that of inner experience—while the Catholics of the Counter-Reformation employed Pyrrhonian and Academic arguments to undermine the criterion.

Following after Erasmus, another humanist, Giovanni Pico della Mirandola II (nephew of the famous count of the same name) and H.C. Agrippa von Nettesheim, a stormy occult philosopher and physician, employed the skeptical arguments against Scholasticism, Renaissance Naturalism, and many other views to win people to the "true religion." The Catholic scholar Gentian Hervet, in the preface to his 1569 edition of Sextus, saw the Skeptical arguments as the definitive answer to Calvinism and the way to true Christianity.

In the 17th century. The new concern with Skepticism was given a general philosophical formulation by

Michel de Montaigne and his cousin Francisco Sanches. Montaigne in *Apology for Raimond Sebond* and Sanches in *Quod nihil scitur*, both written in 1576, explored the human epistemological situation and showed that man's knowledge claims in all areas were extremely dubious. Montaigne recommended living according to nature and custom and accepting whatever God reveals, and Sanches advocated recognizing that nothing can be known and then trying to gain what limited information one can through empirical scientific means.

Montaigne's Skepticism was extremely influential in the early 17th century. His followers, Pierre Charron, J.-P. Camus, La Mothe Le Vayer, and others, further popularized his views. Various French Counter-Reformers used the arguments of Montaigne and Sextus to undermine Calvinism. Montaigne's Skepticism opposed all sorts of disciplines, including the new science, and was coupled with a fideism that many suspected to be insincere.

In the 1620s efforts to refute or mitigate this new Skepticism appeared. A Christian Epicurean, Pierre Gassendi, himself originally a Skeptic, and Marin Mersenne, one of the most influential figures in the intellectual revolution of the times, while retaining epistemological doubts about knowledge of reality yet recognized that science provided useful and important information about the world. The constructive Skepticisms of Gassendi and Mersenne, and later of members of the Royal Society of England like Bishop John Wilkins and Joseph Glanvill, developed the attitude of Sanches into a hypothetical, empirical interpretation of the new science.

Cartesian
Skepticism

René Descartes offered a fundamental refutation of the new Skepticism, contending that, by applying the skeptical method of doubting all beliefs that could possibly be false (due to suffering illusions or being misled by some power), one would discover a truth that is genuinely indubitable, viz., "I think, therefore I am" (*cogito ergo sum*), and that from this truth one could discover the criterion of true knowledge, viz., that whatever is clearly and distinctly conceived is true. Using this criterion, one could then establish: God's existence, that he is not a deceiver, that he guarantees our clear and distinct ideas, and that an external world exists that can be known through mathematical physics. Descartes, starting from Skepticism, claimed to have found a new basis for certitude and for knowledge of reality. Throughout the 17th century Skeptical critics—Mersenne, Gassendi, the reviver of Academic philosophy Simon Foucher, and Pierre-Daniel Huet, one of the most learned men of the age—sought to show that Descartes had not succeeded, and that, if he sincerely followed his skeptical method, his new system could only lead to complete Skepticism. They challenged whether the *cogito* proved anything, or whether it was indubitable; whether Descartes' method could be successfully applied, or whether it was certain; and whether any of the knowledge claims of Cartesianism were *really* true. Nicolas Malebranche, the developer of occasionalism, revised the Cartesian system to meet the Skeptical attacks only to find his efforts challenged by the new Skeptical criticisms of Foucher and by the contention of the Jansenist philosopher Antoine Arnauld that Malebranchism led to a most dangerous Pyrrhonism.

Various English philosophers culminating in Locke tried to blunt the force of Skepticism by appealing to common sense and to the "reasonable" man's inability to doubt everything. They admitted that there might not be sufficient evidence to support the knowledge claims extending beyond immediate experience. But this did not actually require that everything be doubted; by using standards of common sense, an adequate basis for many beliefs could be found. Blaise Pascal, who presented the case for Skepticism most forcefully in his *Pensées*, still denied that there can be a complete Skepticism; for nature prevents it. Lacking rational answers to complete Skepticism, man's only recourse lies in turning to God for help in overcoming doubts.

The culmination of 17th-century Skepticism appears in the writings of Pierre Bayle, especially in his monumental *Dictionnaire historique et critique* (1697–1702). Bayle, a superb dialectician, challenged philosophical, sci-

Pierre
Bayle

entific, and theological theories, both ancient and modern, showing that they all led to perplexities, paradoxes, and contradictions. He argued that the theories of Descartes, Spinoza, Leibniz, and Malebranche, when skeptically analyzed, cast in doubt all information about the world, even whether a world exists. Bayle skillfully employed Skeptical arguments about such things as sense information, human judgments, logical explanations, and the criteria of knowledge in order to undermine confidence in human intellectual activity in all areas. Bayle suggested that man should abandon rational activity and turn blindly to faith and revelation; he can therefore only follow his conscience without any criterion for determining true faith. Bayle showed that the interpretations of religious knowledge were so implausible that even the most heretical views, like Manichaeism, known for its cosmic dualism of good and evil, and Atheism, made more sense. As a result Bayle's work became "the arsenal of the Enlightenment," and he was regarded as a major enemy of religion.

In the 18th century. Most 18th-century thinkers gave up the quest for metaphysical knowledge after imbibing Bayle's arguments. George Berkeley, an Empiricist and Idealist, fought Skeptical doubts by identifying appearance and reality and offering a spiritualistic metaphysics. He was immediately seen as just another Skeptic since he was denying the world beyond experience.

Bayle's chief 18th-century successor was David Hume. Combining empirical and skeptical arguments, Hume charged that neither inductive nor deductive evidence could establish the truth of any matter of fact. Knowledge could only consist of intuitively obvious matters or demonstrable relations of ideas but not of anything beyond experience; the mind can discover no necessary connections within experience nor any root causes of experience. Beliefs about the world are based not upon reason or evidence nor even upon appeal to the uniformity of nature but only on habit and custom. Beliefs cannot be justified. Belief that there is an external world, a self, a God is common; but there is no adequate evidence for it. Although it is natural to hold these convictions, they are inconsistent and epistemologically dubious. "Philosophy would render us entirely Pyrrhonian, were not Nature too strong for it." The beliefs that a man is forced to hold enable him to describe the world scientifically, but when he tries to justify them he is led to complete Skepticism. Before he goes mad with doubts, however, Nature brings him back to common sense, to unjustifiable beliefs. Hume's fideism was a natural rather than a religious one; it is only animal faith that provides relief from complete doubt. The religious context of Skepticism from Montaigne to Bayle had been removed, and man was left with only his natural beliefs, which might be meaningless or valueless.

The central themes in Hume's Skeptical analysis—the basis of induction and causality, knowledge of the external world and the self, proofs of the existence of God—became the key issues of later philosophy. Hume's contemporary Thomas Reid hoped to rebut Hume's Skepticism by exposing it as the logical conclusion of the basic assumptions of modern philosophy from Descartes onward. Such disastrous assumptions should be abandoned for commonsensical principles that have to be believed. As Hume and Kant saw, Reid had not answered Hume's Skepticism but had only sidestepped the issue by appealing to commonsensical living. This provided, however, neither a theoretical basis for beliefs nor a refutation of the arguments that questioned them.

Kant saw that Hume had posed a most fundamental challenge to all human knowledge claims. To answer him, it had to be shown not that knowledge is possible but *how* it is possible. Kant combined a Skepticism toward metaphysical knowledge with the contention that certain universal and necessary conditions are involved in having experience and describing it. In terms of these it is possible to have genuine knowledge about the forms of all possible experience, space and time, and about the categories in which all experience is described. Any effort to apply this beyond all possible experience, however, leads into contradictions and Skepticism. It is not possible to know about things-in-themselves nor about the causes of experience.

Though Kant thought that he had resolved the Skeptical problems, some of his contemporaries saw his philosophy as commencing a new Skeptical era. G.E. Schulze (or Schulze-Aenesidemus) a notable critic of Kantianism, insisted that, on Kant's theory, no one could know any objective truths about anything; he could only know the subjective necessity of his views. The Jewish critic Salomon Maimon contended that, though there are such things as a priori concepts, their application to experience is always problematical, and whether they apply can only be found through experience. Hence, the possibility of knowledge can never be established with certainty. Assured truth on the basis of concepts is possible only of human creations, like mathematical ideas, and it is questionable whether these have any objective truth. The thesis that human creativity is the basis of truth, however, was soon to be developed by Johann G. Fichte, a leading German Idealist, as a new way of transcending Skepticism.

Another Skeptical critic of Kant, J.G. Hamann, saw in Hume's and Kant's work a new basis for fideism. If knowledge of reality cannot be gained by rational means, then one must turn to faith. Based on Hume's efforts, Hamann advanced an antirational Skepticism in an effort to convince Kant to become a fideistic Christian. Hamann's kind of fideism was also developed in France by Catholic opponents of the French Revolution and liberalism—like Joseph de Maistre and H.-F.-R. de Lamennais.

In recent and contemporary philosophy. Irrational Skepticism was developed into Existentialism by Søren Kierkegaard in the 19th century. Using traditional Skeptical themes to attack Hegelianism and liberal Christianity, Kierkegaard stressed the need for faith. Only by an unjustified and unjustifiable "leap into faith" could certainty be found—which would then be entirely subjective rather than objective. Modern neo-orthodox and Existentialist theologians have argued that Skepticism highlights man's inability to find any ultimate truth except through faith and commitment. Nonreligious forms of this view have been developed by Existentialist writers like Albert Camus, combining the epistemological Skepticism of Kierkegaard with the religious and value Skepticism of Nietzsche. The rational and scientific examination of the world shows it to be unintelligible and absurd; and if God is dead, as Nietzsche proclaimed, then the world is ultimately meaningless. But it is necessary to struggle with it. It is thus through action and commitment that one finds whatever personal meaning one can, though it has no objective significance.

Other kinds of Skepticism appear in various forms of recent and contemporary philosophy. The English Idealist F.H. Bradley used classical Skeptical arguments in his *Appearance and Reality: A Metaphysical Essay* to contend that the world could not be understood empirically or materialistically; true knowledge could be reached only by transcending the world of appearance.

George Santayana, an American critical Realist, in *Scepticism and Animal Faith*, presented a naturalistic Skepticism. Any interpretation of immediate or intuited experience is open to question. To make life meaningful, however, men make interpretations by "animal faith," according to biological and social factors. The resulting beliefs, though unjustified and perhaps illusory, enable them to persevere and find the richness of life.

Types of Skepticism also appear in Logical Positivism (see below *Positivism and Logical Empiricism*) and various forms of linguistic philosophy (see below *Analytic and Linguistic Philosophy*). The attack on speculative metaphysics developed by the physicist and early Positivist Ernst Mach, by Bertrand Russell, and by Rudolf Carnap, a leader in the Vienna Circle, where Logical Positivism was nourished, incorporated a Skepticism about the possibility of gaining knowledge beyond experience or logical tautologies. Russell and the important philosopher of science Karl Popper have further stressed the unjustifiability of the principle of induction, and Popper has criticized theories of knowledge based upon empirical verification. A founder of linguistic analysis, Fritz Mauthner, has set forth a Skepticism in which any language is merely relative to its users and thus subjective. Every attempt to tell

David
Hume

Existen-
tialism

Kant and
his critics

Positivism
and
Analysis

what is true just leads one back to linguistic formulations, not to objective states of affairs. The result is a complete Skepticism about reality—a reality that cannot even be expressed except in terms of what he called godless mystical contemplation. Mauthner's linguistic Skepticism bears some affinities to the views expressed in Ludwig Wittgenstein's *Tractatus Logico-Philosophicus*.

CRITICISM AND EVALUATION

In Western thought Skepticism has raised basic epistemological issues. In view of the varieties of human experience, it has questioned whether it is possible to tell which are veridical. The variations that occur in different perceptions of what is presumed to be one object raise the question of which is the correct view. The occurrence of illusory experiences raises the question of whether it is really possible to distinguish illusions and dreams from reality. The criteria employed can be questioned and require justification. On what basis does one tell whether one has the right criteria? By other criteria? Then, are these correct? On what standards? The attempt to justify criteria seems either to lead to an infinite regress or to just stop arbitrarily. If an attempt is made to justify knowledge claims by starting with first principles, what are these based upon? Can it be established that these principles cannot possibly be false? If so, is the proof itself such that it cannot be questioned? If it is claimed that the principles are self-evident, can one be sure of this, sure that one is not deceived? And can one be sure that one can recognize and apply the principles correctly? Through such questioning, Skeptics have indicated the basic problems that an investigator would have to resolve before he could be certain of possessing knowledge; i.e., information that could not possibly be false.

Criticisms

Critics have contended that Skepticism is both a logically and a humanly untenable view. Any attempt to formulate the position will be self-refuting since it will assert at least some knowledge claims about what is supposed to be dubious. Montaigne suggested that the Skeptics needed a nonassertive language, reflecting the claim of Sextus that the Skeptic does not make assertions but only chronicles his feelings. The strength of Skepticism lies not in whether it can be stated consistently but upon the effects of its arguments on dogmatic philosophers. As Hume said, Skepticism may be self-refuting, but in the process of refuting itself it undermines dogmatism. Skepticism, Sextus said, is like a purge that eliminates itself as well as everything else.

Critics have claimed that anyone who tried to be a complete Skeptic, denying or suspending all judgments about ordinary beliefs, would soon be driven insane. Even Hume thought that the complete Skeptic would have to starve to death and would walk into walls or out of windows. Hume, therefore, separated the doubting activity from natural practical activities in the world. Skeptical philosophizing went on in theory, while believing occurred in practice. Sextus and the contemporary Norwegian Skeptic Arne Naess have said, on the other hand, that Skepticism is a form of mental health. Instead of going mad, the Skeptic—without commitment to fixed positions—can function better than the dogmatist.

Some recent thinkers like A.J. Ayer and John Austin have contended that Skepticism is unnecessary. If knowledge is defined in terms of satisfying meaningful criteria, then knowledge is open to all. The Skeptics have raised false problems, because it is, as a matter of fact, possible to tell that some experiences are illusory since we have criteria for distinguishing them from actual events. We do resolve doubts and reach a state of knowledge through various verification procedures, after which doubt is meaningless. Naess, in his book *Scepticism*, has sought to show, however, that, on the standards offered by Ayer and Austin, one can still ask if knowledge claims may not turn out to be false and hence that Skepticism has still to be overcome.

Evaluation

Skepticism throughout history has played a dynamic role in forcing dogmatic philosophers to find better or stronger bases for their views and to find answers to the Skeptical attacks. It has forced a continued reexamination of previous knowledge claims and has stimulated creative thinkers to work out new theories to meet the Skeptical problems.

The history of philosophy can be seen, in part, as a struggle with Skepticism. The attacks of the Skeptics also have served as a check on rash speculation; the various forms of modern Skepticism have gradually eroded the metaphysical and theological bases of European thought. Most contemporary thinkers have been sufficiently affected by Skepticism to abandon the search for certain and indubitable foundations of human knowledge. Instead, they have sought ways of living with the unresolved Skeptical problems through various forms of naturalistic, scientific, or religious faiths. (R.H.P.)

Sophists

The Sophists were certain Greek lecturers, writers, and teachers in the 5th and 4th centuries BC, most of whom travelled about the Greek-speaking world giving instruction in a wide range of subjects in return for fees.

HISTORY OF THE NAME

The term sophist (Greek *sophistes*) had earlier applications. It is sometimes said to have meant originally simply "clever" or "skilled man," but the list of those to whom Greek authors applied the term in its earlier sense makes it probable that it was rather more restricted in meaning. Seers, diviners, and poets predominate, and the earliest Sophists probably were the "sages" in early Greek societies. This would explain the subsequent application of the term to the Seven Wise Men (7th–6th century BC), who typified the highest early practical wisdom, and to Pre-Socratic philosophers generally. When Protagoras, in one of Plato's dialogues (*Protagoras*, 317 a–b) is made to say that, unlike others, he is willing to call himself a Sophist, he is using the term in its new sense of "professional teacher," but he wishes also to claim continuity with earlier sages as a teacher of wisdom. Plato and Aristotle altered the meaning again, however, when they claimed that professional teachers such as Protagoras were not seeking the truth but only victory in debate and were prepared to use dishonest means to achieve it. This produced the sense "captious or fallacious reasoner or quibbler," which has remained dominant to the present day. Finally, under the Roman Empire the term was applied to professors of rhetoric, to orators, and to prose writers generally, all of whom are sometimes regarded as constituting what is now called the Second Sophistic movement (see below).

THE 5TH-CENTURY SOPHISTS

The names survive of nearly 30 Sophists properly so called, of whom the most important were Protagoras, Gorgias, Antiphon, Prodicus, and Thrasymachus. Plato protested strongly that Socrates was in no sense a Sophist—he took no fees, and his devotion to the truth was beyond question. But from many points of view he is rightly regarded as a rather special member of the movement. The actual number of Sophists was clearly much larger than 30, and for about 70 years, until c. 380 BC, they were the sole source of higher education in the more advanced Greek cities. Thereafter, at least at Athens, they were largely replaced by the new philosophic schools, such as those of Plato and Isocrates. Plato's dialogue *Protagoras* describes something like a conference of Sophists at the house of Callias in Athens just before the Peloponnesian War. Antimoerous of Mende, described as one of the most distinguished of Protagoras' pupils, is there receiving professional instruction in order to become a Sophist (*Protagoras*, 315 a), and it is clear that this was already a normal way of entering the profession.

Most of the major Sophists were not Athenians, but they made Athens the centre for their activities, although travelling continuously. The importance of Athens was doubtless due in part to the greater freedom of speech prevailing there, in part to the patronage of wealthy men like Callias, and even to the positive encouragement of Pericles, who was said to have held long discussions with Sophists in his house. But primarily the Sophists congregated at Athens because they found there the greatest demand for what they had to offer, namely, instruction to young men, and the extent of this demand followed from the nature

The Sophistic movement

The
Sophistic
teaching

of the city's political life. Athens was a democracy, and although its limits were such that Thucydides could say it was governed by one man, Pericles, it nonetheless gave opportunities for a successful political career to citizens of the most diverse backgrounds, provided they could impress their audiences sufficiently in the council and the assembly. After Pericles' death this avenue became the highroad to political success.

The Sophists taught men how to speak and what arguments to use in public debate. A Sophistic education was increasingly sought after both by members of the oldest families and by aspiring newcomers without family backing. The changing pattern of Athenian society made merely traditional attitudes in many cases no longer adequate. Criticizing such attitudes and replacing them by rational arguments held special attraction for the young, and it explains the violent distaste which they aroused in traditionalists. Plato thought that much of the Sophistic attack upon traditional values was unfair and unjustified. But even he learned at least one thing from the Sophists—if the older values were to be defended, it must be by reasoned argument, not by appeals to tradition and unreflecting faith.

Seen from this point of view, the Sophistic movement was a valuable function of Athenian democracy in the 5th century BC. It offered an education designed to facilitate and promote success in public life. All of the Sophists appear to have provided a training in rhetoric and in the art of speaking, and the Sophistic movement, responsible for large advances in rhetorical theory, contributed greatly to the development of style in oratory. In modern times the view occasionally has been advanced that this was the Sophists' only concern. But the range of topics dealt with by the major Sophists makes this unlikely, and even if success in this direction was their ultimate aim, the means they used were surely as much indirect as direct, for the pupils were instructed not merely in the art of speaking, but in grammar; in the nature of virtue (*aretē*) and the bases of morality; in the history of society and the arts; in poetry, music, and mathematics; and also in astronomy and the physical sciences. Naturally the balance and emphasis differed from Sophist to Sophist, and some offered wider curricula than others. But this was an individual matter, and attempts by earlier historians of philosophy to divide the Sophistic movement into periods in which the nature of the instruction was altered are now seen to fail for lack of evidence. The 5th-century Sophists inaugurated a method of higher education that in range and method anticipated the modern humanistic approach inaugurated or revived during the Renaissance.

NATURE OF SOPHISTIC THOUGHT

A question still discussed is whether the Sophists in general had any real regard for truth or whether they taught their pupils that truth was unimportant compared with success in argument. Plato's hostile judgment on both counts is still frequently repeated without question. The Platonic writings make frequent reference to what Plato calls "eristic" (Greek *eristikos*, "fond of wrangling") and "antilogic"; the two often have been incorrectly treated as identical. Eristic, for Plato, consists in arguments aimed at victory rather than at truth. Antilogic involves the assignment to any argument of a counterargument that negates it, with the implication that both argument and counterargument are equally true. Antilogic in this sense was especially associated with Protagoras; but Plato, no doubt correctly, attributes its use to other Sophists as well. He regards the use of antilogic as essentially eristic, whether it be used to silence an opponent by making his position seem self-contradictory, or whether it be used mechanically to negate any proposition put forward in debate. He concludes that the widespread use of antilogic is evidence that Sophists had no real regard for the truth, which must itself be free from antilogic.

But Plato himself believed, for much or possibly all of his life, that the phenomenal world was essentially antilogical inasmuch as no statement about it could be made possessing a greater degree of truth than the contradictory of that statement. For example, if a man is tall in relation to one

object, he will be short in relation to another object. In so characterizing the phenomenal world, Plato certainly did not wish to be called eristic—he regarded the application of antilogic to the description of the phenomenal world as an essential preliminary to the search for the truth residing in the Platonic Forms, which are themselves free from antilogic.

Seen in this perspective, the Sophistic use of antilogic must be judged less harshly. To the extent that it was used irresponsibly to secure success in debate it was eristic, and the temptation so to use it must often have arisen. But where it was invoked in the sincere belief that antilogic elements were indeed involved, or where it was used for analyzing a complex situation in order to reveal its complexity, then antilogic was in no way inconsistent with devotion to truth. This raises the question to what extent the Sophists possessed any general view of the world or gave expression to any genuine philosophical views, whether original or derived. Ancient writers, influenced by Plato and Aristotle, seem to have excluded the Sophists, apart from Protagoras, for their schematized accounts of early Greek thinkers. Modern writers have frequently maintained that, whatever else they were, the Sophists were in no sense philosophers. Even those who acknowledge the philosophical interest of certain particular doctrines attributed to individual Sophists often tend to regard these as exceptions and claim that, inasmuch as the Sophists were not a school but only independent teachers and writers, as a class they were not philosophers. Two questions are involved: whether the Sophists held common intellectual doctrines and whether some or all of these could actually be termed philosophical.

Among moderns, Hegel was one of the first to reinsert the Sophists into the history of Greek philosophy. He did so within the framework of his own dialectic, in which every thesis invokes its own opposite, or antithesis; thus he treated the Sophists as representing the antithesis to the thesis of the group of philosophers known collectively as the Pre-Socratics. Pre-Socratics such as Thales, Heraclitus, and Parmenides sought the truth about the external world with a bold enthusiasm that produced a series of explanations, each claiming to be correct. None of these explanations of the physical world paid attention to the observer and each was driven to reject more and more of the phenomenal world itself as unreal. Finally, with the Eleatics, a 5th-century school at Elea in Italy that held that reality is a static one, of which Parmenides and Zeno are representatives, little or nothing of the phenomenal world was left as real. This trend in turn produced a growing distrust of the power of human beings to attain knowledge of the ultimate basis of natural phenomena. Philosophy had reached an impasse, and there was a danger of complete skepticism. Such an extreme position, according to Hegel's view, provoked the "antithesis" of the Sophistic movement, which rejected the "thesis" of the objectivists and concentrated attention upon man rather than upon nature. To Hegel, the Sophists were subjective Idealists, holding that reality is only minds and their contents, and so philosophy could move forward by turning its attention to the subjective element in knowing. Reflection upon the contrast between the thought of the Sophists and that of their predecessors produced the "syntheses" of Plato and Aristotle.

Whether any of the Sophists actually were subjective Idealists may be doubted. The conclusion depends in part on whether Protagoras held that phenomena had subjective existence only, or whether he thought that all things perceived had objective existence but were perceived differently according to the nature of the percipient and their relation to him—i.e., whether he interpreted phenomena subjectively or relativistically. It is fairly clear, however, that the Sophists did concentrate very largely upon man and human society, upon questions of words in their relations to things, upon issues in the theory of knowledge, and upon the importance of the observer and the subjective element in reality and in the correct understanding of reality.

This emphasis helps to explain the philosophical hostility of Plato and Aristotle. Particularly in the eyes of Plato,

Philosophy
of the
Sophists

Moral
views
of the
Sophists

anyone who looks for the truth in phenomena alone, whether he interprets it subjectively or relativistically, cannot hope to find it there; and his persistence in turning away from the right direction virtually amounts to a rejection of philosophy and of the search for truth. Many a subsequent thinker for whom metaphysics, or the investigation of the deepest nature of reality, was the crowning achievement of philosophy has felt with Plato that the Sophists were so antimetaphysical that they have no claim to rank as philosophers. But in a period when, for many philosophers, metaphysics is no longer the most important part of philosophy and is even for some no part at all, there is growing appreciation of a number of problems and doctrines recurring in the discussions of the Sophists in the 5th and 4th centuries BC. In the 18th and early 19th centuries the Sophists were considered charlatans. Their intellectual honesty was impugned, and their doctrines were blamed for weakening the moral fibre of Greece. The charge was based on two contentions, both correct: first, that many of the Sophists attacked the traditionally accepted moral code; and second, that they explored and even commended alternative approaches to morality that would condone or allow behaviour of a kind inadmissible under the stricter traditional code.

Much less weight has been attached to these charges since about the mid-19th century. First, many of the attacks on the traditional morality were in the name of a new morality that claimed to be of greater validity. Attacks upon particular doctrines often claimed that accepted views should be abandoned as morally defective. Furthermore, even when socially disfavoured action seemed to be commended, this was frequently done to introduce a principle necessary in any satisfactory moral theory. Thus when Thrasymachus in the first book of Plato's *Republic* argues that justice is unwarranted when it merely contributes to another's good and not to the good of the doer, Plato agrees. Finally, there is no evidence that any of the Sophists were personally immoral or that any of their pupils were induced to immoral actions by Sophistic teaching. The serious discussion of moral problems and the theory of morality tends to improve behaviour, not to corrupt it.

WRITINGS

In addition to their teaching, the Sophists wrote many books, the titles of which are preserved by writers such as Diogenes Laërtius, who probably derived them from library catalogues. It has usually been supposed that the writings themselves hardly survived beyond the period of Plato and Aristotle, but this view requires modification in the light of papyrus finds, admittedly few, that were copied from Sophistic writings in the Christian Era. It also has been possible to identify in the works of later writers certain imitations or summaries of 5th-century Sophistic writers, whose names are unknown. The most important of these are the discussion of law in the *Protrepticus*, or "Exhortation to Philosophy," by the 3rd-century-AD Syrian Neoplatonist Iamblichus, and the so-called *Dissoi logoi* found in the manuscripts of Sextus Empiricus (3rd century AD). This evidence suggests that while most later writers took their accounts of the Sophists from earlier writers, especially from Plato, the original writings did in many cases survive and were consulted.

PARTICULAR DOCTRINES

As part of his defense of the Sophists against the charge of immoral teachings, the English historian George Grote (1794–1871) maintained that they had nothing in common with each other except their profession, as paid teachers qualifying young men to think, speak, and act with credit to themselves as citizens. This denial of common doctrines cannot be sustained—the evidence is against it. While the Sophists were not a sect, with a set of obligatory beliefs or doctrines, they had a common interest in a whole series of questions to which they sought to apply solutions along certain clearly defined lines.

There are great difficulties, however, in the precise reconstruction of individual Sophistic doctrines. No complete writings survive from any of the Sophists to check the

accounts found in Plato, and later writers were often, but not always, dependent upon what they found in Plato. Plato doubtless knew well the doctrines of individual Sophists; but he was writing for those to whom these doctrines were already well known, and he was always more interested in following the argument where it led than in providing precise statements of other people's views for the sake of posterity. Consequently, almost everything that is said about particular Sophistic doctrines is subject to controversy.

Theoretical issues. Relativism and skepticism have often been regarded as common features of the Sophistic movement as a whole. But it was early pointed out that only in Protagoras and Gorgias is there any suggestion of a radical skepticism about the possibility of knowledge; and even in their case Sextus Empiricus, in his discussion of skepticism, is probably right when he declares that neither was really a skeptic. Protagoras does seem to have restricted knowledge to sense experience, but he believed emphatically that whatever was perceived by the senses was certainly true. This led him to assert that the tangent does not touch the circle at a point only, but along a definite length of the circumference; clearly he was referring to human perception of drawn tangents and circles. Gorgias, who claimed that nothing exists, or if it does exist it cannot be known, or if it exists and is knowable it cannot be communicated to another, has often been accused of denying all reality and all knowledge. Yet he also seems to have appealed in his very discussion of these themes to the certainty of perceived facts about the physical world; e.g., that chariots do not race across the sea. Others dismiss his whole thesis as a satire or joke against philosophers.

Probably neither view is correct. What Gorgias seems to have been attacking was not perceived reality nor one's power to perceive it but the attempt to assign existence or nonexistence (with the metaphysical implications of such an operation) to what we perceive around us. There is evidence that other Sophists (e.g., Hippias) were interested in questions of this kind, and it is likely that they were all concerned to some degree with rejecting claims of any nonsensical existence, such as those of the Eleatics. The Sophists, in fact, were attempting to explain the phenomenal world without appealing to any principles outside of phenomena. They believed that this could be done by including the observer within the phenomenal world. Their refusal to go beyond phenomena was, for Plato, the great weakness in their thinking.

A second common generalization about the Sophists has been that they represent a revolt against science and the study of the physical world. The evidence is against this, inasmuch as for Hippias, Prodicus, Gorgias, and Protagoras there are records of a definite interest in questions of this kind. The truth is rather that they were in revolt against attempts to explain the physical world by appeals to principles that could not be perceived by the senses; and instead of framing new "objective" explanations, they attempted to explain things, where explanation was required, by introducing the perceiver as one element in the perceptual situation.

One of the most famous doctrines associated with the Sophistic movement was the opposition between nature and custom or convention in morals. It is probable that the antithesis did not originate in Sophistic circles but was rather earlier; but it was clearly very popular and figured largely in Sophistic discussions. The commonest form of the doctrine involved an appeal from conventional laws to supposedly higher laws based on nature. Sometimes these higher laws were invoked to remedy defects in actual laws and to impose more stringent obligations; but usually it was in order to free men from restrictions unjustifiably imposed by human laws that the appeal to nature was made. In its extreme form the appeal involved the throwing off of all restraints upon self-interest and the desires of the individual (e.g., the doctrine of Callicles in Plato's *Gorgias* that might, if one possesses it, is actually right), and it was this, more than anything else, that gave support to charges against the Sophists of immoral teaching. On other occasions the terms of the antithesis were reversed and human laws were explicitly acclaimed as superior to

Relativism
and
skepticism

Nature
and law

the laws of nature and as representing progress achieved by human endeavour. In all cases the laws of nature were regarded not as generalized descriptions of what actually happens in the natural world (and so not like the laws of physics to which no exceptions are possible) but rather as norms that people ought to follow but are free to ignore. Thus the appeal to nature tended to mean an appeal to the nature of man treated as a source for norms of conduct.

To Greeks this appeal was not very novel. It represented a conscious probing and exploration into an area wherein, according to their whole tradition of thought, lay the true source for norms of conduct. If Callicles in Plato's *Gorgias* represents a position actually held by a living Sophist when he advocates free rein for the passions, then it was easy for Plato to argue in reply that the nature of man, if it is to be fulfilled, requires organization and restraint in the license given to the desires of particular aspects of it; otherwise the interests of the whole will be frustrated. Both Plato and Aristotle, in basing so much of their ethics on the nature of man, are only following up the approach begun by the Sophists.

Religion
and society

Humanistic issues. The Sophists have sometimes been characterized by their attacks on the traditional religious beliefs of the Greeks. It is true that more than one Sophist seems to have faced prosecution for impiety, as did Socrates also. Protagoras wrote "concerning the gods, I cannot know either that they exist or that they do not exist nor what they are like in form," and Prodicus offered a sociological account of the development of religion. Critias went further when he supposed that the gods were deliberately invented to inspire fear in the evildoer. It is thus probably correct to say that the tendency of much Sophistic thought was to reject the traditional doctrines about the gods. Indeed this follows almost inevitably if the supposition is correct that all the Sophists were attempting to explain the phenomenal world from within itself, while excluding all principles or entities not discernible in phenomena. But in their agnostic attitudes toward the Olympian deities the Sophists were probably at one with most of the Pre-Socratic philosophers of the 6th and 5th centuries and also with most thinking people living toward the end of the 5th century. It is thus probably misleading to regard them as revolutionary in their religious beliefs.

The importance the Sophists attached to man meant that they were extremely interested in the history and organization of human societies. Here again most is known about Protagoras, and there is a danger of treating his particular doctrines as typical of the Sophistic movement as a whole. In the 5th century, human history was very commonly seen in terms of a decline from an earlier golden age. Another view supposed that there were recurring cycles in human affairs according to which a progression from good to bad would give way to one from bad to good. The typical Sophistic attitude toward society rejected both of these views in favour of one that saw human history in terms of progress from savagery to civilization. In a famous myth Protagoras explained how man achieved civilized society first with the aid of arts and crafts and then by gaining a sense of respect and justice in the ordering of his affairs. The general thinking of most of the Sophists seems to have been along similar lines.

One of the most distinctive Sophistic tenets was that virtue can be taught, a position springing naturally from the Sophists' professional claim to be the teachers of young men. But the word virtue (*aretē*) implied both success in living and the qualities necessary for achieving such success, and the claim that *aretē* could be taught by the kind of teaching that the Sophists offered had far-ranging implications. It involved the rejection of the view that *aretē* came only by birth—for example, by being born a member of a noble family—and it involved also the rejection of the doctrine that *aretē* was a matter of the chance occurrence of specified qualities in particular individuals. *Aretē*, in the Sophists' view, was the result of known and controllable procedures, a contention of profound importance for the organization of society. Moreover, what can be taught has some relation to what can be known and understood. The belief that teaching of a high intellectual calibre could produce success both for the individual and

for governments has had a profound influence upon the subsequent history of education. Once again, it is through the acceptance of this doctrine by Plato and Aristotle that the Sophistic position came to be part of subsequent humanist tradition.

THE SECOND SOPHISTIC MOVEMENT

It is a historical accident that the name "Sophist" came to be applied to the Second Sophistic movement. Greek literature underwent a period of eclipse during the 1st century BC and under the early Roman Empire. But Roman dominance did not prevent a growing interest in sophistic oratory in the Greek-speaking world during the 1st century AD. This oratory aimed merely at instructing or interesting an audience and had of necessity no political function. But it was based on elaborate rules and required a thorough knowledge of the poets and prose writers of antiquity. Training was provided by professional teachers of rhetoric who claimed the title of Sophists, just as the 5th-century Sophists had adopted a name already used by others.

The revival of the Greek spirit under Hadrian and other emperors in the 2nd century AD who were also admirers of Greek culture found expression in a fresh flowering of Greek prose following principles developed and applied by the professors of rhetoric in the 1st century AD. Hence a group of Greek prose writers in the 2nd century AD were regarded as constituting the Second Sophistic movement. This was a backward-looking movement that took as its models Athenian writers of the 5th and 4th centuries BC; hence the label "Atticists" (Greek *Attikos*, "Athenian") applied to some of its leading members. The limits of the movement were never clear. It is usually taken to include Polemon of Athens, Herodes Atticus, Aelius Aristides, Maximus of Tyre, and the group of Philostrati. Dio Chrysostom of Prusa is often included, although others would regard him as preparing the way for the main period. Other writers, like Lucian, Aelian, and Alciphron, were influenced by the movement even if not properly members of it; and the writers of prose romances, such as Longus and Heliodorus, and the historians Dio Cassius and Herodian are also associated with the general trend. By the 3rd century AD, however, its impulse was weakening, and it was shortly no longer distinguishable within the general stream of Greek literature. (G.B.K.)

Stoicism

Stoicism, a school of thought that flourished in Greek and Roman antiquity, was one of the loftiest and most sublime philosophies in the record of Western civilization. In urging participation in the affairs of man, Stoics have always believed that the goal of all inquiry is to provide man with a mode of conduct characterized by tranquillity of mind and certainty of moral worth.

NATURE AND SCOPE OF STOICISM

For the early Stoic philosopher, as for all the post-Aristotelian schools, knowledge and its pursuit are no longer held to be ends in themselves. The Hellenistic Age was a time of transition, and the Stoic philosopher was perhaps its most influential spokesman. A new culture was in the making. The heritage of an earlier period, with Athens as its intellectual leader, was to continue, but to undergo many changes. If, as with Socrates, to know is to know oneself, rationality as the sole means by which something outside of the self might be achieved may be said to be the hallmark of Stoic belief. As a Hellenistic philosophy, Stoicism presented an *ars vitae*, a way of accommodation for people to whom the human condition no longer appeared as the mirror of a universal, calm, and ordered existence. Reason alone could reveal the constancy of cosmic order and the originative source of unyielding value; thus, reason became the true model for human existence. To the Stoic, virtue is an inherent feature of the world, no less inexorable in relation to man than are the laws of nature.

The Stoics believed that perception is the basis of true knowledge. In logic, their comprehensive presentation of the topic is derived from perception, yielding not only the

Funda-
mental
tenets

judgment that knowledge is possible but also that *certain* knowledge is possible, on the analogy of the incorrigibility of perceptual experience. To them, the world is composed of material things, with some few exceptions (*e.g.*, meaning), and the irreducible element in all things is right reason, which pervades the world as divine fire. Things, such as material, or corporeal, bodies, are governed by this reason or fate, in which virtue is inherent. The world in its awesome entirety is so ruled as to exhibit a grandeur of orderly arrangement that can only serve as a standard for mankind in the regulation and ordering of his life. Thus, the goal of man is to live according to nature, in agreement with the world design. Stoic moral theory is also based on the view that the world, as one great city, is a unity. Man, as a world citizen, has an obligation and loyalty to all things in that city. He must play an active role in world affairs, remembering that the world exemplifies virtue and right action. Thus, moral worth, duty, and justice are singularly Stoic emphases, together with a certain sternness of mind. For the moral man neither is merciful nor shows pity, because each suggests a deviation from duty and from the fated necessity that rules the world. Nonetheless—with its loftiness of spirit and its emphasis on man's essential worth—the themes of universal brotherhood and the benevolence of divine nature make Stoicism one of the most appealing of philosophies.

Rival
schools in
antiquity

Its chief competitors in antiquity were: (1) Epicureanism, with its doctrine of a life of withdrawal in contemplation and escape from worldly affairs and its belief that pleasure, as the absence of pain, is the goal of man; (2) Skepticism, which rejected certain knowledge in favour of local beliefs and customs, in the expectation that these guides would provide man with the quietude and serenity that the dogmatic philosopher (*e.g.*, the Stoic) could not hope to achieve; and (3) Christianity, with its hope of personal salvation provided by an appeal to faith as an immanent aid to human understanding and by the beneficent intervention of a merciful God.

Along with its rivals, Stoicism enabled the individual to better order his own life and to avoid the excesses of human nature that promote disquietude and anxiety. It was easily the most influential of the schools from the time of its founding through the first two centuries AD, and it continued to have a marked effect on later thought. During the late Roman and medieval periods, elements of Stoic moral theory were known and used in the formulation of Christian, Jewish, and Muslim theories of man and nature, of the state and society, and of law and sanctions—*e.g.*, in the works of Marcus Cicero, Roman statesman and orator; in Lactantius, often called the “Christian Cicero”; and in A.M.S. Boethius, a scholar transitional to the Middle Ages. In the Renaissance, Stoic political and moral theory became more popular to theorists of natural law and political authority and of educational reform—*e.g.*, in Hugo Grotius, a Dutch jurist and statesman, and in Philipp Melancthon, a major Reformation scholar. More recently, Stoicism has become popular again for its insistence on the value of the individual and the place of value in a world of strife and uncertainty—*e.g.*, in Existentialism and in Neo-orthodox Protestant theology. Stoicism also plays an important role in reassessments of the history of logic—*e.g.*, in Jan Łukasiewicz, a Polish logician, and in William and Martha Kneale, mid-20th-century British logicians.

ANCIENT STOICISM

Historical
and
philosophi-
cal setting

Early Greek Stoicism. With the death of Aristotle (322 BC) and that of Alexander the Great (323 BC), the greatness of the life and thought of the Greek city-state (polis) ended. With Athens no longer the centre of worldly attraction, its claim to urbanity and cultural prominence passed on to other cities—to Rome, to Alexandria, and to Pergamum. The Greek polis gave way to larger political units; local rule was replaced by that of distant governors. The earlier distinction between Greek and barbarian was destroyed; provincial and tribal loyalties were broken apart, first by Alexander and then by Roman legions. The loss of freedom by subject peoples further encouraged a deterioration of the concept of the freeman and resulted

in the rendering of obligation and service to a ruler whose moral force held little meaning. The earlier intimacy of order, cosmic and civic, was now replaced by social and political disorder; and traditional mores gave way to uncertain and transient values.

Stoicism had its beginnings in a changing world, in which earlier codes of conduct and ways of understanding proved no longer suitable. But it was also influenced by tenets of the older schools. The earliest Greek philosophers, the Milesians, had called attention to cosmic order and the beauty of nature. Later, the monist Parmenides of Elea stressed the power of reason and thought, whereas Heraclitus of Ephesus, precursor of the philosophy of becoming, had alluded to the constancy of change and the omnipresence of divine fire, which illumined all things. A deeper understanding of man himself came with Socrates, symbol of the philosophic man, who personified *sophia* and *sapientia* (Greek and Latin: “wisdom”). Of the several schools of philosophy stemming from Socrates, the Cynic and Megarian schools were influential in the early development of Stoic doctrine: the Cynics for their emphasis on the simple life, unadorned and free of emotional involvement; and the Megarians for their study of dialectic, logical form, and paradoxes.

The Early
Stoa

Stoicism takes its name from the place where its founder, Zeno of Citium (Cyprus), customarily lectured—the Stoa Poikile (Painted Colonnade). Zeno, who flourished in the early 3rd century BC, showed in his own doctrines the influence of earlier Greek attitudes, particularly those mentioned above. He was apparently well versed in Platonic thought, for he had studied at Plato's Academy both with Xenocrates of Chalcedon and with Polemon of Athens, successive heads of the Academy. Zeno was responsible for the division of philosophy into three parts: logic, physics, and ethics. He also established the central Stoic doctrines in each part, so that later Stoics were to expand rather than to change radically the views of the founder. With some exceptions (in the field of logic), Zeno thus provided the following themes as the essential framework of Stoic philosophy: logic as an instrument and not as an end in itself; human happiness as a product of life according to nature; physical theory as providing the means by which right actions are to be determined; perception as the basis of certain knowledge; the wise man as the model of human excellence; Platonic Ideas—or the abstract Forms that things of the same genus share—as being unreal; true knowledge as always accompanied by assent; the fundamental substance of all existing things as being a divine fire, the universal principles of which are (1) passive (matter) and (2) active (reason inherent in matter); belief in a world conflagration and renewal; belief in the corporeality of all things; belief in the fated causality that necessarily binds all things; cosmopolitanism, or cultural outlook transcending narrower loyalties; and man's obligation, or duty, to choose only those acts that are in accord with nature, all other acts being a matter of indifference.

Cleanthes of Assos, who succeeded Zeno as head of the school, is best known for his *Hymn to Zeus*, which movingly describes Stoic reverence for the cosmic order and the power of universal reason and law. The third head of the school, Chrysippus of Soli, who lived to the end of the 3rd century, was perhaps the greatest and certainly the most productive of the early Stoics. He devoted his considerable energies to the almost complete development of the Zenonian themes in logic, physics, and ethics. In logic particularly, he defended against the Megarian logicians and the Skeptics such concepts as certain knowledge, comprehensive presentation, proposition and argument, truth and its criterion, and assent. His work in propositional logic, in which unanalyzed propositions joined by connectives are studied, made important contributions to the history of ancient logic and is of particular relevance to more recent developments in logic.

In physics, Chrysippus was responsible for the attempt to show that fate and free will are not mutually exclusive conceptual features of Stoic doctrine. He further distinguished between “whole” and “all,” or “universe,” arguing that the whole is the world, while the all is the external void together with the world. Zeno's view of the origin of man

as providentially generated by “fiery reason” out of matter was expanded by Chrysippus to include the concept of self-preservation, which governs all living things. Another earlier view (Zeno’s), that of nature as a model for life, was amplified first by Cleanthes and then by Chrysippus. The Zenonian appeal to life “according to nature” had evidently been left vague, because to Cleanthes it seemed necessary to speak of life in accord with nature conceived as the world at large (the cosmos), whereas Chrysippus distinguished between world nature and human nature. Thus, to do good is to act in accord with both human and universal nature. Chrysippus also expanded the Stoic view that seminal reasons were the impetus for animate motion.

He established firmly that logic and (especially) physics are necessary and are means for the differentiation of goods and evils. Thus, a knowledge of physics (or theology) is required before an ethics can be formulated. Indeed, physics and logic find their value chiefly in this very purpose. Chrysippus covered almost every feature of Stoic doctrine and treated each so thoroughly that the essential features of the school were to change relatively little after his time.

The Middle Stoa

Later Roman Stoicism. The Middle Stoa, which flourished in the 2nd and early 1st centuries BC, was dominated chiefly by two men of Rhodes: Panaetius, its founder, and his disciple Poseidonius. Panaetius organized a Stoic school in Rome before returning to Athens, and Poseidonius was largely responsible for an emphasis on the religious features of the doctrine. Both were antagonistic to the ethical doctrines of Chrysippus, who, they believed, had strayed too far from the Platonic and Aristotelian roots of Stoicism. It may have been because of the considerable time that Panaetius and Poseidonius lived in Rome that the Stoa there turned so much of its emphasis to the moral and religious themes within the Stoic doctrine. Panaetius was highly regarded by Cicero, who used him as a model for his own work. Poseidonius, who had been a disciple of Panaetius in Athens, taught Cicero at his school at Rhodes and later went to Rome and remained there for a time with Cicero. If Poseidonius admired Plato and Aristotle, he was particularly interested—unlike most of his school—in the study of natural and providential phenomena. In presenting the Stoic system in the second book of *De natura deorum* (45 BC), Cicero most probably followed Poseidonius. Because his master, Panaetius, was chiefly concerned with concepts of duty and obligation, it was his studies that served as a model for the *De officiis* (44 BC) of Cicero. Hecaton, another of Panaetius’ students and an active Stoic philosopher, also stressed similar ethical themes.

If Chrysippus is to be commended for his diligence in defending Stoic logic and epistemology against the Skepticism of the New Academy (3rd–2nd century BC), it was chiefly Panaetius and Poseidonius who were responsible for the widespread popularity of Stoicism in Rome. It was precisely their turning of doctrine to themes in moral philosophy and natural science that appealed to the intensely practical Romans. The times perhaps demanded such interests, and with them Stoicism was to become predominantly a philosophy for the individual, showing how—given the vicissitudes of life—one might be stoical. Law, world citizenship, nature, and the benevolent workings of Providence and the divine reason were the principal areas of interest of Stoicism at this time.

The Late Stoa

These tendencies toward practicality are also well illustrated in the later period of the school (in the first two centuries AD) in the writings of Lucius Seneca, a Roman statesman; of Epictetus, a slave freed by Nero; and of Marcus Aurelius, a Roman emperor. Both style and content in the *Libri morales* (Eng. trans., *Moral Essays*) and *Epistulae morales* (*Moral Letters*) of Seneca reinforce the new direction in Stoic thought. The *Encheiridion* (*Manual*) of Epictetus and the *Meditations* of Marcus Aurelius furthered the sublime and yet personal consolation of the Stoic message and increasingly showed the strength of its rivalry to the burgeoning power of the new Christianity. The mark of a guide, of the religious teacher, is preeminent in these writings. It is difficult to establish with any precision, however, the extent of Stoic influence by the

time of the first half of the 2nd century AD. So popular had these ideas become that many specifically Stoic terms (viz., right reason, comprehension, assent, indifference, *logos*, natural law, and the notion of the wise man) commonly were used in debate and intellectual disputes.

Stoic elements in Pauline and patristic thought. There is much disagreement as to the measure of Stoic influence on the writings of St. Paul, the Apostle of Christ. At Tarsus, Paul certainly had opportunities for hearing Stoic lectures on philosophy. And it may be that his discussion of nature and the teaching of it (I Cor. 11:14) is Stoic in origin, for it has a parallel in the *Manual* of Epictetus 1.16, 10. Although not a Stoic technical term, *syneidēsis*, which Paul used as “conscience,” was generally employed by Stoic philosophers. In I Cor. 13 and in the report of Paul’s speech at Athens (Acts 17), there is much that is Hellenistic, more than a little tinged by Stoic elements—e.g., the arguments concerning man’s natural belief in God and the belief that man’s existence is in God.

The assimilation of Stoic elements by the Church Fathers was generally better understood by the 4th century. Stoic influence can be seen, for example, in the relation between reason and the passions in the works of St. Ambrose, one of the great scholars of the church, and of Marcus Minucius Felix, a Christian Apologist. Each took a wealth of ideas from Stoic morality as Cicero had interpreted it in *De officiis*. In general, whereas the emerging Christian morality affirmed its originality, it also assimilated much of the pagan literature, the more congenial elements of which were essentially Stoic.

Earlier, in the 3rd century, Quintus Tertullian, often called the father of Latin Christian literature, seems to have been versed in Stoic philosophy; e.g., in his theory of the agreement between the supernatural and the human soul, in his use of the Stoic tenet that from a truth there follow truths, and in his employment of the idea of universal consent. Even in his polemical writings, which reveal an unrelenting hostility to pagan philosophy, Tertullian showed a fundamental grasp and appreciation of such Stoic themes as the world *logos* and the relation of body to soul. This is well illustrated in his argument against the Stoics, particularly on their theme that God is a corporeal being and identified with reason as inherent in matter—also to be found in his polemics against Marcion, father of a heretical Christian sect, and against Hermogenes of Tarsus, author of an important digest of rhetoric. Yet in his doctrine of the Word, he appealed directly to Zeno and Cleanthes of the Early Stoa. Another important polemic against the Stoics is found in the treatise *Contra Celsum*, by Origen, the most influential Greek theologian of the 3rd century, in which he argued at some length against Stoic doctrines linking God to matter.

Also, St. Cyprian, bishop of Carthage in the 3rd century, revealed the currency of Stoic views; e.g., in his *Ad Demetrianum*, a denunciation of an enemy to Christianity, in which Cyprian castigates the ill treatment of slaves, who, no less than their masters, are formed of the same matter and endowed with the same soul and live according to the same law. The beliefs in the brotherhood of man and in the world as a great city, commonly found in early Christian literature, were current Stoic themes. The Christian attitude appears in what St. Paul said of Baptism: “You are all sons of God through Faith. For as many of you as were baptized into Christ have put on Christ” (Gal. 3:26–27).

Stoic concepts in Tertullian and Origen

STOICISM IN MEDIEVAL AND MODERN PHILOSOPHY

Stoic undercurrents in medieval thought. During the period when Christian institutions and doctrines were developing (AD 230–1450), Stoicism continued to play a popular role. The *De consolazione philosophiae* (524) of Boethius (died AD 524/525) was widely known and appreciated as a discourse on the mysterious questions of the nature of good and evil, of fortune, chance, or freedom, and of divine foreknowledge. If the plan of Boethius was to serve as an interpreter of Plato and Aristotle, he succeeded only in working through some logical theories of Aristotle, together with several commentaries on those theories. In the *Consolazione*, however, the themes are quite different;

Stoic concepts in Boethius and Lactantius

in the fifth book, for example, he attempted to resolve the apparent difficulty of reconciling human freedom with the divine foreknowledge, a problem that among Stoic thinkers—though by no means uniquely among them—had been in general currency for a long time. This work of emancipation from worldly travail through the glories of reason and philosophy, which included Stoic doctrines as found in the writings of Cicero and Seneca, was much more influential for later medieval thought than that of Lactantius, of the late 3rd to early 4th century, who was largely concerned with the writing of a history of religion—a summary statement of Christian doctrine and life from earliest times. Lactantius also wrote a not unimportant work, *De ira Dei* (313), on the possibility of anger in God. It poses a problem of how to deal with the essentially Greek, or philosophic, view that God cannot feel anger because he is not subject to passions and that *apatheia* (“apathy,” or “imperturbableness”) is not merely the mark of the wise man but is also a divine attribute. This view, which had been most thoroughly developed among Stoic thinkers and particularly by Epictetus, raised a peculiarly Christian problem, the concern of the power of God to reward the righteous and punish the transgressor; thus, it challenged the very idea of Providence. Other manifestations of anthropopathism, the attributing of human feelings to God, had also been charged against the early Christian religionists; and the writers of the time—Lactantius and Tertullian among them—took great pains to refute the largely Stoic formulations of these charges. Although the refutations took the form—in St. Augustine, for example—of denying that the wrath of God is a perturbation of the soul and of holding that it is rather a judgment, the concept of the divine essence excludes all passions. Within the monastic tradition, there remained more than a residue of concern over apathy as a divine attribute and as a model for the truly religious.

Stoicism in
legal and
political
theory

Other significant Stoic influences appeared in medieval discussions of the popular origin of political authority, *res publica* and *res populi*, and on the distinctions made in law between *jus naturale*, *jus gentium*, *jus civile*—doctrines of Stoic origin—found in 3rd-century Roman juridical texts gathered together by Isidore of Seville (died AD 636), a Spanish encyclopaedist and theologian. The Stoic belief—as against Aristotle—that men are by nature equal was an integral part of the knowledge that certain rules of law are universally recognized, laws that all people might naturally follow. In this way, the Romans—whose genius lay in organization and in law—fostered the conception of natural, or common, law, which reason was supposed to make evident to all men. Thus, in the second half of the 11th century, the Stoic texts of Cicero and Seneca became important doctrinal sources for the initial discussions of social and political philosophy. These early theories of law, of the natural equality of men, and of the rights of prince and populace were to become the basis for 13th-century systems of social and political privilege and obligation.

In the 12th century, John of Salisbury, an English critical scholar, produced, in his *Polycraticus* (1159), the first complete attempt at a philosophy of the state since Classical times. Stoic doctrines of natural law, society, state, and Providence were important elements in his effort to construct a social philosophy on ethical and metaphysical principles. The impact of these doctrines and the lengthy history of their use in the earlier Middle Ages can also be found in the views of Thomas Aquinas on the philosophy of the state and of man.

Renaissance of Stoicism in modern times. If the influence of Stoic doctrines during the Middle Ages was largely restricted to the resolution of problems of social and political significance, it remained for the Renaissance, in its passion for the rediscovery of Greek and Roman antiquity, to provide a basis for the rebirth of Stoic views in logic, epistemology, and metaphysics, as well as the documentation of the more familiar Stoic doctrines in ethics and politics. Late in the 16th century, Justus Lipsius, a Flemish scholar and Latin Humanist, was responsible for the first restatement of Stoicism as a defensible and thoroughgoing (Christian) philosophy of man. His treatises *De constantia* (1584) and *Politicorum sive civilis doctrinae libri V* (1589)

Stoic
concepts
in Lipsius
and certain
Skeptics

were widely known in many editions and translations. His defense of Stoic doctrine in *Manuductio ad Stoicam Philosophiam* (1604) and *Physiologia Stoicorum* (1604) provided the basis for the considerable Stoic influence during the Renaissance. Around the turn of the 17th century, Guillaume du Vair, a French lawyer and Christian philosopher, made Stoic moral philosophy popular, while Pierre Charron, a French theologian and Skeptic, utilized Stoic themes in *De la sagesse* (1601; Eng. trans., *Of Wisdom*, 1608), as did the Skeptic Michel de Montaigne in his *Essais* (1580; Eng. trans. 1603). Through the work of Lipsius, Stoic doctrines were to influence the thought of Francis Bacon, a precursor of modern philosophy of science, and, later, the *De l'esprit des lois* (1748; Eng. trans., *The Spirit of Laws*, 1750), by the political theorist Charles-Louis, baron de Montesquieu. In the continuing and relentless war against the Aristotelianism of the later Middle Ages, the doctrines of Stoicism influenced many prominent figures of the Renaissance and Reformation periods.

Pietro Pomponazzi, an Aristotelian of early 16th-century Italy, in defending an anti-Scholastic Aristotelianism against the Averroists, who viewed the world as a strictly necessitarian and fated order, adopted the Stoic view of Providence and human liberty. The 15th-century Humanist Leonardo Bruni absorbed Stoic views on reason, fate, and free will. Pantheism, the view that God and nature are unitary in the sense that God is an impersonal being, and naturalism, the view that nothing is supernatural, both of which identify God with the cosmos and ascribe to it a life process of which the world soul is the principle, were widely held Renaissance notions. Such a pantheistic naturalism was advocated—though from diverse standpoints—by Francesco Patrizi, a versatile Platonist, and by Giordano Bruno, defender of an infinite cosmos; and in both authors the inspiration and source were fundamentally Stoic. In the development of a philosophy of public law based upon a study of man, Stoic elements are found in the *Utopia* (1516; Eng. trans. 1551), by Thomas More, and the *De Jure Belli ac Pacis* (1625; Eng. trans. 1682), by Hugo Grotius. This latter work is one of the most famous Renaissance treatises on the theory of natural and social rights.

The foremost Swiss reformer of the early 16th century, Huldrych Zwingli, who regarded justification by subjective belief as the foundation of the new Christianity, utilized Stoic views on the autonomy of the will, on the absolute predestination of the good and evil man, and on moral determinism.

Another Stoic influence of considerable importance in the tradition of Christian Humanism was the view that all religions have a common basis of truths concerning God—a universal Deism. Among those who favoured such a view were Zwingli and Desiderius Erasmus, the great Renaissance Humanist and scholar. More and Grotius also laid special stress on this view, and its influence was felt in the moral, social, and even the artistic life of the 16th century. Later, Herbert of Cherbury, often called the father of Deism, further developed the idea of religious peace and the reduction of opposing religious views to common elements. This view became one of the most popular ideas of the 17th century.

Philipp Melancthon also cultivated Humanism and the philosophy of antiquity as a basis for a reborn Christianity. Although Aristotle was his chief inspiration, Melancthon made telling use of the Stoic theory of knowledge, with its notions of innate principles and the natural light of reason, which teach man the great truths of metaphysical and moral order. Stoicism thus became the basis for the natural-law theory, which holds that the state is of immediately divine origin and independent of the church—a Protestant view opposed by Catholic writers.

The Cartesian revolution in thought in the 17th century brought forward several Stoic notions: that morality consists of obedience to the law of reason, which God has deposited within man; that ethics presupposes a knowledge of nature, because man must learn to know his place in the world, for only then may he act rightly; that self-examination is the foundation of ethics; and that the innateness and commonality of truths bespeak the view that

Stoic
concepts in
Cartesian
and
Spinozistic
thought

only thoughts and the will belong properly to man, for the body is a part of the material world. Such views were particularly developed by René Descartes, often hailed as the father of modern philosophy, in his dualism of mind (or soul) and body.

Benedict de Spinoza, a freethinking Jewish Rationalist, made similar use of Stoic views on the nature of man and the world. That aspect of Spinoza's thought that is debatably labelled pantheist is essentially Stoic in character. Together with the Cartesians, Spinoza insisted upon the importance of internal and right reason as the sole means by which to attain to indubitable truths and to the possibility of human freedom.

Blaise Pascal, a French scientist and religious writer, also was sympathetic to Cartesian conceptions of man and nature. Though he turned his back on philosophy, his religious thought retained the Cartesian and Stoic insistence on the independence of human reason, holding that man is fundamentally a thinking being, innately capable of making right decisions. There is an important and crucial difference and conflict between Pascal's views and those of Spinoza and the Cartesians: for Pascal, though the use of (the Stoic) right reason might result in proofs and demonstrations that lead to the God of truth, it would never lead to the God of love, the one true God. Thus, the Stoic exaltation of reason to an entity in its own right—indeed, to a divine entity—as exemplified among the Cartesians

and in the thought of Spinoza, was rejected by Pascal in the Jansenist Christianity that he finally adopted—a rejection that, because it also repudiated free will, distinguishes Pascal from those who held Stoic as well as alternative conceptions of human freedom and responsibility.

Christianity in general, in spite of striking contrasts with Stoicism, has found elements within it that parallel its own position. As the Stoic, for example, feels safe and protected in the rational care of some immanent Providence, so the Christian senses that a transcendent though incarnate and loving God is looking after him. And in general, Stoicism has played a great part throughout the ages in the theological formulation of Christian thought as well as in the actual realization of the Christian ideals.

Contemporary philosophy has borrowed from Stoicism, at least in part, its conviction that man must be conceived as being closely and essentially connected with the whole universe. And contemporary Humanism still contains some obviously Stoic elements, such as its belief in the solidarity of all peoples based upon their common nature, and in the primacy of reason. It is perhaps just because Stoicism has never become a full-fledged philosophical system that, many centuries after the dissolution of the Stoic school, fundamental themes of its philosophy have emerged again and again, and many have become incorporated into modern thinking. (Ja.L.S.)

Stoic concepts in Christianity and modern philosophical thought

MODERN SCHOOLS

Analytic and Linguistic philosophy

The methods that have dominated British philosophy for most of the 20th century and American philosophy since somewhat more recently have been called Linguistic and Analytic because language and the analysis of the concepts expressed by language have been a central concern. Though Australia and the Scandinavian countries have also contributed to this movement, it has won a very limited following elsewhere. Although there is a unity of outlook in the tradition, individual philosophers and movements within it have differed, often radically, about the goals and methodology of philosophy. A leading figure prior to the mid-20th century, Ludwig Wittgenstein, an Austrian-born Cambridge philosopher, for example, may have been unique in the history of philosophy in having engaged in two periods of profoundly influential philosophical productivity of which the later work was in large part a renunciation and a sustained argument against the earlier. Yet both the early Wittgenstein (represented by his *Tractatus Logico-Philosophicus*, 1922) and the later (represented by the *Philosophical Investigations*, 1953) are central examples of Analytic philosophy.

Moreover, the aims assigned to the philosophical study of language have often been different. Some philosophers, among them Bertrand Russell and the early Wittgenstein, have thought that the underlying structure of language mirrors that of the world—that from an analysis of language a philosopher can grasp important truths about reality. This so-called picture theory of language, though influential, is generally repudiated by current Analytic philosophers. Another important dispute concerns whether everyday language is defective, vague, misleading, and even, at times, contradictory. Some Analytic philosophers have thus proposed the construction of an “ideal” language: precise, free of ambiguity, and clear in structure. The general model for such a language has been symbolic logic, the growth of which in the 20th century has played a central role in Analytic philosophy. An ideal language, it was thought, would resolve many traditional philosophical disputes that have arisen from the misleading structure of natural languages. At the other pole, some philosophers have thought that many philosophic problems have come from paying too little attention to what men say in everyday language about various situations.

Despite such disagreements, Analytic philosophers have much in common. Most of them, for example, have con-

centrated on particular philosophical problems, such as that of induction, or have examined specific concepts, such as those of memory or of personal identity, without attempting to construct any grand metaphysical schemes—an attitude that has roots as ancient as those of the Socratic method exemplified in Plato's dialogues. Almost invariably Plato began with specific questions such as “What is knowledge?” or “What is justice?” and pursued them in a way that can be viewed, without undue strain, as philosophical analysis in the modern sense.

Ideally, a philosophical analysis illuminates some important concept and helps to answer philosophical questions involving the concept. A famous example of such analysis is contained in Bertrand Russell's theory of definite descriptions. In a simple subject–predicate statement such as “Socrates is wise,” he said, there seems to be something referred to (Socrates) and something said about it (that he is wise). If, instead of a proper name, however, a “definite description” is substituted, as in the statement “The president of the United States is wise,” there is apparently still something referred to and something said about it. But a problem arises when nothing fits the description, as in the statement “The present king of France is wise.” Though there is apparently nothing for the statement to be about, one nevertheless understands what it says. Consequently, a pre-World War I philosopher, Alexius Meinong, celebrated for his *Gegenstandstheorie* (“theory of objects”), felt forced by such examples to distinguish between things that have real existence and things that have some other sort of existence; for such statements could not be understood unless they were about something.

In Russell's view, philosophers such as Meinong were misled by surface grammatical form into thinking that such statements are simple subject–predicate statements. In reality they are complex; in fact, an analysis of the foregoing example shows that the definite description, “the present king of France,” is not an independent unit in the statement at all. Upon analysis, the statement is a complex conjunction of statements: (1) “There is a present king of France”; (2) “There is at most one present king of France”; and (3) “If anyone is a present king of France, he is wise.” But, more importantly, each of the three components is a general statement and is not about anything or anyone in particular. There is no phrase in the complete analysis equivalent to “the present king of France,” which shows that the phrase is not an expression, like a proper name, that refers to something as the thing

Theory of definite descriptions

Different approaches to the study of language

that the whole statement talks about. There is no need, therefore, to make Meinong's distinction between things that have real existence and things that have some other kind of existence.

GENERAL VIEWPOINT OF ANALYTIC PHILOSOPHY

Nature, role, and method of analysis. Analytic philosophy is concerned with the close and careful examination of concepts.

Status of philosophy in the Empiricist tradition. In spirit and style Analytic philosophy has strong ties with the Empiricist tradition, which stresses the data received through the senses and which, except for brief periods, has characterized British philosophy for some centuries, distinguishing it from the more Rationalistic trends of continental European philosophy. It is not surprising, therefore, that Analytic philosophy should find its home mainly in the Anglo-Saxon countries. In fact, the beginning of modern Analytic philosophy is generally dated from the time when two of its major figures, Bertrand Russell and G.E. Moore, both Cambridge philosophers, rebelled against an anti-Empiricist Idealism that had temporarily captured the English philosophical scene. The most famous British Empiricists—John Locke, George Berkeley, David Hume, and John Stuart Mill—had many interests, doctrines, and methods in common with contemporary Analytic philosophers. Although many of their particular doctrines are favorite targets of attack by Analytic philosophers today, one feels that this is more the result of a common interest in certain problems than any difference in general philosophical outlook.

Most Empiricists, though admitting that the senses fail to yield the certainty requisite for knowledge, hold nonetheless that it is only through observation and experimentation that justified beliefs about the world can be gained; i.e., a priori reasoning from self-evident premises cannot reveal how the world is. This view has resulted in a sharp dichotomy among the sciences: between the physical sciences, which ultimately must verify their theories by observation, and the deductive or a priori sciences—e.g., mathematics and logic—the method of which is the deduction of theorems from given axioms. Thus, the deductive sciences cannot give justified beliefs, much less knowledge, of the world. This consequence was one of the cornerstones of two important movements within Analytic philosophy, logical atomism and Logical Positivism (see below). In the Positivist's view, for example, the theorems of mathematics are merely the result of working out the consequences of the conventions that have been adopted for the use of its symbols.

The question then arises whether philosophy itself is to be assimilated to empirical or to a priori sciences. Early Empiricists assimilated philosophy to the Empirical sciences. They were less self-reflective about its methods than contemporary Analytic philosophers are. Being preoccupied with epistemology (theory of knowledge) and the philosophy of mind, and holding that fundamental facts can be learned about these subjects from individual introspection, they took their work to be a kind of introspective psychology. Analytic philosophers in the 20th century, on the other hand, have been less inclined to appeal ultimately to direct introspection. Moreover, the development of rigorous methods in formal logic seemed to promise help in solving philosophical problems—and logic is as a priori as a science can be. It seemed, then, that philosophy must be classed with mathematics and logic.

Conceptual, linguistic, and scientific analysis. The question remained, however, what philosophy's function and methodology are. For a great many Analytic philosophers who do philosophy in the minute and meticulous manner of G.E. Moore and, in particular, for those who have made Oxford the centre of Analytic philosophy (see below, *Recent trends in England: Oxford philosophers*), its business is the analysis of concepts. For them, philosophy is an a priori discipline because the philosopher in some sense already possesses the concept in which he is interested and needs no observations in order to analyze it.

Philosophy can be seen either as conceptual or as linguistic analysis. In the analysis of the concept of seeing, for

example, the philosopher is not expressing purely linguistic concerns—with, say, the English verb "to see"—though an investigation of what can be said using that verb may be relevant to his conclusions. For a concept is independent of any particular languages; a concept is something that all languages, insofar as they are capable of expressing the concept, have in common. Thus, philosophers who stress that it is concepts that they analyze attempt to rebut the charge that their problems and solutions are merely verbal.

In contrast, other Analytic philosophers have been concerned with how expressions are used in a particular, nontechnical, everyday language. Thus, the term ordinary language philosophy has been applied by critics as a term of opprobrium to such philosophers. An influential study, *The Concept of Mind* (1949), by Gilbert Ryle, a prominent Oxford Analyst, is an example of a work that some critics took to depend in large part on a trivial appeal to how English speakers talk; but many of Ryle's arguments could equally well have been given by Analytic philosophers who would look upon the term ordinary language with horror.

The problem of perception illustrates how Analytic philosophers who do conceptual analysis think of the goal of philosophy as both different from and complementary to science. Physiologists, psychologists, and physicists—through experiments, observations, and testable theories—have also contributed to man's understanding of perception. There is in the sciences, however, a strong tendency to advance beyond earlier positions, which seems to be absent from philosophy. In philosophy, for example, the account of perception given by such 20th-century Analytic philosophers as G.E. Moore and the Positivist A.J. Ayer has a close connection with that of Locke in the 17th century.

The difference between philosophy and science is that, whereas the scientist investigates an actual occurrence, such as seeing, the philosopher investigates a concept that he already possesses quite independently of what he might discover through the occurrence. Whereas the scientist begins by supposing that he can recognize examples of seeing and is already exercising the concept, the philosopher wants to know what is involved in seeing in the sense of what conditions one can use to classify cases as examples of seeing. He may want to know, for example, whether certain conditions are necessary or sufficient. In testing the philosophical theory that, for an observer to see an object, the object must cause a visual experience in him (the causal theory of perception), one does not set up a scientific experiment. It would be of no use to set up situations in which various physical objects are not causing any visual experiences in order to see whether they still can be seen. For if the theory is correct, no such experimental situation will be an instance of seeing; and if it is wrong, merely describing a hypothetical situation would suffice. The question is one about how situations are classified, and for that purpose hypothetical situations are as good as real ones.

Therapeutic function of analysis. For some philosophers in the Analytic tradition, especially those influenced by Wittgenstein, the analysis of concepts has therapeutic value beyond the intrinsic enjoyment of doing it. Even scientists and laymen in their philosophical moments generate problems by not understanding the proper analyses of the concepts that they employ. They are then tempted to formulate theories to explain these difficulties, when instead they should be sorting out the roles of the concepts, which would show them that there was no problem to begin with. Thus, the failure to see how psychological concepts—sensations, emotions, and desires—are employed has led philosophers to such problems as how one can know what is going on in another's mind or how desires and emotions can produce physical changes in the body, and vice versa. Analysis of the concepts involved would, in this way of looking at philosophy, "dissolve" rather than solve the problems, for philosophers would come to see that their formulations of the problem rest on mistakes about the concepts involved.

This way of looking at philosophy has often been criticized as making it merely a clearing up of the confusions

Philosophy as compared with science

Dissolving of problems by analysis

Physical versus a priori sciences

Function and methodology of philosophy

of other philosophers and therefore a sterile enterprise. The confusions, however, need not be only those of other philosophers. Scientists, for example, can also generate philosophical theories that affect how they design their experiments, which may, thus, be subjects for philosophical therapeutics. Behaviorism in psychology—which views emotions, desires, and attitudes as being dispositions to behave in certain ways—seems to be a philosophical theory and perhaps to be based on a confusion about the analysis of psychological concepts. Yet Behaviorism has influenced psychologists in their approach to the science. Thus, in this view, philosophy can have a therapeutic value beyond the sphere of philosophical games.

Philosophy, in spite of its abstractness, has traditionally been concerned with human needs, and the therapeutic model may even fulfill this ideal. Laymen, as well as philosophers, for example, are bothered by the thought that their actions are determined not by themselves but by prior conditions. This is a problem that, if the therapeutic view is correct, rests on the misunderstanding of such concepts as causation, responsibility, and action, which need clarification.

Formal versus ordinary language. The role of language as a central concern of Analytic philosophers is the dimension most involved in disputes about the methodology employed. Philosophers outside the Analytic movement tend to think that its preoccupation with language is a departure from philosophy as classically conceived. Yet Plato and Aristotle, medieval philosophers, the Empiricists—and, in fact, most of the philosophers whose works have been considered important—have found it essential to talk about language. There are serious differences, however, about what role language should play. One such difference concerns the importance of formal languages (in the sense employed in symbolic logic) for philosophical problems.

Development of mathematical logic. Since the time of Aristotle, logic has been allied to philosophy. Until the late 19th century, however, logic was largely confined to formulating elaborate rules for one fairly simple form of argument—the syllogism; and there was a lack of systematic development of the subject along lines that had been taken in mathematics since early times.

Almost from the beginning, mathematicians had rigorously exploited two important techniques: (1) the use of the axiomatic method (as in Euclid's geometry) in developing the subject; and (2) the use of schematic letters or variables for stating general truths in the subject (thus, one can write " $A + B = B + A$," in which any names or numbers whatsoever can be substituted for A and B , and the result will still be true).

It is surprising that logicians through the ages failed to grasp the power of the use of schematic letters. When they finally began to employ these and other mathematical techniques, they made great contributions to man's understanding of the subject.

Among the developments that occurred in the 19th century, primarily through the work of mathematicians, those of the Englishman George Boole, creator of Boolean algebra, and of Georg Cantor, the Russian-born creator of set theory, are especially important inasmuch as they gave promise of bringing logic and mathematics closer together. The one figure who was both a mathematician and a philosopher and so might be credited with the marriage of logic as a philosophical subject with the techniques of mathematics was Gottlob Frege (died 1925), of the University of Jena in Germany. Historically, Frege, whose works are now appreciated in their own right, was important principally for his influence on Bertrand Russell, whose monumental work, *Principia Mathematica* (1910–13), written in collaboration with Alfred North Whitehead, together with Russell's earlier *Principles of Mathematics* (1903), awakened philosophers to the fact that the use of mathematical techniques in logic might prove to be of great importance for philosophy. Its symbolism had the advantage of being closely connected with ordinary language, whereas its rules can be precisely formulated. Moreover, work in symbolic logic has produced many distinctions and techniques that can be applied to ordinary language.

Divergence of ordinary language from formal logic. Ordinary language, however, seems to differ from the artificial language of symbolic logic in more respects than its lack of precisely stated rules. On the surface, it often appears to violate the rules of symbolic logic. In the English statement "If this is gold [symbolized by p], then this will dissolve in aqua regia [symbolized by q]," for example, which in symbolic logic is expressed in a form known as the material conditional, $p \supset q$ (in which \supset means "If . . . then . . ."), one of the rules is that the statement is true whenever "This is gold" is false. In ordinary language, on the contrary, one would not count the statement as true merely on formal logical grounds but only if there were some real connection in the world of chemical reactions between being gold and dissolving in aqua regia—a connection that plays no role in symbolic logic.

Among Analytic philosophers the existence of many such apparent divergences between symbolic logic and ordinary language has generated attitudes ranging from complete mistrust of symbolic logic as relevant to nonartificial languages to the position that ordinary language is not a proper vehicle for the rigorous statement of scientific truths.

Interpretations of the relation of logic to language. Symbolic logic has been viewed by many Analytic philosophers as providing the framework for an ideal or perfect language. This statement can be taken in two ways:

1. Russell and the early Wittgenstein thought of logic as revealing, in a precise fashion, the real structure of any language. Any seeming departure from this structure in ordinary language must therefore be attributed to the fact that its surface grammar fails to reveal its real structure and is apt to be misleading. As a corollary, philosophers who have held this view have often explained philosophical problems as arising from being taken in by the surface features of the language. Because of the similarity of sentences such as "Tigers bite" and "Tigers exist," for example, the verb "to exist" may seem to function, as other verbs do, to predicate something of the subject. It may seem, then, that existence is a property of tigers just as their biting is. In symbolic logic, however, the symbolic equivalent of the two sentences would be quite different; existence would not be represented by a symbol for a predicate but by what is called the existential quantifier, $(\exists x)$, which means "There exists at least one x such that . . ."

2. The other sense in which symbolic logic has been seen as the framework of an ideal language is exemplified in the work of Rudolf Carnap, a 20th-century semanticist, who was concerned with what the best language—especially the best for the purposes of science—is.

One distinctive feature of the formal language of *Principia Mathematica* is that it becomes, when interpreted, a language of true-or-false statements. In ordinary language, on the contrary, one is not restricted to statements of truths; in it one can also issue commands, ask questions, make promises, express beliefs, give permission, and assert necessities and possibilities. Consequently, many philosophers have developed nonstandard logics that incorporate the nonassertoric features of language. Thus, various systems of logic have been formulated and studied (see LOGIC).

On the other side of the coin, many philosophers—most notably the later Wittgenstein and those influenced by him—have thought that attempting to put language into the straitjacket of a formal system is to falsify the way that language works. Language performs a multitude of tasks, and even among expressions that seem to be alike in the way they function—those sentences, for example, that one might think are used simply for expressing facts—examination of their actual use reveals many differences: differences, for instance, in what is counted as showing them to be true or false and in their relationships to other parts of language. Formal systems, according to this view, at best oversimplify and at worst can lead to philosophical problems generated by supposing that all language operates strictly according to a simple set of rules. Accordingly, far from settling philosophical disputes by getting underneath the misleading exterior of ordinary language, formal systems add their own share of confusion.

Axiomatic method and use of symbols

Non-assertoric uses of language

EARLY HISTORY OF ANALYTIC PHILOSOPHY

Reaction against Idealism. During the last decades of the 19th century, English philosophy was dominated by an absolute Idealism that stemmed from the German philosopher G.W.F. Hegel. For English philosophy this represented a break in an almost solid tradition of Empiricism. The seeds of modern Analytic philosophy were sown when two of the most important figures in its history, Bertrand Russell and G.E. Moore, broke with Idealism at the turn of the 20th century.

Ideal-
ism and
science

Absolute Idealism was avowedly metaphysical in the sense that its adherents thought of themselves as describing, in a way not open to scientists, certain very fundamental truths about the world. Indeed, what pass for truths in the sciences, were, in their view, not really truths at all; for the scientist must, perforce, treat the world as composed of distinct objects and can only describe and state the relationships supposedly holding among them. But the Idealists held that to talk about reality as if it were a multiplicity of objects is to falsify it; in the end only the whole, the absolute, has reality.

In their conclusions and, most importantly, in their methodology, the Idealists were decidedly not on the side of commonsense intuition. Thus, a Cambridge philosopher, J.M.E. McTaggart, argued that the concept of time is inconsistent and cannot therefore be exemplified in reality. British Empiricism, on the other hand, had always thought of common sense as an ally and science as the model of the way in which to find out about the world. Even when their views might seem out of step with common sense, the Empiricists were generally concerned to reconcile the two.

One can hardly claim that Analytic philosophers have universally thought of themselves as on the side of common sense and much less that metaphysical conclusions (on the ultimate nature of reality) are absent from their writings. But there is in the history of the Analytic movement a strong antimetaphysical strain, and its exponents have generally assumed that the methods of science and of everyday life are the authentic ways of finding out the truth.

Founding fathers: Moore and Russell. The first break from the Idealist view that the physical world is really only a world of appearances occurred when Moore, in a paper, "The Nature of Judgment" (1899), argued for a theory of truth that implies that the physical world has the independent existence that, apart from philosophical theories, it is naively supposed to have. Though the theory was soon abandoned, it did represent a return to common sense.

Compari-
son of
the two
founders
of Analytic
philosophy

The influences on Russell and Moore—and thus their methods of dealing with problems—soon diverged, and their different approaches became the roots of two broadly different methodologies in the Analytic tradition.

Russell was a major influence on those who approached philosophical problems armed with the technical equipment of formal logic, who saw the physical sciences as the only means of gaining knowledge of the world, and who regarded philosophy—if a science at all—as a deductive and a priori enterprise on a par with mathematics. Russell's contributions to this side of the Analytic tradition have been important and, in great part, lasting.

Moore, on the other hand, never found much need to employ technical tools nor to turn philosophy into a science. His dominant themes were (1) the defense of commonsensical views about the nature of the world against esoteric, skeptical, or grandly metaphysical views and (2) the conviction that the right way to approach philosophical puzzles is to ask exactly what the question is that generated the puzzle before trying to solve it. Philosophical problems, he thought, are often intractable because philosophers have not stopped to formulate precisely what is at issue.

G.E. Moore. Because of these two themes, Moore enlisted much more sympathy among Analytic philosophers from the 1930s and onward who were followers of Wittgenstein's later writings, of Gilbert Ryle's postwar *The Concept of Mind*, and of John Austin's work (see below *Oxford philosophers*). These philosophers, like Moore, saw little hope in advanced formal logic as a means of solv-

ing traditional philosophical problems and believed that philosophical skepticism about the existence of an independent external world or of other minds—or, in general, about what men label as common sense—must be wrong. The followers of Wittgenstein also shared with Moore the belief that it is often more important to look at the questions that philosophers pose than at their proposed answers. Thus, unlike Russell, who was important for his solutions in formal logic and ideal models of language, it was more the spirit of Moore's conception of philosophy than its lasting contributions that makes him a seminal influence.

The Idealists were given to arguing for what, in Moore's eyes, were outrageous positions. Thus, in his essay "A Defence of Common Sense" (1925), as in others, his defense was not only against such Idealist doctrines as the unreality of time but also against any of the forms of skepticism—about the existence of other minds or of a material world—that philosophers have espoused. The skeptic, he pointed out, usually has some argument for his conclusion. Instead of examining such arguments, however, Moore pitted against the skeptic's premises quite everyday beliefs, such as, for example, that he had breakfast that morning (thus time cannot be unreal) or that he does in fact have a pencil in his hand (thus there must be a material world). His challenge to the skeptic is to show that the premises of the skeptic's argument are more certain than the everyday beliefs that form Moore's premises.

Moore's
attack on
Idealism

Although some commentators have seen Moore as an early practitioner of the appeal to "ordinary language," his appeal was really not to what it is proper to say but rather to the beliefs of common sense. His rejection of anything that offends against common sense, however, was influential not only in the release that it afforded from the metaphysical excesses of absolute Idealism but also in its impact on the continuing attitudes of most Analytic philosophers—even though they may have given it a linguistic turn.

Moore was also important for his vision of the proper business of philosophy—analysis. He was puzzled about what is the proper analysis of "X sees Y," in which Y designates a physical object (e.g., a pencil). There must be a special sense of "see," in which one does not see the pencil but only part of its surface. And finally—and most importantly—there is also a sense in which what is directly perceived is not even the surface of the pencil but, rather, what Moore called "sense data" and which earlier Empiricists had called "visual sensations" or "sense impressions." Moore's problem was to discern the relationships among these various elements in perception and, in particular, to discover how a person can be justified, as Moore fully believed he is, in his claims to see physical objects when what he immediately perceives are really sense data. The idea that sense impressions form the immediate objects of perception has played a large role in Analytic philosophy, showing once again its Empiricist roots. It later became an important source of division, however, among the Logical Positivists (see below). Most post-World War II Oxford philosophers, however, together with those closely influenced by Wittgenstein's later work, have found sense data to be as unpalatable and unwarranted as Moore had found McTaggart's doctrine of the unreality of time to be.

Moore's
notion
of "sense
data"

Bertrand Russell. One of the recurring themes in philosophy is the idea that the subject needs to be given a new methodology. Among Empiricists this has often meant making it more scientific. From an early date, Russell enunciated this viewpoint (which was not shared by Moore), finding in the techniques of symbolic logic a measure of reassurance that philosophy might be put on a new basis. Russell did not see the philosopher, however, as merely a logician. Symbolic logic might provide the framework for a perfect language, but the content of that language is something else. The job of the philosopher is—for Russell, as it was for Moore—analysis. But the purpose is somewhat different. In most of Russell's work, analysis has the task of uncovering the necessary assumptions—especially about the kinds of things that exist—for a description of the world as it is. For the most part this description is the one that science gives and is there-

Russell's
use of the
theory of
descrip-
tions

fore realistic. Thus, Russell's use of analysis was openly metaphysical.

The question then arises of how philosophical analysis, which is concerned with how men talk about the world, can presume to give any answers about how the world is. The search for an answer begins with the above-mentioned theory of descriptions—a theory that seems to be closely tied to linguistic concerns. It will be recalled that Russell considered that such definite descriptions as “the author of ‘On Denoting’” are not really expressions used to refer to things in the world but that, instead, they make the statements in which they occur into quite general propositions about the world, to the effect that one and only one thing of a certain sort exists and that it has a certain property. Because there must be some way, however, of directly speaking of the things in the world, Russell turned his attention to proper names. The name Aristotle, for example, does not seem to carry any descriptive content. But Russell argues, on the contrary, that ordinary names are really concealed definite descriptions (“Aristotle” may simply mean “The student of Plato who taught Alexander, wrote the *Metaphysics*, etc.”). If a name had no descriptive content, one could not sensibly ask about the existence of its bearer, for one could then not understand what is expressed by a statement involving it. If “Bosco” were a name in this sense (without any descriptive content), then merely to understand the statement that Bosco exists or the statement that Bosco does not exist presupposes that one already knows what the name Bosco refers to. But then there cannot be any genuine question about Bosco's existence, for just to understand the question one must know the thing to which the name refers. Ordinary proper names, however—Russell, Homer, Aristotle, and Santa Claus—as Russell pointed out, are such that it makes sense to question the existence of their bearers. Thus, ordinary names must be concealed descriptions and cannot be the means of directly referring to the particular things in the world.

Names in the strict logical sense, then, are very rare; Russell, in fact, suggests that in English the only possible candidates are the demonstrative pronouns, this and that. Yet, if men are ever to talk about the actual things in the world directly, there must be the possibility of such demonstrative expressions underlying their language—in their private thoughts about the world if not in their public language.

To this point, Russell had concluded that things in the world can be talked about only through the medium of a special kind of name; in particular, one about which no question can arise whether it names something or not. At this point there was a transition from questions about the nature of language to results about the nature of the world. Russell asked what sort of thing it is that can be named in the strict logical sense, that can be known and talked about, and that can tell a man something about the world. The important restriction is that no question can arise about whether it exists or not. Ordinary physical objects and other people seem not to fit this requirement.

In his search for something whose existence cannot be questioned, Russell hit upon present experience and, in particular, upon sense data: one can question whether he is really seeing some physical object—whether, for example, there is a desk before him—but a person cannot question that he has had visual impressions or sense data; thus, what a man can name in the strict logical sense and what things he can actually talk about turn out to be the elements of his present experience. Russell therefore made a distinction between what can be known by acquaintance and what can be known only by description; *i.e.*, between those things the existence of which cannot be doubted and those about which, at least theoretically, doubt can be raised. What is novel about Russell's conclusion is that it was arrived at from a fairly technical analysis of language: to be directly acquainted with something is to be in a position to give it a name in the strict logical sense, and to know something only by description is to know only that something uniquely fits the description.

Russell was not constant in his view about physical objects. At one point he thought that the observer must

infer their existence as the best hypothesis to explain his experience. Later he argued that they could be taken as logical constructions out of sense data.

Logical atomism: Russell and the early Wittgenstein. The next important development in Analytic philosophy was initiated when Russell published a series of articles entitled “Philosophy of Logical Atomism” (1918–19), in which he acknowledged a debt to Wittgenstein, who had studied with Russell before the war. Wittgenstein's own work, the *Tractatus Logico-Philosophicus* (1922), which can also justly be said to present a logical atomism, turned out to be not only tremendously influential on developments in Analytic philosophy but also such a deep and difficult text that it has generated a growing body of scholarly interpretation.

Russell's choice of the words logical atomism to describe this viewpoint was, in fact, particularly apt. By using the word logical Russell meant to sustain the position, described earlier, that through analysis—particularly with the aid of the ideal structure provided by symbolic logic—the fundamental truths about how any language functions can be revealed and that this disclosure, in turn, would show the fundamental structure of that which the language is used to describe. And by using the word atomism Russell highlighted the particulate nature of the results that his analyses and those of Wittgenstein seemed to yield.

On the linguistic level, the atoms in question are atomic propositions, the simplest statements that it is possible to make about the world; and on the level of what language talks about, the atoms are the simplest atomic facts, those expressible by atomic propositions. More complex propositions, called molecular propositions, can then be built up out of atomic propositions via logical connectives—such as “either . . . or . . .,” “both . . . and . . .,” and “not . . .”—the truth-value of the molecular proposition being in each case a function of the truth values of its component atomic propositions.

Language, then, must break down, upon analysis, into ultimate elements that cannot be analyzed into any other component propositions; and, insofar as language mirrors reality, the world must then be composed of facts that are utterly simple. Atomic propositions are composed, however, of strings of names understood, as Russell had explained it, in the strict logical sense; and atomic facts are composed of simple objects, the things that could be thus named.

The details of the Russell–Wittgenstein view have fascinated philosophers by the way in which they not only formed a coherent view but also seemed to follow inexorably from the central assumptions. There are close connections between this period, which was perhaps the most metaphysical in contemporary Analytic philosophy, and traditional Empiricism. The breakdown of language and the world into atomic elements had been one of the prominent features in the classical Empiricists, John Locke, George Berkeley, and David Hume. There was also a view of the connection between language and the world—adumbrated in Russell but fully evident in the *Tractatus*—which has been important and influential, *viz.*, the picture theory, which holds that the structure of language mirrors that of the world. Analysis is important because ordinary language does not show immediately, for example, that it is founded on the atomic–molecular proposition model. Another theme is that the deductive sciences—mathematics and logic—are based solely on the way that language operates and cannot reveal any truths about the world, not even about a world of entities called numbers. Finally, logical atomism, in Wittgenstein's thought as opposed to Russell's, was at one and the same time metaphysical—in the sense of conveying via pure reasoning something about how the world is—and antimetaphysical. Wittgenstein's *Tractatus* is unique in the history of Empiricism in its acceptance of the fact that it is itself a metaphysic and that part of its metaphysics is that metaphysics is impossible: the *Tractatus* says of itself that what it says cannot be coherently said. Only empirical science can tell a man anything about the world as it is. Yet the *Tractatus* apparently tells him, for example, about the relationship between language and the

question
of
what can
be known
and talked
about

Logical
atomism
as an
antimeta-
physical
meta-
physic

facts of the world. For Wittgenstein, the solution of this seeming paradox lies in his distinction between what can be said and what can only be shown. There are certain things that can somehow be seen to be so—in particular, the ways in which language is connected with the world. The *Tractatus* could not straightforwardly tell its readers about these matters—metaphysics cannot be a body of facts expressible in any language—but the attempt to say these things, done in the right way, can show them what it cannot coherently express.

Logical Positivism: Carnap and Schlick. Wittgenstein's *Tractatus* was both a landmark in the history of contemporary Analytic philosophy and perhaps its most aberrant example. It not only contained the most highly sophisticated metaphysics but also was an important influence on the most antimetaphysical of the positions taken by Analytic philosophers, viz., that of Logical Positivism, which was mainly developed by a group of philosophers, scientists, and logicians who were centred in Vienna and came to be known as the Vienna Circle. Among these, Rudolf Carnap and Moritz Schlick have perhaps had the most influence on Anglo-American philosophy, although it was an English philosopher, A.J. Ayer—whose *Language, Truth and Logic* (1936) is still the most widely read work of the movement in America and England—who introduced the ideas of Logical Positivism to English philosophy. Its main tenets have struck sympathetic chords in the Analytic philosophers and are still important today, even if in repudiation.

Above all else, Logical Positivism was antimetaphysical; nothing can be learned about the world, it held, except through the methods of the empirical sciences. The Positivists sought a method for showing both (1) when a theory that seemed to be about the world was really metaphysical and (2) that such a theory was, in fact, meaningless, and this they found in the principle of verification. In its positive form, the principle said that the meaning of any statement that is really about the world is given by the methods employed for verifying its truth or falsity—the only allowable methods being, ultimately, those of observation and experiment. In its negative form, the principle said that no statement could both be a statement about the world and have no method of verification attached to it. Its negative form was the weapon used against metaphysics and for the vindication of science as the only possible source of knowledge about the world. The principle would, thus, class as meaningless many philosophical and religious theories that purport to say something about the world but provide no way of testing the truth of the statements; for example, in religion it would render suspect the statement that God exists, which, being metaphysical, would be, strictly speaking, meaningless.

The principle of verification ran almost immediately into difficulties, most of which were first raised by the Positivists themselves. The attempt to work out these difficulties belongs to a more detailed study of the movement (see below *Positivism and Logical Empiricism*). It is sufficient to note here that these problems were sufficient to make most subsequent Analytic philosophers wary of appealing directly to the principle. It has, however, influenced philosophical work in more subtle ways.

With the principle of verification in hand, the Positivists thought that they could show a great many theories to be nonsense. There were several areas of discourse, however, which failed the test of the principle but which were simply impossible to rule out as concealed nonsense. Foremost among these disciplines were mathematics and ethics. Mathematics (and logic) could hardly be written off as nonsense. Yet their theorems are not verifiable by observation and experiment; they are known, in fact, by pure a priori reasoning alone. The answer seemed to be provided in Wittgenstein's *Tractatus*, which held that the propositions of mathematics and logic are, in Kantian terms, analytic; i.e., true—like the statement "All bachelors are unmarried"—in virtue of the conventions that lie behind the use of the symbols involved.

About ethics or, more precisely, about any statements involving value judgments, the Positivist view was different, yet still of lasting importance. In this view, value

judgments are not, like mathematical truths, necessary adjuncts to science. But they cannot be put off as nonsense; nor, obviously, are they true by definition or linguistic convention. The usual view of the Positivists, called emotivism, is that what look like statements of fact (e.g., that one should not tell lies) are really expressions of one's feelings toward a certain action; thus, value judgments are not really true or false. The Positivist's position was that neither mathematical nor ethical statements could be dismissed, as were metaphysical propositions. Both had then to be exempted from the principle of verification; and this was done by arguing that their statements are not really about the world: mathematical truths are conventions, and ethical statements are merely expressions of feelings. The divorce of ethics from science, once again, reflects an old Empiricist theme, to be seen, for example, in David Hume's dictum that from matters of fact one cannot derive a conclusion about what ought to be nor vice versa.

LATER HISTORY OF THE MOVEMENT

"Philosophical Investigations": the later Wittgenstein. A crucial turn that initiated developments that were destined to have a lasting and profound effect on much of contemporary Analytic philosophy occurred in 1929, when Wittgenstein, after some years in Austria during which he was not philosophically very active, returned to England and established his residence at Cambridge. There, the direction of his thought soon shifted radically away from his *Tractatus*, and his views became in many ways diametrically opposed to those of logical atomism. Because he published none of the materials of this period, his influence on other English philosophers—and ultimately on those in all of the countries associated with Analytic philosophy—spread by way of his students and those who heard him in the small groups to whom he spoke at Cambridge. His style, too, changed from the semi-rigorous and formally organized propositions of the *Tractatus* to sets of loosely connected paragraphs and remarks in which the ideas are often conveyed more by suggestion and example than discursively. The result has been that one of the major splits within the ranks of Analytic philosophy is that between those who derive their methods from the later Wittgenstein and those who have followed the *Tractatus*.

Although Wittgenstein's thoughts ranged over almost the entire field of philosophy, from the philosophy of mathematics to ethics and aesthetics, their impact has been felt most, perhaps, where it has concerned the nature of language and the relationship between the mental and the physical.

Language and following rules. In logical atomism, as shown above, language was conceived as having a certain necessary and fairly simple underlying structure that it was the job of philosophy to expose. Wittgenstein began to tear away at this assumption. Language, he now thought, is like an instrument that can be used for an indefinite number of purposes. Hence, any effort to codify how it must operate by giving some small set of rules would be like supposing that there is some rigid necessity that a screwdriver (for instance) can be used only to drive screws and forgetting that screwdrivers are also, quite successfully, used to open jars and to jimmy windows. Language is a human institution that is not bound by an outside set of rules—only by what men consider to be correct and incorrect. And that, in turn, is not really a matter for a priori theories to consider.

The notion of a rule and what it means to follow a rule was especially prominent in his writings. Several concerns made this point of particular interest to Wittgenstein. In mathematics and logic, emphasis was being placed on the rules for manipulating the symbolism. As has been seen, symbolic logic has also been a model for the underlying structure of language. If this fact is coupled with the fact that Russell and the Wittgenstein of the *Tractatus* saw language as reflecting these rules and with the general Empiricist tradition that explains how language operates by each person following internal rules and standards for the use of his words, the picture of the system that Wittgenstein thought mistaken then emerges, and it becomes clear why he placed the notion of a rule so centrally.

Language
as a multi-
purpose
conven-
tional
instrument

Post-
factum
status
of rules

Natural languages, however, are significantly different in that one does not first learn the rules and then use the language; indeed, prior to learning the language, one would not know what to do with rules. Mathematics and logic are, in this sense, bad models for language because they aim at setting out before hand the rules and principles that are subsequently to be used. They encourage the belief that language must have a rigid structure and that, without rules, no language would be possible. The "rules" that one might plausibly discern in the language that one speaks are not, as rules, already there, in a ghostly way, guiding what one says; they are either generalizations from the finite data of what is counted as correct or incorrect, or they are rules that, as Wittgenstein metaphorically expressed it, one puts away in the archives—one adopts the rule but only after the fact.

Following a rule, however, was a concept that Wittgenstein saw as wrongly analyzed in many classical views about language. Thus, he cast irrevocable doubt on the prevalent theory—typified best, perhaps, in John Locke's *Essay Concerning Human Understanding* (1690)—that to use an expression meaningfully is to have in one's mind a standard or a rule for applying it correctly. Against this theme, Wittgenstein's point was that a rule by itself is dead—it is like a ruler in the hands of someone who has never learned to use it, a mere stick of wood. Rules cannot compel nor even guide a person unless he knows how to use them; and the same is true about mental images, which have often been thought to provide the standard for using linguistic expressions. But if rules themselves do not give life to words but require a similar explanation for what gives them life, then there is a useless regress and no (philosophical) explanatory value in the whole apparatus of internal rules and standards.

Relation between mental and physical events. In some respects, Wittgenstein made some significant breaks with the Empiricist tradition—in his views about language and the explanation of the rigour of the deductive sciences. His treatment of the relationship between mental events and physical events also represents an important departure. Empiricists generally have started from the important assumption that what a person is immediately acquainted with is his own sensations, ideas, and volitions, and that these are mental and not physical; and, most importantly, that the things he knows immediately are essentially private and inaccessible to others. For both Moore and Russell there then arose the problem of how, in view of the privacy stressed by the sense-datum theory, the world of physical objects could be known. Wittgenstein's attack on this viewpoint, which has come to be known as "the private language" argument, has become well known, partly because it was in this area that Wittgenstein presented what could most easily be picked out as a more or less formal argument—one that could then be analyzed and criticized in an analytic manner. Even in this case, however, his style of writing was such that his precise formulation of the argument has become a main source of controversy. Wittgenstein argued that the notion of an utterly private experience would imply: (1) that what goes on in the mental life of a person could be talked about only in a language that that person alone whose mental life it was could understand; (2) that such a private language would be no language at all (this has been the main source of controversy); and (3) that the widely held doctrine that there are absolutely private mental events cannot be intelligibly stated, because to do so would be to suppose that one can publically say something about what the doctrine itself says cannot be mentioned in a language accessible to more than one person.

The fact that Wittgenstein's argument against private language depends essentially on the question, "What is it to follow a rule?" illustrates a common characteristic of his writings, viz., that themes developed in one area of philosophy continually emerge in apparently quite divorced areas. His extraordinary ability to see a common source of difficulty in philosophical problems that seem to be unrelated helps to explain his style of writing, which seems at first sight to be a somewhat chaotic arrangement of ideas.

Analytic philosophy has also been attracted to a be-

haviouristic view of mental phenomena that holds that such apparently private events as the feeling of fear are not only not really private but also that they can be identified with publicly observable patterns of behaviour. The disposition toward empirical science, with observation as its foundation, united with the observation that the evidence men have of what goes on in the mental lives of other people must come from what they see of their behaviour, has often warred against the other inclination of Empiricism to regard the starting point of all knowledge of the world, for each person, as being essentially private sense experience. Wittgenstein has had tremendous influence, however, in suggesting that these two extremes are not the only alternatives. Yet attempts to state how Wittgenstein could deny the privacy of experience without espousing some form of behaviourism have not been very successful. Sympathetic interpreters have taken up the notion of "criteria," used, but not developed in any detail, by Wittgenstein. For mental states such as fear, outward behaviour (e.g., running away, blanching, or cringing) does not constitute what it is to be in that state, as behaviourism would have it, but neither is it merely evidence of some completely private event. The problem has been to characterize the relation between behaviour and mental states so that the two are neither identical nor evidence one for the other, while still acknowledging that a knowledge of the person's characteristic behaviour is essential to understanding the notion of a certain mental state.

Recent trends in England. Those philosophers who might fairly be labelled "Wittgensteinians," who follow the methods that Wittgenstein employed in his later period, should be distinguished from those who have been influenced more indirectly by the general trends and philosophical atmosphere that arose in large part from Wittgenstein's work.

Wittgensteinians. Close students of his ideas have tended to work chiefly on particular concepts that lie at the core of traditional philosophical problems. As an example of such an investigation, a monograph entitled *Intention* (1957), by G.E.M. Anscombe, an editor of Wittgenstein's posthumous works, may be cited as an extended study of what it is for a person to intend to do something and of what the relationship is between his intention and the actions that he performs. This work has occupied a central place in a growing literature about human actions, which in turn has influenced views about the nature of psychology, of the social sciences, and of ethics. And, as an extension of this British influence into the United States, one of Wittgenstein's students, Norman Malcolm of Cornell University, has investigated such concepts as knowledge, certainty, memory, and dreaming. As these topics suggest, Wittgensteinians have tended to concentrate on Wittgenstein's ideas about the nature of mental concepts and to work in the area of philosophical psychology. Typically, they begin with classical philosophical theories and attack them by arguing that they employ some key concept, such as that of knowledge, in a manner incongruous with the way in which the concept would actually be employed in various situations. Their works thus abound with descriptions of hypothetical, though usually homely, situations and with questions of the form, "What would a person say if . . . ?" or "Would one call this a case of X?" In doing so, they are following out Wittgenstein's advice that, instead of trying to capture the essence of a concept by an abstract analysis, the philosopher should look at how it is employed in a variety of situations.

Oxford philosophers. After World War II, Oxford University was the centre of extraordinary philosophical activity; and, although Wittgenstein's general outlook on philosophy—his turning away, for example, from the notion of formal methods in philosophical analysis—was an important ingredient, many of the Oxford philosophers could not be called Wittgensteinians in the strict sense. The method employed by many of these philosophers has often been characterized—especially by critics—as an "appeal to ordinary language," and they were thus identified as belonging to the school of "ordinary language" philosophy. Exactly what this form of argument is supposed to be and what exemplifies it in the writings of these

Gilbert
Ryle's *The
Concept of
Mind*

philosophers has been by no means clear. Gilbert Ryle, Moore's successor as editor of a leading journal, *Mind*—and especially in his *The Concept of Mind*—was among the most prominent of those analysts who were regarded as using ordinary language as a philosophical tool. Ryle, like Wittgenstein, pointed out the mistake of regarding the mind as what he called “a ghost in a machine”—to defeat the radical dualism of mind and body that has characterized much of philosophical thinking—by investigating how people employ a variety of concepts, such as memory, perception, and imagination, that designate “mental” properties. He tried to show that, when philosophers carry out such investigations, they find that, roughly speaking, it is the way people act and behave that leads to attributing these properties to them, and that there is no involvement of anything internally private. He also attempted to show how philosophers have come to dualistic conclusions—usually from having a wrong model in terms of which to interpret human activities. A dualistic model may be constructed, for example, by wrongly supposing that an intelligently behaving person must be continually utilizing knowledge of facts—knowledge that something is the case. Ryle contended, on the contrary, that much intelligent behaviour is a matter of knowing how to do something and that, once this fact is acknowledged, there is no temptation to explain the behaviour by looking for a private internal knowledge of facts. Though Ryle's objectives were similar to those of Wittgenstein, his results have often seemed more behavioristic than Wittgenstein's.

It is true that Ryle did ask, in pursuit of his method, some fairly detailed questions about when a person would say, for example, that someone had been imagining something; but it is by no means clear that he was appealing to ordinary language in the sense that his was an investigation into how, say, speakers of English use certain expressions. In any case, the charge, often voiced by critics, that this style of philosophizing trivializes and perverts philosophy from its traditional function would probably also have to be levelled against Aristotle, who frequently appealed to “what we would say.”

The work
of John
Austin

A powerful philosophical figure among postwar Oxford philosophers was John Austin, who was White's professor of moral philosophy until his death, in 1960. Austin felt that many philosophical theories derive their plausibility from overlooking distinctions—often very fine—between different uses of expressions, and he also thought that philosophers too frequently think that any one of a number of expressions will do just as well for their purposes. (Thus, ignoring the difference between an illusion and a delusion, for example, gives credence to the view that what one immediately perceives are not physical objects, but sense data.) Austin's work was, in many respects, much closer to the ideal of philosophy as comprising the analysis of concepts than was that of Ryle or Wittgenstein. He was also much more concerned with the nature of language itself and with general theories of how it functions. This novel approach, as exemplified in *How to Do Things with Words* (1962), set a trend that has been followed out in a growing literature in the philosophy of language. Austin took the total speech act as the starting point of analysis, which allowed him to make distinctions based not only upon words and their place in a language but also upon such points as the speaker's intentions in making the utterance and its expected effect on the audience. There was also in Austin's approach something of the program of Russell and the early Wittgenstein for laying bare the fundamental structure of language.

Recent trends in the United States. Although the Oxford philosophers and the posthumous publication of Wittgenstein's writings have produced a revolution in Anglo-American philosophy, the branch of Analytic philosophy that emphasized formal analyses by means of modern logic has by no means been dormant. Since the appearance of *Principia Mathematica*, striking new findings have emerged in logic, many of which, though requiring for their understanding a high level of mathematical sophistication, are nevertheless important for philosophy.

Among those philosophers for whom symbolic logic occupies a central position, W.V.O. Quine, Pierce professor

of philosophy at Harvard University, has been especially important. Symbolic logic represented for him, as it did for many earlier Analytic philosophers, the framework for the language of science. There were two important themes in his work, however, that represent significant departures from, say, the positions of the logical atomists and the Logical Positivists. In the first place, Quine rejected the distinction between those statements in which their truth or falsity depends upon the meaning of the terms involved and those in which their truth or falsity is a matter of empirical and observable fact—a distinction that had played an essential role in Logical Positivism and was thought by most Empiricists to be the basis for a division between the deductive and the empirical sciences. Quine, in “Two Dogmas of Empiricism” (1951) and subsequent writings, argued that the sort of distinction intended by philosophers is impossible to draw. In the course of his argument, a similar doubt was cast upon concepts traditional not only to philosophy but also to linguistics—in particular, the concept of synonymy or sameness of meaning. Quine's attack has been a threat not only to some long-held doctrines of the Analytic tradition but also to its conception of the nature of philosophy, which has generally depended upon contrasting it with the empirical sciences.

The second important departure of Quine's philosophy has been his attempt to show that science can be successfully conducted without what he calls “intentional entities.” In contrast to “extensional,” used above as an essential feature of standard symbolic logic, intentional entities include many of the common items that Analytic philosophers often assume that they can talk about without difficulty, such as the meanings of expressions, propositions, or the property of certain statements (such as those of mathematics) of being necessarily true. Quine's program—as exemplified by *Word and Object* (1960)—is intended in part to show that science can say everything that it needs to say without using concepts that cannot be expressed in the extensional language of standard logic. Quine's work, though by no means widely accepted, has made Analytic philosophers at least wary of uncritically accepting certain of their standard distinctions.

Since the mid-20th century, there has been an interaction between the science of linguistics and Analytic philosophy. This did not occur before because Analytic philosophers had almost always considered their study of language to be a priori and unconcerned with empirical facts about particular languages. Recently, however, a book by Noam Chomsky, a U.S. generative grammarian, entitled *Syntactic Structures* (1957), has produced a theory of grammar that not only has profoundly affected the course of linguistics but also bears striking resemblances to philosophical analysis. At first, some Analytic philosophers saw in Chomsky's theory a technique that could be applied to philosophy. It was subsequently considered, however, that, whereas the possibility of looking at grammar in Chomsky's way had contributed valuable concepts for philosophers, the possibility that it would become a methodology for Analytic philosophy had receded. The interchange between linguists and philosophers, however, has continued.

Analytic philosophy today. It is not possible to forecast in any detail the future trends of Analytic philosophy in Anglo-American and Scandinavian countries. It seems relatively certain, however, that the two conceptions of the subject that stem from Moore and Russell will both continue.

Analytic philosophers, mainly influenced by Oxford philosophy, and those for whom symbolic logic is a touchstone analyze many of the same problems and benefit from each other's work. Analysis in the more rigorous sense that Russell's theory of definite descriptions represents is more frequently an aim, despite the doubts of Wittgenstein and many of the Oxford philosophers. The general idea that the only ultimate explanations of the world are the scientific ones and the usual corollary that philosophy is in the service of science—which was a central idea for Russell, for the Logical Positivists, and (in recent times) for Quine—has apparently lost nothing of its vigour. The opposing tendencies, noted above, among Empiricists in

The New
Material-
ism

general, and present also in Analytic philosophy, toward behaviourism or Materialism, on the one hand, and toward an Idealism of a phenomenalist sort (such as that of the Irish bishop George Berkeley), on the other, are not present in the same form—mainly because of the sustained criticisms of Wittgenstein, of his followers, and of the Oxford philosophers. The battleground has shifted to a more subtle level. A substantial number of Analytic philosophers who are styled Materialists or physicalists have proposed a novel technique for reducing mental events and states to physical states. They avoid the well-exposed difficulties of older attempts in which it was held that, when one apparently talks about a separate realm of the mind—speaking of such things as thoughts, emotions, and sensations—the proper analysis of its meaning would be in terms of physical properties and events (usually observable behaviour). The novel idea, on the contrary, is that there is, in fact, an identity between so-called mental events and certain physical events, particularly those occurring in the brain, an identity that it is eventually the task of science to specify—in a way modelled after that in which science discovered that lightning is identical with an electrical discharge. The opposition against this new brand of scientific Materialism does not set up against it a view of the mind as a separate realm coexisting with the physical nor as an essentially private collection of nonphysical events and objects. Rather, the issue has been joined on the question whether the language (or perhaps the concepts) of the psychological and the physical are such as to allow for a scientifically discovered identity between items of the one and items of the other. That there still remains a division among Analytic philosophers concerning the problem of the mental and the physical (though in much altered form) shows both the continuity of the movement and the changes that have occurred. (K.S.D.)

Empiricism

In its most general sense, Empiricism is the name applied to the attitude that beliefs are to be accepted and acted upon only if they first have been confirmed by actual experience—a definition that accords with the derivation of the name from the Greek word *empeiria*, “experience.”

More specifically, Empiricism comprises a pair of closely related, but still distinct, philosophical doctrines—one pertaining to concepts and the other to propositions:

1. The first of these doctrines, a theory of meaning, holds that words (e.g., the word *substance*) can be understood or the concepts requisite for any articulate thought possessed only if they are connected by their users with things that they have experienced or could experience (e.g., pieces of wood, or the gases in a gasoline engine).

2. The second doctrine, a philosophical theory of knowledge, views beliefs, or at least some vital classes of beliefs (e.g., that Jane is kind), as depending ultimately and necessarily on experience for justification (Jane is seen performing acts of kindness).

It is not obvious, however, that either of these two doctrines strictly implies the other. Several recognized Empiricists have admitted that there are *a priori* propositions but have denied that there are *a priori* concepts. The reverse disconnection between the two forms of Empiricism, however, has no obvious exponents, since there are hardly any philosophers who totally deny *a priori* propositions and certainly none who would at the same time accept *a priori* concepts.

Stressing experience, Empiricism is thus opposed to the claims of authority, intuition, imaginative conjecture, and abstract, theoretical, or systematic reasoning as sources of reliable belief. Its most fundamental antithesis is with the latter (i.e., with Rationalism, also called intellectualism or apriorism). A Rationalist theory of meaning asserts that there are concepts not derived from or correlated with experienceable features of the world, such as “cause,” “identity,” or “perfect circle,” and that these concepts are *a priori* (Latin: “from the former”) in the traditional sense of being part of the mind’s innate or natural equipment—as opposed to being *a posteriori* (Latin: “from the latter”), or grounded in the experience of facts. On the

other hand, a Rationalist theory of knowledge holds that there are beliefs that are *a priori* (i.e., that depend for their justification upon thought alone), such as the belief that everything must have a sufficient reason or that a process cannot exist by itself but must occur within some substance. Such beliefs can arise either from intellectual intuition, the direct apprehension of self-evident truth, or from purely deductive reasoning.

VARIOUS MEANINGS OF EMPIRICISM

Broader senses. In both everyday attitudes and philosophical theories, the experiences referred to are principally those arising from stimulation of the sense organs, in particular those of sight and touch. Most philosophical Empiricists, however, have maintained that sensation is not the only provider of experience, admitting as empirical the awareness of mental states in introspection or reflection, such as feelings of pain or of fear, often metaphorically described as present to the “inner sense.” It is a controversial question whether still further types of experience, such as moral, aesthetic, or religious experience, ought to be acknowledged as empirical.

Two other viewpoints related to but not the same as Empiricism are the Pragmatism of the American philosopher and psychologist William James, an aspect of which was Radical Empiricism, and Logical Positivism, also called Logical Empiricism (see below *Positivism and Logical Empiricism*). Though these philosophies are, indeed, empirical, each has a distinctive focus that warrants its treatment as a separate movement. Pragmatism stresses the involvement of ideas in practical experience and action, whereas Logical Empiricism is more concerned with scientific experience.

When describing an everyday attitude, the word Empiricism sometimes conveys an unfavourable implication of ignorance of or indifference to relevant theory. Thus, to call a doctor an “Empiric” has been to call him a quack—a usage traceable to a sect of medical men who were opposed to the elaborate medical, and in some views metaphysical, theories of Galen, a prominent Greek physician of the 2nd century AD, theories which dominated medicine until the 17th century. The medical Empiricists opposed to Galen preferred to rely on treatments of observed clinical effectiveness, without inquiring into the mechanisms sought by therapeutic theory. But “Empiricism,” detached from this medical association, may also be used, more favourably, to describe a hard-headed refusal to be swayed by anything but the facts that the thinker has observed for himself, a blunt resistance to received opinion or precarious chains of abstract reasoning.

Stricter senses. As a more strictly defined movement, Empiricism reflects certain fundamental distinctions and occurs in varying degrees.

Fundamental distinctions. If the blurring of the distinction between concepts and propositions has confused discussions of Empiricism, another influence at least equally vexing is that which, embodied in the traditional terminology of the debate, contrasts the empirical not with the *a priori* but with the innate. Since logical problems are easily confused with psychological problems, it is difficult to disentangle the question of the causal origin of man’s concepts and beliefs from that of their meaning and justification.

A concept, such as “Five,” is said to be innate if a man’s possession of it is causally independent of his experience—e.g., of groupings of five objects. A concept, such as “Ought,” is *a priori*, on the other hand, if the logical conditions of its application (or those of the word expressing it) do not include any reference to experienceable states of affairs (thus “Ought” cannot be defined in terms of facts alone). Similarly, a belief is innate if its acceptance is causally independent of the believer’s experience; and it is *a priori* if its justification is logically independent of experience. Propositions could be innate without being *a priori*: for example, the baby’s empirical belief that its mother’s breast will nourish it.

Some colour is lent to the confusion of the *a priori* and the innate by the fact that most empirical concepts are actually acquired through the technique of ostensive defi-

cal Empiri-
cism

Innate
versus a
priori

Empiri-
cism of
concepts
and of
beliefs

nition, in which a concept (such as “long”) is conveyed by introducing instances of it (several long pencils) into the experience of the learner. But it is not in virtue of their mode of acquisition that concepts are empirical; it is the way in which they are applied, once they are possessed, that qualifies them as such. Even if a man were born with an instinctive capacity to use the word blue and never had to learn how to use it, it would still be an empirical concept if the occasion for its use were always his sense experience of a blue object. Furthermore, the fact that men learn, postnatally, to use the word cause does not prove that it expresses an empirical concept if its application to something always implies more than the sense which experience of that kind of thing presents to the mind.

Another supposedly identical but in fact more or less irrelevant property of concepts and beliefs is that of the universality of their possession or acceptance—that a priori or innate concepts must be the common possession of all men and that such beliefs must be accepted by everyone. There may be, in fact, some basis for inferring universality from innateness, since many innate characteristics such as the fear of loud noises appear to be common to the whole species.

Two main kinds of concept have been held to be a priori and thus nonempirical. First, there are certain formal concepts of logic and of mathematics that reflect the basic structure of discourse: “not,” “and,” “or,” “if,” “all,” “some,” “existence,” “unity,” “number,” “successor,” “infinity.” Secondly, there are categorical concepts, such as “substance,” “cause,” “mind,” and “God,” so called after the “categories of thought” as listed by Aristotle and Kant, which the mind imposes upon the given data of experience.

A very large variety of different types of proposition has been held to be a priori. Few would deny this status to such definitional truisms or obvious tautologies as “all hairless heads are bald” or “a rose is a rose.” There are also the truths of logic, of mathematics, and of metaphysics—whether transcendent, such as the existence of God or things-in-themselves (lying behind appearances), or immanent and thus discernible within reality, such as the principles (presupposed by much natural science) of conservation, causality, and sufficient reason. Some have held that the basic principles of ethics or the causal laws of nature are a priori. Empiricism maintains, however, that some of these are a priori.

Degrees of Empiricism. Empiricism, whether concerned with meaning or knowledge, can be held with varying degrees of strength. On this basis, absolute, substantive, and partial Empiricisms can be distinguished.

Absolute Empiricists hold that there are no a priori concepts, either formal or categorical, and no a priori propositions. Absolute Empiricism about knowledge is less common than that about concepts, and nearly all philosophers admit that at least obvious tautologies and definitional truisms are a priori; but many would add that these represent a degenerate case.

A more moderate form of Empiricism is that of the substantive Empiricists, who are unconvinced by attempts that have been made to interpret formal concepts empirically and who therefore concede that formal concepts are a priori but deny that categorical concepts, such as “substance,” “cause,” and “God,” are a priori. In this view, formal concepts would be no longer semantical, pertaining to the relation of words to things; they would be, instead, merely descriptive or purely syntactical, pertaining to the relations between ideas. On this basis “God,” for example, would not be an entity alongside other entities but a device for arranging a man’s factual beliefs about the world; the concept “God” would thus play a structural and not an informative role.

The parallel point of view about knowledge assumes that the truth of logical and mathematical propositions is determined, as is that of definitional truisms, by the relationships between meanings that are established prior to experience. The truth often espoused by moralists, for example, that one is truly obliged to rescue a man from drowning only if it is possible to do so is a matter of meanings and not of facts about the world. On this view,

all propositions that, in contrast to the foregoing example, are in any way substantially informative about the world are empirical. Even if there are a priori propositions, they are all formal or verbal or conceptual in nature, and their necessary truth derives simply from the meanings that man has attached to the words he uses. A priori knowledge is useful because it makes explicit the hidden implications of substantive, factual assertions. But a priori propositions do not themselves express genuinely new knowledge about the world; they are factually empty, “true in all possible worlds.” Thus “All bachelors are unmarried” merely gives explicit recognition to the commitment to describe as unmarried anyone who has been described as a bachelor; but it does not add anything new.

Substantive Empiricism about knowledge, which is fundamental to most contemporary Analytical philosophy, regards all a priori propositions as being more-or-less concealed tautologies, or, in Kantian terms, as being analytic. If a person’s “duty” is thus defined as that which he should always do, the statement “A person should always do his duty” then becomes “A person should always do what he should always do.” Deductive reasoning is conceived accordingly as a way of bringing this concealed tautological status to light. That such extrication is nearly always required means that a priori knowledge is far from trivial.

For the substantive Empiricist, truisms and the propositions of logic and mathematics exhaust the domain of the a priori. Science, on the other hand—from the fundamental assumptions about the structure of the universe to the singular items of evidence used to confirm its theories—is regarded as empirical throughout. The propositions of ethics and those of metaphysics, which deals with the nature of Being as such (for example, “Only that which is not subject to change is real”), are either disguised tautologies or empirical statements or only pseudo-propositions; *i.e.*, combinations of words that, despite their grammatical respectability, cannot be taken as true or false assertions at all.

The least thoroughgoing type of Empiricism here distinguished, ranking third in degree, can be termed partial Empiricism. Many philosophers hold that other concepts besides the formal are a priori and that there are substantially informative propositions about the world that are nevertheless not empirical. The theses of transcendental, or Kantian, metaphysics and those of theology, the general scientific principles of conservation and causality, the basic principles of morality, and the causal laws of nature have all been held to be at once synthetic and a priori—substantial and yet establishable by reasoning alone without recourse to experience. In all versions of this view, however, there remain a great many straightforwardly empirical concepts and propositions: ordinary singular propositions about matters of fact and the concepts that figure in them are held to fall in the empirical domain.

HISTORY OF EMPIRICISM

In ancient philosophy. So-called common sense is inarticulately empiricist; and philosophy, in seeking to correct it, has to start from a rationalistic position. Philosophical Empiricism is thus always critical, a resistance to the pretensions of a more speculative philosophy. The ground was prepared for Plato, the greatest of Rationalist philosophers, by three earlier bodies of thought: the Ionian cosmologies of the 6th century BC—so-called from their concentration along the western coast of Asia Minor—with their distinction between sensible appearance and a reality accessible only to pure reason; the philosophy of Parmenides (early 5th century BC), the important early monist, in which purely rational argument is used to prove that the world is really an unchanging unity; and Pythagoreanism (see above), which, holding that the world is really made of numbers, took mathematics to be the repository of ultimate truth.

The first Empiricists in Western philosophy were the Sophists, who rejected such Rationalist speculation about the world as a whole and took man and society to be the proper objects of philosophical inquiry. Invoking skeptical arguments to undermine the claims of pure reason, they posed a challenge that invited the reaction that comprised

Formal
versus
categorical

Substan-
tive Em-
piricism

Partial
Empiri-
cism

Plato's philosophy (see below, *Criticism and evaluation*).

Plato and to a lesser extent Aristotle were both Rationalists. But Aristotle's successors in the ancient Greek schools of Stoicism and Epicureanism advanced an explicitly Empiricist account of the formation of man's concepts or ideas. For the Stoics the human mind is at birth a clean slate, which comes to be stocked with ideas by the sensory impingement of the material world upon it. Yet they also held that there are some ideas or beliefs, the "common notions," present to the minds of all men; and these soon came to be conceived in a nonempirical way. The Empiricism of the Epicureans, however, was more pronounced and consistent. For them man's concepts are memory images, the mental residues of previous sense experience; and knowledge is as empirical as the ideas of which it is composed.

In medieval philosophy. Most medieval philosophers after St. Augustine (see below, *Criticism and evaluation*) took an Empiricist position, at least about concepts, even if they recognized much substantial but nonempirical knowledge. The standard formulation of this age was: "There is nothing in the intellect that was not previously in the senses." Thus St. Thomas Aquinas (1225–74) altogether rejected innate ideas. Both soul and body participate in perception, and all of man's ideas are abstracted by the intellect from what is given to the senses. Man's ideas of unseen things, like God and angels, are derived by analogy from the seen.

The 13th-century scientist Roger Bacon emphasized empirical knowledge of the natural world and anticipated the polymath Renaissance philosopher of science Francis Bacon (1561–1626) in preferring observation to deductive reasoning as a source of knowledge. The Empiricism of the 14th-century Franciscan Nominalist William of Ockham was more systematic. All knowledge of what exists in nature, he held, comes from the senses, though there is, to be sure, "abstractive knowledge" of necessary truths; but this is hypothetical and does not imply the existence of anything. His more extreme followers extended his line of reasoning toward a radical Empiricism, in which causation is not a rationally intelligible connection but merely an observed regular sequence.

In modern philosophy. In the earlier and unsystematically speculative phases of Renaissance philosophy, the claims of Aristotelian logic to yield substantial knowledge were attacked by several 16th-century logicians, and, in the same century, the role of observation was stressed. One mildly skeptical Christian thinker, Pierre Gassendi (1592–1655), advanced a deliberate revival of the empirical doctrines of Epicurus. But the most important defender of Empiricism was Francis Bacon, who, though he did not deny the existence of a priori knowledge, claimed that, in effect, the only knowledge that is worth having (as contributing to the relief of man's estate) is empirically based knowledge of the natural world, which should be pursued by the systematic, indeed almost mechanical, arrangement of the findings of observation and is best undertaken in the cooperative and impersonal style of modern scientific research. Bacon was, indeed, the first to formulate the principles of scientific induction.

A Materialist and Nominalist, Thomas Hobbes (1588–1679), combined an extreme Empiricism about concepts, which he saw as the outcome of material impacts on the bodily senses, with an extreme Rationalism about knowledge, of which, like Plato, he took geometry to be the paradigm. For him all genuine knowledge is a priori, a matter of rigorous deduction from definitions. The senses provide ideas; but all knowledge comes from "reckoning," from deductive calculations carried out on the names that the thinker has assigned to them. True knowledge is thus not merely a priori but also analytic. Yet it all concerns material and sensible existences: everything that exists is a body.

The most elaborate and influential presentation of Empiricism was made by John Locke (1632–1704), an early Enlightenment philosopher, in the first two books of his *Essay Concerning Human Understanding* (1690). All knowledge, he held, comes from sensation or from reflection, by which he meant the introspective awareness

of the workings of man's own mind. Locke confused the two issues of the nature of concepts and the justification of beliefs. His Book I, though titled "Innate Ideas," is largely devoted to refuting innate knowledge. And even so, he later admitted that much substantial knowledge—in particular, that of mathematics and morals—is a priori. He argued that infants know nothing; that if men are said to know innately what they are capable of coming to know, then all knowledge is, trivially, innate; and that no beliefs whatever are universally accepted. Locke was more consistent about the empirical character of all man's concepts and displayed in detail the ways in which simple ideas can be combined to form complex ideas of what has not in fact been experienced. One group of dubiously empirical concepts—those of unity, existence, and number—he took to be derived both from sensation and from reflection. But he allowed one a priori concept—that of substance—which the mind adds, seemingly from its own resources, to its conception of any regularly associated group of perceptible qualities.

Bishop George Berkeley (1685–1753), a theistic Idealist and opponent of Materialism, applied Locke's Empiricism about concepts to refute Locke's account of man's knowledge of the external world. He drew and embraced the inevitable conclusion that material things are simply collections of perceived ideas, a position that ultimately leads to phenomenalism; i.e., to the view that reality is nothing but sensations. He accounted for the continuity and orderliness of the world by supposing that its reality is upheld in the perceptions of an unsleeping God. The theory of spiritual substance involved in Berkeley's position seems to be vulnerable, however, to most of the same objections as those that he posed against Locke.

The Scottish Skeptical philosopher David Hume (1711–76) fully elaborated Locke's Empiricism and used it deductively to argue that there can be no more to man's concepts of body, mind, and causal connection than what occurs in the experiences that he has of them. For Hume all necessary truth is formal or conceptual, determined by the relations of identity and exclusion that hold between ideas.

Voltaire imported Locke's philosophy into France; and its Empiricism, in a very stark form, is the basis of sensationalism, in which all of the constituents of human mental life are analyzed in terms of sensations alone.

A genuinely original and clarifying attempt to resolve the controversy between Empiricists and their opponents was made in the critical philosophy of Immanuel Kant (1724–1804), drawing upon Leibniz and Hume. With the dictum that, although all knowledge begins with experience it does not all arise from experience, he established a clear distinction between the innate and the a priori. He held that there are a priori concepts, or categories—substance and cause being the most important—and also substantial or synthetic a priori truths. Although not derived from experience, the latter apply to experience. A priori concepts and propositions do not relate to a reality that transcends experience; they reflect, instead, the mind's way of organizing the amorphous mass of sense impressions that flow in upon it.

Lockean Empiricism prevailed in 19th-century England until the turn to Hegel occurred in the last quarter of the century. To be sure, the Scottish philosophers who followed Hume but avoided his Skeptical conclusions insisted that man does have substantial a priori knowledge. But the philosophy of John Stuart Mill (1806–73), logician, economist, and Utilitarian moralist, is thoroughly Empiricist. He held that all knowledge worth having, including mathematics, is empirical. The apparent necessity of mathematics, according to Mill, is the result of the unique massiveness of its empirical confirmation. All real knowledge for Mill is inductive and empirical; and deduction is sterile. On similar lines, the philosopher of evolution Herbert Spencer (1820–1903) offered another explanation of the apparent necessity of some of man's beliefs: they are the well-attested empirical beliefs of his ancestors from whom he has inherited them, an evolutionary revival of the doctrine of innateness. Two important mathematicians and pioneers in the philosophy of modern physics,

and
Positivism

W.K. Clifford (1845–79) and Karl Pearson (1857–1936), defended radically Empiricist philosophies of science, anticipating the Logical Empiricism of the 20th century.

In contemporary philosophy. The most influential Empiricist of the 20th century was the great British philosopher and logician Bertrand Russell (1872–1970), who at first was Lockean in his theory of knowledge—admitting both synthetic a priori knowledge and concepts of unobservable entities. Ludwig Wittgenstein (1889–1951), the influential pioneer of the school of Linguistic Analysis, convinced Russell that the truths of logic and mathematics are analytic; and Russell then came to believe, with Hume, that the task of philosophy is to analyze all concepts in terms of what can be directly present to the senses. In this spirit, he tried to show that even the concepts of formal logic are ultimately empirical though the experience that supplies them may be introspective instead of sensory.

Doctrines developed through the collaboration of Russell and Wittgenstein yielded the Logical Positivism of the German philosopher Rudolf Carnap (1891–1970) and of the Vienna Circle, a discussion group in which that philosophy was worked out. The Empiricism of Logical Positivism is especially evident in its restatement of the fundamental thesis of Hume's philosophy in a form known as "the verification principle," which recognizes as meaningful and synthetic only those sentences that are in principle verifiable by reference to sense experience.

CRITICISM AND EVALUATION

The earliest expressions of Empiricism in ancient Greek philosophy were those of the Sophists. In reaction to them Plato presented the Rationalistic view that man has only "opinion" about changing, perceptible, existing things in space and time; that "knowledge" can be had only of timeless, necessary truths; and that the objects of knowledge—the unchanging and imperceptible forms or universals (such as "Bed," "Man," etc.)—are the truly real. The circles and triangles of geometrical "knowledge," in this view, are quite different in their perfect exactness from the approximately circular and triangular things present to man's senses. In the *Phaedo*, Plato expounded a theory of literally innate ideas; man, for example, has a conception of exact "equality," which, since it could not have been supplied by the senses, must have been acquired by the soul before it was embodied.

Aristotle agreed with Plato that knowledge is of the universal but held that such universal forms should not be conceived as "separated" from the matter embodying them. This belief does not make Aristotle an Empiricist, although he was certainly a less extreme Rationalist than Plato. Aristotle took the Rationalist view that every science or body of knowledge must resemble Euclidean geometry in consisting of deductions from first principles that are self-evidently and necessarily true and that, although the senses acquaint man with the sensible forms of things, he cannot have knowledge of them unless reason is brought into play to acquaint him with their intelligible forms as well.

The Stoic view of "common notions," or beliefs that are held by all men—a Rationalistic element in an otherwise Empirical school of thought—was expanded during the early medieval period by the Christian Platonist St. Augustine (AD 354–430), a thoroughgoing Rationalist. The Stoic common notions, Augustine held, are truths that God has implanted in the human mind through direct illumination.

Although the early modern expression of Empiricism in the 17th century by Francis Bacon heralded the scientific age, its influence was lessened by his failure to appreciate the revolutionary use of mathematics that comprised the genius of Galileo's new physics and, even more fundamentally, by his underestimation of the need for imaginative conjecture in the formation of scientific hypotheses to restrict the overwhelming number of facts that would otherwise have to be handled. In contrast to Bacon's view, the philosopher and mathematician René Descartes (1596–1650), his contemporary and one of the principal founders of modern thought, developed a comprehensive Rationalism that was more immediately influential. For

Descartes all clear and distinct ideas, and in particular those of philosophy and of geometrical physics, are innate; sense experience is at most the agency that elicits ideas already present in the mind. In principle, all knowledge is a priori and demonstrable by pure reasoning, but in practice, because of man's finite intellect, it is necessary to rely on experience to confirm propositions for which rational proof is beyond reach. In England innate ideas and knowledge were defended by Edward Lord Herbert of Cherbury (1582–1648), precursor of Deism, and by a school of Puritan Humanists known as the Cambridge Platonists. The case for innate ideas, however, is hard to establish; there can be in the nature of the case little actual evidence that one can possess concepts before having had some relevant experience.

In the second half of the 17th century, the Empiricist views of John Locke were similarly controverted by a systematic thinker and man of affairs, G.W. Leibniz, who examined Locke's views in minute detail in his book *Nouveaux essais sur l'entendement humain* (1704, published 1765; Eng. trans., *New Essays*, 1916), arguing that ideas can be virtually innate in a less trivial sense than Locke allowed. Interpreting Locke's notion of reflection as reasoning rather than as introspection, Leibniz supposed that Locke was more of a Rationalist than he really was.

In contemporary philosophy, there are thinkers who, though broadly sympathetic to Positivism, have voiced reservations about its more specifically Empiricist elements. One important philosopher of science, Karl Popper, has rejected the inductivism that views the growth of empirical knowledge as the result of a mechanical routine of generalization. To him it is falsifiability by experience that makes a statement empirical. An influential American philosopher and logician, W.V. Quine, has been critical of the Logical Empiricists' frequent recourse to the concept of meaning and has rejected the sharp distinction they make between analytic and factual truths, on which most of contemporary Empiricism rests. For Quine, both human concepts and beliefs are the joint outcome of experience and conventional decision, and he denies that the role of the two factors can be readily distinguished as Empiricists assert.

The theory of knowledge has been the central discipline in philosophy since the 17th century, and its most basic issue is that between Empiricism and Rationalism, an issue that is still being actively debated. On the one hand, the idea that science rests on substantial but nonempirical presuppositions has been put in question by the fact that in some areas it seems to get along without them: without conservation in cosmology, without causality in quantum physics. On the other hand, the traditional theory of the innate powers of the mind has been reanimated by the considerations underlying the theory of language offered by Noam Chomsky, a generative grammarian, who holds that the learning of language is too rapid and too universal to be attributed entirely to an empirical process of conditioning. The basic strength of Empiricism consists in its recognition that human concepts and beliefs apply to a world outside oneself, and that it is by way of the senses that this world acts upon the individual. The question, however, of just how much the mind itself contributes to the task of processing its sensory input is one that no simple argument can answer. (A.M.Q.)

Existentialism

The various philosophies (dating from about 1930) that have been referred to by the term Existentialism have in common an interpretation of human existence in the world that stresses its concreteness and its problematic character.

NATURE OF EXISTENTIALIST THOUGHT AND MANNER

According to Existentialism: (1) Existence is always particular and individual—always *my* existence, *your* existence, *his* existence. (2) Existence is primarily the problem of existence (*i.e.*, of its mode of being); it is, therefore, also the investigation of the meaning of Being. (3) This investigation is continually faced with diverse possibilities, from

The
critique of
Plato and
Aristotle

among which the existent (*i.e.*, man) must make a selection, to which he must then commit himself. (4) Because these possibilities are constituted by man's relationships with things and with other men, existence is always a being-in-the-world—*i.e.*, in a concrete and historically determinate situation that limits or conditions choice. Man is therefore called *Dasein* ("there being") because he is defined by the fact that he exists, or is in the world and inhabits it.

Contrasts
and
directions
of thought

With respect to the first point, that existence is particular, Existentialism is opposed to any doctrine that views man as the manifestation of an absolute or of an infinite substance. It is thus opposed to most forms of Idealism, such as those that stress Consciousness, Spirit, Reason, Idea, or Oversoul. Secondly, it is opposed to any doctrine that sees in man some given and complete reality that must be resolved into its elements in order to be known or contemplated. It is thus opposed to any form of objectivism or scientism since these stress the crass reality of external fact. Thirdly, Existentialism is opposed to any form of necessitarianism; for existence is constituted by possibilities from among which man may choose and through which he can project himself. And, finally, with respect to the fourth point, Existentialism is opposed to any solipsism (holding that I alone exist) or any epistemological Idealism (holding that the objects of knowledge are mental), because existence, which is the relationship with other beings, always extends beyond itself, toward the being of these entities; it is, so to speak, transcendence.

Starting from these bases, Existentialism can take diverse and contrasting directions. It can insist on the transcendence of Being with respect to existence, and, by holding this transcendence to be the origin or foundation of existence, it can thus assume a theistic form. On the other hand, it can hold that human existence, posing itself as a problem, projects itself with absolute freedom, creating itself by itself, thus assuming to itself the function of God. As such, Existentialism presents itself as a radical atheism. Or it may insist on the finitude of human existence—*i.e.*, on the limits inherent in its possibilities of projection and choice. As such, Existentialism presents itself as a humanism.

Diversity
of interests
and
sources

From 1940 on, with the diffusion of Existentialism through continental Europe, its directions have developed in terms of the diversity of the interests to which they are subject: the religious interest, the metaphysical (or nature of Being) interest, the moral and political interest. This diversity of interests is rooted, at least in part, in the diversity of sources on which Existentialism has drawn. One such source has been the subjectivism of the 4th–5th-century theologian St. Augustine, who exhorted man not to go outside himself in the quest for truth, for it is within him that truth abides. "If you find that you are by nature mutable," he wrote, "transcend yourself." Another source has been the Dionysian Romanticism of Nietzsche, who exalted life in its most irrational and cruel features and made this exaltation the proper task of the "higher man," who exists beyond good and evil. Still another source has been the nihilism of Dostoyevsky, who, in his novels, presented man as continually defeated as a result of his choices and as continually placed by them before the insoluble enigma of himself. As a consequence of the diversity of these sources, Existentialist doctrines have focussed on several aspects of existence.

They have focussed, first, on the problematic character of the human situation, through which man is continually confronted with diverse possibilities or alternatives, among which he may choose and on the basis of which he can project his life.

Second, the doctrines have focussed on the phenomena of this situation and especially on those that are negative or baffling, such as the concern or preoccupation that dominates man because of the dependence of all his possibilities upon his relationships with things and with other men; the dread of death or of the failure of his projects; the "shipwreck" upon insurmountable "limit situations" (death, the struggle and suffering inherent in every form of life, the situation in which everyone daily finds himself); the guilt inherent in the limitation of choices and

in the responsibilities that derive from making them; the boredom from the repetition of situations; the absurdity of man's dangling between the infinity of his aspirations and the finitude of his possibilities.

Third, the doctrines have focussed on the intersubjectivity that is inherent in existence and is understood either as a personal relationship between two individuals, I and thou, such that the thou may be another man or God, or as an impersonal relationship between the anonymous mass and the individual self deprived of any authentic communication with others.

Fourth, Existentialism focusses on ontology, on some doctrine of the general meaning of Being, which can be approached in any of a number of ways: through the analysis of the temporal structure of existence; through the etymologies of the most common words—on the supposition that in ordinary language Being itself is disclosed, at least partly (and thus is also hidden); through the rational clarification of existence by which it is possible to catch a glimpse, through ciphers or symbols, of the Being of the world, of the soul, and of God; through existential psychoanalysis that makes conscious the fundamental "project" in which existence consists; or, finally, through the analysis of the fundamental modality to which all the aspects of existence conform—*i.e.*, through the analysis of possibility.

There is, in the fifth place, the therapeutic value of existential analysis that permits, on the one hand, the liberating of human existence from the beguilements or debasements to which it is subject in daily life and, on the other, the directing of human existence toward its authenticity; *i.e.*, toward a relationship that is well-grounded on itself, and with other men, with the world, and with God.

The various forms of Existentialism may also be distinguished on the basis of language, which is an indication of the cultural traditions to which they belong and which often explains the differences in terminology among the various authors. The principal representatives of German Existentialism are Martin Heidegger and Karl Jaspers; those of French personalistic Existentialism are Gabriel Marcel and Jean-Paul Sartre; that of French Phenomenology is Maurice Merleau-Ponty; that of Spanish Existentialism is José Ortega y Gasset; that of Russian Idealistic Existentialism is Nikolay Berdyayev (who, however, lived half of his adult life in France); and that of Italian Existentialism is Nicola Abbagnano. The linguistic differences, however, are not decisive for a determination of philosophical affinities. For example, Marcel and Sartre are farther apart than Heidegger and Sartre; and there is greater affinity between Abbagnano and Merleau-Ponty than between Merleau-Ponty and Marcel.

HISTORICAL SURVEY OF EXISTENTIALISM

Many of the theses that Existentialists defend or illustrate in their analyses are drawn from the wider philosophical tradition.

Precursors of Existentialism. The problem of what man is in himself can be discerned in the Socratic imperative "know thyself," as well as in the work of Montaigne and Pascal, a religious philosopher and mathematician. Montaigne had said: "If my mind could gain a foothold, I would not write essays, I would make decisions; but it is always in apprenticeship and on trial." And Pascal had insisted on the precarious position of man situated between Being and Nothingness: "We burn with the desire to find solid ground and an ultimate sure foundation whereon to build a tower reaching to the Infinite. But our whole groundwork cracks, and the earth opens to abysses."

The stance of the internal tribunal—of man's withdrawal into his own spiritual interior—which reappears in some Existentialists (in Marcel and Sartre, for example) already belonged, as earlier noted, to St. Augustine. In early 19th-century French philosophy, it was defended by a reformed *Idéologue*, Marie Maine de Biran, who wrote: "Even from infancy I remember that I marvelled at the sense of my existence. I was already led by instinct to look within myself in order to know how it was possible that I could be alive and be myself." From then on, this posture inspired a considerable part of French philosophy.

Approach-
es to the
general
meaning
of Being

Socrates,
Montaigne,
and Pascal

The theme of the irreducibility of existence to reason, common to many Existentialists, was also defended by a leading German Idealist, F.W.J. von Schelling, as he argued against Hegel in the last phase of his philosophy, and Schelling's polemic, in turn, inspired the thinker usually cited as the father of Existentialism, the religious Dane Søren Kierkegaard.

The requirement to know man in his particularity and, therefore, in terms of a procedure different from those used by science to obtain knowledge of natural objects was confronted by Wilhelm Dilthey, an expounder of historical reason, who viewed "understanding" as the procedure and thus as the proper method of the human sciences. Understanding, according to Dilthey, consists in the reliving and reproducing of the experience of others. Hence it is also a feeling together with others and a sympathetic participation in their emotions. Understanding, therefore, accomplishes a unity between the knowing object and the object known.

The immediate background and founding fathers. The theses of Existentialism found a particular relevance during World War II, when Europe found itself threatened alternately by material and spiritual destruction. Under those circumstances of uncertainty, the optimism of Romantic inspiration, by which the destiny of man is infallibly guaranteed by an infinite force (such as Reason, the Absolute, or Mind) and propelled by it toward an ineluctable progress, appeared to be untenable. Existentialism was moved to insist on the instability and the risk of all human reality, to acknowledge that man is "thrown into the world"—i.e., abandoned to a determinism that could render his initiatives impossible—and to hold that his very freedom is conditioned and hampered by limitations that could at any moment render it empty. The negative aspects of existence, such as pain, frustration, sickness, and death—which 19th-century optimism refused to take seriously because they do not touch the infinite principle that these optimists believed to be manifest in man—become for Existentialism the essential features of human reality.

The thinkers who, by virtue of the negative character of their philosophy, constituted the exception to 19th-century Romanticism thus became the acknowledged masters of the Existentialists. Against Hegelian necessitarianism, Kierkegaard interpreted existence in terms of possibility: dread—which dominates existence through and through—is "the sentiment of the possible." It is the feeling of what can happen to a man even when he has made all of his calculations and taken every precaution. Despair, on the other hand, discovers in possibility its only remedy, for "If man remains without possibilities, it is as if he lacked air." Karl Marx, in holding that man is constituted essentially by the "relationships of work and production" that tie him to things and other men, had insisted on the alienating character that these relationships assume in capitalistic society, where private property transforms man from an end to a means, from a person to the instrument of an impersonal process that subjugates him without regard for his needs and his desires. Nietzsche had viewed the *amor fati* ("love of fate") as the "formula for man's greatness." Freedom consists in desiring what is and what has been and in choosing it and loving it as if nothing better could be desired.

Emergence as a movement. Contemporary Existentialism reproduces these ideas and combines them in more or less coherent ways. Human existence is, for all the forms of Existentialism, the projection of the future on the basis of the possibilities that constitute it. For some Existentialists (the Germans Heidegger and Jaspers, for example), the existential possibilities, inasmuch as they are rooted in the past, merely lead every project for the future back to the past, so that only what has already been chosen can be chosen (Nietzsche's *amor fati*). For others (such as Sartre), the possibilities that are offered to existential choice are infinite and equivalent, such that the choice between them is indifferent; and for still others (Abba-gnano and Merleau-Ponty), the existential possibilities are limited by the situation, but they neither determine the choice nor render it indifferent. The issue is one of individuating, in every concrete situation and by means of

a specific inquiry, the real possibilities offered to man. For all the Existentialists, however, the choice among possibilities—i.e., the projection of existence—implies risks, renunciation, and limitation. Among the risks, the most serious is man's descent into inauthenticity or into alienation, his degradation from a person into a thing. Against this risk, for the theological forms of Existentialism (as in Gabriel Marcel, a Socratic dramatist; Karl Barth, a Swiss Neo-orthodoxist; Rudolf Bultmann, a biblical interpreter), there is the guarantee of the transcendent help from God, which in its turn is guaranteed by faith.

Existentialism, consequently, by insisting on the individuality and nonrepeatability of existence (following Kierkegaard and Nietzsche), is sometimes led to regard one's coexistence with other people (held to be, however, an ineluctable fact of the human situation) as a condemnation or alienation of man. Marcel has said that all that exists in society beyond the individual is "expressible by a minus sign," and Sartre has affirmed in his major work *L'Être et le néant* (1943; *Being and Nothingness*, 1956) that "the Other is the hidden death of my possibilities." For the other forms of Existentialism, however, a coexistence that is not anonymous (as that of a mob) but is grounded on personal communication conditions man's authentic existence.

Existentialism has had ramifications in various areas of contemporary culture. In literature, Franz Kafka, author of haunting novels, walking in Kierkegaard's footsteps, described human existence as the quest for a stable, secure, and radiant reality that continually eludes it (*Das Schloss* [1926; *The Castle*, 1930]); or he described it as threatened by a guilty verdict about which it knows neither the reason nor the circumstances but against which it can do nothing—a verdict that ends with death (*Der Prozess* [1925; *The Trial*, 1937]).

The theses of contemporary Existentialism were then diffused and popularized by the novels and plays of Sartre, by the writings of the French novelists and dramatists Simone de Beauvoir and Albert Camus. In *L'Homme révolté* (1951; *The Rebel*, 1953), Camus described the "metaphysical rebellion" as "the movement by which a man protests against his condition and against the whole of creation." In art, the analogues of Existentialism may be considered to be Surrealism, Expressionism, and in general those schools that view the work of art not as the reflection of a reality external to man but as the free immediate expression of human reality.

Existentialism made its entrance into psychopathology through Karl Jaspers' *Allgemeine Psychopathologie* (1913; *General Psychopathology*, 1965), which was inspired by the need to understand the world in which the mental patient lives, by means of a sympathetic participation in his experience. Later, Ludwig Binswanger, a Swiss psychiatrist of the *Daseinsanalyse* school, in one of his celebrated works, *Über Ideenflucht* (1933; "On the Flight of Ideas"), inspired by Heidegger's thought, viewed the origin of mental illness as a failure in the existential possibilities that constitute human existence (*Dasein*). From Jaspers and Binswanger, the Existentialist current became diffused and variously stated in contemporary psychiatry.

In theology, Barth's *Römerbrief* (1919; *The Epistle to the Romans*, 1933) started the "Kierkegaard revival," the emblem of which was expressed by Barth himself; it is "the relation of this God with this man; the relation of this man with this God—this is the only theme of the Bible and of philosophy." Within the bounds of this current, on the one hand, there was an insistence upon the absolute transcendence of God with respect to man, who could place himself in relationship with God only by denying himself and by abandoning himself to a gratuitously granted faith. On the other hand, there was the requirement to demythologize the religious content of faith, particularly of the Christian faith, in order to allow the message of the eschatological event (of salvation) to emerge from among the existential possibilities of man.

METHODOLOGICAL ISSUES IN EXISTENTIALISM

The methods that the Existentialists employ in their interpretations have a presupposition in common: the imme-

Kierkegaard, Marx, and Nietzsche

Broader cultural ramifications

Phenomenology, clarification, psychoanalysis

diacy of the relationship between the interpreter and the interpreted, between the interrogator and the interrogated, between the problem of being and Being itself. The two terms coincide in existence; for the man who poses the question "What is Being?" cannot but pose it to himself and cannot respond without starting from his own being.

This common ground notwithstanding, each Existentialist thinker has defended and worked out his own method for the interpretation of existence. Heidegger, an Existentialist with ontological (nature of Being) concerns, availed himself of the philosophy of Edmund Husserl, founder of Phenomenology, which, as *logos* of the *phainomenon*, employs speech that manifests or discloses what it is that one is speaking about and that is true—in the etymological use of the Greek word *alētheia* (i.e., the sense of uncovering or manifesting what was hidden). The phenomenon is, from Heidegger's point of view, not mere appearance, but the manifestation or disclosure of Being in itself. Phenomenology is thus capable of disclosing the structure of Being and hence is an ontology of which the point of departure is the being of the one who poses the question about Being, namely man.

Jaspers, an authority in psychopathology as well as in the philosophy of human existence, on the other hand, employed the method of the rational clarification of existence; he maintained that existence, as the quest for Being, is man's effort of rational self-understanding, or universalizing, of communicating—a method that presupposes that existence and reason are the two poles of man's being. Reason is possible existence; i.e., existence that, as Jaspers writes in his *Vernunft und Existenz* (1935; *Reason and Existence*, 1955), becomes "manifest to itself and as such real, if, with, through and by another existence, it arrives at itself." This activity, however, is never consummated; thus, when the impossibility of its achievement is recognized, it is changed into faith, into the recognition of transcendence as providing the only possibility of its final achievement.

According to the views of Sartre, the foremost philosopher of mid-20th-century France, the method of philosophy is existential psychoanalysis; i.e., the analysis of the "fundamental project" in which man's existence consists. In contrast to the precepts of Freudian psychoanalysis, which stop short at the irreducibility of the libido, or primitive psychic drive, existential psychoanalysis tries to determine the "original choice" through which man constructs his world and decides in a preliminary way upon particular choices (which, however, may place in crisis the primordial choice itself).

According to Marcel, a Christian Existentialist philosopher and dramatist, the method of philosophy depends upon a recognition of the mystery of Being (*Le Mystère de l'être* [1951; *The Mystery of Being*, 1950–51]); i.e., on the impossibility of discovering Being through objective or rational analyses or demonstrations. Philosophy should lead man up, however, to the point of making possible for him "the productive illumination of Revelation."

Finally, according to humanistic Existentialism, as represented by Abbagnano, the leading Italian Existentialist, and by Merleau-Ponty, a French Phenomenologist, the method of philosophy consists of the analysis and the determination—by employing all available techniques including those of science—of the structures that constitute existence; i.e., of the relations that connect man with other beings and that figure, therefore, not only in the constitution of man but in the constitution of the other beings as well.

SUBSTANTIVE ISSUES IN EXISTENTIALISM

Fundamental concepts and contrasts. Both the ontology and manner of human existence are of concern to Existentialism.

Ontic structure of human existence. The fundamental characteristic of Existentialist ontology is the primacy that that study of the nature of existence gives to the concept of possibility. This priority dominated the philosophy of Kierkegaard and also was amply utilized by Husserl, who had explicitly affirmed the ontological priority of possibility over reality. Possibility, however, is not understood by

the Existentialists in the purely logical sense as absence of contradiction nor in the sense of traditional metaphysics as potentiality destined to become actuality but, rather, in the sense of ontic or objective possibility, which is the very structure of human existence; it is thus the specific modality of man's being.

Another way of expressing this thesis is the affirmation of Heidegger and Sartre that "existence precedes essence," which signifies that man does not have a nature that determines his modes of being and acting but that, rather, these modes are simply possibilities from which he may choose and on the basis of which he can project himself. In this sense, Heidegger has said that "*Dasein* is always its own possibility," and Sartre has written: "It is true that the possible is—so to speak—an option on being, and if it is true that the possible can come into the world only through a being which is its own possibility, this implies for human reality the necessity of being its being in the form of an option on its being."

As possibility, human existence is the anticipation, the expectation, the projection of the future. The future is its fundamental temporal dimension, to which the present and the past are subordinate and secondary; existence is always stretched out toward the future. As possibility, existence is also transcendence, being beyond, because all of its constitutive possibilities organize it beyond itself toward the other beings of the world and toward the world in its totality. To transcend thus means to move toward something that is not one's own existence; i.e., toward things and toward other men, with which man is related in every situation in which he finds himself.

Yet for some Existentialists, the being of these other entities has a modality that differs from the being of man's existence: their existence is not possible being but real or factual being. To existence, Heidegger contrasts the presence of the things in the world—a presence that assumes, as man takes notice of these things for his needs, the aspect of utilizability. But utilizability is not a simple quality of things; it is their very being. Analogously, Sartre distinguishes the for-itself—the mode of being of man's existence that he identifies, following Descartes and Husserl, with consciousness—from the in-itself, the being or reality of things that he identifies with their utilizability. According to Jaspers, over against the existence of the possible (man, *Dasein*) stands the world as the infinite horizon that encompasses within itself each possible existence and, therefore, cannot itself be encompassed by any one of them. This is a world that is a reality of fact, at the origin of which there is a Being that is pure transcendence and that, therefore, never reveals itself.

Similarly, the religious forms of Existentialism insist on transcendence, considering it to be the property of the Being that is beyond the existential possibilities and that can enter among them solely under the form of mystery (Marcel) and of the extratemporal revelation of faith (Barth, Jaspers). Marcel, in this regard, has contrasted Being, which is a mystery, with having, which is the condition of man in the world; that is to say, man has objects before him that are foreign to his subjectivity. He tries to organize them and discover the bond that ties them together so as to control and use them.

In all of these doctrines, there is the dominating theme of the contrast between the modality proper to existence, which is possibility, and the modality proper to Being, which is reality or facticity. As a result of this contrast, existence (as possibility) appears as the nothingness of Being, as the negation of every reality of fact. In a brief but famous essay, *Was ist Metaphysik?* (1929), Heidegger affirmed that "Human existence cannot have a relationship with being unless it remains in the midst of nothingness." Rudolf Carnap, a semanticist and leading Logical Positivist, in an equally famous essay, "Überwindung der Metaphysik durch die logische Analyse der Sprache" (1931; "The Elimination of Metaphysics Through Logical Analysis of Language"), criticized this hypostatization (or making real) of Nothingness as one of the grosser fallacies of metaphysics. In truth, Nothingness is, for the Existentialists, possible existence, as the negation of the reality of fact. Sartre has written: "The possible is the *something*

Mystery of Being and the structures of existence

Existence as the nothingness of Being

which the For-itself lacks *in order* to be itself"; it is what the subject lacks in order to be an object; thus it does not exist except as a lacking.

This is also true of value, which is such insofar as it does not exist. For even when value occurs or is perceived in certain acts, it lies beyond them and constitutes the limit or the goal toward which they aim. Analogously, knowledge, in which the object (the in-itself) presents itself to consciousness (the for-itself), is a relationship of nullification, because the object cannot be offered to consciousness except as that which is not consciousness. Furthermore, another existence is such insofar as it is not mine; thus this negation is "the constitutive structure of the being-of-others."

But this reduction of existence to Nothingness can lead in two directions: it can lead to insisting on the lack of meaning—*i.e.*, on the absurdity of existence and of every possible project—as it does in Sartre, in Camus, and in atheistic Existentialism; or it can lead toward the quest for a more direct relationship of existence with Being, beyond the constitutive possibilities of existence, so that Being reveals itself, at least partly, in existence—through language or through faith or through some mystical form of religiousness, as happens in the later phase of Heidegger's thought, in Jaspers, and in all of the forms of theological Existentialism.

Manner and style of human existence. Existentialism is never a solipsism in the proper sense of the term (that I alone exist), because every existential possibility relates man to things and to other men. Sometimes it is presented as humanism in the sense that it places human destiny in the hands of men themselves. But this version is rejected by all of the currents of the movement that, starting with Heidegger, insist on the priority and the initiative of Being with regard to human existence. The opposition between these two points of view depends on how the different Existentialists solve the problem of freedom.

Destiny
versus
freedom of
choice

Man always finds himself in a situation in which his constitutive possibilities are rooted. For Heidegger and Jaspers, this situation determines the choice that he makes among these possibilities; for Sartre, conversely, the situation is determined by the choice. Existentialism fluctuates in this way between the concept of a destiny in which, like Nietzsche's *amor fati*, man accepts what has already been chosen and the concept of a radical freedom whereby the choices are offered to man in an absolute indifference. From the first point of view, every project of life falls back on or is reduced to the situation from which it starts; thus the possibility of being, of acting, of willing, of choosing is really, as Jaspers points out in his *Philosophie* (1932), the impossibility of being, acting, willing, and choosing in a manner different from the way things are; *i.e.*, from the factual conditions of the situation. From the second point of view, the fundamental project, which is the primordial choice, has no conditions; as Sartre says: "Since I am free, I project my total possible, but I thereby posit that I am free and that I can always nihilate this first project and make it past." From the first, or deterministic, point of view, the past determines the future and assimilates it to itself; from the second, or libertarian, point of view, the meaning of the past depends upon the present project. In the latter instance, freedom is a kind of damnation: as Sartre affirms: "We said that freedom is not free not to be free and that it is not free not to exist."

A choice, however, is offered to man even from the destinarian point of view: that between understanding and not understanding one's own nothingness. According to Heidegger, a man achieves what he calls "authentic existence" when he understands the impossibility of all of the possibilities of existence—the impossibility of which the sign or term is death. Jaspers affirms, in his turn, that the only choice offered to man is that between accepting or rejecting the situation with which he is identified. The rejection of it, however, is a betrayal that plunges him back into the situation itself.

Existentialist ontology thus fluctuates between Being and Nothingness and concludes by regarding Nothingness as the only possible revelation of Being. In the atheistic version, it is man, as Sartre affirms, who "strives to be God"

and consumes himself vainly in the effort. In the cosmological or theological version, it is Being that intervenes, in a way that is more or less mysterious or hidden, to redeem man from Nothingness.

Problems of Existentialist philosophy. The key problems for Existentialism are those of man himself, of his situation in the world, and of his more ultimate significance.

Man and human relationships. Existentialist anthropology is strictly connected with its ontology. The traditional distinction between soul and body is completely eliminated; thus the body is a lived-through experience that is an integral part of man's existence in its relationship with the world. According to Sartre, "In each project of the For-itself, in each perception the body is there; it is the immediate Past in so far as it still touches on the Present which flees it." As such, however, the body is not reduced to a datum of consciousness, to subjective representation. Consciousness, according to Sartre, is constant openness toward the world, a transcendent relationship with other beings and thereby with the in-itself. Consciousness is existence itself, or, as Jaspers says, it is "the manifestation of being." In order to avoid any subjectivistic equivocation, Heidegger went so far as to renounce the use of the term consciousness, preferring the term *Dasein*, which is more appropriate for designating human reality in its totality. For the same reasons, the traditional opposition between subject and object, or between the self and the nonself, loses all sense. *Dasein* is always particular and individual. It is always a self; but it is also always a project of the world that includes the self, determining or conditioning its modes of being.

All of these modes of being thus arise, as Heidegger shows in his masterpiece *Sein und Zeit* (1927; *Being and Time*, 1962), from the relationship between the self and the world. Heidegger has regarded concern (in the Latin sense of the term) to be the fundamental aspect of this relationship, insofar as it is man's concern to obtain the things that are necessary for him and even to transform them with his work as well as to exchange them so as to make them more suitable to his needs. Concern demonstrates that man is "thrown into the world," into the midst of other beings, so that in order to project himself he must exist among them and utilize them. Being thrown means, for man, being abandoned to the whirling flow of things in the world and to their determinism.

This happens inevitably, according to Heidegger, in inauthentic existence—day-to-day and anonymous existence in which all behaviour is reduced to the same level, made "official," conventional, and insignificant. Chatter, idle curiosity, and equivocation are the characteristics of this existence, in which "One says this" and "One does that" reign undisputed. Anonymous existence amounts to a simple "being together" with others, not a true coexistence, which is obtained only through the acceptance of a common destiny (see below).

All of the Existentialists are in agreement on the difficulty of communication; *i.e.*, of well-grounded intersubjective relationships. Jaspers has perhaps been the one to insist most on the relationship between truth and communication. Truths are and can be different from existence. But if fanaticism and dogmatism (which absolutize a historical truth) are avoided on the one hand while relativism and skepticism (which affirm the equivalence of all truths) are avoided on the other, then the only other way is a constant confrontation between the different truths through an always more extended and deepened intersubjective communication.

Sartre, however, denies that there is authentic communication. According to him, consciousness is not only the nullification of things but also the nullification of the other person as other. To look at another person is to make of him a thing. This is the profound meaning of the myth of Medusa. Sexuality itself, which Sartre holds to be an essential aspect of existence, fluctuates between sadism and masochism, in which either the other person or oneself is merely a thing. On this basis, the intersubjective relationship is obviously impossible.

cation

ship in dread. When a man decides to escape from the banality of anonymous existence—which hides the nothingness of existence, or the nonreality of its possibilities, behind the mask of daily concerns—his understanding of this nothingness leads him to choose the only unconditioned and insurmountable possibility that belongs to him: death. The possibility of death, unlike the possibilities that relate him to other things and to other men, isolates him. It is a certain possibility, not through its apodictic evidence but because it continuously weighs upon existence. To understand this possibility means to decide for it, to acknowledge “the possibility of the impossibility of any existence at all” and to live for death. The emotive tonality that accompanies this understanding is dread, through which man feels himself to be “*face to face* with the ‘nothing’ of the possible impossibility of [his] existence.”

But neither the understanding of death nor its emotive accompaniment opens up a specific task for man, a way to transform his own situation in the world. They enable him only to perceive the common destiny to which all men are subject; and they offer to him, therefore, the possibility of remaining faithful to this destiny and of freely accepting the necessity that all men share in common. In this fidelity consists the historicity of existence, which is the repetition of tradition, the return to the possibilities from which existence had earlier been constituted, the wanting for the future what has been in the past. And in this historicity participate not only man but all of the things of the world, in their utilizability and instrumentality, and even the totality of Nature as the locus of history.

Dread, therefore, is not fear in the face of a specific danger. It is rather the emotive understanding of the nullity of the possible, or, as Jaspers says, of the possibility of Nothingness. It has, therefore, a therapeutic function in that it leads human existence to its authenticity. From the fall into factuality into which every project plunges him, man can save himself only by projecting not to project; *i.e.*, either by abandoning himself decisively to the situation in which he finds himself or by being indifferent to any possible project—with regard to which Sartre says, “Thus it amounts to the same thing whether one gets drunk alone or is a leader of nations.”

The pivotal point of that conclusion—the conclusion most widely held among the Existentialists and the one in fact often identified with Existentialism—is the antithesis between possibility and reality. On the one hand, existence is interpreted in terms of possibilities that are not purely logical possibilities or manifestations of a man’s ignorance of what exists but are, rather, effective, or ontic, possibilities that constitute man as such; on the other hand, contrasted to possibilities in this sense is a reality, a for-itself, a world, a transcendence that is a factual presence, insurmountable and oppressive, with respect to which possibility is a pure Nothingness. The contradiction to which this antithesis leads becomes clear when the same reality is interpreted in terms of possibility: when the being of things, for example, is reduced to their possibility of being utilized; when the being of other men is reduced to the possibility of anonymous or personal relationships that the individual can have with them; and when the being of transcendence, or of God, is reduced to the possibility of the relationship, although ineffable and mysterious, between transcendence, or God, and man.

It has been said that a coherent Existentialism should avoid the constant mortal leap between Being and Nothingness; should not confuse the problematic character of existence with the fall into factuality; should not confuse the finitude of possibilities with resignation to the situation, choice with determinism; freedom conditioned by the limits of the situation with the acknowledgment of the omnipresent necessity of the Whole. In this inquiry, it is held, Existentialism could well benefit from a more attentive consideration of science, which it has viewed until now only as a preparatory, imperfect, and objectifying knowledge in comparison with the authentic understanding of Being, which it considers to be a more fundamental mode of the being of man in the world. Science, it is submitted, offers today the example of an extensive and coherent use of the concept of the possible in the key no-

tions that it employs, especially in those branches that are interdisciplinary—among them such notions as indeterminacy, chance, probability, field, model, project, structure, and conditionality.

Some steps in this direction have been taken by Abbagnano and by Merleau-Ponty. According to the latter, considerations of probability are rooted in the being of man, inasmuch as he is situated in the world and invested with the ambiguity of his events. Merleau-Ponty has written in his *Phénoménologie de la perception* (1945):

Our freedom does not destroy our situation, but is engaged with it. The situation in which we live is open. This implies both that it appeals to modes of privileged resolution and that it is of itself powerless to obtain one of them.

From this point of view, there is always a certain freedom in situations, although its degree varies from situation to situation.

Significance of Being and transcendence. Among the thinkers most frequently mentioned here, the concept of the necessity of Being prevails as the basis of their metaphysical or theological orientations. Heidegger has come more and more to insist on the massive presence of Being in the face of human existence, by attributing to Being all initiative and to man only the possibility of abandoning himself to Being and to the things that are the modes of the language of Being. For Heidegger, Being is interpreted better through the etymology of those words that designate the most common things of daily life than through the analysis of existential possibilities. Jaspers has seen the revelation of transcendence in ciphers—*i.e.*, in persons, doctrines, or poems—all of which can be interpreted as symbols of existential situations and above all of limit situations, the insurmountability of which, in provoking the total “shipwreck” of human possibilities, makes man feel the presence of absolute transcendence. In a less philosophically elaborate form, Being has been understood as mystery by Marcel; as the perfect actuality that guarantees the existential possibilities by Louis Lavelle, a leader of the French *philosophie de l’esprit*; and as the absolute value that man encounters in his own spiritual intimacy by René Le Senne, also of the *philosophie de l’esprit*.

Problems of Existentialist theology. Existentialism has a theological dimension. Though Heidegger rejects the label of atheist, he also denies to the Being of which he speaks the essential qualifications of divinity, inasmuch as it is not the ultimate cause and the Good. But Jaspers, in his last writings, emphasized more and more the religious character of faith in transcendence. Faith is the way to withdraw from the world and to resume contact with the Being that is beyond the world. Faith is life itself, in that it returns to the encompassing Whole and allows itself to be guided and fulfilled by it. Jaspers has even developed a theology of history. He speaks of an axial age, which he places between the 8th and 2nd centuries before Christ, the age in which the great religions and the great philosophers of the Orient arose—Confucius and Lao-tzu, the *Upanishads*, Buddha, Zoroaster, the great prophets of Israel—and in Greece the age of Homer and of classical philosophy as well as Thucydides and Archimedes. In this age, for the first time, man became aware of Being in general, of himself, and of his limits. The age in which man now lives, that of science and technology, is perhaps the beginning of a new axial age that is the authentic destiny of man but a destiny that is far off and unimaginable.

For Bultmann, the theologian of the demythologization of Christianity, inauthentic existence is tied to the past, to fact, to the world, while authentic existence is open to the future, to the nonfact, to the nonworld; *i.e.*, to the end of the world and to God. Thus, authentic existence is not the self-projection of man in the world but, rather, the self-projection of man in the love of and obedience to God. But this self-projection is no longer the work of human freedom; it is the saving event that enters miraculously through faith into the future possibilities of man.

In these theological speculations and in others that are comparable, the common presupposition of the Existentialists is recognized—*i.e.*, the gap between human existence and Being. There is either an acknowledgment of that gap, with existence assuming the role of the demonic

between
possibility
and reality

Aesthetic,
ethical,
and
religious
levels

(the alternative that Sartre and others have all illustrated above all in their literary works), or an acknowledgment of the hidden participation of human existence in Being through a gratuitous initiative on the part of Being.

Kierkegaard had earlier distinguished three stages of existence between which there is neither development nor continuity but gaps and jumps: the aesthetic stage is the one in which one lives for the pleasure of the moment; the ethical stage is the one based on the stability and continuity of life in work and in matrimony; and the religious stage is the one characterized by faith, which is always a "dreadful certainty"—i.e., a dread that becomes certain of a hidden relationship with God.

The ethical and religious stages correspond roughly to what Heidegger and Jaspers call, respectively, the inauthenticity and the authenticity of existence. Art is not as a rule recognized by contemporary Existentialists as an autonomous stage; it is almost always for them an essential manifestation of existence itself. For Jaspers, it is a mode of reading in nature, in history, and in men the cipher of transcendence; i.e., the negative symbol in which transcendence is revealed. According to Camus, it is an aspect of man's revolt against the world. The artist tries to remake the sketch of the world that is before him and to give it the style—that is to say, the coherence and unity—that it lacks. For this purpose, he selects the elements of the world and freely combines them in order to create a value that escapes man continuously but that the artist perceives and tries to salvage from the flux of history.

From this point of view, art would be a way of reshaping the world beyond its factual forms, in order that it might show their negative and troublesome characteristics. The directions of contemporary art that have deliberately forsaken the imitation of reality find their justification in this point of view.

SOCIAL AND HISTORICAL PROJECTIONS OF EXISTENTIALISM

The metaphysical or theological dimension of Existentialism does not leave man with nothing to do. Once the nullity of the existential possibilities is recognized, man cannot but resign himself to Being, which, in one of its new manifestations in the world or beyond it, conducts him to a new epoch. Even someone like José Ortega y Gasset, the leading Spanish Existentialist and writer, who, in examining the social aspects of existence, has characterized the present epoch by the advent of the masses and the socialization of man, has halted at the recognition of the crisis and the total uncertainty that dominates the future of man (*La rebelión de las masas* [1929; *The Revolt of the Masses*, 1932]).

On the other hand, humanistic Existentialism has recognized the positive and the to-some-degree determining function that man may have in history. It has insisted, as in Merleau-Ponty, on man's duty to assume the responsibility of an effective action for the transformation of society and, in general, of the world that he inhabits.

Along this line of assuming responsibility, Existentialism has moved toward Marxism, with which it shares the diagnoses of existence as the primordial and ineradicable relationship of man with nature and with society. In the *Critique de la raison dialectique* (1960; "Critique of Dialectical Reason"). Sartre attempted a synthesis between Existentialism and Marxism by modifying the notion of "project" that he defended in *L'Être et le néant* and by utilizing the notion of dialectic as understood by Marx. The project of which existence consists is not the result of an arbitrary choice (as Sartre had previously maintained); it is, instead, that of a conditioning by the objective possibilities that Sartre identifies (as does Marx) with "the material conditions of existence." The project remains, however, that of the particular individual of a unique consciousness—but of a consciousness that tries to become totalized; i.e., to enter into relationship with others so as to constitute, with others, human groups that are more and more comprehensive. In this manner it tends toward a complete and definitive totalization without appeals. Dialectical reason would be precisely such a process of growing totalization; and it becomes, moreover, the true protagonist of history and becomes that with which the

interior freedom of any individuals who participate in history is identified.

From the defense of the freedom of the individual, Sartre has thus moved to the defense of the absolute dialectical necessity of history despite its being interiorized and lived by individuals. A historical project of human life that tries to remove the characteristics of inauthenticity or of alienation from existence—a project that may bring Existentialism and Marxism close together—thus ends by losing, in this form, its risky and problematic character and the awareness of the conditions and the modalities of its realization. These features are also lost in the "transcendental project" of a new society elaborated by one of the leaders of the New Left, the German-born American Herbert Marcuse. While insisting on the requirement that the "transcendental project" be "in accord with the real possibilities open at the attained level of the material and intellectual culture," Marcuse entrusts its realization to an impersonal and contemplative Reason, which cannot but invite the "great refusal" of contemporary society.

Having developed in different and contrasting directions, Existentialism has furnished philosophy and the whole of contemporary culture with conceptual tools, of which the nature and techniques of employment have still not been clarified—as, for example, terms like "problematicity," "chance," "condition," "choice," "freedom," and "project." Although these tools can be employed usefully for the interpretation of existence—i.e., to orient philosophical inquiry in the fields of epistemology, ethics, aesthetics, education, and politics—it is nonetheless indispensable that the pivot on which they turn, "possibility," be granted its own ontological status that does not reduce it either to Nothingness or to Being. It is indispensable, moreover, that a positive datum be perceived in possibility, a datum that is verifiable with appropriate techniques and that, while not offering infallible guarantees, allows man to project and to act in the world with calculated risks and with a prudent trust. (N.Ab.)

Idealism

As a philosophical term, Idealism refers to any view that stresses the central role of the ideal or the spiritual in man's interpretation of experience. It may hold that the world or reality exists essentially as spirit or consciousness, that abstractions and laws are more fundamental in reality than sensory things, or, at least, that whatever exists is known to man in dimensions that are chiefly mental—through and as ideas. Thus the two basic forms of Idealism are metaphysical Idealism, which asserts the ideality of reality, and epistemological Idealism, which holds that in the knowledge process the mind can grasp only the psychic or that its objects are conditioned by their perceptibility. In its metaphysics, Idealism is thus directly opposed to Materialism, the view that the basic substance of the world is matter and that it is known primarily through and as material forms and processes; and in its epistemology, it is opposed to Realism, which holds that in human knowledge objects are grasped and seen as they really are—in their existence outside and independently of the mind. As a philosophy often expressed in bold and expansive syntheses, Idealism is also opposed to various restrictive forms of thought: to Skepticism, with occasional exceptions as in the British Hegelian F.H. Bradley (1846–1924); to Positivism, which stresses observable facts and relations as opposed to ultimates and therefore spurns the speculative "pretensions" of every metaphysics; and often to atheism, since the Idealist commonly extrapolates the concept of mind to embrace an infinite Mind. The essential orientation of Idealism can be sensed through some of its typical tenets: "Truth is the whole, or the Absolute"; "to be is to be perceived"; "reality reveals its ultimate nature more faithfully in its highest qualities (mental) than in its lowest (material)"; "the Ego is both subject and object."

APPROACHES TO UNDERSTANDING IDEALISM

What Idealism is may be clarified by approaching it in three ways: through its basic doctrines and principles,

Contrasts
with
opposing
schools

Sartre's
synthesis
of Exis-
tentialism
and
Marxism

Six core concepts

through its central questions and answers, and through its significant arguments.

Basic doctrines and principles. Six common, basic conceptions distinguish Idealistic philosophy:

The union of individuality and universality. Abstract universals, such as “canineness,” which express the common nature or essence that the members of a class (e.g., individual dogs or wolves) share with one another, are acknowledged by all philosophers. Many Idealists, however, emphasize the concept of a concrete universal, one that is also a concrete reality, such as “mankind” or “literature,” which can be imagined as gatherable into one specific thing. As opposed to the fixed, formal, abstract universal, the concrete universal is essentially dynamic, organic, and developing. Thus universality and individuality merge.

The contrast between contemporaneity and eternity. While most philosophers tend to focus on matters of contemporary concern, Idealists always seek a much wider perspective that embraces epochs and eras in the broad sweep of history. In the words of the 17th-century Rationalist Spinoza, they strive to view the contemporary world “under the aspect of eternity.” Thus, in spite of the extensive formative influence of culture, Idealists claim that their philosophy transcends the parochialism of a particular culture; and Idealisms are found, in fact, in all of the major cultures of the world.

The doctrine of internal relations and the coherence theory of truth. It seems natural to suppose, as non-Idealists usually do, that the consideration of two things in their relatedness to one another can have no effect on the things themselves—i.e., that a relation is something in addition to the things or terms related and is thus external. On this basis, truth would be defined as a relation of correspondence between a proposition and a state of affairs. The Idealist believes, however, that reality is more subtle than this. The relationship between a mineral deposit and the business cycle, for example, is an internal one: the deposit changes to an ore when prices render it profitable to mine the mineral. Similarly, it is part of the essence of a brick that it is related to a wall or pavement. Thus terms and relations logically determine one another. Ultimate reality is therefore a system of judgments or propositions, and truth is defined in terms of the coherence of these propositions with one another to form a harmonious whole. Thus a successful spy is judged either a hero or a villain only in relation to a total system of international relations, an accepted philosophy of history, and the moral judgments involved. There are therefore degrees of reality and degrees of truth within a system of truth cohering by internal relations, and the truth of a judgment reflects its place in this system.

The dialectical method. Idealism seeks to overcome contradictions by penetrating into the overall coherent system of truth and continually creating new knowledge to be integrated with earlier discoveries. Idealism is thus friendly to all quests for truth, whether in the natural or behavioral sciences or in art, religion, and philosophy. It seeks the truth in every positive judgment and in its contradictory as well. Thus it uses the dialectical method of reasoning to remove the contradictions characteristic of human knowledge. Such removal leads to a new synthetic judgment that incorporates in a higher truth the degree of truth that was present in each of the two lower judgments.

The centrality of mind in knowledge and being. Idealism is not reductive, as are opposing philosophies that identify mind with matter and reduce the higher level of reality to the protons and electrons of mathematical physics. On the contrary, Idealism defends the principle that the lower is explained by the higher—specifically, that matter can be explained by mind but that mind cannot be explained by matter. The word spirit can be substituted for “mind” or even placed above it; and “Spiritualism” is often used, especially in Europe, as a synonym for Idealism.

The transmutation of evil into good. Nearly all Idealists accept the principle that the evils with which man has to deal may become ingredients in a larger whole that overcomes them. The eminent American Hegelian Josiah Royce (1855–1916) held that the larger whole is the Absolute Mind, which keeps evils under control as a man

might hold a viper under the sole of his boot. Along with this doctrine of the sublimation or transmutation of evil, Royce incorporated into his metaphysics a point from the 19th-century irrationalism of Schopenhauer, itself a voluntaristic form of Idealism, viz., that “the world is my idea.” Schopenhauer, however, was probably the only Idealist who defended the converse principle that good is transmuted into evil.

Basic questions and answers. In defining philosophical Idealism in its historical development as a technical metaphysical doctrine, three most difficult and irreducible questions arise. From the efforts to answer these questions there has been created an extensive literature that is the corpus of philosophical Idealism.

Ultimate reality. The first of the three questions is metaphysical: What is the ultimate reality that is given in human experience? Historically, answers to this question have fallen between two extremes. On the one hand is the Skepticism of the 18th-century Empiricist David Hume, who held that the ultimate reality given in experience is the moment by moment flow of events in the consciousness of each individual. This concept compresses all of reality into a solipsistic specious present—the momentary sense experience of one isolated percipient. At the other extreme, followers of the 17th-century Rationalist Spinoza adopted his definition of ultimate substance as that which can exist and can be conceived only by itself. According to the first principle of his system of pantheistic Idealism, God, or Nature, or Substance is the ultimate reality given in human experience. Hegel said that this dogmatic absolutism was the lion’s den into which all tracks enter and from which none ever returns. In answering the first question, most philosophical Idealists steer between Hume and Spinoza and in so doing create a number of types of Idealism, which will be discussed below.

The given. The second question to arise in defining Idealism is: What is given? What results can be obtained from a logical interpretation and elaboration of the given? According to Idealists the result, though it is frequently something external to individual experience, is, nevertheless, a concrete universal, an order system (like the invisible lattice structure of a crystal), or an ideality in the sense explained earlier. In Hegel’s words: “What is real is rational, and what is rational is real.” Idealists believe that the collective human spirit of intellectual inquiry has discovered innumerable order systems that are present in external, nonhuman reality, or nature, and that this collective creative intelligence has produced the various sciences and disciplines. This production has required a long period of time called history. But history was antedated by the achievements of ancestors who created languages and religions and other primitive institutions. Consequently, the logical interpretation and elaboration of the given is actually the complete transformation of the earth by its various inhabitants; so that the moon flights portend a similar transformation of the planetary system. An inherent part of the collective intelligence is the spiritual force that Idealists call the spirit of philosophy.

Change. The third question is: What position or attitude is a thinker to take toward temporal becoming and change, and toward the presence of ends and values within the given? According to Idealists, reason not only discovers a coherent order in nature but also creates the state and other cultural institutions, which together constitute the cultural order of a civilized society. Idealistic political philosophers recognize the primacy of this cultural order over the private order or family and over the public order—the governing agencies and economic institutions. The conservation and enhancement of the values of all three orders is the basic moral objective of every civilized people. A useful distinction drawn by the German philosopher Ernst Cassirer (1874–1946), a member of the late 19th- and 20th-century Marburg school of Neo-Kantianism (see below), between the efficient energies and the formative energies of a people emphasizes the way in which these moral forces function: the efficient energies are the conserving, and the formative are the creative forces in society. It is on the basis of this distinction that Idealists have made a contribution to international ethics,

Meta-physical and logical issues

Order and value in nature and society

which charges that no nation has a right to use its efficient energies to exercise power over another civilized people except to further the formative energies of that people, to enrich their cultural order. Ethically, then, there can be no power over without power for; economic exploitation is wrong.

Modern Idealists have also created an Idealistic philosophy of history. An eminent early 20th-century Italian Idealist, Benedetto Croce (1866–1952), expressed it in the formula “every true history is contemporary history”; and at the same time in France a subjective Idealist, Léon Brunschvicg (1869–1944), agreed. There are close relations between the philosophy of history and the philosophy of values.

Basic arguments. Idealists delight in arguments. They agree with Socrates and Plato in thinking that every philosopher should follow the argument wherever it leads, and, like them, they believe that it will eventually lead to some type of Idealism. Four basic arguments found in the literature of Idealism may be briefly summarized.

Epistemo-
logical
issues

The esse est percipi (to be is to be perceived) argument of Berkeley. According to this argument all of the qualities attributed to objects are sense qualities. Thus hardness is the sensing of a resistance to a striking action, and heaviness is a sensation of muscular effort when holding the object in one's hand, just as blueness is a quality of visual experience. But these qualities exist only while they are being perceived by some subject or spirit equipped with sense organs. A classical 18th-century British Empiricist, George Berkeley (1685–1753), rejected the idea that sense perceptions are caused by material substance, the existence of which he denied. Intuitively he grasped the truth that “to be is to be perceived.” The argument is a simple one, but it has provoked an extensive and complicated literature, and to some contemporary Idealists it seems irrefutable.

The reciprocity argument. Closely related to the *esse est percipi* argument is the contention that subject and object are reciprocally dependent upon each other. It is impossible to conceive of a subject without an object, since the essential meaning of being a subject is being aware of an object and that of being an object is being an object to a subject, this relation being absolutely and universally reciprocal. Consequently, every complete reality is always a unity of subject and object—i.e., an immaterial ideality, a concrete universal.

The mystical argument. In the third argument, the Idealist holds that in man's most immediate experience, that of his own subjective awareness, the intuitive self can achieve a direct apprehension of ultimate reality, which reveals it to be spiritual. Thus the mystic bypasses normal cognition, feeling that, for metaphysical probings, the elaborate processes of mediation interposed between sense objects and their perceptions reduces its reliability as compared to the direct grasp of intuition.

It is significant that the claims of this argument have been made by numerous thinkers, in varying degrees Idealistic and mystical, living in different periods and in different cultures. In ancient Greece, for example, it was made by Plato, to whom the final leap to the Idea of the Good was mystical in nature. In Indian Hindu Vedānta philosophy it was made by the 9th-century monistic theologian Śāṅkara, by the 12th-century dualistic Brahmin theist Rāmānuja, and by the recent philosopher-president of India Sarvepalli Radhakrishnan. In Buddhism the claims were made by the sometimes mystical, extreme subjectivism of the Vijñānavāda school of Mahāyāna (represented by Aśvaghōṣa in the 1st and Asaṅga in the 4th century) and in China by the Ch'an school and by the 7th-century scholar Hui-neng, author of its basic classic *The Platform Scripture*. In Islāmic lands it was made by Sūfis (mystics)—in particular, by the 13th-century Persian writer Jalāl ad-Dīn ar-Rūmī. And in the recent West it was made by several distinguished Idealists: in Germany, by the seminal modern theologian Friedrich Schleiermacher (1768–1834); in France, by the evolutionary intuitionist Henri Bergson (1859–1941), by the philosopher of action Maurice Blondel (1861–1949), and by the Jewish religious Existentialist Martin Buber (1878–1965); and in English-

speaking countries, by the Scottish metaphysician James Frederick Ferrier (1808–64) and the American Hegelian William E. Hocking (1873–1966).

The ontological argument. This famous argument originated as a proof of the existence of God. It came to the 11th-century Augustinian, St. Anselm of Canterbury, as an intuitive insight from his personal religious experience that a being conceived to be perfect must necessarily exist, for otherwise he would lack one of the essentials of perfection. God's perfection requires his existence. Some Idealist philosophers have generalized the argument to prove Idealism. They distinguish conceptual essences that exist only in the intellect from categorial essences that actually exist *in re* (in the thing). Every actual reality, therefore, is a unity of one or more categorial essences and existence; and again, this means that it is an immaterial ideality or concrete universal. According to Hegel “the ideality of the finite” is “the main principle of philosophy.”

TYPES OF PHILOSOPHICAL IDEALISM

Several types of Idealism have already been distinguished. Some modern types should now be mentioned, classified first by cultures and then by branches of philosophy.

Types classed by culture. Cultural differences suggest a division into Western and Oriental Idealisms.

Western types. Berkeley's Idealism is called subjective Idealism because he reduced reality to spirits (his name for subjects) and the ideas entertained by spirits. In Berkeley's philosophy the apparent objectivity of the world outside the self was accommodated to his subjectivism by claiming that its objects are ideas in the mind of God. The foundation for a series of more objective Idealisms was laid in the late 18th century by Immanuel Kant, whose epochal work *Kritik der reinen Vernunft* (2nd ed., 1787; *Critique of Pure Reason*, 1929) presented a formalistic or transcendental Idealism, so named because Kant thought that the human self, or “transcendental ego,” constructs knowledge out of sense impressions, upon which are imposed certain universal concepts that he called categories. Three systems constructed in the early 19th century by, respectively, the moral Idealist J.G. Fichte, the aesthetic Idealist F.W.J. Schelling, and the dialectical Idealist G.W.F. Hegel, all on a foundation laid by Kant, are called objective Idealisms in contrast to Berkeley's subjective Idealism. The designations, however, are not consistent; and when the contrast with Berkeley is not at issue, Fichte himself is often called a subjective Idealist, inasmuch as he exalted the subject above the object, employing the term Ego to mean God in the two memorable propositions: “The Ego posits itself” and “The Ego posits the non-Ego (or nature).” And in contrast now to the subjective Idealism of Fichte, Schelling's is called an objective Idealism and Hegel's an absolute Idealism.

All of these terms form backgrounds for contemporary Western Idealisms, most of which are based either on Kant's transcendental Idealism or on those of Fichte, Schelling, and Hegel. Exceptions are those based on other great Idealists of the past—Plato, Plotinus, Spinoza, Leibniz, and others. A revised form of Spinoza's spiritual monism, for example, which held that reality is one Substance to be identified with God, has been formulated by the Idealist logician H.H. Joachim (1868–1938), a follower of the British Hegelian F.H. Bradley.

Unwilling to accept any of the above titles, one school of modern Idealists adopted the motto “Back to Kant” and are thus called Kantian Idealists. Edward Caird (1835–1908), who imported German Idealism into England, and the German philosopher of “As If,” Hans Vaihinger (1852–1933), who held that much of man's so-called knowledge reduces to pragmatic fictions, were Kantian Idealists or transcendentalists. On this tradition are based the Idealism of the austere religious essayist Thomas Carlyle (1795–1881) in *Sartor Resartus* (1833–34) and the New England transcendentalism of Ralph Waldo Emerson (1803–82). It must be stated, however, that Kant preferred the name critical Idealism to that of transcendental Idealism.

Another group of Idealists, adopting the motto “From Kant forward,” founded the so-called Marburg school of Neo-Kantian, or scientific, Idealism. They rejected the

Subjective,
transcendental,
objective,
and
absolute
Idealisms

Kantian
and
theistic
Idealisms

Idealisms of Fichte, Schelling, and Hegel and the classical Newtonian dynamics presupposed by Kant and built instead upon the new quantum and relativity theories of modern physics. Founded by Hermann Cohen (1842–1918), champion of a new interpretation of Kant, and his colleague, the Platonic scholar Paul Natorp (1854–1924), who applied Kant's critical method to humanistic as well as to scientific studies, this school underwent a remarkable development, especially under the leadership of Ernst Cassirer, noted for his profound analyses of man defined as that animal that creates culture through a unique capacity for symbolic representation. The Russian novelist Boris Pasternak, in his *Autobiography*, tells of enrolling in Cohen's graduate seminar on Kant at the University of Marburg. Undoubtedly this type of Idealism continues to wield considerable influence on intellectuals in Soviet Russia.

Theistic Idealism was founded by the medical instructor R.H. Lotze (1817–81), who became a broadly learned metaphysician and whose theory of the world ground, in which all things find their unity, has been widely accepted by theistic philosophers and Protestant theologians. To Lotze, the world ground is the transcendent synthesis of an evolutionary world process, which is both mechanical and teleological (purposive); it is an infinite spiritual being, or God. In England, the absolute Idealism of T.H. Green (1836–82), a philosopher influenced chiefly by Plato and Kant, was shared by his disciple, the more Hegelian thinker Bernard Bosanquet (1848–1923), whose views are based upon Lotze's Idealism, and by the somewhat skeptical metaphysician of the movement, F.H. Bradley (1846–1924).

Theistic absolutism is represented by a pioneer of contemporary philosophical theology, F.R. Tennant (1866–1957), and by the eminent German-American theologian Paul Tillich (1886–1956). It differs from the personalistic form of absolute Idealism in accepting the traditional theological monotheism that is essential to the Jewish, Christian, and Islāmic religions. It revives classic arguments for the existence of God that were rejected by Kant and uses recent advances in the physical, biological, and behavioral sciences to support these revisions. The cosmological argument, for example, is restated as the continuing relation of the cosmos to a world ground that is spiritual in essence; thus the concept of God as a first cause is rejected. The concept of the fitness of the environment to life and to human history and other recent scientific concepts are used to modernize the teleological argument. Nevertheless, all of this revision is kept within the framework of Idealistic metaphysics and epistemology. A theistic spiritual pluralism, which interprets reality in terms of a multitude of interacting psychic monads (elementary units), was developed by the English philosopher James Ward (1843–1925). On the other hand, an atheistic spiritual pluralism, which holds that reality consists entirely of individual minds and their contents, was espoused by the Cambridge Hegelian J.M. Ellis McTaggart (1866–1925).

During the late 19th century a movement known as American Hegelian Idealism arose in the United States. The movement found vigorous early expression in the work of W.T. Harris (1835–1909), central figure in a mid-western group of scholars known as the St. Louis school and editor of its *Journal of Speculative Philosophy*, and finds current expression in the recently organized Hegel Society of America. In its later development, American Idealism split into two branches: one, of the aforementioned Bradley–Bosanquet type, and a second, of the Royce–Hocking type, so called because it was founded by one of America's most distinguished philosophers, the absolute Idealist and personal pantheist Josiah Royce (1855–1916), and developed by his disciple W.E. Hocking (1873–1966). The American philosopher of religion Borden Parker Bowne (1847–1910) founded another important American school, that of Personalism, a Kantian- and Lotzean-based variety of theistic Idealism similar to the spiritual pluralism of Ward. Whereas most previous Idealisms had stressed the rational as the highest category of reality and hence as its paradigm, Personalism saw in the centred structures of personhood, both finite and

infinite, an even higher category, displaying dimensions richer than the rational alone. Personalism has had an influential development in America, most notably through the Methodist philosopher E.S. Brightman (1884–1953), known for his defense of the doctrine of a finite God, and through *The Personalist*, edited by one of Bowne's disciples, R.T. Flewelling (1871–1960). Personalism is also found in the French philosopher C.B. Renouvier (1815–1903) and in several Latin American philosophers.

To the above types should be added the vitalism or creative evolutionism of the French anti-intellectualist Henri Bergson (1859–1941), which first found in the apprehension of subjective time a more valid insight into reality than in that of an objective space-time order and then, extending this metaphysics to the cosmic level, discerned there an Idealistic *élan vital* (or vital impetus) that is more fundamental than matter, which subsequently appeared in the role of a husk born of the mechanization of the *élan*. In this same tradition, the voluntarism of Maurice Blondel (1861–1949), a unique theory of belief in God as a live option that must be deliberately willed by the self before it can be found to be true in experience, is an important contribution to Idealistic philosophy. Miguel de Unamuno y Jugo (1864–1936), a Spanish philosopher, developed a unique type of Idealism, more literary than philosophical. He stressed the significance of each individual and argued for personal immortality.

Eastern types. For centuries, philosophical Idealism has dominated the philosophy of India. An Idealism that is quite influential in Japan is that of Nishida Kitarō, a distinguished Berlin-trained philosopher. Prior to World War II, Kitarō created a system of absolute Idealism that employed the dialectical method of Hegel to clarify the Zen Buddhist doctrine of nothingness, which, in his view, is that of which all phenomenal existences are determinations and in which they all appear.

Some classical types of Indian and Chinese Idealism were considered above (see *The mystical argument*). A number of gifted Indian and Chinese scholars have restated and revitalized the principles and arguments of classic Oriental Idealisms in an extensive literature.

Probably the major recent proponent of Indian Idealism has been Radhakrishnan, who has spent a long lifetime expounding and defending its mystical types and has presented authoritative analyses of all of its classical systems. He saw his modernized Idealism as destined to save civilization from exploitation by Western commercial technology. Surendranath Dasgupta, an outstanding Sanskrit and Pāli scholar, in a monumental work, has revived the classic systems of Indian Idealism, concluding that "Idealism has not only been one of the most dominant phases of Indian thought in metaphysics, epistemology, and dialectics, but it has also very largely influenced the growth of the Indian ideal as a whole." Ghose Aurobindo, reinterpreting the Indian Idealistic heritage in the light of his own Western education, rejected the *māyā* doctrine of illusion, replacing it with the concept of evolution. Arguing that the "illumination of individuals will lead to the emergence of a divine community," Aurobindo founded the influential Pondicherry Ashram, a religious and philosophical community, and headed it until his death. Late in the 19th century, Swami Vivekananda, a spiritual monist, promulgated the Idealistic philosophy of mystical Brahmanism in lectures on the Vedānta delivered and published widely.

The inwardness of subjectivity of Indian Idealism has been contrasted with the outwardness of Western objective Idealism, and a synthesis of the two has been advocated in comparative studies made by P.T. Raju, an Indian philosopher who has taught both in Indian universities and in the U.S.

Prior to World War II, Sir Rabindranath Tagore, a distinguished Hindu Idealist poet and Nobel laureate, contributed to what Dasgupta has called the "Indian ideal as a whole." A selection from Tagore's aphorisms will convey its spirit:

Let your life lightly dance on the edges of Time like dew on the tip of a leaf.
Our little heaven, where dwell only two immortals, is too absurdly narrow.

Indian
Idealism

Hegelian
Idealism,
Person-
alism,
and other
Idealisms

Is it then true that the mystery of the Infinite is written on this little forehead of mine?
Where is this hope for human except in thee my God?
Raise my veil and look at my face proudly, O Death, my Death.
All is done and finished in the eternal Heaven. But Earth's flowers of illusion are kept externally fresh by death.
If my claims to immortal fame after death are shattered, make me immortal while I live.
This I know that the moment my God has created me he has made himself mine.

Chinese
Idealism

In addition to the Ch'an and Hui-neng schools mentioned above (see *The mystical argument*), three other notable Idealistic schools have flourished in China. Representing one wing of the Neo-Confucian movement of the 11th and 12th centuries, Ch'eng Hao and his disciple, the rationalist Chu Hsi, developed a dualistic philosophy that has been compared to Cartesianism. In this view, however, reason takes precedence over matter and the two together are the primary cause of the universe or the absolute; thus this view is essentially Idealistic. At the turn of the 15th century, a more purely Idealistic school arose—forming the other wing of Neo-Confucianism—under the leadership of Wang Yang-ming, who, having had an inner experience of enlightenment, sought to understand the cosmos within his own mind and heart. The third school is that of the 20th-century Idealist Hsueh Shih-li, who, borrowing to some extent from Wang Yang-ming, proclaimed a “new doctrine of consciousness only,” of which the basic ideas are the unity of substance and function and the primacy of the original Mind. To Hsueh Shih-li, reality and all of its manifestations are one, and the original Mind is will and consciousness as well as reason.

Types classed by branches of philosophy. Another way of classifying Idealisms is to use branches of philosophy to distinguish the various types. Such types, however, overlap those given above.

Metaphysical,
epistemological,
and
axiological
Idealisms

A term that covers several of the above types (the spiritual, theistic, and Hegelian; Personalism; vitalism) is metaphysical Idealism. A.N. Whitehead (1861–1947), noted for his collaboration with Bertrand Russell in mathematical logic and for his process metaphysics, who was profoundly influenced by Bradley, created an original Idealistic philosophy of science, a highly complicated form of metaphysical Idealism; and the leading metaphysician Charles Hartshorne (1897–) may be regarded as a representative of Whiteheadian Idealism, although rightly claiming originality. Epistemological Idealism, of which the Kantian scholar N.K. Smith's (1872–1958) *Prolegomena to an Idealist Theory of Knowledge* is an excellent example, covers all Idealistic theories of epistemology, or knowledge. Aesthetic Idealism is devoted to philosophical theories of beauty in nature and in all forms of art. Because Schelling claimed that art is the best approach to an understanding of philosophy, his system is designated aesthetic Idealism. Axiological Idealism is a name referring to such philosophies as those of Wilbur M. Urban (1873–1952) and others who have developed Idealistic theories of value and valuation. Ethical Idealism deals with moral values, rights, and obligations. Several of the above-mentioned philosophers, such as Fichte and Green, as well as the Plato scholar A.E. Taylor (1864–1945), the theistic pluralist Hastings Rashdall (1858–1924), and the absolutist W.R. Sorley (1855–1935), could be called ethical Idealists in the sense that they have produced well-thought-out systems of ethics. The writings of the German philosopher of life and action Rudolf Eucken (1846–1926) provide an excellent example of ethical Idealism.

These classifications are not exhaustive. The actual existence of so many types of philosophical Idealism, however, proves its fertility and ubiquity.

CRITICISM AND APPRAISAL

Obviously, some of the types of Idealism in the above classifications conflict with one another. For example, spiritual monism and spiritual pluralism are opposite types; Personalism rejects absolute Idealism; and atheistic spiritual pluralism is in sharp conflict with theistic spiritual pluralism. These and other debatable issues keep Ideal-

ists in dialogue with each other, but each type tends to preserve itself.

Over against these internal disputes stand the criticisms of the anti-Idealists. The wide-ranging Realist Ralph Barton Perry's (1876–1957) article “The Ego-Centric Predicament” (1910) is a widely discussed criticism. Perry admitted that the primary approach of every philosopher to the problem of ultimate reality must be through his own thought, using his own ideas; but this is a human predicament that has been unjustifiably exploited by the Idealists, according to Perry, and turned into the “fallacious” *esse est percipi* argument.

The famous “Refutation of Idealism” prepared by the meticulous Cambridge philosopher G.E. Moore (1873–1958) and a similar refutation by the Realist Bertrand Russell (1872–1970) rest upon the distinction between a subject's act of perceiving and the perceptual object of this act, which they both called a “sense datum.” They claimed that Berkeley's *esse est percipi* argument is vitiated by his failure to make this distinction.

Logical Positivism claims that a basic weakness in Idealism is its rejection of the doctrine of empirical verifiability, according to which every proposition that claims to be true must be verified by searching out the sense experience in which its terms originated. Linguistic philosophy attacks Idealism by making a detailed analysis of its more technical terms in an effort to prove that they are full of ambiguities and double meanings. Critics have also severely attacked the ontological and the mystical arguments for Idealism. Karl Marx (1818–83) and his followers borrowed and adapted the dialectical argument of Hegel and used it effectively to develop dialectical Materialism, an archenemy of all Idealisms. Buttressed by the political endorsements of various Communist regimes, Marxism (*q.v.*) poses a formidable opposition to Idealism; and even in the non-Communist countries of Europe it presents a significant cultural alternative to spiritualism and Thomism.

Idealists consider all of the foregoing criticisms to be external. Instead of answering them in detail, some Idealists prefer to challenge the critics to make really constructive efforts to build an adequate substitute for Idealism—a system to be reached by seriously working at the problems from within philosophy. So far a satisfactory substitute has not been achieved. To produce such a substitute would require careful reconsideration of the arguments of at least some of the above Idealistic systems.

In evaluating the effects of these criticisms and attacks, the question remains: Will they succeed in eradicating philosophical Idealism? Although it is now on the wane, at least in Western culture, the great Idealist tradition has survived many other historic periods of turmoil and has often been reborn in prolonged periods of settled and peaceful social conditions. Will it rise again? Only the future holds the answer. But Idealism shows evidence of being, perhaps, a reflection of some permanent aspect of the human spirit, and it may then be a perennial philosophy. In any case, it seems highly unlikely that such a rich heritage of philosophical thought will vanish entirely.

(D.S.R.)

Materialism

The word Materialism has been used in modern times to refer to a family of metaphysical theories (*i.e.*, theories on the nature of reality) that can best be defined by saying that a theory tends to be called Materialism if it is felt sufficiently to resemble a paradigmatic theory that will here be called mechanical Materialism. This section covers the various types of Materialism and the ways by which they are distinguished and traces the history of Materialism from the Greeks and Romans to modern and contemporary Materialisms.

TYPES OF MATERIALIST THEORY

Mechanical Materialism is the theory that the world consists entirely of hard, massy material objects, which, though perhaps imperceptibly small, are otherwise like such things as stones. (A slight modification is to allow

Perry,
Moore,
Positivism,
Marxism

Prognosis

the void—or empty space—to exist also in its own right.) These objects interact in the sort of way that stones do: by impact and possibly also by gravitational attraction. The theory denies that immaterial or apparently immaterial things (such as minds) exist or else explains them away as being material things or motions of material things.

Physical-
istic,
deistic,
emergent,
and
epiphe-
nomenal
types

Types distinguished by departures from the paradigm. In modern physics (if interpreted realistically), however, matter is conceived as made up of such things as electrons, protons, and mesons, which are very unlike the hard, massy, stonelike particles of mechanical Materialism. In it the distinction between matter and energy has also broken down. It is therefore natural to extend the word Materialist beyond the above paradigm case (of mechanical Materialism) to cover anyone who bases his theory on whatever it is that physics asserts ultimately to exist. This sort may be called physicalistic Materialism. Such a Materialist allows the concept of material thing to be extended so as to include all of the elementary particles and other things that are postulated in fundamental physical theory—perhaps even continuous fields and points of space-time. Inasmuch as some cosmologists even try to define the elementary particles themselves in terms of the curvature of space-time, there is no reason why a philosophy based on such a geometrized cosmology should not be counted as Materialist, provided that it does not give an independent existence to nonphysical things such as minds.

Another sort of departure from the paradigm leads in the direction of what might be called a deistic Materialism. In this view it would be allowed that, although there is a spiritual Creator of the universe, he does not interfere with the created universe, which is itself describable in terms of mechanical or physicalist Materialism.

Still another departure from the paradigm is the theory that holds that everything is composed of material particles (or physical entities generally) but also holds that there are special laws applying to complexes of physical entities, such as living cells or brains, that are not reducible to the laws that apply to the fundamental physical entities. (To avoid inconsistency, such a theory may have to allow that the ordinary laws of physics do not wholly apply within such complex entities.) Such a theory, which could be called “emergent Materialism,” can shade off, however, into theories that one would not wish to call Materialist, such as hylozoism, which ascribes vital characteristics to all matter, and panpsychism, which attributes a mindlike character to all constituents of material things.

Another common relaxation of the paradigm is that which allows as compatible with Materialism such a theory as epiphenomenalism, according to which sensations and thoughts do exist in addition to material processes but are nonetheless wholly dependent on material processes and without causal efficacy of their own. They are related to material things somewhat in the way that a man's shadow is related to the man. A similar departure from the paradigm is a form of what might be called “double-aspect Materialism,” according to which in inner experience men are acquainted with nonphysical *properties* of material processes, though these properties are not causally effective. A form of double-aspect theory in which these properties were allowed to be causally effective would be a species of emergent Materialism.

Of course, more than one of these qualifications might be made at the same time: thus a person might wish to speak of “physicalist deistic epiphenomenalist Materialism.” If no other qualifications are intended, it is convenient to use the word extreme and to speak, for example, of “extreme physicalist Materialism”—which is probably the type most discussed among professional philosophers in English-speaking countries.

Dialectical
Material-
ism

Type distinguished by its view of history. In the wider world, however, the word Materialism most commonly brings to mind dialectical Materialism, which is the orthodox philosophy of Communist countries. This is most importantly a theory of how changes arise in human history, though a general metaphysical theory lies in the background. Dialectical Materialists contrast their view with what they call “vulgar” Materialism; and it does, indeed, appear that their theory is not an extreme Mate-

rialism, whether mechanical or physicalist. They seem to hold merely that mental processes are dependent on or have evolved from material ones. Though they might be akin to emergent Materialists, it is hard to be sure; their assertion that something new emerges at higher levels of organization might refer only to such things as that a wireless receiver is different from a mere heap of the same components. And if so, even an extreme physicalistic Materialist could acquiesce in this view. The distinctive features of dialectical Materialism would, thus, seem to lie as much in its being dialectical as in its being Materialist. Its dialectical side may be epitomized in three laws: (1) that of the transformation of quality into quantity, (2) that of the interpenetration of opposites, and (3) that of the negation of the negation. Nondialectical philosophers find it hard, however, to interpret these laws in a way that does not make them into either platitudes or falsehoods.

Perhaps because of the historical determinism implicit in dialectical Materialism, and perhaps because of memories of the mechanical Materialist theories of the 18th and 19th centuries, when physics was deterministic, it is popularly supposed that Materialism and determinism must go together. This is not so. As indicated below, even some ancient Materialists were indeterminists, and a modern physicalist Materialism must be indeterministic because of the indeterminism that is built into modern physics. Modern physics does imply, however, that macroscopic bodies behave in a way that is effectively deterministic, and, because even a single neuron (nerve fibre) is a macroscopic object by quantum mechanical standards, a physicalistic Materialist may still regard the human brain as coming near to being a mechanism that behaves in a deterministic way.

Types distinguished by their account of mind. A rather different way of classifying Materialist theories, which to some extent cuts across the classifications already made, emerges when the theories are divided according to the way in which a Materialist accounts for minds. A central-state Materialist identifies mental processes with processes in the brain. An analytical behaviourist, on the other hand, argues that, in talking about the mind, one is not talking about an actual entity, whether the brain or an immaterial soul, but, rather, one is somehow talking about the way in which people would behave in various circumstances. According to the analytical behaviourist, there is no more of a problem for the Materialist in having to identify mind with something material than there is in identifying such an abstraction as the average plumber with some concrete entity. Analytical behaviourism differs from psychological behaviourism, which is merely a methodological program to base theories on behavioral evidence and to eschew introspective reports. The analytical behaviourist usually has a not too plausible theory of introspective reports according to which they are what are sometimes called “avowals”: roughly, he contends that to say “I have a pain” is to engage in a verbal surrogate for a wince. Epistemic Materialism is a theory that can be developed either in the direction of central-state Materialism or in that of analytical behaviourism and that rests on the contention that the only statements that are intersubjectively testable are either observation reports about macroscopic physical objects or statements that imply such observation reports (or are otherwise logically related to them).

Central-
state
Material-
ism and
analytical
behaviour-
ism

Before leaving this survey of the family of Materialistic theories, a quite different sense of the word Materialism should be noted in which it denotes not a metaphysical theory but an ethical attitude. A person is a Materialist in this sense if he is interested mainly in sensuous pleasures and bodily comforts and hence in the material possessions that bring these about. A man might be a Materialist in this ethical and pejorative sense without being a metaphysical Materialist, and conversely. An extreme physicalistic Materialist, for example, might prefer a Beethoven record to a comfortable mattress for his bed; and a person who believes in immaterial spirits might opt for the mattress.

HISTORY OF MATERIALISM

Greek and Roman Materialism. Though Thales of Miletus (c. 580 BC) and some of the other Pre-Socratic philoso-

Democritus and Epicurus

phers have some claims to being regarded as Materialists, the Materialist tradition in Western philosophy really begins with Leucippus and Democritus, Greek philosophers who were born in the 5th century BC. Leucippus is known only through his influence on Democritus. According to Democritus, the world consists of nothing but atoms (indivisible chunks of matter) in empty space (which he seems to have thought of as an entity in its own right). These atoms can be imperceptibly small, and they interact either by impact or by hooking together, depending on their shapes. The great beauty of atomism was its ability to explain the changes in things as due to changes in the configurations of unchanging atoms. The view may be contrasted with that of the earlier philosopher Anaxagoras (c. 480 BC), who thought that when, for example, the bread that a person eats is transformed into human flesh, this must occur because bread itself already contains hidden within itself the characteristics of flesh. Democritus thought that the soul consists of smooth, round atoms and that perceptions consist of motions caused in the soul atoms by the atoms in the perceived thing (see above *Atomism*).

Because Epicurus' philosophy was expounded in a lengthy poem by Lucretius, a Roman philosopher of the 1st century BC, Epicurus (died 270 BC) was easily the most influential Greek Materialist. He differed from Democritus in that he postulated an absolute up-down direction in space, so that all atoms fall in roughly parallel paths. To explain their impacts with one another, he then held that the atoms are subject to chance swerves—a doctrine that was also used to explain free will. Epicurus' Materialism therefore differed from that of Democritus in being an indeterministic one. Epicurus' philosophy contained an important ethical part, which was a sort of enlightened egoistic hedonism (see above *Epicureanism*). His ethics, however, were not Materialistic in the pejorative sense of the word.

Gassendi through Büchner and Vogt

Modern Materialism. Materialism languished throughout the medieval period, but the Epicurean tradition was revived in the first half of the 17th century in the atomistic Materialism of the French Catholic priest Pierre Gassendi. In putting forward his system as a hypothesis to explain the facts of experience, Gassendi showed that he understood the method characteristic of modern science, and he may well have helped to pave the way for corpuscular hypotheses in physics. Gassendi was not thoroughgoing in his Materialism inasmuch as he accepted on faith the Christian doctrine that men have immortal souls. His contemporary, the English philosopher Thomas Hobbes, also propounded an atomistic Materialism and was a pioneer in trying to work out a mechanistic and physiological psychology. Holding that sensations are corporeal motions in the brain, Hobbes skirted, rather than solved, the philosophical problems about consciousness that had been raised by another contemporary, the great French philosopher René Descartes. Descartes's philosophy was dualistic, making a complete split between mind and matter. In his theory of the physical world, however, and especially in his doctrine that animals are automata, Descartes's own system had a mechanistic side to it that was taken up by 18th-century Materialists, such as Julien de La Mettrie, the French physician whose appropriately titled *L'Homme machine* (1747; *Man a Machine*, 1750) applied Descartes's view about animals to man himself. Denis Diderot, an 18th-century French Encyclopaedist, supported a broadly Materialist outlook by considerations drawn from physiology, embryology, and the study of heredity; and his friend Paul, baron d'Holbach, published his *Système de la nature* (1770), which expounded a deterministic type of Materialism in the light of evidence from contemporary science, reducing everything to matter and to the energy inherent in matter. He also propounded a hedonistic ethics as well as an uncompromising atheism, which provoked a reply even from the Deist Voltaire.

The 18th-century French Materialists had been reacting against orthodox Christianity. In the early part of the 19th century, however, certain writers in Germany—usually with a biological or medical background—reacted against a different orthodoxy, the Hegelian and Neo-Hegelian tra-

dition in philosophy, which had become entrenched in German universities. Among these were Ludwig Büchner and Karl Vogt. The latter is notorious for his assertion that the brain secretes thought just as the liver secretes bile. This metaphor of secretion, previously used by P.-J.-G. Cabanis, a late 18th-century French Materialist, is seldom taken seriously, because to most philosophers it does not make sense to think of thought as a *stuff*. The Hobbesian view, also espoused by Büchner, that thought is a *motion* in the brain is usually viewed as a more promising one.

The synthesis of urea (the chief nitrogenous end product of protein metabolism), discovered in 1828, broke down the discontinuity between the organic and the inorganic in chemistry, which had been a mainstay of nonmaterialistic biology. Materialist ways of thinking were later strengthened enormously by the Darwinian theory of evolution, which not only showed the continuity between man and other living things right back to the simplest organisms but also showed how the apparent evidences of design in natural history could be explained on a purely causal basis. There still seemed to be a gap, however, between the living and the nonliving, though E.H. Haeckel, a 19th-century German zoologist, thought that certain simple organisms could have been generated from inorganic matter and, indeed, that a certain simple sea creature may well be in process of generation in this way even now. Though Haeckel was wrong, 20th-century biologists have proposed much more sophisticated and more plausible theories of the evolution of life from inorganic matter. Haeckel and his contemporary, the British zoologist T.H. Huxley, did much to popularize philosophical accounts of the world that were consonant with the scientific thought of their time, but neither could be regarded as an extreme Materialist.

Darwin, Haeckel, and Huxley

Contemporary Materialism. Perhaps because recent developments in biochemistry and in physiological psychology have greatly increased the plausibility of Materialism, there has lately been a resurgence of interest in the philosophical defense of central-state Materialism. Central-state Materialists have proposed their theories partly because of dissatisfaction with the analytical behaviourism of the Oxford philosopher Gilbert Ryle. Ryle himself is reluctant to call himself a Materialist, partly because of a dislike of all "isms" and partly because he thinks that the notion of matter has meaning only by contrast with that of mind, which he thinks to be an illegitimate sort of contrast. Nevertheless, it would seem that analytical behaviourism could be used to support a physicalist Materialism that would go on to explain human behaviour by means of neural mechanisms. (Ryle himself is suspicious of mechanistic accounts of biology and psychology.) Analytical behaviourism has been felt to be unsatisfactory, however, chiefly because of its account of introspective reports as avowals (see above), which most philosophers have found to be unconvincing.

Philosophers have distinguished two forms of central-state Materialism, namely, the translation form and the disappearance form. The translation form is the view that mentalistic discourse can be translated into discourse that is neutral between physicalism and dualism, so that the truth of a man's introspective reports is compatible with the objects of these reports being physical processes. The disappearance form is the view that such a translation cannot be done and that this fact, however, does not refute physicalism but shows only that man's ordinary introspective reports are contaminated by false theories.

Translation central-state theories. Among the philosophers who have advocated the translation form is the U.S. philosopher Herbert Feigl, earlier a member of the Vienna Circle, who, in an influential monograph (see *Bibliography*), did the most to get contemporary philosophers to treat central-state Materialism as a serious philosophical theory. Against the objection that, for example, "visual sensation" does not *mean* "process in the visual cortex," advocates of the translation form point out that "the morning star" does not mean the same as "the evening star," and yet the morning star as a matter of fact *is* the evening star. The objection confuses meaning and reference. Against the objection that a purely physical process (a dance of

Feigl, Place, Smart, Armstrong

electrons, protons, and so on) cannot have the sensory quality of greenness that is observed in a visual experience of seeing grass, say, they reply that to talk of the sensory experience of something looking green (or having a green mental image) is not to talk of anything that is literally green, but is simply to report that some internal process is of the sort that normally goes with seeing something, such as a lawn, which really is green. Though an immaterialist might say that the sort of process in question is a spiritual process, the Materialist can equally claim that it is a material process in the brain. The analysis of the introspective report is neutral between these two contentions; the Materialist, however, opts for his contention on various grounds. The British Materialist U.T. Place does so on the ground of normal scientific methodology; and the Australian Materialist J.J.C. Smart does so with a metaphysical application of the principle (called "Ockham's razor") that entities should not be multiplied beyond necessity. A physicalistic Materialist has, of course, an obligation to go on to give a suitable account of such apparently nonphysicalist qualities as the greenness of grass. At one time Smart analyzed colours in terms of the discriminatory behaviour of human beings. Another Australian Materialist, D.M. Armstrong, holds, on the other hand, that colours are as a matter of fact properties of objects, such properties being of the sort describable in the theoretical terms of physics. Feigl, in turn, is to some extent (and rather reluctantly) a double-aspect theorist. He qualifies the position taken by the other translation theorists, conceding that the translations do leave something out, viz., the immediately introspectable properties of "raw feels," such as that of hearing the tone of middle C. He holds, however, that such properties are irrelevant to causal explanations of phenomena. The translation form of central-state Materialism thus has some affinities with the earlier epistemic Materialism of the Positivist philosophers Rudolf Carnap and Hans Reichenbach, Germans who settled in the United States. Thus Carnap has suggested that mental predicates be treated as applying to material entities: for example, "Carnap sees green" could be taken as meaning "the body Carnap is in the state of green-seeing," the state of green-seeing being a purely physical state that explains the behavioral facts that led one to ascribe the predicate "sees green" to Carnap in the first place. David K. Lewis, a United States philosopher of science and language, has developed a translation form of central-state Materialism on the basis of a theory regarding the definition of theoretical terms in science. According to this theory, entities such as electrons, protons, and neutrons are defined in terms of the causal roles that they play in relation to observational phenomena—e.g., phenomena in cloud chambers—but the method of definition is able to do justice to the causal and other interrelations between the theoretical entities themselves. Lewis applies this account to commonsense psychology. Since mental entities, such as pains, are defined in commonsense psychology in terms of their causal roles (in relation to observable behaviour) and since there is empirical reason to ascribe the same causal roles to brain processes, Lewis identifies mental events, processes, and states with brain events, processes, and states.

Disappearance central-state theories. The disappearance form of central-state Materialism is the sort of theory held by P.K. Feyerabend, a U.S. philosopher, who denies that the Materialist can give a neutral analysis of introspective reports. In Feyerabend's view, commonsense introspective reports are irreducibly immaterialist in content. He argues, however, that this admission does not show the untenability of Materialism. Ordinary mentalistic discourse, he holds, is comparable to the medieval discourse about epileptics as being "possessed by the devil." If one now "identified" demon possession with a certain medical condition of the brain, this would really be an assertion that there is no such thing as a demon-possessed state: the medieval way of looking at the matter is thus rejected. It is in this sort of way that Feyerabend wants to "identify" the mind with the brain: he simply rejects the ordinary mentalistic conceptual scheme and so feels no obligation to show its compatibility with Materialism.

The influential American philosophers W.V. Quine and Wilfrid Sellars also hold theories that could be regarded as disappearance forms of physicalistic Materialism, though there is a Kantian twist to Sellars' philosophy that makes it hard to classify. Sellars holds that mentalistic concepts cannot be eliminated from man's commonsense picture of the world, which he calls "the manifest image." In a way reminiscent of Kant he holds that, although the manifest image is inescapable, it does not give metaphysical truth about the world as it really is in itself. This truth is given, instead, by "the scientific image"—i.e., by theoretical science, which is physicalist. In the case of Quine, there is a certain Platonism in that he believes in the objective reality of nonspatiotemporal entities, viz., those that are the subject matter of pure mathematics. Because he holds that the reason for believing mathematics is that it is needed as part of physical theory, his reasons for believing in numbers and the like are not in principle different from those for believing in electrons; thus Quine's Platonism does not really compromise his physicalism.

The Austrian philosopher Ludwig Wittgenstein, who lived to the mid-20th century and was professor of philosophy at Cambridge University, has sometimes been interpreted as a behaviourist, though his insistence that an inner process stands in need of outward criteria could possibly be interpreted as a sort of epistemic and central-state Materialism. Nevertheless, to count Wittgenstein as a Materialist would be to take considerable liberties with him; for, while displaying at times a certain mystical attitude, he also held very strongly that the business of a philosopher is not to put forward any metaphysical theory but to clear up conceptual confusions—to show the fly the way out of the fly bottle.

Eastern Materialism. This historical survey has been concerned with Materialism in Western philosophy. On the whole, Materialism is contrary to the spirit of both Indian and traditional Chinese philosophy, though the Cārvāka school of Materialists flourished from the 6th century BC until medieval times in India. Mention should also be made of the strong naturalistic tendency in Theravāda Buddhism, as also in certain schools of Chinese philosophy that exalt *ch'i* ("ether" or "material force") above principle and mind.

SUBSTANTIVE ISSUES IN MATERIALISM

Reductionism, consciousness, and brain. The main attraction of Materialism today is the way in which it fits in with a unified picture of science—a picture that has become very plausible. Thus, chemistry is reducible to physics inasmuch as there is a quantum-mechanical theory of the chemical bond. Biology is mainly an application of physics and chemistry to the structures described in natural history (including the natural history that one can explore through powerful microscopes). Increasingly, biological explanations resemble explanations in engineering, in which material structures are described and then the laws of physics and chemistry are used to explain the behaviour of these structures. (In the biological case, of course, these structures are often dynamic in the sense that their molecules are continually being replaced.) Through the influence of neurophysiology and also cybernetics (the science of information and control, which can be applied also to artificial automata), scientific psychology is also fitting well into the same mechanistic scheme. The recalcitrant residue appears in the phenomena of consciousness. Here mental events seem, indeed, to be correlated with physical events; but, if the mental events are not the very same as the physical events, one is left with apparently ultimate (or irreducible) physical-mental laws that do not fit happily into unified science, and one is thus faced with a situation unlike that of the rest of science. Looking at science generally, one expects *ultimate* laws to relate simple entities, such as fundamental particles. A physical-mental law, however, would have to refer to something very complex—a brain process involving perhaps millions of neurons, with each neuron being itself an almost fantastically complex entity. There would be a multitude of physical-mental laws, which would look like excrescences on the face of science. Because they would not fit into

Unified science and physical-mental laws

the network of scientific laws, Herbert Feigl has called them "nomological danglers." To get rid of these danglers is one of the chief attractions of Materialism. Of course, an immaterialist might assert that mental entities exist and also that there are no physical-mental laws. But it might be hard for him to reconcile this position with the empirical evidence; and in any case he would be faced with the problem of how to distinguish the free exercise of such anomalous physical-mental interaction from mere chance behaviour.

The development of computers and other devices to take over much of the more routine sort of human behaviour has led to attempts on the part of scientists and technologists, such as the American M.L. Minsky, to develop real artificial intelligence. So far, the success that these scientists hoped for has not been achieved. An American linguistic theorist, Noam Chomsky, has argued on the basis of his theories of generative grammar that the brain is quite unlike any already-understood type of mechanism. Indeed, any physicalistic Materialist must certainly concede that there are very deep problems about the brain, which apparently can no longer be thought of as a bundle of conditioned reflex mechanisms or the like, as it often has seemed to be to many psychologists. The physicalist can stress, however, that the investigator's ignorance need not lead him to assume that he will never be able to find an explanation of intelligence and of linguistic abilities in terms consonant with his present notion of a physical mechanism. (There is also the possibility that physical laws not yet discovered might be needed to explain the workings of the brain. So long as these turned out to be basic laws of physics, such discoveries would not imply a shift to emergentist Materialism.)

Logic, intentionality, and psychical research. Some philosophers, such as the Oxford philosopher J.R. Lucas, have tried to produce positive arguments against a mechanistic theory of mind by employing certain discoveries in mathematical logic, especially Gödel's theorem, which implies that no axiomatic theory could possibly capture all arithmetical truths. In general, philosophers have not found such attempts to extract an antimaterialist philosophy from mathematical logic to be convincing. Nevertheless, the problems of mechanizing intelligence, including the mathematical abilities of human beings, do pose unsolved problems that the Materialist is obliged to take seriously.

Perhaps the most common challenge to Materialism comes from philosophers who hold that it cannot do justice to the concept of intentionality, which Franz Brentano, a pre-World War I German philosopher, made the distinguishing mark between the mental and the nonmental. (A related objection is that Materialism cannot do justice to the distinction between behaviour and mere bodily movements.) Brentano held that mental events and states somehow point toward objects beyond themselves (or have a "content"). Many contemporary philosophers agree with Brentano that purely physical entities cannot have this property. If it is said, for example, that punched holes on the tape of a computer can refer beyond themselves in the way that thoughts do, then it is commonly replied that, in themselves, the holes on the tape have no reference or content—for this belongs only to the thoughts in the mind of a person who reads the tape. The Materialist reply may be to argue, however, that there is a fundamental unclarity in the very notion of intentionality (this is roughly Quine's position) or else to argue that purely physical systems can, after all, possess intentionality.

The alleged spiritualistic and other phenomena reported in psychical research are sometimes adduced against Materialism. The Materialist, however, can well afford to postpone discussion of these phenomena until such time as they are accepted by the general scientific community, which on the whole still remains skeptical of them.

At present, there are reputable philosophers who accept Materialism, and there are also reputable philosophers who either reject it as false or hold that it is not the business of a philosopher to propound any sort of metaphysical system. Perhaps Materialists are still in a minority; but at any rate there is much less tendency than there was

a generation ago for this type of theory to be thought philosophically naive. (J.J.C.S.)

Phenomenology

In the 20th century, Phenomenology is mainly used as the name for a philosophical movement the primary objective of which is the direct investigation and description of phenomena as consciously experienced, without theories about their causal explanation and as free as possible from unexamined preconceptions and presuppositions. The word itself is much older, going back at least to the 18th century, when the Swiss-German mathematician and philosopher Johann Heinrich Lambert applied it to that part of his theory of knowledge that distinguishes truth from illusion and error. In the 19th century the word became associated chiefly with the *Phänomenologie des Geistes* (1807; *Phenomenology of Mind*, 2nd ed., 1931), by G.W.F. Hegel, who traced the development of the human spirit from mere sense experience to "absolute knowledge." The so-called Phenomenological movement did not get under way, however, until early in the 20th century. But even this new Phenomenology includes so many varieties that a comprehensive characterization of the subject requires their consideration.

CHARACTERISTICS OF PHENOMENOLOGY

In view of the spectrum of Phenomenologies that have issued directly or indirectly from the original work of the Austrian-born German philosopher Edmund Husserl, it is not easy to find a common denominator for such a movement beyond its common source. But similar situations occur in other philosophical as well as non-philosophical movements.

Essential features and variations. Although, as seen from Husserl's last perspective, all departures from his own views could only appear as heresies, a more generous assessment will show that all those who consider themselves Phenomenologists subscribe, for instance, to his watchword, *Zu den Sachen selbst* ("To the things themselves"), by which they meant the taking of a fresh approach to concretely experienced phenomena, an approach, as free as possible from conceptual presuppositions, and the attempt to describe them as faithfully as possible. Moreover, most adherents to Phenomenology hold that it is possible to obtain insights into the essential structures and the essential relationships of these phenomena on the basis of a careful study of concrete examples supplied by experience or imagination and by a systematic variation of these examples in imagination. Some Phenomenologists also stress the need for studying the ways in which the phenomena appear in men's object-directed ("intentional") consciousness.

Beyond this merely static aspect of appearance, some also want to investigate its genetic aspect, exploring, for instance, how the phenomenon intended—for example, a book—shapes ("constitutes") itself in the typical unfolding of experience. Husserl himself believed that such studies require a previous suspension of belief in the reality of these phenomena, whereas others consider it not indispensable but helpful. Finally, in existential Phenomenology, the meanings of certain phenomena (such as anxiety) are explored by a special interpretive ("hermeneutic") Phenomenology, the methodology of which needs further clarification.

Contrasts with related movements. It may also be helpful to bring out the distinctive essence of Phenomenology by confronting it with some of its philosophical neighbours. In contrast to Positivism and to traditional Empiricism, from which Husserl's teacher at Vienna, Franz Brentano, had started out and with which Phenomenology shares an unconditional respect for the positive data of experience ("We are the true positivists," Husserl claimed in his *Ideen zu einer reinen Phänomenologie und phänomenologischen Philosophie* [1913; "Ideas for a Pure Phenomenology and Phenomenological Philosophy"]), Phenomenology does not restrict these data to the range of sense experience but admits on equal terms such non-sensory ("categorical") data as relations and values, as long as they present themselves

Artificial
intelli-
gence and
generative
grammar

"To the
things
them-
selves"

intuitively. Consequently, Phenomenology does not reject universals; and, in addition to analytic a priori statements, whose predicates are logically contained in the subjects and the truth of which is independent of experience (e.g., "All material bodies have extension"), and the synthetic a posteriori statements, whose subjects do not logically imply the predicate and the truth of which is dependent on experience (e.g., "My shirt is red"), it recognizes knowledge of the synthetic a priori, a proposition whose subject does not logically imply the predicate but one in which the truth is independent of experience (e.g., "Every colour is extended"), based on insight into essential relationships within the empirically given.

In contrast to phenomenism, a position in the theory of knowledge (epistemology) with which it is often confused, Phenomenology—which is not primarily an epistemological theory—accepts neither the rigid division between appearance and reality nor the narrower view that phenomena are all that there is (sensations or permanent possibilities of sensations). These are questions on which Phenomenology as such keeps an open mind—pointing out, however, that phenomenism overlooks the complexities of the intentional structure of men's consciousness of the phenomena.

In contrast to a Rationalism that stresses conceptual reasoning at the expense of experience, Phenomenology insists on the intuitive foundation and verification of concepts and especially of all a priori claims; in this sense it is a philosophy from "below," not from "above."

In contrast to an Analytic philosophy that substitutes simplified constructions for the immediately given in all of its complexity and applies "Ockham's razor," Phenomenology resists all transforming reinterpretations of the given, analyzing it for what it is in itself and on its own terms.

Phenomenology shares with Linguistic Analysis a respect for the distinctions between the phenomena reflected in the shades of meaning of ordinary language as a possible starting point for phenomenological analyses. Phenomenologists, however, do not think that the study of ordinary language is a sufficient basis for studying the phenomena, because ordinary language cannot and need not completely reveal the complexity of phenomena.

In contrast to an Existential philosophy that believes that human existence is unfit for phenomenological analysis and description, because it tries to objectify the unobjectifiable, Phenomenology holds that it can and must deal with these phenomena, however cautiously, as well as other intricate phenomena outside the human existence. (H.Sp.)

ORIGIN AND DEVELOPMENT OF HUSSERL'S PHENOMENOLOGY

Basic principles. Phenomenology was not founded; it grew. Its fountainhead was Edmund Husserl, who held professorships at Göttingen and Freiburg im Breisgau and who wrote *Die Idee der Phänomenologie* (*The Idea of Phenomenology*, 1964) in 1906. Yet, even for Husserl, the conception of Phenomenology as a new method destined to supply a new foundation for both philosophy and science developed only gradually and kept changing to the very end of his career. Trained as a mathematician, Husserl was attracted to philosophy by Franz Brentano, whose descriptive psychology seemed to offer a solid basis for a scientific philosophy. The concept of intentionality, the directedness of the consciousness toward an object, which is a basic concept in Phenomenology, was already present in Brentano's *Psychologie vom empirischen Standpunkte* (1874): "And thus we can define psychic phenomena by saying that they are those phenomena which, precisely as intentional, contain an object in themselves." Brentano dissociated himself here from Sir William Hamilton, known for his philosophy of the "unconditioned," who had attributed the character of intentionality to the realms of thought and desire only, to the exclusion of that of feeling.

The point of departure of Husserl's investigation is to be found in the treatise *Der Begriff der Zahl* (1887; "The Concept of Number"), which was later expanded into *Philosophie der Arithmetik: Psychologische und logische*

Untersuchungen (1891). Numbers are not found ready-made in nature but result from a mental achievement. Here Husserl was preoccupied with the question of how something like the constitution of numbers ever comes about. This treatise is important to Husserl's later development for two reasons: first, because it contains the first traces of the concepts "reflection," "constitution," "description," and the "founding constitution of meaning," concepts that later played a predominant role in Husserl's philosophy; and second, because it reflected two events—(1) a criticism of his book by Gottlob Frege, a seminal thinker in logic, who had charged him with confusing logical and psychological considerations, and (2) Husserl's discovery of the *Wissenschaftslehre* (1837; *Logic and Scientific Methods*, 1971) by Bernard Bolzano, a Bohemian mathematician, theologian, and social moralist, and his view concerning "truths in themselves"—which led Husserl to an analysis and critical discussion of psychologism, the view that psychology could be used as a foundation for pure logic, which he clearly felt to be no longer possible.

In the first volume of *Logische Untersuchungen* (1900–01; *Logical Investigations*, 1970), entitled *Prolegomena*, Husserl began with a criticism of psychologism. And yet he continued by conducting a careful investigation of the psychic acts in and through which logical structures are given; these investigations, too, could give the impression of being descriptive psychological investigations, though they were not conceived of in this way by the author. For the issue at stake was the discovery of the essential structure of these acts. Here Brentano's concept of intentionality received a richer and more refined signification. Husserl distinguished between perceptual and categorical intuition and stated that the latter's theme lies in logical relationships. The real concern of Phenomenology was clearly formulated for the first time in his *Logos* article, "Philosophie als strenge Wissenschaft" (1910–11; *Philosophy as Rigorous Science*, 1965). In this work Husserl wrestled with two unacceptable views: naturalism and historicism.

Naturalism attempts to apply the methods of the natural sciences to all other domains of knowledge, including the realm of consciousness. Reason becomes naturalized. Although an attempt is then made to find a foundation for the human sciences (*Geisteswissenschaften*) by means of experimental psychology, it proves to be impossible, because in so doing one is unable to grasp precisely what is at stake in knowledge as found in the natural sciences.

What a philosopher must examine is the relationship between consciousness and Being; and in doing so, he must realize that from the standpoint of epistemology, Being is accessible to him only as a correlate of conscious acts. He must thus pay careful attention to what occurs in these acts. This can be done only by a science that tries to understand the very essence of consciousness; and this is the task that Phenomenology has set for itself. Because clarification of the various types of objects must follow from the basic modes of consciousness, Husserl's thought remained close to psychology. In contradistinction to what is the case in psychology, however, in Phenomenology, consciousness is thematized in a very special and definite way, viz., just insofar as consciousness is the locus in which every manner of constituting and founding meaning must take place. In man's intuition, conscious occurrences must be given immediately in order to avoid introducing at the same time certain interpretations. The nature of such processes as perception, representation, imagination, judgment, and feeling must be grasped in immediate self-givenness. The call "To the things themselves" is not a demand for realism, because the things at stake are the acts of consciousness and the objective entities that get constituted in them: these things form the realm of what Husserl calls the phenomena.

Thus, the objects of Phenomenology are "absolute data grasped in pure, immanent intuition," and its goal is to discover the essential structures of the acts (*noesis*) and the objective entities that correspond to them (*noema*).

On the other hand, Phenomenology must also be distinguished from historicism, a philosophy that stresses the immersion of all thinkers within a particular historical

Anti-naturalism

Anti-historicism

Husserl's
earlier
develop-
ment

setting. Husserl objected to historicism because it implies relativism. He gave credit to Wilhelm Dilthey, author of "Entwürfe zur Kritik der historischen Vernunft" ("Outlines for the Critique of Historical Reason," in *Gesammelte Schriften*, 12 vol. [1914–36], vol. 5, 6), for having developed a typification of world views, but he doubted and even rejected the skepticism that flows necessarily from the relativity of the various types. History is concerned with facts, whereas Phenomenology deals with the knowledge of essences. To Husserl, Dilthey's doctrine of world views was incapable of achieving the rigour required by genuine science. Contrary to all of the practical tendencies found in world views, Husserl demanded that philosophy be founded as a rigorous science. Its task implies that nothing be accepted as given beforehand but that the philosopher should try to find the way back to the real beginnings. This is tantamount to saying, however, that he must try to find the way to the foundations of meaning that are found in consciousness. Just as for Immanuel Kant the empirical has merely relative validity and never an absolute, or apodictic, validity, so for Husserl, too, what is to be searched for is a scientific knowledge of essences in contradistinction to a scientific knowledge of facts.

Basic method. The basic method of all Phenomenological investigation, as Husserl developed it himself—and on which he worked throughout his entire lifetime—is the "reduction": the existence of the world must be put between brackets, not because the philosopher should doubt it but merely because this existing world is not the very theme of Phenomenology; its theme is rather the manner in which knowledge of the world comes about. The first step of the reduction consists in the phenomenological reduction, through which all that is given is changed into a phenomenon in the sense of that which is known in and by consciousness; for this kind of knowing—which is to be taken in a very broad sense as including every mode of consciousness, such as intuition, recollection, imagination, and judgment—is here all-important. There are several reasons why Husserl gave a privileged position to intuition: among them is the fact that intuition is that act in which a person grasps something immediately in its bodily presence and also that it is a primordially given act upon which all of the rest is to be founded. Furthermore, Husserl's stress on intuition must be understood as a refutation of any merely speculative approach to philosophy.

This reduction reverses—"re-flects"—man's direction of sight from a straightforward orientation toward objects to an orientation toward consciousness.

Eidetic
and trans-
cendental
reductions

The second step is to be found in the eidetic reduction. To get hold of consciousness is not sufficient; on the contrary, the various acts of consciousness must be made accessible in such a way that their essences—their universal and unchangeable structures—can be grasped. In the eidetic reduction one must forego everything that is factual and merely occurs in this way or that. A means of grasping the essence is the *Wesensschau*, the intuition of essences and essential structures. This is not a mysterious kind of intuition. Rather, one forms a multiplicity of variations of what is given, and while maintaining the multiplicity, one focusses attention on what remains unchanged in the multiplicity; i.e., the essence is that identical something that continuously maintains itself during the process of variation. Husserl, therefore, called it the invariant.

To this point, the discussion of reduction has remained within the realm of psychology, albeit a new—namely, a phenomenological—psychology. The second step must now be completed by a third, the transcendental reduction. It consists in a reversion to the achievements of that consciousness that Husserl, following Kant, called transcendental consciousness, although he conceived of it in his own way. The most fundamental event occurring in this consciousness is the creation of time awareness through the acts of protention (future) and retention (past), which is something like a self-constitution. To do phenomenology was for Husserl tantamount to returning to the transcendental ego as the ground for the foundation and constitution (or making) of all meaning (German *Sinn*). Only when a person has reached this ground can he achieve the insight that makes his comportment trans-

parent in its entirety and makes him understand how meaning comes about, how meaning is based upon meaning like strata in a process of sedimentation.

Husserl worked on the clarification of the transcendental reduction until the very end of his life. It was precisely the further development of the transcendental reduction that led to a division of the Phenomenological movement and to the formation of a school that refused to become involved in this kind of system of problems (see below *Phenomenology of essences*).

Basic concepts. In an effort to express what it is to which this method gives access, Husserl wrote:

In all pure psychic experiences (in perceiving something, judging about something, willing something, enjoying something, hoping for something, etc.) there is found inherently a being-directed-toward Experiences are intentional. This being-directed-toward is not just joined to the experience by way of a mere addition, and occasionally as an accidental reaction, as if experiences could be what they are without the intentional relation. With the intentionality of the experiences there announces itself, rather, the essential structure of the purely psychical.

Inten-
tionality
and
constitu-
tion
theory

The phenomenological investigator must examine the different forms of intentionality in a reflective attitude because it is precisely in and through the corresponding intentionality that each domain of objects becomes accessible to him. Husserl took as his point of departure mathematical entities and later examined logical structures, in order finally to achieve the insight that each being must be grasped in its correlation to consciousness, because each datum becomes accessible to a person only insofar as it has meaning for him. From this position, regional ontologies, or realms of being, develop: for instance, those dealing with the region of "nature," the region of "the psychic," or the region of "the spirit." Moreover, Husserl distinguished formal ontologies—such as the region of the logical—from material ontologies.

In order to be able to investigate a regional ontology, it is first necessary to discover and examine the founding act by which realities in this realm are constituted. For Husserl, constitution does not mean the creation or fabrication of a thing or object by a subject; it means the founding constitution of its meaning. There is meaning only for consciousness. All founding constitution of meaning is made possible by transcendental consciousness. Speaking of this transcendental motif, Husserl wrote:

It is the motif of questioning back to the last source of all achievements of knowledge, of reflection in which the knower reflects on himself and his knowing life, in which all the scientific constructs which have validity for him, occur teleologically, and as permanent acquisitions are kept and become freely available to him.

In the realm of such transcendental problems, it is necessary to examine how all of the categories in and through which one understands mundane beings or purely formal entities originate from specific modes of consciousness. In Husserl's view, the temporalization must be conceived as a kind of primordial constitution of transcendental consciousness itself.

Understood in this way, Phenomenology does not place itself outside the sciences but, rather, attempts to make understandable what takes place in the various sciences and, thus, to thematize the unquestioned presuppositions of the sciences.

In his last publication, *Die Krisis der europäischen Wissenschaften und die transzendente Phänomenologie: Eine Einleitung in die phänomenologische Philosophie* (1936; *The Crisis of European Sciences and Transcendental Phenomenology*, 1970), Husserl arrived at the life-world—the world as shaped within the immediate experience of each man—by questioning back to the foundations that the sciences presuppose. In *Die Krisis* he analyzed the grounds that had led to the European crisis of culture and philosophy, which found its immediate expression in the contrast between the great successes of the sciences of nature and the failure of the sciences of man. In the modern era, scientific knowledge had become fragmented into an objectivistic-physicalist and a transcendental knowledge. Until recently this split could not be overcome. It led, rather, to the attempt to develop the sciences of man in

Husserl's
notion of
the life-
world

accordance with the procedures used in the exact sciences of nature (naturalism)—an attempt doomed to failure. In opposition to this attempt, Husserl wished to show that in the new approach one must reflect on the activities of the scientists.

As the immediately given world, this merely subjective world, was forgotten in the scientific thematization, the accomplishing subject, too, was forgotten and the scientist himself was not thematized.

Husserl demonstrated this point by using the example of Galileo and his mathematization of our world. The truth characteristic of the life-world is by no means an inferior form of truth when compared to the exact, scientific truth but is, rather, always a truth already presupposed in all scientific research. That is why Husserl claimed that an ontology of the life-world must be developed—i.e., a systematic analysis of the constitutive achievements the result of which is the life-world, a life-world that, in turn, is the foundation of all scientific constitutions of meaning. The stimulating change that occurred here consists in the fact that truth is no longer measured after the criterion of an exact determination. For what is decisive is not the exactness but, rather, the part played by the founding act.

It is in this connection that, rather abruptly, historicity, too, became relevant for Husserl. He began to reflect upon the emergence of philosophy among the Greeks and on its significance as a new mode of scientific knowledge oriented toward infinity; and he interpreted the philosophy of René Descartes, often called the father of modern philosophy, as the point at which the split into the two research directions—physicalist objectivism and transcendental subjectivism—came about. Phenomenology must overcome this split, he held, and thus help mankind to live according to the demands of reason. In view of the fact that reason is the typical characteristic of man, mankind must find itself again through Phenomenology.

LATER DEVELOPMENTS

Phenomenology of essences. A different type of Phenomenology, the Phenomenology of essences, developed from a tangential continuation of that of the *Logische Untersuchungen*. Its supporters were Husserl's students in Göttingen and a group of young philosophers in Munich, originally students of Theodor Lipps, a Munich psychologist and philosopher—students who had turned away from Lipps's psychologism and discovered powerful support in Husserl. The Phenomenological movement, which then began to take shape, found its most tangible expression in the publication of the *Jahrbuch für Philosophie und phänomenologische Forschung* (1913–30), a Phenomenological yearbook with Husserl as its main editor, the preface of which defined Phenomenology in terms of a return to intuition (*Anschauung*) and to the essential insights (*Wesenseinsichten*) derived from it as the ultimate foundation of all philosophy.

The 11 volumes of the *Jahrbuch* contained, in addition to Husserl's own works, the most important fruits of the movement in its broader application. Of the co-editors, Alexander Pfänder contributed chiefly to the development of phenomenological psychology and pure logic but developed also the outlines of a complete Phenomenological philosophy. Moritz Geiger applied the new approach particularly to aesthetics and Adolf Reinach to the philosophy of law. The most original and dynamic of Husserl's early associates, however, was Max Scheler, who had joined the Munich group and who did his major Phenomenological work on problems of value and obligation. A Polish philosopher, Roman Ingarden, did major work in structural ontology and analyzed the structures of various works of art in its light; Hedwig Conrad-Martius, a cosmic Realist at the University of Munich, worked intensively in the ontology of nature; and others made comparable contributions in other fields of philosophy. None of these early Phenomenologists, however, followed Husserl's road to transcendental Idealism; and some tried to develop a Phenomenology along the lines of Realism.

Heidegger's hermeneutic Phenomenology. Martin Heidegger, one of Germany's foremost philosophers at the middle of the 20th century, was inspired to philosophy

through Brentano's work *Von der mannigfachen Bedeutung des Seienden nach Aristoteles* (1862; "On the Multifarious Meaning of Being According to Aristotle"). While he was still studying theology, from 1910 to 1911, Heidegger encountered Husserl's *Logische Untersuchungen*. From then on he pursued the course of Phenomenology with the greatest interest, and from 1916 he belonged to the narrow circle of students and followers of the movement. The typical character of the Phenomenological intuition was at that time the focus of Husserl's seminar exercises. To be sure, there appeared very early a difference between Husserl and Heidegger. Discussing and absorbing the works of the important philosophers in the history of metaphysics was, for Heidegger, an indispensable task, whereas Husserl repeatedly stressed the significance of a radically new beginning and—with few exceptions (among them Descartes, Locke, Hume, and Kant)—wished to bracket the history of philosophy.

Heidegger's basic work, *Sein und Zeit* (1927; *Being and Time*, 1962), which was dedicated to Husserl, strongly acknowledged that its author was indebted to Phenomenology. In it, Phenomenology was understood as a methodological concept—a concept that was conceived by Heidegger in an original way and resulted from his questioning back to the meanings of the Greek concepts of *phainomenon* and *logos*. *Phainomenon* is "that which shows itself from itself," but together with the concept of *logos*, it means "to let that which shows itself be seen from itself in the very way in which it shows itself from itself." This conception of Phenomenology, which relied more on Aristotle than on Husserl, constituted a change that was later to lead to an estrangement between Husserl and Heidegger. For in *Sein und Zeit* there is no longer a phenomenological reduction, a transcendental ego, or an intuition of essences in Husserl's sense. Heidegger's new beginning was, at the same time, a resumption of the basic question of philosophy: that concerning the meaning (*Sinn*) of Being. His manner of questioning can be defined as hermeneutical in that it proceeds from the interpretation of man's situation. What he thematized is, thus, the explanation of what is already understood.

At the heart of *Sein und Zeit* lies Heidegger's analysis of the one (the man) who asks the question—who is capable of asking the question—concerning Being, who precisely through this capability occupies a privileged position in regard to all other beings, viz., that of *Dasein* (literally, "being there"). By conceiving of *Dasein* as being-in-the-world, Heidegger made the ancient problem concerning the relationship between subject and object superfluous. The basic structures of *Dasein* are primordial moodness (*Be-findlichkeit*), understanding (*Verstehen*), and logos (*Rede*). These structures are, in turn, founded in the temporalization of *Dasein*, from which future, having-been (past), and present originate. The two basic possibilities of man's existing (from the Latin *ex* and *sistere*, "standing out from") are those in which *Dasein* either comes to its self (called authenticity) or loses itself (called inauthenticity); *Dasein* is inauthentic, for example, when it lets the possibilities of the choice for its own "ek-sisting" be given to it by others instead of deciding for itself. Heidegger's concept of care (*Sorge*, *cura*) has nothing to do with distress (*Bekümmernis*) but includes the unity of the articulated moments of man's being-in-the-world.

The hermeneutic character of Heidegger's thought manifested itself also in his interpretation of poetry, in which he discovered a congenial spirit in Friedrich Hölderlin, one of Germany's greater poets, of whose poetry he inaugurated a completely new interpretation; but it manifested itself equally well in his interpretation of metaphysics, which Heidegger tried to envision as an occurrence determined by the forgottenness of Being, an occurrence in the centre of which man finds himself and of which the clearest manifestation is to be found in "technicity," the attempt of modern man to dominate the earth by controlling beings that are considered as objects.

The concept of transcendental consciousness, which was central for Husserl, is not found in Heidegger—which clearly shows how Heidegger, in *Sein und Zeit*, had already dissociated himself from Husserl's Phenomenology.

Heidegger's return to ontology

Fruits of the movement in broader application

Other developments. Eugen Fink, for several years Husserl's collaborator, whose essay "Die phänomenologische Philosophie Edmund Husserls in der gegenwärtigen Kritik" (1933) led to a radicalization of Husserl's philosophical, transcendental Idealism, later turned in another direction, one that approached Heidegger's position and divorced itself at the same time from that of Husserl.

Ludwig Landgrebe, who was Husserl's personal assistant for many years, published in 1938 *Erfahrung und Urteil* ("Experience and Judgment"), the first of Husserl's posthumous works devoted to the genealogy of logic. Among German-language scholars, Landgrebe remained closest to Husserl's original views and has developed them consistently in several works.

DISSEMINATION OF PHENOMENOLOGY

Phenomenology in various countries. Following upon the work of Husserl, Phenomenology spread into a worldwide movement.

In France. One of the first French authors to become familiar with Husserl's philosophy was Emmanuel Lévinas, a pluralistic Personalist, who combined ideas from Husserl and Heidegger in a very personal way. Similarly, Jean-Paul Sartre, the leading Existentialist of France, took his point of departure from the philosophies of Husserl and Heidegger. His first works, *L'Imagination* (1936; *Imagination: A Psychological Critique*, 1962) and *L'Imaginaire: Psychologie phénoménologique de l'imagination* (1940; *The Psychology of Imagination*, 1950), remain completely within the context of Husserl's analyses of consciousness. Sartre explains the distinction between perceptual and imaginative consciousness with the help of Husserl's concept of intentionality, and he frequently employs the method of ideation (*Wesensschau*).

In *L'Être et le néant* (1943; *Being and Nothingness*, 1956), an essay on Phenomenological ontology, it is obvious that Sartre borrowed from Heidegger. Some passages from Heidegger's *Was ist Metaphysik?* (1929; *What Is Metaphysics?*, 1949), in fact, are copied literally. The meaning of nothingness, which Heidegger in this lecture made the theme of his investigations, became for Sartre the guiding question. Sartre departs from Heidegger's analytic of *Dasein* and introduces the position of consciousness (which Heidegger had overcome).

The distinction between being-in-itself (*en-soi*) and being-for-itself (*pour-soi*) pervades the entire investigation. The in-itself is the opaque, matter-like substance that remains the same, whereas the for-itself is consciousness permeated by nothingness. The influence of the Idealist G.W.F. Hegel becomes apparent when the author tries to interpret everything in a dialectical way; i.e., through a tension of opposites. The dialectic of men's being-with-one-another is central: thus, seeing and being-seen correspond to dominating and being-dominated. The basic characteristic of being-for-itself is bad faith (*mauvaise foi*), which cannot be overcome because facticity (being-already) and transcendence (being-able-to-be) cannot be combined.

The Phenomenological character of Sartre's analyses of consciousness consists in the way in which he elucidates certain modes of behaviour: love, hatred, sadism, masochism, and indifference. Although Sartre sees and describes these forms of behaviour strikingly and precisely, he limits himself to those modes that fit his philosophical interpretation. The significance of psychology, recognized by Husserl, emerges again in Sartre and leads to a demand for an Existential psychoanalysis.

Sartre's definition of man as a being of possibilities that finds or loses itself in the choice that it makes in regard to itself refers to Heidegger's definition of *Dasein* as a being that has to materialize itself. For Sartre, freedom is the basic characteristic of man; thus Sartre belongs to the tradition of the great French moralist philosophers.

In his later works, as in his *Critique de la raison dialectique* (1960; *Search for a Method*, 1963), Sartre turned to Marxism, though he developed a method of understanding that was influenced by hermeneutics. Here the choice made by the individual is limited by social and psychological conditions. Sartre's outstanding two-volume interpretation of Flaubert, *L'Idiot de la famille*; *Gustave*

Flaubert de 1821-1857 (1971), is an example of this new method of understanding and interpretation, which combines Marxist elements with interpretations of a highly personal nature taken from depth psychology.

Maurice Merleau-Ponty (died 1961), who, together with Sartre and his associate Simone de Beauvoir, a writer and novelist, was an important representative of French Existentialism, was at the same time the most important French Phenomenologist. His works, *La Structure du comportement* (1942; *Structure of Behaviour*, 1963) and *Phénoménologie de la perception* (1945; *Phenomenology of Perception*, 1962), were the most original further developments and applications of Phenomenology to come from France. Merleau-Ponty gave a new interpretation of the meaning of the human body from the viewpoint of Phenomenology and, connected with this, of man's perception of space, the natural world, temporality, and freedom.

Starting from Husserl's later phenomenology of the life-world, Merleau-Ponty anchored the phenomena of perception in the phenomenology of the lived body (the body as it is experienced and experiences), in which the perceiving subject is incarnated as the mediating link to the phenomenal world. Such a phenomenology of human "presence" in the world was also to offer an alternative to the rigid dichotomy between Idealism and Realism, in which consciousness and world could be reciprocally related. Phenomenology thus became a way of showing the essential involvement of human existence in the world, starting with everyday perception.

Although it is true that Merleau-Ponty was originally close to Husserl in his thought, he later developed noticeably in the direction of Heidegger, a change that became particularly manifest in *L'Oeil et l'esprit* (1964; "Eye and Mind," in *The Primacy of Perception*, 1964).

Paul Ricoeur, a student of the volitional experience, whose translation of Husserl's *Ideen zu einer reinen Phänomenologie* brought Husserl closer to the younger French generation, writes in a Phenomenological vein but with the intention of further developing Husserl's conception of Phenomenology. Ricoeur's two-volume *Philosophie de la volonté* (1950-60; "Philosophy of the Will") also deals with the problems involved in the theological concept of guilt.

Suzanne Bachelard, who in 1957 translated Husserl's *Formale und transzendente Logik: Versuch einer Kritik der logischen Vernunft*, has pointed to the significance of Husserl for modern logic; and Jacques Derrida, an original French thinker on the limits of thought and language, has combined Phenomenology and Structuralism in his interpretation of literature.

In Germany. After World War II, interest in Phenomenology sprang up again in its own homeland. The influence of Ludwig Landgrebe in Cologne has been particularly felt, as have the activities of the Husserl Archives in Cologne, with editions by Walter Biemel, who also published *Philosophische Analysen zur Kunst der Gegenwart* (1968; "Philosophical Analyses of Contemporary Art") and essays on the relationships between Husserl and Heidegger. The circle around Gerhard Funke in Mainz, author of *Phänomenologie—Metaphysik oder Methode?* (1966), has also had a positive influence.

In other European countries. In Belgium, at the Catholic University of Louvain, are located the entire posthumous works of Husserl, as well as his personal library. Thanks to the initiative of H.L. Van Breda, founder of the Husserl Archives, several scholars worked intensively on the manuscripts for several decades. By 1972, 12 volumes of collected works had been published. Van Breda was also the director of the *Phaenomenologica* series—totalling 42 volumes by 1972—in which the most important publications in the field of Phenomenology (taken in a very broad sense) have been published. Thus, mainly through Van Breda's efforts, Louvain has become the most important centre for Phenomenology. Van Breda also organized international colloquia on Phenomenology. The influence of Alphonse de Waelhens, a Belgian philosopher of fresh experience and author of *Phénoménologie et vérité* (1953) and *Existence et signification* (1958), also bears mentioning.

The Phenomenology of Maurice Merleau-Ponty

Jean-Paul Sartre's use of the method

Husserl scholarship at Cologne and Louvain

In The Netherlands, Stephan Strasser, who is oriented particularly toward phenomenological psychology, is especially influential. And in Italy, the Phenomenology circle centres around Enzo Paci. The Husserl scholar Jan Patočka, a prominent expert in Phenomenology as well as in the metaphysical tradition, is influential in Czechoslovakia; in Poland, Roman Ingarden has represented the cause of Phenomenology; and there are also important representatives in Yugoslavia, Portugal, England, South America, Japan, and India.

In the United States. In the United States, Phenomenology has lived a rather marginal existence for quite some time, notwithstanding the meritorious journal of *Philosophy and Phenomenological Research* founded by Husserl's student Marvin Farber, who is also the author of *The Foundation of Phenomenology* (1943). In recent years, however, a noticeable change has taken place, chiefly because of the work of two scholars at the New School for Social Research in New York, Alfred Schütz, an Austrian-born sociologist and student of human cognition (died 1959), and Aron Gurwitsch, a Lithuanian-born philosopher. Schütz came early to Phenomenology, developing a social science on a phenomenological basis. Gurwitsch, author of *Théorie du champ de la conscience* (1957; *The Field of Consciousness*, 1964), came to Phenomenology through his study of the Gestalt psychologists Adhemar Gelb and Kurt Goldstein. While in Paris, Gurwitsch influenced Merleau-Ponty. The essays on Phenomenology published by Gurwitsch in the United States are among the best. His comprehensive knowledge ranges from mathematics, via the natural sciences, to psychology and metaphysics. The work *The Phenomenological Movement* (2nd ed. 1965), by Herbert Spiegelberg, an Alsatian-American Phenomenologist, is the movement's first encompassing historical presentation.

Phenomenology in other disciplines. Of greater significance is the role of Phenomenology outside of philosophy proper in stimulating or reinforcing phenomenological tendencies in such fields as mathematics and the biological sciences. Much stronger was its impact on psychology, in which Franz Brentano and the German Carl Stumpf had prepared the ground and in which the U.S. psychologist William James, the Würzburg school, and the Gestalt psychologists had worked along parallel lines. But Phenomenology has probably made its strongest contribution in the field of psychopathology, in which the German Karl Jaspers, a foremost contemporary Existentialist, stressed the importance of phenomenological exploration of a patient's subjective experience. Jaspers was followed by the Swiss Ludwig Binswanger and several others. The Phenomenological strand is also very pronounced in American Existential psychiatry and has affected sociology, history, and the study of religion.

CONCLUSION

At the turn of the fourth quarter of the 20th century, it remained to be seen whether Phenomenology could make solid contributions to philosophical knowledge. To this end, it needed to develop rigorous standards, which had not always been observed by some of its most brilliant practitioners, such as Max Scheler, and which were likely to be violated in a philosophy the ultimate appeal of which had to be made to intuitive verification. With this proviso, Phenomenology may well be qualified not only to become a bridge for better international communication in philosophy but also to shed new light on philosophical problems old and new, to reclaim for philosophy parts of man's everyday life-world that have been abandoned by science as too private and too subjective, and, finally, to give access to layers of man's experience unprobed in everyday living, thus providing deeper foundations for both science and life. (W.Bi.)

Positivism and Logical Empiricism

As a philosophical ideology and movement, Positivism first assumed its distinctive features in the work of the French philosopher Auguste Comte, who also named and systematized the science of sociology. It then developed

through several stages known by various names, such as Empiricism, Logical Positivism, and Logical Empiricism, and finally, in the mid-20th century, flowed into the movement known as Analytic and Linguistic philosophy.

The basic affirmations of Positivism are (1) that all knowledge regarding matters of fact is based upon the "positive" data of experience, and (2) that beyond the realm of fact is that of pure logic and pure mathematics, which were already recognized by the Scottish Empiricist and Skeptic David Hume as concerned with the "relations of ideas" and, in a later phase of Positivism, were classified as purely formal sciences. On the negative and critical side, the Positivists became noted for their repudiation of metaphysics; *i.e.*, of speculation regarding the nature of reality that radically goes beyond any possible evidence that could either support or refute such "transcendent" knowledge claims. In its basic ideological posture, Positivism is thus worldly, secular, antitheological, and antimetaphysical. Strict adherence to the testimony of observation and experience is the all-important imperative of the Positivists. This imperative is reflected also in their contributions to ethics and moral philosophy, and most Positivists have been Utilitarians to the extent that something like "the greatest happiness for the greatest number of people" was their ethical maxim. It is notable, in this connection, that Auguste Comte was the founder of a short-lived religion, in which the object of worship was not the deity of the monotheistic faiths but humanity.

There are distinct anticipations of Positivism in ancient philosophy. Though the relationship of Protagoras, a 5th-century-BC Sophist, for example, to later Positivistic thought was only a distant one, there was a much more pronounced similarity in the classical Skeptic Sextus Empiricus, who lived at the turn of the 3rd century AD, and in Pierre Bayle, his 17th-century reviver. Moreover, the medieval Nominalist William of Ockham had clear affinities with modern Positivism. An 18th-century forerunner who had much in common with the Positivistic antimetaphysics of the following century was the German thinker Georg Lichtenberg.

Positivism clearly has its proximate roots, however, in the French Enlightenment, which stressed the clear light of reason, and in the 18th-century British Empiricism, particularly that of Hume and of Bishop George Berkeley, which stressed the role of sense experience. Comte was influenced specifically by the Enlightenment Encyclopaedists (such as Denis Diderot, Jean d'Alembert, and others) and, especially in his social thinking, was decisively influenced by the founder of French Socialism, Claude-Henri, comte de Saint-Simon, whose disciple he had been in his early years and from whom the very designation Positivism stems.

THE SOCIAL POSITIVISM OF COMTE AND MILL

Comte's Positivism was posited on the assertion of a so-called law of the three phases (or stages) of intellectual development. There is a parallel, as Comte saw it, between the evolution of thought patterns in the entire history of man, on the one hand, and in the history of an individual's development from infancy to adulthood, on the other. In the first, or so-called theological, stage, natural phenomena are explained as the results of supernatural or divine powers. It matters not whether the religion is polytheistic or monotheistic; in either case, miraculous powers or wills are believed to produce the observed events. This stage was criticized by Comte as anthropomorphic; *i.e.*, as resting on all-too-human analogies. Generally, animistic explanations—made in terms of the volitions of soullike beings operating behind the appearances—are rejected as primitive projections of unverifiable entities.

The second phase, called metaphysical, is in some cases merely a depersonalized theology: the observable processes of nature are assumed to arise from impersonal powers, occult qualities, vital forces, or entelechies (internal perfecting principles). In other instances, the realm of observable facts is considered as an imperfect copy or imitation of eternal ideas, as in Plato's metaphysics of pure Forms. Again, Comte charged that no genuine explanations result; questions concerning ultimate reality,

Affirmations and negations

Comte's law of three phases

The work of Farber, Schütz, and Gurwitsch

first causes, or absolute beginnings are thus declared to be absolutely unanswerable. The metaphysical quest can lead only to the conclusion expressed by the German biologist and physiologist, Emil du Bois-Reymond: "*Ignoramus et ignorabimus*" ("We are and shall be ignorant"); it is a deception through verbal devices and the fruitless rendering of concepts as real things.

The sort of fruitfulness that it lacks can be achieved only in the third phase, the scientific, or "positive," phase—hence the title of Comte's magnum opus: *Cours de philosophie positive* (1830–42; *The Positive Philosophy of Auguste Comte*, 1853)—because it claims to be concerned only with positive facts. The task of the sciences, and of knowledge in general, is to study the facts and regularities of nature and society and to formulate the regularities as (descriptive) laws; explanations of phenomena can consist in no more than the subsuming of special cases under general laws. Mankind reached full maturity of thought only after abandoning the pseudoexplanations of the theological and metaphysical phases and substituting an unrestricted adherence to scientific method.

Classification of the sciences; sociology

In his three stages Comte combined what he considered to be an account of the historical order of development with a logical analysis of the levelled structure of the sciences. By arranging the six basic and pure sciences one upon the other in a pyramid, Comte prepared the way for Logical Positivism to "reduce" each level to the one below it. He placed at the fundamental level the science that does not presuppose any other sciences—viz., mathematics—and then ordered the levels above it in such a way that each science depends upon, and makes use of, the sciences below it on the scale: thus arithmetic and the theory of numbers are declared to be presuppositions for geometry and mechanics, astronomy, physics, chemistry, biology (including physiology), and sociology. Each higher level science, in turn, adds to the knowledge content of the science or sciences on the levels below, thus enriching this content by successive specialization. Psychology is conspicuously missing in Comte's system of the sciences. Anticipating some ideas of 20th-century Behaviourism and physicalism, Comte assumed that psychology should become a branch of biology (especially of brain neurophysiology), on the one hand, and of sociology, on the other. As the "father" of sociology, Comte maintained that the social sciences should proceed from observations to general laws, very much as (in his view) physics and chemistry do. He was skeptical of introspection in psychology, being convinced that, in attending to one's own mental states, these states would be irretrievably altered and distorted. In thus insisting on the necessity of objective observation, he was close to the basic principle of the methodology of 20th-century Behaviourism.

Among Comte's disciples or sympathizers were Cesare Lombroso, an Italian psychiatrist and criminologist, and Paul-Emile Littré, J.-E. Renan, and Louis Weber.

Despite some basic disagreements with Comte, the 19th-century English philosopher John Stuart Mill, also a logician and economist, must be regarded as one of the outstanding Positivists of his century. In his *System of Logic* (1843), he developed a thoroughly Empiricist theory of knowledge and of scientific reasoning, going even so far as to regard logic and mathematics as empirical (though very general) sciences. The broadly synthetic philosopher Herbert Spencer, author of a doctrine of the "unknowable" and of a general evolutionary philosophy, was, next to Mill, an outstanding exponent of a Positivist orientation.

THE CRITICAL POSITIVISM OF MACH AND AVENARIUS

The influences of Hume and of Comte were also manifest in important developments in German Positivism, just prior to World War I. The outstanding representatives of this school were a philosophical critic of the physics of Newton, an Austrian, Ernst Mach, who was also an original thinker as a physicist and excelled as a historian of mechanics, thermodynamics, and optics, and Richard Avenarius, founder of a philosophy known as Empiriocriticism.

Mach, in the introductory chapter of his book *Beiträge zur Analyse der Empfindungen* (1886; *Contributions to the*

Analysis of the Sensations, 1897), reviving the Humean antimetaphysics, contended that all factual knowledge consists of a conceptual organization and elaboration of what is given in the elements; i.e., in the data of immediate experience. Very much in keeping with the spirit of Comte, he repudiated the transcendental Idealism of Kant. For Mach, the most objectionable feature in Kant's philosophy was the doctrine of the *Dinge an sich*—i.e., of the "things-in-themselves"—the ultimate entities underlying phenomena, which Kant had declared to be absolutely unknowable though they must nevertheless be conceived as partial causes of man's perceptions. Hermann von Helmholtz, a wide-ranging scientist and philosopher and one of the great minds of the 19th century, by contrast, held that the theoretical entities of physics are, precisely, the things-in-themselves—a view which, though generally Empiricist, was thus clearly opposed to the Positivist doctrine. Theories and theoretical concepts, according to the Positivist understanding, were merely instruments of prediction. From one set of observable data, theories formed a bridge over which the investigator could pass to another set of observable data. Positivists generally maintained that theories might come and go, whereas the facts of observation and their empirical regularities constituted a firm ground from which scientific reasoning could start and to which it must always return in order to test its validity. In consequence, most Positivists were reluctant to call theories true or false but preferred to consider them merely as more or less useful.

The task of the sciences, as it earlier had been expressed by the German physicist Gustav Kirchhoff, was the pursuit of a compendious and parsimonious description of observable phenomena. Concern with first causes or final reasons was to be excluded from the scientific endeavour as fruitless, or hopeless (if not meaningless). Even the notion of explanation became suspect and was at best taken (as already in Comte) to be no more than an ordering and connecting of observable facts and events by empirically ascertainable laws.

Mach and, along with him, Wilhelm Ostwald, the originator of physical chemistry, were the most prominent opponents of the atomic theory in physics and chemistry. Ostwald even attempted to derive the basic chemical laws of constant and multiple proportions without the help of the atomic hypothesis. To the Positivist the atom, since it could not be seen, was to be considered at best a "convenient fiction" and at worst an illegitimate ad hoc hypothesis. Hans Vaihinger, a subjectivist who called himself an "idealistic Positivist," pursued the idea of useful fictions to the limit, and was convinced that the concept of the atom, along with the mathematical concepts of the infinite and the infinitesimal, and those of causation, free will, the economic man, and the like, were altogether fictitious, some of them even containing internal contradictions.

The anti-atomistic strand in the thought of the Positivists was an extreme manifestation of their phobia regarding anything unobservable. With the undeniably great success of the advancing microtheories in physics and chemistry, however, the Positivist ideology was severely criticized, not only by some contemporary philosophers but also by outstanding scientists. The Austrian Ludwig Boltzmann and the German Max Planck, for example, both top-ranking theoretical physicists, were in the forefront of the attack against Mach and Ostwald. Boltzmann and Planck, outspoken Realists, were deeply convinced of the reality of unobservable microparticles, or microevents, and were clearly impressed with the ever-growing and converging evidence for the existence of atoms, molecules, quanta, and subatomic particles. Nevertheless, the basic Positivist attitude was tenaciously held by many scientists, and striking parallels to it appeared in American Pragmatism and instrumentalism; in parts of the work of the Pragmatists Charles Sanders Peirce, William James, and John Dewey, there is a philosophy of pure experience essentially similar to that of Mach.

Though Richard Avenarius has not become widely known, he too anticipated a good deal of what the American Pragmatists propounded. His Positivism, like that of Mach, comprised a biologically oriented theory of knowl-

Anti-atomism of Mach and Ostwald

Mach's phenomenism

The Positivism of Avenarius

edge. From the needs of organisms in their adaptation to the exigencies of their environment develop the conceptual tools needed for prediction of future conditions. In Avenarius' view, the raw material of the construction of the concepts of common sense and of the sciences, however, was "the given"; i.e., the data of immediate sensory experience. Just as Mill in the 19th century considered ordinary physical objects as "permanent possibilities of sensation," so Mach and Avenarius construed the concepts pertaining to what men commonsensically regard as the objects of the real world as "complexes of sensations." Thus, it was maintained that a stone, for example, is no more than a collection of such sensory qualities as hardness, colour, and mass. The traditional assumption that there must be an underlying substance that has these properties was repudiated. To the question "What would be left over if all of the perceptible qualities were stripped (in thought) away from an observable object?" these Positivists answered: "Precisely nothing." Thus the concept of substance was declared not only superfluous but meaningless as well.

In similar fashion, the concept of causation was explicated not as a real operating principle but as regularity of succession or as functional dependency among observable or measurable variables. Because these dependencies are not logically necessary, they are contingent and ascertained by observation, and especially by experimentation and inductive generalization.

The Newtonian doctrine according to which space and time are absolute or substantive realities had been incisively criticized by the 17th-century Rationalist Gottfried Leibniz and was subjected by Mach to even more searching scrutiny. While Leibniz had already paved the way for the conception of space and time as exclusively a matter of relations between events, Mach went still further in attacking the arguments of Newton in favour of a dynamic and absolute space and time. In particular, the inertial and centrifugal forces that arise in connection with accelerated or curvilinear motions had been interpreted by Newton as effects of such motions with respect to a privileged reference medium imagined as an absolute Cartesian mesh system graphed upon a real space. In a typically Positivist manner, however, Mach found the idea quite incredible. How, he asked, could an absolutely empty space have such powerful effects? Mach conjectured that any privileged reference system must be generated not by an imperceptible grid but by material reality—specifically, by the total mass of the universe (galaxies and fixed stars), an idea that later served as an important starting point for Einstein's general theory of relativity and gravitation.

The Positivist theory of knowledge, as proposed by Mach and Avenarius, impressed many scholars, most notable among whom was probably the leading British logician and philosopher Bertrand Russell in one of the earlier phases of his thought. In a work entitled *Our Knowledge of the External World* (1914), Russell analyzed the concept of physical objects as comprising classes of (perceptual) aspects or perspectives, an idea that later stimulated the work of Rudolf Carnap, an outstanding philosophical semanticist and Analyst, entitled *Der logische Aufbau der Welt* (1928; *The Logical Structure of the World*, 1967). Mach remained the most influential thinker among Positivists for a long time, though some of his disciples, like Josef Petzoldt, are now largely forgotten. But *The Grammar of Science* (1892), written by Karl Pearson, a scientist, statistician, and philosopher of science, still receives some attention; and in France it was Abel Rey, also a philosopher of science, who, along the lines of Mach, severely criticized the traditional mechanistic view of nature. In the United States, John Bernard Stallo, a German-born American philosopher of science (also an educator, jurist, and statesman), developed a Positivist outlook, especially in the philosophy of physics, in his book *The Concepts and Theories of Modern Physics* (1882), in which he anticipated to a degree some of the general ideas later formulated in the theory of relativity and quantum mechanics.

LOGICAL POSITIVISM AND LOGICAL EMPIRICISM

A first generation of 20th-century Viennese Positivists began its activities, strongly influenced by Mach, around

1907. Notable among them were a physicist, Philipp Frank, mathematicians Hans Hahn and Richard von Mises, and an economist and sociologist, Otto Neurath. This small group was also active during the 1920s in the Vienna Circle of Logical Positivists, a seminal discussion group of gifted scientists and philosophers that met regularly in Vienna, and in the related Berlin Society for Empirical Philosophy.

These two schools of thought, destined to develop into an almost worldwide and controversial movement, were built on the Empiricism of Hume, on the Positivism of Comte, and on the philosophy of science of Mach. Equally important influences came from several eminent figures who were at the same time scientists, mathematicians, and philosophers—G.F. Bernhard Riemann, the author of a non-Euclidean geometry; Hermann von Helmholtz, a pioneer in a broad range of scientific studies; Heinrich Hertz, the first to produce electromagnetic waves in his laboratory; Ludwig Boltzmann, a researcher in statistical mechanics; Henri Poincaré, equally eminent in mathematics and philosophy of science; and David Hilbert, distinguished for his formalizing of mathematics. Most significant, however, was the impact of Albert Einstein, as well as that of the three great mathematical logicians of the past 100 years—the ground-breaking German Gottlob Frege and the authors of the monumental *Principia Mathematica* (1910–13), Bertrand Russell and Alfred North Whitehead.

The earlier Positivism of Viennese heritage. The confluence of ideas from these sources and the impressions that they made upon the Vienna and Berlin groups in the 1920s gave rise to the philosophical outlook of Logical Positivism—a label supplied in 1931 by A.E. Blumberg and the Minnesota philosopher of science Herbert Feigl. The leader of the Vienna Circle between 1924 and 1936 was Moritz Schlick, who in 1922 succeeded to the chair (previously held by Mach and Boltzmann) for the philosophy of the inductive sciences at the University of Vienna. By 1924 an evening discussion group had been formed with Schlick, Hans Hahn, Otto Neurath, Victor Kraft, Kurt Reidemeister, and Felix Kaufmann as the prominent active participants. The most important addition to the circle was Rudolf Carnap, who joined the group in 1926. One of the early activities was the study and critical discussion of the *Tractatus Logico-Philosophicus* (1922) of Ludwig Wittgenstein, a seminal thinker in Analytical and Linguistic philosophy. It seemed at the time that the views of Carnap and Wittgenstein, although they had been formulated and elaborated quite differently, shared a large measure of basic agreement. Parallel, but not completely independent, developments occurred in the Berlin group, in which Hans Reichenbach, Richard von Mises, Kurt Grelling, and Walter Dubislav were the leading spirits.

Both the Vienna and Berlin groups consisted mainly of philosophically interested scientists or scientifically trained and oriented philosophers. Schlick had already anticipated some of the basic epistemological tenets of the groups in his *Allgemeine Erkenntnislehre* (1918; "General Theory of Knowledge"). But the philosophical outlook was sharpened and deepened when, in the late 1920s, the Viennese Positivists published a pamphlet *Wissenschaftliche Weltauffassung: Der Wiener Kreis* (1929; "Scientific Conception of the World: The Vienna Circle"), which was to be their declaration of independence from traditional philosophy—and, in the minds of its authors (Carnap, Hahn, and Neurath, aided by Waismann and Feigl), a "philosophy to end all philosophies."

Language and the clarification of meaning. The basic ideas of Logical Positivism were roughly as follows: the genuine task of philosophy is to clarify the meanings of basic concepts and assertions (especially those of science)—and not to attempt to answer unanswerable questions such as those regarding the nature of ultimate reality or of the Absolute. Inasmuch as an extremely ambitious Hegelian type of metaphysics, Idealistic and absolutist in orientation, was still prevalent in the German-speaking countries, there were many who believed that the antidote was urgently needed. Moreover, the Logical Positivists also had

The Vienna Circle and the Berlin Society

Influence of Mach and Avenarius

Scientific, antimetaphysical orientation

only contempt and ridicule for the ideas of the German Existentialist Martin Heidegger, whose interminable torment regarding such questions as "Why is there anything at all?" and "Why is what there is, the way it is?" and especially his pronouncements about Nothingness seemed to them to be not only sterile but so confused as to be nonsensical. The Logical Positivists viewed metaphysics as a hopelessly futile way of trying to do what great art, and especially poetry and music, already do so effectively and successfully. These activities, they held, are expressions of visions, feelings, and emotions and, as such, are perfectly legitimate as long as they make no claims to genuine cognition or representation of reality. What Logical Positivism recommended positively, on the other hand, was a logic and methodology of the basic assumptions and of the validation procedures of knowledge and of evaluation.

An adequate understanding of the functions of language and of the various types of meaning is another of the fundamentally important contributions of the Logical Positivists. Communication and language serve many diverse purposes: one is the representation of facts, or of the regularities in nature and society; another is the conveying of imagery, the expression and arousal of emotions; a third is the triggering, guidance, or modification of actions. Thus, they distinguished cognitive-factual meaning from expressive and evocative (or emotive) significance in words and sentences. It was granted that, in most utterances of everyday life (and even of science), these two types of meaning are combined or fused. What the Logical Positivists insisted upon, however, was that the emotive type of expression and appeal should not be mistaken for one having genuinely cognitive meanings. In such expressions as moral imperatives, admonitions, and exhortations there is, of course, a factually significant core; viz., regarding the (likely) consequences of various actions. But the normative element—expressed by such words as "ought," "should," "right," and their negations (as in "Thou shalt not. . .")—is by itself not cognitively meaningful but has primarily emotional and motivative significance.

Early statements about moral value judgments, such as those by Carnap or by A.J. Ayer, a more radical British Positivist, seemed shocking to many philosophers, to whom it seemed that, in their careless formulation, moral norms were to be treated like expressions of taste. Equally shocking was their condemnation as nonsense (really non-sense; i.e., complete absence of factual meaning) of all moral, aesthetic, and metaphysical assertions. More adequate and delicate analyses, such as that of the American Positivist Charles Stevenson, were soon to correct and modify those extremes. By proper allocation of the cognitive and the normative (motive) components of value statements, many thinkers rendered the originally harsh and implausible Positivist view of value judgments more acceptable. Nevertheless, there is—in every Positivist view—an ineluctable element of basic, noncognitive commitment in the acceptance of moral, or even of aesthetic, norms.

The verifiability criterion of meaning and its offshoots. The most noteworthy, and also most controversial, contribution of the Logical Positivists was the so-called verifiability criterion of factual meaningfulness. In its original form, this criterion had much in common with the earlier Pragmatist analysis of meaning (as in Charles Sanders Peirce and William James). Schlick's rather careless formulation: "The meaning of a [declarative sentence] is the method of its verification," which was really intended only to exclude from the realm of the cognitively meaningful those sentences for which it is logically inconceivable that either supporting or refuting evidence can be found, was close to the Pragmatist and, later, to the operationalist slogan that may be paraphrased by: "A difference must make a difference in order to be a difference"—or (more fully explicated): only if there is a difference in principle, open to test by observation, between the affirmation and the denial of a given assertion does this assertion have factual meaning. To take the classical example from Hume's analysis of the concept of causation, there is no difference between saying "A is always followed by B" and saying "A is necessarily always followed by B." That all effects have causes is true by virtue of the (customary) definitions of

"cause" and "effect"; it is a purely formal or logical truth. But to say (instead of speaking of effects) that all events have causes is to say something factual—and conceivably false. (It should be noted that these rather crude uses of "causality" and "necessity" were later replaced by much more subtle analyses.)

One of the most important examples that stimulated the formulation of the meaning criterion was Einstein's abandonment, in 1905, of the ether hypothesis and of the notion of absolute simultaneity. The hypothesis that there exists a universal ether, as a medium for the propagation of light (and of electromagnetic waves generally), had been quite plausible and was widely accepted by physicists during the second half of the 19th century. To be sure, there were a number of serious difficulties with the idea: the properties that had to be ascribed to the ether were difficult to conceive in a logically compatible manner; and the ether hypothesis in the last stage of its development (by the Dutch physicist Hendrik Lorentz and the Irish physicist George Fitzgerald) had become objectionable in that it sought to provide excuses for the absolute unobservability of that mysterious, allegedly all-pervasive, universal substance. Similarly, it had become impossible, except at the price of intolerably ad hoc hypotheses, to maintain the notions of absolute time and of absolute simultaneity. Thus Einstein, by eliminating these empirically untestable assumptions, was led to his special theory of relativity.

Several important changes in the formulation of the meaning criterion took place in the ensuing decades from 1930 to 1960. The original version formulated in terms of verifiability was replaced by a more tolerant version expressed in terms of testability or confirmability. Obviously, universal propositions, such as "All cats have claws," being only partially supportable by positive instances (one cannot examine every cat that exists), are not conclusively verifiable. Nevertheless, scientists do accept lawlike statements on the basis of only incomplete, as well as indirect, verification—which is what "confirmation" amounts to. It was in coming to this juncture in his critique of Positivism that Karl Popper, an Austro-English philosopher of science, in his *Logik der Forschung* (1935; *The Logic of Scientific Discovery*, 1959), insisted that the meaning criterion should be abandoned and replaced by a criterion of demarcation between empirical (scientific) and transempirical (nonscientific, metaphysical) questions and answers—a criterion that, according to Popper, is to be testability, or, in his own version, falsifiability; i.e., refutability. Popper was impressed by how easy it is to supposedly verify all sorts of assertions—those of psychoanalytic theories seemed to him to be abhorrent examples. But the decisive feature, as Popper saw it, should be whether it is in principle conceivable that evidence could be cited that would refute (or disconfirm) a given law, hypothesis, or theory. Theories are (often) bold conjectures. It is true that scientists should be encouraged in their construction of theories—no matter how far they deviate from the tradition; it is also true, however, that all such conjectures should be subjected to the most severe and searching criticism and experimental scrutiny of their truth claims. The growth of knowledge thus proceeds through the elimination of error; i.e., through the refutation of hypotheses that are either logically inconsistent or entail empirically refuted consequences.

Despite valuable suggestions in Popper's philosophy of science, the Logical Positivists and Empiricists continued to reformulate their criteria of factual meaningfulness. The Positivist Hans Reichenbach, who emigrated from Germany to California, proposed, in his *Experience and Prediction* (1938), a probabilistic conception. If hypotheses, generalizations, and theories can be made more or less probable by whatever evidence is available, he argued, then they are factually meaningful. In another version of meaningfulness, first adumbrated by Schlick (under the influence of Wittgenstein's thought), the philosopher's attention is focussed on concepts rather than on propositions. If the concepts in terms of which theories are formulated can be related, through chains of definitions, to concepts that are definable ostensibly—i.e., by pointing to or exhibiting items or aspects of direct experience—

simul-
taneity

then those theories are factually meaningful. This is the version also advocated by Richard von Mises, an Austro-American mathematician and methodologist, in his *Positivism* (1951) and, later, more technically elaborated by Carnap, in *Minnesota Studies in the Philosophy of Science*, vol. 1 (1956).

Other issues. These views of meaningfulness are essentially refinements of the doctrine of so-called protocol sentences, developed in the late 1920s and early 1930s and elaborated especially by Carnap, by Otto Neurath, a polymath sociologist and philosopher, and also (with some differences) by Schlick. Protocol sentences, originally conceived along the lines of an interpretation, developed in the Vienna Circle, of Wittgenstein's elementary propositions, were identified as those sentences that make statements about the data of direct experience. But Neurath—and independently also Popper—warned of the danger that this doctrine might lead to subjective Idealism and recommended that it be given a rational reconstruction on an intersubjective basis. Thus, Neurath and Carnap preferred that a physicalistic thing-language be employed as the starting point and testing ground of all knowledge claims. Propositions in this language would describe objectively existing, directly observable states of affairs or events. Because all objective and intersubjective knowledge was seen, in such a physicalism, to rest on statements representing things and their properties, relations and ongoing processes as they are found in unbiased, and presumed theory-free, observation, the physicalists were thus proclaiming a first thesis of the so-called Unity of Science principle. Though Mach had proceeded from the basis of (neutral) immediate experience, his insistence on the unity of all knowledge and all science was retained—at least in general spirit—by the later Positivists. In this view, all classifications of the sciences, or divisions of their subject matter, were seen as artificial, valuable at best only administratively, but without philosophical justification.

Sharply to be distinguished from this first thesis of the Unity of Science is a second that formulates a reductionism of a very different type: whereas the first thesis concerns the unity of the observational basis of all the sciences, the second proposes (tentatively) a unity of the explanatory principles of science. Reductions within physics itself, such as that of thermodynamics to the kinetic theory of heat (statistical mechanics) and of optics to electromagnetics; and, beyond that, the explanation of chemical phenomena, with the help of the quantum theory, in terms of atomic and molecular processes; and, furthermore, the progress that has been made in the physical explanation of biological phenomena (especially in the recent development of molecular biology)—all of these encourage the idea of a unitary set of physical premises from which the regularities of all of reality could be derived. But it must be admitted that, in contrast to the first thesis (which, by comparison is almost trivial), the second, being a bold conjecture about future reductions in the sciences, might well prove to be limited in the scope of its validity. The most controversial part of this reductionist ideology, however, concerns the realms of organic life and especially that of mind; it concerns, in other words, the reducibility of biology to physics and chemistry and of psychology to neurophysiology—and (though this is clearly utopian at present) of both ultimately to basic physics.

The most serious alternative to this reducibility thesis of the Unity of Science movement is the theory of emergent evolution, according to which life or mind (or both) are genuinely novel forms of reality that could not possibly have been derived from, or predicted by, any laws or theories of the lower or earlier levels of existence.

Historically, it may be plausible that the notorious perplexities of the traditional problem of how mind relates to body motivated both the phenomenalist Positivists as well as the Behaviourists and physicalists. In either view, the mind-body problem conveniently disappears; it is branded as a metaphysical pseudoproblem. The phenomenalism of Mach and the early Russell was expressed in a position called neutral monism, according to which both psychological and physical concepts are viewed as logical constructions on the basis of a neutral set of data of im-

mediate experience. There are thus not two realities—the mental and the physical; there are merely different ways of organizing the experiential data. In the Behaviourist-physicalist alternative, on the other hand, the philosopher, considering the concepts that are ordinarily taken to characterize private mental acts and processes, defines them on the basis of publicly (intersubjectively) observable features of the behaviour, including the linguistic behaviour, of man.

The absolute privacy of mental events was first criticized, however, by Carnap and later by an Oxford Analytical philosopher, Gilbert Ryle; and Wittgenstein, in an argument against the very possibility of a private language, maintained that, unless men have objective criteria for the occurrence of mental states, they cannot even begin to communicate meaningfully with each other about their direct experiences. Wittgenstein thus repudiated the traditional view according to which a man's knowledge of other persons' minds must be based on analogical inference from his own case. In a similar vein, an American psychologist, B.F. Skinner, tried to account for man's acquisition of subjective terms in his language by a theory of verbal behaviour. A man learns to describe his mental states, explained Skinner, from the utterances of others who ascribe these states to him by virtue of their observation of his behaviour (*e.g.*, in the social context; or when a certain stimulus situation prevails in his environment).

Both Carnap and Ryle have emphasized that many mental features or properties have a dispositional character. Dispositional terms, whether used in psychology or more broadly, have to be understood as shorthand expressions for test conditions—or test-result conditionals. Thus, even in ordinary life, a man appraises, for example, the intelligence of a person in the light of what he does, how he does it, how fast he does it, when confronted with various tasks or problems. Just as such physical properties as malleability, brittleness, or thermal or electrical conductivity must be defined in terms of what happens when certain conditions are imposed, so also mental dispositions are to be construed as similarly hypothetical; *i.e.*, as (in the simplest case) stimulus-response relationships.

The later Positivism of Logical Empiricism. Logical Positivism, essentially the doctrine of the Vienna Circle (*c.* 1924–38), underwent a number of important changes and innovations in the middle third of the century, which suggested the need for a new name. The designation Positivism had been strongly connected with the Comte-Mach tradition of instrumentalism and phenomenalism. The emphasis that this tradition had placed, however, on the positive facts of observation and their negative attitude toward the atomic theory and the existence of theoretical entities in general were no longer in keeping with the spirit of 20th-century science. Nevertheless, the requirement that hypotheses and theories be empirically testable, though it became more flexible and tolerant, could not be relinquished. It was natural, then, that the word “empiricism” should occur in any new name. Accordingly, retaining the term “logical” in roughly its same earlier meaning, the new name “Logical Empiricism” was coined.

The status of the formal and a priori. The intention of the word “logical” was to insist on the distinctive nature of logical and mathematical truth. In opposition to Mill's view, according to which even logic and pure mathematics are empirical (*i.e.*, are justifiable or refutable by observation), the Logical Positivists—essentially following Frege and Russell—had already declared mathematics to be true only by virtue of postulates and definitions. Expressed in the traditional terms used by Kant, logic and mathematics were recognized as a priori disciplines (valid independently of experience) precisely because their denial would amount to a self-contradiction, and statements within these disciplines were expressed in what Kant called analytic propositions; *i.e.*, propositions that are true or false only by virtue of the meanings of the terms they contain. In his own way, the broad-ranging scholar Gottfried Leibniz had seen this in the 17th century long before Kant. The truth of such a simple arithmetical proposition as, for example, “ $2 + 3 = 5$ ” is necessary, universal, a priori, and analytic because of the very meaning of “2,” “+,”

"3," "5," and "=". Experience could not possibly refute such truths because their validity is established (as Hume said) merely by the "relation of ideas." Even if—"miraculously"—putting two and three objects together should on some occasion yield six objects, this would be a fascinating feature of those objects (rabbits, perhaps); but it would not in the least tend to refute the purely definitional truths of arithmetic.

The case of geometry is altogether different. Geometry can be either an empirical science of natural space or an abstract system with uninterpreted basic concepts and uninterpreted postulates. The latter is the conception introduced in rigorous fashion by a late 19th-century mathematician, David Hilbert, and, still later, by a United States geometer, Oswald Veblen. In the axiomatizations that they developed, the basic concepts, called primitives, are implicitly defined by the postulates: thus, such concepts as point, straight line, intersection, betweenness, and plane are related to each other in a merely formal manner. The proof of theorems from postulates, and with explicit definitions of derived concepts (such as of triangle, polygon, circle, or conic section), is achieved by strict deductive inference. Very different, however, is geometry as understood in practical life, and in the natural sciences and technologies, in which it constitutes the science of space. Ever since the development of the non-Euclidean geometries in the first half of the 19th century, it has no longer been taken for granted that Euclidean geometry is the only geometry uniquely applicable to the spatial order of physical objects or events. In Einstein's general theory of relativity and gravitation, in fact, a four-dimensional Riemannian geometry with variable curvature was successfully employed, an event that amounted to a final refutation of the Kantian contention that the truths of geometry are "synthetic a priori." With respect to the relation of postulates to theorems, geometry is thus analytic, like any other rigorously deductive discipline; but the postulates themselves, when interpreted—i.e., when construed as statements about the structure of physical space—are indeed synthetic, but also a posteriori; i.e., their adequacy depends upon the results of observation and measurement.

Developments in Linguistic Analysis and their offshoots. Important contributions, beginning in the early 1930s, were made by Carnap, by Kurt Gödel, a Moravian-American mathematical logician, and others to the logical analysis of language. Charles Morris, a Pragmatist concerned with Linguistic Analysis, had outlined the three dimensions of semiotics (the general study of signs and symbolisms): syntax, semantics, and pragmatics (the relation of signs to their users and to the conditions of their use). Syntactical studies, concerned with the formation and transformation rules of language (i.e., its purely structural features), soon required supplementation by semantical studies, concerned with rules of designation and of truth. Semantics, in the strictly formalized sense, owed its origin to Alfred Tarski, a leading member of the Polish school of logicians, and was then developed by Carnap and applied to problems of meaning and necessity. As Wittgenstein had already shown, the necessary truth of tautologies simply amounts to their being true under all conceivable circumstances. Thus the so-called eternal verity of the principles of identity (p is equivalent with itself), of noncontradiction (one cannot both assert and deny the same proposition), and the principle of excluded middle (any given proposition is either true or false; there is no further possibility) is an obvious consequence of the rules according to which the philosopher uses (or decides to use) the words "proposition," "negation," "equivalence," "conjunction," "disjunction," and others. Quite generally, questions regarding the meanings of words or symbols are answered most illuminatingly by stating the syntactical and the semantical rules according to which they are used.

Two different schools of thought originated from this basic insight: (1) the philosophy of "ordinary language" Analysis—initiated by Wittgenstein, especially in his later work, and (following him) developed in differing directions in the works of Gilbert Ryle and John Langshaw Austin, both Oxford philosophers, of the Cambridge Analyst John Wisdom, and others; and (2) the ideology, essentially that

of Carnap, usually designated as logical reconstruction, which builds up an artificial language. In the procedures of "ordinary language" Analysis, an attempt is made to trace the ways in which a person commonly expresses himself. In this manner, many of the traditional vexatious philosophical puzzles and perplexities are shown to arise out of deviant uses of language. (Lewis Carroll had already anticipated some of these oddities in his whimsical manner in *Alice in Wonderland*.) The much more rigorous procedures of the second school—of Tarski, Carnap, and many other logicians—rest upon the obvious distinction between the language (and all of its various symbols) that is the object of analysis, called the object language, and that in which the analysis is formulated, called the metalanguage. If needed and fruitful, this process can be repeated, in that the erstwhile metalanguage can become the object of a metametalinguage, and so on—without the danger of a vicious infinite regress.

With the help of semantical concepts, an old perplexity in the theory of knowledge can then be resolved. Positivists have often tended to conflate the truth conditions of a statement with its confirming evidence, a procedure which has led to certain absurdities committed by phenomenologists and operationalists, such as the pronouncement that the meanings of statements about past events consist in their (forthcoming future) evidence. Clearly, the objects—the targets or referents—of such statements are the past events. Thus the meaning of a historical statement is its truth conditions; i.e., the situation that would have to obtain if the historical statement is to be true. The confirmatory evidence, however, may be discovered either in the present or in the future. Similarly, the evidence for an existential hypothesis in the sciences may consist, for example, in cloud-chamber tracks, spectral lines, or the like, whereas the truth conditions may relate to subatomic processes or to astrophysical facts. Or, to take an example from depth psychology, the occurrences of unconscious wishes or conflicts are the truth conditions for which the observable symptoms (Freudian lapses, manifest dream contents, and the like) serve merely as indicators or clues; i.e., as items of confirming evidence.

The third dimension of language (in Morris' view of semiotic)—i.e., the pragmatic aspect—has not been as fully and formally analyzed as the other two dimensions. There is even some disagreement as to whether some of the cognitive activities (such as verifying, refuting, or interpreting), in addition to the noncognitive functions (such as the motivative and persuasive appeals), are to be included in studies of pragmatics.

One of the most surprising and revolutionary offshoots of the metalinguistic (formal) analyses was Kurt Gödel's discovery, in 1931, of an exact proof of the undecidability of certain types of mathematical problems, a discovery that dealt a severe blow to the expectations of the Formalistic school of mathematics championed by Hilbert and his collaborator, Paul Bernays. Before Gödel's discovery, it had seemed plausible that a mathematical system could be complete in the sense that any well-formed formula of the system could be either proved or disproved on the basis of the given set of postulates. But Gödel showed rigorously (what had been only a conjecture on the part of the Dutch Intuitionist L.E.J. Brouwer and his followers) that, for a large class of important mathematical systems, such completeness cannot be achieved.

Both Carnap and Reichenbach, in their very different ways, made extensive contributions to the theory of probability and induction. Impressed with the need for an interpretation of the concept of probability that was thoroughly empirical, Reichenbach elaborated a view that conceived probability as a limit of relative frequency and buttressed it with a pragmatic justification of inductive inference. Carnap granted the importance of this concept (especially in modern physical theories) but attempted, in increasingly refined and often revised forms, to define a concept of degree-of-confirmation that was purely logical. Statements ascribing an inductive probability to a hypothesis are, in Carnap's view, analytic, because they merely formulate the strength of the support bestowed upon a hypothesis by a given body of evidence.

CURRENT CRITICISMS AND CONTROVERSIES

Logical Positivism and Logical Empiricism have from their very beginnings been subjected to searching criticisms. At first it was the verifiability criterion of meaningfulness that produced a storm of oppositions. One group of critics asked whether the criterion was meaningful in the light of its own standard. Carnap replied that the criterion itself was not intended as a factual assertion but rather as a proposal for a better and clearer use of language. Nevertheless, the Logical Empiricists felt that the (tolerant-liberal) formulation of the meaning criterion—far from being an arbitrary injunction—came rather close to what enlightened common sense, and especially the scientific attitude, intended by the difference between sense and non-sense.

Other recent and current criticisms concern the Logical Empiricist views regarding the nature of scientific explanation, in regard to which matters are not as simple as they were originally conceived to be. Closer attention to the history of scientific theories has revealed important discontinuities, or revolutions, in the conceptual schemes of the sciences. The significant role of statistical (or probabilistic) explanations in most modern sciences, for example, is receiving increasingly sophisticated analyses.

Nevertheless, the prevalence of scientific revolutions and anarchism or subjectivism in scientific method has been exaggerated in differing ways by several scholars. As has been conceded by all competent philosophers of science and even by the greatest scientist-philosophers of the century—Albert Einstein, Niels Bohr, Erwin Schrödinger, and others—there is no straight logical path, no standard recipe, by which to move from the data of observation and arrive at scientific theories. It may also be admitted that, though scientific creativity has psychologically much in common with artistic creation, the criteria of appraisal are certainly quite different. And, although, from the present critical point of view, all and any scientific assertions are in principle subject to revision, it is nonetheless felt to be grotesque to deny the relative stability of the empirical laws that serve as the testing ground of alternative theories.

(H.Fe.)

Pragmatism

In its broadest and most familiar sense, “pragmatism” refers to the usefulness, workability, and practicality of ideas, policies, and proposals as criteria of their merit and claims to attention. Achieving results, “getting things done” in business and public affairs is often said to be “pragmatic.” There is a harsher and more brutal connotation of the term in which any exercise of power in the successful pursuit of practical and specific objectives is called “pragmatic.” The character of American business and politics is often so described. In these cases “pragmatic” carries the stamp of justification: a policy is justified pragmatically if it is successful. The familiar and the academic conceptions have in common an opposition to invoking the authority of precedents or of abstract and ultimate principles. Thus in law, judicial decisions that have turned on the weighing of consequences and probable general welfare rather than on being deduced from precedents have been called pragmatic.

The word pragmatism goes back to the Greek *πράγμα* (“action,” “affair”). The Greek historian Polybius (died 118 bc) called his writings “pragmatic,” meaning thereby that they were intended to be instructive and useful to his readers. In his introduction to the *Philosophy of History*, Hegel commented on this “pragmatical” approach as the second kind of reflective history, and for this genre he cited Johannes von Müller’s *History of the World* (Eng. trans. 1840). As the psychologist and leading Pragmatist William James remarked, “the term is derived from the same Greek word *πράγμα* meaning action, from which our words ‘practice’ and ‘practical’ come.” Charles Peirce, another pioneering Pragmatist, who may have been the first to use the word to designate a specific philosophic doctrine, had Kant’s German term rather than the Greek word in mind: *Pragmatisch* refers to experimental, empirical, and purposive thought “based on and applying to experience.” In the philosophy of education the notion

that children learn by doing, that critical standards of procedure and understanding emerge from the application of concepts to directly experienced subject matters, has been called “pragmatic.” In semiotics, the general theory of language, that part that studies the relation of the user to the words or other signs that he uses is called pragmatics (as distinct from semantics and syntax).

MAJOR THESES OF PHILOSOPHIC PRAGMATISM

During the first quarter of the 20th century, Pragmatism was the most influential philosophy in America, exerting an impact on the study of law, education, political and social theory, art, and religion. Six fundamental theses of this philosophy can be distinguished. It is, however, unlikely that any one thinker would have subscribed to them all; and even on points of agreement, varying interpretations mark the thought and temper of the major Pragmatists. The six theses are:

1. Responsive to Idealism and evolutionary theory, Pragmatists have emphasized the “plastic” nature of reality and the practical function of knowledge as an instrument for adapting to reality and controlling it. Existence is fundamentally concerned with action, which some Pragmatists exalted to an almost metaphysical level. Change being an inevitable condition of life, Pragmatists have called attention to the ways in which change can be directed for individual and social benefit. They have consequently been most critical of moral and metaphysical doctrines in which change and action are relegated to the “merely practical,” on the lowest level of the hierarchy of values. Some Pragmatists anticipated the more concrete and life-centred philosophy of Existentialism by arguing that only in acting—confronted with obstacles, compelled to make choices, and concerned to give form to experience—is man’s being realized and discovered.

2. Pragmatism is a continuation of critical Empiricism in emphasizing the priority of actual experience over fixed principles and a priori reasoning in critical investigation. For James this meant that the Pragmatist

turns away from abstraction and insufficiency, from verbal solutions, from bad *a priori* reasons, from fixed principles, closed systems, and pretended absolutes and origins. He turns towards concreteness and adequacy, towards facts, towards action It means the open air and possibilities of nature, as against . . . dogma, artificiality, and the pretence of finality in truth.

3. The pragmatic meaning of an idea, belief, or proposition is said to reside in the distinct class of specific experimental or practical consequences that result from the use, application, or entertainment of the notion. As Peirce commented: “Our idea of anything is our idea of its sensible effects.” Two propositions for which no different effects can be discerned have merely a verbal appearance of dissimilarity, and a proposition for which no definite theoretical or practical consequences can be determined is pragmatically meaningless. For Pragmatists “there is no distinction of meaning so fine as to consist in anything but a possible difference of practice.” Meaning thus has a predictive component, and some Pragmatists came close to identifying the meaning of a term or proposition with the process of its verification.

4. While most philosophers have defined truth in terms of a belief’s “coherence” within a pattern of other beliefs or as the “correspondence” between a proposition and an actual state of affairs, Pragmatism has, in contrast, generally held that truth, like meaning, is to be found in the process of verification. Thus truth *is* the verification of a proposition, or the successful working of an idea. Crudely, truth is “what works.” Less crudely and more theoretically, truth is in Peirce’s words, the “limit towards which endless investigation would tend to bring scientific belief.” For John Dewey, founder of the “Instrumentalist” school of Pragmatism, these are beliefs “warranted” by inquiry.

5. In keeping with their understanding of meaning and truth, Pragmatists have interpreted ideas as instruments and plans of action. In contrast to the conception of ideas as images and copies of impressions or of external objects, Pragmatist theories have emphasized the functional character of ideas: ideas are suggestions and anticipations of

possible conduct; they are hypotheses or forecasts of what will result from a given action; they are ways of organizing behaviour in the world rather than replicas of the world. Ideas are thus analogous in some respects to tools; they are efficient, useful, and valuable, or not, depending on the role that they play in contributing to the successful direction of behaviour.

6. In methodology, Pragmatism is a broad philosophical attitude toward the formation of concepts, hypotheses, and theories and their justification. To Pragmatists man's interpretations of reality are motivated and justified by considerations of efficacy and utility in serving his interests and needs; the molding of language and theorizing are likewise subject to the critical objective of maximum usefulness according to man's various purposes.

HISTORY OF PRAGMATISM

Idealism,
Empiri-
cism,
Kant-
ianism

Antecedents in modern philosophy. Pragmatism was a part of a general revolt against the overly intellectual, somewhat fastidious, and closed systems of Idealism in 19th-century philosophy. These boldly speculative Idealists had expanded man's subjective experience of mind till it became a metaphysical principle of cosmic explanation. To the Idealist, all of reality was one fabric, woven from parts that cohered by virtue of the internal relations that they bore to one another; and this reality was often interpreted in abstract and fixed intellectual categories. The theory of evolution, then still new, seemed to the Pragmatists, on the other hand, to call for a new, non-Idealist interpretation of nature, life, and reason—one that challenged the long-established conceptions of fixed species. The new emphasis was on the particular variations and struggles of life in adapting to the environment. Philosophically, the fact of growth and the development of techniques for instituting changes favourable to life became the significant factors rather than the Idealist's ambitious rationalistic account of human goals and of the universe in general, and important developments in natural science and logic also encouraged a critical attitude toward earlier systems.

There were two main influences on the early formation of Pragmatism: One was the tradition of British Empiricism in the work of John Stuart Mill, Alexander Bain, and John Venn, which had stressed the role of experience in the genesis of knowledge—and particularly their analyses of belief as being intimately tied in with action and, indeed, as definable in terms of one's disposition and motive to act. The work of George Berkeley, an important 18th-century empirical Idealist, which presented a theory of the practical and inferential nature of knowledge, of sensations as signs (and thus predictive) of future experience, led Peirce to refer to him as "the introducer of Pragmatism." The other major influence came from modern German philosophy: from Kant's analysis of the purposive character of belief and of the roles of will and desire in forming belief and his doctrine of "regulative ideas," such as God or the Soul, which guide the understanding in achieving systematic completeness and unity of knowledge; from Romantic Idealists, for whom all reason is "practical" in expanding and enriching human experience; and from Hegel's historical and social conception of changing and developing subject matters. In sum, Peirce was profoundly impressed by Kant and by the Scottish philosophy of common sense, James by British Empiricism and by the voluntarisms (stressing the role of choice or will) of the genetic epistemologist James Ward and the relativistic French Personalist Charles Renouvier, Dewey by Coleridge's version of Kant's active conception of mind and by neo-Kantian and Hegelian Idealism.

Finally, to these influences must be added that of American social experience in the 19th century: the rapid expansion of industry and trade and a popular optimism, with its roots in Puritan theology, holding that hard work and virtue are bound to be rewarded. Both the precariousness of frontier life, however, and the rapidly expanding economy weakened the prevailing Calvinistic belief in a predestined future and encouraged the emergence of inventiveness, a sense of living still in the New World experiment, and adoption of the ideal of "making good."

The Metaphysical Club. It was in the critical group

discussions of the "Metaphysical Club" in the 1870s in Cambridge, Massachusetts, that Pragmatism first received philosophic expression. In addition to Peirce and James, membership in the club included Chauncey Wright, F.E. Abbot, and Justice Oliver Wendell Holmes, Jr. A version of Peirce's now classic paper "The Fixation of Belief" (November 1877) seems to have been presented at the club. But James also published a paper in 1878, "Spencer's Definition of Mind as Correspondence," in which his Pragmatism and analysis of thought and belief are clearly discernible. It was in a lecture delivered 20 years later, however, that James introduced Pragmatism, then fully crediting the idea to Peirce. It was primarily James's exposition that became famous and was received by the world at large.

The classical Pragmatists. The Pragmatic philosophy of Charles Sanders Peirce was part of a more general theory of thought and of signs. Thought, or "inquiry," it was held, results from doubt, a state in which habitual actions are blocked or confused and from which organic irritation and irresolution result. Resolution, unobstructed conduct, on the other hand, are products of belief, which is a form of stability and satisfaction. It is the function of scientific thought to produce true beliefs. In a prolonged effort to embed this analysis of doubt and inquiry within a more comprehensive theory of signs in which communication, thought, knowledge, and intelligent conduct could be fully understood, Peirce achieved a wealth of original insights. A sign is a socially standardized way by which something (a thought, word, object) refers man (the community of sign users) to something else (the interpretant), which, in turn, is itself another sign. Peirce's Pragmatism is thus a method for translating certain kinds of signs into clearer signs in order to surmount linguistic or conceptual confusion. Getting at the interpretant involves determining the "effects" or consequences of the signs or ideas in question.

Peirce's Pragmatism is therefore primarily a theory of meaning that emerged from his first-hand reflections on his own scientific work, in which the experimentalist understands a proposition as meaning that, if a prescribed experiment is performed, a stated experience will result. The method has two different uses:

(1) It is a way of showing that when disputes permit no resolution, the difficulties are due to misuses of language, to subtle conceptual confusions. Such questions as whether the physical world is an illusion, whether man's senses always mislead him, or whether his actions are fated are "not real problems."

(2) The method may be employed for clarification. As Peirce wrote:

Consider what effects, that might conceivably have practical bearings, we conceive the object of our conception to have. Then our conception of these effects is the whole of our conception of the object.

To say, for example, that an object *O* is hard means that if the operation of scratching *O* is performed, *O* will not be scratched by most substances. One thus achieves clarity when one can supply a conditional statement of this kind.

Similarly, in his theory of truth, one means by truth of belief that if a certain operation is the subject of continuous scientific inquiry by the community of investigators, assent to the belief would increase and dissent decrease "in the long run." Consequently, not only is thought purposive but meaning carries a reference to the future. Peirce's concept of the community of sign users and inquirers also has social and moral relevance, for it is nothing less than the ideal of rational democracy.

Witnessing his doctrine undergo a medley of dubious interpretations, Peirce eventually dissociated himself from these by calling his own view "Pragmaticism," a term he called so ugly as to be safe from uninformed use. Parts of the work of Dewey, of the social Pragmatist G.H. Mead, and of the conceptualistic Pragmatist C.I. Lewis are a further development of the logical Pragmatism of Peirce. The English logician F.P. Ramsey and the Italians Giovanni Vailati and Mario Calderoni also undertook significant extensions of Peirce's Pragmatism.

An alternative, though not wholly different, version of Pragmatism was developed by William James. It took a

Peirce's
Pragma-
tism

James's
Prag-
matism

psychological and moral form largely unforeseen and unintended by Peirce.

A basic difference between Peirce and James is discernible in their respective conceptions of the direction to be taken by Pragmatic analysis. While Peirce construed meaning in general, conditional schema, and interpretants, James focussed upon the distinct contributions that ideas and beliefs make to specific forms of human experience on the living level of practical wants and purposes. Between the two close friends there persisted a fundamental philosophical difference in outlook that affected even their styles. While James was a Nominalist, holding that the full significance of ideas, meanings, and actions lies in their particular concrete existent occurrence, Peirce—as a scholastic Realist—sharply criticized him at this point, arguing that “a thing in general is as real as in the concrete.”

The most conspicuous feature of James's writings on Pragmatism is the dominant place given to considerations of value, worth, and satisfaction—consequences of his teleological (purposive) conception of mind (cf. his *Principles of Psychology*). James maintained that thought is adaptive and purposive but also suffused with ideal emotional and practical interests—“should-be's”—which, as conditions of action, work to transform the world and create the future, even to “make the truth which they declare.” Consequently, truth and meaning are species of value: “*The true is the name of whatever proves itself to be good in the way of belief.*”

James took meaning to be an intimate part of the use of ideas for expediting action. The notion of the difference that a proposition makes in experience was fundamental in James's Pragmatic methodology. He remarked that “it is a good rule in physiology, when we are studying the meaning of an organ,” to look to the specific function that it performs. In like manner, the special difference that the presence of mind makes in observable cases, reflected in its unique functioning, defines the use of “mind”; “In particular, the pursuance of future ends and the choice of means . . . are thus the *mark and criterion of the presence of mentality.*”

With his training in medicine and psychology and the influence of Darwin in the background, James considered that the main function of thought is to help us establish “satisfactory relations with our surroundings.” Thus man helps to mold the character of reality according to his needs and desires. Indeed, this is fundamental in James's defense of the right to believe in his famous essay “The Will to Believe” (1897). James argued that we may have a reasonable right to hold a religious or metaphysical belief (e.g., that there is a perfect, eternal, and personal aspect of the universe) when the belief in question would supply a vital psychological and moral benefit to the believer, when evidence for and against the belief is equal, and when the decision to believe is forced and momentous. In James's functional conception of truth, the “working,” and hence the truth, of ideas is their role in opening up valuable possible directions of thought and action—“a leading that is worth while.”

James's “working” view of truth and of a reality that man in part makes by acting out and realizing ideas, and especially his essay “The Will to Believe,” were enthusiastically received by F.C.S. Schiller in England and by Giovanni Papini in Italy, and these doctrines became a cause célèbre for Pragmatists and their critics.

Schiller's
Prag-
matism

An admirer and friend of James, Schiller, now nearly forgotten, was once the most famous Pragmatist in England and Europe. Schiller was initially a humanist in the sense that, for him, both reality and knowledge are reflections of human activity—“the taken” rather than “the given.” He first came to appreciate James's “The Will to Believe” in 1897 and subsequently acknowledged its impact on his thinking in an early and important paper, “Axioms As Postulates” (1902). He was a tireless critic of the “closed” systems of Idealism of F.H. Bradley, J.M.E. McTaggart, and Bernard Bosanquet and an advocate of the intellectual freedom that consists in “open,” plural, changing, and to some extent never finished philosophical theorizing. According to Schiller, reality and truth are “man-made” rather than eternal verities. The true and

the false are basically forms of good and bad and are relative to the private purposes of some particular person. He attempted to describe and analyze the “logic” of the experimental “trying” through which such needs are satisfied. For Schiller, reality is wholly plastic; and, starting out from initial postulates, one proceeds to construct one's schemes for achieving a satisfactory outcome of desire, finally rendering one's unformed possibilities (*hylē*) into a common world of language and action. On this view, all of science derives from and is inescapably guided by the psychological process of human thought; man is the measure of all things.

John Dewey once noted that “Peirce wrote as a logician and James as a humanist.” This distinction characterizes not only the course of Pragmatism but also the shaping of Dewey's own thought. Dewey first felt the influence of James in the 1890s, during the period in which he was struggling to free himself from the hold of Hegelian Idealism. Later, he recognized the value of Peirce's work, which clearly prefigured certain ideas that he had developed independently.

With indefatigable effort and care Dewey reformulated Pragmatism, critically readjusting some of its conflicting doctrines, drawing upon his own work in psychology and education, and finding stimulation in the social Pragmatism of his friend George Herbert Mead. The resulting construction was Instrumentalism, which Dewey conceived as a single coherent theory embracing both the logical and humanistic currents of Pragmatism and thus integrating the methods and conclusions of scientific knowledge with beliefs about values and purposes.

While scientific, moral, and social experiences may differ in subject matter, the method of thought functioning “in the experimental determinations of future consequences” remains the same for all inquiry. Initially provoked by doubtful or problematic conditions, intelligent conduct is addressed to a resolution and settling of these conditions and to a “warranted assertion”—Dewey's version of “truth.” Such is the “mediative function” of reason. “Truth” is thus identified with the outcome of competent inquiry. Actions occurring on the organic level, if they be at first confused and obstructed, can then become organized, coherent, and liberated through such inquiry.

Dewey's analysis of the organic, cultural, and formal conditions of intelligent action implies that all reflective conduct issues in an evaluation of a situation with respect to future action and consequences: thus inquiry is essentially an evaluative procedure. This method, most impressively applied in the sciences, is nonetheless a paradigm of moral activity as well. In ethics, “the action needed to satisfy” the situation is not to be found simply by the application of moral codes. The meaning

has to be searched for [since] there are conflicting desires and alternative apparent goods Hence inquiry is exacted The good of the situation has to be discovered, projected and attained on the basis of the exact defect and trouble to be rectified.

In general, for Instrumentalism, moral ideals and “ends” function as means and hypotheses in guiding the deliberative process directed to controlling experience and attaining future goods.

Not health as an end fixed once for all, but the needed improvement in health—a continual process—is the end and good Not perfection as a final goal, but the ever-enduring process of perfecting, maturing, refining is the aim of living Growth itself is the only moral ‘end.’

Inquiry possessed a genuine religious significance for Dewey, and in its functioning as a critical, self-corrective social process of human growth he envisaged the working ethic of democracy.

Other American Pragmatists. Two important contributions to American Pragmatism, which have not yet received the attention that they deserve, came from Mead and Lewis.

Mead's orientation was social psychology. He had studied physiological psychology in Germany, had earlier worked under James and Josiah Royce at Harvard, and was also familiar with Peirce's analyses of thought and signs. Dewey

Dewey's
Instru-
mentalism

Mead's
social and
Lewis'
conceptualistic
Pragmatism

regarded him as one of the most fertile minds in American philosophy.

Mead developed the most comprehensive of the Pragmatist theories of mind. He depicted the evolution of mind and self-consciousness as emerging from social interactions and the use of gestures and "significant symbols" such as words. In contrast to other creatures, an individual regarded as having mind, engaging with others in social acts, can respond to his own gestures as others respond to them—thus taking on social roles and becoming an "other" in respect to himself. It is therefore by means of language, the use of "significant symbols," that mind emerges.

Fundamental to Mead's philosophy is his conception of the social act, in which individuals modify and direct one another's activities, work out their purposes, and accordingly transform their environments. In the social act the future controls present conduct, and this is distinctive of consciousness. Since the function of intelligence is to render the world "favourable for conduct," Mead viewed the development of scientific knowledge and the evolutionary process as coinciding.

Lewis's theory of "conceptualistic Pragmatism" was derived partly from his study of modern logic and partly from the influence of Royce and the classic Pragmatists. The critical results of a careful study of Kant are traceable in his work.

Lewis's Pragmatism focusses upon concepts, categories, and principles through which experience is interpreted. Though the sensuously given is "unalterable," how it is taken, how conceptually interpreted, depends on the purposes and initiatives of the mind—the a priori element in knowledge, which, functioning as categorical criteria of reality, is "true no matter what." It is by means of these that a systematic interpretation of reality is developed. However,

there may be alternative conceptual systems, giving rise to alternative descriptions of experience, which are equally objective and equally valid When this is so, choice will be determined . . . on pragmatic grounds.

In stressing the purposive character of conceptualization, Lewis is thus in the main course of American Pragmatism.

Pragmatism in Europe. In his preface to *Pragmatism*, James commented that the Pragmatic movement was the focal expression of a number of philosophic tendencies suddenly becoming conscious of themselves and of "their combined mission." He mentioned the French thinkers Maurice Blondel, Édouard Le Roy, and B. de Saligny and the Italian Giovanni Papini. Blondel was the author of *L'Action* (1893) and spokesman for a voluntaristic and activist theory of knowledge. He was a founder of the "school of action," a liberal Catholic group that was part of the modernist movement (which employed the new historico-critical approach to the Bible and promoted a rationalistic interpretation of the faith). As early as 1888, Blondel appropriated the term *Pragmatisme*, only to abandon it when he learned of American Pragmatism, which was a more naturalistic philosophy than his own. Le Roy, closer to James than other French thinkers, also called his views Pragmatism. In broad respects he was like James in holding that the truth and the full significance of beliefs is found in acting them out. Le Roy was a disciple of Henri Poincaré, who had argued that scientific theories are not mere summaries of data, nor deduced from axioms, but are creative constructions, products of human thought and ingenuity, "conventions." To the question of what limits are imposed on otherwise arbitrary conventions, of what justifies them, Le Roy suggested their convenience in use. James saw similar forms of Pragmatism in Ernst Mach, Wilhelm Ostwald, Pierre Duhem, and Théodore Ruyssen in "the notion that no theory is absolutely a transcript of reality" and that "their great use is to summarize old facts and lead to new ones" so that they are a "man-made language, a conceptual shorthand . . . in which we write our reports of nature."

Another French thinker, Georges Sorel, undertook to reformulate James's Pragmatism into a "useful" doctrine of social criticism. Mussolini later cited Sorel and James as two of his philosophic mentors. He claimed to find in

James "that faith in action, that ardent will to live and fight, to which Fascism owes a great part of its success." To the democratic James, no lesson could have been more badly learned.

A more immediate and direct form of James's Pragmatism occurred in Italy with its centre in the journal *Leonardo*, under the leadership of the iconoclastic critic Giovanni Papini. James referred to Papini as "a brilliant, humorous and witty writer." He called him a genius and was addressed in turn by him as "the Master." Papini's Pragmatism, derived from James's "The Will to Believe," became a theory of the will to action. In action, through creative power and passion, man achieves a kind of divinity. This romantic exaltation of action was appealing to artists but also to fanatics. Papini and his associate Giuseppe Prezzolini comprised the "magical" school of Pragmatism (in the sense of seeking "divinely-creative" power) in contrast to the "logical" school inspired by Peirce of G. Vailati and M. Calderoni.

Later tendencies. Certain extensions and applications of Pragmatism are to be found in current American philosophy. Sidney Hook has directed some of the critical techniques of analysis against a number of ideologies. In the tradition of the scientifically oriented Pragmatisms of Peirce and Dewey, he has explored the relation between the logic of experimental inquiry and the ethic of democracy. A converging of Pragmatism and Logical Positivism resulted in the movement of "logical empiricism" which, in addition to Dewey and Lewis, included the top-rank philosophers of science P.W. Bridgman, Rudolf Carnap, and Ernest Nagel, and the philosophical semanticist Charles W. Morris, all of whom were responsive to the Pragmatisms of Peirce, James, and Dewey. More recent and detailed studies of the structure of science, the nature of theories and explanation, by Carnap, Lewis, and Nagel, and a new interest in Instrumentalism deriving from the work of F.P. Ramsey, Ludwig Wittgenstein, W.H. Watson, and Gilbert Ryle (as well, of course, as from Dewey) exhibit a further continuation of Pragmatism.

Maintaining a "more thorough Pragmatism" than that of Carnap and Lewis, who viewed choices made within scientific frameworks as pragmatic decisions, the prominent logician W.V. Quine has argued against the alleged boundary between analytic and synthetic truths. No portion of the conceptual scheme of science is exempt (as analytic truths were supposed to be) from possible revision in the flux of experience and in the light of pragmatic interests in efficacy and comprehension in predicting future experience. In important respects Quine's view of the evolution, organization, and function of the conceptual structure of science is close to that of Schiller, James, and Dewey.

Quine has also defended a methodological Pragmatism and relativism on ontological questions on the nature of being or reality. This position, also taken by another contemporary philosopher of science and language, Nelson Goodman, recalls the earlier Pragmatists' notion of the "plastic" character of reality, now seen as conceptually plastic in the sense of being expressible in a variety of systems of symbols and languages. It is conceptually misguided to seek the nature of objects, since what there is is not describable *in abstracto* from the particular language in which an ontological question has been put. Objects declared to be real, be they classes, numbers, atoms, or stones, may differ widely. But differences between the "theoretical" and the "factual" entities are basically differences of degree and purpose in evolving conceptualization. Hence reality is anything that it is truly said to be—in any of many linguistic and symbolic systems; and where differences in ways of speaking about objects call for choices, the ensuing adjudications will be pragmatic.

EVALUATION OF PRAGMATISM

Pragmatism has been vulnerable to certain criticisms. It has often been portrayed as a rationalization of the American business ethos—a portraiture perhaps inspired, but not by any scrutiny of the writings of the philosophers themselves. Similarly, the Pragmatic theory of truth has been assailed. Concerning an idea or belief, James had held that one can say: "It is useful because it is true" or

Positivists
and
Nominalists

Blondel,
Le Roy,
Papini,
and others

that 'it is true because it is useful.' " "Both phrases," he added, "mean the same thing." Most scholars, however, have denied this equivalence. His position may seem, moreover, to allow for an idea to be true (*i.e.*, useful or expedient) for one person and false (inexpedient) for others. Finally, James was accused of reducing truth to a subjective play of opinions that one happens to relish or find useful to believe. To these charges James replied that "what immediately feels most 'good' is not always most 'true' when measured by the verdict of the rest of experience." He also warned: "Woe to him whose beliefs play fast and loose with the order which realities follow in his experience."

As a single movement, Pragmatism is no longer extant; but as a body of ideas it contributes a heritage that is destined for future analysis and development. Chief among these are the interpretation of thought and meaning as forms of purposive behaviour, of knowledge as evaluative procedure in which normative and descriptive materials are integrally related, and of the logic of scientific inquiry as a norm of intelligent conduct in the affairs of men. Finally, Pragmatism has succeeded in its critical reaction to the 19th-century philosophy from which it emerged. It has influenced the current conception of philosophy as a critical method of investigating problems and clarifying communication rather than as a universal synthesis of knowledge. Pragmatism thus has certain affinities with the critical philosophizing of G.E. Moore and Bertrand Russell, as well as with the thought of the French intuitionist and vitalist Henri Bergson and his disciple Édouard Le Roy, of Blondel, of the early positivists Mach and Duhem, of the fictionalist Hans Vaihinger, of the Vienna Circle and the philosopher of logic and language Ludwig Wittgenstein, and also of the founder of Phenomenology, Edmund Husserl, and some of the continuing forms of Phenomenology and Existentialism. It has recognized the relative, contingent, and fallible (yet still authentic) character of human reason, rather than perpetuating the dubious ideal of philosophy as a system of eternal truths. In so doing, and in thus altering the philosophical scene, Pragmatism has become vitally implicated in the practices of current intellectual life; and in the light of this fact, a more pragmatic justification of Pragmatism is difficult to imagine. (H.S.T.)

Rationalism

Rationalism is the philosophical view that regards reason as the chief source and test of knowledge. Holding that reality itself has an inherently logical structure, the Rationalist asserts that a class of truths exists that the intellect can grasp directly. There are, according to the Rationalists, certain rational principles—especially in logic and mathematics, and even in ethics and metaphysics—that are so fundamental that to deny them is to fall into contradiction. The Rationalist's confidence in reason and proof tends, therefore, to detract from his respect for other ways of knowing. Rationalism has long been the rival of Empiricism, the doctrine that all knowledge comes from, and must be tested by, sense experience. As against this doctrine, Rationalism holds reason to be a faculty that can lay hold of truths beyond the reach of sense perception, both in certainty and generality. In stressing the existence of a "natural light," Rationalism has also been the rival of systems claiming esoteric knowledge, whether from mystical experience, revelation, or intuition, and has been opposed to various irrationalisms that tend to stress the biological, the emotional or volitional, the unconscious, or the existential at the expense of the rational.

TYPES AND EXPRESSIONS OF RATIONALISM

Rationalism has somewhat different meanings in different fields, depending upon the kind of theory to which it is opposed.

In the psychology of perception, for example, Rationalism is in a sense opposed to the genetic psychology of the Swiss scholar Jean Piaget, who, exploring the development of thought and behaviour in the infant, argued that the categories of the mind develop only through the infant's

experience in concourse with the world. Similarly, Rationalism is opposed to Transactionalism, a point of view in psychology according to which man's perceptual skills are achievements, accomplished through actions performed in response to an active environment. On this view, the experimental claim is made that perception is conditioned by probability judgments formed on the basis of earlier actions performed in similar situations. As a corrective to these sweeping claims, the Rationalist defends a nativism, which holds that certain perceptual and conceptual capacities are innate—as suggested in the case of depth perception by experiments with "the visual cliff," which, though platformed over with firm glass, the infant perceives as hazardous—though these native capacities may, at times, lie dormant until the appropriate conditions for their emergence arise.

In the comparative study of languages, a similar nativism was developed in the 1950s by the innovating syntactician Noam Chomsky, who, acknowledging a debt to Descartes, explicitly accepted the rationalistic doctrine of "innate ideas." Though the 4,000 languages spoken in the world differ greatly in sounds and symbols, they sufficiently resemble each other in syntax to suggest that there is "a schema of universal grammar" determined by "deep structures" or "innate presettings" in the human mind itself. These presettings, which have their basis in the brain, set the pattern for all experience, fix the rules for the formation of meaningful sentences, and explain why languages are readily translatable into one another. It should be added that what Rationalists have held about innate ideas is not that some ideas are full-fledged at birth but only that the grasp of certain connections and self-evident principles, when it comes, is due to inborn powers of insight rather than to learning by experience.

Common to all forms of speculative Rationalism is the belief that the world is a rationally ordered whole, the parts of which are linked by logical necessity and the structure of which is therefore intelligible. Thus in metaphysics it is opposed to the view that reality is a disjointed aggregate of incoherent bits and is thus opaque to reason. In particular, it is opposed to the logical atomisms of such thinkers as David Hume and Ludwig Wittgenstein, who held that facts are so disconnected that any fact might well have been different from what it is without entailing a change in any other fact. Rationalists have differed, however, with regard to the closeness and completeness with which the facts are bound together. At the lowest level, they have all believed that the law of contradiction "A and not-A cannot coexist" holds for the real world, which means that every truth is consistent with every other; at the highest level, they have held that all facts go beyond consistency to a positive coherence; *i.e.*, they are so bound up with each other that none could be different without all being different.

In the field where its claims are clearest—in epistemology, or theory of knowledge—Rationalism holds that some, at least, of man's knowledge is gained through a priori (prior to experience), or rational, insight as distinct from sense experience, which too often provides a confused and merely tentative approach. In the debate between Empiricism and Rationalism, Empiricists hold the simpler and more sweeping position, the Humean claim that all knowledge of fact stems from perception. Rationalists, on the contrary, urge that some, though not all, knowledge arises through direct apprehension by the intellect. What the intellectual faculty apprehends is objects that transcend sense experience—universals and their relations. A universal is an abstraction, a characteristic that may reappear in various instances: the number three, for example, or the triangularity that all triangles have in common. Though these cannot be seen, heard, or felt, Rationalists point out that man can plainly think about them and about their relations. This kind of knowledge, which includes the whole of logic and mathematics as well as fragmentary insights in many other fields, is, in the Rationalist view, the most important and certain knowledge that the mind can achieve. Such a priori knowledge is both necessary (*i.e.*, it cannot be conceived as otherwise) and universal, in the sense that it admits of no exceptions. In critical

Rationalism

philosophy, epistemological Rationalism finds expression in the claim that the mind imposes its own inherent categories or forms upon incipient experience (see below *Kant and Hegel*).

In ethics Rationalism holds the position that reason, rather than feeling, custom, or authority, is the ultimate court of appeal in judging good and bad, right and wrong. Among major thinkers, the most notable representative of rational ethics is Immanuel Kant, who held that the way to judge an act is to check its self-consistency as apprehended by the intellect: to note, first, what it *is* essentially, or in principle—a lie, for example, or a theft—and then to ask if one can consistently will that the principle be made universal. Is theft, then, right? The answer must be “No,” because, if theft were generally approved, no one’s property would be his own as opposed to anyone else’s and theft would then become meaningless; the notion, if universalized, would thus destroy itself, as reason, by itself, is sufficient to show.

In religion Rationalism commonly means that all of man’s knowledge comes through the use of his natural faculties, without the aid of supernatural revelation. “Reason” is here used in a broader sense, referring to man’s cognitive powers generally, as opposed to supernatural grace or faith—though it is also in sharp contrast to so-called existential approaches to truth. Reason, for the Rationalist, thus stands opposed to many of the religions of the world, including Christianity, which have held that the divine has revealed itself through inspired persons or writings and which have required, at times, that its claims be accepted as infallible, even when they do not accord with natural knowledge. Religious Rationalists hold, on the other hand, that if the clear insights of man’s reason must be set aside in favour of alleged revelation, then human thought is everywhere rendered suspect—even in the reasonings of the theologians themselves. There cannot be two ultimately different ways of warranting truth, they assert; hence Rationalism urges that reason, with its standard of consistency, must be the final court of appeal. Religious Rationalism can reflect either a traditional piety, when endeavouring to display the alleged sweet reasonableness of religion, or an anti-authoritarian temper, when aiming to supplant religion with the “goddess of reason.”

HISTORY OF RATIONALISM

Pre-Socratics

Epistemological Rationalism in ancient philosophies. The first Western philosopher to stress rationalist insight was Pythagoras, a shadowy figure of the 6th century BC. Noticing that, for a right triangle, a square built on its hypotenuse equals the sum of those on its sides and that the pitches of notes sounded on a lute bear a mathematical relation to the lengths of the strings, Pythagoras held that these harmonies reflected the ultimate nature of reality. He summed up the implied metaphysical Rationalism in the words “All is number.” It is probable that he had caught the Rationalist’s vision, later seen by Galileo, of a world governed throughout by mathematically formulable laws.

The difficulty in this view, however, is that, working with universals and their relations, which, like the multiplication table, are timeless and changeless, it assumes a static world and ignores the particular, changing things of daily life. The difficulty was met boldly by the Rationalist Parmenides, who insisted that the world really is a static whole and that the realm of change and motion is an illusion, or even a self-contradiction. His disciple Zeno of Elea further argued that anything thought to be moving is confronted with a row of points infinite in number, all of which it must traverse; hence it can never reach its goal, nor indeed move at all. Of course, perception tells us that we do move; but Zeno, compelled to choose between perception and reason, clung to reason.

Plato and Aristotle

The exalting of rational insight above perception was also prominent in Plato (c. 427–347 BC). In the *Meno*, Socrates dramatized the innateness of knowledge by calling upon an illiterate slave boy and, drawing a square in the sand, proceeding to elicit from him, step by step, the proof of a theorem in geometry of which the boy could never have heard (to double the size of a square, draw a square on the

diagonal). Such knowledge, Rationalists insist, is certain, universal, and completely unlearned.

Plato so greatly admired the rigorous reasoning of geometry that he is alleged to have inscribed over the door of his Academy “Let no one unacquainted with geometry enter here.” His famous “ideas” are accessible only to reason, not to sense. But how are they related to sensible things? His answers differed. Sometimes he viewed the ideas as distilling those common properties of a class in virtue of which one identifies anything as a member of it. Thus what makes anything a triangle is its having three straight sides; this is its essence. At other times, Plato held that the idea is an ideal, a non-sensible goal to which the sensible thing approximates; the geometer’s perfect triangle “never was on sea or land,” though all actual triangles more or less embody it. He conceived the ideas as more real than the sensible things that are their shadows and saw that the philosopher must penetrate to these invisible essences and see with the eye of his mind how they are linked together. For Plato they formed an orderly system that was at once eternal, intelligible, and good.

Plato’s successor Aristotle (384–322 BC) conceived of the work of reason in much the same way, though he did not view the ideas as independent. His chief contribution to Rationalism lay in his syllogistic logic, regarded as the chief instrument of rational explanation. Man explains particular facts by bringing them under general principles. Why does one think Socrates will die? Because he is a man, and man as such is mortal. Why should one accept the general principle itself that all men are mortal? In human experience such principles have so far held without exception. But the mind cannot finally rest in this sort of explanation. Man never wholly understands a fact or event until he can bring it under a principle that is self-evident and necessary; and he then has the clearest explanation possible. On this central thesis of Rationalism, the three great Greeks were in accord.

Nothing comparable in importance to their thought appeared in Rationalistic philosophy in the next 1,800 years, though the work of Thomas Aquinas in the 13th century was an impressive attempt to blend Greek Rationalism and Christian revelation into a single harmonious system.

Thoroughgoing Rationalism is to be found only in the philosophical tradition that has come down from Greece; the mysticism of India and the practicality of China have offered a less congenial soil for it. The nearest parallels to it in Eastern thought are found in the work of the Indian philosopher Śaṅkara, who flourished about AD 800, and in that of the Chinese sage Chu-Hsi (1130–1200). Both were commentators on the ancient scriptures of their lands; and in ordering the scattered insights of these sources into intelligible systems, they did for their respective peoples something like what Aquinas did for the West in his harmonizing of Greek with Christian thought. Śaṅkara held, as Sir Sarvepalli Radhakrishnan has expressed it, that “the Absolute is the unattainable goal towards which the finite intellect strives.” Perception is confined to what is transient and fragmentary; reason rises to truth that is timeless and universal; but even reason falls short of full understanding, which is achieved, if at all, only through mystical vision. Chu Hsi, who has influenced Chinese thought for the past six centuries, was a disciple of Confucius, though he had a stronger speculative interest than his master. He held that in all human minds a single reason was at work, which he called “the Way.” All things were in some degree manifestations of it, and hence the understanding of the world lay in more complete identification with it.

Epistemological Rationalism in modern philosophies. The first modern Rationalist was René Descartes (1596–1650), who was an original mathematician whose ambition was to introduce into philosophy the rigour and clearness that delighted him in mathematics. He set out to doubt everything in the hope of arriving in the end at something indubitable. This he reached in his famous *cogito ergo sum*, “I think, therefore I am”; for to doubt one’s own doubting would be absurd. Here then was a fact of absolute certainty, rendered such by the clearness and distinctness with which it presented itself to his reason. His task was to build on this as a foundation, to deduce from it a

Rationalism in non-Western thought

Continental Rationalists

series of other propositions, each following with the same self-evidence. He hoped thus to produce a philosophical system on which men could agree as completely as they do on the geometry of Euclid. The main cause of error, he held, lay in the impulsive desire to believe before the mind is clear. The clearness and distinctness upon which he insisted was not that of perception but of conception, the clearness with which the intellect grasps an abstract idea, such as the number three, or its being greater than two.

His method was adopted in essentials by both Benedict Spinoza (1632–77) and G.W. Leibniz (1646–1716), who agreed that the framework of things could be known by a priori thinking. They differed from him, however, in their starting points. What was most undeniable to Spinoza was not the existence of his self but that of the universe, called by him Substance. From the idea of Substance, and with the aid of a few definitions and axioms, he derived his entire system, which he set forth in his *Ethics* in a formal fashion patterned after Euclid's geometry. Still, for both Spinoza and Leibniz much in nature remained stubbornly opaque. Leibniz distinguished necessary truths, those of which the opposite is impossible (as in mathematics), from contingent truths, the opposite of which is possible, such as "snow is white." But was this an ultimate distinction? At times Leibniz said boldly that if only man knew enough, he would see that every true proposition was necessarily true—that there are no contingent truths, that snow must be white.

How, then, does reason operate and how is it possible to have knowledge that goes beyond experience? A new answer was given by Immanuel Kant (1724–1804) in his *Critique of Pure Reason*, which, as he said, involved a Copernican revolution in philosophy. The reason man can be certain that his logic and mathematics will remain valid for all experience is simply that their framework lies within his own mind; they are forms of arrangement imposed from within upon the raw materials of sensation. Man will always find things arranged in certain patterns because it is he who has unwittingly so arranged them. Kant held, however, that these certainties were bought at a heavy price. Just because a priori insights are the reflection of man's own mind, he cannot trust them as a reflection of the world outside himself. Whether the rational order in which man arranges his sensation—the order, for example, of time, space, and causality—represents an order holding among things-in-themselves (German *Dinge-an-sich*) he cannot hope to know. Kant's Rationalism was thus the counterpart of a profound Skepticism.

G.W.F. Hegel (1770–1831), the most thoroughgoing of Rationalist thinkers, attempted to break out of this Skepticism. He argued that to think of an unknowable is already to bring it within the sphere of what is known and that it is meaningless to talk of a region in which logic is invalid. Further, to raise the question "Why?" is to presume that there is an intelligible answer to it; indeed the faith of the philosopher must be that the real is the rational and the rational real, for this faith is implicit in the philosophic enterprise itself. As an attempt to understand and explain the world, philosophy is a process of placing something in a context that reveals it as necessary. But this necessity is not, as earlier Rationalists had supposed, an all-or-nothing affair issuing in a self-evident finality. Understanding is a matter of degree. What alone would wholly satisfy thought is a system that is at once all-inclusive and so ordered that its parts entail each other. Hegel believed that the universe constitutes such a whole and, as an idealist, held that it is a single, absolute mind. To the degree that the philosopher embodies and realizes this mind, his own mind will achieve both truth and reality. Indeed, the advance of civilization reflects the enlarging presence and control of such a system in the human spirit. Broadly similar Rationalistic systems were developed in England by F.H. Bradley (1846–1924) and Bernard Bosanquet (1848–1923) and in America by Josiah Royce (1855–1916).

Ethical Rationalism. The views of Kant were presented above as typical of this position (see above, *Types and expressions of Rationalism*). But few moralists have held to ethical Rationalism in this simple and sweeping form. Many have held, however, that the main rules of conduct

are truths as self-evident as those of logic or mathematics. Lists of such rules were drawn up by Ralph Cudworth and Henry More among the Cambridge Platonists of the 17th century, who were noted for holding that moral principles were intrinsic to reality; and in the 18th century Samuel Clarke and Richard Price, defenders of "natural law" ethics, and the "common sense" moralist Thomas Reid also presented such lists. A 20th-century revision of this Rationalism has been offered by the Rational Intuitionists H.A. Prichard and Sir David Ross of Oxford under the name of deontology (Greek *deon*, "duty"), which respects duty more than consequences. Ross provides a list of propositions regarding fidelity to promises, reparation for injuries, and other duties, of which he says: "In our confidence that these propositions are true there is involved the same trust in our reason that is involved in our trust in mathematics." What is taken as self-evident, however, is not specific rules of conduct, but *prima facie* duties—the claims that some types of action have on men because of their nature. If a man is considering whether to repay a debt or to give the money to charity, each act has a self-evident claim on him; and their comparative strengths must be settled by a rational intuition.

The most influential variety of 20th-century ethical Rationalism has probably been the Ideal Utilitarianism of the British moralists Hastings Rashdall (1858–1924) and G.E. Moore (1873–1958). Both were teleologists (Greek *telos*, "end") inasmuch as they held that what makes an act objectively right is its results (or end) in intrinsic goods or evils. To determine what is right, reason is required in two senses: firstly, the inference to the consequences is an act of inductive reasoning; secondly, the judgment that one consequence is intrinsically better than another is a priori and self-evident. Moore thought that there is a single rule for all conduct—one should so act as to produce the greatest good—and that this is also a principle self-evident to reason.

Religious Rationalism. Stirrings of religious Rationalism were already felt in the Middle Ages regarding the Christian revelation. Thus the skeptical mind of Abelard (1079–1142) raised doubts by showing in his *Sic et Non* ("Yes and No") many contradictions among beliefs handed down as revealed truths by the Church Fathers. The greatest of the Medieval thinkers, Thomas Aquinas (1225–74), was a Rationalist in the sense of believing that the larger part of revealed truth was intelligible to and demonstrable by reason, though he thought that a number of dogmas opaque to reason must be accepted on authority alone.

Expansion of religious Rationalism. Religious Rationalism did not come into its own, however, until the 16th and 17th centuries, when it took two chief forms: the scientific and the philosophic.

Galileo (1564–1642) was a pioneer in astronomy and the founder of modern dynamics. He conceived of nature as governed throughout by laws statable with mathematical precision; the book of nature, he said, is "written in mathematical form." This notion not only ruled out the occasional appeal to miracle; it also collided with dogmas regarding the permanent structure of the world—in particular with that which viewed the Earth as the motionless centre of the universe. When Galileo's demonstration that the Earth moves around the Sun was confirmed by the work of Newton and others, a battle was won that marked a turning point in the history of Rationalism, since it provided a decisive victory in a crucial case of conflict between reason and apparently revealed truth.

The Rationalism of Descartes, as already shown, was the outcome of philosophic doubt rather than of scientific inquiry. The self-evidence of the *cogito*, seen by his "natural light," he made the ideal for all other knowledge. The uneasiness that the church soon felt in the face of such a test was not unfounded, for Descartes was in effect exalting the natural light into the supreme court even in the field of religion. He argued that man's guarantee against the possibility that even this natural light might deceive him lay in the goodness of the Creator. But then to prove this Creator, he had to assume the prior validity of the natural light itself. Logically, therefore, the last word lay with rational insight, not with any outside divine warrant.

Galileo
and
Descartes

Descartes was inadvertently beginning a Copernican revolution in theology. Before his time, the truths regarded as most certain were those accepted from revelation; afterwards these truths were subject to the judgment of human reason, thus breaking the hold of authority on the European mind.

Deism

Four waves of religious Rationalism. The Rationalist attitude quickly spread, its advance forming several waves of general interest and influence. The first wave occurred in England in the form of Deism. Deists accepted the existence of God, but spurned supernatural revelation. The earliest member of this school, Lord Herbert of Cherbury (1583–1648), held that a just God would not reveal himself to a part of his creation only and that the true religion is thus a universal one, which achieves its knowledge of God through common reason. The Deistic philosopher John Toland (1670–1722), in his *Christianity Not Mysterious*, sought to show that “there is nothing in the Gospels contrary to reason, nor above it”; any doctrine that is really above reason would be meaningless to man. Attacking revelation, the freethinking polemicist Anthony Collins (1676–1729) maintained that the prophecies of the Old Testament failed of fulfillment; and the religious controversialist Thomas Woolston (1670–1733) urged that the New Testament miracles, as recorded, are incredible. Matthew Tindall (1657–1733), most learned of the English Deists, argued that the essential part of Christianity is its ethics, which, being clearly apparent to natural reason, leaves revelation superfluous. Thus the Deists, professing for the most part to be religious men themselves, did much to reconcile their public to the free play of ideas in religion.

Voltaire
and
Diderot

The second wave of religious Rationalism, less moderate in tone and consequences, was French. This wave, reflecting an engagement with the problem of natural evil, involved a decay in the natural theology of Deism such that it merged eventually with the stream that led to materialistic Atheism. Its moving spirit was Voltaire (1694–1778), who had been impressed by some of the Deists during a stay in England. Like them, he thought that a rational man would believe in God but not in supernatural inspiration. Hardly a profound philosopher, he was a brilliant journalist, clever and humorous in argument, devastating in satire, and warm in human sympathies. In his *Candide* and in many other writings, he poured irreverent ridicule on the Christian scheme of salvation as incoherent and on the church hierarchy as cruel and oppressive. In these attitudes he had the support of Diderot (1713–84), editor of the most widely read encyclopaedia that had appeared in Europe. The Rationalism of these men and their followers, directed against both the religious and the political traditions of their time, did much to prepare the ground for the explosive French Revolution.

Hegelian-
ism

The next wave of religious Rationalism occurred in Germany under the influence of Hegel, who held that a religious creed is a halfway house on the road to a mature philosophy, the product of a reason that is still under the sway of feeling and imagination. This idea was taken up and applied with learning and acuteness to the origins of Christianity by David Friedrich Strauss (1808–74), who published in 1835, at the age of 27, a remarkable and influential three-volume work, *Das Leben Jesu* (*The Life of Jesus, Critically Examined*, 1846). Relying largely on internal inconsistencies in the Synoptic Gospels, Strauss undertook to prove these books to be unacceptable as revelation and unsatisfactory as history. He then sought to show how an imaginative people innocent of either history or science, convinced that a Messiah would appear, and deeply moved by a unique moral genius, inevitably wove myths about his birth and death, his miracles, and his divine communings.

Strauss's thought as it affected religion was continued by the philosophical historian Ernest Renan (1823–92) and as it affected philosophy by the humanist Ludwig Feuerbach (1804–72) of the Hegelian left. Renan's *Vie de Jésus* (1863; *Life of Jesus*) did for France what Strauss's book had done for Germany, though the two differed greatly in character. Whereas Strauss's work had been an intellectual exercise in destructive criticism, Renan's was an attempt

to reconstruct the mind of Jesus as a wholly human person—a feat of imagination, performed with a disarming admiration and even reverence for its subject and with a felicity of style that gave it a large and lasting audience. Feuerbach's *Wesen des Christentums* (1841; Eng. trans. by George Eliot, *Essence of Christianity*, 1853) applied the myth theory even to belief in the existence of God, holding that “man makes God in his own image.”

The fourth wave occurred in Victorian England, following the publication in 1859 of Darwin's *Origin of Species*. This book was taken as a challenge to the authority of Scripture because there was a clear inconsistency between the Genesis account of creation and the biological account of man's slow emergence from lower forms of life. The battle raged with bitterness for several decades but died away as the theory of evolution gained more general acceptance.

Evolution

STATUS OF RATIONALISM

Religious. With increasing freedom of thought and wider acceptance of scientific views, Rationalism in religion has lost its novelty and much of its controversial excitement. To the contemporary mind, it is too obvious to warrant debate that reason and revelation cannot both qualify as sources of ultimate truth for, were they to conflict, truth itself would become self-contradictory. Hence theologians have sought accommodation through new interpretative principles that discern different grades of authenticity within the Scriptures and through new views of religious truth, existential rather than cognitive, that turn from propositional dogmas to the explication of lived human existence. Criticism of supernaturalism, however, is still carried on by such societies as the Rationalist Press Association, in Great Britain, and the Humanist Association, in the United States.

Ethical. Rationalism in ethics has suffered its share of criticism. Regarding its lists of rules—on the keeping of promises, the return of loaned goods, etc.—it has been argued, for example, that if they were specific enough to be useful (as in the rule against lying or stealing), they would tend to have exceptions—which no rule laid down by reason ought to have. On the other hand, if without exceptions, they would often prove to be tautologies: the rule of justice, for example, that we should give everyone his due would then mean only that we should give him what is justly his. After enduring a period of eclipse, however, during which noncognitive theories of ethics (emotive and existential) and relativism had preempted the field, rationalistic views, which agree in holding that moral standards do not depend upon the varying attitudes of persons or peoples, were receiving renewed attention in the mid-20th century. Prominent among these developments has been the “good-reasons” approach taken by the broadly gauged scholar Stephen Toulmin, by Kurt Baier, and others, which examines the contexts of various moral situations and explores the kinds of justification appropriate for each.

Metaphysical. Typical of the ways of reasoning employed by Rationalists are two approaches taken to the metaphysical doctrine that all things are connected by internal relations: one a logical, the other a causal argument. An internal relation is one that could not be removed without affecting the terms themselves between which the relation holds. The argument runs: Everything is related to everything else at least by the relation “A is different from B.” But difference is itself an internal relation, since the terms could not remain the same if it were removed. Hence everything is so connected with everything else that it could not be what it is unless they were what they are. The appeal to internal relations played an important part in the philosophies of Hegel, F.H. Bradley, and A.N. Whitehead (1861–1947).

The other line of argument is causal. Every event, it is maintained, is connected with every other, either directly or indirectly. Sir James Jeans argued that if the law of gravitation is valid, a man cannot crook his little finger without affecting the fixed stars. Here the causal relation is direct. It can also be shown that seemingly unrelated events are joined indirectly through their common con-

nection with some remote historical event, by a chain of events leading back, for example, to Columbus' discovery of America. But if this had been different, all of its consequences would presumably have been different; thus an indirect and internal relation proves to have been present.

Many Rationalists have held with Spinoza that the causal relation is really a logical one—that a causal law, if precisely stated, would reveal a connection in which the character of the cause logically necessitates that of its effect; and if this is true, they maintain, the facts and events of the world must thus compose a single rational and intelligible order.

Rationalism and quantum physics

In the 20th century, such Rationalism met with a new and unexpected difficulty presented by quantum physics. According to the indeterminacy principle, formulated in 1927 by the German physicist Werner Heisenberg, it is impossible to discover with precision both the position and the velocity of a moving electron at the same time. This implies that definite causal laws for the behaviour of these particles can never be attained, but only statistical laws governing the behaviour of immense aggregates of them. Causality, and with it the possibility of rational understanding, seemed to be suspended in the subatomic world. Some interpreters of the new physics, however, notably Max Planck, Albert Einstein, and Bertrand Russell, sustained the hopes of the Rationalists by insisting that what was excluded by the indeterminacy principle was not the fact of causality in this realm, but only the precise knowledge of it.

Indeed, some leaders of 20th-century science took the new developments in physics as on the whole supporting Rationalism. Protons and electrons, they contended, though beyond the reach of the senses, can still be known; and their behaviour, at least in groups, is increasingly found to conform to mathematical law. In 1932, Sir James Jeans, an astrophysicist and popularizer of science, said with a curious echo of Galileo, "the universe appears to have been designed by a pure mathematician."

Challenges to epistemological Rationalism. At first glance the claim of Empiricism that knowledge must come from sense experience seems obvious: how else could one hope to make contact with the world around one? Consequently, Rationalism has been sharply challenged—in the 19th century by the Empiricism of John Stuart Mill (1806–73) and in the 20th by that of the Logical Positivists. Mill argued that all a priori certainties are illusory: why does man believe, for example, that two straight lines cannot enclose a space? Is it because he sees it as logically necessary? No; it is because he has experienced so long and so unbroken a row of instances of it—a new one whenever he sees the corner of a table or the bordering rays of a light beam—that he has formed the habit of thinking in this way and is now unable to break it. A priori propositions, Mill claimed, are merely empirical statements of very high generality.

This theory has now been abandoned by most Empiricists themselves. Its implication that such statements as " $2 + 2 = 4$ " are only probably true and may have exceptions has proved quite unconvincing. The Rationalist's rejoinder is that one cannot, no matter how hard one tries, conceive $2 + 2$ as making 5; for its equalling 4 is necessary. But a priori knowledge is also universal. Neither of these two characteristics can be accounted for by sense experience. That a crow is black can be perceived, but not that it must be black or that crows will always be black; no run of perceptions, however long, could assure us of such truths. On the other hand, a priori truths can be seen with certainty—that if a figure, for instance, is a plane triangle within a Euclidean space, its angles must and always will equal two right angles.

Perhaps the most formidable challenge to Rationalism has come in the 20th century from such Logical Positivists as the Oxford Empiricist A.J. Ayer (1910–) and Rudolf Carnap (1891–1970), who had been a central figure in the Vienna Circle, where this movement first arose. Unlike Mill, they accepted a priori knowledge as certain; but they laid down a new challenge—the denial of its philosophic importance. A priori propositions, they said, are (1) linguistic, (2) conventional, and (3) analytic: (1) They are

statements primarily of how one proposes to use words; if one says that "a straight line is the shortest line between two points," this merely reports one's definition of "straight" and declares one's purpose to use it only of the shortest. (2) Being a definition, such a statement expresses a convention to which there are alternatives; it may be defined in terms of the paths of light rays if one chooses. (3) The statement is analytic in that it merely repeats in its predicate a part or the whole of the subject term and hence tells nothing new; it is not a statement about nature but about meanings only. And since Rationalistic systems depend throughout upon statements of this kind, their importance is illusory.

To this clear challenge some leading Rationalists have replied as follows: (1) Positivists have confused real with verbal definition. A verbal definition does indeed state what a word means; but a real definition states what an object is, and the thought of a straight line is the thought of an object, not of words. (2) The Positivists have confused conventions in thought with conventions in language. One is free to vary the language in which a proposition is expressed, but not the proposition itself. Start with the concept of a straight line, and there is no alternative to accepting it as the shortest. (3) Some a priori statements are admittedly analytic, but many are not. In "whatever is coloured is extended," colour and extension are two different concepts of which the first entails the second, but is not identical with it in whole or part. Contemporary Rationalists therefore hold that the a priori has emerged victorious from the Empiricists' efforts to discredit such knowledge and the Positivists' attempts to trivialize it.

(B.Bl.)

Utilitarianism

The fundamental principle of Utilitarianism, a tradition in ethics stemming from the late 18th- and 19th-century English philosophers and economists Jeremy Bentham and John Stuart Mill, is that an action is right if it tends to promote happiness and wrong if it tends to produce the reverse of happiness—not just the happiness of the performer of the action but that of everyone affected by it. Such a theory is in opposition to egoism, the view that a man should pursue his own self-interest, even at the expense of others, and to any ethical theory that regards some acts or types of acts as right or wrong independently of their consequences. Utilitarianism also differs from ethical theories that make the rightness or wrongness of an act dependent upon the motive of the agent; for, according to the Utilitarian, it is possible for the right thing to be done from a bad motive.

THE NATURE OF UTILITARIANISM

Utilitarianism is an effort to provide an answer to the practical question "What ought a man to do?" Its answer is that he ought to act so as to produce the best consequences possible.

Basic concepts. In the notion of consequences the Utilitarian includes all of the good and bad produced by the act, whether arising after the act has been performed or during its performance. If the difference in the consequences of alternative acts is not great, some Utilitarians do not regard the choice between them as a moral issue. According to Mill, acts should be classified as morally right or wrong only if the consequences are of such significance that a person would wish to see the agent compelled, not merely persuaded and exhorted, to act in the preferred manner.

In assessing the consequences of actions, Utilitarianism relies upon some theory of intrinsic value: something is held to be good in itself, apart from further consequences, and all other values are believed to derive their worth from their relation to this intrinsic good as a means to an end. Bentham and Mill were hedonists; *i.e.*, they analyzed happiness as a balance of pleasure over pain and believed that these feelings alone are of intrinsic value and disvalue. Utilitarians also assume that it is possible to compare the intrinsic values produced by two alternative actions and to estimate which would have better consequences. Bentham believed that a hedonic calculus is theoretically

Assessment of consequences

possible. A moralist, he maintained, could sum up the units of pleasure and the units of pain for everyone likely to be affected, immediately and in the future, and could take the balance as a measure of the overall good or evil tendency of an action. Such precise measurement as Bentham envisioned is perhaps not essential, but it is nonetheless necessary for the Utilitarian to make some interpersonal comparisons of the values of the effects of alternative courses of action.

Methodologies. As a normative system providing a standard by which an individual ought to act and by which the existing practices of society, including its moral code, ought to be evaluated and improved, Utilitarianism cannot be verified or confirmed in the way in which a descriptive theory can; but it is not regarded by its exponents as simply arbitrary. Bentham believed that only in terms of a Utilitarian interpretation do words such as "ought," "right," and "wrong" have meaning and that whenever anyone attempts to combat the principle of utility, he does so with reasons drawn from the principle itself. Bentham and Mill both believed that human actions are motivated entirely by pleasure and pain; and Mill saw that motivation as a basis for the argument that, since happiness is the sole end of human action, the promotion of happiness is the test by which to judge all human conduct.

One of the leading Utilitarians of the late 19th century, a Cambridge philosopher, Henry Sidgwick, rejected their theories of motivation as well as Bentham's theory of the meaning of moral terms and sought to support Utilitarianism by showing that it follows from systematic reflection on the morality of "common sense." Most of the requirements of commonsense morality, he argued, could be based upon Utilitarian considerations. In addition, he reasoned that Utilitarianism could solve the difficulties and perplexities that arise from the vagueness and inconsistencies of commonsense doctrines.

Most opponents of Utilitarianism have held that it has implications contrary to their moral intuitions—that considerations of utility, for example, might sometimes sanction the breaking of a promise. Much of the defense of Utilitarian ethics has consisted in answering these objections, either by showing that Utilitarianism does not have the implications that they claim it has or by arguing against the moral intuitions of its opponents. Some Utilitarians, however, have sought to modify the Utilitarian theory to account for the objections.

Criticisms. One such criticism is that, although the widespread practice of lying and stealing would have bad consequences, resulting in a loss of trustworthiness and security, it is not certain that an occasional lie to avoid embarrassment or an occasional theft from a rich man would not have good consequences, and thus be permissible or even required by Utilitarianism. But the Utilitarian readily answers that the widespread practice of such acts would result in a loss of trustworthiness and security. To meet the objection to not permitting an occasional lie or theft, some philosophers have defended a modification labelled "rule" Utilitarianism. It permits a particular act on a particular occasion to be adjudged right or wrong according to whether it is in accordance with or in violation of a useful rule; and a rule is judged useful or not by the consequences of its general practice. Mill has sometimes been interpreted as a "rule" Utilitarian, whereas Bentham and Sidgwick were "act" Utilitarians.

Another objection, often posed against the hedonistic value theory held by Bentham, holds that the value of life is more than a balance of pleasure over pain. Mill, in contrast to Bentham, discerned differences in the quality of pleasures that made some intrinsically preferable to others independently of intensity and duration (the quantitative dimensions recognized by Bentham). Some philosophers in the Utilitarian tradition have recognized certain wholly nonhedonistic values without losing their Utilitarian credentials. A British philosopher, G.E. Moore, a pioneer of 20th-century Analysis, regarded many kinds of consciousness—including love, knowledge, and the experience of beauty—as intrinsically valuable independently of pleasure, a position labelled "ideal" Utilitarianism. Even in limiting the recognition of intrinsic value and disvalue

to happiness and unhappiness, some philosophers have argued that those feelings cannot adequately be further broken down into terms of pleasure and pain and have thus preferred to defend the theory in terms of maximizing happiness and minimizing unhappiness. It is important to note, however, that even for the hedonistic Utilitarians, pleasure and pain are not thought of in purely sensual terms; pleasure and pain for them can be components of experiences of all sorts. Their claim is that, if an experience is neither pleasurable nor painful, then it is a matter of indifference and has no intrinsic value.

Another objection to Utilitarianism is that the prevention or elimination of suffering should take precedence over any alternative act that would only increase the happiness of someone already happy. Some recent Utilitarians have modified their theory to require this focus or even to limit moral obligation to the prevention or elimination of suffering—a view labelled "negative" Utilitarianism.

HISTORICAL SURVEY

The ingredients of Utilitarianism are found in the history of thought long before Bentham.

Antecedents of Utilitarianism among the ancients. A hedonistic theory of the value of life is found in the early 5th century BC in the ethics of Aristippus of Cyrene, founder of the Cyrenaic school, and 100 years later in that of Epicurus, founder of an ethic of retirement, and their followers in ancient Greece. The seeds of ethical universalism are found in the doctrines of the rival ethical school of Stoicism and in Christianity.

Growth of classical English Utilitarianism. In the history of English philosophy, some historians have identified Bishop Richard Cumberland, a 17th-century moral philosopher, as the first to have a Utilitarian philosophy. A generation later, however, Francis Hutcheson, a British "moral sense" theorist, more clearly held a Utilitarian view. He not only analyzed that action as best that "procures the greatest happiness for the greatest numbers" but proposed a form of "moral arithmetic" for calculating the best consequences. The Skeptic David Hume, Scotland's foremost philosopher and historian, attempted to analyze the origin of the virtues in terms of their contribution to utility. Bentham himself said that he discovered the principle of utility in the 18th-century writings of various thinkers: of Joseph Priestley, a dissenting clergyman famous for his discovery of oxygen; of the Frenchman Claude-Adrien Helvétius, author of a philosophy of mere sensation; of Cesare Beccaria, an Italian legal theorist; and of Hume. Helvétius probably drew from Hume, and Beccaria from Helvétius.

Another strand of Utilitarian thought took the form of a theological ethics. John Gay, a biblical scholar and philosopher, held the will of God to be the criterion of virtue; but from God's goodness he inferred that God willed that men promote human happiness.

Bentham, who apparently believed that an individual in governing his own actions would always seek to maximize his own pleasure and minimize his own pain, found in pleasure and pain both the cause of human action and the basis for a normative criterion of action. The art of governing one's own actions Bentham called "private ethics." The happiness of the agent is the determining factor; the happiness of others governs only to the extent that the agent is motivated by sympathy, benevolence, or interest in the good will and good opinion of others. For Bentham, the greatest happiness of the greatest number would play a role primarily in the art of legislation, in which the legislator would seek to maximize the happiness of the entire community by creating an identity of interests between each individual and his fellows. By laying down penalties for mischievous acts, the legislator would make it unprofitable for a man to harm his neighbour. Bentham's major philosophical work, *An Introduction to the Principles of Morals and Legislation* (1789), was designed as an introduction to a plan of a penal code.

With Bentham, Utilitarianism became the ideological foundation of a reform movement, later known as "philosophical radicalism," that would test all institutions and policies by the principle of utility. Bentham attracted as his

disciples a number of younger (earlier 19th-century) men. They included David Ricardo, who gave classical form to the science of economics; John Stuart Mill's father, James Mill; and John Austin, a legal theorist. James Mill argued for representative government and universal male suffrage on Utilitarian grounds; he and other followers of Bentham were advocates of parliamentary reform in England in the early 19th century. John Stuart Mill was a spokesman for women's suffrage, state-supported education for all, and other proposals that were considered radical in their day. He argued on Utilitarian grounds for freedom of speech and expression and for the noninterference of government or society in individual behaviour that did not harm anyone else. Mill's essay "Utilitarianism," published in *Fraser's Magazine* (1861), is an elegant defense of the general Utilitarian doctrine and perhaps remains the best introduction to the subject. In it Utilitarianism is viewed as an ethics for ordinary individual behaviour as well as for legislation.

Late 19th- and 20th-century Utilitarianism. By the time Sidgwick wrote, Utilitarianism had become one of the foremost ethical theories of the day. His *Methods of Ethics* (1874), a comparative examination of egoism, the ethics of common sense, and Utilitarianism, contains the most careful discussion to be found of the implications of Utilitarianism as a principle of individual moral action.

The 20th century has seen the development of various modifications and complications of the Utilitarian theory. G.E. Moore argued for a set of ideals extending beyond hedonism by proposing that one imaginatively compare universes in which there are equal quantities of pleasure but different amounts of knowledge and other such combinations. He felt that he could not be indifferent toward such differences. The recognition of "act" Utilitarianism and "rule" Utilitarianism as explicit alternatives was stimulated by the analysis of moral reasoning in "rule" Utilitarian terms by Stephen Toulmin, a British philosopher of science and moralist, and by Patrick Nowell-Smith, a moralist of the Oxford linguistic school; by the interpretation of Mill as a "rule" Utilitarian by another Oxford Analyst, J.O. Urmson; and by the analysis by John Rawls, a Harvard moral philosopher, of the significance for Utilitarianism of two different conceptions of moral rules. "Act" Utilitarianism, on the other hand, has been defended by J.J.C. Smart, a British-Australian philosopher.

EFFECTS OF UTILITARIANISM IN OTHER FIELDS

The influence of Utilitarianism has been widespread, permeating the intellectual life of the last two centuries. Its significance in law, politics, and economics is especially notable.

Legal and
political
theory

The Utilitarian theory of the justification of punishment stands in opposition to the "retributive" theory, according to which punishment is intended to make the criminal "pay" for his crime. According to the Utilitarian, the rationale of punishment is entirely to prevent further crime by either reforming the criminal or protecting society from him and to deter others from crime through fear of punishment.

In its political philosophy Utilitarianism bases the authority of government and the sanctity of individual rights upon their utility, thus providing an alternative to theories of natural law, natural rights, or social contract. What kind of government is best thus becomes a question of what kind of government has the best consequences—an assessment that requires factual premises regarding human nature and behaviour.

Generally, Utilitarians have supported democracy as a way of making the interest of government coincide with the general interest; they have argued for the greatest individual liberty compatible with an equal liberty for others on the ground that each individual is generally the best judge of his own welfare; and they have believed in the possibility and the desirability of progressive social change through peaceful political processes.

With different factual assumptions, however, Utilitarian arguments can lead to different conclusions. If the inquirer assumes that a strong government is required to check man's basically selfish interests and that any change

may threaten the stability of the political order, he may be led by Utilitarian arguments to an authoritarian or conservative position. On the other hand, William Godwin, an early 19th-century political philosopher, assumed the basic goodness of human nature and argued that the greatest happiness would follow from a radical alteration of society in the direction of anarchistic Communism.

Classical economics received some of its most important statements from Utilitarian writers, especially Ricardo and John Stuart Mill. Ironically, its theory of economic value was framed primarily in terms of the cost of labour in production rather than in terms of the use value, or utility, of commodities. Later developments more clearly reflected the Utilitarian philosophy. William Jevons, one of the founders of the marginal utility school of analysis, derived many of his ideas from Bentham; and "welfare economics," while substituting comparative preferences for comparative utilities, reflected the basic spirit of the Utilitarian philosophy. In economic policy, the early Utilitarians had tended to oppose governmental interference in trade and industry on the assumption that the economy would regulate itself for the greatest welfare if left alone; later Utilitarians, however, lost confidence in the social efficiency of private enterprise and were willing to see governmental power and administration used to correct its abuses.

Economic
and social
theory

As a movement for the reform of social institutions, 19th-century Utilitarianism was remarkably successful in the long run. Most of their recommendations have since been implemented unless abandoned by the reformers themselves; and, equally important, Utilitarian arguments are now commonly employed to advocate institutional or policy changes.

SUMMARY AND EVALUATION

As an abstract ethical doctrine, Utilitarianism has established itself as one of the small number of live options that must be taken into account and either refuted or accepted by any philosopher taking a position in normative ethics. In contemporary discussion it has been divorced from adventitious involvements with the analysis of ethical language and with the psychological theory with which it was presented by Bentham. Utilitarianism now appears in various modified and complicated formulations. Bentham's ideal of a hedonic calculus is usually considered a practical if not a theoretical impossibility. Present-day philosophers have noticed further problems in the Utilitarian procedures. One of them, for example, is with the process of identifying the consequences of an act—a process that raises conceptual as well as practical problems as to what are to be counted as consequences, even without precisely quantifying the value of those consequences. The question may arise whether the outcome of an election is a consequence of each and every vote cast for the winning candidate if he receives more than the number necessary for election; and in estimating the value of the consequences, one may ask whether the entire value or only a part of the value of the outcome of the election is to be assigned to each vote. There is also difficulty in the procedure of comparing alternative acts. If one act requires a longer period of time for its performance than another, one may ask whether they can be considered alternatives. Even what is to count as an act is not a matter of philosophical consensus.

Problems
in
Utilitarian
procedures

These problems, however, are common to almost all normative ethical theories since most of them recognize the consequences—including the hedonic—of an act as being relevant ethical considerations. The central insight of Utilitarianism, that one ought to promote happiness and prevent unhappiness whenever possible, seems undeniable. The critical question, however, is whether the whole of normative ethics can be analyzed in terms of this simple formula. (H.R.W.)

BIBLIOGRAPHY. For bibliographies of Platonism and Aristotelianism, see the *Macropædia* articles PLATONISM and ARISTOTELIANISM, respectively.

Atomism: E. CANTORE, *Atomic Order: An Introduction to the Philosophy of Microphysics* (1969); F. COPLESTON, *A History of Philosophy*, 8 vol. (1950–66); E.J. DIJKSTERHUIS, *Die Mecha-*

nisierung des Weltbildes (1956; Eng. trans., *The Mechanization of the World Picture*, 1961), a history of science from antiquity to the 17th century; A.S. EDDINGTON, *The Philosophy of Physical Science* (1939); K. LASSWITZ, *Geschichte der Atomistik vom Mittelalter bis Newton*, 2 vol. (1890, reprinted 1963), a 19th-century classic; A.G.M. VAN MELSEN, *Van atomos naar atoom* (1949; Eng. trans., *From Atomos to Atoom: The History of the Concept Atom*, 2nd ed. 1960), including references for the primary sources; L.K. NASH, *The Atomic-Molecular Theory* (1950), a discussion of the first phase of the chemical atomic theory; E.T. WHITTAKER, *History of the Theories of Aether and Electricity*, rev. ed., 2 vol. (1951–54), only for readers with a solid background in science; L.L. WHYTE, *Essay on Atomism: From Democritus to 1960* (1961), a brief introduction to the idea of Atomism and its history. See also MRINALKAUTI GAN-GOPADHYAYA, *Indian Atomism: History and Sources* (1980).

Eleaticism: The main edition of the fragments of the Eleatic, as of all the Pre-Socratic, philosophers is still HERMANN DIELS, *Die Fragmente der Vorsokratiker* (1903; 11th ed. rev. by WALTHER KRANZ, 3 vol., 1964), which is a critical edition of the Greek fragments with German translations; for English translations see KATHLEEN FREEMAN, *Ancilla to the Pre-Socratic Philosophers* (1948, reprinted 1962); PILO ALBERTELLI, *Gli Eleati: testimonianze e frammenti* (1939), is a good Italian translation with commentary. Much of the best material is in general works on ancient Greek or Pre-Socratic philosophy. The most comprehensive treatment is in EDUARD ZELLER, *Die Philosophie der Griechen*, 6–7th ed., 3 vol., ed. by W. NESTLE (1920–23); in the revised Italian trans. of Zeller, ed. with extensive additions by ROLDOLFO MONDOLFO, the portion on the Eleatic school by GIOVANNI REALE (1967) occupies the whole 3rd volume of the 1st section and contains a good selected bibliography; an English translation of Zeller is entitled *A History of Greek Philosophy, from the Earliest Period to the Time of Socrates*, 2 vol. (1881). See also JOHN BURNET, *Early Greek Philosophy*, 4th ed. (1930, reprinted 1963); GEOFFREY KIRK and JOHN E. RAVEN, *The Presocratic Philosophers*, pp. 263–306 (1957); W.K.C. GUTHRIE, *A History of Greek Philosophy*, vol. 2 (1965); and GUIDO CALOGERO, *Storia della logica antica*, vol. 1, pp. 109–208 (1967).

Epicureanism: The first complete collection of the extant works and fragments of Epicurus is H. USENER (ed.), *Epicurea* (1887, reprinted 1966). A smaller selection, with Eng. trans. and commentary, is CYRIL BAILEY (ed.), *Epicurus: The Extant Remains* (1926), a very useful book that includes the “Vatican Fragments.” All of the ethical fragments (and several other items) are published in CARLO DIANO (ed.), *Epicuri Ethica* (1946), with extensive Latin commentaries. CARLO DIANO (ed. and trans.), *Lettere di Epicuro e dei suoi* (1946), contains 14 letters of Epicurus and his friends taken from Pap. Herc. 1418. G. ARRIGHETTI (ed.), *Epicuro, Opere* 2nd ed. (1967), contains all of the works and fragments (including the *Peri Physios*), with notes and an *index verborum*; to be used with caution. Lucretius can be read in the three volumes prepared, with introduction, translations, and comments, by CYRIL BAILEY, *Lucreti, De Rerum Natura* (1947).

English translations of Epicurus and Lucretius include WHITNEY J. OATES (ed.), *The Stoic and Epicurean Philosophers* (1940), which contains translations by CYRIL BAILEY and by H.A.J. MUNRO. See also *The Philosophy of Epicurus: Letters, Doctrines, and Parallel Passages from Lucretius*, trans. by GEORGE K. STRODACH (1963); DIOGENES LAERTIUS, *Lives of Eminent Philosophers*, bk. 10 on Epicurus, trans. by R.D. HICKS (1925); and LUCRETIUS, *On the Nature of the Universe*, trans. by R.E. LATHAM (1964).

Valuable for its breadth and richness of detail, CYRIL BAILEY, *The Greek Atomists and Epicurus* (1928; new ed., 1964), is a fundamental work. For Epicurus’ psychology and his relation to Aristotle, see CARLO DIANO, “La psicologia d’Epicuro e la teoria delle passioni,” in *Giornale critico della filosofia italiana* (1939–42). A book that stresses Epicurus’ anti-Platonism is N.W. DEWITT, *Epicurus and His Philosophy* (1954). Also important for its perceptive study of Epicurus’ religiosity and ethics is A.J. FESTUGIERE, *Épicure et ses dieux* (1946; Eng. trans., *Epicurus and His Gods*, 1956). See also the article “Epicur,” by W. SCHMID in the *Reallexikon für Antike und Christentum*, 5:681–819 (1961); L.L. WHYTE, *Essay on Atomism: From Democritus to 1960* (1961); and BENJAMIN FARRINGTON, *The Faith of Epicurus* (1967). G.D. HADZITS, *Lucretius and His Influence* (1935), traces the influence of Epicurean ideas, especially since Roman times, in a broad perspective. For further bibliography, see PHILLIP DE LACY, “Some Recent Publications on Epicurus and Epicureanism (1937–1954),” in *Classical Weekly*, 48:169–177 (1955). BERNARD FRISCHER, *The Sculpted Word: Epicureanism and Philosophical Recruitment in Ancient Greece* (1982), a discussion of the school’s success.

Pythagoreanism: The collection of the fragments in HERMANN DIELS and WALTHER KRANZ, *Die Fragmente der Vor-*

sokratiker, 6th ed., vol. 1 (1951), is insufficient; additions are given in MARIA TIMPANARO CARDINI (ed.), *Pitagorici: Testimonianze e frammenti*, 3 vol. (1958–64); and in CORNELIA J. DE VOGEL, *Pythagoras and Early Pythagoreanism* (1966). For the pseudo-Pythagoreans, see HOLGER THESLEFF (ed.), *The Pythagorean Texts of the Hellenistic Period* (1965).

The best comprehensive introduction to Pythagoreanism is the long chapter “Pythagoras and the Pythagoreans,” in W.K.C. GUTHRIE, *A History of Greek Philosophy*, vol. 1, pp. 146–340 (1962). Somewhat different approaches have been taken by DE VOGEL (*op. cit.*); and JAMES A. PHILIP, *Pythagoras and Early Pythagoreanism* (1966), works that demand more active criticism by the reader. Fairly full references to the discussion of Pythagoreanism up to 1960 are in WALTER BURKERT, *Weisheit und Wissenschaft: Studien zu Pythagoras, Philolaos, und Platon* (1962; Eng. trans., *Lore and Science in Ancient Pythagoreanism*, 1972), a highly technical and at times rather overcritical work. Among later technical discussions, likely to become influential, are the articles “Pythagoras” and “Pythagoreer” in *Pauly-Wissowa Realencyclopädie*, vol. 47, (1963), and suppl. vol. 10 (1965)—of the contributors, KURT VON FRITZ and H. DORRIE arrive at less controversial conclusions than B.L. VAN DER WAERDEN.

Hellenistic Pythagoreanism is treated in HOLGER THESLEFF, *An Introduction to the Pythagorean Writings of the Hellenistic Period* (1961); additions and corrections in *Entretiens Fondation Hardt*, vol. 18 (1972). Neo-Pythagoreanism is treated in PHILIP MERLAN, *From Platonism to Neoplatonism* (1953).

For up-to-date bibliographical accession, see *L’Année philologique* (annual), under the subject heading “Pythagorica” and the various Pythagoreans.

Realism: There is no single monograph that covers comprehensively the whole topic of Realism. The following works will be helpful for the study of its particular phases.

For Medieval Realism, see M.H. CARRÉ, *Realists and Nominalists* (1946, reissued 1967). For Neo-realism and critical Realism, see E.B. HOLT *et al.*, *The New Realism* (1912, reprinted 1970); DURANT DRAKE *et al.*, *Essays in Critical Realism* (1920, reprinted 1968); RENÉ KREMER, *La Théorie de la connaissance chez les néo-réalistes anglais* (1928); T.E. HILL, “Realistic Theories,” *Contemporary Theories of Knowledge*, pp. 77–205 (1961, reissued 1980), good general coverage of the American and English fields.

Neoscholastic Realisms are treated in LÉON NOËL, *Le Réalisme médiéval* (1938); and works by ÉTIENNE GILSON: *Le Réalisme méthodique* (1936), which presents the author’s own views; ch. 5, “Vade Mecum of a Young Realist,” trans. by W.J. QUINN, in R. HOUE and J. MULLALLY (eds.), *Philosophy of Knowledge* (1960); and *Réalisme Thomiste et critique de la connaissance* (1939), a critique of the leading Neoscholastic views. For the linguistic approach, see MARTIN LEAN, *Sense-Perception and Matter* (1953, reprinted 1973); J.L. AUSTIN, *Sense and Sensibilia* (1962).

Universals in contemporary thought are treated in I.M. BOCHENSKI, ALONZO CHURCH, and NELSON GOODMAN, *The Problem of Universals* (1956); FARHANG ZABEEH, *Universals* (1966); PANAYOT BUTCHVAROV, *Resemblance and Identity: An Examination of the Problem of Universals* (1966, reissued 1982); NICHOLAS WOLTERSTORFF, *On Universals: An Essay in Ontology* (1970).

For Scientific Realism, see BERTRAND RUSSELL, *Our Knowledge of the External World*, rev. ed. (1926, various printings); W.H. WERKMEISTER, *The Basis and Structure of Knowledge* (1948, reissued 1968), bibliography, pp. 420–438; MORITZ SCHLICK, “Are Natural Laws Conventions?” in H. FEIGL and MAY BRODBECK (eds.), *Readings in the Philosophy of Science*, pp. 181–188 (1953); ROMANO HARRÉ, *Theories and Things* (1961); GROVER MAXWELL, “The Ontological Status of Theoretical Entities,” in *Minnesota Studies in the Philosophy of Science*, 3:3–27 (1962); J.J.C. SMART, *Philosophy and Scientific Realism* (1963); DAVID M. ARMSTRONG, *Universals and Scientific Realism*, 2 vol. (1980).

Other 20th-century Realisms are discussed in G.D. HICKS, *Critical Realism* (1938); JAMES FEIBLEMAN, *The Revival of Realism* (1946, reissued 1972); WILFRID SELLARS, *Science, Perception and Reality* (1963); R.M. CHISHOLM (ed.), *Realism and the Background of Phenomenology* (1961), convenient bibliography, pp. 290–304; J.D. WILD (ed.), *The Return to Reason: Essays in Realistic Philosophy* (1953); E.B. MCGILVARY, *Toward a Perspective Realism* (1956); D.M. ARMSTRONG, *A Materialist Theory of the Mind* (1968); INGEBORG WIRTH, *Realismus und Apriorismus in Nicolai Hartmanns Erkenntnistheorie* (1965); GUSTAV BERGMANN, *Realism: A Critique of Brentano and Meinong* (1967).

Scholasticism: For the latest and most detailed bibliography, see W. TOTOK, *Handbuch der Geschichte der Philosophie*, vol. 2, *Mittelalter und frühe Neuzeit* (1970). Among the most reliable, best grounded presentations of the whole period are: E. GILSON, *History of Christian Philosophy in the Middle Ages* (1955); F. COPLESTON, *A History of Philosophy*, vol. 2, *Mediaeval Philosophy*, vol. 3, *Late Mediaeval and Renaissance Philosophy* (1950, 1953; paperback edition, 1962, 1963); M. DE WULF, *Histoire de la philosophie médiévale*, 6th ed., 3 vol. (1934–47; Eng.

trans. of vol. 1, 1951); and E. BREHIER, *La Philosophie du moyen âge*, 2nd ed. (1949). Still indispensable, though obsolete in some details is: F. UEBERWEG, *Grundriss der Geschichte der Philosophie*, vol. 2, B. GEYER, *Die patristische und scholastische Philosophie*, 11th ed. (1928). Lucidly arranged and divided is the 13th volume of FLICHE-MARTIN, *Histoire de l'Église: Le Mouvement doctrinal de XI^e au XIV^e siècle* (1951), which includes contributions by A. FOREST, F. van Steenberghen, and M. de Gandillac. M. GRABMANN's masterpiece, *Die Geschichte der scholastischen Methode*, 2 vol. (1909–11, reprinted 1956), covers only the time until the first years of the 13th century. For a first introduction for the general reader, see J. PIEPER, *Scholastik* (1960; Eng. trans., *Scholasticism*, 1960). Special problems concerning the continuing influence of medieval Scholasticism are treated in the following monographs: A. KOYRE, *Descartes und die Scholastik* (1923); A. TELKAMP, *Das Verhältnis John Locke's zur Scholastik* (1927); and J.O. FLECKENSTEIN, *Scholastik, Barock, exakte Wissenschaften* (1949). The following are sources on Neoscholasticism: J.P. GOLINAS, *La Restauration du Thomisme sous Leon XIII et les philosophes nouvelles* (1959); GIOVANNI ROSSI, *Le origini del Neotomismo nell'ambiente di studio del Collegio Alberoni* (1957); A. VIEL, "Le Mouvement thomiste au XIX^e siècle," *Revue Thomiste* (1909–10); E. BETTONI, *La Situation actuelle de la philosophie parmi les catholiques dans les divers pays* (1948), a survey of centres of study, institutes, and publications; and J.S. ZYBURA (ed.), *Present-Day Thinkers and the New Scholasticism: An International Symposium* (1926).

Skepticism: The basic statements and arguments of various forms of Skepticism are given in: (Academic Skepticism)—CICERO, *Academica* and *De natura deorum*, both with trans. by H. RACKHAM, Loeb Classical Library (1956). (Pyrrhonian Skepticism)—SEXTUS EMPIRICUS, *Adversus Mathematicos*, with trans. by R.G. BURY, Loeb Classical Library: vol. 1–2, *Against the Logicians and Outlines of Pyrrhonism* (1933–36); vol. 3, *Against the Physicists, Against the Ethicists* (1936); vol. 4, *Against the Professors* (1959–60); and *Scepticism, Man and God: Selections from the Major Writings of Sextus Empiricus*, ed. by P. HALLIE, trans. by S.G. ETHERIDGE (1964). (Renaissance Skepticism)—MICHEL DE MONTAIGNE, "L'Apologie de Raimond Sebond," in PIERRE VILLEY (ed.), *Les Essais de Michel de Montaigne*, new ed. (1922). (Skepticism and fideism)—BLAISE PASCAL, *Pensées*, ed. by L. BRUNSCHWIG (1951). (Skepticism in relation to modern philosophy)—PIERRE BAYLE, *Dictionnaire historique et critique*, esp. the articles "Pyrrho" and "Zeno of Elea," both of which appear in BAYLE'S *Historical and Critical Dictionary: Selections*, trans. and ed. by RICHARD H. POPKIN (1965); DAVID HUME, *Dialogues Concerning Natural Religion*, ed. by N. KEMP SMITH (1947); *Enquiries Concerning the Human Understanding and Concerning the Principles of Morals*, 2nd ed. (1957), and *A Treatise of Human Nature*, both ed. by L.A. SELBY-BIGGE (1958).

The standard studies of ancient Skepticism are: EDWYN R. BEVAN, *Stoics and Sceptics* (1959); VICTOR BROCHARD, *Les Sceptiques grecs* (1887); NORMAN MACCOLL, *The Greek Sceptics from Pyrrho to Sextus* (1869); MARY MILLS PATRICK, *The Greek Sceptics* (1929); LEON ROBIN, *Pyrrhon et le scepticisme grec* (1944); and EDUARD ZELLER, *The Stoics, Epicureans and Sceptics*, trans. by O.J. REICHEL (1880). A recent fine study of the epistemological problems involved in ancient Skepticism is CHARLOTTE L. STOUGH, *Greek Skepticism* (1969). See also RAOUL RICHTER, *Der Skeptizismus in der Philosophie* (1904–08); RICHARD H. POPKIN, "Skepticism," *Encyclopedia of Philosophy*, vol. 7, pp. 449–461 (1967), which contains a bibliography on the subject; these examine Skepticism from ancient times to the 19th century. JOHN OWEN, *The Sceptics of the French Renaissance* (1893), is an interesting discussion of Renaissance and 17th-century Skepticism, though not particularly scholarly. DON CAMERON ALLEN, *Doubt's Boundless Sea: Skepticism and Faith in the Renaissance* (1964); and RICHARD H. POPKIN, *The History of Scepticism from Erasmus to Descartes*, rev. ed. (1968), which contains a lengthy bibliography, are studies of Renaissance Skepticism and its impact on philosophy and religion. RICHARD H. POPKIN, "Berkeley and Pyrrhonism," *Review of Metaphysics*, 5:223–246 (1951–52); "David Hume and the Pyrrhonian Controversy," *ibid.*, 6:65–81 (1952–53); "David Hume: His Pyrrhonism and His Critique of Pyrrhonism," *Philosophical Quarterly*, 1:385–407 (1950–51); "The High Road to Pyrrhonism," *American Philosophical Quarterly*, 2:1–15 (1965); "The Skeptical Crisis and the Rise of Modern Philosophy," *Review of Metaphysics*, 7:132–151, 307–322, 499–510 (1953–54); "The Skeptical Precursors of David Hume," *Philosophy and Phenomenological Research*, 16:61–71 (1955–56); and "Scepticism in the Enlightenment," in T. BESTERMANN (ed.), *Studies on Voltaire and the Eighteenth Century*, 26:1321–1345 (1963), are specialized studies on aspects of Skepticism in relation to modern philosophy. ARNE NAESS, *Scepticism* (1968), is a most interesting attempt to clarify Skepticism in relation to contemporary thought and to defend it as a viable outlook

today. BENSON MATES, *Skeptical Essays* (1981), discusses epistemological problems and free will.

Sophists: Ancient sources and fragments are presented in R.K. SPRAGUE, *The Older Sophists, a Complete Translation* (1972), and in K. FREEMAN, *Ancilla to the Pre-Socratic Philosophers* (1948), to be used together with Freeman's *The Pre-Socratic Philosophers*, 2nd ed. (1949). The original Greek texts are in H. DIELS and W. KRANZ (eds.), *Die Fragmente der Vorsokratiker*, 6th ed., vol. 2 (1952); and are edited with an Italian translation and commentary in M. UNTERSTEINER, *Sofisti*, 4 vol. (1949–62). (General discussions): T. GOMPERZ, *Greek Thinkers*, Eng. trans. by L. MAGNUS, vol. 1, bk. 3, ch. 5–7 (1901); M. UNTERSTEINER, *The Sophists*, Eng. trans. by K. FREEMAN (1954); W.K.C. GUTHRIE, *A History of Greek Philosophy*, vol. 3, *The Fifth-Century Enlightenment* (1969). G.B. KERFERD, *The Sophistic Movement* (1981), is a study of the intellectual contributions made by the movement.

The Second Sophistic period is treated in G.W. BOWERSOCK, *Greek Sophists in the Roman Empire* (1969).

Stoicism: HANS VON ARNIM, *Stoicorum Veterum Fragmenta*, 4 vol. (1905–24), is the standard text collection. The following works of classic Stoic authors and substantive issues in Stoicism in antiquity are most conveniently available in the "Loeb Classical Library": MARCUS AURELIUS, *Meditations*; EPICETUS, *Discourses*; CICERO, *De fato, De finibus, De natura deorum, and Academica*; DIOGENES LAERTIUS, *Lives of Eminent Philosophers*, vol. 2, book 7; SENECA, *Epistulae Morales and Moral Essays*; SEXTUS EMPIRICUS, *Outlines of Pyrrhonism and Against the Dogmatists*, 4 vol.; GEORGE MURRAY, *The Stoic Philosophy* (1915), the classical statement of the grandeur of the Stoic philosophy; MAX POHLENZ, *Die Stoa*, 2 vol. (1948–49); and PAUL BARTH, *Die Stoa* (1903), are representative of scholarly studies of Stoic philosophy; JOHNNY CHRISTENSEN, *An Essay on the Unity of Stoic Philosophy* (1962), is a recent and comprehensive essay; LUDWIG EDELSTEIN, *The Meaning of Stoicism* (1966); and JOSIAH B. GOULD, *The Philosophy of Chrysippus* (1970), are among the best of recent studies of Greco-Roman Stoicism; EDUARD ZELLER, *Die Philosophie der Griechen in ihrer geschichtlichen Entwicklung*, 5 vol. (1856–68; in part translated as *Stoics, Epicureans, and Sceptics*, rev. ed., 1962); EDWYN R. BEVAN, *Stoics and Sceptics* (1913, reprinted 1959); and ROBERT D. HICKS, *Stoic and Epicurean* (1910, reprinted 1962), are illustrations of Stoic philosophy in the Hellenistic period. See also JASON L. SAUNDERS, *Greek and Roman Philosophy After Aristotle* (1966); and HARRY A. WOLFSON, *Philo: Foundations of Religious Philosophy in Judaism, Christianity and Islam*, 2 vol. (1962). EDWARD V. ARNOLD, *Roman Stoicism* (1911, reprinted 1958); and FREDERICK W. BUSSELL, *Marcus Aurelius and the Later Stoics* (1910), are excellent statements of Stoicism in the later Roman period. PIERRE DE LABRIOLLE, *Histoire de la littérature latine chrétienne* (1920; Eng. trans., *History and Literature of Christianity from Tertullian to Boethius*, 1924), an excellent presentation of the influence of Stoic views in late antiquity and the patristic period; ETIENNE GILSON, *History of Christian Philosophy in the Middle Ages* (1955); HARRY A. WOLFSON, *The Philosophy of the Church Fathers*, 3rd ed. rev. (1970); MAURICE DE WULF, *Histoire de la philosophie médiévale*, 2 vol. (1925; Eng. trans., *History of Mediaeval Philosophy*, 2 vol., 1926); and ISAAC HUSIK, *A History of Medieval Jewish Philosophy* (1940), are careful introductions to Stoic influences in patristic and medieval times; JASON L. SAUNDERS, *Justus Lipsius: The Philosophy of Renaissance Stoicism* (1955); HAROLD HOFFDING, *A History of Modern Philosophy*, 2 vol. (1950); and FREDERICK C. COPLESTON, *A History of Philosophy*, rev. ed., vol. 3–6 (1962), trace the Stoic influence from its revival in the Renaissance into modern philosophy. JOHN M. RIST (ed.), *The Stoics* (1978), is an excellent collection of essays covering logic, cosmology, ethics, psychology, and aesthetics.

Stoic logic and physics are treated in BENSON MATES, *Stoic Logic* (1953); SAMUEL SAMBURSKY, *The Physical World of the Greeks*, 2nd ed. (1960; orig. pub. in Hebrew) and *Physics of the Stoics* (1959).

Analytic and Linguistic philosophy: G.J. WARNOCK, *English Philosophy Since 1900* (1958), is a very readable account covering much of the history. J.O. URMSON, *Philosophical Analysis* (1956), is especially good on logical atomism and its demise. BERTRAND RUSSELL, *The Problems of Philosophy* (1959), is a nontechnical account of his views just prior to the period of logical atomism. A collection of Russell's papers, *Logic and Knowledge*, ed. by R.C. MARSH (1956), contains his "Lectures on Logical Atomism," together with more technical papers. G.E. MOORE, *Some Main Problems of Philosophy* (1953), gives a good introduction to his methods and philosophical concerns. Two key papers by Moore are "A Defence of Common Sense," in *Contemporary British Philosophy*, Second Series (1925), and "Proof of an External World," in *Proceedings of the British Academy*, 25:273–300 (1939). Among anthologies are those of A.J. AYER (ed.), *Logical Positivism* (1959), which also includes

papers critical of the movement and has an excellent bibliography; BERNARD WILLIAMS and ALAN MONTEFIORE (eds.), *British Analytical Philosophy* (1966); RICHARD RORTY (ed.), *The Linguistic Turn* (1967); J.A. FODOR and J.J. KATZ (eds.), *The Structure of Language* (1964); and LEONARD LINSKY (ed.), *Semantics and the Philosophy of Language* (1952). The 1961 translation of WITTGENSTEIN'S *Tractatus Logico-Philosophicus* by D.F. PEARLS and B.F. MCGUINNESS is superior to the original English version. Wittgenstein's *Philosophical Investigations* (1953) is the best known and historically the most influential of the posthumously published works from his later period. A.J. AYER, *Language, Truth and Logic*, 2nd ed. (1946), remains the best introduction to Logical Positivism. GILBERT RYLE, *The Concept of Mind* (1949), is the most famous example of what has been called "ordinary language" philosophy. J.L. AUSTIN, *How To Do Things with Words* (1962), contains the most discussed features of his views. W.V.O. QUINE, *From a Logical Point of View* (1953), is a collection of fairly nontechnical essays that provide good examples of the continuing influence of formal logic.

Empiricism: Classic texts include JOHN LOCKE, *An Essay Concerning Human Understanding*, 2 vol. (1690); DAVID HUME, *A Treatise of Human Nature*, book 1, pt. 1 (1739); IMMANUEL KANT, *Kritik der reinen Vernunft* (1781; Eng. trans., *Critique of Pure Reason*, 1929); JOHN STUART MILL, *A System of Logic, Ratiocinative and Inductive*, books 1 and 2 (1843).

W.H. WALSH, *Reason and Experience* (1947); and H.H. PRICE, *Thinking and Experience*, 2nd ed. (1969), are good general surveys. For a comprehensive selection of standard works from Locke to J.S. Mill, see A.J. AYER and R. WINCH (eds.), *The British Empirical Philosophers* (1952). Modern works in the Empiricist tradition include BERTRAND RUSSELL, *Human Knowledge* (1948); W.T. STACE, *Theory of Knowledge and Existence* (1932); RUDOLF CARNAP, *Der logische Aufbau der Welt* (1928; Eng. trans., *The Logical Structure of the World*, 1967); and A.J. AYER, *Language, Truth and Logic*, 2nd ed. (1946), a short exposition of the extreme Empiricist position. HAROLD MORICK (ed.), *Challenges to Empiricism* (1980), is a collection of essays.

Existentialism: Fundamental texts include SOREN KIERKEGAARD, *Philosophiske smuler* (1844; *Philosophical Fragments*, 1936); *Afsluttende uvidenskabelig efterskrift til de filosofiske smuler* (1846; *Concluding Unscientific Postscript*, 1941). FRIEDRICH NIETZSCHE, *Also sprach Zarathustra* (1883–84; *Thus Spoke Zarathustra*, trans. by W. KAUFMANN in *The Portable Nietzsche*, 1954); *Zur Genealogie der Moral* (1877; *Toward a Genealogy of Morals*, trans. by W. KAUFMANN in *Basic Writings of Nietzsche*, 1966). KARL JASPERS, *Psychologie der Weltanschauungen* (1919), the first work of contemporary Existentialism, announcing all of the fundamental theses; *Philosophie*, 3 vol. (1932; *Philosophy*, 3 vol., 1969–71); *Vernunft und Existenz* (1935; Eng. trans., *Reason and Existenz*, 1955). MARTIN HEIDEGGER, *Sein und Zeit* (1927; 10th ed., 1963; *Being and Time*, 1962); *Was ist Metaphysik?* (1929; "What Is Metaphysics?" trans. by R.F.C. HULL and A. CRICK in *Existence and Being*, 1949); *Einführung in die Metaphysik* (1953; *An Introduction to Metaphysics*, 1959). GABRIEL MARCEL, *Être et Avoir* (1935; *Being and Having*, 1949); *Le Mystère de l'être*, 2 vol. (1950; *The Mystery of Being*, 1950–51); *The Philosophy of Existence*, (1949). NICOLA ABBAGNANO, *La struttura dell'esistenza* (1939); N. LANGIULLI (ed. and trans.), *Critical Existentialism* (1969). JEAN-PAUL SARTRE, *L'Être et le néant* (1943; *Being and Nothingness*, 1956); *L'Existentialisme est un humanisme* (1946; *Existentialism and Humanism*, 1948). MAURICE MERLEAU-PONTY, *La Structure du comportement* (1942; *The Structure of Behavior*, 1963); *Phénoménologie de la perception* (1945; *The Phenomenology of Perception*, 1962).

Important surveys and analyses include MARJORIE GRENE, *Dreadful Freedom* (1948); HELMUT KUHN, *Encounter with Nothingness: An Essay on Existentialism* (1951); MAURICE NATANSON, *A Critique of Jean-Paul Sartre's Ontology* (1951); JAMES COLLINS, *The Existentialists: A Critical Study* (1952); WILLIAM BARRETT, *What Is Existentialism?* (1964); ADOLPH LICHTIGFELD, *Jaspers' Metaphysics* (1954); MARJORIE GRENE, *Martin Heidegger* (1957); MARY WARNOCK, *Existentialism* (1970); and ROBERT D. CUMMING, *Starting Point* (1979).

Idealism: The two best books on Idealism in English are A.C. EWING, *Idealism: A Critical Survey* (1933); and R.F.A. HOERNLE, *Idealism as a Philosophy* (1927). A.C. EWING (ed.), *The Idealist Tradition from Berkeley to Blanshard* (1957), is a useful volume containing selections from the texts of the major Idealists and selected criticisms of Idealism. Other important collections are C. BARRETT (ed.), *Contemporary Idealism in America* (1932); J.H. MUIRHEAD (ed.), *Contemporary British Philosophy: Personal Statements*, First–Second Series, 2 vol. each (1924); and G.P. ADAMS and W.P. MONTAGUE (eds.), *Contemporary American Philosophy*, 2 vol. (1930). Works on the history and theory of the subject include: B. BLANSHARD, *Reason and Analysis* (1962), a careful critical examination of schools of philosophy

opposed to Idealism; G.W. CUNNINGHAM, *The Idealistic Argument in Recent British and American Philosophy* (1933), a thorough and dependable treatise; S.N. DASGUPTA, *Indian Idealism* (1933); NICOLAI HARTMANN, *Die Philosophie des Deutschen Idealismus*, vol. 1, Fichte, Schelling, und die Romantik (1923), vol. 2, Hegel (1929), 2nd ed. (1 vol., 1960); A.J.M. MILNE, *The Social Philosophy of English Idealism* (1962); J.H. MUIRHEAD, *The Platonic Tradition in Anglo-Saxon Philosophy: Studies in the History of Idealism in England and America* (1931); P.T. RAJU, *Idealistic Thought of India* (1953); L.S. ROUNER (ed.), *Philosophy, Religion, and the Coming World Civilization: Essays in Honor of William Ernest Hocking* (1966); and A. STERN, *Philosophy of History and the Problem of Values* (1962), a good secondary source.

On the classical systems of Indian philosophy, see S. RADHAKRISHNAN, *Indian Philosophy*, 2 vol. (1923–27), an authoritative exposition; S.N. DASGUPTA, *A History of Indian Philosophy*, 5 vol. (1922–55), an erudite examination of the Sanskrit and Pali texts; *Indian Idealism* (1933); SRI AUROBINDO, *The Life Divine* (1949), a reinterpretation of the heritage; and SWAMI VIVEKANANDA, *The Yogas and Other Works* (1953), a collection with biography. In *Pragmatism* (1907) and in *The Varieties of Religious Experience* (1902), WILLIAM JAMES quoted Vivekananda at length as a typical representative of spiritual monism. In the *Sacred Books of the East*, 50 vol., ed. by F. MAX MULLER (1879–1910), see especially vol. 1 and 15, *The Upanishads* and vol. 8, *The Bhagavadgītā*. In the *Harvard Oriental Series*, 47 vol., ed. by CHARLES ROCKWELL LANMAN (1890–1968), see especially vol. 3, *Buddhism in Translations*, and vol. 17, *The Yoga-System of Patanjali*.

Writings of Idealists are listed in their biographies. P.A. SCHILPP, editor of "The Library of Living Philosophers Series," has issued four important volumes on Idealists: *The Philosophy of Alfred North Whitehead*, 2nd ed. (1951); *The Philosophy of Ernst Cassirer* (1949); *The Philosophy of Sarvepalli Radhakrishnan* (1962); and *The Philosophy of Martin Buber* (1967); and a volume on Brand Blanshard is in preparation. Other works on Idealists include: J.H. COTTON, *Royce on the Human Self* (1954), one of the best books on Royce; D.S. ROBINSON, *Royce and Hocking: American Idealists* (1968); and GABRIEL MARCEL, *La Métaphysique de Royce* (1945; Eng. trans., 1956), which shows the relation of Marcel to Royce and Hocking. H.T. KIM, "Nishida and Royce," *Philosophy East and West*, 1:18–29 (1952), and "The Logic of the Illogical: Zen and Hegel," *ibid.*, 5:19–29 (1955), are informative accounts of Nishida's contributions to Idealism. The following volumes of the *Revue Internationale de Philosophie* contain valuable bibliographies: *Henri Bergson*, vol. 3 (1948); *Léon Brunschvicg*, vol. 5 (1951); *Hegel*, vol. 6 (1952); *George Berkeley*, vol. 7 (1953); *Benedetto Croce*, vol. 7 (1953); *Kant*, vol. 8 (1954); *Whitehead*, vol. 15 (1961); *Leibniz*, vol. 20 (1966); and *Josiah Royce*, vol. 21 (1967). GODFREY VESEY (ed.), *Idealism Past and Present* (1982), includes historical essays on idealistic thought of the past 2,500 years.

Materialism: For the period up to about 100 years ago, see F.A. LANGE, *Geschichte des Materialismus und Kritik seiner Bedeutung in der Gegenwart*, 2 vol. (1902; Eng. trans., *History of Materialism and Criticism of Its Present Importance*, 3rd ed., 3 vol. (1925). For more recent times, see JOHN PASSMORE, *A Hundred Years of Philosophy*, 2nd ed. (1966). There are excellent articles by KEITH CAMPBELL and H.B. ACTON on "Materialism" and "Dialectical Materialism" in the *Encyclopedia of Philosophy*, vol. 5, pp. 179–188 and vol. 2, pp. 389–397 (1967), which also contains excellent articles on nearly all of the noncontemporary philosophers here mentioned. Examples of work by most of the contemporary writers are given in JOHN O'CONNOR (ed.), *Modern Materialism: Readings on Mind-Body Identity* (1969); and C.V. BORST (ed.), *The Mind-Brain Identity Theory* (1970). See also HERBERT FEIGL, *The "Mental" and the "Physical": The Essay and a Postscript* (1967); J.J.C. SMART, *Philosophy and Scientific Realism* (1963); D.M. ARMSTRONG, *A Materialist Theory of the Mind* (1968); and WILFRID SELLARS, *Science, Perception and Reality* (1963), especially ch. 1. A rather difficult book defending Materialism from the difficulties about intentionality is D.C. DENNETT, *Content and Consciousness* (1969). For two very different styles of antimaterialist argument, see J.R. LUCAS, *The Freedom of the Will* (1970); and NORMAN MALCOLM, *Problems of Mind* (1971). Another interesting critique of Materialism is in JOHN BELOFF, *The Existence of Mind* (1962). A mainly mechanistic philosophy of biology is presented by the German biologist B. RENSCH in *Biophilosophie auf erkenntnistheoretischer Grundlage (Panpsychistischer Identismus)* (1968; Eng. trans., *Biophilosophy*, 1971), though Rensch's philosophy is also panpsychist.

Some classic Materialist works are: LUCRETIVS, *On the Nature of the Universe*, trans. by R.E. LATHAM (1951); THOMAS HOBBES, *Body, Mind and Citizen: Selections*, ed. by R.S. PETERS (1962); RENE DESCARTES, *Philosophical Writings*, trans. and ed. by ELIZABETH ANSCOMBE and P.T. GEACH (1954); and A. VARTANIAN,

La Mettrie's "L'Homme Machine": A Study in the Origins of an Idea (1960), which is a critical edition with introductory monograph and notes.

For epistemic Materialism, see RUDOLF CARNAP, "Psychology in Physical Language," in A.J. AYER (ed.), *Logical Positivism* (1959); Carnap's replies to Herbert Feigl and A.J. Ayer in P.A. SCHILPP (ed.), *The Philosophy of Rudolf Carnap* (1964); and H. REICHENBACH, *Experience and Prediction* (1938).

The most relevant and important works by Ryle and Wittgenstein are: GILBERT RYLE, *The Concept of Mind* (1949); and LUDWIG WITTGENSTEIN, *Philosophical Investigations* (1953). For a Materialist critique of Ryle, see BRIAN MEDLIN, "Ryle and the Mechanical Hypothesis," in C.F. PRESLEY (ed.), *The Identity Theory of Mind*, 2nd ed. (1971).

Phenomenology: Most of the classical works on Phenomenology were written by Husserl himself (see the bibliography of the HUSSERL article). In EDMUND HUSSERL, *Logische Untersuchungen*, 2nd ed., 2 vol. (1913–21; Eng. trans., *Logical Investigations*, 2 vol., 1970), one of the fundamental texts on Phenomenology, the phenomenological method is applied in the area of logic. The following works appeared in the journal *Jahrbuch für Philosophie und phänomenologische Forschung* (1913–30); Husserl's *Ideen zu einer reinen Phänomenologie und phänomenologischen Philosophie* (1913; Eng. trans., *Ideas: General Introduction to Pure Phenomenology*, 1931, reprinted 1969), through which Phenomenology established itself as transcendental philosophy and received worldwide reaction; *Vorlesungen zur Phänomenologie des inneren Zeitbewusstseins* (1928; Eng. trans., *The Phenomenology of Internal Time-Consciousness*, 1964); and *Formale und transzendente Logik* (1929; Eng. trans., *Formal and Transcendental Logic*, 1969); MAX SCELER, *Der Formalismus in der Ethik* (1916); and MARTIN HEIDEGGER, *Sein und Zeit* (1927; Eng. trans., *Being and Time*, 1962). The following works appeared in the series *Husserliana* (Husserl's collected works): *Cartesianische Meditationen und Pariser Vorträge* (1950; Eng. trans., *The Paris Lectures*, 1964), which contains the text of the Paris lectures of 1929 and the subsequent elaboration; *Die Idee der Phänomenologie* (1950; Eng. trans., *The Idea of Phenomenology*, 1964), an introduction to Phenomenology in five lectures from 1907; *Ideen*, 3 vol. (1950–52); *Die Krisis der europäischen Wissenschaften und die transzendente Phänomenologie* (1954; Eng. trans., *The Crisis of European Sciences and Transcendental Phenomenology*, 1970), Husserl's later work (1934–37), significant for the problems regarding the life-world; *Erste Philosophie*, 2 vol. (1956–59), a critical history of ideas and a theory of reduction presented in a series of lectures, 1923–24; *Phänomenologische Psychologie* (1962), lectures from 1925, a different wording of the *Encyclopædia Britannica* article of 1927, with remarks by Heidegger and the Amsterdam addresses of 1925; *Zur Phänomenologie des inneren Zeitbewusstseins* (1966), text on the problem of time from 1893–1917 with lectures (in the middle) from 1905 on the inner time-consciousness (first edited by Heidegger); *Analysen zur passiven Synthesis* (1966), a phenomenological analysis having sensation as its subject matter; and *Philosophie der Arithmetik* (1970), early manuscripts from 1890 to 1901. His *The Basic Problems of Phenomenology*, trans. by ALBERT HOFSTADTER (1982; originally published in German, 1975), reproduces a course of lectures given in 1927. See also JOSEPH J. KOCKELMANS, *Edmund Husserl's Phenomenological Psychology* (1967); and RUDOLF BOEHM, *Vom Gesichtspunkt der Phänomenologie* (1968).

In the series "Phaenomenologica" works are published that are written from a Phenomenological perspective, HERBERT SPIEGELBERG, *The Phenomenological Movement*, 2nd ed., 2 vol. (1965), worthy of particular mention, also appeared in this series. Since 1904 MARVIN FARBER has edited the journal *Philosophy and Phenomenological Research* (by no means, however, exclusively dedicated to Phenomenology). In England *The Journal of the British Society for Phenomenology* first appeared in 1970. In the United States the following journals have appeared: *Journal of Phenomenological Psychology* (semi-annual); *Research in Phenomenology* (1971); and *Analecta Husserliana: The Yearbook of Phenomenological Research*.

Positivism and Logical Empiricism: Literature on Classical Positivism includes J. WATSON, *Comte, Mill and Spencer* (1895); W.M. SIMON, *European Positivism in the Nineteenth Century* (1963); JOHN STUART MILL, *Auguste Comte and Positivism* (1865); AUGUSTE COMTE, *Cours de philosophie positive*, 6 vol. (1830–42; Eng. trans. and cond. by H. MARTINEAU, *The Positive Philosophy of Auguste Comte*, 2 vol., 1853). For further references to the ethical views of the classical Positivists, see the bibliography of Utilitarianism in the *Encyclopedia of Philosophy*.

Many of the original classics of Logical Positivism and Logical Empiricism, both books and articles, are listed in the ample bibliography of A.J. AYER (ed.), *Logical Positivism* (1959), an anthology that contains, among other important essays,

RUDOLF CARNAP's "Psychology in Physical Language." The early history of Viennese Positivism is well told in VICTOR KRAFT, *Der Wiener Kreis: Der Ursprung des Neopositivismus* (1950, 2nd ed. 1968; Eng. trans., *The Vienna Circle*, 1953, reprinted 1969). Another important source is J. JOERGENSEN, *The Development of Logical Empiricism*, vol. 2, no. 9 of the *International Encyclopedia of Unified Science* (1951). For a brief account of the European movement of Logical Positivism and its migration and impact in the United States, see H. FEIGL, "The Wiener Kreis in America," in D. FLEMING and B. BAYLIN (eds.), *The Intellectual Migration: Europe and America 1930–1960* (1969). Books, mainly in the foundations of the sciences, but also in philosophy of language and epistemology, many by the leading Logical Empiricists, are listed in the ample *Bibliography and Index*, in HERBERT FEIGL and CHARLES MORRIS (eds.), *International Encyclopedia of Unified Science*, vol. 2, no. 10 (1969). Of direct relevance are the major works of R. Carnap, O. Neurath, M. Schlick, P. Frank, H. Reichenbach, E. Nagel, C.G. Hempel, R. von Mises, and Charles Morris. For criticisms, those of KARL R. POPPER may be used; and the intellectual autobiography of Carnap, the 26 descriptive and critical essays, and his replies, in P.A. SCHILPP (ed.), *The Philosophy of Rudolf Carnap* (1963). For more recent evaluations and reactions, see P. ACHINSTEIN and S.F. BARKER (eds.), *The Legacy of Logical Positivism: Studies in the Philosophy of Science* (1969); and *Minnesota Studies in the Philosophy of Science*, vol. 1–5 (1956–70).

Pragmatism: Classic works include CHARLES SANDERS PEIRCE, "The Fixation of Belief," "How to Make Our Ideas Clear," and "What Pragmatism Is," in *Collected Papers*, vol. 5, ed. by C. HARTSHORNE and P. WEISS (1934); WILLIAM JAMES, *Principles of Psychology*, 2 vol. (1890), *The Will to Believe and Other Essays in Popular Philosophy* (1897), *Pragmatism: A New Name for Some Old Ways of Thinking* (1907), and *The Meaning of Truth* (1909); JOHN DEWEY, *How We Think* (1910), *The Influence of Darwin on Philosophy* (1910), *Democracy and Education* (1916), *Essays in Experimental Logic* (1916), *Reconstruction in Philosophy* (1920, 1948), *Human Nature and Conduct* (1922), *Logic: The Theory of Inquiry* (1938), *Theory of Valuation* (1939), and *Problems of Men* (1946). On F.C.S. Schiller see R. ABEL, *The Pragmatic Humanism of F.C.S. Schiller* (1955), with a bibliography of Schiller's writings; on French and Italian pragmatists, H.S. THAYER, *Meaning and Action: A Critical History of Pragmatism*, part 3 (1968), with further bibliographical references.

For surveys of the movement, see H.S. THAYER, *Meaning and Action: A Critical History of Pragmatism* (1968), with bibliography; "Pragmatism," in D.J. O'CONNOR (ed.), *A Critical History of Western Philosophy*, pp. 437–462 (1964); and H.S. THAYER (ed.), *Pragmatism: The Classic Writings* (1970), the basic writings in the Pragmatism of Peirce, James, Dewey, Mead, and Lewis, and further bibliographical references; John Dewey, "The Development of American Pragmatism," in *Philosophy and Civilization*, pp. 13–35 (1931); and CHARLES W. MORRIS, *The Pragmatic Movement in American Philosophy* (1970). JACQUES BARZUN, *A Stroll with William James* (1983), is an excellent discussion of his ideas.

Rationalism: The classic Ancient Greek work is PLATO, *Meno*; essential modern works are DESCARTES, *Meditationes de Prima Philosophia*... (*Meditations on First Philosophy*); SPINOZA, *Ethics*; LEIBNIZ, *Monadologie* (*Monadology* and *Other Philosophical Writings*); KANT, *Kritik der reinen Vernunft* (*Critique of Pure Reason*); 19th century. Rationalism is epitomized in HEGEL, *Phänomenologie des Geistes* (*Phenomenology of Mind*); FRANCIS HERBERT BRADLEY, *Appearance and Reality*.

For Rationalism in the theory of knowledge, see BRAND BLANSHARD, *Reason and Analysis* (1962); GEORGE BOAS, *Rationalism in Greek Philosophy* (1961); ERNST CASSIRER, *Die Philosophie der Aufklärung* (1932; Eng. trans., *Philosophy of the Enlightenment*, 1951); M.R. COHEN, *Reason and Nature: An Essay on the Meaning of Scientific Method*, 2nd ed. (1953); A.C. EWING, *Idealism: A Critical Survey* (1934); H.H. JOACHIM, *The Nature of Truth* (1906); A.E. MURPHY, *The Uses of Reason* (1943); H.J. PATON, *In Defence of Reason* (1951); BERTRAND RUSSELL, *Problems of Philosophy* (1912); W.H. WALSH, *Reason and Experience* (1947).

For Rationalism in metaphysics, see the classics listed above. For two outstanding examples from the present century, see J.M.E. MC TAGGART, *The Nature of Existence*, 2 vol. (1921–27), together with the commentary of C.D. BROAD, *Examination of McTaggart's Philosophy*, 2 vol. (1933–38); and ALFRED NORTH WHITEHEAD, *Process and Reality* (1929). For Rationalism in ethics, see WILLIAM WOLLASTON, *The Religion of Nature Delineated* (1722); and KANT, *Die Metaphysik der Sitten* (1785; Eng. trans., *The Metaphysics of Morals*, 1799). For early forms of the appeal to self-evident rules, see RICHARD PRICE, *A Review of the Principal Questions in Morals* (1758). For later types of Rationalism, see G.E. MOORE, *Principia Ethica* (1903); W.D.

ROSS, *The Right and the Good* (1930), and *Foundations of Ethics* (1939); BRIAN ELLIS, *Rational Belief System* (1979).

For Rationalism in religion, excellent standard works are: W.E.H. LECKY, *History of the Rise and Influence of the Spirit of Rationalism in Europe*, 2 vol. (1865); A.D. WHITE, *History of the Warfare of Science with Theology in Christendom*, 2 vol. (1910); J.M. ROBERTSON, *A Short History of Freethought, Ancient and Modern*, 2nd ed., 2 vol. (1906); A.W. BENN, *History of English Rationalism in the Nineteenth Century*, 2 vol. (1906); J.B. BURY, *A History of Freedom of Thought* (1913). SIGMUND FREUD, *Die Zukunft einer Illusion* (1927; Eng. trans., *The Future of an Illusion*, 1928), offers a psychoanalytic study of religious belief.

Utilitarianism: The classical texts are JEREMY BENTHAM, *An Introduction to the Principles of Morals and Legislation* (1789; 2nd ed., 1823); JOHN STUART MILL, *Utilitarianism* (1861; 4th ed., 1871); HENRY SIDGWICK, *The Methods of Ethics* (1874; 7th ed., 1907); G.E. MOORE, *Principia Ethica* (1903) and *Ethics* (1912); D.D. RAPHAEL (ed.), *British Moralists: 1650–1800*, 2 vol. (1969), containing selected readings.

Useful anthologies include MARY PETER MACK (ed.), *A Ben-*

tham Reader (1969); J.B. SCHNEEWIND (ed.), *Mill's Ethical Writings* (1965); SAMUEL GOROVITZ (ed.), *Utilitarianism: John Stuart Mill with Critical Essays* (1971).

Secondary, historical, and contemporary studies include DAVID LYONS, *Jeremy Bentham* (1972); ERNEST ALBEE, *A History of English Utilitarianism* (1902, reprinted 1957); LESLIE STEPHEN, *The English Utilitarians*, 3 vol. (1900, reprinted 1968); ELIE HALEVY, *La Formation du radicalisme philosophique*, 3 vol. (1901–04; Eng. trans., *The Growth of Philosophical Radicalism*, 1928); J.P. FLAMENATZ, *The English Utilitarians* (1949); J.B. SCHNEEWIND (ed.), *Mill: A Collection of Critical Essays* (1968); STEPHEN TOULMIN, *An Examination of the Place of Reason in Ethics* (1950); P.H. NOWELL-SMITH, *Ethics*, ch. 16 (1954); RICHARD BRANDT, *Ethical Theory*, ch. 12–15 (1959); DAVID LYONS, *Forms and Limits of Utilitarianism* (1965); JAN NARVESON, *Morality and Utility* (1967); MICHAEL D. BAYLES (ed.), *Contemporary Utilitarianism* (1968); J.J.C. SMART, *An Outline of a System of Utilitarian Ethics* (1961). DONALD REGAN, *Utilitarianism and Cooperation* (1980), a presentation of a new utilitarian theory with a good survey of disputes among utilitarians.

Philosophies of the Branches of Knowledge

It is no longer possible for any one individual to be a leader in all branches of learning. Perhaps Leibniz, who died in 1716, was the last universal scholar, and his life is a warning rather than an example. In such a situation the enterprise of philosophy is in a sense more difficult than ever before; no one can hope to contribute much to the clarification of ideas in logic who is not himself a logician, or to the clarification of ideas in physics who is not himself a physicist, and so on throughout the fields of specialized knowledge. It thus seems inevitable

that there should have evolved philosophical disciplines corresponding to the various branches of study and providing the frameworks upon which they may be studied and evaluated in and of themselves. (Discussions of particular schools of philosophy mentioned in this article are found in PHILOSOPHICAL SCHOOLS AND DOCTRINES, WESTERN.) (Ed.)

Philosophy of science

Taken broadly as the progressive improvement of man's understanding of nature, the intellectual enterprise of science originally formed an integral part of philosophy, and the two areas of inquiry have never finally separated. Little more than a hundred years ago, theoretical physics—concerned with the fundamental debate about physical nature—was still described as “natural philosophy,” as distinguished from the two other chief divisions of abstract discussion, viz., moral philosophy and metaphysical philosophy—the latter including ontology, the study of the deepest nature of reality or being. In fact, only during the 20th century, following the professionalization and specialization of the natural sciences, did the philosophy of science become recognized as a separate discipline.

Methodological and epistemological issues—i.e., issues regarding the investigator's manner of approach to nature—are treated in this section. Issues regarding the substantive character of nature as so revealed—i.e., as it is in and of itself—are treated below in *Philosophy of nature*.

NATURE, SCOPE, AND RELATIONS OF THE SUBJECT

The philosophy of science attempts first to elucidate the elements involved in scientific inquiry—observational procedures, patterns of argument, methods of representation and calculation, metaphysical presuppositions—and then to evaluate the grounds of their validity from the points of view of formal logic, practical methodology, and

metaphysics. The philosophy of science is thus a topic for explicit analysis just as are other subdivisions of philosophy. The boundaries between these subdivisions are, at certain points, somewhat arbitrary; it is not easy to separate completely, for example, the philosophical validation of scientific hypotheses from the formal study of inductive logic (which reasons from facts to general principles), or the debate about observation in philosophy of science from that in epistemology (the theory of knowledge).

Historically, the preoccupations of those who, if living today, would be called philosophers of science have been of two main kinds—ontological and epistemological, or epistemic. This division reflects a long-standing distinction between object and subject—i.e., between nature, regarded as that about which man sets out to acquire scientific knowledge, and man himself, regarded as the creator and either discoverer or possessor of that knowledge. Since 1920, new directions within physics, particularly in quantum mechanics, have discredited any hard-and-fast distinction between the knower and the known or between the observer and his observation. Nevertheless, the distinction remains relevant on an everyday level and can be cautiously retained for the purposes of initial exposition.

The ontological preoccupations of philosophers of science frequently overlap into the substantive areas of the sciences themselves, for they explore the general problem,

What kinds of entities and elements or theoretical terms can properly figure in man's scientific theories? And what sort of existence, or other objective status, do such things possess?

Ontological
versus
epistemic
concern

In particular cases, this general problem has inevitably raised questions of substance as well as of intellectual method. An early 20th-century debate between two Austrian physicists, Ernst Mach and Ludwig Boltzmann, and a German physical chemist, Wilhelm Ostwald, about the existence and reality of atoms, for instance, involved both substantive issues of physics and chemistry and philosophical issues of a more strictly analytical kind.

Until recently the epistemic concerns of the subject have been more purely philosophical, though this autonomy is now being challenged by studies in psychology that explore cognitive processes and others in sociology that examine the conditioning of cognition through interpersonal and group relationships. Epistemologically, philosophers of science have analyzed and evaluated the concepts and methods employed in studying natural phenomena and human behaviour, whether individual or collective; this analysis has covered the general concepts and methods characteristic of all scientific inquiries and also the more particular ones that distinguish the subject matters and problems of different special sciences. In treating the epistemic issues that arise about science and scientific procedures, the emphasis in this article is placed upon their consideration in general terms; the concepts and methods peculiar to a discipline, say, sociology, are discussed elsewhere.

With its vast range of concerns, the philosophy of science has attracted the attention of men with very different professional backgrounds and interests. At one extreme, as in the writings of Ernest Haeckel, the German Darwinian evolutionist, it has merged into a sweeping kind of popular science; at an opposite extreme, as in 20th-century Logical Positivism or Logical Empiricism (see below), which holds that knowledge is only what is scientifically verifiable, it has been treated as an extension of formal logic and conceptual analysis. Between these extremes, as in the work of the British astrophysicist Arthur Eddington and the German quantum physicist Werner Heisenberg, the philosophy of science has moved to the frontiers of the sciences and has directly confronted problems about the existence, status, and validity of theoretical entities and concepts.

Correspondingly, the philosophy of science has been approached in very diverse spirits, ranging from the highly abstract and mathematical to the concrete and historical and from the severely positivistic to the frankly theological. From René Descartes in the 17th century to the Logical Positivist Otto Neurath in the 20th, the success of pure mathematics and logic has inspired the mathematically minded to cast the whole of natural science into a single formal system after the pattern of geometry. Their opponents—from John Locke, an 18th-century British Empiricist, to N.R. Hanson, a recent U.S. philosopher of science—have sought the proper basis of man's intellectual confidence in the nature of scientific investigation, regarded as a human activity. Equally, Positivists such as Hans Reichenbach, a 20th-century German-American philosopher, have looked to philosophy for proof that scientific inquiries alone can provide knowledge worthy of the name; while theists such as Pierre Duhem, a French theoretical physicist, have argued that the claims of science are inherently limited and so leave room for other, more embracing varieties of metaphysical and religious truth.

This diversity of concerns and approaches within the philosophy of science has affected its relation with other neighbouring disciplines. On a practical plane, for instance, different philosophical interpretations have implied different procedures for testing and assessing the strength of rival concepts and hypotheses. Thus, no clear dividing line can be drawn between the philosophical analysis of scientific theories and the statistical analysis of scientific procedures and experiments or, notably, between the philosophy of science and the history of scientific ideas. Recent debates indicate that the particular questions that a historian of science brings to his analysis of scientific change inescapably depend on his philosophical attitudes and commitments.

On a more general and abstract level, the philosophy of science has never been definitively separated from metaphysics and epistemology. Indeed, some 20th-century

philosophers—for instance, the U.S. philosophical logician Willard V. Quine—effectively restrict the legitimate areas of metaphysics and epistemology to what have here been called the ontal and epistemic aspects of the philosophy of science. In Quine's view, the traditional ontological problem of what there is in the world as man knows it must be attacked by a logical analysis of the claims about what kinds of things exist that are implicit in alternative theoretical systems. Meanwhile, the work of such cognitive psychologists as Switzerland's Jean Piaget, who explored the processes involved in the genesis of knowledge, is eroding the barriers between the logical analysis of conceptual systems, the psychological investigation of thought processes, and the epistemological validation of intellectual procedures. Piaget, for instance, based his investigations into the acquisition of concepts on a philosophy akin to that of Kant, who held that all knowledge bears the imprint of the mind's own structure; and, though a psychologist himself, Piaget referred to certain aspects of his work as "genetic epistemology," a philosophical designation.

The present survey of the philosophy of science, therefore, contains no effort to prejudice the central question, whether the methods of logical analysis alone are legitimate or whether at certain points the subject legitimately overlaps into such neighbouring subjects as cognitive psychology, the history of science, and epistemology. Philosophers of science themselves have been sharply divided, some rejecting any alliance except with logic, others cultivating its wider historical and behavioral connections; and both points of view must thus be taken into account.

HISTORICAL DEVELOPMENT

Classical and medieval periods: the beginnings of a philosophy of nature. At the outset the problems of science were as much those of method as of substance and were inseparable from those of what has long been called natural philosophy. The first attempts to move beyond traditional mythologies to a rational account of nature, beginning with the Ionian and south Italian philosophers around 600 BC, involved the sorts of elements that any such account should comprise. Detailed empirical, or observational, considerations favouring one or another of the rival accounts were premature. Were, for example, the diverse phenomena of nature manifestations of one single enduring form of matter or of several elementary substances mixed together, and was the fundamental substance continuous and fluid-like, or discrete and atomic? Others asked whether the observed forms of phenomena were evidence, rather, of some universal, underlying mind or of a variety of coexisting kinds of spirit responsible for phenomena having different orders of complexity.

The Pre-Socratics based their answers at least as much on epistemic grounds—i.e., on what type of account would be genuinely intelligible—as on ontal or empirical ones—i.e., on what sorts of enduring entities could possibly have, or be found in experience to have, the required kind of existence. Their answers ranged from the ontal Realism of Parmenides, foremost philosopher of Eleaticism—a school of southern Italy according to which all changes are transitory appearances concealing the mutual relations of deeper, unchanging realities—to the critical skepticism of Heraclitus—the Ephesian philosopher according to whom nothing in nature as man knows it can ever have this Parmenidean reality, and everything empirical is in flux.

Though Plato and Aristotle displayed more precise concern for actual cases, their philosophies of science still rested on the same mixture of ontological, epistemological, and empirical considerations. Questions about nature discussed in Plato's *Timaeus* and Aristotle's *Physics*, for instance, were neither purely metaphysical nor purely empirical in character though they had a methodological aspect akin to that of modern philosophy of science. Moreover, Plato's construction of the fundamental theories of science around concepts and patterns borrowed from geometry have had a profound influence in the modern period—upon René Descartes, for example, in the 17th century and upon the founder of modern logic, the German mathematician Gottlob Frege, in the 1880s and after.

Mathematical entities alone, Plato argued, have the sort

The Pre-Socratics

Plato and Aristotle

Relations
with other
disciplines

of enduring intelligibility that Parmenides had rightly demanded of the ultimate constituents in a rational science of nature. Thus, only a physical theory built on a numerical and geometrical framework will reveal the truly permanent structures and relationships behind the evident flux of phenomena. Within such a theory, all inferences will be self-evidently valid at all times and so exempt from the mutability of empirical events; correspondingly, the numbers and figures of formal mathematics will have an immutability denied to familiar physical objects. Planetary astronomy and the theory of matter were, in Plato's view, scientific fields within which this mathematical methodology showed immediate promise; the movements of the planets must be explained by constructions drawn from three-dimensional geometry, and the physics of matter seemingly involved atoms with shapes reflecting the geometry of the five regular solids (the tetrahedron, dodecahedron, etc.). In either case the mathematical theories themselves would alone be fully exact and intelligible, whereas empirical objects and processes could be no more than transitory and approximate illustrations of the enduring entities and theoretical relations underlying them.

Given that Aristotle's scientific preoccupations were centred on marine biology rather than planetary movements, he naturally developed a very different scientific methodology. In his view, mathematical entities and relations were too completely general and too remote from actual experience to explain the qualitative details of empirical entities. So the ultimate elements of nature must be not Plato's abstract mathematical forms that supposedly existed apart from actual phenomena but rather certain more specific entities, recognizable within the familiar sequences of empirical experience. Instances of such basic essences could be discovered in the typical life cycles of different creatures; for example, the morphogenesis of a seed exemplifies the "coming into being" of the corresponding type of animal or plant, of which the mature specific form—as defined by its essence—is the natural destination of its development. Having recognized the natural destinations toward which natural processes of different kinds were directed, it was then possible to construct a comprehensive classification of essences in terms of which the whole natural world would, in principle, be intelligible. Explanations within such an all-embracing natural history might not be self-evidently general and immutable, as were those of Plato's geometry, but the theoretical inferences involved would be no less deductive or necessary. It would also account directly for the specific qualitative characters of different observed objects and processes.

Atomists
and Stoics

The themes stated by Plato and Aristotle are still represented today by two rival approaches to the philosophy of science—one (Platonic) based in logic, the other (Aristotelian) based in the history of science. Between them they dominated the subject during the later period of Greek antiquity, otherwise notable only for the debate between the Atomist successors of Democritus and Epicurus and the Stoic philosophers, led by Zeno of Citium. This debate provided the first profound analysis of the strengths and weaknesses of atomistic explanation. Epicureans argued for a purely corpuscular view in which the individual units of matter moved quite independently, except when they were in actual contact. For the Stoics the empirical world was intelligible only in terms of interactions and stable patterns maintained by harmonies operative at a distance.

These two debates—between Platonists and Aristotelians and between Stoics and Epicureans—presented clearly and for the first time the chief alternative modes of explanation available to science and analyzed their possibilities and limitations in general terms. More than 2,000 years before the rise of modern thermodynamics and field theory, for instance, Aristotle had already recognized the difficulties of explaining changes in physical state (*e.g.*, melting and evaporation) within a purely atomistic theory of matter. Even earlier, Plato had demonstrated the possibility of a unified mathematical explanation of the differences between different kinds of material substance. In the 20th century the theoretical physicist Werner Heisenberg cited pre-Socratic arguments regarding the ultimate constitution of nature as relevant to contemporary problems.

By contrast with the period before Euclid the geometer (*i.e.*, to 300 bc), the ensuing Hellenistic, Islāmic, and medieval periods added little to the understanding of scientific methodology and explanation. From the Alexandrian astronomer Ptolemy, who detailed the geocentric theory, most natural philosophers deliberately restricted their intellectual claims in an instrumentalist manner—*i.e.*, by endeavouring merely to "save the phenomena" by devising successful mathematical procedures for predicting, for example, lunar eclipses and planetary motions. In this way they disregarded the mechanisms responsible for those phenomena, thus preserving the computational techniques of the sciences from the risk of conflict with theology for the following 1,250 years, until the time of Copernicus.

In the High Middle Ages, accordingly, the possibility that man could make himself the intellectual master of nature was largely neglected. Human understanding was dependent on God's illumination. The reliability of scientific knowledge lay not in the merits of its methodology but in the divine grace. Hence, man had no direct line of access to nature; the only road to knowledge was through the divine mind. Thus, all the central questions in the philosophy of science were restated as theological questions about the relationship between God's omniscience and the more limited knowledge of man. In this context the metaphor of "illumination" was taken so seriously in the 13th century that the subject of optics was cultivated by a distinguished Oxford scholar as much for its theological implications as for its physical content.

The Renaissance and after: from manifesto to critique. Although the intellectual Renaissance of the 16th and 17th centuries was accompanied by a secularization of learning, which shifted the centre of philosophical and scientific debate from monasteries to universities—and even to salons—the link between philosophy and theology was not abruptly snapped. Descartes, Newton, and Leibniz, the leading scholars of the time, were concerned to demonstrate that their positions were compatible with sound theology. Medieval controversies about human knowledge and divine grace found an echo in such arguments as Descartes's assertion that the rational methods of inquiry can be relied on only provided that God does not deliberately deceive us. Two new factors, however, combined to give the 17th-century debate about scientific methodology a new autonomy. First, philosophy now posed the central questions in the philosophy of science—both about the origins and functions of scientific concepts and about the structure and validity of scientific arguments—and faced them directly, instead of only as refracted through a theological prism. Second, these questions were acquiring an immediate relevance and significance, simply because men were then launching new, empirically based theories of nature with a seriousness unknown for some 1,200 years.

Between 1600 and 1800 the debate in the philosophy of science was barely separable from that within science itself. From Bacon and Galileo by way of Descartes and Leibniz to Laplace and Kant, the major participants in the philosophical debate played significant roles on the scientific stage as well. Thus, Bacon, author of the method of exhaustive induction (see below), and Descartes both attempted to formulate explicitly a new method for the improvement of the intellect—*i.e.*, codifying the rational procedures of science in a way that would free them from arbitrary and unfounded or superstitious assumptions (Bacon's idols) and ground them in a logically impregnable manner on the properties of "clear and distinct," or self-evidently valid, concepts (as distinguished by Descartes).

To be sure, the two men offered different recipes for a rational science and described the outcome of a properly conducted scientific inquiry in quite different terms. On the one hand, Bacon was preoccupied with empirically observed facts as the starting point for all science and relied on theories only insofar as they were derived from those facts. Ideally, he held that the scientist should provide an exhaustive enumeration of all examples of the empirical phenomenon under investigation as a preliminary to identifying the natural "form" of which they were the manifestation. Though Bacon remained unclear about the exact character of the abstraction involved, he

Hellenistic
through
medieval
times

Francis
Bacon and
Descartes

is commonly assumed to have claimed that theoretical propositions in science are justified only if they have been deduced formally from such an enumeration.

In contrast to such so-called "Baconian induction," Descartes focussed upon the problem of constructing self-consistent and coherent deductive systems of theory, within which argument would proceed with the formal security familiar in Euclidean geometry. Whereas Bacon had reacted against the Scholastic reliance on Aristotle's authority by calling for a return to firsthand experience, Descartes reacted against the Skepticism of 16th-century humanists by pointing to mathematics as the pattern to which all genuinely certain knowledge about nature could aspire. Inasmuch as Euclid's axioms, definitions, and postulates had captured the intrinsic characteristics of spatial relations and provided a theoretical starting point from which the whole of geometry could be deductively inferred, the task for 17th-century physics was to extend Euclid's intellectual structure by adding further, equally self-evident axioms, definitions, and postulates. Only in this way could the theories of motion, magnetism, and heat—eventually those of physiology and cosmology, too—achieve the same necessary deductive authority. Descartes set out to show, in the four volumes of his *Principia Philosophiae* ("Principles of Philosophy"), how all of the familiar phenomena of physics could be accounted for by a single, fully comprehensive system of mathematical theory, based on Euclidean foundations and conforming to his own deductivist principles. The very possibility of so interpreting nature was so impressive to Descartes that it lent a "moral certainty" to his conclusions.

Newton's
hypo-
thetico-
deductive
method

The arguments of Bacon and Descartes were really manifestos; both offered intellectual programs for a natural science yet to be built, and, while it is true that during the next 150 years, Galileo, Newton, and many others actually constructed the new physical science for which the philosophers had been calling, it is also true that the form of the resulting theories was, nonetheless, not exactly what either man had foreseen. On the one hand, there was little Baconian induction in Newton's intellectual procedures. Those 17th-century scientists, such as Robert Boyle—one of the founders of modern chemistry—who seriously attempted to apply Bacon's maxims found his pedestrian advice to be more of a hindrance than a help in the formulation of illuminating theoretical concepts. (It was said, somewhat unkindly, that Bacon "philosophized like a Lord Chancellor.") On the other hand, though Newton was powerfully influenced by Descartes's mathematical example, he followed his methodological maxims only up to a point. Granted that the theory of motion and gravitation of Newton's *Principia* did indeed conform to Descartes's recipe—adding further dynamical axioms, definitions, and postulates to those of Euclid's geometry—Newton nonetheless made no pretense of proving, in advance of empirical evidence, that these additional assumptions were uniquely self-evident and valid. Instead, he treated them as working assumptions to be accepted hypothetically for just so long as their consequences threw light, in exact detail, on hitherto-unexplained phenomena. Inevitably, the epistemic claims to be made on behalf of such explanations fell short of Descartes's full "deductivist" ambitions. Newton knew of no phenomena, for instance, that evinced the mechanisms of gravitational attraction and saw no point in "feigning hypotheses" about them.

In this way, Newton devised in practice—almost inadvertently—what philosophers of science have since labelled the hypothetico-deductive method, in which, as theorized by Descartes, the proper form of a theory is seen as a mathematical system in which particular empirical phenomena are explained by relating them back deductively to a small number of general principles and definitions. The method, however, abandons the Cartesian claim that those principles and definitions can themselves be established, finally and conclusively, before inquiring what light their consequences throw on actual scientific problems and phenomena.

From 1700 on, the terrain of debate in the philosophy of science shifted. At first, attacks on Newton's methods and assumptions by Leibniz, Berkeley, and the remaining

Cartesians continued, from different points of view. But by 1740 the time for both manifestos and objections was past; the basic scientific soundness of Newton's concepts was no longer in doubt, and the philosophical question thus became retrospective, viz., How had Newton done it? Over this new question, 18th-century philosophers were divided into three camps: Empiricism, Rationalism, and Kantianism. There were those who believed, like the Scottish Skeptic David Hume, that Newton's philosophy conformed to the Empiricist maxims of Francis Bacon and John Locke. Again, there were those—like the Swiss mathematician Leonhard Euler, one of the founders of modern analysis, and Immanuel Kant in his younger days—who assumed that Newton's physical principles would eventually be put on a fully demonstrative or self-evident basis as required by Cartesian Rationalism. Neither of these positions proved entirely successful, as Kant himself came to recognize: the Empiricists failed to do justice to the deductive rigour of Newton's theoretical arguments; and the Rationalists could not rigorously demonstrate the mathematical uniqueness of Newton's system. As was already known, even Euclidean geometry, which involves the axiom of parallels (according to which one, and only one, line can be drawn through a given point parallel to another line) could no longer claim a formal uniqueness. It had been shown, in 1733 and again in 1766, that alternative geometrical systems can consistently be developed in which the axiom of parallels is replaced by other mathematically acceptable alternatives. Clearly, the authority claimed for Newton's concepts and methodology could no longer be sustained in the old Rationalist way; thus a third alternative, that of Kantianism, arose.

One of the prime goals of Kant's so-called critical philosophy, with its famous so-called transcendental method, in which knowledge reflects the categorial structure of the mind, was to provide an alternative philosophical justification of Newton's results. The system of concepts used in Euclidean geometry and Newtonian physics is uniquely relevant to man's actual experience, Kant argued, not because the empirical applicability of their principles is self-evident—no such self-evidence can tell the inquirer anything about external nature. Still less is it because their inductive support is so strong—no Baconian argument can yield the required kind of certainty. Rather, it is because the scientist can arrive at a coherent, rational system of empirically applicable explanations only by constructing his theories around just those (Euclidean and Newtonian) concepts. He could, in fact, go even further. Euclidean axioms are required, Kant claimed, not merely for science alone; they specify explicitly cognitive structures (of the mind) that are implicitly involved also—as so-called forms of intuition (specifically of space and time)—in the prescientific rational organization of sensory experience into a coherent, intelligible world of substantial objects seen as interacting by causal processes. A grasp of Kant's transcendental method would then enable a thinker to recognize (or so Kant hoped) how and in what respects the use of his established system of rational forms and categories is indispensable alike for any coherent understanding or even for any experience.

Through World War I: philosophy of classical physics. Kant's ambitious philosophical enterprise took a long time to digest. A century later, in the 1880s, philosophers of science as different in other ways as the Austrian phenomenalist Ernst Mach and Heinrich Hertz, pioneer in electromagnetic wave theory, were both pursuing questions opened up by Kant; and some of their implications were still being explored in the 1970s, as, for example, in cognitive psychology. In general terms, Kant's central thesis—i.e., that man confers a structure on his knowledge through the concepts and categories that he brings to the formation and interpretation of experience—has proved extremely fertile: it has helped in the analysis of theory construction, and it has suggested in sensory psychology that man's very capacity for perception can yield effective knowledge only to the extent that his sensory inputs themselves have a cognitive or conceptual structure.

In one respect, to be sure, Kant seems in retrospect to have attempted too much. Including in man's framework

cists,
Rational-
ists, and
Kant

of sensory and intellectual organization all of Euclidean geometry and of fundamental Newtonian physics and the prescientific notions of substance and cause, Kant set out to demonstrate a priori that man's actual current framework is the one and only effective framework—a proof which, as is known today, was misguided, for its thesis is simply not the case. This is so, not merely because alternative systems of geometry and dynamics can be developed consistently in mathematical terms (for Kant himself was aware of that fact); rather, it is so because 20th-century astrophysics and quantum mechanics have succeeded in giving non-Euclidean and post-Newtonian concepts an entirely coherent empirical application in the scientific explanation of natural phenomena—and this was something that Kant was not prepared to contemplate. Pure mathematics aside, indeed, Kant and most of his immediate successors were convinced that Euclid and Newton between them had somehow hit on a uniquely adequate system of geometry and physics—if not on the final mathematical truth about nature.

For about 100 years, then, the epistemic foundations and ontal commitments of this so-called classical science were largely taken for granted. The 19th-century debate in philosophy of science, accordingly, concentrated on peripheral topics and skirted all issues that might have called into question the ascendancy of Euclid and Newton. The validity of the classical system having been assumed, the questions remaining for debate involved only its interpretation and implications; and the resulting positions can be classified, with slight oversimplification, under the headings of mechanistic (or Materialist) and Idealist doctrines, respectively.

Idealism
versus
mech-
anistic
Material-
ism

The Idealists took to heart Kant's thesis that the cognitive structure of experience is imposed upon nature rather than discovered in it and sought to explore its broader consequences. The psychology of sensory perception, for example, previously barred from direct scientific study by Descartes's absolute separation of mind from matter, was now opened up for exploration; thus, by the mid-19th century, Hermann von Helmholtz, pioneer in a broad range of scientific studies, embarked on the remarkable investigations into the production of man's sensory experiences or ideas set out in his monumental *Handbuch der physiologischen Optik* (1856–67; Eng. trans., *Physiological Optics*, 1921–25).

For most of Kant's successors, however, the Idealist road led away from philosophy of science into other areas—particularly, into political ideology, philosophy of history, and sociology. Thus, it was not until well into the 20th century that the distinguished joint relativity–quantum theorist Sir Arthur Eddington, in his *Fundamental Theory* (1946), once again took up seriously the basic task of Kantian Idealism, viz., that of demonstrating, on a priori epistemological principles, that man's physical interpretation of nature embodies certain necessary structures imposed on physics by the character of his theoretical procedures themselves.

Meanwhile, the 19th-century mechanistic Materialists were disregarding Kant's central insights and concentrating instead on the apparent implications of the Newtonian system for other branches of science. A vigorous philosophical debate resulted, particularly in those fields that were just developing effective explanatory methods and theoretical concepts of their own. One good example of such a field was physiology, in which the work of a pioneering experimental physiologist, Claude Bernard, with its striking theoretical analysis of the vasomotor system and other regulatory mechanisms in the body, which anticipated 20th-century ideas about feedback systems, finally broke a long-standing deadlock between two opposed groups of scientists—the extreme mechanists, who recognized no difference at all between organic or physiological processes and the physicochemical phenomena of the inorganic world, and the outright vitalists, who insisted that the two kinds of phenomena were absolutely different. The debate also encouraged an epiphenomenal view of experience—as a kind of subjective mental froth without causal influence on the underlying physical mechanisms—and so sharpened the apparent threat to all claims about human

“free will.” Today it seems, indeed, that the sweeping conclusions of such scientific popularizers as the German evolutionist Ernst Haeckel, who wedded the ideas of classical physics with the new Darwinian history of nature to form a comprehensive Materialistic cosmology, or “anti-theology,” carried more weight at the time than they seem in retrospect to have deserved.

There was one promising exchange about the central epistemic issues in the philosophy of science in mid-century, that which took place between William Whewell, a British philosopher and historian of science noted for his work on the theory of induction, and the political essayist, John Stuart Mill; but this was abortive. The debate ended in cross-purposes, largely on account of differences in temperament and preoccupations. Whewell's knowledge—not merely of contemporary physical science but of its whole historical background—was both broad and detailed. The mathematical necessity of arguments such as those in Newtonian dynamics impressed him quite as much as it had impressed Kant; but he gave a less grandiose account of the reasons for this necessity. Whewell's philosophy, a Kantian variation on Newton's hypothetico-deductive method, was historicized: it was only by a progressive approach that physicists arrived at the most coherent and comprehensive systems of what Whewell called “consilient” hypotheses—or separately derived, yet concordant, sets of laws—that were compatible with the empirical knowledge then at their disposal. Mill, on the other hand, principally concerned with the methodology of the social sciences, concentrated on the observational basis of science to the neglect of its theoretical organization and so emphasized the contingent, or unnecessary, nature of all genuine empirical knowledge. In due course, certain of his doctrines, such as his account of arithmetical formulas as being a variety of empirical generalization, exposed him to some ridicule; but, for the time being, while the sheer bulk and learning of Whewell's writings muffled the force of his arguments, Mill's more fluent and less technical style of exposition captured the popular attention.

Whewell
versus
J.S. Mill

In consequence, it was not until the 1890s and early 1900s that serious doubts grew up about the finality of the Newtonian synthesis; and the writings of Ernst Mach, Heinrich Hertz, the eminent German physicist Max Planck, Pierre Duhem, and others inaugurated the new phase of far-reaching critical reanalysis characteristic of 20th-century philosophy of science. In one way or another, all of these men stood back and looked at the Euclidean and Newtonian systems with fresh and less committed eyes. They had learned Kant's lesson about the constructive character of formal theories, without sharing his belief in the unique rationality of the classical synthesis; and, as a result, the central topics of their discussions turned on the best ways of restating the Kantian problem. Granting that the intellectual activity of theory construction has the effect of building a physical necessity into man's theoretical arguments, they asked, what then follows, ontologically, about the reality or conventionality of the resulting atoms, forces, electrons, etc., and what can be said, epistemologically, about the cognitive status and logical validity of its theoretical principles?

Empirio-
criticism;
Realism;
conven-
tionalism

At one extreme, an Austrian physicist and philosopher Ernst Mach, and Richard Avenarius, the author of a philosophy known as empiriocriticism, expounded a sensationalist form of Empiricism reminiscent of David Hume, who had insisted that all ideas be traceable to “impressions” (sensations). On their view, theoretical concepts are intellectual fictions, introduced to achieve economy in the intellectual organization of sensory impressions, or observations, for which alone ontal primacy can be claimed. Correspondingly, all claims to scientific knowledge had epistemic validity for them only insofar as they could be grounded in such sense impressions. As against this instrumentalist or reductionist position, Max Planck, author of the quantum theory, defended a qualified Realism, which, at the least, expressed the ideal toward which all conceptual development in physics proceeds; for, without a belief in the enduring reality of external nature, he argued, all motive for theoretical improvement in science would vanish. Between these two extremes, Henri Poincaré, equally

distinguished in mathematics and the philosophy of science, and Pierre Duhem, a French theoretical physicist, occupied a range of intermediate so-called conventionalist positions, which attempted to do justice to the arbitrary elements in theory construction while avoiding the sort of radical doubt about the ontal status of theoretical entities that led Mach into lifelong Skepticism about the reality of atoms.

The 20th-century debate: Positivists versus historians. In the mid-20th century, debate in the philosophy of science became notably detailed, elaborate, and critical; those 50 years, in fact, have seen the subject finally achieving the status of a well-established professional discipline. Not least among the causes of this development have been the profound changes that have taken place since 1900 within theoretical physics and other fundamental branches of natural science. So long as the classical synthesis of Euclid and Newton retained its unquestioned authority, there had been little occasion to probe its ontological and epistemological bases at all deeply; but relativity theory—which qualified earlier geometries and laws in terms of new insights into the tie-ins between space and time—and quantum mechanics—which qualified them in terms of a statistical and indeterministic formulation—posed a frontal challenge to that synthesis and inevitably provoked critical and philosophical questions about the validity of the methods and assumptions on which it had relied. Consequently, between 1920 and 1940 there arose a renewed interaction between theoretical physicists and philosophers of science—especially between the Viennese Positivists and the authors of the new quantum mechanics.

The main themes of the subsequent debate were largely those introduced into discussion in the period around 1900. Mach's critical reductionism, based on his *Beiträge zur Analyse der Empfindungen* (1886; Eng. trans., *Contributions to the Analysis of the Sensations*, 1897), in which he tried to reduce all knowledge to statements about sensations, was a prime source both of the Positivism and Logical Empiricism of the Vienna Circle—a group of eminent philosophers and scientists that met regularly in Vienna during the 1920s and 1930s—and also of the epistemological theories about sense-data and logical constructions developed in Britain about the same time by Bertrand Russell, perhaps the foremost logician and philosopher then in England; by G.E. Moore, a meticulous pioneer in Linguistic Analysis; and by others. Meanwhile, the qualified Realism of Planck and Hertz was carried further by such men as Norman Campbell, an English physicist known for his sharpening of the distinction between laws and theories, and Karl Popper, an Austro-English philosopher recognized for his theory of falsifiability, both of whose views reflect the explicit methodology of many working scientists today. A notable exception would be the Positivist followers of Niels Bohr in the Copenhagen school of theoretical physics. Finally, there has continued to be substantial support for intermediate, conventionalist compromises, with Kantian overtones, along the general lines developed by Poincaré and Duhem.

From the rich complexity of recent philosophy of science, two main strands may be selected for special mention here. The first is the strand of neo-Humean Positivism, which first developed in the Vienna Circle and has flourished more recently in the United States and has been fundamentally preoccupied with epistemological issues. While largely abandoning Mach's belief that sensations are the sole ultimate ground of knowledge, its proponents have continued, with Mach, to regard theoretical entities as fictions or logical constructs, the validity of which depends entirely on the capacity to give them a basis in empirical observations. This neo-Humean position has derived much encouragement, if not formal confirmation, both from Einstein's emphasis on the essential role of the observer in relativity physics and from the attack from the side of quantum theory made by the German physicist Werner Heisenberg on any sharp distinction, at the subatomic level, between the observer, his observation, and the system observed (see below *Philosophy of nature*).

The Logical Positivists and Empiricists harnessed to these epistemic arguments a formal apparatus taken over from

the philosophy of mathematics—specifically, from Russell and Whitehead's *Principia Mathematica* (1910–13). In their view, the activity of theory construction is logically equivalent to the creation of propositional systems, in which groups of propositions are ideally set out in axiomatic form. So interpreted, the hypothetico-deductive method becomes a recipe for devising a succession of progressively more comprehensive axiom systems, based on alternative sets of general postulates (or primitive propositions) posited without proof, from which particular, empirical propositions can be inferred. As in the case of the special theory of relativity, these particular propositions—for instance, that the axis of Mercury's orbital ellipse will precess (or turn) at a certain rate—can then be used to validate the general postulates by comparing them with actual experience thus—directly or indirectly—substantiating the more general primitive propositions as well. The subsequent debate within the Viennese school has been concerned, very largely, with the exact character and force of this substantiation—whether it be verification, confirmation, or corroboration and/or falsification. At its most ambitious extreme, the Viennese school aimed at constructing a single system of unified science, by which the entire corpus of positive knowledge would be embraced in a single, all-embracing axiom system to be constructed around Russell's abstract symbolic logic. According to this program, all truly scientific knowledge must, first of all, be validated by appeal to neutral empirical observations, on pain of being dismissed as meaningless; and it must then be incorporated into the larger scheme of unified science.

The strongest opposition to this Empiricist or Positivist strand has come, correspondingly, from a Neo-Kantian school that has questioned the very possibility of identifying the pool of theoretically neutral observations necessary for substantiating or discrediting alternative theories in a strictly logical manner. This Neo-Kantian strand in 20th-century philosophy of science was inaugurated by the pioneering thinkers Heinrich Hertz (in electromagnetic wave theory) and Ludwig Wittgenstein (in philosophy of language). Rejecting Mach's central epistemological questions about sensations and ideas, these men have started instead from Kantian questions about the use of representations or models in the explanation of phenomena. Hertz's treatise on *The Principles of Mechanics* (1894), for instance, expounded Newtonian dynamics as a formal representation that logically entailed empirical conclusions only insofar as the phenomena concerned were already describable in terms drawn from the theory itself; and Wittgenstein's *Tractatus Logico-Philosophicus* (1922) extended Hertz's analysis to provide a general philosophical theory of language as an instrument for the representation of facts. The implications of this approach for the philosophical analysis and methodology of science have been explored further by some of Wittgenstein's pupils and successors, who have shifted the focus of discussion away from the verification of scientific propositions to the establishment of scientific concepts and theories; by highlighting the problem of conceptual change, they have revived interest in the philosophical significance of the history of scientific ideas. For, from this point of view, logical questions about the structure of propositional systems must be joined by other, equally fundamental rational questions about the manner in which different theoretical systems come to succeed one another (see below *Conceptual change and the development of science*).

During this same period, the remarkable changes taking place within such sciences as theoretical physics, biochemistry, and psychology have been provoking philosophical discussions among scientists themselves. For instance, the displacement of classical Newtonian physics by Heisenberg's quantum mechanics has stimulated a new round of arguments about causality and determinism, with some people hailing Heisenberg's Principle of Indeterminacy—which holds that the location of a particle is intrinsically imprecise in the measure that its momentum is precise (and vice versa)—as giving human free will the foothold that rigorous 19th-century determinism did not seem to allow. Progress in cellular and subcellular physiology, moreover, has given rise to further rounds of debate in

Controversy among scientists

Relativity and quantum mechanics

Logical Positivism versus Neo-Kantianism

the philosophy of biology. Claude Bernard, the foremost experimentalist of 19th-century medicine, had never managed to extend his analysis of regulatory mechanisms, such as those of the nerves that control the size of blood vessels, to cover the processes of embryology and morphogenesis (development of organic forms); and, on this finer level, there had been a renewed deadlock, around the years 1900–20, between the vitalism of Hans Driesch, which posited an almost “soul-like” reality that guides development, and the mechanism of Jacques Loeb, both experimental biologists with philosophical concerns. Once again, supporters of neither extreme position could make out their case entirely; instead, biologists have tended toward the mediating systemic conceptions first introduced by Paul A. Weiss, a distinguished developmental biologist, in the mid-1920s, and subsequently developed in detail as applications of the new theories of cybernetics and feedback, which conduct comparative studies of automatic control systems in the nervous system and in electromechanical engineering. More recently still, the development of molecular biology has compelled scientists to reformulate the problem of morphogenesis yet again—this time as the problem of seeing how the structural patterns of nucleic acid macromolecules in the hereditary genetical material find a structural expression in the developing body as a result of interacting with the environment. At present, this question is still very largely unanswered.

Controversy
in the
behavioral
sciences

Methodologically, since 1940 one new centre of philosophical debate has developed, this time in the behavioral sciences. Ever since Descartes and Hobbes, there has been sharp disagreement about the legitimacy of extending the methods and categories of physical science to the sphere of the higher, distinctively human mental processes; and, even in the 1970s, theoretical psychologists were still far from agreed in their explanations of human behaviour. Some psychologists insist that human actions are subject to laws and mechanisms of the same kind as physical processes; others deny that any direct analogy exists between rules of conduct and laws of nature. Currently, this dispute is most lively in the psychology of language. Behaviorists follow B.F. Skinner, an American psychologist, in rejecting any distinctive class of mental laws and processes, whereas cognitive psychologists and generative grammarians, led by Noam Chomsky, argue that linguistic activities are creative and rule conforming in respects that no behaviorist can explain. In sociology and anthropology, equally, the 20th century has been a period of methodological controversy. Here the unresolved conflict has to do with the significance of history in the explanation of collective human behaviour. On one side, there is, in sociology, a school of so-called structuralists or functionalists that follows another American scholar, Talcott Parsons; or, in anthropology, there are the British ethnologists A.R. Radcliffe-Brown and Bronisław Malinowski, students of primitive mentality and behaviour, who regard all of the cultural practices and social institutions that function within a given community at any time as related together systematically within an overall structure: to explain any one of those practices or institutions, they hold, it is enough to show how it connects up with all of the other contemporaneous aspects of the culture. On the other side, a more historically minded school, notably the German “critical Marxists” (such as Jürgen Habermas), emphasizes the dynamic, developing character of social structures and relationships. Here again, the methodological debate is still in progress, and its eventual outcome cannot yet be clearly foreseen.

ELEMENTS OF SCIENTIFIC ENTERPRISE

It is appropriate at this point to define the recurrent problems that have played a central part in the philosophical debate about science and the crucial elements that any adequate philosophy of science must include in its account. From the beginning, scientists themselves have been interested not merely in cataloging and describing the world of nature as they find it but in making the workings of nature intelligible with the help of compact and organized theories. Correspondingly, philosophers of science are obliged to consider not merely nature in isolation—as

a mere assemblage of empirical facts, mutely waiting to be discovered by man—but also the manner in which man himself perceives and interprets those facts when bringing them within the grasp of an intelligible theory and the respects in which the validity of the resulting theoretical ideas (or concepts) is affected by that processing of the empirical data.

Historically speaking, the problems posed by this interaction of man and nature have been complex and confused. Though philosophers of science face, even today, many of the same questions that were already being debated in classical Athens, the range and relevance of those questions has been greatly clarified in the meanwhile. For instance, when philosophers in the 17th century analyzed the nature and possible scope of a mathematical and experimental account of nature, they helped to clear the ground for Newton to develop the intellectual program and methodology of modern theoretical physics; while the subsequent philosophical debate about natural and artificial classification similarly cleared the ground for the scientific taxonomy of the Swedish systematist Carolus Linnaeus and the theory of natural selection of Charles Darwin. Methodological clarification in the philosophy of science has, in this way, repeatedly led to creative advance in science itself and so given rise, in turn, to new experience on which philosophers can draw in taking their methodological analyses further.

It is easy enough to list the chief elements that must find a place in any philosophy of science, but problems arise in mapping the relations between them.

Empirical data and their theoretical interpretation. First are the empirical elements. The task of science is to explain actual events, processes, or phenomena in nature; and no system of theoretical ideas, technical terms, and mathematical procedures—or mathematical procedures alone—qualifies as scientific unless it comes to grips with those empirical facts at some point and in some way and helps to make them more intelligible. On the one hand, the facts in question may be discovered by using observational methods—*i.e.*, by recording them as and when they occur naturally, without employing any special contrivances affecting their occurrence. This situation is, of course, the normal case in astronomy, in which the objects of study cannot be influenced or controlled. Alternatively, they may be discovered by using experimental methods—*i.e.*, by devising special equipment or apparatus with the help of which those processes or phenomena are caused to occur on demand and under specially controlled conditions. In that case, the scientist can attack scientific problems—to use Kant’s vivid metaphor—by “putting Nature to the question,” as in much of physics and fundamental biology. Either way, a philosophical difficulty at once arises about the results of the scientist’s empirical studies: for he must ask how such raw empirical facts can be sifted, stated, and described in a way that throws light on the scientist’s own theoretical problems. Do all empirical facts whatever serve as raw material for science? Or is this true only of those that have been preselected for their theoretical relevance—or even, to some extent, reshaped to ensure it? Is a scientist concerned with every particular empirical event, as such, or only with general phenomena or regularities recognizable in those events? Different schools of philosophers treat this raw material in very different ways.

Empirical
elements

In the second place, there are conceptual elements. Every science employs its own characteristic abstractions, terminology, and techniques of interpretation and explanation, which can be of very different kinds. They may be ideal types, as in gas theory and parts of sociology; conservation principles, as in dynamics and energetics; taxa, as in biological systematics; particles or constituents, as in genetics and subatomic physics; models or flow diagrams, as in econometric analysis. Such conceptual elements are the intellectual keys by which phenomena are made intelligible, and a most active philosophical debate has turned around the part they play in the interpretation of phenomena. If, for instance, the idea of particles or ultimate constituents of matter is regarded as a concept created by scientists for the purpose of their own theoretical analysis, can an independent existence then be claimed for such

Conceptual
and formal
elements

theoretical entities in the world of nature itself? Or must all such ideas be regarded as fictions or constructs for which the claim to reality goes no further than the paper on which the scientific explanations are written? Similarly, if the theoretical descriptions of nature arrived at in science are unavoidably idealized and abstract, does this imply that the necessity attaching to arguments in, say, theoretical physics is itself only an artifact, or by-product, of scientists' own procedures for interpreting phenomena? Or can one, after all, speak of natural events themselves as happening "of necessity"?

Finally, every natural science includes also formal and mathematical elements or mathematical elements alone. These may be mathematical algorithms, or procedures of calculation, like those used in computational astronomy since Babylonian days, or like the computer programs that are their 20th-century counterparts; or geometrical constructions, as in certain branches of optics; or methods of graphical analysis, such as those used in handling statistical data; or the axiomatic systems by which, from classical times on, geometry and physics have been organized into formal schemata of propositions bound together by logical relations. Philosophers in the Platonic tradition give such formal elements special consideration, viewing as authentically intelligible only those theories the content of which can be presented explicitly in formal, and preferably in mathematical, systems of propositions. Theories of this kind alone are capable—as the seminal German logician Gottlob Frege expressed it—of employing "concepts in their pure form." Thus, 20th-century philosophers of science have devoted much time and effort to the question: How far, and on what conditions, can other branches of natural science (*e.g.*, quantum mechanics or genetics) be cast in the same definitive, axiomatic form as classical mechanics and electrical theory? Or is this formal construction itself merely a human convenience, adopted to simplify the handling of the empirical data, which reveals nothing more about the underlying structure of nature itself?

Relation of
theory to
observa-
tion

Each of these three groups of elements poses problems about which philosophers of science are still in deep disagreement; and these differences of view can usefully be illustrated by indicating the various approaches adopted by members of rival schools when discussing each of the groups. At one extreme can be cited philosophers of a radically Empiricist frame of mind, who regard it as important, above all, to emphasize the empirical foundations of scientific knowledge; for them, the raw facts of experience are primary and entitled to absolute respect. On this view, general theoretical principles have authentic scientific content only when interpreted as empirical generalizations about directly grasped empirical data; and, correspondingly, abstract theoretical entities must be understood as logical constructions from more fundamental elements that can be directly identified in empirical experience. (This belief, of course, was the basis of Mach's conclusion that submicroscopic atoms were merely intellectual fictions and derived their scientific meaning entirely from the macroscopic sense experiences that they were used to explain.)

At the other extreme, philosophers of a fully Rationalist, or Cartesian, bent can be cited who reject the idea that raw empirical facts, in and of themselves, display any intelligible or law-governed relationships whatsoever—and still less any necessary ones. For them, as for Plato, the scientist's bare experience of nature is a disorganized aggregate, or flux, unless and until he is able to discover some rational structure or principles relating these disconnected facts to a larger, more intelligible whole. Rather than allow equal significance and authority to every passing occurrence, the scientist, on this view, must be highly selective in the observations to which he pays attention; indeed, the very function of a well-designed experiment is now to create phenomena that can illustrate the intelligible relationships that are the true concern of science and so deserve the status of scientifically authenticated facts.

Both of these approaches, the Empiricist and the Rationalist, emphasize valid and important points; but, in their extreme forms, they give rise to difficulties that are

probably insuperable. As to the Empiricist approach, the credentials of any scientific concept or theory certainly depend to a substantial extent on its basis in empirical experience. Indeed, much has been learned about statistics, the calculus of probabilities, and the design of scientific experiments from careful analysis of the procedures by which empirical data are actually handled, even before questions of theoretical interpretation were directly raised. Yet it is questionable whether sense impressions alone could ever serve as evidence for any scientific position, as Mach and the sense-data philosophers assumed. All genuine scientific observations, as Kant expressed it, have the form of judgments—*i.e.*, are expressed in statements answering questions formulated beforehand. It is probably an exaggeration to insist that all legitimate theoretical statements in science must be related in a strictly deductive manner to the everyday empirical observations that they are used to explain; and it is a caricature to treat the explanatory power of theoretical laws and principles, as for example in physics, as no different in kind from that of such an elementary generalization as "All robins' eggs are greenish blue."

As to the Rationalist approach, one of the chief tasks for philosophers of science is certainly to account for the rational interconnections that give scientific explanations their characteristic intelligibility. In this respect, such men as Descartes, Kant, and Hertz have deepened the philosopher's understanding of the scientific enterprise by obliging him to recognize the ways in which the intellectual organization of scientific theories rests on the scientist's own constructive activities, rather than on the specific facts. Yet, it would again be misleading to use this fact as an excuse for regarding physical theories—to echo a phrase of Einstein's—as entirely "free creations of the human mind." While the step from observations to theories does not rest on formal entailments alone, it would be an equally serious counter-exaggeration to suggest that theory construction is totally arbitrary or unconstrained by the imperative demands of the specific problems to be solved.

The outstanding task for most philosophers of science is, accordingly, to find an acceptable middle way between the Rationalist and Empiricist extremes and thus to do justice both to the empirical foundations of theories and to their internal organization. The different emphases of philosophers commonly reflect, at most, differences in their substantive preoccupations. Those who are interested (as was Mill) in possible methods for developing the human or social sciences naturally place most stress on the empirical basis of scientific knowledge. Those who are familiar (as was Whewell) with the actual outcome of theory construction in established sciences, such as physics, naturally underscore the systematic coherence and structure of scientific understanding. Those who are concerned with the nature and validity of historical understanding (as Giambattista Vico was) likewise end by giving a very different account of certainty and necessity from those (like Descartes) whose ideal of scientific knowledge is a formal, mathematical one.

If the philosopher comes to grips with the full complexity of the scientific enterprise, this approach can lead him to a more exact understanding of the varied intellectual problems of the natural and human sciences. Once it is recognized how different are the kinds of questions arising within such diverse fields as quantum electrodynamics and developmental biology, clinical neurology and historical sociology, the goal of formulating a single scientific method—with a universally applicable set of procedures and criteria for judging new theories or ideas in all fields of science—may come to appear a mirage. Yet the philosopher's legitimate insistence on generality has already helped to promote important extensions and integrations of man's scientific understanding. So again, he must now avoid taking too dogmatic a stand, either for or against complete generality, bearing in mind Kant's warning that the reason can hope to map its own proper boundaries only at the price of occasionally overstepping them.

The empirical procedures of science. Along with the three groups of elements already discussed, each phase in the scientific enterprise—empirical, formal, and con-

Science
as a
multiform
enterprise

ceptual, or interpretative—involves its own characteristic procedures. On the level of empirical observation and description, three topics may be briefly touched upon, all of which are discussed at greater length in other articles (see MEASUREMENT THEORY; CLASSIFICATION THEORY; and articles on the basic sciences).

Measurement theory

First, there are the procedures of measurement through which scientists arrive at quantitative estimates of the variables and magnitudes considered in their theories. By now, there is a well-developed body of knowledge upon which scholars are agreed about many of the techniques and precautions to be employed in practice in the measurement of empirical quantities, in the calculation of probable errors or significant deviations, and so on. About the deeper significance of measuring procedures and their outcomes, however, there are still unresolved philosophical disputes. These disagreements reflect the same differences of approach already noted. Thus, some philosophers regard any scientific theory concerned with measurable (or quantifiable) magnitudes as intrinsically superior to a qualitative (or, as they would say, an impressionistic) one, however rich and well organized the latter may be. Others, by contrast, would argue that any insistence on employing numerical measures at all costs, even in such a science as, for example, systematic biology, can only lead the investigator to misconceive the true nature of the problems involved. Again, philosophers of an extremely Empiricist or Positivist persuasion have sometimes interpreted the experimental procedures for measuring theoretical magnitudes in, for example, physics as providing implicit definitions of the associated technical terms—the so-called operational definitions—and have thus felt able to claim that the logical entailments that the scientist is seeking between observations and theories are established by linguistic fiat (see below *Status of scientific propositions and concepts or entities*).

Design of experiments

Secondly, there are statistical analytical procedures for the design of scientific experiments. The mathematical techniques employed for this purpose are, in fact, closely related to those involved in the theories of measurement, probable error, statistical significance, and others. In this area, the connection between philosophical discussions of inductive logic and the practical procedures of working scientists is at its closest. Whereas a religious scientist (Blaise Pascal), a Nonconformist minister (Thomas Bayes), and an astronomer (Pierre, marquis de Laplace), all mathematicians as well, analyzed the philosophical foundations of the modern calculus of probabilities in the 17th and 18th centuries, 20th-century mathematicians and inductive logicians have similarly explored the intellectual basis for the design and interpretation of significant experiments; and, by now, the relevant procedures form a full-fledged branch of mathematical statistics with many valuable applications, particularly in fields such as sociology and economics, in which large numbers of variables are involved.

Problems of experimental design, however, can be stated clearly and unambiguously only in situations in which questions of fundamental theoretical interpretations are not actively at issue; e.g., in experiments to determine which of two antibiotics is the more effective against a given infection or to learn whether significant correlation exists between two known physical variables. As soon as more fundamental questions of theory arise, however, the problems of experimental design go beyond the scope of any purely statistical analysis. Moreover, the same is true of computer-programming procedures: the numerical data obtained from a straightforward scientific experiment can in many cases be fed into a computer programmed to select the graph or formula in best statistical accord with the data from among those hypotheses conforming to a predetermined set of conceptual or interpretative requirements; thus, in this sense, a computer can be used to perform inductive inferences. Devising brand-new styles of conceptual or theoretical interpretation, by contrast, involves extending or modifying present explanatory procedures to satisfy novel intellectual requirements; and these tasks call for something more than formal statistical or programming techniques.

Classification theory

Finally, the initial handling of the scientist's empirical

data requires him to employ procedures of systematic classification. The nature and validity of scientific classification procedures and of the species, genera, families, and so on into which scientists divide their empirical subject matter have been the subject of a long and contentious debate. A long-standing philosophical deadlock between supporters of natural and artificial classification systems was largely broken—in zoological taxonomy, at any rate—through the success of Darwin's theory of natural selection. As Darwin showed, the species to which organic evolution gives rise are neither eternally unchanging natural entities nor mere fictions of the zoologist's arbitrary creation; considered as coherent, self-isolating populations, they have a genuine though temporary reality that is preserved by the contrary processes of variation and selection perpetuation. In some other areas of thought, however, the preliminary identification and classification of the empirical material still raises contentious philosophical questions. When the sociologist theorizes about social groups or systems in the human sciences, for instance, he has to decide what collections of men and institutions do, or do not, fall under those general headings. Can objective tests be found for identifying natural units of sociological analysis? Or, is this choice of units merely set up for the sociologist's own convenience? This uncertainty about the very subject matter of sociology is itself an obstacle to the creation of an agreed-upon body of social theory; and comparable difficulties can arise in anthropology, linguistics, and psychology as well. It is, therefore, not surprising that some critics have even questioned whether these disciplines can truly be called sciences.

The character of these continuing difficulties underscores one point of general significance about the relation of empirical evidence to scientific theories: though philosophers may find it necessary to distinguish the empirical phases, elements, and procedures of science from the theoretical ones analytically, it does not follow that they can be kept wholly separate in actual practice. Satisfactory measuring procedures, experimental designs, and systematic classification principles are, no doubt, necessary preconditions for effective theorizing; but they themselves are subject, in turn, to revision and refinement in the light of subsequent theoretical considerations. In arriving at his dynamical theories, for example, Newton had to begin by relying on older commonsensical notions of effort, weight, and amount of movement; but he soon replaced these by the more exact, theoretically defined concepts of force, mass, and momentum, and this change reacted back onto the empirical procedures of physics also. Likewise in other fields of science, the decision as to whether or not the outcome of any empirical procedure is scientifically relevant or significant soon ceases to be a purely empirical question, as theoretical changes react back onto those empirical procedures and compel the scientist to modify his manner of collecting and describing the supposedly raw data of science. In this way, the empirical evidence by which his scientific conclusions are justified rapidly loses its pure and theoretically neutral character.

The formal structures of science. In this section and the next, those aspects of the scientific enterprise will be considered that have dominated recent debate in the philosophy of science, viz., the formal structures of scientific theory and the processes of conceptual change. It will soon be clear that the philosophical problems to which these two aspects, respectively, give rise are correlative and complementary—the one being static, the other being dynamic.

Since 1920, most analytical philosophers of science have explicitly based their program on a presupposition inherited from Descartes and Plato, viz., that the intellectual content of any natural science can be expressed in a formal propositional system, having a definite, essential logical structure—what a leading American philosopher of science, Ernest Nagel, concisely called “the structure of science” in his book of that title (1961). One immediate inspiration of this program was the work of David Hilbert, a late 19th-century mathematician. To make the methods of mathematical proof more explicit and more perspicuous and thus more rigorous, Hilbert employed the

Ideal of a formalized science

techniques of formalization, a reduction to relations while disregarding the nature of the relata, and axiomatization, a tracing of entailments back to accepted axioms.

The same techniques were taken over into the philosophy of mathematics by a pioneer German logician, Gottlob Frege, and into symbolic logic by Bertrand Russell and his collaborator Alfred North Whitehead; and, from 1920 on, the Viennese Positivists and their successors attempted to employ them in the philosophy of science also, hoping to demonstrate the validity of formal patterns of scientific inference by the straightforward extension of methods already familiar in deductive logic.

According to the resulting program, the primary task for the philosophy of science was to repeat in quite general terms the kind of analysis by which, in the science of mechanics, Heinrich Hertz, the formulator of electromagnetic wave theory, had already sorted out the formal aspects of science from its empirical aspects. The program was founded on the expectation that it would be possible, first, to demonstrate the existence of formal structures that were essential to any science, properly so-called, and second, to identify the nature of scientific laws, principles, hypotheses, and observations by their characteristic logical functions. Once this had been done, rigorous formal definitions could then be given of validity, probability, degree of confirmation, and all of the other evidential relations involved in the judgment of scientific arguments.

The actual working out of this program has involved complex and highly technical investigations, in the course of which great ingenuity has been displayed—as, for instance, by an outstanding philosophical semanticist and analyst, Rudolf Carnap, in his system of inductive logic, for the criticism of arguments in support of empirical generalizations, and by Hans Reichenbach, an eminent German-American Positivist, in his analysis of probabilistic arguments. So far, however, the program has yielded substantial results only as applied to arguments expressed in an idealized formal symbolism modelled on the lower functional calculus of mathematical logic. By contrast, little has been done to show how one might extend the resulting formal procedures to arguments expressed in the practical terminologies of working science. That extension, in fact, raises difficulties and ambiguities that are so far unresolved and may prove unresolvable. The goal of a purely formal analysis of scientific inference has generated difficulties, for instance, by tempting logicians to play down important differences between mere descriptive generalizations about natural phenomena and the explanatory theories (laws, principles, etc.) that a scientist develops to make those phenomena intelligible; and succumbing to this temptation creates problems both within inductive logic and in its applications.

One distinguished supporter of this program, Carl Hempel, originally a member of the Berlin group (allied with the Vienna Circle), has discussed what he calls the theoretician's dilemma: if the task of explaining natural phenomena requires a proof that the character of those phenomena is formally entailed by the conditions of their occurrence, taken together with certain straightforward generalizations based on previous empirical experience, and if those empirical generalizations include references to hypothetical entities, then the theorist is faced with an invidious choice: for, in that case, either his generalizations (his laws) do in fact provide a logical link between the conditions of the phenomena and their actual occurrence and the assumption of hypothetical entities is formally superfluous; or else they do not succeed in doing so, and that assumption will not have strictly explained the phenomena. Clearly, this dilemma can be evaded only by challenging the identification of laws with generalizations and insisting that any appeal to laws of nature always involves the scientist in reinterpreting natural phenomena, not in merely generalizing about them.

Looking beyond the internal structure of inductive logic, the dubious equation of scientific laws with empirical generalizations has also been criticized on the ground that it treats the content of those laws as matters of happenstance, far more accidental or contingent than those expressed in any genuine law of nature. In the opposing view, the

explanatory force of, say, the physicist's law of inertia is totally different from that of such a generalizing statement as "All swans are white"; and one can learn nothing about the validity of actual physical arguments unless his philosophical analysis respects that crucial difference. It has not proved easy, however, to analyze the formal structure of the sciences in any less abstract manner than that of the Viennese Positivists or to give a true representation of the working language and arguments of science. In his *Essay on Metaphysics* (1940), R.G. Collingwood, a British philosopher and historian, made one striking attempt, in which the formal structure of intellectual systems was explained in terms not of direct entailments between more or less universal propositions but rather of mutual presuppositions between more or less general concepts. In this account, the principle of inertia was not the most universally true assertion in dynamics but was, rather, the most generally applicable presupposition, or principle of interpretation. Such an account has the merit of explaining why, within a particular science, certain formal patterns of argument carry the apparent necessity that they do; but at the same time it lays itself open to the charge of yielding too much to relativism and so of destroying the objectivity of scientific knowledge by giving the impression that the conceptual structures of science are imposed on phenomena by the arbitrary choice of the scientific theorist himself.

The late 1960s, accordingly, saw a renewal of questioning about the original assumption, viz., that the entire intellectual content of a science can be captured in a propositional or presuppositional system. Certain of the doubts about this thesis revive criticisms put forward at the turn of the century by a U.S. Pragmatist, Charles Sanders Peirce, who argued that the logical status of the theoretical terms and statements in a science is—in the nature of the case—subject to historical change as the conceptual organization of the science develops. (This same insight has been explored more recently by a U.S. logician, Willard Quine, who rejects any attempt to classify statements within scientific theories using the traditional hard-and-fast dichotomies—contingent—necessary and synthetic—analytic—as fallacious and dogmatic.) Other criticisms of the thesis go deeper. By focussing his philosophical attention exclusively on the static formal structure of propositional systems and, so, on the intellectual content of the sciences at particular temporal cross sections in their development—they point out—the philosopher is distracted from the complementary questions about the manner in which the conceptual organization of a science changes and, so, from the traditional claims of natural science to be a rational as well as a logical enterprise. At this point in the debate, therefore, the spotlight shifts away from the static problem of analyzing a science in static logical terms to the historical problem of analyzing the dynamic processes of intellectual and conceptual change.

Conceptual change and the development of science. The problem of conceptual change has recently come back to the fore. The crucial question it poses is: "What is a concept?" In the heyday of Logical Empiricism, that question had largely been disregarded. Following the example of Frege, the Viennese Positivists had condemned any tendency to regard the philosophy of science as concerned with scientific thinking—which was in their view a matter for psychologists—and had restricted themselves to the formal analysis of scientific arguments. This preoccupation with logic was also reflected in their view of concepts. To interpret a concept such as force as referring either to a feeling of effort or to a mental image could lead, they argued, only to confusion. Instead, the philosopher must equate concepts with the terms and variables appearing in the propositional systems of science and define them, in part by reference to their roles in the formal structures of those propositional systems—thus fixing their systematic import—and in part by reference to the specific events and phenomena they are used to explain—thus fixing their empirical import. In the 1920s and 1930s, accordingly, all substantive philosophical questions about the concepts of science were dealt with summarily: they were simply translated into logical or linguistic questions about the

generaliza-
tions
versus
laws

Styles of
explanatory
procedure

formal roles and empirical references of technical terms and mathematical variables.

Once the philosophy of science is approached more historically, however, those substantive questions must be faced afresh in their own right. Rival scientific theories will now be distinguished not merely as so many alternative formal systems, based on different primitive terms and axioms, but also as alternative ways of organizing the knowledge of nature, based on different explanatory techniques and modes of representation. The distinctive features of different scientific concepts will lie, as a result, not in their respective formal roles and empirical references but in the styles of explanatory procedure involved in their application. Those procedures may be of many different kinds: *e.g.*, physical conservation calculations, optical-ray diagrams, functional analyses, taxonomic classifications, historico-evolutionary reconstructions, or dynamical axiom systems. Correspondingly, they provide occasions for employing mathematical formulas, or intuitively intelligible models, or genealogical trees, or other styles of representation. In each case, however, the philosopher can describe the conceptual organization of the resulting explanations in terms neither of intuitive models nor of mathematical formulas and variables taken alone: what he must now consider is the entire pattern of theoretical interpretation—models, mathematics, and all.

Viewed from this alternative standpoint, the philosophy of science will begin by identifying the different styles of explanation characteristic of different sciences or of different stages in a given science and will recognize how those differences in explanatory style reflect the characteristic problems of different scientific fields and periods. So considered, empirical generalizations and descriptive classifications will serve to organize the empirical data of science in a preliminary way; but serious theoretical interpretation can begin only after that point. The central philosophical task now is to analyze, clearly and explicitly, (1) the standards by appeal to which scientists have to decide whether or not some interpretation is legitimate, justified, and conclusively established and (2) the considerations that justify giving up one currently accepted interpretation in favour of an alternative, novel one.

The first of these questions is one that the Logical Empiricists set out to answer in their own manner. They treated the empirical data and the theoretical principles of science as being connected by purely logical relations and attempted to define the required standards in terms of a formal theory of confirmation, corroboration, or falsification. The second question is one that they never seriously tackled. Instead, they assumed that one could, first, work out a quantitative index of acceptability for individual theories taken separately and, afterward, use this as a scale for measuring and comparing the merits of rival theoretical interpretations. By now, however, it is evident that, when biophysicists, say, abandon one theoretical approach in favour of another—as being more fruitful from the standpoint of biophysics—the considerations that lead them to do so are by no means analyzable in formal terms alone. On the contrary, the ability of a biochemist, say, to judge whether or not such a change in approach will effectively help to solve his theoretical problems is one of the most severe assessments of his substantive grasp of what biochemistry is about.

Reinterpretation of
concepts
and
principles

In this way, the shift of attention from the propositions of science to its concepts is making philosophers more aware of the extent to which theoretical understanding involves the reinterpretation of empirical results, not merely their formal transformation. Similarly, the problem of conceptual change is raising questions about the processes by which theoretical interpretations succeed one another and about the procedures of conceptual judgment that are applied in the rational development of a science. These questions are currently under active discussion, and several lines of attack are being considered, none of which has finally established itself.

At one extreme, there are some who still regard theoretical concepts and principles as organized into compact, logical systems and who attempt to define the alternative standpoints of different sciences as the consequences

of different basic premises or presuppositions. Having adopted this systematic approach, the investigator then discovers that conceptual change at a fundamental level finds adequate scope only through the replacement of one complete formal system by another, distinct and separate successor system. As a result, fundamental theoretical change is, in this view, intelligible only as the outcome of thoroughgoing intellectual revolutions, in which one entire theoretical system—axioms, principles, criteria of relevance, standards of judgment, and all—is swept aside in favour of another.

Alternatively, there are those who distinguish two different kinds of fundamental principles in a science—marking off the basic theoretical assertions such as “Matter consists of atoms combining into molecules” from its methodological maxims and standards of judgment, such as “All physical phenomena are to be explained in mechanical terms”—and who recognize fundamental conceptual changes in the science as legitimate, just so long as they respect the methodological maxims that are definitive of the science in question. In this second view, conceptual changes of any depth in the intellectual substance of a science will continue to be intelligible, provided only that the new views are still governed by the established program and framework concepts of the science in question. There will then be revolutions in science only when some entire intellectual approach is discredited—*e.g.*, that of 16th- and 17th-century iatrochemistry, which studied chemistry as a means of treating disease—or when some entirely new science is created, with its own complete system of interpretation—*e.g.*, molecular biology.

At the other extreme, there are some who doubt whether any sharp distinction can be drawn between substantive theoretical assertions and maxims of methodological procedure and who argue that all aspects of a natural science are alike open to historical reconsideration and modification. The more specific the theoretical doctrines and concepts being considered, the more risky they will be, and the more readily they will be modified or abandoned or both. From this third point of view, however, it is questionable whether any change, however drastic—even the hybridization of crystallography, viral genetics, and biochemistry, which led to the inauguration of molecular biology—is ever as discontinuous or revolutionary as the two former views imply. Instead, the attempt may be made to account for the procedures and processes involved in the historical development of scientific concepts by using the same general form of theory on every level—explaining innovation as requiring a selective choice between intellectual variants of different kinds; and, in this way, the theory of conceptual development can be brought into line with other historically based theories of natural and cultural change.

Whichever alternative is adopted, one point must be kept in mind: the moment that problems about the changing theoretical organization of science begin to be treated in an authentically developmental manner, philosophical inquiries are given a quite new direction. This step compels one to view all questions about the logical structure and propositional systems of science against a broader historical background. In this new context the natural sciences are seen not as static formal structures but as rational enterprises characterized by certain typical intellectual procedures or movements. These basic procedures of intellectual development in science are the topic to which attention is directed in the next section.

Developmental
nature
of
science

MOVEMENTS OF SCIENTIFIC THOUGHT

Discovery and rationality. In analyzing the natural sciences for philosophical purposes as historically developing enterprises, the question “What is it that makes the sciences rational?” is raised in a new form: do the intellectual procedures that scientists actually employ to investigate and explain natural phenomena have definite and objective intellectual merits that make their adoption rationally prudent, wise, and obligatory? In answering this question, philosophical opinion has tended to polarize in recent years toward two extreme positions: on the one hand, a

formalist or positivist extreme, on the other, a romantic or irrationalist one.

Given their mathematical inspiration and preoccupations, both the Viennese Empiricists and their successors in Britain and the United States have interpreted the rationality of scientific procedures as depending solely on the formal validity, or logicity, of scientific arguments. In their view, questions of rationality can be raised about the scientist's work only at the final stage in his inquiries—*i.e.*, when he sets out, as the final outcome of his work, the explicit explanatory arguments in support of his novel theories or interpretations—only then, they declare, will there be anything about science that is capable of being criticized in logical or philosophical terms.

Formalist
versus
irrational-
ist

It is therefore a commonplace of recent Empiricist analysis in the philosophy of science that one must distinguish at the very outset between discovery and justification. The term discovery refers to all the stages in a scientific inquiry preceding the formulation of the new explanatory arguments that are its final outcome. The term justification refers, by contrast, to the demonstration that the formal validity or explanatory power of those arguments justifies the scientist in accepting their conclusions as scientifically validated or established. In this view, the rational concerns of the philosopher of science are restricted solely to this final phase of justification. All questions about the earlier stages—*i.e.*, about discovery—are matters of mere psychology, not of serious philosophy. As one widely accepted epigram expresses it, "There is no logic of discovery"; and this distinction—given the equation of rationality within logicity—seemingly invalidates all questions about the rationality of the preliminary steps by which a scientist arrives at a discovery.

At the opposite extreme, there are those, such as Michael Polanyi, a Hungarian-born scientist and philosopher, and Arthur Koestler, a novelist and journalist, who emphasize the parts played by intuition, guesswork, and chance in scientific investigation, citing these as evidence that theoretical achievement calls into play an intellectual creativity superior to mere rationality. According to this anti-Positivist argument, the modern scientist is a sleepwalker whose creative insight guides him to intellectual destinations that he could never clearly see or state beforehand: any excessive preoccupation with the rationality of scientific procedures, by contrast, springs from a pedestrian desire to clip the wings of imagination and to confine the scientist to stereotyped procedures, thus destroying the creative fertility of science. Rather than subjecting scientific intuition to the barren intellectual accountancy of the Positivists, the conclusion runs, one should embrace a romantic anti-rationalism.

In each of these extreme cases, however, the initial equation of rationality with logicity demands closer examination. Certainly, the activity of investigation and discovery can be examined with advantage from a psychological point of view as it has been, in fact, by a French mathematician, Jacques Hadamard, as well as from a philosophical point of view. Yet the possibility of such psychological inquiries does not obviously prove, entirely by itself, that procedures of intellectual investigation in science and mathematics are essentially nonrational. Chance, for instance, may help to bring relevant material to a scientist's attention. But chance—as has often been remarked—favours the prepared mind, and it is fair to ask how far the scientist acted rationally, after all, in picking out the items he did as being relevant to his particular problems. Similarly, in the case of creative intuition and the rest: once again, the man with the best trained mind can afford to give the freest rein to his intellectual imagination because he will be best qualified to appraise the rational context of his current problems and to recognize significant clues, promising new lines of analysis, or possible answers to his questions, as they come to mind.

Problematics
of
scientific
inquiry

Neither denigrating the early phases of scientific inquiry as of merely psychological interest nor overpraising them as exercises of creative imagination disposes therefore of the philosophical problem that is here involved, *viz.*, that of showing what makes certain procedures of investigation more rational than others. To find a middle way between

formalism and irrationalism, it is necessary to look more closely at the nature of the problems of scientific inquiry. If the improvement of scientific concepts and theories depends on the development of more powerful explanatory procedures, the philosophical analysis of discovery then requires that one show what is essentially involved in devising such procedures, testing them out, and determining the range of their application. This problem must be dealt with, furthermore, not by a formal analysis of the resulting arguments alone but first and foremost by establishing what tasks any novel explanatory procedure in science can be required to perform, what demands its performance can properly be asked to satisfy, and so what intellectual goals a scientist is expected to be aiming at in all the phases of his investigations. Posed in these alternative terms, the problem of scientific rationality becomes a problem of showing how conceptual changes in science result in the introduction of novel ideas, which are—in a phrase coined by Mach as early as 1910—"better adapted, both to the facts and to one another." It is rational for older scientific theories to be displaced by newer ones that are functionally superior; and the task for philosophers of science is to demonstrate explicitly in what such functional adaptedness consists.

At the present time, many younger philosophers of science are actively analyzing the nature of the problems of science in these terms. Significantly, most of these men have had their own primary training within the natural sciences proper rather than in formal logic or pure mathematics, for the task requires a much more detailed analysis of the processes of intellectual innovation than has been customary hitherto. In place of the simple dichotomy between discovery and justification, for instance, it calls for a subdivision of the innovation process into a more complex sequence of distinct stages; and at each stage both rational and causal considerations are relevant. Thus, at the initial stage in any inquiry, a scientist must decide which among all of the philosophically conceivable variants from the current repertory of explanatory methods are to be taken seriously at all; which, that is, are genuine possibilities. This preliminary sorting of initially plausible from implausible innovations must be dealt with—and dealt with in the most rational manner possible—long before any question of justification arises.

This initial sorting procedure is one about which scientists themselves also speak cogently and eloquently. Far from deciding what novel suggestions are genuinely possible or plausible on a purely psychological basis or by the exercise of some mysterious, nonrational intuition, scientists will commonly explain their reasons for accepting one set of conceptual variants rather than another as deserving serious consideration. At the same time, such microanalyses of scientific innovation must certainly leave room for causal as well as rational questions. During certain periods in the historical development of science, for instance, scientists have notoriously disregarded novel possibilities that later turned out to hold a key to the solution of crucial theoretical difficulties. Looking back at such periods, it is possible to reconstruct with care the rational considerations that might have been advanced at the time to explain this neglect; but even so, one is occasionally forced to conclude that the men involved were prejudiced against those possibilities by factors external to their sciences; *e.g.*, by influences originating in the wider social, cultural, or political framework of their time. Thus, Newton was particularly afraid that his theory of material particles might be accused of supporting Epicureanism, whereas Darwin concealed his private speculations about the cerebral basis of mental activities because of public objections to Materialism.

In analyzing the microstructure of scientific problem solving, it is necessary, accordingly, to resist any temptation to generalize prematurely. Scientific investigators working in different fields, or at different times, apparently face theoretical difficulties of quite different kinds. One must therefore begin by studying the specific needs and tasks of each particular science, at one or another stage in its evolution, separately—seeking to recognize, in each individual case, the particular intellectual demands to be met by any new

Diverse
approaches
in different
fields

concept or theory if it is to be successful. Eventually, the accumulated results of specific microanalyses may bring the investigator to a point at which he can again afford to generalize about all of the assorted theoretical problems confronting, say, physics and about the broader intellectual demands to be met by successful theoretical changes in a variety of scientific situations. At the present stage, however, though philosophers of science still cannot afford to beg these questions, they are compelled to conduct their analyses in a more piecemeal way—building up their picture of scientific innovation and discovery by considering a wide range of sample cases and working their way only gradually toward a more comprehensive account of the problematics of the scientific enterprise.

Validation and justification. If this situation is true of the earlier stages in discovery, it is no less true in the case of justification itself. Here again, from 1920 on, the debate in the philosophy of science focussed predominantly on two sharply opposed positions, both of which appear in retrospect to be excessively narrow. On the one hand, Empiricist philosophers argued for a view that made prediction the crucial test of scientific validity; on the other hand, philosophers of a more Rationalist temperament saw coherence and scope as the crucial requirements.

For Empiricists, the fundamental presupposition is that the facts justifying changes in scientific ideas are both intellectually prior to the theories that are, in due course, developed to explain them and also capable of being recognized independently and in advance of all theory construction. Given this presupposition, they regard prediction and validation as the crucial and distinctive steps in scientific procedure, arguing that, to establish the validity of any general scientific proposition, it is necessary to show that the theoretical generalization of which the validity is in question entails particular factual statements that are borne out by independent empirical observations. This validation process then involves two essential steps: (1) the formal step of inferring novel predictions from the theory and (2) the empirical step of comparing those predictions with the facts and so confirming the theory or proving it false.

On closer inspection, both steps in the received Empiricist procedure face serious difficulties, and these have lent strength—by reaction—to the alternative, constructivist position. As to step (1), there appears to be no objection to the idea of deducing particular factual predictions directly from theoretical hypotheses, so long as one accepts the Empiricist interpretation of laws of nature as universal empirical assertions on the same logical level as “All polar bears are white.” Once that interpretation is questioned, however, it is less clear that direct deductive inferences from theory to fact are always practicable. On the contrary, if theoretical laws and purely empirical reports are, in the nature of the case, framed in terms of distinct and diverse sets of concepts, no general procedure can be available for passing deductively from one to the other. For the theory will then be a reinterpretation of the facts, not a mere generalization from them. Similarly, with step (2), an empirical confrontation of theories and facts gives rise to a more complex range of choices than those implied by the Empiricist account. When faced with discrepancies between prediction and observation, scientists certainly have to modify their theoretical explanations; but this modification can normally be made in any of several alternative ways. For instance, the theoretical relevance of a particular observation may be questioned; or some alternative theoretical interpretation may be put forward; or further refinements may be made within the structure of the theory concerned—and all of this can be done before any question arises of a direct and necessary conflict between the discordant observation and the general theoretical doctrine under investigation.

The rival, constructivist position derives its attractions from such objections as these. This position follows lines of thought already sketched by the French theoretical physicist Pierre Duhem at the turn of the century. On this account, the essential test of a science is that it should provide coherent, consistent, and wide-ranging theoretical organizations. Empirical facts will then be recognized as

scientifically relevant only to the extent that they exemplify these interpretations and make them more discriminating. Thus, no single factual observation can ever serve as a logically crucial experiment and confirm or refute any one specific doctrine conclusively, taken apart from a whole complex of theory and interpretation. What is at risk in any experiment or observation, therefore, is the whole body of the theory, together with the current conventions governing its empirical application; and the more comprehensive a theory is, the more are scientists free to vary the details of their specific applications of it, rather than to accept any single counter-example as a challenge to its general validity.

If these two philosophical approaches are reconsidered today against a broader and more historical background, however, they no longer appear to be either as exhaustive or as contradictory as they did in the 1920s and 1930s. By choosing suitable illustrations, of course, one can make each position highly attractive and plausible since, in one situation or another, the rational considerations that carry genuine weight in the actual justification of novel scientific theories include both predictive success and conceptual coherence. But the “Book of Nature,” as Galileo called it, is like Holy Scripture: it offers texts to suit all occasions and purposes. And, on second thought, it can be argued that both Empiricist and constructivist philosophers oversimplify the justification process in science and the criteria by which scientists judge the validity of novel concepts and theories. Far from there being any single or simple test of validity, the question whether predictive success or coherence, simplicity, historical authenticity, or mechanical intelligibility is the key consideration—and in what sense of each ambiguous phrase—must be considered afresh from case to case, with an eye to the specific demands of each new scientific problem situation.

Within the historically developing enterprise of science, intellectual problems arise of many different types, depending both upon the kinds of subject matter under investigation and upon the stage of development of the science concerned. In one science and at one stage, particular weight may attach to a single unexpectedly successful prediction: as when the wave theory of light led to the totally unexpected discovery that a perfectly circular obstacle placed in front of a point source of light produces a circular shadow having a bright spot at its centre. In another science or at another time, however, it may be neither practicable nor relevant to infer such specific predictions, and new theories and concepts may be validated by considerations of quite other kinds. Even within a single science such as physics, indeed, scientists are not faced at every stage by problems and judgments of a single, uniform type. Instead, the historical evolution of physics—down the centuries from Nicole Oresme, Galileo, and Newton to Maxwell, Rutherford, and Heisenberg—has generated an entire genealogy of varied problems; and the considerations bearing on the theoretical difficulties facing physicists at different stages have themselves changed, quite legitimately, along with the substantive concepts and theories of the science. So, within the more complex framework of a developing rational enterprise, the philosopher’s task is no longer to impose any single or simple criterion of intellectual choice upon scientific judgments of all kinds. Rather, his task is to recognize how the rational considerations and criteria of validity relevant to particular judgments vary with the theoretical problem situations that provide their historical contexts.

Unification, pluralism, and reductionism. As one notable illustration of the tug-of-war between logical and pragmatic issues in the philosophy of science, the “unity of science” movement may be cited. Under the vigorous leadership of Otto Neurath, a polymath sociologist and philosopher, this movement represented the high point in the ambitions of Viennese Positivism between World Wars I and II; for the general philosophical aims that motivated the search for a unified science are in striking contrast with the specific problem-solving considerations that lead working physicists to unify or integrate their theoretical concepts and explanatory procedures in actual scientific practice.

Complementarity of the modes of justification

The unity of science philosophy

Empiricist versus constructivist positions

Aside from the primary test of predictive success, the Positivists of the Vienna Circle also did allow—on their own terms—for the further theoretical virtues of coherence and comprehensiveness. Their logico-mathematical approach to the propositional structure of scientific theories, however, led them to interpret this demand for coherent and comprehensive theories in a formal sense. On their interpretation, a totally unified body of scientific ideas would be a comprehensive, quasi-Euclidean system of scientific theorems, based on a single set of general axioms, postulates, and primitive propositions and applicable to natural phenomena of all kinds. Given sufficiently all-embracing empirical generalizations as the starting points of such a unified science, it would then be possible, in their view, to deduce particular statements about all the phenomena covered by the varied special sciences unified within its axiomatic scope. Taking the symbolic logic of Russell and Whitehead as their formal core, philosophical advocates of the unity of science then set out to construct, on a single axiomatic pattern, a fully comprehensive account of nature capable of explaining (*i.e.*, entailing) all natural phenomena whatsoever.

At first glance, this ambition seemed laudable and legitimate, but once again the Empiricist program subsequently encountered unforeseen entanglements. The reasons for this situation were not merely the discovery that the theoretical ideas employed within different branches of a science (*e.g.*, of mathematical physics) are more resistant to conceptual integration than had originally been hoped (the task of constructing a self-consistent relativistic theory of quantum electrodynamics, for instance, is one that still defeats the physicists); but, what is worse, it has now become apparent that several well-founded and properly respected branches of scientific theory do not lend themselves to exposition in a formal mathematical manner at all. Any satisfactory theory of organic evolution, for instance, has an irreducibly historical dimension; and there is no possibility of putting historical zoology on the sort of predictive basis that Empiricists have demanded, still less of incorporating it into Neurath's larger unified axiom system. Faced with this particular example, indeed, one distinguished Empiricist philosopher, Carl Hempel, has drawn a somewhat extreme conclusion, *viz.*, that the theory of natural selection is not really an explanation of organic evolution at all—not even a bad one—but is merely an elaborate redescription of the historical episodes concerned. Yet this is simply a roundabout way of conceding that neither the historical problems nor the theoretical ambitions of evolutionary zoologists conform to the quasi-mathematical pattern that the Logical Empiricists have set out to impose on all of the natural sciences alike in the interests of a longer term axiomatic unification.

If, on the other hand, the demand for integration or unification is considered as a practical problem of methodology, it will then be found that the scientists are facing problems of a different and more pragmatic kind. The science of physiology poses an interesting example because, within this field, the problem of reductionism—*i.e.*, of whether all phenomena whatsoever can be reduced to physico-chemical terms alone—has repeatedly drawn active debate. Since the time of Antoine Lavoisier, who first explained correctly the process of combustion—*i.e.*, since the late 18th century and even before—there has been a methodological division of opinion, involving, on the one hand, those chemists and physiologists who dreamed of equating physiological functions with chemical reactions and planned their program for biochemistry around that ambition and, on the other hand, those clinical scientists and functionally minded physiologists who questioned the legitimacy of this so-called physicalist program and insisted that physiological phenomena displayed certain features or aspects inexplicable in physio-chemical terms alone. The scientific issues in debate in this case have never been concerned with formal matters of axiomatization and logical integration alone: once again, they have involved substantive questions of interpretation. Correspondingly, the provisional resolution of this dispute, accomplished by Claude Bernard in the mid-19th century, was not arrived at by constructing a single, unified axiom

system of biochemistry-cum-physiology. Rather, Bernard distinguished the proper questions and concerns of the two sciences and demonstrated the substantive character—and limits—of their mutual relevance.

Regarded as specific, localizable processes within the main organs of the body, he argued, all physiological phenomena do, indeed, come within the scope of the same general physico-chemical laws and concepts as govern similar processes in inorganic systems. Within the special micro-environments of the body, however, those same general types of phenomena serve certain unique physiological functions, having no inorganic counterparts; and, to this extent, special problems and questions arise within physiology that cannot be exhaustively translated into the language of inorganic physics and chemistry. Though biochemistry and physiology in no sense conflict, there accordingly remains an essential plurality in the explanatory aims of the two sciences; and this plurality gives rise, in turn, to a corresponding plurality of methods and concepts.

Yet even this example does not yield conclusions from which one can safely generalize. Though in certain respects the explanatory aims of physiology and biochemistry will, most probably, always be distinct and separate, in other cases matters have gone the other way. When, in 1873, the Scottish physicist James Clerk Maxwell, for instance, integrated the previously independent sciences of electricity, magnetism, and optics into the unified physics of electromagnetism, there was no comparable division of opinion and no such methodological peace treaty was needed. In this case it remained possible, after Maxwell's work as before, to distinguish between straightforwardly electrical, magnetic, and optical phenomena on the empirical level; but on a more general, theoretical level such distinctions lost their earlier significance, and it ceased to be necessary to keep the problems, methods, and explanatory categories of the three earlier sciences separated.

To sum up: in the methodological drive toward the unification of the sciences, as in the earlier phases of discovery and validation, the intellectual temptation to generalize prematurely exposes the philosopher to certain real dangers. In practice, the case for unifying the theories and concepts of two or more sciences has to be considered afresh in every instance, and it can rarely be decided in advance whether or not such a unification will achieve anything useful for the sciences. Instead, one has to analyze the practical demands of the current problems in the different fields and see how far those requirements can be met by developing a unified explanatory treatment for all of the special sciences in question. The integration of theoretical concepts achieved in the process will not consist solely in the formal running together of different propositional systems: more typically, it will require the development of a whole new pattern of theoretical interpretation. And, though it may be possible, in certain cases, to expound the resulting theory in axiomatic form, it must be established, in each case separately, whether or not this can be done. In this sense, conceptual and methodological unification represents a genuine movement in the development of scientific thought; but the logical form of the unified science towards which the philosopher is working is not something that he can lay down definitively before the event.

PHILOSOPHICAL STATUS OF SCIENTIFIC THEORY

Status of scientific propositions and concepts or entities. The section of this article entitled *Conceptualization and methodology of science* examined, first, the raw material (or elements) with which scientists have to work in developing their theories about the operations of the natural world and, second, the intellectual steps (or movements) by which they arrive at a scientific understanding of nature. By way of summary, it is appropriate to consider finally the main points of view about the intellectual status of the scientific concepts and doctrines embodying the understanding of nature that have emerged from the philosophical debate about science. Beginning with the epistemic status of theoretical propositions in science, it is well to consider the different claims that are made about the objectivity of their applications or their truth or both.

Limited
scope of
unification

Unifica-
tion in
scientific
praxis:
reduction-
ism

Then, turning to the ontological status of the scientific concepts or entities, it is likewise necessary to consider the claims that are made about the objectivity of their reference or of their meaning or both. In either case, the purpose of a philosophical critique of science is to establish just how far the content and reference of scientific knowledge can be regarded as a true report about the actual structure and operations of nature and just how far they represent, on the contrary, intellectual constructs or artifacts in terms of which men have chanced, chosen, or found it desirable to organize their thoughts about the structure and operations of nature.

Epistemic
aspects

Starting with the epistemic status of scientific theories, three main views can be distinguished: At one extreme is a strict Realist position, which underscores the factual basis of all scientific knowledge and emphasizes the logical contingency that this basis implies for all substantive propositions in science. In this view, all but the most purely formal statements in science make assertions about how the world of nature is constituted and operates in fact—as contrasted with all of those alternative states of affairs that are clearly intelligible and so possible but which turn out not to be true of the actual world. Seen from this Realist standpoint, every proposition in science, from the most particular observational report to the most general theoretical principle, simply reports a more or less comprehensive empirical set of facts about nature and aspires to be an accurate, objective mirror of the more or less universal facts about which it speaks.

At the opposite extreme, there is a strict conventionalist position, which underscores the constructive role of the scientist's own theory articulation and emphasizes the logical necessity that is thereby built into the resulting conceptual structure. In this view, all but the most purely observational statements in science reflect the patterns by which the scientist shapes his conceptual picture of the world of nature—the patterns in terms of which all states of affairs clearly conceivable on the basis of current ideas have necessarily to be formulated. Seen from this conventionalist standpoint, theoretical thermodynamics, say, determines the character of all possible worlds consistent with the principles of energy conservation and entropy (or randomness) increase: a world to which thermodynamics is not applicable will then be not so much factually false as inconceivable in present terms.

Finally, a wide range of intermediate views seeks to evade the central opposition between Realists and conventionalists. One representative view of this kind, first made popular by Mach toward the end of the 19th century, invoked Kant's attack on things-in-themselves, viewing the attack as providing grounds for dismissing all debates about reality and objectivity as inescapably barren and empty. In its most developed form, this so-called operationalist position encourages the philosopher to regard theoretical propositions in science as meaningful only insofar as scientific practice includes specific operations—either manual measuring operations, or computational pencil-and-paper operations—in terms of which those propositions are given operational meaning. Nothing is then to be read into scientific knowledge beyond its operational meaning; in particular, scientists are not to be understood as claiming or disclaiming anything about the reality or conventionality of the states of affairs that they report. The idea of nature as a thing-in-itself is thus eliminated, as being an intellectual superstition and an obstacle to better scientific understanding, which survives from an earlier metaphysical era.

Ontological
aspects

Three main views should here be distinguished. The central question is, now, whether the nouns and noun phrases used as technical terms in the theoretical propositions of science rely for meaning on any claim that they refer to objective, external entities; and current approaches to this question parallel existing views about the epistemological issues, viz., whether the propositions themselves rely for their truth on a claim to be mirroring or reporting objective, external facts. Here, too, the Realist interprets all of the chief technical terms of scientific theory as the names of objective entities existing in nature independently of all human theories and interpretations. In this view, entropy,

say—a measure of the increase in randomness that every total system undergoes—is a genuine, objective magnitude that has, at all times, played a crucial part in the operations of nature even though physicists have only recently had the wit to discover it; and it just happens, correspondingly, to be the case—in those parts of the cosmos that can be observed—that the total entropy of an isolated system nowhere decreases.

The instrumentalist, for his part, regards all theoretical notions such as entropy as intellectual fictions or artifacts created by the scientist's own theory construction and quite distinct from the natural world of objects, systems, and phenomena that scientific theories have to explain. No doubt, scientific theory and the external reality of nature do come into contact on the everyday or empirical level of tables and chairs, rocks and flowers. Given the intellectual tasks of scientific theorizing, however, the resulting concepts are essentially abstract; and any grasping after real entities, as the objective external reference of the theoretical terms, reflects a plain misunderstanding of this theoretical enterprise.

Meanwhile, the phenomenalist repeats, in the case of the technical terms of science, the same agnostic criticism as that offered by the operationalist in the case of its theoretical propositions. In this view, it is simply a meaningless waste of time for scientists to debate the existence of enduring theoretical entities, regarded as external, objective things-in-themselves; just as it is similarly wasteful for them to interpret scientific theories as making, or denying, similar claims about the existence of objective, external states of affairs. Instead, the terms and concepts of science are all to be understood as the product of so many logical, or semantic, operations or constructions, and questions about their real existence are to be swept aside as damaging metaphysical superstitions.

Philosophical analysis and scientific practice. The arguments about these rival ontological and epistemological views cannot be safely left or judged without first looking more closely at the complex relationship between the general analytical interests of philosophers and the more specific intellectual concerns of working scientists themselves. For the degree to which each view about the reality of scientific entities and facts can carry conviction depends substantially on what branches of science are at issue. As the focus of philosophical attention has shifted historically from one scientific terrain to another, so, too, have the relative degrees of plausibility of these rival positions varied.

Since the 1920s, for instance, there has been a marked revival of philosophical discussion among scientists working in several specialized fields—particularly, among physicists concerned with the structure and development of quantum mechanics. In epistemic terms, the statistical character of quantum-mechanical explanations has prompted some fundamental questions about the status and limitations of human knowledge. Clearly, the extent and accuracy of human knowledge about nature are limited by the modes of operation of scientific instruments. Is it not also possible, however, that the significance of this statistical character lies at a deeper level? Perhaps the relevant objective relationships and states of affairs in nature itself are governed intrinsically by a merely probabilistic causality and so are essentially indeterminate. Or is there a point to be reached on the microphysical level at which any such distinction between subjective human knowledge and the objective state of affairs has finally broken down? The ontal implications of quantum mechanics have been as puzzling as the epistemic. Is an electron, say, a discrete particle that just happens to elude man's exact observation; is it an essentially blurred wave bundle having no precise dynamical characteristics; is it a concentration of probability, a mere theoretical symbol, or what? Or must one set all these ontological questions aside as lacking any significance for physics and as standing in the way of the physicist's proper task, that of extending the direct explanatory power of quantum-mechanical explanation itself?

Elsewhere, the philosophical debate about science has taken on other specific forms. Just as in Aristotle's natural philosophy the metaphysical controversy about Ideas and

Quantum
mechanics;
taxonomy;
perception

essences was reflected in Aristotle's own methodological approach to biology and to the study of the natural relations and classification of organisms, so once again 20th-century reappraisals of traditional taxonomy—in the light of evolution theory, genetics, and population dynamics—have been an occasion for renewed philosophical debate. As a result, earlier disagreements about natural and artificial classifications have been reformulated and have generated a new dispute, about the possibility of basing taxonomy on a mathematical science of phenetics—in which the defining properties of different species, genera, etc. are all given quantitative numbers or measures—and so harnessing the technical resources of modern computers to its purposes.

Similarly, in the psychology of perception and related fields, the extension of understanding in recent years at last has permitted the framing of authentically empirical questions about perception and cognition, which lend themselves to direct investigation instead of being restricted to general a priori speculations. The result has been a theoretical debate, the final outcome of which will have profound effects on both philosophical epistemology and natural science. In areas of this debate where even Mach was content to pose entirely general questions, in the philosophical tradition of David Hume, about the role of sense impressions as the raw material of all cognition and perception whatsoever, it is now clear that many preliminary differences and complexities must be unravelled before one can hope to recognize the truly operative questions in this field. Far from all modes of knowledge and perception conforming to a single common pattern, man's sensory and practical dealings with the world call into play a variety of perceptual systems of which the operations justify no simple epistemological formula about impressions and ideas, sense-data and logical constructions, or intuitions and schemata. Thus, at the present time, the investigations of some physiologists, psychologists, and cyberneticists are bringing man's sensory and cognitive activities within the scope of natural science while at the same time preserving a feeling for the more general philosophical problems and insights of such philosophers as Locke and Leibniz, Hume and Kant, Helmholz and Mach.

At this point, the alliance between science and philosophy is simply carrying over into fields of science that are areas of methodological perplexity today the same interactions that were fruitful in earlier centuries within sciences having methods by now well understood. These interactions are unlikely to vindicate finally any one of the rival positions in the philosophy of science, whether ontological (Realist, instrumentalist, or phenomenalist) or epistemological (Realist, conventionalist, or operationalist). Probably such a vindication was, in any event, too much to expect. For in all the different special sciences—both natural and social—historical development eventually brings the investigator to a point at which he is ready to operate with a variety of technical terms or entities having very different logical characters and functions and at which his most general theoretical propositions or principles display corresponding differences in their logical status and implications.

So long as philosophical discussion is confined within the limits of an artificial, ideal language or propositional system, it is possible, perhaps, to continue posing purely abstract, general dilemmas about, say, theoretical entities or confirmation theory. But the bearing of such formal dilemmas on the actual content of contemporary scientific thought is becoming increasingly unclear. In debating the ontal status of theoretical entities, for instance, the question must at some stage be faced whether that phrase is intended to cover such notions as gene or pi-meson, species or cold front, momentum or superego, social class or economic market. (Certainly, not all of these terms have identical characters and functions.) In debating the epistemic status of scientific theories, likewise, it must be made clear whether one has in mind, say, the mathematical schema of quantum-mechanical field theory, the populational analysis of natural selection, the microstructures and mechanisms of molecular biology, the developmental sequences of cognitive psychology, the labour theory of

economic value, the general regularities of terrestrial meteorology, or what. (Once again, not all of these theories have identical kinds of status or implications.)

Philosophical doctrines and approaches that carry great conviction when applied to the theories and ideas of one science may—not surprisingly—lose all of their plausibility when extended to other fields. Thus, an Empiricist analysis may apply quite straightforwardly to meteorology, yet entirely misrepresent the structure and implications of electromagnetic theory; while, in return, a Neo-Kantian account of theoretical physics may lack any direct relevance, say, to ideas about animal behaviour. Today as in classical Athens, analytical clarification in the philosophy of science goes, in this respect, hand in hand with methodological refinements in the sciences themselves. In retrospect, the methodological insights of Aristotle the marine biologist and of Plato the theoretical astrophysicist can be seen to have been complementary, rather than incompatible. Similarly, today, the philosopher must look at rival positions in the philosophy of science not merely as contradictory answers to technical questions within philosophy itself but equally as complementary contributions to the methodological improvement of theoretical understanding over the whole varied range of different scientific fields.

INTERRELATIONSHIPS OF SCIENCE AND CULTURE

This survey has been concerned, almost exclusively, with philosophical problems and arguments about the sciences regarded as sources of theoretical knowledge. In pitting Realism against instrumentalism, mechanistic ideas against organicist ones, divine knowledge against human fallibility, or Platonic Ideas against Aristotelian essences, the philosopher is in each case concerned with the intellectual status, implications, and validity of certain general scientific concepts, methods, or entities. To confine oneself entirely to these intellectual aspects, however, would mean accepting a total abstraction of theory from practice and of scientific ideas from their behavioral expression. Thus, along with the present-day shift of emphasis from the physical to the human and social sciences, one finds that all such abstract approaches are coming once again under criticism, as over-intellectualizing the nature and implications of science.

Some of these attacks come from the neo-Marxist direction and reflect a traditional Marxian insistence on the unity of theory and action. (It was not for nothing that Lenin picked on Ernst Mach as a special target for scorn.) Analogous criticisms, however, are also coming from men with very different intellectual loyalties—e.g., from the urban sociologist Lewis Mumford and from many contemporary Existentialists. In conclusion, therefore, a concise discussion is here given of some of the views about the relations between science and the rest of culture; i.e., about the relevance of scientific knowledge to other spheres of experience and concern and, conversely, about the significance of broader, practical considerations for man's understanding of scientific theory itself.

The variety of these views has always been very great. Their exponents have ranged all the way from those who, like the energeticist Wilhelm Ostwald and the evolutionist Julian Huxley—both of whom rooted ethics in nature—present scientific ideas and procedures as rational panaceas for intellectual and practical problems of all kinds to those who, like Pierre Duhem and Carl von Weizsäcker, physicist and philosopher of nature, both of whom are theists, deliberately limit the claims of science so as to preserve a freedom of manoeuvre for ethics, for example, or theology. At each stage, most advocates of extreme claims for science have been ontological Realists; and, in strengthening their ontal and epistemic claims, they have also staked a claim to overriding intellectual priority on behalf of scientific knowledge, in contrast to other forms of experience. Similarly, those who would restrict the broader cultural claims of science have tended to be phenomenologists; and, in weakening their philosophical claims, they have also attempted to limit the authority of science to its own intellectual concerns as narrowly defined.

Whatever one's general philosophical position with re-

Turn to broader human concerns

Pluralism and complementarity

Science, technology, and ethical values

spect to the reality of scientific knowledge and entities may be, however, there are other more practical questions to be faced, questions about the specific implications of different scientific ideas and beliefs for parallel fields of human action and experience. On this point, one particular theme unites a wide range of radical critics of science, including both Lewis Mumford, U.S. social critic, and the Existentialists. Just as the Christian Dane Søren Kierkegaard, an early and seminal figure of Existentialism, condemned Kant's universalized system of ethics for ignoring the individuality of actual ethical problems and decisions, so today there is a widespread reaction against any tendency to treat social or practical decisions as technical matters, which can be left to the judgment of scientific or technological experts. The general methods of technology may, indeed, represent practical applications of the theoretical understanding arrived at by science; but all individual decisions about putting those general techniques to use—e.g., in constructing an airport or power station—must be made not by appealing to any general formula or rule of thumb but by balancing a whole range of diverse considerations—economic and aesthetic, environmental and human, as well as merely technical.

According to another contemporary critique, the theoretical points of view adopted in natural science are general and abstract, but the practical demands of sociopolitical action and, *a fortiori*, of individual action, are concrete and particular; and, by itself, this contrast places an immediate restriction on the existential relevance of scientific ideas and engineering techniques. Such scholars as Thomas Huxley, a versatile scientist and defender of evolution, or Wilhelm Ostwald, a pioneer in electrochemistry, who viewed reality as essentially energy, might argue in general, abstract terms for interpreting ethical principles in evolutionary or thermodynamical terms if they pleased (so the critics continue); but such abstract speculative arguments have no bearing on the actual tasks of ethical decision and action. Here again, every ethical choice involves a unique constellation of considerations and demands; and this problem cannot be dealt with by appealing to any universal rule but must be appraised on an individual basis, as and when it arises.

Others take a more positive approach toward the contribution of science to an understanding of human values. Without necessarily claiming to transform ethics itself into a "science," they at any rate argue that the personal attitudes needed for effective work in science—adventurous skepticism and critical open-mindedness—have a wider relevance also to human conduct and social affairs. Supposing only that social and political discussion were conducted in this same tentative and critical spirit (they claim), its typical and deplorable passion and confusion could be replaced by the more rational consideration of the means required in order to achieve explicitly stated ends. While specific scientific ideas and doctrines may not be enough to direct social and political action by themselves, the scientific attitude may, nonetheless, have a profound significance for social policy and individual ethics alike.

This contrast, between existentially minded critics of the claim that science is all-embracing and socially minded believers in the scientific attitude, may be epitomized by referring to contemporary discussions about the social significance of science itself. On the one hand, there has recently been a revival of explicitly anti-scientific views, which had been more or less dormant since the time of Blake, Johann Wolfgang von Goethe, and their successors in the Romantic movement. Supporters of this anti-science position point to the central role of military technology in the financial support of 20th-century scientific research and dismiss the average scientist's plea that he is not responsible for the uses to which his ethically neutral discoveries are put, as pallid and insincere. On the contrary (they argue), there is a long-standing and unholy alliance linking the collective institutions of the scientific and technological professions to the economic, industrial, and political powers that be. Faced with the fruits of this historical union (they conclude), it is time that scientists acknowledged their social responsibilities; and, failing better institutional controls, the outcome of this moral self-

scrutiny may well prove to be a moratorium on further scientific research. Perhaps man already knows too much for his own good and needs to digest the significance of his existing stock of knowledge much further before adding to it and so widening yet again the gulf between theoretical knowledge and practical wisdom.

On the other hand, there are those who recognize science as playing a crucial role in modern society, but who go on to draw the opposite conclusion. Rather than putting a stop to science (these men would argue), its scope should be broadened; that is, scholars should be studying and understanding better the manner in which science serves as an element in the larger social order—perhaps by developing more adequate analyses of the social structure or perhaps by a large-scale extension of the methods of operations research. Aside from anything else (they point out), a moratorium on science is as impracticable as a moratorium on sin. It could be enforced only if political unanimity prevailed to an unimaginable degree among scientists. In the absence of such enforcement, liberal-minded countries will merely put themselves at a needless disadvantage—both economic and military—as compared with totalitarian states. Instead of pursuing this will-o'-the-wisp, scholars should put more effort into the task of understanding both the social preconditions of effective scientific development and the economic and political priorities involved in the practical application of scientific research.

As compared with the controversies of earlier centuries, the debate between science and religion is curiously muted today. There seems little room nowadays for the theological passions that engulfed the discussion of Copernicus' new planetary theory, James Hutton's history of the Earth, or Darwin's theory of natural selection; and one would hesitate to speak any longer, as so many of our forefathers did, of warfare between science and religion as unavoidable. It is true that a few partisan writers can still find it a perplexing problem to decide such issues as whether the existence of life on other worlds would require a re-enactment there of the Christian fall and redemption or can insist—conversely—that the results of astronomical exploration refute any religious belief that God is an Old Man up in the sky. For most people, however, such questions have so far lost their earlier bite that they appear, by now, quite naïve.

What is the reason for this change? In earlier times, the term cosmology embraced not only the structure of the astronomical cosmos and the origins of the human species but also the religious significance of man's place in nature. Contemporary theologians, by contrast, see physics and biology as having much less bearing on man's religious attitudes and preoccupations than their predecessors had supposed that they had. As a result, men's earlier ambition to construct a single, comprehensive world view, embracing the essential truths of both science and religion, no longer plays the active part in intellectual life that it formerly did. The only branches of science still capable of provoking vigorous theological debate, even now, are the human, rather than the natural sciences. The implications of Freudian psychology for the doctrine of grace and the use of psychedelic drugs for inducing quasi-mystical experiences are topics for live discussion today, in a way that evolution, astrophysics, and historical geology no longer are.

This change of focus has been accompanied by a change in ideas about the intrinsic limits of science. It was formerly assumed that the boundaries between science and other aspects of human experience could be defined by marking off certain types of subject matter as essentially closed to scientific investigation. To one generation, the heart of this forbidden territory was the mind; to another, it was life; to a third, the creation. In this view, something in the essential nature of mental or vital activities, or in the origins of the present order of nature, made it impossible to treat these as phenomena open to study and explanation by the rational methods and intellectual procedures available to science. In fact, this view always had defects, from both the scientific and the theological points of view. To scientists, it seemed to impose an arbi-

Science
and
religion

Limita-
tions of
science

Social
signifi-
cance of
science

trary restriction on their sphere of operations and so acted as a standing challenge and irritation. For theologians, it had the disadvantage of placing the essential claims of religion, so to speak, on a sandbank, where they risked being submerged in time by the rising tide of scientific knowledge. So, by tacit consent, the essential limits of science are now defined in quite different terms. These limits are now identified by recognizing that the character of scientific procedures themselves places restrictions on the relevance of their results. A scholar may choose to study whatever objects, systems, or processes he may please, but only certain of the questions that he asks about them will be answerable in the general, theoretical terms characteristic of science.

This change of approach may not have made the substantive problem—that of delimiting the frontiers of science exactly at all points—very much easier to deal with than it was before, but it has one genuine merit: it respects the crucial fact, to which attention has been drawn at several points in this present survey, that the distinctive features of science lie not in the types of object and event to which the scientist has access but in the intellectual procedures that his investigations employ and so in the kinds of problem that lend themselves to a scientific solution.

(S.E.T.)

Philosophy of nature

The discipline here entitled “the philosophy of nature” consists in the investigation of substantive issues regarding the actual features of nature as a reality and is divided into two parts: the philosophy of physics and the philosophy of biology. In this discipline, the most fundamental, broad, and seminal features of natural reality as such are explored and assessments are made of their implications for man’s metaphysics, or theory of reality; for his *Weltanschauung*, or “world view”; for his anthropology, or doctrine of man; and for his ethics, or theory and manner of moral action. These implications are explored on the assumption that man’s understanding of the natural setting in which his life is staged strongly conditions his beliefs and attitudes in many fields.

In its German form, *Naturphilosophie*, the term is chiefly identified with Friedrich Schelling and G.W.F. Hegel, early 19th-century German Idealists who opposed it to *Logik* and to the *Phänomenologie des Geistes* (“of the spirit or mind”). Employment of the term spread, in due time, beyond its narrower historical context in German Idealism and came to be used, particularly in Roman Catholic parlance, in the sense that it bears in this article (e.g., the philosophies of physics and biology). Despite a notable decline in its usage in more recent years, the term is here employed, in the interest of the clear delineation of topics, as a complement to the philosophy of science, the discipline to which its subject matter has been allocated by recent philosophers. Thus in this work, the article on the philosophy of science is largely restricted to man’s approach to nature, and thus to epistemological (theory of knowledge) and methodological issues, while that on the philosophy of nature encompasses the more substantive issues about nature as it is in itself.

PHILOSOPHY OF PHYSICS

Physics as a field of inquiry. *Essential features.* Physics is concerned with the simplest inorganic objects and processes in nature and with the measurement and mathematical description of them. Inasmuch as the binding forces of chemistry can now, at least in principle, be reduced to the well-known laws of physics, or calculated from quantum mechanics (the theory that all energy is radiated or absorbed in small unitary packets), chemistry can henceforth be considered as a part of physics in theory if not in practice. Moreover, it has become clear, through the general theory of relativity (which formulates nature’s laws as viewed from various accelerating perspectives), that there is an aspect of geometry, too, that can be regarded as a part of physics. The fact that, over a wide range of circumstances, Euclidean, or ordinary uncurved, geometry presents a good approximation to reality is considered

today not as a fact stipulated by a necessity of thought, nor a derivative from such a necessity, but as a fact to be established empirically; i.e., by observation. In their application, the laws of Euclidean geometry refer to those experiences that arise with measurements of length and angle and optical sightings as well as with surface and volume measurements. The possibility—already extensively elucidated in antiquity—of deriving geometrical propositions by deduction from a few axioms, assumed without proof to be correct, had given rise in earlier philosophy to the opinion that the truth of these axioms must and could be guaranteed by a kind of knowledge that is independent of experience. The recognition of such a priori knowledge, however, has been superseded by the modern development of physics. While it is granted that a pure geometry is free to posit any axioms that it pleases, a geometry purporting to describe the real world must have true axioms. Today it is considered that, if Euclidean geometry is true of the world, this truth must be established empirically; the axioms would be true because the conclusions drawn from them correspond to experience. Actually, the world appears Euclidean, however, only when this experience is limited to cases in which the distances are not too great (not much greater than 10^9 light-years) and in which gravitational fields are not too strong (as they are in the vicinity of a neutron star).

The possibility of deducing all known laws or regularities as logical inferences from a few axioms, which was discovered in Euclidean geometry, became a model for the construction also of another chapter in the history of physics. The classical physics of Newton, the 17th–18th-century father of modern physics, had employed Euclidean geometry as a foundation and had portrayed the solar system as a system of mass points subject to his mechanical axioms. The laws for falling bodies framed by the 16th–17th-century Italian physicist Galileo are the simplest logical consequences of Newton’s axioms, and the laws framed by Johannes Kepler, a 16th–17th-century German astronomer, which precisely describe the motions of the planets, follow from them.

In addition to the laws of mechanics there are those of the broad sphere of electromagnetic phenomena as summarized in the equations of James Clerk Maxwell, a 19th-century Scottish physicist, which describe both the electric and magnetic fields and the laws of their mutual changes, equations that may thus be considered as the axioms of electrodynamics. Because they assume the mathematical form of partial differential equations—which express the rates at which differentials (small or infinitesimal distances or quantities) in several dimensions change with respect to their neighbours—electrodynamics is a local-action theory rather than an action-at-a-distance theory as in older formulations modelled after Newton’s law of gravitation. The principle of local action states that the variations of electromagnetic magnitudes at a point in space can be influenced only by the electromagnetic conditions in the immediate vicinity of this point. The finite velocity of propagation for electromagnetic disturbances, which follows from this principle, leads on the one hand to the existence of electromagnetic wave events and on the other hand to conformity with the requirements of special relativity (a theory that formulates nature’s laws as viewed from the perspectives of various velocities), which demand a maximum finite velocity for signals—the velocity of light in a vacuum.

The most important division of physics today is one that replaces the traditional distinctions between mechanics, acoustics, and other classical branches of physics with that between macroscopic and microscopic physics, in which the latter investigates the conformity of atoms to law and their reactions in discrete quantum jumps, whereas the former extends from the level of ordinary human experience into astronomy to a total comprehension of the universe, attained through theoretical endeavours in the field of cosmology. Because it is now possible to observe especially bright objects (quasars) that are located perhaps 10^{10} light-years from the Earth, the possibility of empirically testing cosmological models is beginning to arise. In particular, the application of non-Euclidean, or curved,

Macroscopic versus microscopic physics

Axiomatic versus empirical geometry

geometries to the cosmos has suggested the conception of a finite, yet boundless, world space (positively curved), in which the maximum possible distance between two points would no longer be much greater than 10^{10} light-years.

Historical sketch. In the historical development of physics before the 17th century, geometry was the only field in which extensive advances were made; besides geometry, only the rudiments of statics (the laws of levers, the principle of hydrostatics of the 3rd-century BC scientist Archimedes) were clarified. After Galileo had discovered the laws of falling bodies, Kepler's laws describing the motions of the planets and Newton's reduction of them to a set of dynamical axioms established the science of classical mechanics, to which was annexed the investigation of electromagnetism. These developments culminated in the discovery of induction by Michael Faraday, an English physical scientist, the knowledge of local action by Faraday and Maxwell, and the discovery of electromagnetic waves by a German physicist, Heinrich Hertz. It was not until the 19th century that the law of the conservation of energy was first recognized as a general law of nature, through the work of Julius von Mayer in Germany and James Joule in England, and that the concept of entropy (see below *Entropy and the direction of time*) was formulated by Rudolf Clausius, a mathematical physicist. At the beginning of the 20th century, the German physicist Max Planck introduced the so-called quantum of action, $h = 6.626 \times 10^{-27}$ erg-seconds, which, when multiplied by the vibration frequency, symbolized by the Greek letter nu, ν , demarcates a basic packet of energy. Albert Einstein then extended the quantum theory to light. The real existence of atoms was proved by him and other investigators, and the science of microphysics thus arose. The researches of Niels Bohr on the quantum-theoretical significance of atomic spectra paved the way for broader search into the fine details of quantum laws, the final comprehension of which was introduced by Werner Heisenberg in 1924 and then systematically developed by Max Born, Heisenberg, and Pascual Jordan, of Germany, and by P.A.M. Dirac, of England. Moreover, Erwin Schrödinger, an Austrian physicist, pursuing a line of thought pointed out by Einstein and Louis de Broglie, arrived at results that were outwardly quite different from those of Heisenberg *et al.*, but were mathematically equivalent. The quantum mechanics, or wave mechanics, created by these men, which formulated quantum phenomena, were later extended to quantum electrodynamics.

General and special theories of relativity

Einstein's theory of relativity, first formulated in 1905, which was eventually extended from a special to a general formulation, brought about a revolutionary transformation in physics similar to that induced by quantum theory. The Newtonian mechanics of mass points turned out to have been merely an approximation to the more exact relativistic mechanics. The most important consequence of the special theory of relativity, the equivalence of mass (m) and energy (E),

$$E = mc^2, \quad (1)$$

in which c is the velocity of light, was formulated by Einstein himself.

After 1916 Einstein strove to extend the theory of relativity to the so-called general theory, a formulation that includes gravitation, which was still being expressed in the form imparted to it by Newton; *i.e.*, that of a theory of action at a distance. Einstein did succeed in the case of gravitation in reducing it to a local-action theory, but, in so doing, he increased the mathematical complexity considerably, as Maxwell, too, had done when he transformed electrodynamics from a theory of action at a distance to a local-action theory.

The great importance of physics for the technology that depends upon it—which has become a leading factor in the rapidly increasing development in the conditions of human existence—is shown historically in the close connection of decisive technical developments with basic advances in physical knowledge. Einstein's equivalence of mass and energy—to cite but one example—pointed to the atomic nucleus as an energy source that could be opened up through the study of nuclear physics. More-

over, the intellectual influence proceeding from physics and affecting the development of modern thought has become especially strong through the deepened grasp of the concept of causality that has followed from quantum theory (see below *Modalities of the natural order*).

Basic characteristics and parameters of the natural order. *Framework of the natural order.* Earlier mathematicians and particularly Richard Dedekind, a pre-World War I number theorist, have precisely defined the concept of real numbers, which include both rational numbers, such as $\frac{277}{931}$, expressible as ratios of any two whole numbers

(integers), and irrational numbers, such as $\sqrt{27}$, π , or e , which lie between the rationals. By reference to these numbers, the Newtonian concept of space and time, which presupposes a Euclidean geometry of space, may be made precise: the values of the time t , ordered according to the ideas of earlier and later, can be made to correspond to the single real numbers, ordered according to those of smaller and larger. Also, the points on a straight line can be brought into correspondence with the real numbers in such a manner that the location of a point P between two other points P_1 and P_2 corresponds to a number assigned to P that lies between those assigned to P_1 and P_2 .

Guided by the wish to find a method that allows the systematic proof of all philosophical truths, René Descartes, often called the founder of modern philosophy, established in the 17th century the analytic geometry of Euclidean planes. In it the points of a plane can be designated by two numbers x , y , their coordinates. One chooses two orthogonal coordinate axes, $x = 0$ and $y = 0$, like those of a graph, and, with any point P , associates its two projections, one upon each coordinate axis, which define the location of P . A curve in the $x - y$ plane is then expressed by an equation $f(x, y) = 0$, shorthand for any equation ("function") containing x 's and y 's. In the context of analytic geometry, every theorem of plane Euclidean geometry may be expressed by equations and thus be analytically proved.

Cartesian analytic geometry

This procedure can also be extended to three-dimensional Euclidean space by introducing three mutually perpendicular axes x, y, z . In this case, there are two different axis systems—either congruent or mirror reflections—analogs to right-handed and left-handed screws.

The simple space-time relationships of Newtonian physics have been changed in many ways by modern developments. The concept of simultaneity has been made relative by the special theory of relativity; every time measurement t is thus tied to a definite inertial system or moving frame of reference. It is accordingly appropriate to speak not primarily of points in time but of events, which are defined in each case by giving both a point in space and a point in time.

Metrology in modern physics

More specifically, an inertial system is a coordinate system that, relative to the fixed stars, is in uniform, straight-line motion (or at rest) with no rotation. In all inertial systems, Newton's principle of inertia, which states that all mass points not acted upon by some force persist in uniform motion with a constant velocity, is valid.

Moreover, cosmological theories make it probable that space in the real astronomical universe corresponds only approximately to the relationships of Euclidean geometry and that the approximation can be improved by replacing Euclidean space with a space of constant positive curvature. Such a space can be mathematically defined as a three-dimensional hyperspherical "surface"

Hyperspherical space-time: x, y, z, u

$$R^2 = x^2 + y^2 + z^2 + u^2 \quad (2)$$

in a hypothetical Euclidean space of four dimensions with mutually perpendicular x, y, z , and u coordinate axes.

The assertion that the foregoing statement has no operationally comprehensible content—*i.e.*, no content provable by performable measurements—is designated conventionalism, a view that is based on a remark by a French mathematician, Henri Poincaré, who was also a philosopher of science, that a fixed non-Euclidean space can be mapped point by point on a Euclidean space so that both are suitable for the description of the astronomical reality. The range of this remark is limited, however, in that this mapping, though it can indeed carry over points

into points, can in no way carry over straight lines into straight lines. Hence, many philosophers of science have held that, as long as astronomical light rays are held to be straight lines, the question of a possible curvature of space (*i.e.*, a deviation from Euclidean conditions) will by no means be solved by some arbitrary convention; that it signifies, instead, a problem to be solved empirically. If the universe in fact has a positive constant curvature, then every straight line has a length that is only finite, and its points no longer correspond, as in the Euclidean case, to the set of all real numbers.

In a very definite manner, cosmological facts have further indicated that time is by no means unlimited both forward and backward. Rather, it seems that time as such had a beginning about 10^{10} to 2×10^{10} years ago; thus, with an explosive beginning, the cosmic development began as an expansion.

The foregoing discussion has considered only the replacement of Euclidean spatial concepts by an elementary non-Euclidean geometry corresponding to a space with a constant curvature. According to Einstein, however, the fundamental idea of a still more generalized Riemannian geometry, so-called after Bernhard Riemann, a geometer and function theorist, must be brought into play in order to produce a local-action theory of gravitation.

Riemannian space:
 g_{kl}

Riemannian geometry is a further development of the theory of surfaces created by the 18th- and 19th-century German mathematician and astronomer Carl Friedrich Gauss, often called the founder of modern mathematics, a theory that aimed to investigate the curved surfaces of three-dimensional (Euclidean) spaces with exclusive regard to their own inner dimensions and no consideration of their being imbedded in a three-dimensional space.

Gauss thought that the points on such a surface could be specified by reference to two arbitrary coordinates u and v defined with the help of two single-parameter families of curves, $u = \text{constant}$ and $v = \text{constant}$. The square of the infinitesimal distance between two adjacent points of the surface, ds^2 , is then a quadratic form of the differentials du and dv , belonging to the pair of points, namely,

$$ds^2 = g_{11}du^2 + 2g_{12}dudv + g_{22}dv^2, \quad (3)$$

in which the coefficients g_{kl} are functions of position. One can then calculate the curvature corresponding to the location of the pair of points according to a prescription given by Gauss, a curvature that measures the deviation from Euclidean plane behaviour that exists at this point. The curvature is a definite function of the g_{kl} and their first derivatives.

Riemann extended Gauss's considerations to the case of a three-dimensional space that can have different curvature properties from place to place (expressed by several functions of position that are collectively called the curvature tensor); and Einstein generalized these ideas still further, applying them to the four-dimensional space-time continuum, and thereby attained a reduction of the Newtonian action-at-a-distance theory of gravitation to a local-action theory.

Contents of the natural order. Among the most basic constituents of the physical world are symmetries, fields, matter, and action.

Symmetries

Symmetry is one of the chief concepts of modern mathematics, which combines the different symmetries belonging to an object or a concept into groups of relevant symmetries. The a priori investigation of the totality of possible groups, defined with respect to some operation (such as multiplication), comprises a division of modern mathematics called group theory.

Three-dimensional Euclidean space displays several important symmetry properties. It is homogeneous; *i.e.*, arbitrary shifts in the origin or zero point of the coordinate system produce no change in the analytic expression of the geometrical laws. It is also isotropic; that is, rotations of the coordinate system leave all geometrical laws in effect. Further, it is symmetric with regard to mirror reflections. It is tempting to suppose that these symmetry properties of space are also valid for the physical processes that occur in space, and this is indeed true over a wide range of cases,

but not in all cases (for exceptions, see below *Charge/parity/time symmetry*).

That Newtonian mechanics and Maxwellian electrodynamics display in fact all of the symmetries of Euclidean space is revealed by the fact that they can be formulated in the language of vector analysis. Passing over the more familiar Newtonian mechanics, a few points about Maxwell's theory may be mentioned. This theory can be made to satisfy the requirements of operational thinking by ascribing to the electric and magnetic field strengths the significance of measurable physical realities, which makes it unnecessary to interpret them as states of a mysterious, hypothetical substance or ether, for which, in any case, the special theory of relativity (with the equivalence of all inertial systems) has no place.

Mathematically interpreted, a vector a represents a quantity with both magnitude and direction, which preserves its length or value and its direction when displaced. The vector field—*i.e.*, the association of a vector with every point in space (*e.g.*, electric field strength, or electric current density)—and the line integral (or summation) of a vector field V along a curve K leading from a point P to a point P' are basic concepts in vector analysis. To obtain the line integral, the curve K is divided into infinitesimal elements ds , the scalar (numerical or nonvector) product of ds with the value of V at that point is taken, and the results are summed with an integration.

A small surface area envisioned with a given sense of rotation around its boundary curve can also be described by a vector. In this instance, the vector, dF is perpendicular to the surface and forms, with the sense of rotation about the boundary, a right-handed system. Its magnitude is the area of the surface. The flux of the vector field V through the surface dF is called the scalar product $V \cdot dF$.

If V has the property that the line integral along every closed curve K is equal to zero, then V is said to be irrotational. This property is equivalent to the requirement that the vector field be a so-called gradient field; *i.e.*, that there exist a scalar field quantity W with the property that the difference in the value of W at two points P and P' is equal to the line integral of the vector field V from P to P' (along any arbitrary curve K). If V is, for example, an electrostatic (charged) field, the significance of being irrotational is that one can gain no mechanical work in leading a small test charge around any closed curve; the work involved is equal to zero. For an unclosed curve K , however, the movement of the test charge yields an amount of mechanical work that is proportional to the potential difference between the endpoints of the curve. The components of the gradient of W , expressed in partial derivatives ∂ , are

$$\text{grad } W = \frac{\partial W}{\partial x}, \frac{\partial W}{\partial y}, \text{ and } \frac{\partial W}{\partial z}. \quad (4)$$

If the vector field is not irrotational, there can then be constructed from it an adjunct rotational field, called curl V , by considering a small (infinitesimal) surface area dF located at a point P and forming the line integral of V along the boundary curve of dF . Then, when this line integral is divided by the magnitude of the surface area, the component of the curl V parallel to the vector dF is obtained.

On the other hand, the flux of a vector field V out of a closed surface can be formed by integration. If this flux is always zero (for every choice of a closed surface), V is called source-free. Otherwise, there is a so-called divergence of V at a point P , which is defined as follows: one divides the net flux of V out of a small surface that surrounds P by the volume enclosed by the surface. The limit of this quotient for infinitesimally small surfaces is called the divergence of V at P or the source field $\text{div } V$.

The formulation of the basic laws of electrodynamics given by Maxwell is called the Maxwell equations. These equations contain, for example, the statement that, in a vacuum, the source field of the electric field strength is proportional to the spatial electric charge density, symbolized by the Greek letter rho, ρ , and that the magnetic field strength is source-free (divergence equal to zero). Thus, magnetic monopoles having no correlate of opposite sign

Vector fields: directional quantities

Curl; divergence; charge; and current density

do not exist. Remembering that every source-free vector field may be expressed mathematically as a rotation field (and vice versa), it is possible to derive the magnetic field strength H as a rotation field from a vector field A , which is usually called the vector potential of H

$$H = c \cdot \text{curl } A. \quad (5)$$

The fundamental law of the conservation of charge results from Maxwell's equations in the form of the continuity equation

$$\dot{\rho} + \text{div } i = 0, \quad (6)$$

in which $\dot{\rho}$ is the time derivative of the charge density, and the vector field i is the electric current density.

In the case of a vacuum, the Maxwell equation that expresses Faraday's law of induction takes the form of a proportionality between the rotation field of the electric field strength and the time derivative of the magnetic field strength:

$$H = c \cdot \text{curl } E. \quad (7)$$

Matter and action It is a significant fact that Maxwell's theory leads to a localization of energy, which in electromagnetic fields is propagated somewhat in the manner of a substance, with a density that, for the vacuum case, is

$$W = (E^2 + H^2)/8\pi. \quad (8)$$

There remains also the unsolved problem of clarifying the relation of gravitation to quantum theory, which is much aggravated by the fact that gravitational energy allows of no similar localization.

In both mechanics and electrodynamics, the fundamental equations have such a form that they can be understood as the conditions for a variational or an extremal principle: that, through the fulfillment of these conditions, a certain integral receives an extreme value. This integral, which has the dimensions of action—i.e., of energy times time—is one of the most fundamental quantities of nature. Although the concept of action is less obvious to man's physical intuition than that of energy, it is of even greater significance, as it appears also in connection with the quantum laws. For the basic constant of all of quantum physics, which always occurs in the laws of this domain, is likewise of this dimension: namely, Planck's quantum of action

$$h = 6.626 \times 10^{-27} \text{ erg-seconds}. \quad (9)$$

Modalities of the natural order. In a purely phenomenalist theory of matter—i.e., a theory that does not go into the details of atomic physics but considers matter only in a first approximation as a spatially extended continuum—numerous material properties are ascribed to every type of matter, properties such as density, electrical conductivity, magnetizability, dielectric constant, thermal conductivity, and specific heat. To be complete, a theory must provide a means of deriving all of these material properties theoretically from the laws of atomic physics.

Causality and statistical approach The hiatus-free causality envisioned throughout the science of physics before the rise of quantum theory cannot be separated conceptually from the far-reaching assumption that all physical processes are continuous. It had been supposed that continuous changes in antecedent causal processes would issue in continuous changes in the sequence of processes that are causally dependent upon them. Quantum physics, however, has expressly breached the old philosophical axiom that *natura non facit saltus* ("nature does not make leaps") and has introduced a granularity not only in the matter filling space, but also in the finest processes of nature. It is therefore only logical that, with respect to causality, the quantum theory would arrive at new and modified ideas as well. Renouncing unbroken causality, it speaks only of a probability that is statistical and a predetermination for the discrete saltatory events of which physical processes consist—a view that must now, in spite of Einstein, be regarded as irrevocable.

The special theory of relativity demands that the fundamental validity of the local-action principle be acknowledged: all actions have only finite velocities of propagation, which cannot exceed the velocity of light. Thus, in relativistic cosmology it is quite possible that two partial regions of the total spatial manifold may exist between which no causal interaction can occur: causal influences could then assert themselves only inside the so-called interdependent regions in the space-time manifold. These remarks also apply to the quantum theory, in which, however, instead of a causal dependence of physical processes upon each other, there is only an induction of statistical probabilities for possible quantum transitions.

Levels of the natural order. Moving in quite different directions, the theory of relativity on the one hand and the quantum theory on the other have diverged far from the earlier basic ideas of classical physics, which were considered unalterable. There are also some physical problems, however, that can be thought through only by appealing to both the relativistic and the quantum-theoretical modifications. A so-called joint relativistic and quantum-mechanical theory suitable for such problems is quantum electrodynamics, the development of which, however, is not yet complete. Its development was greatly hindered at first by certain mathematical difficulties (so-called divergences), which it later became possible to mitigate by renormalization; i.e., by a technique of correcting the calculated results. The more generally conceived quantum theory of wave fields finds a broad area of possible application in the physics of the different kinds of elementary, though short-lived, particles produced by the huge high-energy accelerators. In its final form, the theory of elementary particles should not only formulate, in general, the laws valid for all known elementary particles but should also allow a deductive derivation for all possible kinds of elementary particles—analogueous to the derivations of elements in the periodic table. Heisenberg has endeavored to set up this far-reaching problem, which has been called the world formula, for a solution. Imposing mathematical difficulties, however, have arisen in the attempt to clarify its consequences for a quantitative comparison with experience, and considerable further work may still be required.

Special problems in the philosophy of physics. *Problems at the formal level.* Euclidean space, in contrast to imaginable spatial structures that deviate from it, is distinguished by the simplicity of the topological properties (those preserved through rubberlike distortions) that arise from its unusually simple continuity relationships. One may ask, then, whether the empirical knowledge of modern physics gives any cause to consider deviations from the topological relations of Euclidean space. The U.S. physicist John A. Wheeler, author of a new theory of physics called geometrodynamics, has speculated about this question. In particular, he has pointed to the possibility of so-called worm holes in space, analogueous to the way in which the cylindrical surface of a smooth tree trunk is changed topologically if a worm bores a hole into the trunk and emerges from it again elsewhere: the surface of the trunk has thus obtained a "handle." Similarly, one can envision certain handles being added to three-dimensional Euclidean space. Whether this hypothesis can be fruitful for the theory of elementary particles is yet to be determined. From the methodological and epistemological standpoints, it is obvious that a geometrical structure is here being assumed, the measurement of which is fundamentally hindered by the lack of rulers with calibrations smaller than the structure itself. Presumably, the practical possibility of appealing to such topological modifications of the ordinary notion of space is to be found in astrophysics rather than in elementary particle physics. Viktor A. Ambartsumian, a Soviet astrophysicist, is convinced that the processes involved in the origins of galaxies are connected with explosions in which the matter of new stellar systems arises from prestellar material; and it has been found tempting to suppose that this prestellar material exists in regions with unusual topological properties.

The basic idea of the special theory of relativity can also be understood as a statement about the symmetry

Special topological properties

Lorentz transformations

properties of the four-dimensional space-time manifold. The special principle of relativity states, in fact, that the same physical laws are valid in all of the various inertial coordinate systems—in particular the law that the velocity of light in a vacuum always has the value c . This equivalence of the space-time coordinates x, y, z, t with other coordinates x', y', z', t' that are linear, homogeneous functions of the unprimed coordinates can be expressed by the equation

$$x^2 + y^2 + z^2 - c^2 t^2 = x'^2 + y'^2 + z'^2 - c^2 t'^2. \quad (10)$$

In this formulation, the isotropy of space—its sameness in all directions—appears as a special case of a more comprehensive symmetry property of the space-time manifold. When $t = t'$, the special case of a purely spatial rotation of coordinates is obtained; and in the general case, in which the primed coordinates are moving with velocity u with respect to the unprimed, the famous Lorentz transformations are obtained, which, to adjust to the finiteness of c , add a factor, symbolized by the

Greek letter gamma, $\gamma = \sqrt{1 - \frac{u^2}{c^2}}$, to the ordinary

Galilean transformation, $x = x' + ut'$, thus yielding

$$x = (x' + ut')\gamma. \quad (11)$$

The group of symmetries of the four-dimensional space-time manifold thus produced is called Poincaré group.

Problems at the quantum level. Problems of particle theory, complementarity, and symmetry have arisen in studies at the quantum level.

Elementary
particle
theory

Whereas the atomic nuclei beyond hydrogen-1 (the proton) are compounded structures, consisting of neutrons and protons, modern physics also deals with numerous elementary particles—neutrinos; π (pi), μ (mu), and κ mesons; hyperons; etc.—that are thought of as uncompounded. The elementary particles of each particular kind show no individual differences. Except for light quanta, for each kind of particle a corresponding antiparticle has come to light (which, for charged particles, always carries a charge of opposite sign). For instance, to each of the two known forms of neutrino there corresponds an antineutrino with charge zero and zero rest mass; *i.e.*, with a mass that would be zero were it not moving at a velocity of the order of (in fact, at) that of light. Whether Heisenberg's world formula can provide a complete framework for all possible kinds of elementary particles is undecided.

Every type of elementary particle has a definite value for its spin, either integral (*e.g.*, light quanta) or half-integral (*e.g.*, electrons, protons, neutrinos). Particles with half-integral spin obey Fermi–Dirac statistics; those with integral spin obey Bose–Einstein statistics, which differ in form as $u/(1+u)$ differs from $u/(1-u)$ — u being any function. The conformity to law that underlies the Fermi–Dirac statistics for electrons was first recognized by Wolfgang Pauli and formulated as the Pauli exclusion principle, which played a decisive role in settling upon the shell structure in the periodic system of the elements.

Heisenberg's
uncertainty
principle

The basic duality of waves and corpuscles is of universal significance for all kinds of elementary particles, even for composite particles in those experiments that cannot lead to a breakup of the particles into their component parts.

An electron (and analogously any other elementary particle or even, for example, an alpha particle) can appear just as well in the form of a wave as in that of a localized corpuscle. In an idealized thought experiment, one can imagine that the position of an electron can be ascertained with a gamma-ray microscope. If the electron is described in terms of wave processes in the sense of Schrödinger's wave mechanics, a very sharply concentrated wave packet appears at the stated position. In an investigation of this packet by Fourier analysis—a technique that analyzes a function into its sinusoidal components—wave components of quite different wavelengths occur; thus an electron in this condition has no definite value for its de Broglie wavelength and consequently none also for its translational momentum. Then, as stated in the so-called de Broglie relation,

$$\lambda = h/mv, \quad (12)$$

there is for an electron moving free from impinging forces a corresponding wavelength, symbolized by the Greek letter lambda, λ , that is inversely proportional to its momentum mv . And conversely, an electron moving inertially with a definite momentum (which in the limiting case of small velocities is equal to the product of the mass and the velocity vector) has no definite position. If an electron that is moving inertially (especially an electron at rest) is constrained by the use of a gamma-ray microscope to “make up its mind,” as it were, on a location, then the probability of its appearance at a point in space is the same for all locations. More precisely stated, the probability of the appearance of the electron in a definite volume is proportional to the magnitude of this volume.

In particular, it will be helpful to consider an electron moving in the x -direction and to suppose that it has a wave amplitude that depends only upon x , an electron in which the most representative wavelengths are confined to a narrow interval while the amplitudes that are discernibly different from zero are likewise confined to a certain interval Δx . If, on the other hand, Δp is the range of discernible momentum values—computed from the discernible wavelengths that represent them according to the de Broglie relation (12)—then the product of the uncertainties Δx and Δp cannot be smaller than Planck's fundamental quantum of action h . This statement comprises the famous Heisenberg uncertainty relation, which expresses the “complementarity” of position and momentum—as Niels Bohr characterized it.

If one assumes, as above, that all physically possible states of an electron can be represented by Schrödinger's wave mechanics, then the complementarity of the position coordinate x and its corresponding conjugate momentum p_x is a simple mathematical fact. When one thinks primarily of physical-measurement experiments, it should be emphasized that stringent limitations are imposed on the simultaneous measurement of the position and momentum of a particle that, according to the uncertainty principle, make it impossible to measure simultaneously both of these complementary quantities with unlimited precision. In an experiment that measures its position, the electron is forced into a sharper localization; and its particle nature comes to light. By contrast, in an experiment that measures its momentum, an interference experiment is involved; the electron must be able to display a certain wavelength, which requires an adequately extended region in space for its reacting. These two complementary and opposing demands can only be brought into harmony in the sense of a compromise; and the Heisenberg uncertainty relation formulates the best possible compromise.

Thus, it becomes at the same time clear that the state of the electron given in the wave-mechanical description before carrying out a new measurement experiment can establish only a statistical prediction for the result. The probability density for the appearance of an electron at a point in space is given by the square of the absolute value of the (complex) Schrödinger wave amplitude; for a definite result in measuring a wavelength or a momentum, the square of the absolute value of the (complex) Fourier coefficient belonging to it provides the standard. The general statistical transformation theory of quantum mechanics (as developed by Dirac and Jordan) gives a complete review of the measurable physical quantities for a microscopic mass point (or a system of such points). According to this theory, two different measurable quantities A and B can be simultaneously determined with unlimited precision only if the operators or matrices that describe A and B commute; *i.e.*, if $AB = BA$.

A transformation in which the nucleus emits an electron and a neutrino is called beta decay, an example of nuclear radioactivity. The forces that thus come to light are those of the so-called weak interactions. It has been experimentally determined that for these forces the symmetry associated with reflections in a mirror does not hold. At least in certain circumstances, however, a remnant of this symmetry continues to hold, in which the so-called CPT (for the initials in charge/parity/time) theorem applies. This theorem states that basic physical laws remain of unaltered validity when a reflection of the space coordinates

Charge/
parity/
time
symmetry

as in a mirror is combined with an interchange of positive and negative charge (which is largely synonymous with the interchange of particles and antiparticles) and with a reversal of the direction of time. Whether or not this symmetry law is valid without exception is by no means fully clarified at present.

Problems at the macrophysical level. Proceeding from the properties of atoms and molecules that are described in terms of quantum theory, a theory of macrophysical substance aggregates has been built using statistical mechanics. The theories of heat, of gases, and of solid-state aggregates (crystal lattices) have been extensively clarified. Only the liquid state still poses certain unsolved problems for the statistical theory of heat.

In any case, Newtonian mechanics may be derived as a macroscopic consequence of the laws of the mechanics of atoms, and its validity for the motions of astronomical bodies presents no problem. It is not so simple to prove, however, that the statements of Newtonian mechanics for rotating bodies (*i.e.*, the mechanical laws of centrifugal force and the Coriolis force) may be established from Einstein's general theory of relativity. Ernst Mach, a physicist and philosopher of science whose train of thought has substantially fertilized the modern development of physics from the point of view of the theory of knowledge, raised objections against Newton's idea that centrifugal force is a consequence of the absolute rotation of a body; he asserted instead that the rotation of a body relative to the very distant giant mass of the universe was the true cause of centrifugal force. This idea, often referred to as Mach's principle, has been corroborated, though in a different form, within the conceptual framework of Einstein's general theory. An irrotational coordinate system—specifically, a system not rotating with respect to the fixed stars (or, better, to the spiral nebulae)—is distinguished from a rotating system by the difference in the metric field for the two cases (*i.e.*, in the properties of their respective space-times as expressed by the equation—(3) above—for the interval between two events). It is true that the local metric field (in the vicinity of the solar system) is influenced by the distant masses of the universe, but of course only in the sense of a local-action principle and therefore in no way such that the metric in the solar system is directly given as a function of these distant masses and of their motions.

The question of the precise circumstances in which Mach's principle can still be defended on the basis of Einstein's theory is somewhat complicated and thus remains obscure. In any case, it is certain that a deduction of this principle from Einstein's theory can only be given in conjunction with a complete solution of the cosmological problem; *i.e.*, of the problem of what are the overall geometric and dynamic properties of the universe considered in its totality. The remaining problems involved in justifying the application of classical Newtonian mechanics in astronomy by means of Einstein's theory contain, however, no additional fundamental difficulties.

There is one more influence of cosmological relationships upon macroscopic physics, which arises in connection with thermodynamics. The existence of irreversible processes in thermodynamics indicates a distinction between the positive and negative directions in time. As Clausius recognized in the 19th century, this irreversibility reflects a quantity, first defined by him, called entropy, which measures the degree of randomness evolving from all physical processes by which their energies tend to degrade into heat. Entropy can only increase in the positive direction of time. In fact, the increase in entropy during a process is a measure of the irreversibility of that process. In contrast, it is true of the quantum theory of the atom that the positive and negative directions in time are equally justifiable (in the sense of the principle of CPT symmetry). Consequently, it is difficult to understand how statistical mechanics can make possible a thermodynamics in which the entropy grows with time.

It is true that there are fluctuating thermodynamic phenomena, even in a system in overall thermodynamic equilibrium—and here theory and experiment agree. Thus, the states that arise within any small partial volume of the

system may be not only those that are thermodynamically most probable but also transitory deviations from the most probable state. The mention of these fluctuations, however, does not help to remove the above paradox.

Most physicists now hold that, until recently, this problem was treated erroneously in the usual textbook presentations. In the statistical theory of heat, entropy was regarded as proportional to the logarithm of the thermodynamic probability, and students came to regard it as a necessity of thought that nature progresses from states of lower probability to states of higher probability. In truth, however, the increase of entropy is a real physical property of the positive direction in time. Nonetheless, it was supposed that shaking a vessel containing red and white balls (or even grains of sand) in an originally ordered condition with the two colours neatly separated must result in a condition of extreme intermixing of balls. This result does not correspond, however, to some necessity of thought but to an empirical property of the real universe in which men live and experiment.

This interpretation, which was held for a long time and has only quite recently been recognized as erroneous, was allegedly supported by a famous mathematical theorem of Boltzmann, which seemed to show that, in an ideal gas for which the entropy—measured by its number of particles and its total energy—was not yet at its maximum value, the entropy must increase. If collisions of gas molecules are characterized by velocity vectors that are mechanically allowable (both before and after the collision), and if these vectors must satisfy both energy and momentum conservation, then what Boltzmann actually proved is that the entropy increase follows only when a correct count of the collision rate is made, according to which every kind of collision of gas molecules has a frequency of occurrence proportional to the product of the number of collision pairs that were present and the velocities that existed before the impact.

As one can subsequently see, the positive direction in time is already marked out by the collision rate count in a manner that no longer corresponds to the CPT principle. Although it is in fact possible to reason out the continuous increase in entropy on this basis, the paradox is not overcome. The question then remains of how it is physically justifiable—*i.e.*, how it can correspond to reality—to regard this principle of collision rates as valid even though it fundamentally contradicts the CPT principle.

An answer to this paradox can now be given, thanks to the insight of modern theoreticians—among them Hermann Bondi, a mathematician and cosmologist—who have shown that the entropy principle must be understood in the sense that in the universe as a whole, one definite time direction is singled out, namely, the one for which the universe expands. The thermodynamic distinction of a positive direction in time—with increasing entropy on the macroscopic level and with collision rate counts on the microscopic level—results from an expansion of the universe. Surprisingly, the Hubble expansion of the system of all the galaxies—so named after Edwin Hubble, an extragalactic astronomer—thus displays physical effects right down to the level of everyday physics; specifically, when two bodies at different temperatures are brought into thermal contact, the temperature equalization that results is an irreversible process corresponding to an asymmetry of the positive and negative directions in time that depends upon the expansion of the universe.

Problems at the cosmological level. A mathematical discovery by Alexander Friedmann has become of great significance for the mathematical derivation of cosmological models from Einstein's general theory of relativity. According to Friedmann, if the average mass density is constant throughout space, the gravitational field equations can be satisfied by a metric that embraces a three-dimensional space of constant curvature together with a time coordinate t such that the radius of curvature $R(t)$ is a definite function of time; and these cosmologies turn out differently depending upon whether the curvature of space is positive, negative, or zero. Among the models of the universe that are mathematically allowable are models in which the time coordinate may run through all values

Mach's
principle

mann's
theorem

Entropy
and the
direction
of time

The
steady-
state
theory

from zero to infinity, models in which the time is limited to a finite interval, and models in which it may run from minus infinity to plus infinity.

For a time, many specialists working in the field of cosmology found the so-called steady-state theory, first projected by an astronomer, Sir Fred Hoyle, especially convincing. In a modified version, this theory was adapted to the Friedmann model by Bondi. By adopting the so-called perfect cosmological principle, which holds that the broadest features of the universe are the same at all times as well as at all places, the theory then satisfied the unusually high symmetry or homogeneity requirements not only of a three-dimensional space with constant time but also of the entire space-time manifold. This high-degree homogeneity was so convincing to many authors that, in deference to it, a fundamental deviation from Einstein's field equations was tolerated: Bondi and Hoyle supposed that a small but constant creation of hydrogen occurs in the intergalactic vacuum. This hypothesis was introduced in order to achieve, in spite of the Hubble expansion of space, a mass density that remained constant in the universe.

This theory, which in spite of its deviation from Einstein's field equations certainly advocates an allowable hypothesis worthy of consideration, no longer seems tenable, however, because of the discovery of background radiation with a present temperature of 3° Kelvin, which is interpreted as a remnant of an original "big-bang" beginning of the universe. It thus appears that it is no longer possible to uphold the steady-state theory or the perfect cosmological principle upon which it is based. Instead, one must favour either a Friedmann model, which has a beginning, from which it expands monotonically and without limit; or a Lemaître model, in which a quantity λ , called the cosmical constant, arises that is, mathematically, a constant of integration, and physically, a force of cosmic repulsion that partially neutralizes that of gravitational attraction, and which lends a curvature to space even in its empty regions. For both of these models the time coordinate increases without limit from some initial value, which would naturally be called zero. For the beginning of time, one thinks, moreover, of a singularity $R(0)=0$ and thus of a space that at the null point of time is still a mass point. Cyclical models that alternately expand and contract in an endless sequence have also been discussed.

The empirical cosmological data, some of which, indeed, are more estimated than ascertained, seem to suggest that, in the present-day universe, the positive energy corresponding to the total rest mass of all the material existing in the universe may be exactly equal to the negative gravitational energy existing in the universe; thus, the total energy would then be equal to zero. This interesting singularity, however, needs further support. At one time, Dirac advocated the speculation that the total mass of the universe is not constant in time but is increasing—at a rate somewhat slower, however, than that in the steady-state theory. Ambartsumian's notion concerning prestellar material, which was mentioned above (see *Problems at the formal level*), could perhaps be considered support for this idea. Many further discussions have followed another conjecture by Dirac, according to which the gravitational constant G should be liable to change in the course of cosmic development. This constant would thus have to be considered a scalar field quantity, which in a Friedmann universe is approximately independent of the three space variables but dependent on the time variable. In spite of extensive theoretical deliberations on this theme, no decision has yet been reached.

Fundamen-
tal ratios

The way has been opened for some fundamental conjectures on certain emerging themes by the fact that the product of the mean mass density in the universe and the gravitational constant has the same order of magnitude as the square of the reciprocal of the radius of curvature of the universe. The aforementioned relation between the mass and gravitational energy in the universe presents a different expression for this ratio. The total mass of the universe divided by the proton mass probably has approximately the order of magnitude 10^{80} , according to present

cosmological notions. The order of magnitude of the radius of curvature of the universe is approximately 10^{40} , when expressed as a multiple of an elementary length of which the order of magnitude is approximately that of the nuclear radius. Whether it is justifiable to presume that there is here a functional dependence—i.e., a proportionality of M to R squared—is a question for the present still undecidable. The speculative attempt of Dirac to find an answer, however, is still—at least provisionally—judged with skepticism by the majority of physicists. (P.W.J.)

PHILOSOPHY OF BIOLOGY

The sharp increase in man's understanding of biological processes that has occurred in recent years has stimulated philosophical interest in biology to an extent unprecedented since the development of evolutionary theory in the 19th century. Biologists and philosophers alike have devoted much attention to a variety of issues regarding the subject matter and the methodology of biology, resulting in a sizable output of written material, formulating philosophical questions that are still arising and framing answers to acknowledged difficulties. Most of the problems of the philosophy of biology are old questions now being investigated afresh in the light of biological advances and new standards of philosophical rigour. In this account contemporary questions will be stressed.

The range of topics. An investigation of recent writings in biophilosophy reveals a continued preoccupation with unanswered—some say unanswerable—questions about evolutionary theory and a growing concern for a critical reappraisal of the question of whether biology is an autonomous discipline unamenable to reduction to mere physical and chemical underpinnings. Until the mid-20th century the biological sciences suffered from a lack of attention by philosophers; the principles that were generated were far less rigorously examined than were those of the physical sciences. There is now renewed hope, however, for a fresh approach to the age-old puzzles regarding life and its *raison d'être*. This hope rests on the recrudescence of interest in all biological matters as a direct result of an increased understanding of biological processes, of the changing quality of life, of the growing awareness of man's stewardship of the Earth, and of the exploration of space. Biology has just begun to make the sort of impact that the physical sciences have already made. It has generated a life technology with genetic engineering, organ transplants, and artificial organs. Each innovation, each technical masterstroke, each conceptual knot united emphasizes the need for a definitive philosophy of biology, and developments toward this goal are now under way. Good biological work has been accomplished by investigators with varied philosophical outlooks ranging from Neo-Thomism to skeptical naturalism. No inevitable metaphysics evolves from the study of biology or any other natural science; nevertheless, some of the general conclusions of biology have a philosophical interest, defining the limits of reasonable belief about the nature of the living world.

Categorical discontinuities that are recognized for the purpose of scientific methodology often seem impossible to justify as "natural" distinctions. Many biologists have noted, for example, that it is easier to study life than it is to define it. Properties such as metabolism and reproduction undeniably characterize organisms and might be said to define them, yet such a definition is arbitrary to the extent that such properties are logically independent. What is true of all life forms today may not have been true of the very earliest ones and, what is more, might not be true of extra-terrestrial ones that might be encountered in the future. There is not as yet a set of nonarbitrary characteristics that mark the distinction between living and nonliving systems. Moreover, in the course of analysis, it becomes necessary to arrange all of the phenomena of nature in a more or less linear, continuous sequence of classes and then to describe events occurring in the class of more complex phenomena in terms of events in the classes of less complex phenomena (principle of hierarchical continuity). Within each class, however, there are numerous interrelations observed between events of the same order of complexity. It is thus possible to recognize a number of

Natural
distinc-
tions

Living and
nonliving
systems

more or less autonomous disciplines, each permitting generalization, but ordered so that the more complex events treated by one discipline can also be analyzed in terms of less complex events treated by another discipline. It is possible, for example, to establish a body of generalizations about human society independent of the behaviour of individual persons; a number of generalizations about individual behaviour without consideration of the physiology of the sensory, conductor, and effector mechanisms involved; and a large body of generalizations about muscle or nerve physiology without considering the molecular mechanisms involved. A particularly striking feature of the hierarchy is that an increase in complexity is coupled with the emergence of new characteristics. The origin and development of life from small systems that synthesized biochemicals to organisms that perform highly complicated functions suggests that the hierarchical arrangement of nature and the sciences is correlated with the temporal order of evolution. The maintenance of a steady state by metabolism, reproduction, responsiveness, modification of response by experience, tradition, and social phenomena are just some of the more dramatic examples of emergent phenomena. The emergence of new qualities as evolution proceeds might generally characterize the universe.

Moreover, photosynthesis, on the one hand, and reproduction followed by natural selection, on the other, provide a mechanism by which physically less probable systems can emerge locally from physically more probable ones. Though it frequently has been supposed that physical evolution is at an end, there is no reason to suppose that this is true of social development, for which Sir Julian Huxley, a biologist, philosopher, and educator, provided an evolutionary context. In his *Romanes Lectures*, published in 1943, Huxley wrote:

It is only through social evolution that the world-stuff can now realize radically new possibilities. Mechanical interaction and natural selection still operate, but have become of secondary importance. For good or evil, the mechanism of evolution has in the main been transferred [in man] onto the social or conscious level. . . . The slow methods of variation and heredity are outstripped by the speedier processes of acquiring and transmitting experience. . . .

And in so far as the mechanism of evolution ceases to be blind and automatic and becomes conscious, ethics can be injected into the evolutionary process. Before man that process was merely amoral. After his emergence onto life's stage it became possible to introduce faith, courage, love of truth, goodness—in a word moral purpose—into evolution. It became possible, but the possibility has been and is often unrealized.

It may well be that social evolution is only in its early stages. These stages, moreover, have for the most part taken place in a period during which systematic knowledge was undeveloped. A Russian mineralogist, Vladimir Vernadsky, the founder of biogeochemistry, regarded the envelope of the Earth as passing from a stage determined primarily by biological processes to one determined by conscious human effort. He called this layer of consciousness the *noösphere*. The concept was later extended, notably by Pierre Teilhard de Chardin, a French priest and paleontologist, who began the building of a new philosophic bridge between biology and religion.

The nature of biological systems. Questions about the character of biological systems and of the biological world merge with those about the concepts and methods required for their understanding. Although the two cannot be wholly separated, in this account those matters most clearly related to the substantive philosophical aspects of biology will be stressed. Methodological issues will be touched on in respect to the concepts being elucidated.

Origin and definition of life. Space exploration has directly influenced the development of life-detecting devices. This technological need spurred intensive study regarding the kinds of evidence living things display reflecting their aliveness. In his *Chance and Necessity* (1972) Jacques Monod, a biologist, deals with the invariance of genetic endowment, morphological autonomy, reproductive invariance, and telonomy (the tendency to have a purpose or project written into their molecules) as the major properties of living systems; he considers that they involve the chance and necessity that determine

the course and character of the entire biological world.

Philosophers have long deliberated over the definitive features of living systems. The distinction between living and nonliving, which was widely discussed at the turn of the 20th century, has lost much of its interest for current biology. A growing conviction, intuitively felt by many biologists, is that no clear line can be drawn between the living and the nonliving. The bridge between what is and is not obviously alive consists of a range of problematic agents, including viruses and genes, which appear to be living at times and nonliving at other times.

Viewpoints on the nature of life. Basically and traditionally, there are three distinct philosophical stands regarding the biological nature of life: vitalism, mechanism, and organicism.

Essentially, vitalism holds that there exists in all living things an intrinsic factor—elusive, inestimable, and unmeasurable—that activates life. In its classic form, as espoused by many biologists at the turn of the 20th century—in particular, by Hans Driesch, a German biologist and philosopher—it has suffered severe criticism. Ernest Nagel, a philosopher of science, rang its death knell in 1951, when he wrote in *Philosophy and Phenomenological Research* (11:327 ff.):

Vitalism of the substantial type . . . is now a dead issue . . . less, perhaps, because of the methodological and philosophical criticism that has been leveled against the doctrine than because of the infertility of vitalism as a guide in biological research and because of the superior heuristic value of alternative approaches.

And whereas most biologists concur in renouncing this so-called naïve vitalism, some continue to espouse a so-called critical vitalism, perhaps indistinguishable from organicism (see below).

Simply stated, the view of the mechanists is that organisms are no different from subtle machines: the whole is the sum of its parts, which are arranged in such a way that an internal energy source can move them in accordance with a built-in program of purposeful action. In the mechanist's view, advances in molecular biology corroborate this claim and demonstrate that in principle organisms are no more than complicated physical systems. This is, in essence, the reductionist position, which states that biological principles can be reduced to physical and chemical laws. Antireductionists, of course, contend that molecular biology cannot explain all aspects of living forms.

It has often been said that, whereas biologists may think as vitalists—and hold the conviction that organisms are more than just complex machines—they perforce become practicing mechanists in the laboratory, required by the demands of scientific inquiry to view their experiments in terms of the measurable parameters of physics and chemistry. K.F. Schaffner, an American philosopher, suggested in 1967 that, even though reductionism may be correct, a better strategy may be to strive toward an independent biology.

The basic claim of organicism is that organisms must be interpreted as functioning wholes and cannot be understood by means of physics and chemistry alone. Few scientists today call themselves organismic biologists or endorse the doctrines put forward by such organismic theorists as Ludwig von Bertalanffy and Edward Stuart Russell. Nevertheless, most antireductionists subscribe at least to part of the organismic doctrine, in particular to its wholistic claim. Russell, a foremost proponent of organicism, stated in his work *The Interpretation of Development and Heredity* (1930):

Any action of the whole organism would appear then to be susceptible of analysis to an indefinite degree—and this is in general the aim of the physiologist, to analyze, to decompose into their elementary processes the broad activities and functions of the organism. But . . . by such a procedure something is lost, for the action of the whole has a certain unifiedness and completeness which is left out of account in the process of analysis. . . . In our conception of the organism we must . . . take account of the unifiedness and wholeness of its activities . . . since . . . the activities of the organism all have reference to one or other of three great ends, and that both the past and the future enter into their determination. . . . Bio-chemistry studies essentially the *conditions* of action of

Philosophic
views

Vitalism

Mechanism

Organicism

cells and organisms, while organismal biology attempts to study the actual modes of action of whole organisms, regarded as conditioned by, but irreducible to, the modes of action of lower unities.

In some special sense, then, an organism is regarded as being more than a simple sum of its parts; an additional "something" has accrued to it as a result of the unique arrangement of its components. As Morton O. Beckner, a philosopher of biology, asserted in an article in *The Encyclopedia of Philosophy* (5:549):

In the history of biology it is difficult to disentangle vitalistic and organismic strands, since both schools are concerned with the same sorts of problems and speak the same sort of language. The distinction between them was drawn clearly only in the twentieth century. Organismic biology may be described as an attempt to achieve the aims of the murky organismic-vitalistic tradition, without appeal to vital entities.

Further (p. 551):

Organismic biology is to be interpreted as a series of methodological proposals, based on certain very general features of the organism—namely, the existence in the organism of levels of organization with the biological ends of maintenance and reproduction. These features are sufficient to justify "a free, autonomous biology, with concepts and laws of its own," whether or not the higher levels are ultimately reducible to the lower ones.

Organisms as systems. The concept of an organism as a cybernetic, or automatic-control, system is currently influential in biology.

Holism
and
emergence

The holistic concept of an organism—i.e., the theory that the determining factors in biology are its irreducible wholes—owes its success primarily to the existence of control and regulation mechanisms operating at the molecular level that determine development and behaviour. The character of such systems at all levels of analysis—molecular through total organism—is nothing other than a sophisticated kind of cybernetics. Holism and reductionism are similar in this respect. Closely allied to organicism is the old problem of emergent properties dealt with earlier: at each successive level of organization, qualities emerge that cannot be anticipated by the components and that confer an added dimension to each hierarchical level in the biological world.

General
systems
theory

A theoretical and methodological program called general systems theory—presented in its fullest and most persuasive form by Bertalanffy—is an extension of the tenets of organismic biology. It is an attempt to provide a common methodological approach for all of the sciences, based upon the idea that systems of any kind—physical, biological, psychological, and social—operate in accordance with the same fundamental principles. Ideally, it should be possible to deduce the principles applying to a particular sort of system from the more general ones. This approach is one still very much in need of development.

Teleology

Attributions of purpose (teleology) appear frequently in biological writing. Not only do biologists say that parts of organisms have a purpose with respect to the whole, but some hold that life itself is inherently purposive. But the term purpose is both vague and ambiguous. That every biological system—from self-replicating molecules (DNA) to biotic communities—involves specific and identifiable functions is undeniable. But whether, or in what way, functional ends like the reproduction of a cell resemble human intentions or purposes is a matter of some controversy. Even if this matter were settled, a larger question would still remain, viz., whether a biological system as a whole can have a goal that is in some way similar to a human goal—i.e., whether it is programmed with an ultimate purpose. Although resolution of this matter has long been and will continue to be a critical point in the philosophy of biology, much has been done to clarify the issues involved.

Philosophy in evolution. Teleology and determinism. Vitalists and those who subscribe to a Lamarckian view of evolution involving the inheritance of acquired characteristics claim that evolution involves a deterministic finalism, or directedness toward an end. Most evolutionists—among them George Gaylord Simpson—reject that claim and hold that natural selection is the non-random element

in evolution, that which gives evolution direction. Other evolutionists—among them Theodosius Dobzhansky—argue that the chance factors in mutation and selection, in addition to the unpredictability of environmental change, make it impossible to formulate deterministic laws even in experimental populations, let alone in natural populations. Similar considerations by others have led to the claim that evolutionary biology is a paradigm of an after-the-fact exploratory science and that the course of evolution can never be predicted.

The species problem. Whether biological species can be said to have a real existence in the world is a question that has been receiving much consideration. The issue may be posed in the words of Benjamin Burma, a paleontologist, who, writing in *Evolution* (3:369), asked:

What, then, is a species? It would seem thus far to be the whole of any one series of breeding populations. . . . [But the] definition as it stands unfortunately puts all living and fossil animals in one species, since there is a continuity of germ-plasm back from John [an individual animal] to the original primordial cell, and from it forward to every living animal (not to mention plant). Thus, if we ignore time, we end up with only one species. . . .

The temporal difficulty, however, is not the only stumbling block to the question of species reality; for, if the species is redefined as the whole of any one series of breeding populations as it exists at any one time, then there is an infinity of species, since time itself is infinitely divisible. On the basis of these and other objections, some biologists have concluded that species have only a subjective existence merely as convenient labels for arbitrary assemblages and have only a minimum of biological significance. On the other hand, there are proponents of the idea that species have an objective reality. Ernst Mayr, a U.S. evolutionist representing the latter group, has written—also in *Evolution* (3:372):

In all multidimensional situations an inference has to be made (Simpson, 1943) on the basis of the objective species of the non-dimensional system. The subjectivity of this expanded species concept by no means invalidates the species concept per se. The species of the local naturalist or of the paleontologist within a given horizon is clearly delimited against other species and can thus be considered as having objective reality.

Although the controversy is confused by semantic difficulties, one of the chief contributions of the philosophy of biology has, in fact, been to separate mere linguistic puzzles from matters of substance. Many taxonomists are guilty of ambiguity of reference; they often fail to distinguish their entities clearly, with the result that there is widespread befuddlement over just what stand is held by whom. The problems are now clearer than they have ever been, and with few exceptions biologists and philosophers tend to agree about the nature of biological species and the definition of the species category.

Evolutionary theory. Although most of the issues connected with evolution as a theory are methodological ones, two issues go beyond the limits of logic. Some philosophers have tried to demonstrate, for example, that evolutionary theory is circular and offers no real understanding of the process of evolution. Others have argued that the notions of types of organisms must be used to understand evolution and that evolutionary change takes place when a new type emerges.

Two clear viewpoints regarding evolutionary theory have come to the fore since 1950. One is expressed in detail by George Gaylord Simpson, in his work *The Major Features of Evolution* (1953), and the other is put forward by a paleontologist, Otto Schindewolf, in his *Grundfragen der Paläontologie* (1950). In 1959, Marjorie Grene, a philosopher of biology, writing in the *British Journal of the Philosophy of Science* (9:11 ff.), summarized their positions as follows:

Professor Simpson is the principal American spokesman of neo-Darwinism. . . . He sees evolution as a continuous series of minute changes in innumerable directions, in which all alterations of any significance, larger as well as smaller, quicker as well as slower, are determined by the great cooperating "pressures" of mutation, geographical isolation, and selection, with adaptation as the universal effect, and criterion, of systematic change. The basic concept, ultimately is variation in

The
views of
Simpson
and
Schinde-
wolf

the occurrence of genes; out of such variations all the systematic relations of living things have been gradually evolved.

Schindewolf's principles are simpler. He sees typical shapes, and sees again and again what appear to be new shapes. Therefore he assumes that living things are able to originate novel types. Mutation, he agrees, must have been the mechanism by which they originated; but the adaptive control of mutation occurs only within, not between types. The basic pattern is of change from type to type, and always, as we have seen, with the more general appearing before its specialised subdivisions.

The controversy between these two opposing viewpoints is a complex one filled with both philosophical and scientific issues. In the opinion of most biologists, Schindewolf's view is persuasive only with respect to the paleontological evidence and is not supported by the experimental study of evolution in current organisms. Most of them thus tend to accept the synthetic theory in more or less the form expressed by Simpson. It remains possible, however, that the process that Schindewolf is talking about is fundamentally different from that explored in population genetics and that tyostrophic mutations are so rare, on the time scale of man, as to be beyond hope of detection in the laboratory.

Evolution as a world view. Very few attempts have been made in recent years to employ the concept of evolution as a scheme for viewing all knowledge and experience. Sir Julian Huxley, who remains one of the best representatives of such an effort, continues to claim that the entire universe is in a process of evolution, which, however, has different aspects, viz., physical, biological, and social. Life and nonlife alike must be understood as part of the process of cosmic evolution, and from this follows a host of metaphysical and ethical implications. The other chief representative of this viewpoint is the evolutionist priest Teilhard de Chardin, who has woven into the fabric of cosmic evolution the panoply of a Christocentric religion that sees the perfection of all things in an "Omega" point toward which evolution is moving.

Metaphysics of the more piecemeal kind—exploring the implications that biological knowledge has on beliefs and attitudes—is fostered by Simpson, a consistent antagonist of Huxley and Chardin. Simpson suggests, for instance, that knowledge of man's origins and of the process that has brought him to his current state in no way threatens belief in his own uniqueness. Man is an animal, but a very special sort of animal. Other matters of a similar kind—purpose in nature and man's evolutionary future—are considerations that constitute the implications of biology in general and of evolutionary biology in particular.

Biology and ethics. *The question of innate aggressiveness.* One of the best known issues threatening accepted beliefs about moral responsibility is probably that raised by the proponents of the theory of innate aggression, in particular by such spokesmen as Konrad Lorenz, an Austrian student of animal behaviour, and Robert Ardrey, a U.S. writer. If there is an instinct for aggressiveness, then the notion that it is acceptable to blame individuals and society for outbreaks of violence or war loses its validity. The thrust must then be elsewhere: not in faultfinding but in shoring up against what is felt to be pedestrian and inevitable. As Ardrey puts the theory in his *African Genesis* (1961):

But we were born of risen apes, not fallen angels, and the apes were armed killers besides. And so what shall we wonder at? Our murders and massacres and missiles, and our irreconcilable regiments? Or our treaties whatever they may be worth; our symphonies however seldom they may be played; our peaceful acres, however frequently they may be converted into battlefields; our dreams however rarely they may be accomplished. The miracle of man is not how far he has sunk but how magnificently he has risen. We are known among the stars by our poems, not our corpses.

Raymond Dart, a South African anatomist and anthropologist, in an article entitled "The Predatory Transition from Ape to Man," published in the *International Anthropological and Linguistic Review* (1:201–208), expressed the thesis of innate depravity on which Ardrey's more popular presentation is based.

Another aspect of the innate aggression inherited from man's primate forebears is militant enthusiasm,

which Lorenz described in *Das sogenannte Böse: zur Naturgeschichte der Aggression* (1963; Eng. trans., *On Aggression*, 1966):

In reality, militant enthusiasm is a specialized form of communal aggression, clearly distinct from and yet functionally related to the more primitive forms of petty individual aggression. Every man of normally strong emotions knows, from his own experience, the subjective phenomena that go hand in hand with the response of militant enthusiasm. A shiver runs down the back and, as more exact observation shows, along the outside of both arms. One soars elated, above all the ties of everyday life, one is ready to abandon all for the call of what, in the moment of this specific emotion, seems to be a sacred duty. All obstacles in its path become unimportant; the instinctive inhibitions against hurting or killing one's fellows lose, unfortunately, much of their power. Rational considerations, criticism, and all reasonable arguments against the behavior dictated by militant enthusiasm are silenced by an amazing reversal of all values, making them appear not only untenable but base and dishonorable. Men may enjoy the feeling of absolute righteousness even while they commit atrocities. Conceptual thought and moral responsibility are at their lowest ebb. As a Ukrainian proverb says: "When the banner is unfurled, all reason is in the trumpet."

Equally notable opponents of the theory of innate aggression see it much as M.F. Ashley Montagu, a British-U.S. anthropologist, does, as "original sin revisited," and deplore the tendency to neglect authoritative studies in favour of simplistic popularization. In *Man and Aggression* (1968), he writes:

While the findings of these disciplines [anthropology and the behavioral sciences] are wholly opposed to the deeply entrenched view that man is an innately aggressive creature, most people tend to dismiss these findings out of hand or ridicule them as a rather eccentric idealistic heterodoxy, which do not deserve to become generally known. In preference to examining the scientific findings they choose to cast their lot with such "authorities" as William Golding who, in his novel *Lord of the Flies*, offers a colorful account of the allegedly innate nastiness of human nature, and Robert Ardrey who, in *African Genesis* and more recently in *The Territorial Imperative*, similarly seeks to show that man is an innately aggressive creature. . . .

. . . when through the distorting glass of his prejudgments he looks at a tool it becomes not simply a scraper but a weapon, a knife becomes a dagger, and even a large canine tooth becomes "the natural dagger that is the hallmark of all hunting animals," while in "the armed hunting primate" it becomes "a redundant instrument." "With the advent of the lethal weapon natural selection turned from the armament of the jaw to the armament of the hand." But the teeth are no more an armament than is the hand, and it is entirely to beg the question to call them so. Virtually all the members of the order of primates, other than man, have large canine teeth, and these animals, with the exception of the baboons, are predominantly vegetarians. . . . that such teeth may, on occasion, serve a protective purpose is entirely secondary to their main function, which is to rip and shred the hard outer coverings of plant foods.

Further responses to Ardrey's and Lorenz' thesis are the interpretations of field studies of primate groups, such as those on the gorilla, chimpanzee, and orangutan. These researches suggest that the majority of such groups are singularly free of belligerence. According to Montagu,

The myth of the ferocity of "wild animals" constitutes one of Western man's supreme rationalizations, for it not only has served to "explain" to him the origins of his own aggressiveness, but also to relieve him of the responsibility for it—for since it is "innate," derived from his early apelike ancestors, he can hardly, so he rationalizes, be blamed for it! And some have gone so far as to add that nothing can be done about it, and that therefore wars and juvenile delinquents, as Mr. Ardrey among others tells us, will always be with us! From one not-so-minor error to another Mr. Ardrey sweeps on to the grand fallacy.

The matter remains moot; but there appears to be a growing consensus that, given a certain genetic constitution—and within the bounds of that endowment—whatever man is, he learns to be, especially in respect to values, morality, and customs. Baser appetitive needs, however, may have a genetic component that is greater than an environmental one.

New understanding of environmental factors and the consequences of man's actions with respect to them has made

Montagu's
view

Views
of the
ethologists

it clear that man has acquired responsibilities that he did not recognize before. It has become increasingly accepted that standards and values with respect to the environment must be established; this is perhaps the most dramatic case in which recent biological knowledge has generated a crisis of a moral kind. The classic work *Science and Survival* (1966) by a biologist, Barry Commoner, is particularly noteworthy in connecting theoretical and philosophical issues about reductionism and holism to practical matters of environmental understanding and problem solving.

The metaphysical issue of man's place in nature is now being construed as one that requires that man make value decisions, assign responsibilities, and plan for the future of his planet. Environmental problems have become intertwined with problems of social planning, racial tension, transportation and housing crises, genetic engineering, and a host of other current concerns.

Evolutionary ethics. The question of whether nature provides guides to the actions of humankind has held a fascination for many biologists. Those who call themselves evolutionary ethicists say that it does. The defenders of evolutionary ethics contend that external moral standards exist in the facts and process of evolution.

Toward the end of the 19th century, Herbert Spencer, in England, and others advanced a series of principles that came to be called Social Darwinism. It espoused such ideas as the inevitability of progress, survival of the fittest, and the struggle for existence, expressions that have become bywords although they have since been discredited in their original sense, as applied to social phenomena. Social Darwinism, as C.H. Waddington, a biologist, explains in his book *The Ethical Animal* (1960, has been superseded by

... the more recent phase of evolutionary ethical thought beginning in the early 1940s, [which] comprises a number of rather different methods of approach. At one extreme we have discussions framed in terms of extremely wide scope, which treat of evolution not only in the animal world but throughout the cosmos, and attempt to relate such broad concepts to man's religious and spiritual life. The pre-eminent example of this tendency in recent years is Teilhard de Chardin, but a rather similar approach can be found in the works of several biologists, such as Conklin, Holmes, and Huxley. The opposite tendency, which of course is also found expressed to various extents in these authors, particularly in Julian Huxley, is the attempt to demonstrate, in a logically coherent argument, a real connection between evolutionary processes and man's ethical feelings.

Some biologists continue to insist, therefore, that biological facts can provide a yardstick by which to measure the morality of a given course of action. Julian Huxley, for one, has long claimed that moral principles can be found in nature and in the evolutionary process in particular:

When we look at evolution as a whole, we find, among the many directions which it has taken, one which is characterized by introducing the evolving world-stuff to progressively higher levels of organization and so to new possibilities of being, action, and experience. This direction has culminated in the attainment of a state where the world-stuff (now moulded into human shape) finds that it experiences some of the new possibilities as having value in or for themselves; and further that among these it assigns higher and lower degrees of value, the higher values being those which are more intrinsically or more permanently satisfying, or involve a greater degree of perfection.

Huxley further asserts that, although the Golden Rule, the policy of action based on sympathy—doing as one would be done to by others—may be an immediate good, it ultimately leads to the suppression of those qualities most needed for survival and the continuation of a species. Rather, he argues:

The facts of nature, as demonstrated in evolution, give us assurance that knowledge, love, beauty, selfless morality, and firm purpose are ethically good. . . . In the broadest possible terms evolutionary ethics must be based on a combination of a few main principles: that it is right to realize ever new possibilities in evolution, notably those which are valued for their own sake; that it is right both to respect human individuality and to encourage its fullest development; that it is right to construct a mechanism for further social evolution which shall satisfy these prior conditions as fully, efficiently, and as rapidly as possible.

Simpson, however, contends, in the article "Biological Sciences," in *The Great Ideas Today* (1965):

The facts and the processes of evolution are neither ethical nor unethical. The questions of good or bad are simply irrelevant to this field, with the important reservation that evolution has produced a species, *Homo sapiens*, concerned with ethics. Denial of man's naturalistic origin and animal nature is flatly false, and any ethic based on such denial is invalid. Evolution controverts primitive creation myths, but it is consistent with higher values in the Judeo-Christian tradition and those in most now-current religions and philosophical systems. One need only think of the brotherhood of mankind—a biological fact, not only an ethical idea.

Beyond such considerations as those, efforts to combine science and religion may be noble in intention but usually end up distorting or stultifying both. One of the most striking examples at present is the cult, as it may fairly be called, of Pierre Teilhard de Chardin. He preaches—necessarily posthumously, for the Roman Catholic Church suppressed his views during his life—a mystical Christianity ostensibly derived from evolutionary principles. But since the mysticism is primary, the evolutionary principles are distorted and downright falsified for seeming coherence with the nonscientific, nonnaturalistic premises. In turn, the mystical views advanced as having that false basis are thereby vitiated. The result (in my opinion) has been a disservice to true religion and to true science.

At the same time, no one can deny the purity of Father Teilhard's intentions or the correctness of his view that evolution and religious feeling should be considered congruent aspects of the nature of man. It is almost as irrational to deny evolution as to deny gravity. The management of life and the goals of aspiration, to be sane, must take account of all such truths of nature. They need not thereby become brutal or earthbound.

(J.R.Mn./R.C.Y.)

Philosophy of history

The term history may be employed in two quite different senses: it may mean (1) the events and actions that together make up the human past, or (2) the accounts given of that past and the modes of investigation whereby they are arrived at or constructed. When used in the first sense, the word refers to what as a matter of fact happened, while when used in the second sense it refers to the study and description of those happenings. The notion of philosophical reflection upon history and its nature is consequently open to more than one interpretation, and contemporary writers have found it convenient to regard it as covering two main types of undertaking. On the one hand, they have distinguished philosophy of history in the traditional or classical sense; this is conceived to be a first-order enquiry, its subject matter being the historical process as a whole and its aim being, broadly speaking, one of providing an overall elucidation or explanation of the course and direction taken by that process. On the other hand, they have distinguished philosophy of history considered as a second-order enquiry; here attention is not focussed upon the actual sequence of events themselves but, instead, upon the procedures and categories used by practicing historians in approaching and comprehending their material. The former, often alluded to as speculative philosophy of history, has had a long and varied career; the latter, which is generally known as critical or analytical philosophy of history, has only risen to prominence during the 20th century.

SPECULATIVE THEORIES

The idea of an order or design in history. The belief that it is possible to discern in the course of human history some general scheme or design, some all-encompassing purpose or pattern, is very old and has found expression in various forms at different times and places. The reasons for its persistence and vitality are numerous, but two very general considerations may be identified as having exercised a fairly continuous influence. First, it has often been supposed that, if the belief in an overall pattern is abandoned, one is obliged to acquiesce in the view that the historical process consists of no more than an arbitrary succession of occurrences, a mere agglomeration or patchwork of random incidents and episodes. But such a view (it has been contended) cannot be seriously entertained, if only because it conflicts with the basic demand for system

The necessity for a meaningful view of history

Social
Darwinism

Evolution
and
morality

and order that underlies and governs all rational enquiry, all meaningful thought about the world. Second, it has frequently been felt that to refuse to allow that history is finally intelligible in the required manner implies a skepticism concerning the value of human life and existence that constitutes an affront to the dignity of human nature. The 18th-century German philosopher Immanuel Kant, for example, spoke of the “repugnance” that is inevitably experienced if the past is viewed

as if the whole web of human history were woven out of folly and childish vanity and the frenzy of destruction, so that one hardly knows in the end what idea to form of our race, for all that it is so proud of its prerogatives.

In more recent times, a comparable attitude is discernible beneath Arnold Toynbee's uncompromising repudiation of the idea that history is “a chaotic, disorderly, fortuitous flux, in which there is no pattern or rhythm of any kind to be discerned.” Thus, it has been the object of a long line of theorists, representative of widely divergent outlooks, to demonstrate that such pessimism is unjustified and that the historical process can, when appropriately viewed, be seen to be both rationally and morally acceptable.

Theological origins. Western speculation concerning the meaning of history derived in the first instance chiefly from theological sources. The belief that history conforms to a linear development in which the influence of providential wisdom can be discerned, rather than to a recurrent cyclical movement of the kind implicit in much Greco-Roman thought, was already becoming prevalent early in the Christian Era. Traces of this approach are to be found in the conception of the past set forth by St. Augustine in his *City of God* and elsewhere; it is, for example, compared on one occasion to “the great melody of some ineffable composer,” its parts being “the dispensations suitable to each different period.” Yet the cautious subtlety of Augustine's suggestions and the crucial distinction he drew between sacred and secular history make it important not to confuse his carefully qualified doctrines with the cruder positions advanced by some of his self-proclaimed successors. This applies, *par excellence*, to the work of the most renowned and thorough of these, Jacques-Bénigne Bossuet. Written 1,250 years after Augustine's death, Bossuet's *Discours sur l'histoire universelle* (1681; “Discourse on Universal History”) is imbued throughout with a naïve confidence that the entire course of history owes its pervasive character to the contrivance of a “higher wisdom.” In the eyes of Bossuet, to grasp and understand the great procession of empires and religions was “to comprehend in one's mind all that is great in human affairs and have the key to the history of the universe.” For the rise and fall of states and creeds depended in the end upon the secret orders of Providence, the latter being the source of that manifest historical justice and retribution to which, on nearly every page, the annals of the past bore clear and unmistakable witness. Bossuet's vast survey was, in fact, the last major contribution to its genre. Though it made a considerable impression when it was first published, it appeared just before the discoveries of Sir Isaac Newton effected a massive transformation of the European outlook, and the book's impact was short-lived. Thus, the development of historical speculation in the 18th century was generally marked by a tendency to reject theological and providential interpretations in favour of an approach more closely aligned, in method and aim, to that adopted by natural scientists in their investigations of the physical world.

Secular approaches: the Enlightenment and beyond. For many Enlightenment and post-Enlightenment thinkers, the project of establishing a science of history and society, comprising hypotheses and laws of an explanatory power analogous to that attained by theories in the physical sciences, acquired an almost obsessive importance. The age of religious and metaphysical conjectures concerning the destiny of human affairs had, in their opinion, come to a close. The task that now presented itself was one of constructing, upon the basis of hard observable facts, interpretations that would not only rescue the human studies from ignorance, uncertainty, and primitive superstition but also put into men's hands an instrument for predict-

ing and controlling their fate. Thus, the idea of creating a universally valid social science, capable of accounting for the phenomena of history in terms of causal principles comparable to those employed in the natural sphere, came to be linked with the promotion of reformist and revolutionary ideals. Men such as Condillac and Condorcet in the 18th century and Henri de Saint-Simon, Auguste Comte, John Stuart Mill, and Henry Thomas Buckle in the 19th century all believed that it was feasible to apply scientific procedures to the study of human development. But equally—though in widely different ways—they were men deeply concerned with practical objects and committed to changing existing institutions and ways of life. To these men, theory was complementary to practice; knowledge was power.

Yet even in the 19th century, when speculation of this type was at its height, there were informed skeptics—Joseph de Maistre and Arthur Schopenhauer, for example, and later the great Swiss historian Jacob Burckhardt—who challenged the optimistic and rationalistic presuppositions on which it was founded. It was pointed out that notions such as that of the perfectibility of man or of the existence of some foreseeable goal toward which the course of events was inexorably leading were not empirically established truths but mere articles of faith; in subscribing to them, historical theorists often appeared to be tacitly importing into their allegedly scientific interpretations teleological conceptions of a kind that it had been their declared intention to banish forever from social enquiry. These objections have been repeated and amplified by 20th-century critics such as Karl Popper, who have also maintained that the theorists in question were, in any case, working with an unacceptably crude notion of scientific reasoning and that their high-sounding generalities conspicuously failed to measure up to the requisite standards of conceptual precision and observational testability.

Although such strictures have considerable force, they should not obscure the significant contribution that had been made toward extending human knowledge and understanding. The tendency, for example, to insist upon the relevance of scientific modes of procedure to the areas of historical and social investigation at least achieved the salutary effect of throwing into relief the inadequacy of previous work in these domains; moreover, it indirectly brought to the fore the entire question of the status of history as a legitimate form of thought. For, if history should prove resistant to attempts to assimilate it to other accredited branches of enquiry, it would be necessary to show why this was so and to exhibit those features of historical thinking that lent it its distinctive and irreducible character.

The new science: Vico and Herder. Among the 18th-century theorists, two writers can indeed be picked out who—while remaining firmly within the speculative tradition—at the same time possessed sufficient genius and prescience to realize that the solution to the problem of establishing history as a reputable discipline might be found by pursuing a course different from one modelled upon the methodology of the natural sciences. Partly because of the obscure and scholastic manner in which it was written, Giambattista Vico's *Scienza nuova* (3rd ed. 1744; “New Science”) was a work whose importance remained for a long time wholly unrecognized, and it is only fairly recently that its significance and originality have been fully appreciated.

Central to the book is the contention that the kind of knowledge that men can achieve of their own actions, creations, and institutions is of a radically different type from the knowledge that is acquired by the observation and investigation of the nonhuman or natural world; knowledge of the former variety is, moreover, held to be in principle superior to that of the latter. For, in Vico's opinion, in order truly to know something it is necessary in some sense to have made it: it followed that, whereas the reality studied by the physical scientist is the creation of God and therefore only properly known by God, the “world of nations” that forms the subject matter of history is the creation of men and is therefore something that men can “hope to know.” Thus, Vico was led to

19th-century skepticism

Augustine and Bossuet

Vico's notion of unique historical knowledge

stress the differences rather than the analogies between historical and other forms of enquiry; in particular, he emphasized the need for the historian to enter imaginatively into the spirit of past ages, re-creating the outlooks and attitudes that informed them as opposed to seeking to impose upon them inappropriate or falsifying interpretations—"pseudomyths"—that derived from the cultural ethos of his own time. Vico propounded a cyclical theory of human history, according to which "nations" or societies pass through determinate stages, and he combined this with the idea that a providential principle is in some manner immanent within the various forms of life that men construct. He employed such conceptions, however, in a fashion that underlined man's nature as a historical being, whose powers and capacities do not conform to a fixed or static pattern but are necessarily subject to change and development in the course of time.

Herder's
rejection
of static
laws

In a similar vein, the German writer Johann Gottfried von Herder, in his influential *Ideen zur Philosophie der Geschichte der Menschheit* (4 vol., 1784–91; Eng. trans., *Outlines of a Philosophy of the History of Man*, 1800), implied that it was vital to view human actions and achievements from a standpoint that took proper account of "time, place and national character"—in other words, cultural milieu and the inevitable limits imposed by historical situation and circumstance. In its general direction, Herder's historical thought reflected the Enlightenment preconceptions of man as a progressive being. Herder's chief importance lies, however, in his insistence upon the misconceptions involved in treating the products of past thought and action as if they were the manifestations of an unchanging human consciousness and as if they could be explained by reference to abstract laws eternally valid for men everywhere. According to Herder, such an approach failed to recognize the complex influences that act upon human beings as members of particular historical societies; each of these societies possessed its unique life-style, subtly but inescapably determining the mentalities of those born within its confines in a manner that rendered futile all attempts to reduce human propensities and needs to the terms of some simple set of abstract formulas.

Many of Vico's and Herder's ideas appear familiar today, but it is easy to forget that the emergence of what has come to be known as the "historical sense" is a comparatively recent phenomenon, one that represents a genuine revolution in European thought. It is largely because of this revolution that social and political theories of the kind elaborated by men such as Thomas Hobbes and Benedict de Spinoza in the 17th century seem oddly artificial to 20th-century eyes, so remote are the categories in which they sought to explain human life and behaviour from those that have subsequently found acceptance.

History as a process of dialectical change: Hegel and Marx. The suggestion that there is something essentially mistaken in the endeavour to comprehend the course of history "naturalistically" and within an explanatory framework deriving from scientific paradigms was powerfully reinforced by conceptions stemming from the development of German Idealism in the 19th century. Hegel's "philosophy of the spirit" made its appearance upon the intellectual scene contemporaneously with Saint-Simonian and Comtean Positivism, rivalling the latter in scope and influence and bringing with it its own highly distinctive theory of historical evolution and change. Hegel's stress upon the "organic" nature of social wholes and the incommensurability of different historical epochs owed evident debts to Herderian ideas, but he set these within an overall view that pictured the movement of history in dynamic terms. Regularities and recurrences of the sort that typically manifest themselves in the realm of nature are foreign, Hegel maintained, to the sphere of mind or spirit, which was characterized instead as involving a continual drive toward self-transcendence and the removal of limitations upon thought and action. Man was not to be conceived according to the mechanistic models of 18th-century Materialism; essentially he was free, but the freedom that constituted his nature could only achieve fulfillment through a process of struggle and of overcoming obstacles that were themselves the expression of his own

History as
a dynamic
process

activity; it was in this sense that Hegel claimed that spirit was "at war with itself"—"it has to overcome itself as its most formidable obstacle" (*Lectures on the Philosophy of History*). In concrete terms, this meant that historical advance did not proceed through a series of smooth transitions. Once the potentialities of a particular society had been realized in the creation of a certain mode of life, its historical role was over; its members became aware of its inadequacies, and the laws and institutions they had previously accepted unquestioningly were now experienced as fetters, inhibiting further development and no longer reflecting their deepest aspirations. Thus, each phase of the historical process could be said to contain the seeds of its own destruction and to "negate" itself; the consequence was the emergence of a fresh society, representing another stage in a progression whose final outcome was the formation of a rationally ordered community with which each citizen could consciously identify himself and in which there would therefore no longer exist any sense of alienation or constraint. Somewhat curiously, the type of community Hegel envisaged as exemplifying this satisfactory state of affairs bore a striking resemblance to the Prussian monarchy of his own time.

The notion that history conforms to a "dialectical" pattern, according to which contradictions generated at one level are overcome or transcended at the next, was incorporated—though in a radically new form—in the theory of social change propounded by Karl Marx. Like Hegel, Marx adopted a "directional" view of history; but, whereas Hegel had tended to exhibit it as representing the unfolding in time of an inner spiritual principle, Marx looked elsewhere for the ultimate determinants of its course and character. Man, according to Marx, was a creative being, situated in a material world that stood before him as an objective reality and provided the field for his activities; this primitive truth, which had been obscured by Hegel's mystifying abstractions, afforded the key to a proper understanding of history as a process finally governed by the changing methods whereby men sought to derive from the natural environment the means of their subsistence and the satisfaction of their evolving wants and needs. The productive relations in which men stood to one another, resulting in such phenomena as the division of labour and the appearance of economically determined classes, were the factors fundamental to historical movement. What he termed the superstructure of society—which covered such things as political institutions and systems of law, ethics, and religion—was in the last analysis dependent upon the shape taken by the "material production" and the "material intercourse" of human beings in their struggle to master nature: "it is not the consciousness of men that determines their being, but, on the contrary, their social being that determines their consciousness." Hence, the inner dynamic of history was held to lie in conflicts arising from changes in the means of production and occurring when modes of social organization and control, adapted to the development of the productive forces at one stage, became impediments to it at another; they were to be resolved, furthermore, not by abstract thought but by concrete action. Thus, the Hegelian conception of spirit as involved in a relentless struggle with itself and with what it had created underwent a revolutionary transformation, explosive in its implications.

Marx's interpretation of the historical process, with its stress upon necessity and the operation of ineluctable laws, has often been portrayed by its proponents as being scientific in character. It has, however, more than one aspect, and it would be an error to identify its underlying methodology with that associated with Comtean Positivism. Generally speaking, the basic categories within which it was framed derived from a theory of human nature that had more in common with the postulates of German romantic thought than with those of British and French Empiricism: to this extent, the logical structure Marx sought to impose upon the data of history belonged to a tradition that stressed the differences rather than the resemblances between the human and the natural world.

Twentieth-century systems. The tendency to detect in history the presence of large-scale patterns and compre-

Economic
determin-
ism

Toynbee's
system

hensive uniformities continued into the 20th century in the work of a number of writers, most notably Oswald Spengler and Arnold Toynbee. Spengler's *Decline of the West* (originally published in German, 1918–22), wherein the history of mankind was presented in terms of biologically conceived cultures whose careers conformed to a predetermined course of growth and decay, was widely acclaimed during the years of disillusionment that followed World War I; and a somewhat similar reception was given to Toynbee's massive *A Study of History* (1934–61) immediately after World War II. Toynbee, like Spengler, undertook a comparative study of civilizations, thereby repudiating attempts to treat the past as if it exhibited a single linear progression: at the same time, he diverged from Spengler in suggesting that current Western society might not after all be necessarily doomed to extinction and in tempering a predominantly deterministic mode of thought with reservations that allowed a place for human free will and the possibility of divine intervention. Yet, as some of his critics were quick to point out, such qualifications were not easy to reconcile with his original insistence upon the need to adopt "a scientific approach to human affairs"; nor was it clear that his own use of inductive methods to establish the laws governing the development of civilizations was above logical suspicion or reproach. Toynbee's experiment might have been impressive as an individual achievement; nevertheless, with the multiplication of objections and in a theoretical climate that had become skeptical of speculative system-building of any kind, the very feasibility of engaging upon a project of the type he had undertaken came to be seriously questioned. It was felt increasingly that philosophy of history in the traditional sense—resting largely upon uncriticized assumptions concerning the nature of historical enquiry and its relations with other disciplines—had reached something of an impasse; if history was still to be treated as a proper subject for philosophical examination, it must be along lines quite different from those previously pursued.

ANALYTICAL PROBLEMS

The concept of history. The task of trying to delineate the specific character of historical knowledge and understanding, rather than of seeking to construct vast speculative schemes in the earlier manner, first began to attract the attention of philosophers toward the end of the 19th century. To such thinkers as Wilhelm Dilthey and Benedetto Croce, the claim that, in the absence of some all-embracing system of a teleological or quasi-scientific kind, the course of history could be regarded as constituting nothing better than a meaningless chaos appeared to be totally unacceptable. History is intelligible, they believed, in the sense that historians make it so; moreover, this was the only type of intelligibility it was either necessary or legitimate to demand. What could reasonably be looked for was a clearer and deeper insight into the conditions that render historical knowledge possible, an elucidation of the presuppositions upon which historical enquiry is founded and of the principles according to which it proceeds. It was with such an investigation in mind that R.G. Collingwood, a British philosopher who owed much to Crocean ideas, wrote in his *Autobiography* that "the chief business of twentieth-century philosophy is to reckon with twentieth-century history." By contending that the philosopher should eschew the grandiose ambition of providing a synoptic vision of the entire historical process and concern himself, instead, with the articulation and justification of existing historical procedures, Collingwood and his continental precursors made, in effect, a crucial contribution toward setting philosophy of history on a new path. Their proposals were, moreover, given additional impetus by the widespread acceptance of analytical approaches in other branches of philosophy. In consequence, contemporary thinkers have tended to focus attention upon the explication of concepts and terms that perform a key role in historical thought and description as these are actually carried on: among other things, they have been led into discussing the ways in which historians typically divide up and classify the past, the manner in which they argue for and substantiate their interpretations,

and the logical structure of the explanations they are accustomed to offer.

Explanation and understanding. Both Croce and Collingwood, in their criticisms of earlier theorists, were especially anxious to expose what they believed to be recurrent and fundamental misconceptions regarding the method and subject matter of history: central to these was the assumption that historical occurrences could be subsumed under, and explained in terms of, universal laws of the sort that played an essential part in scientific interpretations of inanimate nature. This assumption was, in their opinion, a gross error. As Collingwood put it, the moment had arrived for history to be released from "its state of pupillage to natural science." With this in mind, he went on to develop an account of historical understanding according to which the historian explains events by exhibiting them as the expressions of past thinking on the part of self-conscious purposive agents—thinking that the historian must imaginatively reconstruct or re-enact in his own mind—rather than by showing the events to be instances of general uniformities or regularities that are established by induction. In propounding this view—which Croce, though he formulated it less clearly and precisely, basically shared—Collingwood set in motion a controversy concerning knowledge and explanation in history that has been central to much subsequent discussion. As Collingwood himself was fully aware, a position similar to his own had been originally advanced (though in a very different context) by Vico; and it is indeed noteworthy that the general division, evident at the speculative level, between those who wished to comprehend historical phenomena in ways suggested by the physical sciences and those who, by contrast, argued for an altogether distinct pattern of interpretation has tended, in recent times, to re-emerge at the level of methodological and conceptual analysis.

Thus, on one side of the dispute, there have ranged philosophers who have taken their stand upon what has been called "the unity of science" and who have insisted that the categories and procedures appropriate to the human studies do not enjoy a unique or privileged status that somehow sets them apart from those characteristic of systematic empirical enquiry in other domains. In a classical 18th-century discussion, David Hume had argued that, if two events were said to be causally related, this could only be in the sense that they instantiated certain regularities of succession that had been repeatedly observed to hold between such events in the past: to presume otherwise was to fall back upon an unacceptable belief in "intuitable" connections that had no warrant either in reason or experience. This doctrine may be said to have been given more rigorous expression among Positivist philosophers of the present century in the shape of what is variously known as the "deductive-nomological" or "covering law" theory of explanation; as originally applied to history by Carl Hempel, it amounted to the claim that explaining a given historical occurrence in terms of some other event or set of events necessarily involves an appeal, which need not be more than tacit, to laws or general propositions correlating events of the type to be explained with those of the kind cited as its causes or conditions. Although the proposed analysis has received a variety of different formulations, each designed to meet specific objections that have been raised against it, its adherents have not wavered from the conviction that some such account must be in principle correct if explanations in history are to be open to rational assessment of the sort properly demanded within any legitimate branch of empirical investigation. It is for this reason, together with others, that they have been strongly opposed to *Verstehen*, or "empathy," theories of historical knowledge, regarding the contention that historical understanding presupposes an allegedly direct identification with the mental processes of past human agents as representing at best a heuristic recommendation of doubtful utility, at worst an obscurantist doctrine that transparently fails to provide an objective criterion whereby divergent historical interpretations can be evaluated.

Resistance to the Positivist approach has come from more than one direction. To a number of practicing historians, for instance, the account offered has appeared implausible

The unity
of science
approach

The work
of R.G.
Colling-
wood

The
criterion
of appro-
priateness

inasmuch as it overlooks the “irreducible particularity” of historical occurrences and because it postulates an unjustifiably high degree of reliance upon the presence of discernible uniformities in the sphere of human affairs. So far as philosophers are concerned, dissatisfaction has been voiced both by those to whom the Croce-Collingwood notion of historical thinking as the “re-enactment of past experience” has seemed to contain an important element of truth and also by those followers of Ludwig Wittgenstein who have been impressed by the skepticism concerning the adequacy of scientific models apparent in his later discussions of mental concepts. A leading representative of the former group, W.H. Dray, not only constructed a series of arguments to demonstrate the deficiencies of the covering-law theory but further proposed an alternative conception of “rational explanation,” which—it was suggested—fitted many of the familiar ways whereby historians seek to render the past intelligible. Thus, Dray has maintained that the function of much historical explanation consists of showing the actions of historical persons to have been “appropriate” when viewed within the perspective of their specific beliefs, aims, and principles: it was this consideration, he claims, that was uppermost in the minds of theorists who were concerned to stress the part played by imaginative or empathetic understanding in historical reconstruction, their point being primarily a “logical” one and not necessarily carrying any of the dubious epistemological implications attacked by Positivist critics. From a different standpoint, Anglo-U.S. writers influenced by Wittgenstein have challenged the entire assumption that explanations involving the notions of human intention and purpose are susceptible to a Humean pattern of causal analysis; they have also (for example, in the work of Peter Winch) stressed the extent to which historical descriptions of past behaviour require to be framed in terms the agents themselves would have recognized as giving meaning to their activities, terms embodying references to ideas and conventions that defined the social reality in which they participated.

Objectivity and evaluation. Fundamental issues concerning the status of historical enquiry of the kind just mentioned have arisen in another crucial area of discussion, centring upon the question of whether—and, if so, in what sense—history can be said to be an objective discipline. Some modern philosophers have inclined to the view that the entirely general problem of whether history is objective cannot sensibly be raised; legitimate questions regarding objectivity are only in place where some particular piece of historical work is under consideration, and in that case there are accepted standards available, involving such matters as documentation and accuracy, by which they can be settled. To others, however, things have not seemed so clear, and they have drawn attention to the doubts that may be felt when history is compared with different branches of investigation, such as chemistry or biology: by contrast with such enquiries, the historian’s procedure, including the manner in which he conceptualizes his data and the principles of argument he employs, may appear to be governed by subjective or culturally determined predilections that are essentially contestable and, therefore, out of place in a supposedly reputable form of knowledge. One topic that has been recurrently examined in this connection has been the role of evaluation (specifically, of moral evaluation) in historical writing—a subject, incidentally, about which historians themselves are apt to exhibit a certain uneasiness. Nevertheless, recommendations to the effect that value judgment can and should be totally excluded from history and, indeed, from the social studies as a whole have met with a mixed philosophical reception. Among Positivists and Logical Empiricists, traditionally skeptical of the rationality of value judgments and anxious in any case to reduce the differences between the human and the natural sciences, they have found some measure of support. But that has been by no means a general response. Thus, objectors have pointed out that the language the historian customarily uses, adapted as it is to the assessment and appraisal of human motives and characteristics, makes some degree of evaluation unavoidable; they argue that, even if the possibility of a drastically

The
question
of value
judgments

revised historical vocabulary allows the ideal of a *wertfrei*, or objective history, to be theoretically conceivable, such an ideal can scarcely be seriously entertained as a realizable practical goal. These considerations have been reinforced by the further point that every historian, insofar as he has to select from the mass of material confronting him, is necessarily committed to forming judgments ascribing relative importance and significance; such attributions cannot, however, be simply read off from the facts and must, rather, be said to depend upon the prior acceptance of certain critical standards. To this extent, then, one is required to acknowledge the presence in historical writing of an ineliminable evaluative component, which is liable to obtrude itself into even so “objective” a field as that of causal analysis: it is notorious that disputes between historians as to the “true” causes of occurrences such as wars or revolutions often appear to resist resolution at a purely empirical level, and it has been persuasively maintained by some philosophers that the basic grounds for such disputes may often be traced back to one historian’s adherence to a moral or political standpoint not shared by his opponent.

Conclusions. Although the topics discussed above have occupied a central position in 20th-century critical discussion, they represent only a sample of the issues with which analytical philosophers of history have been concerned: other problems that have attracted attention have related to the freedom and responsibility of historical agents, the nature and description of historical events, and the role of narrative in history. Here, as elsewhere, the approach adopted has often produced results of considerable interest, throwing a revealing light on features of historical enquiry that are easily missed or ignored by theorists in the grip of some powerful dogma or ideology. Even so, it has perhaps been accompanied by a too ready acquiescence in the view that history is “in order as it is,” the philosopher’s function being confined to offering a purely descriptive elucidation of typical modes of historical thought and argument. In accepting this conception of their role, analytical philosophers of history have no doubt been partly, and understandably, influenced by a desire to avoid emulating the heady ambitions of their speculative predecessors. Yet, normative questions regarding the validity or adequacy of established procedures within any domain can always be legitimately raised; in the case of history, there seems to be no compelling reason to assume that such problems necessarily lie beyond the scope of philosophical criticism and appraisal. (P.L.G.)

Philosophy of religion

In addition to treating what is commonly called the philosophy of religion, this section considers a wide spectrum of situations, experiences, and issues recognized as “religious” and endeavours to appraise the characteristic approaches and attitudes not only of the adherents of particular religions but also of those who stand outside any particular religion, whether as sympathizers or caustic critics. Outside the scope of this section, however, are questions relating to the study of religions and its methodology or questions relating to the types of argument by which one interpretation of a religious claim is preferred to another (see also RELIGIONS, THE STUDY AND CLASSIFICATION OF).

RELIGION AS A FACT IN HUMAN EXPERIENCE, CULTURE, AND HISTORY

Evidences of religious attitudes and loyalties exist in every sector of human life—in human experience in general; in “culture,” the complex interweaving of attitudes, concerns, and views; and in history, the record of social and personal behaviour.

The findings of psychology. Religion incorporates certain characteristic feelings and emotions such as wonder, awe, and reverence. The religious person tends to show a concern for values, moral and aesthetic, and to seek appropriate action to embody these values. He is likely to characterize behaviour not only as good or evil but also as holy or unholy and people as not only virtuous or unvirtuous but also as godly or ungodly.

Charac-
teristic
feelings
and
emotions
of religion

As a feature of human existence, religious life can be studied, for example, in terms of psychology, sociology, and history. Among the first books in the psychology of religion were two by Jonathan Edwards, an 18th-century American theologian: *A Faithful Narrative of the Surprising Work of God* (1737) and *A Treatise Concerning Religious Affections* (1746). About a century later, during a period of religious "revivals," interest developed concerning the age at which conversions most often took place—the period of adolescence. Reflections on such facts, and in this sense the psychology of religion, only came, however, with the works of two American psychologists: Edwin Diller Starbuck's *Psychology of Religion* (1889) and the classical treatment by William James's *Varieties of Religious Experience* (1902). Generally, the psychology of religion has shown that though religion for some is a crisis experience, for others it is a natural growth.

As psychology became more analytical it became more interested in the abnormal, in neuroses and dreams, in the techniques of hypnosis, and in the kinds of experience induced by drugs. When Freud spoke of religion as an illusion, he maintained that it is a fantasy structure from which a man must be set free if he is to grow to maturity; and in his treatment of the unconscious he moved toward atheism. The study of the unconscious by the Swiss psychiatrist Jung, however, suggested that dominant archetypes (implying innate tendencies to form symbolic images) are supplied by a racial unconscious, thus providing a psychological approach to belief in God.

Classifications of individuals In classifying individuals into different types, psychology has distinguished between religious people who are: "extrovert" or "introvert" (Jung), "healthy minded" or "sick" (William James), and "objective" or "subjective" worshippers (J.B. Pratt). There is always the danger, however, that psychological distinctions may beg too many philosophical questions.

One of the most widely accepted studies of religious experience in regard to feelings was written by the modern German Protestant theologian Rudolf Otto. In his *Idea of the Holy*, Otto analyzed what is distinctively religious in terms of the unique concept of the "numinous"; i.e., something both awesome and appealing, both fearful and attractive.

Psychology, however, is concerned not only with individuals but also with what is known about group behaviour, which can also be of importance in any study of the Christian Church or other religious institutions regarded as communities of religious people. The authority of a religious leader, like that of all leaders, is derived from his symbolic character and the extent to which the leader and his followers share a common ideal.

The findings of sociology. The ideas and images of a religion are much influenced by the social culture in which it emerges. Some of the oldest social institutions and practices, such as those concerning birth and death, marriage and the family, and art and music, have developed in a religious context. Religion has often been a driving force in the reform of social abuses, but also it has been associated with reaction and oppression. More recently, the sociology of religion—influenced by contemporary sociology—has been concerned with making use of sociological criteria and of demographical and statistical studies in planning the church's mission and appraising its significance.

The findings of the history of religions. Conclusions in the history of religions have been largely determined by the particular ideas of man or history with which the study was approached. Some scholars have supposed that at the dawn of human existence there was a belief in a single god and that only later there occurred a development into a belief in many gods as well as animism (a belief in souls or spirits in man and other aspects of nature). Other scholars have supposed an evolutionary development of religion, which only reached monotheism—considered to be the highest form of religious belief—after a long period of purification. The two approaches sponsor, respectively, two contrasting myths about primitive man. According to the one, there was once a golden age of innocence and harmony; according to the other, the life of the earliest man was nasty, brutish, and short.

Granted the ubiquity of religion and its diversity, historians have found no universal essence expressible in terms of common beliefs. What is probably common to all religions is nothing more than the claim that reality is not restricted solely to what is yielded by sense experience itself.

The role of religion in culture. Religion has had a strong but ambiguous cultural influence. The thought that a man depended for his life and existence on a power not his own has encouraged some persons to be lazy, as it has inspired others to greater effort. A conviction about another world has led some religious people to disvalue human life; it has led others to view human life as having the significance of a state of probation. It has been plausibly argued by some (e.g., the German sociologist Max Weber) that Protestantism provided a seedbed for modern capitalism; Catholicism, according to others, easily accommodates a Socialist point of view.

Because a religious view is generally associated with a conviction about the inadequacy of "things seen and temporal," religion as a cultural influence usually shows itself dissatisfied with things as they are. Often, however, when confronted with novelty, religion has tended to be conservative. Thus, religion has alternately opposed or fostered social and cultural development.

VIEWS WITH TRANSCENDENT REFERENCES

A situation is regarded as religious when through its spatiotemporal features what can be termed depth or another dimension can be disclosed objectively. In this sense, there cannot be such a thing as a religion that is nontranscendent. On the subjective side, there will be a matching self-disclosure, a "coming to one's self" that occurs as a response to a vision of the eternal in and through the temporal.

Relation to an ultimate power or being, to values, or to ideals. Different religious approaches can be distinguished by the different interpretations they give of what is objectively disclosed, of what in this sense is the transcendent. In primitive religion, for example, the transcendent is always interpreted in terms of an ultimate power or activity expressing itself, whether singly (monism) or with multiplicity (pluralism), through the objects and events of the world.

Animism views the world as having life, power, and feeling as do men. A monistic view of the universe is conceptually akin to the view according to which people or objects exert the peculiar influence they do and have the strange significance they possess because of mana—a power or force somewhat similar to the scientific concept of energy—that they embody. Animism becomes more diversified and pluralistic when it becomes spiritism, which locates the cosmic life, power, and feeling in particular objects. Totemism involves a highly complex system of beliefs and practices whereby an animal or plant becomes a totem, or a focal symbol for the life and well-being of a tribe. Just as tribal communities are sustained by a power that the totem symbolizes and expresses, so the patterns of tribal behaviour are maintained by taboos. Persons, things, and behaviour are taboo, or are prohibited to members of a society, when they are judged to be so highly charged with sacred power that ordinary "profane" persons must keep their distance.

These primitive viewpoints have a certain conceptual kinship with what the more sophisticated religious viewpoints have labelled with such terms as theism, polytheism, pluralism, and Idealism. Theism interprets the one cosmic, life-giving power in personal terms—different versions varying in their views of the adequacy of those personal terms. Polytheism posits a multiplicity of cosmic personal powers on whose activity (whether in cooperation or conflict) the universe depends. Pluralism views cosmic power as mediated and expressed through a multiplicity of ultimates (e.g., finite persons) or otherwise views the universe as best understood in terms of ultimate atomic units, with no claim made for the absolute supremacy of any one of them. In this way, pluralism—even of a personal kind—differs from theism, which holds that God is a Supreme Person.

The ambiguity of religion's influence on culture

Animism, totemism, and interpretations of cosmic power

Absolute Idealism maintains that activity is an ultimate category but makes no claim, as does theism, for this activity to be personal. Instead, it takes a biological organism as its dominant model. Theism, like deism, has sometimes posited an ultimate personal power or being beyond, above, and certainly separated from the changing scenes of life, whereas absolute Idealism posits an ultimate power or being that is considered to be the whole, of which the changing scenes of life are but a part.

Interpreta-
tions of
salvation

Seeking salvation in a life beyond. Religion is not merely a matter of being aware of a transcendent dimension nor is it merely a claim for a broader and more comprehensive view of the reality. Fundamental to religion is the conviction that through a right relation with a cosmic power or powers, man will find his salvation. Various views of such salvation have been held. Salvation has been regarded as something attainable only after this life. Other views, however, tend to posit a salvation for man through escape rather than fulfillment. Alternatively, salvation may be viewed as something anticipated in the present but fulfilled perfectly after this life. Salvation also has been interpreted in terms of fellowship with God or as a state of bliss needing no God (as by the early 20th-century British philosopher J.M.E. McTaggart), as a state of ultimate peace that arises when man sees his peculiar and rightful place in the whole universe (as by Spinoza), and as a state of bliss in which man cannot properly speak of himself as a self-conscious individual as in the Buddhist state of Nirvāṇa.

IEWS WITH ANTHROPIC REFERENCES

Inner attitudes and dispositions. A religious view of the universe contends that a new dimension and depth can be disclosed within the person who responds. Though religious faith has its characteristic inner attitudes and dispositions, they must be of a transcendently self-involving kind, and there must be a depth to any attitude or disposition before it can be called religious. Thus, the attitude of awe is related to the feeling of fear. For fear to become awe, however, it must be characterized by a particular depth and self-involvement that come from responding to the presence and activity of God, or of the sacred or holy that call it forth.

The
concept of
conversion

Religion relates to the whole of a man's personality and because of this totality of human response, people speak of "conversion" in relation to religious attitudes. Generally, a person who becomes religious or ceases to be religious undergoes a profound transformation. Persons who have become converted to religion speak of the world as having taken on a fuller and richer dimension; those for whom the religious vision has disappeared speak of a world as having become flat, dead, and bleak.

Behavioral discipline with prescribed practices. Many religions bind their adherents to specific practices and particular moral codes. Thus, conversion has often shown itself in radical changes of behaviour; *e.g.*, an alcoholic becoming a total abstainer. Such behaviour as murder, lying, breaking promises, stealing, and committing adultery have been condemned by the world religions. So strong is the ethical element in Confucianism that some regard it more as an ethical system than a religion. Yet, ethical (and ceremonial) codes can be transformed imperceptibly into no more than current social conventions and mere customs. Whether such codes have changed or not, their range and detail vary widely. Pork is eaten by Christians but is considered to be unclean by Jews and Muslims. Muslims and Buddhists abstain totally from alcohol; Christians and Jews need not. A Sikh will not shave his beard; but Hindus, Christians, and Muslims are free to do so if they wish. In contrast with Christians, Buddhists will not kill animals, and Muslims may practice polygamy.

Participation in a social institution. Whatever the diversities, religious faith is not only self-involving, but it has a social dimension as well. Hermits apart, religion brings people together as children of one family having a common father. For Christians, the significance of the universal religious community, the church, has been variously interpreted. Some, with a Protestant emphasis, have viewed the church as a voluntary institution created ad

hoc for the convenience of its members to enable them to gather together to worship, to sing hymns, and to share common interests and beliefs. The Catholic view is that the church is a social institution that is derived from God and whose structure expresses the givenness of God himself.

To be of religious significance, however, social practices and moral codes, like inner experiences must have depth, a transcendent dimension, or they become superficial and dangerous parodies of religion, all the more dangerous for being in their outward features so similar.

THE VIEW FROM WITHIN AS PRIVILEGED

The assertion that the view of religion from within is privileged needs careful analysis.

First, religious faith is logically privileged insofar as it is characterized by a self-involvement, commitment to which partial commitments can only point. A temporary loyalty, however intensive, is at best a distant pointer to a conversion. Further, because religious faith is grounded in a disclosure, there is something logically privileged about it in the same sense that some are "privileged" to understand a joke when others do not. Yet, even though religion has a disclosure basis, it is still true that just as there are techniques for jokes so also are there techniques for meditation, whether in Christianity or in other religions. By virtue of such techniques men can have a reasonable expectation of a view of religion from within. In another sense, the view that religion from within is privileged may merely mean that if a man believes something and is committed, he is more involved than a man who does not believe.

One aspect of the logically privileged position of religion might be called its semantic privilege; *i.e.*, the fact that a religious vision cannot adequately be expressed. One fundamental problem for religious language, according to linguistic analysts, is to discover more reliable rather than less reliable ways of talking. One need not presuppose, however, so fundamental a distinction between the sacred and the secular that men become committed to total silence on religious matters. When St. Paul, for example, wrote of being "caught up" (in II Cor.) he "heard things that cannot be told, which man may not utter." If this statement of Paul's were generally true of religion, however, religious people would be so privileged that they would be living in a segregated silence.

Some scholars have argued that the privileged character of religion makes it unsuitable as a proper study for the philosopher, who must in principle be detached, not committed, and have an openness to all truth. The lack of finality in philosophical thought is contrasted with religious commitment and the final claims sometimes made for religious doctrine. Nevertheless, insofar as anyone has a coherent world view, there will be some degree of commitment.

Religion is not, however, altogether beyond argument, and those who are outside a religion can still have some inkling of what is being discussed within a religion and the manner in which it is being discussed, especially when the social, cultural, historical, and psychological embodiments of the religion are described. For this reason Western Christians and Jews, for example, are able to know something about the primitive religion of an African or Indonesian tribe.

Thus, much about religion can be known by those outside it, however, views about the nature of religion and definitions of religion have a systematic inadequacy about them. Like everything of the spirit, religion cannot be described so as to make clear to the detached observer the characteristic quality and depth of religious awareness and commitment.

THE DIMENSION OF RELIGION FOR INSIDERS

The essence or core of religion. For the insider, the essence of religion is given in a moment of vision and disclosure. Friedrich Schleiermacher, a German philosopher of the 18th and 19th centuries, described the basic religious experience in terms of a kiss or an embrace. Attempts to understand such a unity can only be made in terms of

Faith,
prayer,
and ritual

the particulars into which the unity subsequently breaks, and such particulars then fall broadly into subjective and objective compartments.

The subjective and objective aspects of religion. Faith describes a subjective state that accepts what a disclosure discloses and is akin to personal trustfulness, to a conation or striving that, according to Spinoza, all living things display. Prayer is the utterance of words (rite) with or without some dramatic context (ceremonial) designed either to carry one into the presence of what is worshipped or to express appropriate sentiments in the presence of what is worshipped. Most prayers incorporate words that function in both ways. Ritual is especially concerned with events in human life that have disclosure possibilities and in which mystery is at its highest.

Mystery in the context of religion refers to situations, such as birth, reproduction, death, and suffering, in which there are numerous possibilities for new insights and yet further insights. Public worship must constantly renew and realize in the liturgy the possibilities of the past disclosures. If the outward expressions and forms come to dominate, ritual can become an empty shell, and religious practices can become devoid of religious significance.

Effects of religious beliefs and practices. One of the effects of religious beliefs and practices is sacralization, a process in which certain persons, days, or objects become regarded as sacred. If such objects are granted more than the status of symbols, they may become objects of idolatry or superstition.

Belief in salvation, which often accompanies religious commitment, can have various practical results. If salvation is viewed as something that inspires progress and may be accomplished in the realm of time, such doctrines of salvation encourage social reforms and projects that envision an abundant life for humanity. If, on the other hand, salvation is viewed as something that is beyond the realm of time and set entirely apart from this world—something for which at best this world is a probation and at worst a sink of misery and iniquity from which the sooner man is released the better—such doctrines of salvation can be excessively individualistic and may even encourage oppression and tyranny.

Conclu-
sions about
nature and
history

Religious belief has sometimes led men to detailed conclusions about nature and history. Good harvests have been interpreted as due rewards for appropriate worship or good behaviour, or both; calamities have been viewed as the results of sin, either ceremonial or moral. If God is believed to be in control of history, a nation that does what is right and follows his guidance, as expressed through its prophets and other religious personages, is expected to experience national prosperity and success. In previous periods, when this did not occur, the ensuing calamities were attributed to the backslidings of earlier generations.

Many observers of religion claim that in the modern world few would suppose that God intervenes in this direct and predictable way. According to this view, God's activity in the world, apart from being expressed in its constant creativity and conservation, is effective through man's own intellectual and physical activity. Insofar as man's own creativity is exercised, however, within the framework of the order that the world displays, and in no way violates it, one cannot exclude a similar creativity on the part of God. Admittedly, the fact that man expresses his activity through an intermediate organism (his body) indicates that there is no exact parallel between God and man; nevertheless, because God's activity terminates with the universe, the analogy with God's activity might very well be expressed in the number of ways in which man can effect creative development in his own body.

INTERNAL CRITICISMS OF RELIGION

Internal criticisms of religion have their basis in the imbalance that occurs when one aspect or one understanding of religion is allowed to dominate the rest. Heresies have arisen when one way of understanding has been developed without balancing it with another. In the development of doctrines concerning the nature and person of Christ within Christianity, for example, heresies arose when a particular model (*e.g.*, that of fatherhood and sonship)

was believed to be capable of infinite development. The model of the Father–Son relationship was pressed too far, and the Son was subordinated to the Father in a way inconsistent with Christian orthodoxy, thus leading to what became heresy. Sectarianism develops when religious insights are associated exclusively with one particular doctrinal or theological phrase, such as justification by faith, or with one particular theological view regarding religious practices; *e.g.*, baptism. Because religion is at once infinite and mysterious, it is important that religious belief does full justice to a wide variety of approaches.

Another criticism of religion has been that it has tended to be overintellectual; and when this trait has been combined with moral laxity and factional rivalries, it has led to protests about the arrogance of intellectualized religion, often leading to the opposite error of supposing that belief does not matter as long as common sentiments are shared. Religious believers have not always recognized that for the most part their belief explicates metaphors, images, and symbols. Though ways of religious reasoning are appropriately informal and variegated, having their origins in a multitude of images and symbols, it nevertheless is considered a religious duty to produce the most reliable overall discourse based on the various images and models.

The fundamental difficulty of all religious understanding, however, is to balance intelligibility and mystery. If the intelligibility is neglected, religious belief can become dishonest and religious men can lose integrity; if mystery is neglected, there may be splendid controversy and exercises in logical appraisal, but the heart of religion will have disappeared.

Balancing
intelligi-
bility and
mystery

The basic difficulty of all religions and of historical religions in particular is to effect a constant rebirth of symbols in changing cultures. In the course of time some of the most powerful images and symbols lose their fertility in promoting ideas that inform a religious community. This might be said of the image of sacrifice in the Christian religion. Religious practices and institutions, though they may have social merits, can all become stereotyped routine, as happens when they fail to preserve a sense of reverence and fail to disclose the givenness of the sacred or holy. Because religious belief is so important and influences all aspects of a society, there is a tendency for religious institutions to become authoritarian and oppressive. If a religious institution becomes interwoven with political views it can become tyrannical. Religion's only compulsion, according to some scholars, must be the compelling power of a vision, as the modern English–American philosopher Alfred North Whitehead expressed it: "The power of God is the worship He inspires." The authority of any religion is the authority of a vision, the authority of that which, in being disclosed, inspires men and leads them to fulfillment in their lives. For a Christian, the final authority is the love of God in Christ, and love is not love if its power is anything but inspiration. For other religions there is the compelling inspiration of that to which—Nirvāṇa or the Qur'ān, the Buddha or Muḥammad—point.

Internal criticisms of religion usually focus on such themes as narrowness, sectarianism, traditionalism, conventionalism, materialism, and immorality. Some criticism is also reserved for religiosity, which, though granting a dimension of faith, treats faith in an altogether superficial and often unbalanced way. Religiosity represents an excessive preoccupation with religion that is depicted in an incoherent and oversimplified relating of religious faith to intellectual views and social and personal practices.

THE REJECTION OF RELIGION OR RELIGIOUSNESS

Because religious commitment is so all-embracing and tends to influence thought, feelings, and behaviour, it is not surprising that there are many reasons why religious claims have been rejected.

Rejections on the grounds of alleged incoherence. Religious claims have been rejected because of their alleged logical or moral incoherence.

Alleged logical incoherence. Logical incoherence may arise internally or externally and in relation to different issues. In regard to internal coherence, critics have maintained that man should be able to expect that God would

External
incoher-
ence, in
conflict
with other
views of
world

see to it that there could be no possibility of ignoring his existence or of making mistakes about religious beliefs and behaviour, if religious convictions are so important. They have also claimed that it is altogether too naïve, though inevitable, to think of God as made in the image of man. Some have rejected theistic belief because of the incoherence of the idea of God, which must—they claim—combine so many incompatible predicates; e.g., God is eternal, yet acts in time, or he is loving and yet incapable of suffering or feeling.

Religious beliefs have been alleged to be externally, as well as internally, incoherent because of their conflict with other views about the universe, especially scientific views. The doctrines of heaven and hell, in particular, which have given great personal and social significance to religious belief, have been rejected by many critics when these doctrines were viewed literally. Yet it has been the supposed actuality of heaven and hell that has given religious persons their hope and their terror respectively. Absolute Idealism, it has sometimes been alleged, is incoherent insofar as it states that time is not “real” and that evil does not really exist. This is not to say, however, that there is no temporal succession or nothing evil, claims that would be obviously incoherent. What is being claimed is that within a particular interpretation of the universe, time and evil are not left as ultimate categories but are in some sense derivative from other categories.

It has been argued that by far the greatest problem of external incoherence that belief in God has to face is that of the evil and suffering that characterize the world. Critics have stated that if God cannot rid the world of evil and suffering, he is not all-powerful; if he could, but he won't, then he isn't all-good; if he is powerful and good but not all-wise, then, even though he is trying his best, there are bound to be disasters. The most serious classical expression of this problem was given by David Hume, in his *Dialogues Concerning Natural Religion* (1779). With such considerations in mind, some philosophers, such as John Stuart Mill, have been willing to argue for a limited God—i.e., the great fellow-sufferer who understands and has compassionate sympathy.

Alleged moral incoherence. Though religious conviction shows itself in moral behaviour, it has been argued that religious people have not shown outstanding moral qualities. An 18th-century English philosopher and churchman, Bishop George Berkeley, when presented with this objection, remarked that nothing evil can be attributed as such to the Christian religion and that the only legitimate comparison is that between a person who is a Christian and what the same person would have been otherwise. The distinctiveness of the Christian faith, however, has sometimes been supported by arguing a stark contrast with morality. The 19th-century Danish philosophical theologian Søren Kierkegaard, for example, by a too literal misreading of the biblical story of Abraham and Isaac (Gen. 22), supposed that religious obedience must be in radical opposition to moral duty. However that may be, religious men often may be only too well aware of their moral lapses, their sins, and for this very reason they seek the grace and power of God. The good that they would do they do not do, and the evil that they despise they continually do, as St. Paul noted in his letter to the Romans. In this moral predicament, those with a Christian commitment believe that the grace and power of God comes to inspire and release them from the dominion of sin. This does not mean that the Christian never sins, but it does mean that he is assured of ultimate victory over sin. The Christian Church is viewed not as a society of saints but a school for sinners.

The exclusiveness of religious sects is regarded by those outside the sects as hardly to the sectarians' credit. For Christians, sectarian exclusiveness is viewed as a scandal to the gospel that they preach. On the other hand, the criticisms of Puritanism that hold it as inevitably negative and oppressive sometimes fail to see that it may be neither negative nor oppressive if it is grounded in a spiritual and religious vision.

The doctrine of grace (the view that God grants man abilities that man does not merit by his own efforts)

has sometimes appeared to make God himself—interpreted as the spirit dwelling in a man—the actual agent of good behaviour. In this way, some interpretations of the doctrines of grace have compromised man's freedom and come close to denying man responsibility for his actions.

Outside Christianity, critics have pointed to the gap between religious profession and moral action, though within Christianity, with its strong emphasis on moral transformation, the gap has been very wide and the criticism most challenging. In Hinduism for instance, Gandhian reformational and nonviolence ideals have not mixed well with social corruption or with the type of neutralism that allowed China to persecute Tibetan Buddhists. Again, the Buddhist who goes to a temple is not necessarily compassionate as his religion dictates, and the Muslim who attends services in a mosque may be less filled with an inner sense of justice and patience than with thoughts of a holy war. In Sri Lanka (Ceylon) and Vietnam nationalist loyalties have given rise to a violence untypical of Buddhism. In the last resort, however, each religion will appeal to its doctrine of salvation when presented with a gap between its moral ideals and the actual actions and behaviour of its adherents.

Other grounds for the rejection of religion. *Rejection of historical beliefs, practices, and institutions as spurious or irrelevant.* When a religion appeals to historical events, other grounds for its rejection arise. The Old Testament view of history appears to have been exceedingly selective in order to emphasize a particular point about God and his activity. The miracles of Jesus—both those relating to his own person (his birth and Resurrection) and those that he himself performed (especially nature miracles)—conflict with what men experience in the normal course of their natural lives and experience. Prayers requesting favourable weather, plentiful crops, or safety in a journey are characterized by many as spurious and irrelevant. Ideas of God intervening in the universe, according to such critics, satisfy neither science nor religion. From a scientific point of view, “laws” of nature are no longer viewed as divine prescriptions; and the word law becomes, in fact, misleading. Furthermore, in order to allow for miraculous intervention of this kind, God's providential care is viewed as a compromise. He thus becomes the absentee landlord who absented himself from the world, which must take care of itself except for some spectacular visitation. According to this view, the only coherent way to speak of an intervention of God is to interpret it in the context of personal intervention.

Religious institutions have been criticized on the grounds that they conflict with the ideas of the founder and are supported by claims that cannot be historically verified. These claims, according to critics, depend on taking certain historical events on which the religion is founded, and reinterpreting them by theological speculation or a very full imagination, to produce, for example, a doctrine of papal supremacy according to which Christ is believed to have given explicitly to the successors of St. Peter final jurisdiction over the church.

Rejection of religious sentiments or dispositions as valueless. According to some views, anyone who prizes “another world” must despise this world and be uncertain in his attitude toward the world around him. In this way, it is said, religion dries up the sources of its activity and attacks such happiness as this world can provide—though promising happiness hereafter, which has been called “pie in the sky” or “opiate of the people” by critics of religion. A humanist concern to liberalize and relax laws (e.g., on abortion and divorce), to abolish capital punishment, and to encourage birth control has always been opposed, according to humanists, by Christian orthodoxy, which they interpret as having a negative and conservative attitude that has proceeded from a nervous fear of a decline in moral standards. At the same time, humanists would continue, moral standards have hardly been upheld by sectarian strife and persecutions. Further, they point out, too often the church, in its desire to indicate what abides, has confused what is abiding with current social and political institutions and traditions inherited from the

The
problem
of sin
and grace

Humanist
criticisms
of religion

past, generally resulting in an illiberal obscurantism and a reactionary outlook.

Some critics of religion have contended that almost all scientific progress has been hindered by religious beliefs and attitudes. Biology, physics, and geology, they have claimed, only made the rapid progress that they did when they were freed from a context of religious belief by the 17th-century philosopher René Descartes, who devised a metaphysical myth of the separation of mind and body.

Naturalistic or skeptical views of the origin and development of religion. In the matter of the origins and development of religion, many (e.g., the psychologist James Henry Leuba in his *Psychology of Religious Mysticism* [1925]) have argued that there is a close connection between mysticism and hallucination, between hysteria and ecstatic institutionalized inspiration as, for example, in Pentecostal churches. Religious people, according to such views, often have personality weaknesses and are psychologically disturbed. Freud, the founder of psychoanalysis, maintained that inner conflicts—often the result of repression, particularly in relation to sex—become expressed in peculiarities of behaviour and mood, especially in the vivid imagery of dreams that erupt from the unconscious area of one's personality. By comparing the symbolism of dreams and mythology, Freud held that belief in God—in particular, the father image—merely perpetuates in fantasy what the individual must in actual fact overcome as part of his growth to maturity, thus giving religious belief a treatment that not only made belief in God unnecessary but positively unhelpful.

Carl Jung, a former disciple of Freud, gave a different account of the psychology of the unconscious. Each person displays a libido, a fundamental striving that is creative and purposive and of which there is evidence in the symbolic language of dreams. Behind all such symbolic language are archetypes (innate tendencies to form symbolic images), which all humanity shares and which inspire a person to move toward a balanced integration to which the energy of the libido would creatively move, if given proper freedom and encouragement. Thus, Jung posits a racial or impersonal unconscious in which, at the deepest level, all individual human beings share. Jung's archetypes raise the metaphysical question of whether they are symbols of an existent God or gods—a question that psychology leaves open. For many psychologists it is a question of little interest, because for them the archetypes themselves suffice in practice.

In addition to such naturalistic or skeptical views about the origin and development of religion are other claims that religion is merely an infantile reaction to fear, a more or less harmful sublimation of sex, a projection of wishful thinking, or a social device for use in the class struggle. On the other side, however, it is likely to be pointed out that one must be careful not to indulge in the genetic fallacy: no account of the origin and development of anything, of religion in particular, is necessarily a reliable analysis of what that particular phenomenon is now; a single explanation of the origin and development of a phenomenon as complex and variegated as religion is difficult to describe and maintain. It is also necessary to beware of the "really only," or reductionist, fallacy. To say "x is really only y" is, in effect, denying the significance of y language despite the fact that y-talk as well as x-talk already occurs; e.g., persons are really only "machines," or worship is really only a social occasion. Over-simplification streamlines discourse at the cost of adequacy and truth.

Some have thought of religion as no more than a body of stories designed to encourage a noble attitude toward life and humanity. If, however, one asks why or how these attitudes encourage and why a particular attitude is valued, what begins as a simple account of religion becomes, in the end, as complicated as any. Another criticism of religion, arguing for its redundancy, claims that the progress of man in society can and should be determined by scientific considerations. This contention, however, goes beyond the particular conclusions of the individual sciences; it is to make a philosophy out of science. On the one hand, such a scientific view of man and society would be open to philosophical criticism, not the least if it were sug-

gested that man's subjectivity—that which makes him the unique person he is—has to be analyzed in terms of the objects of science. On the other hand, if science becomes a philosophy, it might be said to have assumed a religious dimension itself.

In the realm of religion in the latter part of the 20th century, in what might still be called the Christian societies of the West, the attitude of very many people lies in an intermediate zone between religious belief and atheism, but the content appears rather to be given to agnosticism. Such persons believe in God but dislike any kind of formal worship, pray only on exceptional occasions, and find it difficult to have a sense of sin but admire saintliness. They are critical of the need for a Christian ministry except insofar as a priest or pastor can show sympathy and act as a vehicle of social concern. They are distrustful of dogma and critical of Christian sectarianism. They may be uncertain of Christ's divinity, but the words and example of Jesus are viewed as a guide to the good life. This outlook has many affinities with the "natural religion" of the 18th century in which the ethical example and teachings of Jesus were emphasized. Though, as in the 18th century, there may be an intent to reject revelation, persons holding such an outlook may rather be rejecting certain stylings of Christian revelation.

Examples of occurrence of such a "natural piety" can also be found in religions other than Christianity, though significantly not in Islām—unless the Bahā'ī movement be taken as an approximation of this outlook. This attitude, for example, has provided the basic cohesion for the State of Israel in the latter half of the 20th century. Further, the spread of technology has gradually been alienating many Hindus and Buddhists from their traditional beliefs, but the Hindu has continued to treasure his spiritual ideology, which may well give to technological development its needed direction and wider setting. Buddhism in Japan, and perhaps elsewhere in the East, is still valued in the 20th century insofar as it supplies a local religious dimension to a society whose public and industrial life has been increasingly Westernized. Thus, an attitude has arisen that is sympathetic to the broad claims of religion, but has been critical, if not disdainful, of theological dogma and rivalries.

THE ACKNOWLEDGMENT OF RELIGION OR RELIGIOUSNESS AS VALID

Traditional justifications. Religion as pointing to an ultimate power, being, or value. More generally, persons who are outside the particular religions and who have nevertheless acknowledged religion as significant often seem to base their views on a fundamental feeling of absolute dependence. The grandeur of the universe, the character of the moral struggle, reflections on human nature, and an awareness of moral values inspiring men to reform society have all joined together to point men to an ultimate power or being—a "power, not ourselves, which makes for righteousness," according to the 19th-century English poet Matthew Arnold.

The fundamental difference in the latter part of the 20th century between the secularist and the religious person most likely has been between someone who takes a narrower and someone who takes a wider view of humanity. That there is an acknowledged need in modern times to give a moral direction to technology seems to many to bring with it the need for a religious view of the universe, even though they may not themselves be adherents of a particular religion.

Religion as producing wholesome spiritual or moral effects. Others point to examples of the wholesome moral and spiritual effects that religion has had. They mention that society has ceased to practice child exposure and there has been a notable development in the status of women in society. Religion, where it is not parodied, misrepresented, or misunderstood, broadens rather than narrows vision. Insofar as human nature is inadequately understood, if no place is granted to the spirit of man, human nature, it is argued, will never find satisfaction except through the self-realization and self-fulfillment that come from responding to the inspiring ideal.

Ambiguities in attitudes of persons in Christian societies

Problem of the genetic and reductionist fallacies

The pragmatic view

Alternatives to traditional beliefs, practices, and institutions. *The quest for authentic existence.* In the 20th century various alternatives to traditional religious beliefs, practices, and institutions have become apparent. Chief among these is the quest for authentic existence. This has been encouraged and portrayed by various Existentialists (those who view man in terms of his existing thoughts and actions rather than in terms of his "essence"), who have been concerned in one way or another with emphasizing the significance of certain situations. In this way, they have given their own versions of salvation—that situation in which a person finds his true significance. For some, such as the German philosopher Martin Heidegger, a sense of authentic existence is given to each person when he realizes his true subjectivity, which his life in the world and his social transactions so often conceal. Authentic existence is often contrasted with cosmic anxiety—*i.e.*, anxiety of a deep and far-reaching kind to which the antidote is to find oneself and one's freedom in a total commitment to what is called the ground of Being.

Existentialists of an atheistic persuasion, such as the philosopher and Nobel laureate Jean-Paul Sartre, regard human existence as absurd and other people as hell, because, though one needs other people, they can never be other than "other people"—their subjecthood, their freedom is inaccessible. Love is, thus, doomed to permanent frustration. The need to know others like oneself is matched by its impossibility. According to Sartre, this condition only reflects the absurdity of man's own existence, which is always attempting to overcome a radical estrangement between man as the object of scientific study and man himself (*en soi*) and the subjectivity man knows in consciousness (*pour soi*). Suicide is the final absurdity, for in getting rid of *en soi*, what man is, *pour soi* disappears at the same time.

Religious
Existen-
tialism
as a
God-given
fellowship

This pessimistic estimate of human life and its apparent absurdity, however, has been converted into a religious view by other Existentialists, such as Gabriel Marcel, another French philosopher, who point to a participation—a mysterious self-involvement that persons can have intersubjectively with each other—in a kind of fellowship that is viewed as God-given. According to this view, man needs to open himself to the presence and grace of God for a dynamic transformation in which the mysterious transcends the purely problematic. Common to all Existentialists, however, is the view that the authentic man is not merely satisfied with playing a role, with being a cog in industrial society. One way or another, the quest for authentic existence is to discover the means by which man can recapture and enjoy occasions of self-disclosure. So significant are these occasions that they have been viewed by some theologians to be the paradigm for the kind of situation that the Christian gospels recount.

Secular religion. Another feature of 20th-century development has been society's rediscovery of the significance of the secular. This change has led to an outlook and attitude that has been characterized as "religionless Christianity," a Christianity influenced by its residual social and political ideal, but bereft of its specifically religious practices, doctrines, or institutions. Such practices as traditional intercessory prayer are dismissed as empty approximations to magic; doctrine is condemned as outdated and expressed in terms of past cultures; institutions are criticized as oppressive and conservative.

Behind all this suspicion of structures and doctrinal schemes and practices, however, is a desire to get back to basic principles and origins, to learn again what is distinctive about the religious point of view. According to some proponents, such a goal might be attained by beginning with the secular, with activities in the secular world, not least with compassionate service, by seeing where the need arises for religious conviction and by ascertaining what contribution faith will make to secular endeavour. Though secular religion broadens out into a more sympathetic and a more positive attitude than agnosticism, it is never as explicit or particularized as orthodoxy.

Marxism. Marxism, which provides remarkable evidence of the power of dominant key ideas to inspire and direct man, is undoubtedly one of the greatest challenges

to traditional religious belief. Based on the socio-economic philosophical thought of the 19th-century thinker Karl Marx, Marxism can be said to be a quasi-religion on two counts. First, Marxism had connections with the metaphysics of G.W.F. Hegel, an 18th–19th-century German philosopher who interpreted reality in terms of a spiritual Absolute. Furthermore, the thinking of Marx had religious overtones, whether from his own Jewish background or from a Christian atmosphere, not least in Britain where he lived from 1849 to 1883. Second, Marxism can be called a quasi-religion insofar as it calls from its followers a devotion and a commitment that in their empirical character greatly resemble the commitment and devotion that characterize religious people. Marxism has undoubtedly fired the spirit of man and given to revolutions, whether in Russia or China, a powerful direction that has maintained stability and avoided anarchy. Furthermore, like a religion, it has provided themes of fulfillment and hope—a revolution interpreted as the initiation of a Communist world society that would be a final consummation. There are many logical similarities between the doctrine of the Marxist millennium and the Christian doctrine of Christ's Second Coming. Marxism has also stressed the significance of cooperating with the immanent spirit of the times—something comparable to the providence of God—in economic and military struggles that are viewed as the travail by which society would be reborn. The main difference between Marxism and Christianity in the 19th and early 20th centuries, according to some scholars, was that for many the Christian vision encouraged men to endure tyranny, while the Marxist view inspired men to rebel. Yet, once it can be established that religion is not the servant of oppression, is not necessarily linked with an illiberal regime, and does not use concepts of "other worldliness" to make men content with tyranny and injustice, then religion may yet have a place in the Communist state. Such a religion would not have to concern itself with the kind of supernaturalism that Marxism now rejects; it would not have to appeal to an invisible world entirely other than the present world. It is not without significance that Marxism has its own form of public ceremonial and its own language of glorification. If it has to be granted that many religions have a ceremonial, a symbolism, and a moral code that has lost the vision they once had, Marxism is a social program, a doctrine, and a ceremonial searching for a vision that haunts it and that may at some time bring it to fruition. In this regard, Chinese Marxism is particularly significant insofar as Marxism in China cannot escape some interweaving with Chinese Buddhism. Chinese Buddhism brings with it a natural framework of absolute Idealism, which may yet supply Marxism with the spiritual dimension that for many critics appears to be Marxism's main inadequacy, something it lost when it shed its Hegelian metaphysics and became the anti-God Materialistic world-view of the U.S.S.R.

Marxism
as a
quasi-
religion

HISTORY OF THE PHILOSOPHY OF RELIGION

Most philosophies have incorporated religious views in the wide sense of being concerned with a reality beyond appearance, and in this sense they have provided a philosophy of religion.

Developments in the West. *Ancient and medieval concepts.* For the Greek philosophers Plato and Aristotle, wonder was the beginning of philosophy. From such wonder, according to Plato, emerged religious knowledge that was also mediated through Ideas, eternal entities or concepts in which the things of time participate. In performing every good act, man realizes his link with eternity and the Idea of the Good. For the moment, however, man, as in a cave, is chained by his earthly existence so that he cannot see the light outside; he can only see shadows on the wall, which are signs and tokens of the eternal light behind him. This was Plato's way of styling the relationship between time and eternity, between appearance and reality, and it is a styling that found a particular welcome in the Christian tradition and not least by Christian Platonists, whether of the 2nd or 17th centuries. Plato's philosophy also led to belief in God, and his *Timaeus* is a philosophical creation story.

Religious
ideas of
Plato and
Aristotle

Aristotle, impressed with organic life in man and animals, took as his fundamental category growth and development. The nature of anything was thought of as a form by which its movement and development as an organism was to be understood. It was as if the form supplied the driving force. In this context, God was thought of as pure form, as final cause, and as prime mover. Aristotle provided for St. Thomas Aquinas, the great medieval philosopher of Western Christendom, the foundation on which he developed Scholasticism, which has been a distinctive feature of Christian philosophy of religion since the 13th century. Other medieval philosophers, such as Erigena, with his pantheism (God in all); Abelard, with his critical questions; Eckehart, with his mysticism; and Duns Scotus and Bonaventure, with a wider view of reason than could be contained in the Scholastic philosophy, all illustrate the variety and independence of Christian thinkers.

Modern concepts. Descartes, the “father of modern philosophy,” is significant in terms of his reacting against external authority in matters of belief, seeking a fresh basis for certainty, and finding it in the existence of his own mind. He must think in order to doubt his existence, hence his famous statement, *Cogito ergo sum* (“I think, therefore, I am”). Henceforward, much significance was given to the individual mind, and the resulting myth of the body–mind separation enabled both physics and biology to develop without the risk of ecclesiastical interference. Only in recent years has the inadequacy of the Cartesian body–mind myth come under general criticism not only because of the metaphysical problems it poses but also because it fails to do justice to the unity of personality that recent developments in medicine, such as those pertaining to psychosomatic disorders, presuppose.

Many of Descartes’s 17th- and 18th-century successors can be best understood by reference to him. Nicolas Malebranche, a French Cartesian philosopher, and the occasionalist philosophers, were more radical than Descartes; they dispensed with any unity whatever in man himself and linked together man’s mind and body by means of the constant correlation effected by God himself, claiming that mental events were merely “occasions” for God effecting material change. For Spinoza, the whole universe had not only Descartes’s two attributes of mentality and materiality but an infinite number of attributes, and it could be alternatively named God or Nature. Each existent in the world could be pictured as a particular whirlpool in an infinitely deep sea made up of endless layers of particular fluids of which man knows only two—mentality and materiality. Gottfried Leibniz viewed Descartes’s minds as the only ultimate existents, so that even material things were colonies of souls. God was viewed as the supreme monad (the ultimate substance) that establishes coherence and harmony among all other monads. What appears to men as the external world is, so to speak, the result of blurred vision on the part of those groups of monads that are human beings.

After Descartes there appeared the British Empiricists: John Locke, George Berkeley, Joseph Butler, and David Hume. Locke, though rejecting some of Descartes’s characteristic doctrines, nevertheless took over Descartes’s view of the human mind and then concerned himself with the philosophical psychology of how the mind comes to have the ideas it possesses. By the time of David Hume (died 1776), the mind was viewed as nothing more than a collection or bundle of ideas thought of as very similar to images, which means, as Hume frankly admitted, that it becomes impossible to do justice to the subjectivity that makes each person distinctively the person he is. The significance of Berkeley (died 1753) in this sequence is that he saw the need for an extended Empiricism that took the notion of personality seriously and that regarded activity as a key concept. Indeed, for Berkeley the fundamental unit for thought was “activity-directed-towards-and-terminating-in ideas,” and it was the activity of God directed to those ideas, which make up the external world, that gave to this world its continuous independent existence. His contemporary Butler also argued for a broader Empiricism, which for him centred on the significance of man as a moral agent and on a reasonableness that need

not always conform to a mathematical paradigm. In a matter of great consequence, a man’s action can be reasonable even though there may be little supporting evidence for his decision and though, indeed, the evidence may be very much against it. It may, thus, often be a moral duty to act in such problematical circumstances. This led to Butler’s famous doctrine of probability—“probability is the very guide of life”—a view that influenced the treatment of belief in *The Grammar of Assent* (1870), by the English theologian John Henry Newman.

Immanuel Kant has been called the second founder of modern philosophy. With Kant, late 18th-century philosophy began to take an interest in human knowledge, its varieties, scope, and limits. In Kant’s critical philosophy, which emerged in his old age, he showed how scientific knowledge left room for morality. Though he was inclined to interpret all religious assertions in terms of morality, belief in God was justified as the holding of a regulative idea that brings coherence into all of man’s thinking. The foundation of this idea is to be found, in fact, in those experiences of unity to which moral ideals, beauty, and the notion of a purposive universe all point. This idea of unity, largely implicit in Kant, was developed by Hegel, who came to regard the universe and its cultural, social, and political progress as but manifestations in time of an unchanging absolute spirit. In this way, Hegelianism provided a spiritual interpretation of the universe, but it regarded particular religions as no more than visual aids toward understanding Hegelian truths. A century later, the British philosopher F.H. Bradley was able to use a Hegelian approach in a much more empirical and far less intellectual context. Whatever form Hegelianism took and though its spiritual insights seemed on first view to make it a friend to religion, it has proved to be a position in opposition to Christianity, whether by its minimizing the historical element or by the way in which it compromises belief in a personal God.

Since the absolute Idealists, there has perhaps been only one philosopher in the mainstream of tradition—Alfred North Whitehead—who, in taking becoming rather than being as the fundamental category, made “process philosophy” possible. This philosophical view maintains a metaphysics that not only provides an interpretative scheme linking God, man, and the world but one that incorporates scientific and historical thinking, though in taking growth and process as fundamental, Whitehead seems, to some, to have an evolutionary God.

There were two main reactions against Hegelianism. The first, initiated by Kierkegaard, viewed Hegelianism as altogether too detached and objective and its ways of reasoning entirely unsuited to the deepest experiences of human life, the tragic situations in which human beings find themselves. From Kierkegaard, the Existentialist movement began. Also, in reaction against Hegel, were the modern Empiricists, such as Bertrand Russell and G.E. Moore from England, whose watchword was clarification in their attempts to create a straightforward, unambiguous language. This movement passed easily into Logical Positivism (a philosophical position that accepts only scientific knowledge as factual and rejects metaphysics), which challenged not only the truth but the meaning of theological assertions.

Developments in the East. *Buddhist concepts.* Among the religious philosophies of the East, the conservative Theravāda (Way of the Elders and another term for Hinayāna) Buddhism regarded all existence as a succession of transitory states: what alone was permanent was Nirvāṇa, a deathless realm the existence of which was revealed to the Buddha himself in the Enlightenment that came to him while he meditated beneath the bo tree (late 6th century bc). About Nirvāṇa, the wise will say little more except to affirm its existence and to express their conviction that the plurality of individual souls that man knows in this world cannot in the same way exist in that deathless realm where there is no rebirth. Such ideas find a natural home in the philosophical standpoint of absolute Idealism, and Nirvāṇa can be regarded as an alternative word for the Absolute. Broadly speaking, Buddhism is agnostic both about a personal creator and personal im-

The Kantian and Hegelian idea of unity

The concept of Nirvāṇa

The myth of the body–mind separation

mortality, though Theravāda Buddhism explicitly rejects belief in a creator. Undoubtedly, the dominant theme of Buddhism is the quest for release from the changes and chances of this world, which will lead to the serenity and peace of Nirvāṇa. A Buddhist saint is someone who has indeed become the Absolute, which thus incorporates and transcends all human imperfections and struggles and all the imperfect ideas, ideals, and deities of popular religion and popular ways of thinking. The difference between the *arhat* of Theravāda, and the *bodhisattva* of the Mahāyāna is one between two different routes of realizing Nirvāṇa—the one through self-concentration; the other through self-sacrifice for the welfare of others. The difference is one between two “saintly” routes to the one saintliness—being possessed by and dwelling in the Absolute.

Thus, Buddhism, by embracing what is, in effect, a metaphysical concept of the absolute, not only could but did hold together a complex mythology within a unifying philosophical insight and was able, as in Japan and China, to incorporate a complex popular pantheon of the cult of ancestors. Furthermore, it could combine a popular devotion to a personal lord with a mystical contemplation that had encouraged the development of Buddhist monasteries. In sponsoring such a broad synthetic (all-embracing) view, the philosophical significance of Mahāyāna (Greater Vehicle) Buddhism emerged. Such developments began about 100 BC and lasted for several centuries; it was Mahāyāna Buddhism that spread to China and East Asia to influence and modify the religions native to those areas. In Mahāyāna, the humanitarian saviour notion of the *bodhisattva* has some echoes in Kenotic Christianity (*i.e.*, emptying oneself to become a suffering servant), and attitudes to the Buddhist scriptures have parallels with those of Christians toward the Bible. Common to both is the view that revelation can express itself in developing forms and that it is a mistake to concentrate on the texts themselves, sacred though they are, rather than on that which transcends them and of which they are symbols and to which they point. In this respect, one may contrast the open and exploratory attitudes of many Buddhists and Christians toward their sacred books with the closed and rigid attitudes of most Muslims.

Confucian, Taoist, and Japanese concepts. Prior to the introduction of Buddhism into China in the 1st century AD, the two main strands of religious thought in that country were represented by Confucianism and Taoism. Confucianism displays a reverential propriety that is expressed and developed in social relationships and fulfilled in Heaven. Taoism claims that the wise man will constantly seek harmony and rapport with Tao (the Way), which, at one and the same time, is the way for men to follow if they would reach blessedness and the principle that underlies and sustains the world. As a concept that is both moral and cosmological, Tao has a logical status similar to that of the Logos (or Word, the active principle of God in creation and revelation) in Christian philosophy. The Taoist thinks little of the ways of the world, including the decorum of the Confucianist; his outlook rather encourages a laissez-faire policy toward the world and even withdrawal from its affairs. The immediate mystical experience of Taoism or the inspired behaviour of Confucianism can easily blend with Buddhism, which sets both within a metaphysics of the Absolute.

In Japanese religion are found the same two themes that are found in most religions, though in their extreme forms they are mutually exclusive. On the one hand is mysticism—specifically, nature mysticism, of which the mysticism of the Zen practitioner belonging to an intuitive meditative form of Buddhism is a specific example. In Zen Buddhism, religion is scarcely distinguished from an aesthetic experience in which shrines, gardens, mountains, woods, and streams reveal a mysterious beauty and in which the exercise of the intellect is at a minimum. In contrast to mysticism, there is devotion to a supreme personal lord, at one time symbolized in the emperor as a descendant of Amaterasu, the Sun-Goddess. At other times Shintō (“Way of the gods”) devotion focussed on particular shrines and particular deities, just as Zen Buddhism could concentrate on a particular image or on

particular events. In both types of devotions, however, it could be argued that such particularity was fulfilled and transcended in the unity revealed to a mature mystical insight. These different philosophical positions have an interesting reflection in the Christian position in which the Christian claims to find evidence of God’s presence and activity in particular places and situations (especially in the incarnation of Christ), though at the same time allowing for God to be omnipresent.

Hindu concepts. This mixture of a mystical contemplation, which sees the divine everywhere, and a personal devotion to a particularized divinity recur in Hinduism. The most characteristic feature of Hinduism, however, is the doctrine of an eternal soul and its rebirth. The universe is pictured as the arena in which the immortal soul engages in a succession of incarnations from which man seeks release, a release that true contemplation can give him, especially when approached through Yoga (a mental, physical, and spiritual meditation technique). At the same time, a sensitivity to the numinous (spiritual) has left open the possibility of and certainly encouraged personal devotion. The most famous of Indian scriptures, the *Bhagavadgītā* (“Song of God”) has for its recurrent theme the majesty, glory, and terror of God and the devotion due to him, though as in Christianity these attributes are compatible with a loving God. In the matter of revelation and incarnation, it is an open question as to how far the Hindu conception of revelation is the same or similar to Christian or Muslim conceptions. The Hindu view of *avatāra* (“incarnation”), however, implies many incarnations and in a Christian context would demand many Christs; thus, the concept of *avatāra*, a salient feature of Vaiṣṇavism (centring on the veneration of Vishnu, the preserver), cannot be easily reconciled with the uniqueness attributed to Jesus.

Depending on the particular questions that determine a particular content of discussion, Hinduism can talk of a plurality of souls, when it would concentrate on the theme of reincarnation, but, especially when influenced by Buddhist (and also pre-Buddhist) ideas, it can also sponsor an absolutism, or a monism; yet, again, it can come very close to a traditional Western theism. On the whole, however, it might be said that Hinduism holds together in a creative tension both theism and monism, though often it appears that in conceptual foundations and philosophical discussion the theistic strand predominates. Even in its classical period (600 BC to 450 BC) Hinduism was characterized by an astonishing variety of doctrines and cultures. Indeed, it well illustrates a characteristic of Indian thought that is becoming more acceptable to Western ways of thinking—the notion that there are many different approaches to the truth, which matches the concept of a multiple theology. It was regarded, however, as a retrograde step when these varieties of culture, ritual, and mythology became hardened into social strata and castes.

In the medieval period, Śaṅkara (*c.* 788–820), the leading exponent of Advaita Vedānta, or nondualism, is the most significant Hindu figure in the philosophy of religion. Arguing in a way very reminiscent of absolute Idealism, he claimed that the only existent was an absolute and that all else was an illusion. In this context he equated *ātman* (the individual soul) with Brahman (the universal or absolute soul). Both were viewed as one in a cosmic consciousness. For Śaṅkara, only ignorance or lack of insight into the nature of being prevents a man from realizing his identity with Brahman and thus becoming here and now aware of the freedom that is his. Śaṅkara also allows as permissible, without being accepted as the truth, talk of God as personal and as creator and of men as separate souls related to one another and to him. This, however, is only considered a way of talking—salvation in the Absolute transcends all such imperfect discourse. The same logical problems recur here in the concept of Nirvāṇa in Buddhism. In Hinduism, the *Upaniṣads*, Hindu philosophical treatises, and the *Bhagavadgītā* use the imperfect language of finite man, who has not yet found release, and in this way they can only point beyond themselves to that which they cannot adequately express. Here again are ideas reminiscent of some of those in Western philosophy of religion in the

Doctrine
of an
eternal
soul and
rebirth

Concepts
of *ātman*
and
Brahman

modern world: the importance of theological reticence, the limitations of theological language, and, in another context, the significance of "existential situations."

Twentieth-century Hinduism has been chiefly characterized by attempts to purify and reform the doctrines of its medieval period, to deepen its spirituality, to reassert its moral dimension, and to inspire social reform. Mahatma Gandhi and Sri Aurobindo, the founder of a spiritual community and a Communist, were significant in such ventures. Aurobindo has been compared with the French Jesuit paleontologist and theologian Teilhard de Chardin insofar as both have a repeated experience of cosmic consciousness and a profound belief in evolution, both of which point to a divinization of man.

Islamic concepts. At the heart of Islām is an experience of awe before the one, all-powerful, mysterious creator Allāh. Thus, its dominant theme has been surrender, though it must not be forgotten that it has nurtured mystics to whom the mysterious and awesome God has revealed himself through created things. Allāh controls man's destiny, whether to salvation or damnation, which points to the ultimacy of God, to his majesty and power. The concept of heaven inspired warriors to fight to the death; the concept of hell encouraged loyalty by showing what terrible punishments awaited the disloyal. The Qur'ān (the Islāmic sacred scriptures) is regarded as an infallible book—a transcript of a tablet that is eternal in the heavens. Islām shows pre-eminently the strength and limitations of a total surrender based on clear-cut beliefs, themselves arising from a basis in infallible texts, the whole being translated into vigorous political and social practices associated with a rigorous ritual and ceremonial discipline. Its mixture of both rigour in theology and vigour in politics in India and the Middle East from the Middle Ages to the 20th century can perhaps be compared with the same mixture as has been seen in the Protestant and Catholic communities in Ireland since the 17th century. However much the concept and practice of holy warfare is repugnant to many minds today, in the context of Islām it implies a sensitivity to evil and a conviction that evil has to be resisted and overcome in a total dedication. In this way the faith of Islām has shaped human history by obedience to a resolute and powerful God. Islām also illustrates the point that predestination need not bring with it a submissive fatalism. Furthermore, it has to be granted that Islām has allowed, within itself, for some allegorical interpretations of the scriptures—explicitly by the Sūfis (mystics)—and it has also allowed for differences of piety and beliefs and even intellectual exploration on the part of particular disciples. Nevertheless, to other religions Islām has shown itself to be very conservative and with a distrust of compromise and a passionate desire to proselytize.

East and West: common ground. In reviewing the different philosophical understandings of religions in both East and West, two points clearly emerge. First, that however great the variety, there is almost universal agreement that "what there is" is not restricted to the facts and features of the world as they are given to or received by man's senses. Secondly, what has been for the philosophy of religion in the East almost a permanent problem is coming to be a crucial problem for the West, viz., how to preserve both the concept of absolute spirit and the significance of personal individuality or, alternatively, how far one can speak reliably of God as a person. The West is becoming aware of the problematic character of religious discourse. If, in such ways, Western philosophy of religion can benefit from some of the insights of the East, so also can the East—as a growing interest in the Empiricists of the West demonstrates—gain from the West. Not least, scientific developments have created Eastern interest in the English Empiricists, particularly John Locke; Eastern philosophers also have been impressed by the political liberalism of some modern Western Empiricists, such as Bertrand Russell. The Empirical philosophy of religion, as it has been recently developed in the West, may provide basic approaches and techniques for a closer mutual study of religions in East and West.

BASIC THEMES AND PROBLEMS IN THE PHILOSOPHY OF RELIGION

The problem of God, the Absolute, or the supreme value.

The existence of God. The so-called proofs of God's existence are of two kinds: independent logical exercises or particular conclusions set within an overall metaphysics. Either way, the discourse of these independent proofs or metaphysical schemes is best viewed as speech designed to evoke a disclosure. A particular argument recommends, as a way of speaking about what the disclosure discloses, a particular brand of discourse offering an interpretation of the world and man and one that develops from a specific key idea grounded in the disclosure. The existence of an Absolute or a supreme value has never been concluded as a result of an isolated logical exercise but has always arisen in the context of a total metaphysics. Thus, a quasi-mathematical structure, for Spinoza; a dialectic method, for Hegel; and evolutionary considerations, for the modern French philosopher Henri Bergson, determined the discourse that these three philosophers used in order to evoke that situation to which God or Nature, the Absolute Spirit, or the life force became for them respectively key concepts of interpretation. Bradley similarly reached a belief in an Absolute Spirit by reflecting on the logical problems of relatedness.

The following are some traditional arguments for the existence of God restyled along the lines suggested above:

The ontological argument of Anselm of Canterbury (c. 1033–1109) takes a phrase "that than which nothing greater can be conceived" and uses it as a technique for disclosure, directing one without limit to an ever-increasing perspective, in the hope that at some point the light will dawn, whereupon the phrase "necessary being" will be used to develop talk of the God.

The cosmological argument uses as a technique for disclosure such questions as "Why is this thus?" or "Why is there anything at all?" In receiving replies to these questions in causal terms, the cosmological argument builds up an ever-increasing causal spread until a disclosure occurs, whereupon the phrase "first cause" specifies what is disclosed and advocates certain ways of talking.

The argument from design takes a story with acknowledged disclosure possibilities—e.g., the interrelated parts of a watch—and uses this as a catalyst to evoke a disclosure around some ever-broadening purpose patterns of the universe, in relation to which one can speak of God in terms, for example, of eternal purpose.

What is, in different ways, implied by these arguments is that the word God is unique in its logic, that it works in discourse as no other word exactly works. Thus, one cannot say "God exists" but rather "God necessarily exists." This is sometimes expressed by remarking that the existence of God is not the existence of a physical object or even the existence of a person, though what can be said about persons is less misleading in speaking about God than in speaking about the logic of things. This point is sometimes made, albeit misleadingly by saying that God does not exist, but this is only a picturesque way of saying that he does not exist in the way that a table exists.

The nature of God. These reflections are of wider applicability in relation to the nature and attributes of God. Such attributes are spoken of in terms of personal models, such as wisdom, goodness, power, love, mercy, righteousness, and so on. These models, however, will always need qualification by words such as infinite, perfect, and all. What is quite clear is that grammar itself is no clue to the logic of phrases such as "infinitely wise." Although that phrase is similar in grammar to one such as "exceedingly wise"—a phrase that is entirely descriptive in its logic—it is logically quite different, because "infinitely wise" has both descriptive and what has been called performative force. In other words, it not only describes some matters of fact—some specimens of wisdom—because of the word wise, which works descriptively as a model, but it also generates something—the word infinite acting as an operator, continually directing persons to expand their understanding until a moment of vision emerges. Alternatively, the point that God is not a being has sometimes been made by saying that God is the ground of Being—

The kinds of proofs of God's existence

The strength and limitations of a total surrender

Qualifications for personal models

"the ground of" functioning as a qualifier, operating as the model of beings, or things. The emphasis of such qualifiers is twofold. First, they remind one of the inadequacy of all language used to speak of God—language authorized by particular models that, arising in a moment of vision or disclosure, naturally originate speech about what the disclosure discloses. Secondly, qualifiers constantly point one back through developed discourse to that moment of vision in which the discourse originated and in which alone one knows what the discourse is speaking about. The logic of models and qualifiers is a way of combining the intelligibility and mystery that any philosophy of religion must preserve.

Language about God thus develops as a multiple discourse, having various strands of which each is authorized by a particular model and of which each must, somewhere along the line, be modified by the presence of the others. Thus, theological understanding is a complex interweaving of different strands, and not least is the task of the philosopher of religion to produce the most comprehensive, coherent, consistent, and simple discourse he can. When problems arise that seem to be problems about the nature of God—for example, the conflict between different attributes—these are most profitably translated into problems of language. They then become problems of how to create discourse of the kind that in the end produces the best understanding of a cosmic disclosure with a single individuation, in which all the pertinent discourse originates and about which all the different strands endeavour to speak.

The knowledge of God. Natural theology is the name given to the kind of discourse about God and the world that originates in natural moments of vision without reference to God's revelation of himself in an incarnation, and in this sense "natural theology" is distinguished from "revealed theology." Among some philosophers—e.g., Locke—the distinction is one between general and special revelation. In natural theology are generally included the "proofs" of the existence of God, discussions about the immortality of the soul, and discussions about God's providential control of the world, which provides for man a state of moral probation.

Some have viewed religious experience as affording direct evidence for the existence of God. In any discussion of religious experience, however, it is important at the outset to distinguish religious experience in general—a sense of awe or reverence, or a sense of the numinous—from mystical experience. The language of mystics is notoriously confusing to those not accustomed to the mystical idiom, and a leading question is how far mystical experience can establish the kind of objective reference it claims. Words such as immediate, direct, and intuitive refer rather to the way in which the experience occurs as a disclosure rather than justifying one in taking as guaranteed the interpretation that this disclosure appears to bring with it. If one already has an interpretative scheme, then mystical experience may provide an instance of such a scheme, but this has been rightly described as supporting belief in God "on the way back" rather than "on the way out." The concept of revelation is used by Christians to describe the way in which God's activity is uniquely disclosed in Christ, and faith relates to the human attitude and response that matches revelation subjectively. Revelation is sometimes contrasted with discovery, the former being said to relate to a passive subject, the latter to an active subject, but the distinction is largely one of emphasis. Philosophers of religion are now inclined to view revelation in terms of activity that waits to be interpreted rather than as a revelation of propositions. Revelation thus relates to events rather than to doctrine. According to this view, doctrine could never have the ultimacy and finality that necessarily belongs to the givenness of God in his incarnation or incarnations.

Special problems. *Freedom.* Among the classical problems in the philosophy of religion are those of free will, self-identity, immortality, evil, and suffering. The freedom of the will is a claim for the uniqueness of the subject, known in occasions of activity in which the subject "comes alive" and realizes his subjectivity as that which

cannot be reduced to the behaviour patterns and facts—i.e., the objects—of the natural and social sciences. Such freedom is realized in responding to a situation that has equally come alive objectively to inspire a person and call forth such response. Some claim the predictable character of human behaviour rules out man's freedom; others state that the extent to which human behaviour is unpredictable argues for freedom. This controversy, however, does not in any way solve the problem of freedom; it only makes evident what kind of problem the problem of freedom is, viz., how far human nature is capable of being analyzed into behavioral terms without any residue.

Self-identity and immortality. When there has been a self-disclosure of transcendence, of what cannot be characterized in space and time, one cannot say that any self so disclosed entirely comes to an end. In this sense, there is an argument for personal immortality, though one can only talk sensibly about it by expressing immortality in terms of continuing personal life. In Christianity this becomes speech about the resurrection of the body, and in Hinduism it becomes speech about reincarnation in this world or in the universe at large. All detailed talk about a future life, whether in Christianity or other religions, is only a way of spelling out and pointing back to that experience of man's transcendence here and now, in terms of language that expresses the claim that such a transcendent element is not annihilated by death. To be articulate about immortality, emphasis is placed on features of life that, at first view, have high significance and point here and now to experiences in which man's self-disclosure is most often found—e.g., inspiring music or the intimate and deep fellowship of a particularly significant meal. General claims for immortality in relation to an objective disclosure (whether it be spoken of in terms of God or moral ideals) have to be distinguished from, though they have evident similarities to, the Christian claim for eternal life. Eternal life is, according to the Christian view, a subjective self-disclosure alongside the objective disclosure of God's activity in Jesus Christ, and it is as unique as the uniqueness of God in Christ, a uniqueness that is, however, an inclusive, and not exclusive, uniqueness.

Evil and suffering. The problem of evil arises (1) from the loss of a sense of God's presence in the face of evil or suffering and (2) from an apparent conflict between the language used to describe God (e.g., all powerful, all good, and all wise) and that to describe the world as being characterized by evil and suffering. The solution proffered by the Book of Job in the Old Testament is that of evoking such a sense of awe around the created universe that, discovering in this way a renewed sense of God's presence, one accepts both evil and good and contents himself verbally by acknowledging a final incomprehensibility.

Other solutions relate good and evil to God and thus seek consistency by relating good and evil to God's primary and secondary will or to God's willing and permitting, respectively. In demanding some overall purpose to complete such a story, however, these solutions point to others that seek to resolve the conflict between good and evil within some reconciling model, which is then used to specify, with suitable qualification, a purpose or attribute of God. Thus, the conflict necessarily involved in the creation of a community of freely responsible persons is used as a model to illuminate a personal conflict exhibited, for example, by war. Also, the conflicts resulting from general rules imposed for the sake of training are used to provide a model to illuminate the disharmony exhibited in, for example, earthquakes or floods. These models are then developed and amplified in order to lead one to a renewed disclosure of God's presence. These solutions—by raising questions about God's character—perhaps point to another solution that attributes to God redeeming love—something that, as directed to evil, can be creative of personal maturity and fulfillment in a way not otherwise attainable. This attribute must then be appropriately qualified so as to lead to a renewed disclosure of God's presence, in this way enabling one both to face evil and to talk of it more coherently in relation to God.

In the matter of absolute Idealism, which is the kind of metaphysics implied in Eastern religions generally, evil

tality

and good are transcended in the Absolute Spirit that is beyond good and evil. Logically, this is akin to the solution of the Book of Job.

THE PRESENT SITUATION IN THE PHILOSOPHY OF RELIGION

Interest in
religious
language

In the latter part of the 20th century in western Europe and the United States there has been an Empirical philosophy of religion, the interest of which has been in religious language and the kind of Empirical basis there can be for religious discourse. The definitive question has been concerned with what are the patterns of religious reasoning and what is the character of religious language if such discourse points back to and articulates situations of the particular kind that have been discussed above. The approach originated in what has been called Logical Positivism. According to the verification principle, which gave what the Positivists considered to be the touchstone of meaning, an assertion had meaning if and only if it was verifiable at least in principle by sense experience. Logical Positivists were not at all daunted when this seemed to exclude the whole of theology and a good deal of ethics from meaningful discourse.

Since the 1950s, however, there has been a reaction against the Positivist's veto, and the works of the Austrian British philosopher Ludwig Wittgenstein are symptomatic of those who broadened Empiricism so that it has become interested in displaying and elucidating the variegation of language, in setting language in actual contexts, and in relating it to specific situations. Significantly, this mellowing of Empiricism has been accompanied by a growing interest in personality and the self. This newer emphasis of Empiricism unites with Existentialism in suggesting that personal situations may very well provide helpful parallels to religious situations. There has been introduced into the philosophy of religion a renewed sense of the significance of mystery and a new emphasis on theological reticence. With this has come a renewed awareness of the significance of metaphor, myth, and symbol, and there has also emerged a significant use of the concept of the model. The use of terms like myth and mythological, it is important to recognize, does not mean that the assertions so called are false. Myth includes stories that try to articulate what is objectively given in a certain religious situation. Myths also relate to historical events—though the myth may be selective in its choice of such events—when speech about these events is used to articulate a claim of a transcendent kind. In other words, myth, metaphor, symbol, and model are all ways of expressing in ordinary language an extraordinary point.

Questions
of
reference
and
criteria

The present stress on metaphors and models in religious language, however, inevitably raises two far-reaching questions: the question of reference and the question of criteria. The former concerns the possibility of the assurance that one is talking about anything at all. The latter concerns what the criteria are for better and worse ways of talking. The question of criteria has been answered in terms of the logical character and the empirical pattern of the multimodel discourse to which the different strands arising from the different metaphors or models give rise. That this discourse talks about something must in the end rest on the claim that, in a disclosure situation, a subject is relatively passive—*i.e.*, aware of an activity bearing on his own and thus aware of something other than himself about which he is talking.

In this context the significance of the Existentialist approach is to underline, as does recent Empiricism, the importance of a wider view of human experience than ordinary scientific experience might allow and to point one to highly significant personal situations that cannot be netted in scientific terms. The phenomenological approach, as developed by the Moravian philosopher Edmund Husserl, represents an attempt to be objective and scientific about experience, an endeavour to set out facts uncompromised and unprejudiced by metaphysical frameworks. As an endeavour to reach agreement on what is being talked about and as an attempt to seek the simplest and clearest interpretations, the phenomenological approach has been applauded by many philosophers of religion and theolo-

gians. There can be no question, however, about a purely scientific account of a religious situation—that would be a contradiction in terms, and, though there can be a phenomenological approach to religious situations, there can be no phenomenological explanation of them that claims to be adequate. The main contribution of Phenomenology is that of encouraging scholars to describe situations with as much critical analysis as possible.

Logical Empiricism, it might be said, has absorbed something of the Phenomenologists' concern. It has certainly raised questions about and directed interest toward the way situations are talked about and interpreted, the possibility of there being different interpretations of the same situation, and so on. In this way it has provided the tools for and greatly stimulated contemporary interest in hermeneutics (critical interpretations)—a second order appraisal of interpretations together with an interest in their empirical bases.

As to the future of the philosophy of religion, a merging of the Empirical and Existential strands may well be expected. Metaphysical and religious views of the future most likely will combine conviction with tolerance and commitment with openness. The commitment and the conviction will probably come from moments of vision. Claims to finality, fanaticism, and bigotry will disappear, it is hoped, when it is made obvious that no self-guaranteed translations of what disclosure is are given, and tolerance and openness will arise from the acknowledgment that all understanding of these moments of vision is a multiple exploration, an exploration yielding different strands of discourse. Solutions to contemporary problems, social and intellectual, demand a multiple consideration by scholars from many disciplines of all the issues involved in the problem, a consideration set within a framework of faith and morality in which man is interpreted as distinctively human, characteristically a person. From such interprofessional, interdisciplinary groups may emerge a new metaphysics and a new theology linked with, but by no means prescriptive of, assertions in other subjects. In this way there may be created a new culture—scientific, moral, religious, and technological at the same time. To be involved in such groups would seem to be the main task of the philosopher of religion, as of the metaphysician, today. If he is successful and if these interdisciplinary groups are creative, the modern period will then take its place among those that have marked crucial turning points in the history of mankind and its culture. (I.T.R.)

of religion

Philosophy of art

DISTINGUISHING CHARACTERISTICS

The philosophy of art is distinguished from art criticism, which is concerned with the analysis and evaluation of particular works of art. Critical activity may be primarily historical, as when a lecture is given on the conventions of the Elizabethan theatre in order to explain some of the devices used in Shakespeare's plays. It may be primarily analytical, as when a certain passage of poetry is separated into its elements and its meaning or import explained in relation to other passages and other poems in the tradition. Or it may be primarily evaluative, as when reasons are given for saying that the work of art in question is good or bad, or better or worse than another one. Sometimes it is not a single work of art but an entire class of works in a certain style or genre (such as pastoral poems or Baroque music) that is being elucidated; and sometimes it is the art of an entire period (such as Romantic). But in every case, the aim of art criticism is to achieve an increased understanding or enjoyment of the work (or classes of works) of art, and its statements are designed to achieve this end.

The test of the success of art criticism with a given person is: has this essay or book of art criticism increased his understanding or enhanced his appreciation of the work of art in question? Art criticism is particularly helpful and often necessary for works of art that are more than usually difficult, so that the average person would be unable adequately to understand or enjoy them if left to himself.

The task of the philosopher of art is more fundamental than that of the art critic in that the critic's pronounce-

Difference
be-
tween the
philosophy
of art and
art
criticism

ments presuppose answers to the questions set by the philosopher of art. The critic says that a given work of music is expressive; but the philosopher of art asks what is meant by saying that a work of art is expressive and how one determines whether it is. In speaking and writing about art, the critic presupposes that he is dealing with clear concepts, the attainment of which is the task of the philosopher of art.

The task of the philosopher of art is not to heighten understanding and appreciation of works of art but to provide conceptual foundations for the critic by (1) examining the basic concepts underlying the critic's activities to enable him to speak and write more intelligibly about the arts, and by (2) arriving at true conclusions about art, aesthetic value, expression, and the other concepts that the critic employs.

Upon what does the philosopher of art direct his attention? "Art," is the ready answer; but what is art and what distinguishes it from all other things? The theorists who have attempted to answer this question are many, and their answers differ greatly. But there is one feature that virtually all of them have in common: a work of art is a man-made thing, an artifact, as distinguished from an object in nature. A sunset may be beautiful, but it is not a work of art. A piece of driftwood may have aesthetic qualities, but it is not a work of art since it was not made by man. On the other hand, a piece of wood that has been carved to look like driftwood is not an object of nature but of art, even though the appearance of the two may be exactly the same. This distinction is being challenged in the 20th century by artists who declare that *objets trouvés* ("found objects") are works of art, since the artist's perception of them as such makes them so, even if the objects were not man-made and were not modified in any way (except by exhibition) from their natural state.

Nevertheless, according to the simplest and widest definition, art is anything that is man-made. Within the scope of this definition, not only paintings and sculptures but also buildings, furniture, automobiles, cities, and garbage dumps are all works of art: every change that human activity has wrought upon the face of nature is art, be it good or bad, beautiful or ugly, beneficial or destructive.

The ordinary usage of the term is clearly less wide. In daily life when works of art are spoken of, the intention is to denote a much narrower range of objects, namely, those responded to aesthetically. Among the things in this narrower range, a distinction, although not a precise one, is made between fine and useful art. Fine art consists of those works designed to produce an aesthetic response or that (regardless of design) function as objects of aesthetic appreciation (such as paintings, sculptures, poems, musical compositions)—those man-made things that are enjoyed for their own sake rather than as means to something else. Useful art has both an aesthetic and a utilitarian dimension: automobiles, glass tumblers, woven baskets, desk lamps, and a host of other handmade or manufactured objects have a primarily useful function and are made for that purpose, but they also have an aesthetic dimension: they can be enjoyed as objects of beauty, so much so that a person often buys one brand of car rather than another for aesthetic reasons even more than for mechanical reasons (of which he may know nothing). A borderline case is architecture: many buildings are useful objects the aesthetic function of which is marginal, and other buildings are primarily objects of beauty the utility of which is incidental or no longer existent (Greek temples were once places of worship, but today their value is entirely aesthetic). The test in practice is not how they were intended by their creators, but how they function in present-day experience. Many great works of painting and sculpture, for example, were created to glorify a deity and not, insofar as can be ascertained, for an aesthetic purpose (to be enjoyed simply in the contemplation of them for their own sake). It should be added, however, that many artists were undoubtedly concerned to satisfy their aesthetic capabilities in the creation of their work, since they were highly perfectionistic as artists; but in their time there was no such discipline as aesthetics in which they could articulate their goals; in any case, they chose to create "for

the greater glory of God" by producing works that were also worthwhile to contemplate for their own sake.

This aesthetic sense of the word "art," whether applied to fine art or useful art, is the one most employed by the majority of critics and philosophers of art today. There are two other senses of "art," however, that are still narrower, and, to avoid confusion, their use should be noted: (1) Sometimes the term "art" is restricted to the visual arts alone or to some of the visual arts. Thus, the art department in 20th-century colleges and universities is usually the department of painting and sculpture (and sometimes architecture). But as philosophers of art use the term (and as it is used here), art is not limited to visual art; music and drama and poetry are as much arts as painting, sculpture, and architecture. (2) Sometimes the term "art" is used in a persuasive sense, to include only those works considered good art. "That's not art!" exclaims the viewer at an art gallery as he examines a painting he dislikes. But if the term "art" is to be used without confusion, it must be possible for there to be bad art as well as good art; the viewer, then, is not really denying that the work in question is art (it is a man-made object presented to be contemplated for its own sake) but only that it is worthwhile.

The word "art" is also ambiguous in another way: it is sometimes used to designate the activity of creating a work of art, as in the slogan "Art is expression"; but it is more often used to designate the product of that process, the completed artwork or artifact itself, as in the remark "Art is a source of great enjoyment to me." There will be occasion later to remark on this ambiguity.

Countless proffered definitions of "art" are not definitions at all but theories about the nature of art that presuppose that the ability to identify certain things in the world as works of art already exists. Most of them are highly unsatisfactory even as theories. "Art is an exploration of reality through a sensuous presentation"—but in what way is it an exploration? Is it always concerned with reality (how is music concerned with reality, for example)? "Art is a re-creation of reality"—but is all art re-creation, even music? (It would seem likely that music is the creation of something, namely, a new set of tonal relationships, but not that it is the re-creation of anything at all.) "Art is an expression of feeling through a medium"—but is it always an expression (see below *Art as expression*) and is it always feeling that is expressed? And so on. It appears more certain that Shakespeare's *King Lear* is a work of art than that these theories are true. All that seems to be required for identifying something as a work of art in the wide sense is that it is not a natural object but something made or transformed by man; and all that is required for identifying it as art (not as good art but as art) in the narrower sense is that it functions aesthetically in man's experience, either wholly (fine art) or in part (useful art); it is not even necessary, as has been shown, that it be intended by its creator to function in this way.

THE INTERPRETATION OF ART

Works of art present problems of both interpretation and evaluation. Evaluation is not the concern of this article (see AESTHETICS); but one problem about interpretation deserves to be mentioned. Works of art are often difficult, and how to interpret them properly is far from obvious. The question then arises as to what factors should guide efforts at interpretation.

At one extreme lies the view known as isolationism, according to which a knowledge of the artist's biography, historical background, and other factors is irrelevant to an appreciation of the work of art and usually is harmful in that it gets in the way, tending to substitute a recital of these facts for the more difficult attempt to come to grips with the work of art itself. If the work of art is not understood on first acquaintance, it should be read (or heard, or viewed) again and yet again. Constant re-exposure to it, so that the recipient is totally absorbed in and permeated by it, is the way to maximum appreciation.

At the other extreme, contextualism holds that the work of art should always be apprehended in its context or setting and that not merely knowledge about it but total appreciation of it is much richer if it is approached with

Other
senses of
the term
"art"

Isola-
tionism
and con-
textualism

The
meaning
of "art"

this knowledge. According to the contextualists, not only literature (ordinarily appreciated contextually) but also the other arts, even nonrepresentational painting and music, should be apprehended in this way.

No critic or art lover need hold to either position in its undiluted form: a person could well be an isolationist about some kinds of art, such as music, a contextualist about others, such as historical dramas and religious paintings. It is essential to be more specific, however, about the factors—other than careful and repeated perusal of the work of art itself—that the contextualist holds are either necessary or extremely helpful in the appreciation of works of art:

1. Other works of art by the same artist. If the artist has created other works, particularly in the same genre, acquaintance with them may enhance appreciation of the work at hand. Quantity of works has no particular merit in itself; but, when, say one of the piano concertos of the 18th-century Austrian composer Wolfgang Amadeus Mozart is heard, the auditor may (often largely unconsciously) compare its mode, thematic material, and method of development and resolution with some of Mozart's 25 other piano concertos. Knowledge of the entire corpus of his work in a certain genre may heighten enjoyment of a particular work.

2. Other works of art in the same genre by other artists, particularly in the same style or tradition. Appreciation of the pastoral poem "Lycidas," by the English poet John Milton, is doubtless enhanced by a study of the pastoral tradition in poetry, with which Milton supposed his readers to be acquainted. To study "Lycidas" in isolation would needlessly deprive the reader of much of the richness of texture of the poem and would even make some of the references in it unintelligible.

3. A study of relevant facts about the artistic medium, such as the instrumental limitations or advantages of pipe organs in the time of the German composer Johann Sebastian Bach (1685–1750) or the modes of presentation of ancient Greek tragedies in the Athenian theatre. An acquaintance with the artistic conventions and idioms in which the artist operated often leads to better understanding of certain aspects of his work and helps to avert misunderstandings of it.

4. A study of the age in which the artist lived—the spirit of the time and its current ideas, the complex influences that molded the artist, even the social, economic, and political conditions of the time and place in which he worked. Sometimes such knowledge is of dubious relevance: it can be argued that no aid to the study of the 82 string quartets and 104 symphonies of the 18th-century Austrian composer Joseph Haydn is provided by reading about the political and economic conditions of his day. It is interesting to study the evolution of the string quartet or symphony from its origin through Haydn to the present; but this would appear to be an evolution traceable entirely within the art form and not dependent on factors outside it. This, however, is not always so: particularly in literature, where a study of such exterior factors seems to be of much more relevance. It would seem important to know, for example, that Milton was aware of the new Copernican astronomy but deliberately chose in *Paradise Lost* to make his cosmos Ptolemaic, the antiquated astronomical system that was already steeped in literature, mythology, and tradition.

5. A study of the artist's life. Anthologists of literature constantly assume that this is an important consideration, since they supply detailed biographies prior to their selections by each author. It is true, of course, that knowledge of the artist's life can distract attention from his work, as with those who cannot hear Beethoven's late quartets without constantly thinking, "What a pity it was that he was deaf at the time!" Yet such knowledge may also heighten experience of a work; some would say, at any rate, that it helps to know that Milton was blind when he wrote the sonnet "On His Blindness." It is the relevance of this kind of knowledge to an appreciation of the poem, as a poem, that is in dispute. In every case, however, it should be kept in mind that acquaintance with the artist's biography is a means toward an end, the enhanced ap-

preciation and understanding of the work of art, and that otherwise it is aesthetically irrelevant. The facts about the artist's life are the means and the enhanced appreciation the end, not the other way around, as is often found, for example in psychoanalytic essays attempting to infer facts about the artist's subconscious conflicts from his work; in these cases the work is being taken as the means and the study of his life as the end.

6. A study of the artist's intentions. It is this factor that has prompted the principal controversy in the mid-20th century. When difficulties arise as to what to make of a work of art or when several conflicting interpretations come to mind, how is the difficulty to be resolved? One obvious suggestion is to consult the artist or his records or memoirs or the testimony of people who knew him, to discover what his intentions were with regard to the work or the passage. It is tempting to believe that whichever way he intended it this is the way the work should be interpreted; for in regard to his own work, surely the author's own word should be law.

This temptation is hotly decried by other critics as "the intentional fallacy"—the fallacy (if it is a fallacy) of believing that whichever way the artist intended it is by definition the way it really is. A work of art should stand on its own, without help from the artist; if he has not sufficiently realized his intentions within the work, forcing the recipient to go outside for help, this is held to be an artistic defect. Once the artist has completed his work, moreover, and presented it to the world, it belongs to the world and no longer exclusively to him: in the interpretation of it he now becomes just one critic among many, whose word should be respected but not taken as the final authority. Perhaps other critics can think of better interpretations than he did, which give a greater aesthetic reward in subsequent encounters with the work; perhaps there are even acceptable interpretations (such as the Freudian interpretations of Shakespeare's *Hamlet*) that he could not possibly have thought of himself at the time.

In the late 18th and early 19th centuries, Johann Wolfgang von Goethe set forth three criteria for critics to consider in interpreting and evaluating a work of art: (1) What was the artist trying to do? (2) Did he do it? (3) Was it worth doing? The first of the three is intentionalistic; and, says the intentionalist, surely this is plausible: an artist can hardly be blamed for failing to do what he had no intention of doing. It must first be known, then, what he was trying to do.

But the anti-intentionalist points out that the intention makes no difference, only the product does. If the ballerina excuses her fall in the middle of the dance by saying that she intended it, the dance is just as marred aesthetically as if she had fallen accidentally. And if a poet admits that he wrote rubbish and says that this is just what he intended to write, one does not rate the poem any higher because the poet's intention was fulfilled.

The persistent questioner might ask, however, if there are not at least some works of art in which the intentions of the artist have to be known? Suppose that a contemporary critic reads a dull, stodgy, moralistic Victorian novel and says at the end, "What an excellent parody of a Victorian novel!" But it was not a parody; its intentions were deadly serious—and should not this be known in order to interpret and evaluate it properly? Not at all, replies the anti-intentionalist; all the critic has to say is, "As a Victorian novel, this is deadly dull; as a parody of a Victorian novel, it is brilliant; if the author intended it in the former way, so much the worse for him—his work can still be praised for being brilliant parody, even if it wasn't intended as one. He just achieved something better than he knew at the time."

Still, the intentionalist has a point: sometimes the clue to unlock an otherwise intransigent work may come from the author's statement of intention, and a plausible interpretation might be unobtainable without it. Such a suggestion might have come from a reader other than the author; but there is no point in disdaining helpful hints, regardless of their source. If the suggestion does come from the artist himself, that is nothing against it. Perhaps a work is less aesthetically perfect because it requires outside clues to its

"Intentional fallacy"

External influences on the artist

The author's statement of intention

interpretation, but few works of art even approach perfection, and they may yet amply repay attention, all the more if some plausible suggestion comes from the outside. The 20th-century Russian composer Sergey Prokofiev intended his *Classical Symphony* to be a parody of the classical symphonies of Mozart and Haydn—and regardless of whether the suggestion that it be construed this way came from Prokofiev (as it did) or from someone else, if it is rewarding to listen to it in this way, then no one gains by refusing to accept the suggestion. A statement of intention is not the only key to unlocking the secrets of works of art, but it is one key among many, and there appears to be no good reason why it should not be used.

THE MEDIUMS OF ART

In the context of every work of art there are three items to consider:

1. The genesis of the work of art.
2. The artifact, or work of art, which is a publicly available object or thing made by the artist and viewed by the audience.
3. The effects of the work of art upon the audience.

The first item comprises all the artist's mental states, both conscious and unconscious, in the creation of the work, including his intention with regard to the work, as well as all the factors that led to these states of mind: for example, the spirit of the age, the socio-economic conditions of the times, his exchange of ideas with other artists, and so forth. Whatever factors helped to form the work of art in the artist's mind fall under this heading. The experiences undergone by the artist in the creation of the work constitute the artistic experience.

The third item includes all the effects of the work of art upon those who experience it, including both aesthetic and nonaesthetic reactions, the influence of the work of art upon the culture, on the state of knowledge, on current morality, and the like. The experience that involves the observer's attention to the work of art for its own sake and not for the sake of some ulterior end is called aesthetic, but of course art has many effects that are not aesthetic. The aesthetic experience belongs to the consumer of art, as opposed to the artistic experience, which belongs to the creator of art.

The second item is what is usually called the work of art itself. According to some writers, such as the Italian philosopher Benedetto Croce (1866–1952), the work of art exists only in the mind of the artist, and the physical artifact then counts as an effect of the work of art. But in ordinary usage, as well as the usage of most philosophers of art, the work of art is identified with the physical artifact, as it exists in the physical medium. What goes on in the creator's mind is already contained in the first item.

Every work of art occurs in a medium; that is, there is some physical object or series of events by which the work is communicated to the recipient (listener, observer, reader) by means of his senses. In painting, the medium is paint; in sculpture, such materials as stone or wood or plastic. It might at first be thought that the medium of music consists of the musical score on which the composer writes the notes; but the written notes are not music, they are a set of visual cues for the production of the tones to be emitted by the various instruments. If every player had a perfect memory, he would have no need for the written score; indeed, music existed long before there were any written scores and was played or sung from memory from one year or generation to the next. It could be said more plausibly that the medium of music consists of the physical sound waves by means of which the sound sensations enter the consciousness of the listener. The medium of literature can truly be said to be words, yet not words as abstract entities conceived in the mind but words as spoken (in oral presentation) or written. The physical medium of literature, then, is either auditory or visual, although what is conveyed through the medium is not.

Classifying arts by their mediums. There are many ways of classifying the arts—by their purpose, by their intentions, by their effects. But the most usual and the most fundamental method of classifying the arts is by their mediums:

Visual art. This includes two-dimensional visual arts such as drawing and painting and also three-dimensional visual arts such as sculpture and architecture. Some of these should doubtless be called visuo-tactual art: buildings are ordinarily touched as well as seen, sculptures could be more fully appreciated if touched as well as seen, and even paintings may sometimes have enough three-dimensionality to repay touch experience. At any rate, all these arts appeal first and foremost, though not exclusively, to the sense of sight; and the artifact is an object in the visual medium.

Auditory art. This includes music in all its forms but not song, opera, and those arts that combine music with literature (see below). Just as the medium of visual art is sight, so the medium of auditory art is sound.

In auditory art there is—unlike visual art—no physical object (other than the score, which as has been seen is not the music). There is only the temporally successive series of sounds: sound waves emanating from the various instruments. While no such tones are being emitted, no sounds exist; only the musical score exists (and the memories of listeners, some of whom might enable the score to be reproduced if it were lost), from which music can be reproduced. Unlike the existence of paintings and sculptures, the existence of musical sounds is intermittent. In what sense, then, does the music exist between performances? It exists only in the sense that it is reproducible from the written score.

Verbal art. The art of literature is clearly different from both visual and auditory art. There are sound values in poetry, particularly when read aloud; but as sound alone, literature would be the most poverty-stricken of arts: what makes the sounds of poetry effective is (at least 99 percent) knowledge of the meanings of the words heard. Listening to the sounds of a poem or play uttered in an unfamiliar language gives some idea of the importance in literature of knowing the meanings of the words. Note that “murmuring,” one of the most pleasant sounding words in English, has almost the same sounds as “murdering.” It is almost exclusively a knowledge of word meanings that makes it possible to appreciate the art of literature.

Nor is literature a visual art, although it is customary to read works of literature from a printed page. A critic who said, “I think this poem is a bad one, because it is written in unpleasant small type in double-column pages on yellowed paper,” might be giving advice to typesetters and book designers (these two groups are engaged in the practice of visual arts), but he would be saying nothing about the merits of the poem. The printed or written word or for that matter the spoken word is only a vehicle for the meanings. Literature, then, must be placed in a separate class from either auditory or visual arts.

Mixed arts. Other arts variously combine the above three types of arts; this group includes all the arts of performance. Drama combines the art of literature (verbal art) with the visual arts of costuming, stage designing, and so on. Opera combines the art of music (its predominant component) with the art of literature (the libretto) and the visual arts of stage design. Dance combines the visual spectacle of moving bodies (the principal component) with musical accompaniment, sometimes with accompanying words and often with stage design. Song combines words with music. The motion picture combines the visual component (a series of pictures presented in such rapid succession that they appear to be moving) with the verbal component (the script) and usually an intermittent musical background as well.

All the visual arts are also spatial arts, or arts of space; music and literature are both temporal arts, or arts of time. This leads to very great differences in the things each can do. In temporal arts, the parts do not appear together before the audience but appear successively in time, the second moment not beginning until the first one has finished. In spatial arts, the entire work of art is present simultaneously; attention to the parts of it is successive—it is impossible to concentrate on the whole at once, at least on first viewing—but the entire object is nevertheless there, and it is up to the viewer which part he shall examine first. In three-dimensional art, such as

The meanings of words

Spatial arts and temporal arts

The medium of music

sculpture and architecture, the entire object is present, but it is impossible even to see (much less to look at) all of it at once: the back of a statue cannot be seen at the same moment as the front and the exterior of a cathedral cannot be viewed by someone inside it.

Temporal arts must be attended to in a certain order: it is impossible to hear the symphony played backward, or the drama, or the movie; even when technically it can be done (as in running a motion picture in reverse), the results usually are an aesthetic catastrophe. The recipient is supposed to attend to the temporal work's various parts in an order predetermined by the artist. For this reason, painting is not capable of telling a story in the way that a novel is; for a story is a series of temporally successive happenings, and a painting can at best take a series of represented persons and objects and show them as they exist at one moment only, one knife-edge of time; whereas a novel can depict the temporally successive happenings in the order of their occurrence (or in a different order, such as flashback).

The German aesthetician and dramatist Gotthold Lessing made this distinction the basis of his study *Laokoon*, contending that the function of visual art is to create beautiful objects and that the artist should select that stance or moment at which the person or object appears most beautiful, to enable the viewer to continue looking at it with pleasure; whereas literature, being temporal, is equipped to tell a story that includes many moments other than pleasing ones (moreover, the scenes in literature are not seen with the eyes but only imagined). Lessing's thesis that each art should restrict itself to what it can do best or is peculiarly equipped by its medium to do is a highly controversial one: it would virtually eliminate program music, for example, and descriptions of nature in novels. The tendency of art today is to attempt to curtail distinctions between time and space rather than to preserve them.

Differences in the arts related to mediums. Very significant differences among the arts occur because of the differences in their mediums:

Literary and nonliterary. The greatest difference among the arts is between the literary and the nonliterary. Literature consists of a system of symbols with assigned meanings. A word is not simply a noise (or a mark on a printed page); a word is a noise or a printed mark with an assigned meaning. In different languages, different noises have been assigned meanings, and the language must be learned in order to understand what is being said. To appreciate the work of the 11th-century novelist Lady Murasaki Shikibu, one must learn Japanese; to fully appreciate Molière, the 17th-century playwright, one must learn French. No other art has this problem: the Englishman can appreciate German music as well as a German—or if he does not, it is not for lack of learning a language.

Shapes, colours, and tones do not have assigned meanings. That is not to say that these elements when present in art cannot be said to have some sense of the term "meaning." There are many meanings of the word "meaning," and a colour, for example, can have meaning in that it may symbolize something, as red symbolizes courage; or it may have strong emotional or other effects upon the viewer, evoking all manner of strong associations. But a colour or a tone has no assigned meaning: if the question were asked, "What does middle C mean?", the answer would be, "It has no assigned meaning at all; in that sense, it means nothing—it just has certain effects." But if the meaning of a certain word in a poem is not known, the reader is to that extent prevented from appreciating the poem; for the medium of poetry is not noises, not printed marks, but words, and the difference between a noise and a word lies in the fact that a word is a noise with a meaning.

This fact makes for an enormous difference between literature and the other arts. A colour in a painting may be the colour of an object represented; a colour may even "mean" something; for example, the white of a white flag that a person depicted in a battle painting is holding up as a sign of surrender. But a colour, as a colour, has no meaning at all; and the same is true of musical tones. A pattern of musical tones may occasionally acquire a mean-

ing (the first four tones of Beethoven's *Fifth Symphony* were used to symbolize victory in World War II), but when this happens it really has very little to do with the music, and in any case most music is appreciated without any such symbolism being present. But a noise, however pleasing to the ear, is only a noise and not a word unless it has an assigned meaning; and one must know what that meaning is in order to appreciate a poem or any other work of literature.

The translation problem. Because literature consists of conventional symbols, there exists in literature the problem of translation, which does not exist in the other arts. When one seeks to make a work of literature available to a wider audience than that composed of only the native speakers of the language in which the work was written, the process of translation must be resorted to, and, in this process, a great deal of the work's original character is lost.

In a poem there are (1) the sounds, (2) the dictionary meanings of the words, and (3) the connotations of the words—the manifold associations that they evoke (sensory, intellectual, and emotional) in the minds of readers. The sounds are the least important of the three, and many a great poem as sheer sound is hardly even pleasing. The finding of like dictionary meanings is usually a simple matter, and when there is a word that has no rough equivalent in the other language, it may be simply retained in the original language (for example, the German word *Weltanschauung*, meaning something like "world outlook," is often retained in English translations of German works). As for the associations that hover about a word, they may vary from language to language, so that if a work is translated rather literally, the associative values of the words are lost. Thus, "My God!" is a much stronger expletive in English than "mon dieu" is in French, so that if the French expression is translated into the English one, it is, though literally correct, quite unfaithful to the weaker emotive force of the French expression. Words can often be found in the second language that have a roughly equivalent associative value to the original one, but these will usually not provide a literal translation; thus, the translator is faced with the dilemma of being able to provide a literal-meaning translation or a translation that renders the spirit or "feel" of the original but not both.

The question of correspondence to actuality. The arts also differ from one another, according to their mediums, in whether the items in the medium correspond to items in the world. Objects with colours and shapes are represented on canvas, and objects with colours and shapes also exist in the outside world. Even when a painting is non-representational, it consists of colours and shapes, which are items in the outside world (even though certain individual colours and shapes in the painting may not exist in the outside world). But the case with music is different: though the visual arts may (to varying degrees) convey the sights of nature, music does not convey the sounds of nature. Even when a work of music attempts to represent the sound of an iron foundry or the clattering of horses' hooves, it really does not sound like these things: musical instruments emit tones, and in nature are found largely noises, and between the two there is an enormous auditory difference. Some rhythms of nature can be duplicated by musical instruments but hardly the sounds themselves.

The medium of literature, words, is indeed man created; but of course this feature is far from unique to literature. Words were devised and employed in countless situations of daily life before they were ever embodied in literature; so in literature, as in visual art, a medium is being employed that existed before the art itself.

ART AS IMITATION (REPRESENTATION)

The view that "art is imitation" is at least as old as the Greek philosopher Plato (428–347 BC), and, although not widely held today, its long and distinguished history is evidence of its continuing hold on human beings as an account of the distinctive function of art. A terminological point, however, is in order here: in the interests of clarity, an artist should be spoken of as representing in his work the persons and things and scenes of the world but as imitating the work of other artists. Thus, "In this

Difficulties in translating poetry

Assigned meanings of words

painting he represents a barn and some wheat fields, and in his style he is imitative of Vincent van Gogh." This distinction will be employed here, with the result that these traditional theories of art will be spoken of as theories of representation rather than of imitation.

At some period in the history of art, aestheticians and critics wrote as if nature should be recorded by the artist with photographic fidelity. The invention of photography (which can do this better than any painter) could plausibly be said to have relieved the artist of any such responsibility. Still, art can represent reality: the representation of a house in a painting may not look exactly like a house—it cannot, since the real house is three-dimensional and the painting is two-dimensional—but it looks enough like one to enable everyone unhesitatingly to identify it as a house.

Distinction
between
depiction
and
portrayal

A distinction should be made between depiction and portrayal. A painting may be said to depict a house if it looks more like a house than like anything else. Thus, most persons unhesitatingly classify this as a man, that as a tree, and so on; only when the painter has distorted or abstracted so much that a thing looks somewhat like a wolf and also somewhat like a bobcat, do they hesitate in saying what the object represented is. A picture may depict a rather short man in a French general's uniform of the early 19th century; but it may, in addition, portray Napoleon. It portrays Napoleon if (1) the artist intended it to represent Napoleon (for example, if the title of the painting is "Napoleon") and (2) the painting does look like Napoleon to some degree at least—at any rate it contains no important characteristics known to be incompatible with those of Napoleon. Clearly, if it is a painting that depicts a tree in someone's yard, it cannot be considered a portrait of Napoleon, no matter how much the artist said he intended it to be one. Depiction subjects can ordinarily be recognized at once with a little knowledge of the world and the names of the things in it. Portrayal subjects require knowledge of whomever the artist intended to portray; even when that seems obvious, as in the case of Napoleon (who would be instantly recognized, unlike the portrait of a private in his army), the viewer would have to be told, by the title or otherwise, that not only does the painting depict a man in a French general's uniform but that it was intended by the artist to be a portrait of this particular man. Otherwise, how would the viewer know that it did not actually portray his double, or his stand-in? The word represent, as used in connection with art, can mean either "depict" or "portray."

Analysis of representation. Representation always involves a certain degree of abstraction; that is, the taking away of one characteristic or more of the original. Even a fairly realistic painting of a person, for example, lacks some features that characterize actual persons: the painting is two-dimensional, whereas every actual person is three-dimensional; the surface of a painting is paint, but not so the person; the actual person has very numerous pores and other marks on his face that are lacking (in whole or in part) in the painting, and so on. The depiction of a person in a painting is usually sufficient to enable human viewers to recognize the figure as a person—though it is apparently not sufficient for an animal, who sees only a coloured canvas where people see on the coloured canvas a representation. When the degree of abstraction is so great that it is no longer possible to recognize this shape as a human shape or as the shape of any identifiable object, the painting is then spoken of as non-representational. (In popular parlance such paintings are called abstract; but this is misleading, for abstraction is a matter of degree, and, as has just been shown, all depictions are necessarily abstract—that is, abstracted from reality to some degree.) The actual object with all its millions of qualities is at one end of the spectrum, and the painting so abstracted that a depiction subject is unrecognizable is at the other end; between the two extremes lie all the possible degrees of abstraction.

Representation
in
literature

Literature can be representational but not in the same way as visual art. It is quite natural to say that in a novel or drama a number of characters and actions are represented. The representation is, of course, not a visual one; it is representation through language. The painter

portrays Napoleon by making a portrait of him; the writer does so by describing him in words. The writer, unlike the painter, can also depict action. Not all literature, of course, is representational in this way: a sonnet may contain no characters at all and no action, consisting solely of an expression of feeling by some unspecified speaker.

Any of the mixed arts that include words as part of their medium, such as drama or film, can be, like literature, representational. Indeed, they have a further advantage: they can depict action not only through words but also by showing the characters and exhibiting the action before the spectator. These arts are visual as well as verbal, and since they are not limited to one moment in time, as painting and sculpture are, they are temporal arts as well as spatial. These mixed arts, then, can be doubly representational.

Is it possible for music, too, to be representational? Music cannot visually show characters or objects, nor can it describe them in words; can it "depict them in tones"? Program notes at concerts usually assume without question that it can. The audience is told about the tone poem *Don Quixote*, by the Austrian composer Richard Strauss, "The composer has given us a musical representation of the Don's adventures. The 17th-century Spanish writer Miguel de Cervantes has described them in words, and Strauss has done so in tones." But the claim to representation in music is, to say the least, quite dubious. Without the title, with the music alone, would there be any clue that the music was supposed to be "about" the adventures of Don Quixote? True, there is a passage that resembles the bleating of sheep sufficiently for that much to be guessed; but even to conjecture that this passage is a representation of sheep bleating is a far cry from being able to reconstruct the entire story. Suppose that Strauss had left every note in the score just as it was but changed the title; would the piece then have been a representation of something else? The very fact that this question can be asked shows how different music is from visual art: if a painter has drawn a house but indicated in the title that it was supposed to be a tree, the viewer could still say, on the basis of what he saw in the picture, that it was not a tree but a house. But in music the listener is never in this situation: if he says that this series of tones represents the adventures of Don Quixote, he says this because of the title Strauss used. If the composer had given it no programmatic title, one listener might think of one represented subject, another a different one, and a third none at all, and there would be no way of showing who was right or even whose opinion was to be preferred. The conclusion seems to be that music by itself—without title, without words, without depicted action (as in a combination of music and drama such as opera)—is incapable of representing anything. There is simply a series of musical tones that may suggest differing associations, programmatic or otherwise; but the musical tones by themselves cannot be said to represent anything at all.

This might be objected to as an overstatement. If a picture can represent a house by looking more like a house than anything else, cannot a work of music represent the sea by sounding more like the sea than any alternative? And is this not the case in, for example, the French composer Claude Debussy's tone poem *La Mer*? Even this, however, is highly questionable; almost no one guesses the title to Debussy's tone poem without first knowing what it is; it may seem obvious enough after the composer has channelled the listener's response by means of his title but not beforehand. And surely this is because the sounds in the tone poem do not sound more like the sea than like anything else: the tone poem consists, after all, of a series of complex musical tones, emitted by violins, cellos, clarinets, flutes, trumpets, and so on; and it would be difficult indeed for these sounds, which are musical tones, to sound very much like the sea, whose sounds consist after all of a series of complex noises. There is no great similarity between any one series of musical tones and any one series of nature's noises. Hence, the first cannot be said to constitute a representation of the second.

The matter is even more obvious in the case of those

Musical attempts to represent the soundless

numerous programmatic titles in which the supposedly represented subject contains no sounds at all. Debussy's *Reflets dans l'eau* (*Reflections in the Water*) is taken by some as a musical representation of reflections in the water. But reflections in the water emit no sounds at all, not even noises. No one, then, could say that the sounds in Debussy's piano composition resemble the sounds of reflections in water. The resemblance, if there is any, is much more remote: it may be that the feeling obtained when Debussy's composition is heard is somewhat like the feeling that arises when reflections in water are seen. This is highly improbable without knowledge of the title, but at most it would provide a mood resemblance, which is far removed from a representation by music of things in the world. The conclusion seems inescapable that music is not to be classified as a representational art, at least not in the same straightforward meaning of "representation" that applies to the other arts.

So much, then, for the capacities of the various arts as far as representation is concerned. But the question remains: in those arts that are properly called representational, what should be the nature of the representation?

That art should be an outright duplication (incorrectly called "imitation") of reality is a view that was put forward by the French novelist Émile Zola in his book *Le Roman expérimental* (*The Experimental Novel*) and has been occasionally held (though not practiced) by painters reacting against Romanticism, such as the 19th-century French artist Gustave Courbet. Zola advocated a novel that resembled a scientific investigation into reality. Plot was to be of no importance, rather an aspect of reality was to be examined searchingly, and from this the story would unfold without imaginative effort. Persons or groups of persons would be depicted, and from them the action would evolve.

Objections to Zola's theory of duplicating reality

It would be impossible, of course, to carry out such an ideal of art as "report" and undesirable even if it were possible. First, the author or painter must select a subject; and, within the subject, he must select which details to treat, for he cannot in a hundred lifetimes describe them all: since every object and event has an indefinitely large array of qualities, there is no point at which a description of it would be completed. Besides, the very language used (no matter how neutral a description is attempted) will colour the account. Even if the words were colourless, the mode of putting them together would yield a style, which would colour the account once again. Indeed, should such an ideal be achieved (as in the verbatim transcription of an actual trial) it would be the deadliest possible bore.

Art, even representational art, is not a reproduction of reality; it is a transformation of reality. How, specifically, is reality transformed in being represented in art? There is probably no general satisfactory answer to this question. Each art, each style of art, and each work of art transforms reality in its own way—the 19th-century French painters Paul Cézanne in one way, Pierre-Auguste Renoir in another; the 19th-century Russian writers Fyodor Dostoyevsky in one way, Leo Tolstoy in another. No set of rules can lead to predictions as to what transformation of reality will be conceived in the mind of the next creative artist. Reality is the common base, but each artist deals with it in his own unique way.

Subject matter. Do all works of art have a subject matter? The answer to this depends on what is meant by the term subject matter, which signifies basically what the work is about. There are several senses of being "about" that may be referred to:

1. "What is the subject matter of the *Odyssey* by the ancient Greek poet Homer?" The most natural answer would be: "The wanderings of Odysseus." This is the "representational content" of the work. A person who read it simply for the story could easily give this answer. There is contained in the work itself an account of the wanderings of a character named Odysseus, who has no counterpart in the outside world (that is, he is a fictional character) but who does resemble people in the outside world in that he is a man, he is away from home, he is beset by many vicissitudes, and so on. If the subject matter were stated in greater detail, the result would be an account of the plot.

Does painting have subject matter in this sense? If "subject matter" is taken to mean representational content, the answer is often yes; representations of people and trees and the like are easily identifiable in the painting. Sometimes the subject could not be ascertained except for the title, which is not strictly a part of the painting (the title is not a piece of visual art, consisting as it does of words). But quite clearly it cannot be said that the subject matter of the painting is whatever the title says it is: if the title says "Clouds" and the painting is obviously a still life with pears and grapes, it can hardly be said that the painting has clouds as its subject matter simply because the title says so. It was long said that the painting called "Sacred and Profane Love" by the 16th-century Italian artist Titian had sacred and profane love as its subject matter; but Titian himself gave it no such title—the title was added more than a century later by someone else. It cannot be said that the subject matter is what whatever title it came to be given says it is (it could be given numerous incompatible titles); the subject matter, in this sense, must be evident from—or at least not incompatible with—what is seen in the painting itself. The same remarks apply to music: music cannot be "about" anything that the composer happens to seize on as a title; if it were, and he changed the title without changing a note of the music, would the subject matter of the music have changed? Strong reasons already have been given to doubt that music can have a subject matter at all.

2. In addition to a subject matter in the sense of representational content, a work of art may have subject matter in the sense of theme, or underlying idea. The subject matter in the sense of representational content of *Jude the Obscure*, by English novelist and poet Thomas Hardy, is the intellectual ambitions of the main character, Jude, and the vicissitudes befalling him along the way; but the subject matter in the sense of theme or underlying idea is man's struggle to realize his ambitions; and the thesis (implicit message) of the novel is (or may be) that man's highest ambitions are doomed to frustration. Not all novels and dramas and poems have a theme or thesis; they may simply tell a story and nothing more. Works of literature do sometimes operate in both dimensions: a story and a theme or thesis underlying the story. Works of representational visual art may also do so: one might allege that the theme of "Guernica," by the 20th-century Spanish artist Pablo Picasso, is the horror of war. Again, it is doubtful whether works of music can be said to have a theme at all (indeed, the term theme applied to music has a very different meaning: it refers to a set of tones around which variations or developments are composed). If someone were to say that the theme of a work of music was the human condition or man's fear of death, how would such a view be supported? Since music is not representational, what musical passages would he take as evidence for his theory, and why? A composer might indeed title his work "The Human Condition," but this would no more show that the music was about the human condition (had the human condition as its subject matter) than giving the programmatic title "Clouds" to a musical composition shows that the composition actually is about clouds.

Symbols in art. Works of art may not only have subject matter, they may also contain symbols. Certain elements in a work of art may represent, say, a whale; but the whale thus represented may be (as it is in *Moby Dick* by the 19th-century U.S. writer Herman Melville) a symbol of evil. In Tolstoy's *Anna Karenina* is represented a gallery of characters dominated by Anna herself, and a tremendous number of actions in which these characters engage; but there is a constantly recurring item in the representational content, namely, the train. Time and again the train causes or accompanies frustration, disaster, betrayal, and other evils—so much so that before the novel is ended it becomes apparent that the train here is a symbol of the iron forces of material progress toward which Tolstoy had such great antipathy.

What is it that makes an item in a work of art a symbol? It is something represented in the work of art—an object, an action, or a pattern of objects and actions, or even (less frequently) simply a nonrepresentational item such

Thematic subjects

Conven-
tional
and natural
symbols

as a colour or a line—that does the symbolizing; what is symbolized is a characteristic, such as evil or progress or courage. But by virtue of what does the first (A) become a symbol of the second (B)?

The answer is not the same for all symbols, since some are conventional and some are natural. The cross is a symbol of Christianity, and it is a conventional symbol of suffering; in order for it to become a symbol, people had to adopt or accept the cross as standing for suffering. Other symbols are natural—the sun as the symbol of life and strength, a river as the symbol of eternal change and flowing, and so forth; in these cases there was no agreement (convention) as to what would stand for what, for the relation is too obvious—the symbolism is much the same in the tradition of all nations and civilizations.

Various symbols have, to varying degrees, elements of both the conventional and the natural: the eagle on the standard of the United States of America symbolizes strength—this is natural, because the eagle is strong, and conventional, because the eagle was officially adopted as the symbol of the United States. In the case of many symbols, the natural relation between symbol and thing symbolized is not strong enough by itself to achieve the symbolism, and the conventional relation was entered into in order to effect a symbolism that already had a certain natural basis. When A is a symbol of B, there must be some relation, either natural or conventional, between the symbol and what is symbolized. When the natural relation is strong, the conventional is minimal or nonexistent, and vice versa.

But there is another element to symbolism if it is to function with full-bodied effectiveness in a work of art, and that is what has been called a “vital basis” provided by history and tradition. In the U.S. flag there is very little natural basis for symbolism; it is almost wholly conventional. But the fact that it has been saluted for so long, that it has been present on battlefields, that the bodies of military dead have been wrapped in it, and so on—that is, the fact that it has acquired a life, a history—have given it an “affect” (human emotion or mood) it did not have before. Melville and Tolstoy not only represented the whale and the train: they invested these representations with such strong emotional affect that the reader is much more inclined than he would be otherwise to say that these objects are the symbols of the qualities he ascribes to them.

When some item in a work of art is construed as a symbol, it is always infused with these vital qualities. Clearly, not every case of one thing standing for something else is a symbol in this sense: a carrot in a painting does not, just by itself, symbolize growth. But barbed-wire fences do symbolize tyranny, not only because many prisoners have been enclosed in barbed-wire fences (this is the natural basis for the symbolism) but also because of concentration camps and the countless tragic events of recent history that have provided the “vital basis” for the symbolism.

Meaning. Do works of art have meaning? The answer depends once again on how the question is construed: the word “meaning” is an equivocal term that can itself mean many different things.

Clouds mean rain, a falling barometer means that a storm is coming, a twister in the sky means an approaching tornado—that is, the one is a sign of the other; these relations exist in nature and were discovered, not invented, by man. On the other hand, a bell ringing means the end of class, this note on the score means that D sharp is to be played on a certain instrument, and the word cat to someone who knows English means a certain species of domesticated quadruped; these relations are conventional, established by man. But both the natural and the conventional items are examples of meaning in its most general sense—one thing (A) standing for another (B).

Since the medium of literature is words, and words are conventional vehicles of meaning, literature has meaning in a way that the other arts do not, since every word, to be a word at all, must have a meaning. In the sense in which the word cat means something, middle C and an ellipse do not have meanings at all.

When the question is asked about meaning in art, however, it is not usually the individual ingredients in it that

are being referred to: if it were, the answer could simply be, “Yes, this word has a meaning and that word has; so does the sentence as a whole; and items in paintings sometimes have meaning; for example, the halo over the Madonna’s head symbolizes holiness.” What is being asked is whether the work of art as a whole has a meaning. But what does the question itself mean? Several different things can be meant: (1) The inquirer may be asking, “What is it about?” in which case the question is about subject matter, already discussed. (2) He may be asking, “What is its theme?”—for example, is the motion picture *He Who Must Die* really a parable about the life of Christ? (3) He may be asking, “What is its thesis?” For example, what is the message of the Anglo-Irish author Jonathan Swift to the reader in “A Modest Proposal”? (4) The inquiry may be about the effects of a work of art on the recipient—either what these effects are or what they could or should be. In this sense, all works of art have meaning, since they all have effects (whether there is one type of effect that a given work of art should have is another question). This is, however, an extremely misleading use of the word “meaning.” Indeed, the entire discussion of “meaning in art” is a most confusing one—and the fault does not lie in art, but in the human users of words. Endless unnecessary mysteries can be created by using such nebulous words as “meaning” as if they were simple, straightforward, and susceptible to one interpretation. It would contribute greatly to the clarification of discussions of philosophy of art if the word meaning were not used in them at all but some conception clearer and more specific.

ART AS EXPRESSION

The view that “art is imitation (representation)” has not only been challenged, it has been moribund in at least some of the arts for more than a century. It has largely been replaced by the theory that art is expression. Instead of reflecting states of the external world, art is held to reflect the inner state of the artist. This, at least, seems to be implicit in the core meaning of “expression”: the outer manifestation of an inner state. Art as a representation of outer existence (admittedly “seen through a temperament”) has been replaced by art as an expression of man’s inner life.

But the terms “express” and “expression” are ambiguous and do not always denote the same thing. Like so many other terms, “express” is subject to the process-product ambiguity: the same word is used for a process and for the product that results from that process. “The music expresses feeling” may mean that the composer expressed his feeling in writing the music or that the music when heard is expressive (in some way yet to be defined) of human feeling. Based on the first sense are theories about the creation of art; founded on the second are theories about the content of art and the completion of its creation.

Expression in the creation of art. The creation of a work of art is the bringing about of a new combination of elements in the medium (tones in music, words in literature, paints on canvas, and so on). The elements existed beforehand but not in the same combination; creation is the re-formation of these pre-existing materials. Pre-existence of materials holds true of creation quite apart from art: in the creation of a scientific theory or the creation of a disturbance. It applies even to creation in most theologies, except some versions of Christian theology, in which creation is *ex nihilo*; that is, without pre-existing matter.

That creation occurs in various art mediums is an obvious truth. But once this is granted, nothing has yet been said about expression; and the expressionist would say that the foregoing statement about creation is too mild to cover what he wants to say about the process of artistic creation. The creative process, he wants to say, is (or is also) an expressive process; and for expression something more is necessary than that the artist be creating something. Great care must be taken at this stage: some say that the creation of art is (or involves) self-expression; others say that it is the expression of feeling, though not necessarily of one’s own feeling (or perhaps that and something more, such as the feeling of one’s race, or of one’s nation, or of all men);

The terms
“express”
and “ex-
pression”

Meaning
in
literature

others say that it is not necessarily limited to feelings, but that ideas or thoughts can be expressed, as they clearly are in essays. But the distinctively expressionist view of artistic creation is the product of the Romantic movement, according to which the expression of feelings constitutes the creation of art, just as philosophy and other disciplines are the expression of ideas. It is, at any rate, the theory of art as the expression of feelings (which here shall be taken to include emotions and attitudes) that has been historically significant and developed: art as specially connected with the life of feeling.

When a person is said to be expressing a feeling, what specifically is he doing? In a perfectly ordinary sense, expressing is "letting go" or "letting off steam": man expresses his anger by throwing things or by cursing or by striking the person who has angered him. But, as many writers have pointed out, this kind of "expressing" has little to do with art; as the U.S. philosopher John Dewey said, it is more of a "spilling over" or a "spewing forth" than expression. In art at least, expression requires a medium, a medium that is recalcitrant and that the artist must bend to his will. In throwing things to express anger, there is no medium—or, if the man's body is called the medium, then it is something he does not have to study to use for that purpose. It is still necessary to distinguish a "natural release" from an expression. If poetry were literally "the spontaneous overflow of powerful feelings," as William Wordsworth said, it would consist largely of things like tears and incoherent babblings. If artistic creation can plausibly be said to be a process of expression, something different from and more specific than natural release or discharge must be meant.

Emotional
expression
in art

One view of emotional expression in art is that it is preceded by a perturbation or excitement from a vague cause about which the artist is uncertain and therefore anxious. He then proceeds to express his feelings and ideas in words or paint or stone or the like, clarifying them and achieving a release of tension. The point of this theory seems to be that the artist, having been perturbed at the inarticulateness of his "ideas," now feels relieved because he has "expressed what he wanted to express." This phenomenon, indeed a familiar one (for everyone has felt relieved when a job is done), must still be examined for its relevance. Is it the emotion being expressed that counts or the relief at having expressed it? If the concern here is with art as therapy or doing art to provide revelations for a psychiatrist, then the latter is what counts; but the critic or consumer of the art is surely not concerned with such details of the artist's biography. This is an objection to all accounts of expression as process: how is any light at all cast upon the work of art by saying that the artist went through any expressive process or through any process whatever in the genesis of it? If the artist was relieved at the end of it, so much the better for him; but this fact is as aesthetically irrelevant as it would be if he had committed suicide at the end of it or taken to drink or composed another work immediately thereafter.

Another problem should be noted: assuming that the artist does relieve his oppressed state of mind through creating, what connection has this with the exact words or score or brushstrokes that he puts on paper or canvas? Feelings are one thing, words and visual shapes and tones are quite another; it is these latter that constitute the art medium, and in it that works of art are created. There is doubtless a causal connection between the feelings of the artist and the words he writes in his poem; but the expression theory of creation talks only about the artist's feelings, while creation occurs within the art mediums themselves; and to speak only of the former is not to tell anything about the work of art—anything, that is, that would be of interest other than to the artist's psychiatrist or biographer. Through what paroxysms of emotion the artist passed does not matter anymore, insofar as one's insight into his work is concerned, than knowing that a given engineer had had a quarrel with his wife the night before he began building his bridge. To speak of anything revelatory of works of art, it is necessary to stop talking about the artist's emotions and talk about the

genesis of words, tones, and so on—items in the specific art mediums.

The expressionists have indeed brought out and emphasized one important distinction: between the processes involved in art and in craft. The activity of building a bridge from the architect's blueprint or constructing a brick wall or putting together a table just like a thousand others the artisan has already made is a craft and not an art. The craftsman knows at the beginning of the processes exactly what sort of end product is wanted: for example, a chair of specific dimensions made of particular materials. He knows at the beginning how much material it will take to do the job, which tools, and so forth, and, if he does not know these things, he is not a good (efficient) craftsman. But the creative artist cannot work in this manner: "The artist doesn't know what he is going to express until he has expressed it" is a watchword of the expressionist. He cannot state in advance what the completed work of art will be like: the poet cannot say what words will constitute the completed poem or how many times the word "the" will occur in it or what the order of the words will be—when he knows that, he has completed the creation of the poem, and until then he cannot say. Nor could he set about working with such a plan: "I shall compose a poem that contains the word 'the' 563 times, the word 'rose' 47 times," and so on. What distinguishes art from craft is that the artist, unlike the craftsman, "does not know the end in the beginning"; he cannot state until his work is finished what the completed product will be like—if he could, he would not have to undergo the "divine agonies" of creation in order to produce it.

Distinction
between art
and
craft

The distinction seems valid enough, but whether it supports the expressionist's view is more dubious; for it can be held regardless of the attitude assumed toward the theory of expression. The open-ended process described as art rather than craft characterizes all kinds of creation: of mathematical hypotheses and of scientific theory, as well as art. What distinguishes creation from all other things is that it results in a new combination of elements, and it is not known in advance what this combination will be. Thus, one may speak of creating a work of sculpture or creating a new theory, but rarely of creating a bridge (unless the builder was also the architect who designed it, and then it is to the genesis of the idea for the bridge, not to its execution, that the word creation applies). This, then, is a feature of creation; it is not clear that it is a feature of expression (whatever is being done in expressing that is not already being done in creating). Is it necessary to talk about expression, as opposed to creation, to bring out the distinction between art and craft?

There does not seem to be any true generalization about the creative processes of all artists nor even of great artists. Some follow their "intuitions," letting their artistic work grow "as the spirit moves" and being comparatively passive in the process (that is, the conscious mind is passive, and the unconscious takes over). Others are consciously active, knowing very much what they want in advance and figuring out exactly how to do it (for example, the 19th-century U.S. writer Edgar Allan Poe in his essay "The Philosophy of Composition"). Some artists go through extended agonies of creation (the 19th-century German composer Johannes Brahms, weeping and groaning to give birth to one of his symphonies), whereas for others it seems to be comparatively easy (Mozart, who could write an entire overture in one evening for the next day's performance). Some artists create only while having physical contact with the medium (for example, composers who must compose at the piano, painters who must "play about" in the medium in order to get painterly ideas), and others prefer to create in their minds only (Mozart, it is said, visualized every note in his mind before he wrote the score). There appears to be no true generalization that can be made about the process of artistic creation—certainly not that it is always a process of expression. For the appreciation of the work of art, no such uniformity, of course, is necessary, greatly though it may be desired by theorists of artistic creation.

Problems
in drawing
con-
clusions
about the
creation
of art

The main difficulties in the way of accepting conclusions about the creative process in art are (1) that artists differ so much from one another in their creative processes that no generalizations can be arrived at that are both true and interesting or of any significance; and (2) that in the present stage of psychology and neurology very little is known about the creative process—it is surely the most staggeringly complex of all the mental processes in man, and even his simpler mental processes are shrouded in mystery. In every arena hypotheses are rife, none of them substantiated sufficiently to compel assent over other and conflicting hypotheses. Some say—for example, Graham Wallas in his book *The Art of Thought*—that in the creation of every work of art there are four successive stages: preparation, incubation, inspiration, and elaboration; others say that these stages are not successive at all but are going on throughout the entire creative process, while still others would produce a different list of stages. Some say that the artist begins with a state of mental confusion, with a few fragments of words or melody gradually becoming clear in his mind and the rest starting from there, working gradually toward clarity and articulation; whereas others hold that the artist sets himself a problem, which he gradually works out during the process of creation, but his vision of the whole guides his creative process from its inception. The first view would be a surprise to the dramatist who sets himself from the beginning to write a drama in five acts about the life and assassination of Julius Caesar; and the second would be a surprise to artists like the 20th-century English artist Henry Moore, who has said he sometimes begins a drawing with no conscious aim but only the wish to use pencil on paper and make tones, lines, and shapes. Again, as to psychological theories about the unconscious motivations of artists during creation, an early Freudian view is that the artist is working out in his creation his unconscious wish fulfillments; a later Freudian view is that he is engaged in working out defenses against superego charges, “proving something to himself.” Views based on the ideas of the 20th-century Swiss psychologist Carl Jung reject both these alternatives, substituting an account of the unconscious symbol-making process. Until a great deal more is known about the empirical sciences that bear on the issue, there is little point in attempting to defend one view of artistic creation against another.

The expressive product. Although talk about expression as a process is hedged with difficulties and in any case seems irrelevant to the philosophy of art (as opposed to the psychology of art), there is another way in which talk about expression may be both true and important to the philosophy of art. Mention is made about expressive properties as belonging to works of art: for example, it is said that a certain melody expresses sadness, that there is a feeling of great calm expressed in a particular painting, or that tension is expressed in the thrusts of a tower or the development of the plot of a novel or drama.

The question arises at once of what it means to say such things. Melodies and sentences are not joyous or tense or melancholy; only persons have these qualities. The artist can have them, but how can the work of art? Clearly, to speak of a work of art as having emotions, if it is not to be utter nonsense, must be metaphorical. But what is the meaning of this metaphor? What does it mean to say that the music expresses sadness, if not in the sense of process; i.e., that in writing it the composer expressed his sadness?

The music is heard, the painting is seen; each presents itself to the senses. But there is much more involved in music than simply hearing (or even listening to) the sounds and in visual art than simply seeing (or even looking at) the colours and shapes. Even very simple combinations of sounds and shapes and colours seem to express certain qualities of life: a curved line, it is said, is graceful or sprightly; the drooping willow tree is sad, as are certain passages in music. It is virtually impossible for most persons to view art as a series of sensory stimuli only. Even when a picture contains no story, no plot, no program, the viewer “reads into the script”: he attributes to works of art qualities of human moods, feelings, emotions—in short, “affects.” It would be safe to say that in all art, every percept is suffused with affect. The problem is: What is it

that makes certain percepts expressive of certain affects?

The simplest answer, that “The melody is sad” means no more or less than “Hearing the melody makes me (or other listeners, or most listeners) feel sad,” is surely inadequate. (This would be a theory of evocation, not of expression.) “The music expresses whatever feelings it arouses in me when I hear it.” But often the listener does not feel emotions at all (he may imagine them), or, if he does, he feels very different emotions from the ones he believes to be expressed in the music. He may consider the rondo delirious with joy, but if he is grief stricken on a given day he hears it without feeling joy; and if he has heard the same rondo 30 times that day he feels only boredom or fatigue, while still believing that the piece is expressive of joy. Nor is it an adequate analysis to say that “The melody expresses joy” means “I am disposed to (or inclined to) feel joy when I hear it,” for many people seem to recognize joy as a quality of the music without feeling it at all: or they may imagine it or just recognize the emotion without feeling it or believe that what they hear sounds the way joy feels—or any of a number of other accounts.

The true analysis of expressiveness in art must be more complex than this: it is not that the melody evokes emotion X, but that emotion X is somehow embodied in the music. But this leads back again to the question, how can an emotional quality be in a work of art? There is no single answer to this question that would be accepted by all philosophers of art, but most accounts begin by noting certain similarities, or analogies, between features of music and features of human feeling; so that when X (a passage of music, for example) is said to express Y (a state of feeling), there are certain similarities (for example, of structure) between X and Y. The physical accompaniments to a mood, say, of restlessness, such as rapid breathing and drumming fingers, have their musical equivalents: trills, quavers, increases in tempo, and the like.

When a listener says that a certain melody is sad, he is saying that the music literally has certain qualities A, B, C, D that can be perceived in the music. Slowness is surely one such quality (the same melody played fast would not be called sad); another is the absence of large intervals between tones; another is that the sounds tend to be hushed rather than, for example, strident; another is that the tendency of the musical movement is downward rather than rising. When a listener says that the music is sad, he is saying that it has these qualities.

But why these qualities rather than others? Why is it said that the music is sad when it has A, B, C, D rather than when it has M, N, O, and P? Because A, B, C, D are the qualities that also characterize people when they are sad, such as slowness and soft and low speaking voices. If this theory or anything like it is true, it explains how emotional characteristics can be attributed to works of art—why it can be said that the melody is sad, that the horizontal lines in a painting make it calm (horizontal being the position of rest and peace, sleep and maximum relaxation, and from which one does not fall), why the lines in a painting are droopy (they are lines similar in shape to that of, say, an old woman with hunched shoulders), and so on. These qualities, it should be noted, are qualities of the work of art, not of the artist (whether he was sad when he wrote sad music is a separate question, to which the answer may sometimes be no) and not of the listener or observer (the melody is sad even if I am not sad when I hear it). They are, so to speak, embodied in the music, quite independently of the state of the artist or of the observer, or listener, though of course it requires the presence of a listener to recognize them and be moved by them.

Talk about artistic expressiveness, then, can be justified. But there is no need to resort to the language of expression in order to state it: instead of saying, “The music expresses sadness,” it can simply be said, “The music is sad.” But regardless of the terminology employed, it is important to have justified this conclusion.

ART AS FORM

The formalist position. Against all the foregoing accounts of the function of art stands another, which belongs

Emotional
qualities
embodied
in art

Meta-
phorical
expression
of
emotion

“Art for
art’s sake”

distinctively to the 20th century—the theory of art as form, or formalism. The import of formalism can best be seen by noting what it was reacting against: art as representation, art as expression, art as a vehicle of truth or knowledge or moral betterment or social improvement. Formalists do not deny that art is capable of doing these things, but they believe that the true purpose of art is subverted by its being made to do these things. “Art for art’s sake, not art for life’s sake” is the watchword of formalism. Art is there to be enjoyed, to be savoured, for the perception of the intricate arrangements of lines and colours, of musical tones, of words, and combinations of these. By means of these mediums it is true that objects in the world can be represented, scenes from life depicted, and emotions from life expressed; but these are irrelevant to the principal purpose of art—indeed, art is much less adapted to the telling of a story or the representation of the world than it is to the presentation of colours, sounds, and other items in the art medium simply for their own sake.

Most people who claim to enjoy paintings, for example, enjoy them not as presentations but as representations of things and situations in life; and thus their response is not of a kind that is unique to art, but one that takes them back to the emotions of life, from which they came. They could use art to take them into a realm of pure form unknown to anyone who is unacquainted with art; but instead they use it to direct them back to the feelings and situations of life. Thus, according to the formalists, these viewers miss the opportunity of being taken into a fresh world of purely aesthetic experience and get from a work only what they bring to it: familiar experiences and emotions they employ the work to recall.

What, then, should be brought from life to art? Knowledge of life’s struggles and emotions? Knowledge at least of what people are like, and what visual objects look like? Not even these things, for even they get in the way. Representation is not bad in itself, it is merely irrelevant. Only if the representation is satisfactory as form and contributes to the general abstract design can it be said to matter aesthetically.

Most formalists have directed their attention primarily to visual art. The prerequisite for appreciating this, they believe, is a sense of form and colour and a knowledge of three-dimensional space (the last required because otherwise a cube, for example, would appear in a painting as a flat pattern and would be unable to play the architectural role intended for it). Armed with this bit of knowledge from life, they have all they need (as far as knowledge of the world outside art is concerned) for appreciating visual art. Armed with more than this, they would find their attention drawn away from the sublimities of art to the more approachable concerns of humanity (such as representation). Shorn of this extraneous knowledge and coming to painting with eyes innocent of extraneous concepts, the viewer could then be in a position to look at what painting presents directly to his vision—complex arrangements of forms and colours—which, for reasons thus far unexplained, have the capacity to move the recipient deeply with emotions utterly alien to the emotions of life.

The formalist’s account of music runs along similar lines: not only representation (program music) is excluded but so is the entire realm of human feeling—not the feeling that the contemplation of pure form can give but only the feelings of life, such as love or terror. As to literature and all those arts in which words play a part (song, opera, drama, cinema), the formalist position would seem to be impossible; and indeed formalists have seldom attempted to extend their theory to literature. The medium of literature is words and sentences; and words and sentences are not merely noises but noises with meanings; and these meanings inevitably have to do with the objects, actions, qualities, and situations of life. As sound, literature is a poor thing—as a complex of meanings, it can be profound and beautiful. Take these away, and literature could cease to be. Literature does have formal properties—a drama can be as tightly knit as a fugue or a symphony—but the appreciation of it can never consist of these formal properties alone; and the reason lies in the very nature of the medium. It is the role of words to indicate images and

meanings and emotions, and these are the stuff of life—therefore verbal art is inescapably humanistic. Whatever sensory beauty words have in their sounds is slight and secondary; not so with painting, where colour, line, and space have a beauty all their own and need stand for nothing outside themselves to satisfy the eye.

Formal principles in art. What, then, are the specific qualities in works of art that the formalist is seeking? Most formalists have held that a partial account can be given of these but that, in the end, the presence of the qualities must be felt intuitively and cannot be described. Accounts of formal qualities in works of art go back as far as Aristotle’s *Poetics*, written in the 4th century BC, and usually include (though sometimes in different terminology) the following as principal ingredients:

Organic unity. A work of art must have what Aristotle called “a beginning, a middle, and an end”; it must be unified, it must “hang together” as one entity. Everything, of course, has some degree of unity or other; even a collection of things, such as a woodpile, has some unity inasmuch as it can correctly be called one thing: it is a collection, but it is a single collection. But the unity desired in works of art is much greater than this: it is more like the unity of the higher organisms in which every part functions not independently of the others but interdependently with them; and it is this interdependency of the parts that constitutes an organic unity. Take away one part, and the remainder of the parts fail to function as before. This is only approximately true of organisms: without a heart or a brain a person could not continue to exist, and the activity of the other organs would cease; but without an ear or a toe they surely would. Philosophers of art have often noted that the purest examples of organic unity in the universe are not organisms but works of art: here the interdependency of parts often achieves a state of such perfection that it could often be said, of a melody or a sonnet, that if this note (or word) were not there, in just the place that it is, the effect on the entire remainder of the melody or poem would be disastrous.

Complexity, or diversity. This principle is the natural accompaniment of the first one. A blank wall has unity but no variety and is not long worth contemplating. Nor is there any triumph in achieving unity at so small a price. The work of art must hold in suspension (as it were) a great diversity of elements and unify them—the greater the complexity that is integrated into a unity, the greater the achievement. This fact is so universally recognized that the two criteria are often stated as one, unity-in-diversity, or variety-in-unity.

Very many great works of art are much less than perfect organic unities (which is another way of saying that unity-in-variety is not the only criterion for excellence in works of art). Particularly in long poems or novels or operas, some parts are clearly more important than the others, though contributing to the whole, and some parts may be simply “padding.” One could hardly allege that the entire ancient Greek epic the *Iliad* is an organic unity and that if (for example) the catalog of ships were removed the entire epic would be ruined (some even say it would be improved). In Dostoyevsky’s novels there are whole chapters that are unnecessary from the point of view of relevance to the rest of the story, and, aesthetically (though perhaps not in other ways), these are a pure excrescence. In most works of art there are high spots and low spots, and there is a great deal of elasticity as to what could follow what. But in spite of this, unity-in-variety is quite universally recognized as a criterion for artistic excellence. If a drama consisted of two plots that never connected with one another, even at the end, such a play would be condemned at once for lack of unity; and a work of art is never praised for being disjointed or disunified, though it might be praised in spite of being disunified.

Theme and thematic variation. In many works of art there is a dominant theme, or motif, which stands out and upon which the other portions are centred. This theme is then varied in different ways in other portions of the work. This is a special case of unity-in-variety: if every line in a work of music or literature were entirely novel and different from the other ones, there would be enor-

Unity-in-
variety in
works of
art

Inappli-
cability
of the
formalist
position

mous diversity but no unifying connecting links; whereas if there were simply a repetition of the initial theme or of entire sections of the work (as sometimes happens when a composer does not know how to develop the thematic material with which he has begun) there is unity but no variety. Both unity and variety are preserved by having central themes, with other material that is related to them (unity) but not identical with them (variety).

Development, or evolution. In works of temporal art, each part develops or evolves into the next, each part being necessary to the succeeding part, so that if an earlier part were altered or deleted, all the subsequent parts would have to be altered in consequence. If a portion of Act IV could be interchanged with a portion of Act II without loss of effect, the principle of development has not been observed, for then the material occurring in between would not have made any difference.

Balance. The arrangement of the various parts should be balanced, usually in contrasting ways (the adagio movement coming between two faster movements, for example). In painting, there should be a balance between the right and left halves of the canvas. The many ways, other than simple mechanical symmetry ("for every item on the left there should be an item on the right," which soon becomes monotonous), in which a painting may have variety and yet retain balance are too complex to be discussed other than in a book of art criticism. But in its simplest essentials, the principle is acknowledged by everyone: the housewife who places all the furniture on one half of the living room while leaving the other half empty finds the arrangement aesthetically displeasing because the room lacks balance.

There are many descriptions of principles of form in art, which differ from one another in their terminology more than in their final outcome. In general, however, few if any of these principles would be denied (only the detail of their formulations might be) by most philosophers of art. Why certain principles of form are found satisfactory and others are not is a fascinating psychological question, leading back to a discussion (necessarily vague in the present state of knowledge) of the nature of the human organism and the discriminatory powers of the human mind. But however obscure the explanation, the facts of the case seem clear enough: certain formal principles in art must be observed, and, to the degree that they are ignored or violated, aesthetic catastrophe occurs: the work of art cannot evoke our interest or sustain it long once it is initiated.

Though a discussion of these formal principles is helpful particularly to those who have little native sense of form and who want "to know what to look for" in art, they are sufficiently vague so that many critics can agree on a formal principle, such as unity, and yet disagree on the degree to which a specific work possesses it.

In addition, these principles are far from complete: a work of art can possess unity and the other requirements in high degree and yet be unsuccessful even as form. The requirements listed seem only to have skimmed the surface. Yet what more is required to distinguish a formally correct but dull work of art from a brilliant one seems to defy precise analysis. Moreover, the majority of critics who have assented to these principles are not formalists: they have acknowledged and even insisted on the great importance of form in works of art, but they have not alleged, as formalists do, that these principles constitute the sole criteria of excellence in works of art. They have held that the fulfillment of formal criteria counts as a necessary condition for artistic excellence but not a sufficient condition.

PRAGMATIC THEORIES OF ART

There are theories of art that differ from one another in what they allege to be the real purpose or function of art but are at one with each other in the belief that art is a means to some end, whether that end be the titillation of the senses or the communication of the nations of the world or the conversion of mankind to belief in God or the improved moral beliefs or moral tone of the reader or viewer. In every case, the work of art is considered

as a means to some end beyond itself, and hence what counts in the final analysis is not the nature of the work of art itself but its effects upon the audience—whether those effects be primarily sensory, cognitive, moral, religious, or social.

Hedonistic theories of art. According to one kind of theory, the function of art is to produce just one kind of effect upon its audience: pleasure. It may also inform or instruct, represent or express, but first and foremost it must please. The more pleasure it gives, the better the art.

If the theory is left in this simple form, it yields the result that glossy and superficial works and those containing nothing difficult or obscure are the best works of art: thus, on the hedonistic account, *King Lear* might come out far behind Henry Wadsworth Longfellow's *The Song of Hiawatha*, or Joyce Kilmer's "Trees," in view of the difficulty of comprehending Shakespeare by many people and the pleasant, easy lilting quality of Longfellow's poem; and similarly a simple ditty might come out ahead of Bach's *Mass in B Minor*. True, Shakespeare and Bach might produce more pleasure in the long run since their works have endured through more centuries. But on the other hand, the simple works can be apprehended and enjoyed by vastly more people.

In any case, the theory has often been amended to read "aesthetic pleasure" rather than simply "pleasure"—thus placing great importance on exactly how the term "aesthetic" is to be defined. The definition of this troublesome term is beyond the scope of this article (see AESTHETICS); it will simply be said here that no quick and easy way of distinguishing aesthetic pleasures from other pleasures will suffice for the task at hand. If it is said, for example, that aesthetic pleasure consists in satisfaction taken in the contemplation of sensuous particulars (tones, colours, shapes, smells, tastes) for their own sake—that is, for no further end and without ulterior motive—then one confronts the fact that as much pleasure may be taken in single smells and tastes for their own sakes, without any reference beyond them, as may be taken in the most complex works of art. For that matter, pleasure in playing a game (one not played for money) is pleasure in doing something for its own sake, as is the pleasure of robbing a house if it is done not for money but for "kicks." If something is found pleasurable, ordinarily the pleasure is what one wants from it, not something else beyond it.

Moreover, if it is said that a work of art should be a means toward pleasure, that is treading suspiciously near to the opposed view that art should not be a means to an end but an end in itself. If someone says, "Why do you go jogging every morning for three miles? Because you feel the exercise is good for you?" and another person answers, "No, not that at all, I just enjoy doing it," this would ordinarily and quite sensibly be taken as saying that he did not do exercise as a means toward an end but as an end in itself. If something is done just because it is enjoyed, in common parlance this would be taken to be "doing it as an end in itself"; and if one objected, "No, I'm not doing it as an end in itself, I'm doing it as a means toward the enjoyment I'll get out of it," his reply would be considered sophistical, for doing it for enjoyment's sake is precisely what is ordinarily meant (or one thing that is ordinarily meant) by the statement that a thing is being done for its own sake.

In any case, the effect of great works of art upon a reader or viewer or listener can hardly be described as merely hedonistic. No one would presumably wish to deny that art can and should give us pleasure; but few would wish to assert that pleasure is all that it should give us. If one were to ask, "How did viewing Picasso's 'Guernica' affect you?" and the reply was, "I found it pleasant," we would conclude that his reaction to the painting was, to say the least, inadequate. Great art may please; it may also move, shock, challenge, or change the lives of those who experience it deeply. Pleasure is only one of many kinds of effects it produces.

Art as a means to truth or knowledge. One of the things that has been alleged to be the purpose of art is its cognitive function: art as a means to the acquisition of truth. Art has even been called the avenue to the highest

The meaning of "aesthetic pleasure"

Generalizations based on formal principles

knowledge available to man and to a kind of knowledge impossible of attainment by any other means.

Knowledge in the most usual sense of that word takes the form of a proposition, knowing that so-and-so is the case. Thus, it can be learned from sense observation that the sun is setting, and this is knowledge. Is knowledge acquired in this same sense from acquaintance with works of art? There is no doubt that there are some propositions (statements) that can be made after acquaintance with works of art that could not be made before: for example, that this performance of Beethoven's *Eroica Symphony* was 47 minutes long, that this painting predominates in green, that this piece of sculpture originated around 350 B.C. The question is whether there is anything that can be called truth or knowledge (presumably knowledge is of truths, or true propositions) that can be found in works of art.

The
cognitive
function
of
literature

Literature is surely the most obvious candidate; for literature consists of words, and words are combined into sentences, and sentences (at least declarative sentences) are used to convey propositions; that is, to make assertions that are either true or false. And works of literature do certainly contain many true statements: a novel about the French Revolution conveys facts about the series of events; in a verse of the English scholar and poet A.E. Housman (1859–1936), it is said that “The tears of all that be/ Help not the primal fault.” Since literature contains statements, it would be surprising indeed if at least some of them were not true.

But the relevance of this fact to literature as an art is extremely dubious. If an 18th-century novel gives a true picture of English country life of that time, this makes it useful to read as history; does it also make it a better novel? Many, at any rate, would say that it does not: that a tenth-rate novel might give more facts about 18th-century life than a first-rate novel of the same century. For that matter, many of the propositions in a novel are, taken at face value, false; it is false, for example, that there was a foundling named Tom Jones who had an uncle named Squire Western. The thousands of pages of description in novels of fictional characters, ascribing to them thoughts and actions, are all false, since these characters never actually existed. Yet this fact in no way impugns their value as literature. Shakespeare, in *The Winter's Tale*, sets part of the action on the seacoast of Bohemia; but the fact that Bohemia has no seacoast does not damage *The Winter's Tale* as literature, though it would as geography. The fact that Milton used the outdated Ptolemaic astronomy does not make *Paradise Lost* less valuable, nor does the nonexistence of the lands described in *Gulliver's Travels* in any way diminish Swift's work. There is no doubt, then, that works of literature can contain true statements and false ones; but it is tempting to ask, what does their truth or falsity matter? Literature is not astronomy or geography or history or any branch of knowledge, particular or general.

Many would hold that the above statements are indeed irrelevant, as are any that encroach upon the domain of science; but, they would add, there are other assertions that matter a great deal: for example, the statements in which a world view is presented in a poem or drama or novel. The main burden of the ancient Latin poet Lucretius' *De rerum natura* (“On the Nature of Things”) is a presentation of the materialism of the Greek philosopher Democritus; and an embodiment of the world view of medieval Catholicism is the very warp and woof of Dante's *Divine Comedy*—and such considerations (it would be contended) are relevant to these works as literature.

In reply, however, it might be said that while it is true that these world views must be understood and taken into consideration in the reading of these poems and that they cannot be understood or appreciated without knowing them, the truth or falsity of these views still does matter aesthetically. If Lucretius' view is true, then Dante's must be false, and vice versa, since they are incompatible; but in order to appreciate the poem it is not necessary to know which (if either) is true. Appreciating art, unlike taking a stand for or against a cause in life, does not require a yes or no to statements. It requires only that the viewer look and appreciate, that he experience as richly and fully as possible the feeling and attitudes involved in the

world view that is presented. Philosophers and scientists are concerned with whether the Democritean materialism of Lucretius is true; appreciators of art are concerned only to capture the feeling appropriate to the world view in question.

Many statements in works of literature are not explicitly made at all but are implicit: Hardy never tells in his novels what his world view is, but it emerges rather clearly before the reader is halfway through any of them. Probably the most important points made in works of literature that contain a central thesis are implicit rather than explicit. How, in that case, can it be determined what thesis it is that is implied? In a court of law, if someone says, “He didn't say it exactly, he just implied it,” the judge would be likely to rule that this was insufficient evidence of slander, since the person did not actually say it. Still, many statements in daily life are not stated but implied—in the sense that they are intended; the trouble lies in proving that the speaker intended them, since no one else is in a comparable position to say what his intentions were; and, in the case of deceased authors, there is no evidence of their intentions other than what they said. One is doubtless on safer ground, therefore, saying that many statements are implied in the sense that they are suggested (whether the speaker intended to do so or not) by the tone of voice and the juxtaposition of the words used. Thus, “They had children and got married” suggests, though it does not state, that they had the children before they were married; any normal user of the English language would tend to construe it thus. And it is surely no overstatement to say that Swift's *Gulliver's Travels* suggests that the author was misanthropic or that the novels of the French author Marcel Proust (1871–1922) suggest a pessimistic view of love and other human relationships close to that of the German philosopher Arthur Schopenhauer (1788–1860). A serious reader of literature will become increasingly sensitive to what is suggested in the works he is reading.

But, once again, the importance of the suggested statements, even when they are true, in no way shows that they must be accepted as true by the reader if he is to value them as works of art. Is the sincere Roman Catholic who finds Dante's world view congenial and Lucretius' repellent committed to saying that Dante's is the better poem? If so, he may be accused of confusing his moral and theological judgments with his aesthetic ones. Still, it should be noted that there are some critics who believe that if two works of literature are both equal in excellence on all counts, yet one presents a true view of reality and the other fails to, the one presenting a true view is better—better even as a work of art—than is the other one.

There is, however, another way of talking about truth in literature that is not or is not as obviously connected to propositions. A characterization in a novel or drama is spoken of as being true to human nature, true to the way people actually speak or behave or feel. No matter that Becky Sharp—in the English novelist William Thackeray's *Vanity Fair*—is a fictional character, it would be said, as long as she is depicted as a person of a certain type would behave, she is being depicted truly; truth in fiction does not mean truth of the statements (for the statements in Thackeray's novel describing her are false), but truth to human nature.

But what exactly does “truth to human nature” mean? The criterion is as old as Aristotle, who wrote that poetry is more true than history because it presents universal truths whereas history gives only particular truths and that poetry (dramatic fiction) shows how a person of this or that kind probably or necessarily would behave (or think, or feel). This criterion, however, is too vague as it stands: what is probable or plausible behaviour in one person is not in another, and what is probable in one set of circumstances is not so in another. The test of truth to human nature would be roughly as follows: Would a person such as has been described thus far (in the novel or drama) behave (or think or feel or be motivated) in the way that the author depicts this character as behaving in the circumstances described? It is often very difficult to decide this question, because knowledge of human beings is insufficient or because the dramatist himself has not

Explicit
and
implicit
statements
in
literature

The notion
of “truth
to human
nature” in
literature

provided enough clues. Still, once readers or critics are convinced that the character described would not have behaved as the novelist depicts him as behaving, they may criticize the characterization (at least with regard to this bit of behaviour or motivation) as implausible. If a character who has been described as spending years working toward a certain goal is represented by the novelist as abandoning it once he is within sight of it, the reader will have considerable reservations about this delineation unless the author has depicted the character as being unstable or masochistic or in some way as being the kind of person who might in these circumstances do this kind of thing. It is true that there are people in the world who abandon their goals within sight of them after years of labour, but the conviction must be implanted that the character already presented by the novelist belongs to this classification or the behaviour will seem reasonless and unmotivated.

Is truth to human nature aesthetically relevant? That is, when present does it make the work of literature better and when absent or flawed does it make the work worse as literature? Here again there would be some difference of opinion, but a very large number of critics and aestheticians, in the tradition of Aristotle, would say that it matters aesthetically a great deal. The novelist does not have to be true to geography or history or astronomy, but he must be, as the 19th-century U.S. author Nathaniel Hawthorne said of all literary artists, true to the human heart. A literary artist may tamper with all the other truths with impunity, but not this one: his characters must be convincing, and they will not be convincing if they are not depicted as having anger, love, jealousy, and other human emotions that real people have and in pretty much the contexts in which real people have them. If a novelist's characters were not motivated in much the way that human beings are motivated, the reader would not even be able to understand them—they would be alien and unintelligible to him. Even when a writer (such as the Englishman Kenneth Grahame in *The Wind in the Willows*) depicts animals as central characters in novels, however much they may differ from human beings in external appearance, they must psychologically be presented as human beings—how else and in what other terms could their behaviour and their motivation be understood? Such, then, are the reasons for saying that whatever else a literary artist does, his depictions must be truthful to human nature.

Can works of art other than literature possess truth to human nature? It would seem that in a limited degree they can. Motion pictures and operas and other mixed arts clearly can, but they employ words, and literature is a principal ingredient in them. But what of arts that employ no words at all? Painting and sculpture, not being temporal arts, cannot depict action, and action is all-important in the representation of human character. These arts contain depictions of persons (real or imaginary) only on a knife-edge of time. Still, sometimes something may be inferred even from a knife-edge. The late self-portraits of the 17th-century Dutch artist Rembrandt do seem to reveal an agonized yet sometimes serene inner spirit, suggesting that there are flashes of human insight to be found in depictions of human beings in visual art. As for musical art (music without the accompaniment of words), it contains nothing that could be called depiction, not even depiction on a knife-edge of time; and, if this is so, there can be no such thing here as true depiction or false depiction. Music may be expressive of human feelings, in the sense already described, but this is a far cry from saying that it contains depictions that are true to human nature.

Even if truth to human nature in the depiction of character is aesthetically relevant (which many would question), to say this is still far from saying that it is the only criterion for excellence in works of art, or even that this is the principal thing that art gives or its main excuse for being. To go so far would be to discount colour and form and expressiveness as criteria for excellence in art; and this virtually no one is willing to do. It would seem, then, that in no case is truth (even truth to human nature) necessary in works of art, seeing that entire genres of art, such as music, exist without it; and that even when it

is present and when its presence increases the merit of a work of art (which again many would deny), it is only one virtue among many. Thus, the view that the purpose or function of art is to provide truth is quite surely mistaken; perhaps the person who wants truth and is indifferent to the presence of anything else had better turn to science or philosophy rather than to the arts.

Art as a means to moral improvement. To say that a work of art is aesthetically good or has aesthetic value is one thing; to say that it is morally good or has a capacity to influence people so as to make them morally better is another. Yet, though the two kinds of judgments differ from one another, they are not entirely unrelated. Three views on the relation of art to morality can be distinguished:

Moralism. According to this view, the primary or exclusive function of art is as a handmaiden to morality—which means, usually, whatever system of morality is adhered to by the theorist in question. Art that does not promote moral influence of the desired kind is viewed by the moralist with suspicion and sometimes with grudging tolerance of its existence. For art implants in people unorthodox ideas; it breaks the molds of provincialism in which people have been brought up; it disturbs and disquiets, since it tends to emphasize individuality rather than conformity; and works of art are often created out of rebellion or disenchantment with the established order. Thus, art may undermine beliefs and attitudes on which, it is thought, the welfare of society rests and so may be viewed with suspicion by the guardians of custom. When art does not affect people morally one way or the other (for example, much nonrepresentational painting), it is considered a harmless pleasure that can be tolerated if it does not take up too much of the viewer's time; but, when it promotes questioning and defies established attitudes, it is viewed by the moralist as insidious and subversive. It is viewed with approval only if it promotes or reinforces the moral beliefs and attitudes adhered to by the moralist.

Plato is the first champion in the Western world of the moralistic view of art—at least in *The Republic* and *Laws*. Plato admired the poets and was himself something of a poet; but, when he was founding (on paper) his ideal state, he was convinced that much art, even some passages in Homer, tended to have an evil influence upon the young and impressionable, and accordingly he decided that they must be banned. Passages that spoke ill or questioningly of the gods, passages containing excessive sexual passion (and all works that would today be described as pornographic), and even passages of music that were disturbing to the soul or the senses were all condemned to the same fate. Plato's concern here was with the purity of soul of the men who would become members of the council of rulers of the state; he was not concerned with censorship for the masses, but, since one could not predict which young people would pass the series of examinations required for membership in the council of rulers and since it was (and is) practically impossible to restrict access to works of art to a certain group, the censorship, he decided, would have to be universal. The objection might be raised, to be sure, that rulers to be should not be hothouse plants separated from the influences of the outside world and that they would be better off facing all of reality, including its evils. But Plato's view was that these influences should be kept from them during their formative years—that during this critical time, when the whole tenor of their lives was being shaped, art could be an influence for evil and had to be sacrificed in the interests of morality. In other dialogues of Plato, such as the *Ion* and the *Phaedrus*, when he was not concerned with building a state, he extolled the virtues of art and even held the artist to be divine (although madly divine); but when it came to a conflict between art and morality, it was art that would have to go.

The most famous champion of the moralistic view of art in modern times is Tolstoy. Long after he had finished writing his novels, he fell under the influence of primitive (prechurch) Christianity, the principal tenet of which was the brotherhood of all mankind. This one idea became such an obsession with him that everything else, including the pursuit of art to which he had devoted his life,

Plato's
moralistic
view of
art

Tolstoy's
moralistic
view of
art

Truth to
human
nature in
arts other
than
literature

became subordinate to it. Almost all the literature of his own time, including all his own novels, he condemned as inimical to the brotherhood of man by emphasizing class distinction and pitting one group of mankind against another. Even art that appealed primarily (in his opinion) to "upper class" tastes, such as the symphonies of Beethoven and the operas of Richard Wagner, both 19th-century German composers, were condemned as "false art." The art that remained after these colossal excisions included such items as folk songs that peasants might sing in the fields as they worked and pictures and stories either illustrating the tenets of primitive Christianity or fostering the spirit of Christianity by promoting the brotherhood of all mankind.

The moralistic view of art is still, on the whole, the unarticulated view of art held by the masses, particularly when they are under the sway of a dominant religious or political doctrine. Historically, Christianity has been suspicious of all art except those works that depicted some aspects of biblical history or could be used to further the spread of Christian belief and practice (although this is no longer strictly true). It would probably be fair to say that the view of art held by the Soviet government is a moralistic one: works of fiction and poems must praise Communism or further its doctrines, and works of music must be melodic and singable (Soviet composers such as Dmitry Shostakovich have often been condemned by the official hierarchy as "too German" or "too materialistic"). Whenever a culture or nation is under the sway of a dominant view, whether moral or religious or political, the tendency of the rulers of that nation is to promote it at all costs—and one of the casualties in the process is art, at any rate that great body of art that is either indifferent or hostile to the reigning dogma.

Aestheticism. Diametrically opposed to the moralistic view is aestheticism, the view that instead of art (and everything else) being the handmaiden of morality, morality (and everything else) should be the handmaiden of art. The proponents of this view hold that the experience of art is the most intense and pervasive experience available in human life and that nothing should be allowed to interfere with it. If it conflicts with morality, so much the worse for morality; and if the masses fail to appreciate it or receive the experience it has to offer, so much the worse for the masses. The vital intensity of the aesthetic experience is the paramount goal in human life. If there are morally undesirable effects of art, they do not really matter in comparison to this all-important experience which art can give. When the son-in-law of the 20th-century Italian dictator Benito Mussolini waxed lyrical in his description of the beauty of a bomb exploding in the midst of a crowd of unarmed Ethiopians, he was carrying to its fullest extent the aestheticist's view of art.

Few persons would wish to go so far. Even the most ardent lovers of art would stop short of saying that the value of art holds a monopoly over all other values. It may well be that the experience of works of art is the greatest experience available to human beings (though this, too, could be questioned), but at any rate it is not the only one available, and, this being the case, the others should be considered as well. There is a plurality of values; and aesthetic values, although far greater, admittedly, than most persons realize, are still just a few among many. It is therefore necessary to consider the relation of the values derived from art to the values derived from other things, such as the conduct of life apart from art: no one can devote every waking hour to the pursuit of art, even if for no other reason than the need for survival, and thus the values of such mundane things as food and shelter have also to be considered.

Mixed positions. The moralistic and aesthetic positions are extremes, and the truth is likely to be found somewhere between them. Indeed, art and morality are intimately related, and neither functions wholly without the other. But to trace the precise relations between art and morality is far from easy; for want of a better term, "interactionism" could be used to label the view that aesthetic and moral values each have distinctive roles to play in the world but that neither operates independently of the other.

It would be admitted, first of all, that works of literature (which will be examined first, since of all the arts the relation of literature to morality is most obvious) can teach valuable moral lessons through explicit presentation: the genre that has this as its aim is didactic literature, as exemplified by *Pilgrim's Progress* by the English Puritan John Bunyan and *Back to Methuselah* by the Irish dramatist George Bernard Shaw. But most works of literature do not exist to teach a moral lesson: possibly, Shakespeare did not write *Othello* merely to attack racial prejudice or *Macbeth* to prove that crime does not pay. Literature does teach but in a far more important way than by explicit preachment: it teaches, as John Dewey said, by being, not by express intent.

How does literature achieve this moral effect? It presents characters and situations (usually situations of difficult moral decision) through which the reader can deepen his own moral perspectives by reflecting on other people's problems and conflicts, which usually have a complexity that his own daily situations do not possess. He can learn from them without himself having to undergo in his personal life the same moral conflicts or make the same moral decisions. The reader can view such situations with a detachment that he can seldom achieve in daily life when he is immersed in the stream of action. By viewing these situations objectively and reflecting on them, he is enabled to make his own moral decisions more wisely when life calls on him in turn to make them. Literature can be a stimulus to moral reflection unequalled perhaps by any other, for it presents the moral choice in its total context with nothing of relevance omitted.

Perhaps the chief moral potency of literature lies in its unique power to stimulate and develop the faculty of the imagination. Through literature the reader is carried beyond the confines of the narrow world that most persons inhabit into a world of thought and feeling more profound and more varied than his own, a world in which he can share the experiences of human beings (real or fictitious) who are far removed from him in space and time and in attitude and way of life. Literature enables him to enter directly into the affective processes of other human beings, and, having done this, no perceptive reader can any longer condemn or dismiss en masse a large segment of humanity as "foreigners" or "wastrels," for a successful work of literature brings them to life as individuals, animated by the same passions as he is, facing the same conflicts, and tried in the same crucible of bitter experience. Through such an exercise of the sympathetic imagination, literature tends to draw all men together instead of setting them apart from one another in groups or types with convenient labels for each. Far more than preaching or moralizing, more even than the descriptive and scientific discourses of psychology or sociology, literature tends to unite mankind and reveal the common human nature that exists in everyone behind the facade of divisive doctrines, political ideologies, and religious beliefs.

This is not to say, of course, that those who read great works of literature are necessarily tolerant or sympathetic human beings. Reading literature alone is not a cure for human ills, and people who are neurotically grasping or selfish in their private lives will hardly cease to be so as a result of reading works of literature. Still, wide and serious reading of literature has an observable effect: people who do this kind of reading, no matter what their other characteristics may be, do tend to be more understanding of other people's conflicts, to have more sympathy with their problems, and to be able to empathize more with them as human beings than do people who have never broadened their horizons by reading literature at all. No one who has read great literature widely and for a considerable period, so as to make it an integral part of his life, can any longer share the same provincialism and be dominated by the same narrow prejudices that seem to characterize most people most of the time. Literature, perhaps more than anything else, exercises a leavening influence on the temper of a man's moral life. It looses him from the bonds of his own position in space and time; it releases him from exclusive involvement with his own struggles from day to day; it enables him to see his own local problems and

Expression of morality in literature

Aesthetic values versus moral values

The leavening influence of literature

trials from the perspective of eternity—he can now view them as if from an enormous height.

To have moral effects, it is not necessary that a work of literature present a system of morality. Its moral potency is perhaps greatest when it presents not systems but human beings in action, so that through the exercise of the imagination the reader can see his own customs and philosophies as he sees theirs: as some among many of the countless adjustments and solutions to human problems that different circumstances and man's endlessly varied and resourceful nature have produced.

Works of literature, then, develop more than anything else the human faculty of the imagination; and the 19th-century English poet Percy Bysshe Shelley said that the imagination is the greatest single instrument of moral good. Perhaps this sounds like an absurd overstatement, but consider what morality is like without the imagination. Consider the average morality of a small community, relatively isolated from centres of culture and unacquainted with any artistic tradition. Its morality is rigid and circumscribed; the details of each member's personal life are hedged about with constant annoyances, and everyone's life is open to the prying eyes of others who are unfailingly quick to judge, with or without evidence. Outsiders are looked upon askance; people of a different religion, race, or culture are viewed with suspicion and distrust; and anyone who does not subscribe to whatever moral code is dominant in the community is condemned or ostracized. No doubt these people are sincere—they are dreadfully sincere, deadly sincere. But sincerity without enlightenment can be as harmful to the achievement of good as intelligence without wisdom when that intelligence is possessed by political leaders playing with hydrogen bombs. Generally speaking, the people of a small community have not known the leavening influence of literature. Their morality is rigid, cramped, and arid. If these same people had been exposed from early youth to great masterpieces of literature and had learned through them to appreciate the tremendous diversity of human mores and beliefs held by other groups, with the same degree of sincerity that they themselves possess, they would be less likely to be as harsh, intolerant, and rigid as they are.

People are usually inclined to separate art and morality into two hermetically sealed compartments. They talk as if morality were already complete and self-sufficient without art, and that art, if it is to be tolerated at all, can grudgingly be permitted, provided that it conforms to the moral customs of the time and place of those judging it. But this view is surely to conceive the relation between art and morality in far too one-sided a manner. If art must take cognizance of morality, equally morality must take cognizance of art. Almost everything that is alive and imaginative about morality comes from the leavening influence of art.

Influence
of ancient
dramatists

To consider examples from ancient Greece alone, what would morality be today without the influence of the dramatists Aeschylus and Sophocles, without Socrates as described in Plato's dialogues, even without the historians Herodotus and Thucydides with their quiet humour, gentle prodding skepticism, and tolerance for other customs and views? It is through great works of art that the most vivid conceptions of various ways of life are obtained. What is it about other times and places that people most remember? Is it their political squabbles, their wars, their economic upheavals? These events are known in general to intelligent laymen and in detail to historians, but even then such events do not usually make much of a dent in peoples' personal lives in the way that art does. What is alive today about ancient Greece is its sculpture, its poetry, its epic and drama; what is alive today about the Elizabethan period, even more than the defeat of the Spanish Armada and the reign of Queen Elizabeth I, is its poetic drama, with its vivid characterizations and boundless energy. Other civilizations and cultures may be sources of facts and theories that enlighten modern understanding, but what enables contemporary man to share directly their feelings and attitudes toward life is not their politics nor even their religion but their art. Art alone is never out of date. Science is cumulative; even the science

textbooks of ten years ago are now discarded as obsolete; the science of the ancient Greeks and the Elizabethans is studied today primarily for its historical value. But great art is never obsolete; it can still present to modern man its full impact, undiminished by time. Shakespeare will not be out of date as long as human beings continue to feel love, jealousy, and conflict in a troubled world. A biblical statement might be paraphrased and applied to past cultures: "By their arts shall ye know them." The artists whose works are now revered may have died unsung; most of them, even those who were appreciated during their lifetimes, were considered far less important than the latest naval victories or the accession of the current king; yet today these things have all passed into history, but art survives with undiminished vigour. The art of the past molds in countless ways the attitudes, responses, and dispositions of modern man's daily life. Most of what is perceptive and imaginative in morality owes its origin to art, and, when morality loses contact with the tradition of art, it becomes dead and sterile. Yet, in spite of this, some people tell us that art is merely the salve of morality, to soothe its stringency.

Already, in the preceding paragraph, mention has begun of arts other than literature. How, it could be asked, can they have any moral effects on those who view them or listen to them? Yet there are effects of these arts on the observer that, in a broad sense, are moral (as opposed to nonmoral) and that account for the attempts of many people to censor them.

Historically, the most famous supposition about the moral effect of art on its audience is Aristotle's theory of catharsis; Aristotle applied the theory to tragedy only, but many since his day have applied it to art in general. According to this view, art acts as an emotional cathartic and achieves a "purgation of the emotions." Certain emotions man would be better off without (Aristotle limited them to pity and fear, but they could easily be extended) are generated during the course of daily life. Art is the principal agency that should help to dispel these emotions. By observing works of art (witnessing a drama, listening to a powerful symphony, looking at certain works of sculpture or painting) the recipient can work off these emotions rather than let them fester inside him or take them out in unpleasant ways on his fellow men. Art siphons off these disturbing inner states rather than letting them grow rancid within man.

Aristotle's
theory of
catharsis

As it stands, this view is undoubtedly somewhat crude, especially in the light of modern psychology; and fault could be found in many respects with the Aristotelian doctrine of catharsis. Yet the experience of reading, viewing, or listening to a work of art does give a peculiar release, a feeling of freedom from inner turbulence. The mere act of plunging, for a few hours, into an entirely different world when attending a play or a concert is often enough to transform, however temporarily, the tone of people's daily lives. It is not merely that for a few hours they can forget their troubles—any form of entertainment, however worthless, might do this. It is not merely that art provides a break or interruption in the course of people's lives at the end of which they are exactly what they were before. It is that through the aesthetic process itself, in the very act of concentrating energies on an art object of great unity and complexity and depth, a kind of inner clarification is achieved that was not present before.

It is not true, therefore, that reading novels of crime and detection leads people to indulge in a life of crime; on the whole, those who read such novels are law-abiding people, and, if anything, the reading of such novels is a substitute for aggressive activity (it is aggression vicariously experienced) rather than an incitement to it. Nor do works of art of a licentious nature usually incite people to rape or adultery; far from acting as incitements to action, they are safety valves against action by providing a kind of substitute gratification. It has been said, for example, that Shakespeare's *Antony and Cleopatra* is an immoral work because it celebrates the passionate surrender to an illicit love and the victory of this love over practical, political, and moral concerns. But is there any evidence that people who read this play will behave like the lovers in question

because they read the play? On the contrary: it could be argued that reading the play has an instrumental value in that it presents another example of a complex moral situation, the perusal of which provides many avenues for moral reflection, and that the play also possesses the intrinsic value of acute characterization, dramatic power, and poetry whose imagery and intensity are among the most splendid in the English language. Again, it is said that American youth has been demoralized by such 20th-century U.S. writers as Ernest Hemingway and William Faulkner in that these writers set an example of bad behaviour. But to say that they are capable of demoralizing an entire generation is certainly to attribute to them too much moral power, especially over people who have never even heard of them. Even among those who do read serious literature, the effects are probably more beneficial than harmful: through books the horizons of such readers have been expanded to include other ways of life than they would have previously known.

The
essential
morality
of the
aesthetic
experience

Quite apart from the ultimate effect of a work of art on a man's emotions, it would appear that the very act of experiencing the work may itself have a moral effect. If he is really concentrating on the details of a work of art and not just passively letting it play upon his senses, this effect—the heightening of his sensibilities and the refining of his capacities for perceptual discrimination—will make him more receptive to the world around him, thus raising the tone of his daily life and making his experience of the world richer than before.

Most of what passes for aesthetic appreciation does not begin to have this effect; but its failure is only because it is not aesthetic appreciation at all—it is a kind of tired reverie rather than an intense absorption in the aesthetic object. Most people, when they hear music, simply allow themselves to be inundated by the sheer flow of sound. Such people do not actively listen to the music and are not even aware of the most elementary kind of ebb and flow occurring within it; they only receive it passively, perhaps using it as a springboard for a private reverie or an emotional debauch of their own. Music has for them not an aesthetic effect but an anesthetic effect. It is not just hearing music that will have the required effect. The aesthetic experience, which involves nothing less than a total concentration on the perceptual details of the aesthetic object, is an experience that heightens consciousness, exercises man's capacity for perceptual awareness and discrimination, and helps him come alive to the sight and texture of the world around him. After a viewer has seen an exhibition of landscapes by Cézanne, the entire world may seem to him to have changed its structure and complexion: it may, indeed, take on the look of Cézanne's landscapes. And is not anything that increases awareness and subtlety of discernment and discrimination a potentially moral agent? Art provides the most intense, concentrated, and sharply focussed of the experiences available to man. Because of this, art can have an enormous influence on the tenor of a person's life, more influential no doubt than any particular system of morality. In its ability to do this, it has an effect on man's life that, in an extended sense at least, can surely be called moral. Morality transcends particular systems of morality; and art, by being for many persons the dominant influence in their lives, thus transcends them also.

(Jo.Ho.)

Philosophy of logic

The term logic comes from the Greek word *logos*. The variety of senses that *logos* possesses may suggest the difficulties to be encountered in characterizing the nature and scope of logic. Among the partial translations of *logos*, there are "sentence," "discourse," "reason," "rule," "ratio," "account" (especially the account of the meaning of an expression), "rational principle," and "definition." Not unlike this proliferation of meanings, the subject matter of logic has been said to be the "laws of thought," "the rules of right reasoning," "the principles of valid argumentation," "the use of certain words labelled 'logical constants'," "truths (true propositions) based solely on the meanings of the terms they contain," and so on.

LOGIC AS A DISCIPLINE

Nature and varieties of logic. It is relatively easy to discern some order in the above embarrassment of explanations. Some of the characterizations are in fact closely related to each other. When logic is said, for instance, to be the study of the laws of thought, these laws cannot be the empirical (or observable) regularities of actual human thinking as studied in psychology; they must be laws of correct reasoning, which are independent of the psychological idiosyncrasies of the thinker. Moreover, there is a parallelism between correct thinking and valid argumentation: valid argumentation may be thought of as an expression of correct thinking, and the latter as an internalization of the former. In the sense of this parallelism, laws of correct thought will match those of correct argumentation. The characteristic mark of the latter is, in turn, that they do not depend on any particular matters of fact. Whenever an argument that takes a reasoner from *p* to *q* is valid, it must hold independently of what he happens to know or believe about the subject matter of *p* and *q*. The only other source of the certainty of the connection between *p* and *q*, however, is presumably constituted by the meanings of the terms that the propositions *p* and *q* contain. These very same meanings will then also make the sentence "If *p*, then *q*" true irrespective of all contingent matters of fact. More generally, one can validly argue from *p* to *q* if and only if the implication "If *p*, then *q*" is logically true—i.e., true in virtue of the meanings of words occurring in *p* and *q*, independently of any matter of fact.

Logic may thus be characterized as the study of truths based completely on the meanings of the terms they contain.

In order to accommodate certain traditional ideas within the scope of this formulation, the meanings in question may have to be understood as embodying insights into the essences of the entities denoted by the terms, not merely codifications of customary linguistic usage.

The following proposition (from Aristotle), for instance, is a simple truth of logic: "If sight is perception, the objects of sight are objects of perception." Its truth can be grasped without holding any opinions as to what, in fact, the relationship of sight to perception is. What is needed is merely an understanding of what is meant by such terms as "if-then," "is," and "are," and an understanding that "object of" expresses some sort of relation.

The logical truth of Aristotle's sample proposition is reflected by the fact that "The objects of sight are objects of perception" can validly be inferred from "Sight is perception."

Many questions nevertheless remain unanswered by this characterization. The contrast between matters of fact and relations between meanings that was relied on in the characterization has been challenged, together with the very notion of meaning. Even if both are accepted, there remains a considerable tension between a wider and a narrower conception of logic. According to the wider interpretation, all truths depending only on meanings belong to logic. It is in this sense that the word logic is to be taken in such designations as "epistemic logic" (logic of knowledge), "doxastic logic" (logic of belief), "deontic logic" (logic of norms), "the logic of science," "inductive logic," and so on. According to the narrower conception, logical truths obtain (or hold) in virtue of certain specific terms, often called logical constants. Whether they can be given an intrinsic characterization or whether they can be specified only by enumeration is a moot point. It is generally agreed, however, that they include (1) such propositional connectives as "not," "and," "or," and "if-then" and (2) the so-called quantifiers "($\exists x$)" (which may be read: "For at least one individual, call it *x*, it is true that") and "($\forall x$)" ("For each individual, call it *x*, it is true that"). The dummy letter *x* is here called a bound (individual) variable. Its values are supposed to be members of some fixed class of entities, called individuals, a class that is variously known as the universe of discourse, the universe presupposed in an interpretation, or the domain of individuals. Its members are said to be quantified over in "($\exists x$)" or "($\forall x$).". Furthermore, (3) the concept of identity (expressed by $=$) and (4) some notion of predication

Valid
argument
and
matters
of fact

The
various
branches of
logic

(an individual's having a property or a relation's holding between several individuals) belong to logic. The forms that the study of these logical constants take are described in greater detail in the article LOGIC, in which the different kinds of logical notation are also explained. Here, only a delineation of the field of logic is given.

When the terms in (1) alone are studied, the field is called propositional logic. When (1), (2), and (4) are considered, the field is the central area of logic that is variously known as first-order logic, quantification theory, lower predicate calculus, lower functional calculus, or elementary logic. If the absence of (3) is stressed, the epithet "without identity" is added, in contrast to first-order logic with identity, in which (3) is also included.

Borderline cases between logical and nonlogical constants are the following (among others): (1) Higher order quantification, which means quantification not over the individuals belonging to a given universe of discourse, as in first-order logic, but also over sets of individuals and sets of n -tuples of individuals. (Alternatively, the properties and relations that specify these sets may be quantified over.) This gives rise to second-order logic. The process can be repeated. Quantification over sets of such sets (or of n -tuples of such sets or over properties and relations of such sets) as are considered in second-order logic gives rise to third-order logic; and all logics of finite order form together the (simple) theory of (finite) types. (2) The membership relation, expressed by \in , can be grafted on to first-order logic; it gives rise to set theory. (3) The concepts of (logical) necessity and (logical) possibility can be added.

This narrower sense of logic is related to the influential idea of logical form. In any given sentence, all of the nonlogical terms may be replaced by variables of the appropriate type, keeping only the logical constants intact. The result is a formula exhibiting the logical form of the sentence. If the formula results in a true sentence for any substitution of interpreted terms (of the appropriate logical type) for the variables, the formula and the sentence are said to be logically true (in the narrower sense of the expression).

Features and problems of logic. Three areas of general concern are the following.

Logical semantics. For the purpose of clarifying logical truth and hence the concept of logic itself, a tool that has turned out to be more important than the idea of logical form is logical semantics, sometimes also known as model theory. By this is meant a study of the relationships of linguistic expressions to those structures in which they may be interpreted and of which they can then convey information. The crucial idea in this theory is that of truth (absolutely or with respect to an interpretation). It was first analyzed in logical semantics around 1930 by the Polish-American logician Alfred Tarski. In its different variants, logical semantics is the central area in the philosophy of logic. It enables the logician to characterize the notion of logical truth irrespective of the supply of nonlogical constants that happen to be available to be substituted for variables, although this supply had to be used in the characterization that turned on the idea of logical form. It also enables him to identify logically true sentences with those that are true in every interpretation (in "every possible world").

The ideas on which logical semantics is based are not unproblematic, however. For one thing, a semantical approach presupposes that the language in question can be viewed "from the outside"; *i.e.*, considered as a calculus that can be variously interpreted and not as the all-encompassing medium in which all communication takes place (logic as calculus versus logic as language).

Furthermore, in most of the usual logical semantics the very relations that connect language with reality are left unanalyzed and static. Ludwig Wittgenstein, an Austrian-born philosopher, discussed informally the "language-games"—or rule-governed activities connecting a language with the world—that are supposed to give the expressions of language their meanings; but these games have scarcely been related to any systematic logical theory. Only a few other attempts to study the dynamics of the representa-

tive relationships between language and reality have been made. The simplest of these suggestions is perhaps that the semantics of first-order logic should be considered in terms of certain games (in the precise sense of game theory) that are, roughly speaking, attempts to verify a given first-order sentence. The truth of the sentence would then mean the existence of a winning strategy in such a game.

Limitations of logic. Many philosophers are distinctly uneasy about the wider sense of logic. Some of their apprehensions, voiced with special eloquence by a contemporary Harvard University logician, Willard Van Quine, are based on the claim that relations of synonymy cannot be fully determined by empirical means. Other apprehensions have to do with the fact that most extensions of first-order logic do not admit of a complete axiomatization; *i.e.*, their truths cannot all be derived from any finite—or recursive (see below)—set of axioms. This fact was shown by the important "incompleteness" theorems proved in 1931 by Kurt Gödel, an Austrian (later, American) logician, and their various consequences and extensions. (Gödel showed that any consistent axiomatic theory that comprises a certain amount of elementary arithmetic is incapable of being completely axiomatized.) Higher-order logics are in this sense incomplete and so are all reasonably powerful systems of set theory. Although a semantical theory can be built for them, they can scarcely be characterized any longer as giving actual rules—in any case complete rules—for right reasoning or for valid argumentation. Because of this shortcoming, several traditional definitions of logic seem to be inapplicable to these parts of logical studies.

These apprehensions do not arise in the case of modal logic, which may be defined, in the narrow sense, as the study of logical necessity and possibility; for even quantified modal logic admits of a complete axiomatization. Other, related problems nevertheless arise in this area. It is tempting to try to interpret such a notion as logical necessity as a syntactical predicate; *i.e.*, as a predicate the applicability of which depends only on the form of the sentence claimed to be necessary—rather like the applicability of formal rules of proof. It has been shown, however, by Richard Montague, an American logician, that this cannot be done for the usual systems of modal logic.

Logic and computability. These findings of Gödel and Montague are closely related to the general study of computability, which is usually known as recursive function theory (see MATHEMATICS, FOUNDATIONS OF: *The crisis in foundations following 1900: Logicism, formalism, and the metamathematical method*) and which is one of the most important branches of contemporary logic. In this part of logic, functions—or laws governing numerical or other precise one-to-one or many-to-one relationships—are studied with regard to the possibility of their being computed; *i.e.*, of being effectively—or mechanically—calculable. Functions that can be so calculated are called recursive. Several different and historically independent attempts have been made to define the class of all recursive functions, and these have turned out to coincide with each other. The claim that recursive functions exhaust the class of all functions that are effectively calculable (in some intuitive informal sense) is known as Church's thesis (named after the American logician Alonzo Church).

One of the definitions of recursive functions is that they are computable by a kind of idealized automaton known as a Turing machine (named after Alan Mathison Turing, a British mathematician and logician). Recursive function theory may therefore be considered a theory of these idealized automata. The main idealization involved (as compared with actually realizable computers) is the availability of a potentially infinite tape.

The theory of computability prompts many philosophical questions, most of which have not so far been answered satisfactorily. It poses the question, for example, of the extent to which all thinking can be carried out mechanically. Since it quickly turns out that many functions employed in mathematics—including many in elementary number theory—are nonrecursive, one may wonder whether it follows that a mathematician's mind in thinking of such functions cannot be a mechanism and whether the possibly nonmechanical character of mathematical thinking

Incompleteness of higher-order logics

Truth as defined in model theory

may have consequences for the problems of determinism and free will. Further work is needed before definitive answers can be given to these important questions.

ISSUES AND DEVELOPMENTS IN THE PHILOSOPHY OF LOGIC

In addition to the problems and findings already discussed, the following topics may be mentioned.

Analytical
truth

Meaning and truth. Since 1950, the concept of analytical truth (logical truth in the wider sense) has been subjected to sharp criticism, especially by Quine. The main objections turned around the nonempirical character of analytical truth (arising from meanings only) and of the concepts in terms of which it could be defined—such as synonymy, meaning, and logical necessity. The critics usually do not contest the claim that logicians can capture synonymies and meanings by starting from first-order logic and adding suitable further assumptions, though definitory identities do not always suffice for this purpose. The crucial criticism is that the empirical meaning of such further “meaning postulates” is not clear.

Logical semantics of modal concepts. In this respect, logicians’ prospects have been enhanced by the development of a semantical theory of modal logic, both in the narrower sense of modal logic, which is restricted to logical necessity and logical possibility, and in the wider sense, in which all concepts that exhibit similar logical behaviour are included. This development, initiated between 1957 and 1959 largely by Stig Kanger of Sweden and Saul Kripke of the U.S., has opened the door to applications in the logical analysis of many philosophically central concepts, such as knowledge, belief, perception, and obligation. Attempts have been made to analyze from the viewpoint of logical semantics such philosophical topics as sense-datum theories, knowledge by acquaintance, the paradox of saying and disbelieving propounded by the British philosopher G.E. Moore, and the traditional distinction between statements *de dicto* (“from saying”) and statements *de re* (“from the thing”). These developments also provide a framework in which many of those meaning relations can be codified that go beyond first-order logic, and may perhaps even afford suggestions as to what their empirical content might be.

Intensional logic. Especially in the hands of Montague, the logical semantics of modal notions has blossomed into a general theory of intensional logic; *i.e.*, a theory of such notions as proposition, individual concept, and in general of all entities usually thought of as serving as the meanings of linguistic expressions. (Propositions are the meanings of sentences, individual concepts are those of singular terms, and so on.) A crucial role is here played by the notion of a possible world, which may be thought of as a variant of the logicians’ older notion of model, now conceived of realistically as a serious alternative to the actual course of events in the world. In this analysis, for instance, propositions are functions that correlate possible worlds with truth-values. This correlation may be thought of as spelling out the older idea that to know the meaning of a sentence is to know under what circumstances (in which possible worlds) it would be true.

Logic and information. Even though none of the problems listed seems to affect the interest of logical semantics, its applications are often handicapped by the nature of many of its basic concepts. One may consider, for instance, the analysis of a proposition as a function that correlates possible worlds with truth-values. An arbitrary function of this sort can be thought of (as can functions in general) as an infinite class of pairs of correlated values of an independent variable and of the function, like the coordinate pairs (x, y) of points on a graph. Although propositions are supposed to be meanings of sentences, no one can grasp such an infinite class directly when understanding a sentence; he can do so only by means of some particular algorithm, or recipe (as it were), for computing the function in question. Such particular algorithms come closer in some respects to what is actually needed in the theory of meaning than the meaning entities of the usual intensional logic.

This observation is connected with the fact that, in the usual logical semantics, no finer distinctions are utilized

in semantical discussions than logical equivalence. Hence the transition from one sentence to another logically equivalent one is disregarded for the purposes of meaning concepts. This disregard would be justifiable if one of the most famous theses of Logical Positivists were true in a sufficiently strong sense, *viz.*, that logical truths are really tautologies (such as “It is either raining or not raining”) in every interesting objective sense of the word. Many philosophers have been dissatisfied with the stronger forms of this thesis, but only recently have attempts been made to spell out the precise sense in which logical and mathematical truths are informative and not tautologous.

Problems of ontology. Among the ontological problems—problems concerning existence and existential assumptions—arising in logic are those of individuation and existence.

Individuation. Not all interesting interpretational problems are solved by possible-world semantics, as the developments earlier registered are sometimes called. The systematic use of the idea of possible worlds has raised, however, the subject of cross identification; *i.e.*, of the principles according to which a member of one possible world is to be found identical or nonidentical with one of another. Since one can scarcely be said to have a concept of an individual if he cannot locate it in several possible situations, the problem of cross-identification is also one of the most important ingredients of the logical and philosophical problem of individuation. The criticisms that Quine has put forward concerning modal logic and analyticity (see above) can be deepened into questions concerning methods of cross identification. Although some such methods undoubtedly belong to everyone’s normal unarticulated conceptual repertoire, it is not clear that they are defined or even definable widely enough to enable philosophers to make satisfactory sense of a quantified logic of logical necessity and logical possibility. The precise principles used in ordinary discourse—or even in the language of science—pose a subtle philosophical problem. The extent to which special “essential properties” are relied on in individuation and the role of spatio-temporal frameworks are moot points here. It has also been suggested that essentially different methods of cross identification are actually used together, some of them depending on impersonal descriptive principles and others on the perspective of a person.

Existence and ontology. Because one of the basic concepts of first-order logic is that of existence, as codified by the existential quantifier “ $(\exists x)$,” one might suppose that there is little room left for any separate philosophical problem of existence. Yet existence, in fact, does seem to pose a problem, as witnessed by the bulk of the relevant literature. Some issues are relatively easy to clarify. In the usual formulations of first-order logic, for instance, there are “existential presuppositions” present to the effect that none of the singular terms employed is without a bearer (as “Pegasus” is). It is a straightforward matter, however, to dispense with these presuppositions. Though this seems to involve the procedure, branded as inadmissible by many philosophers, of treating existence as a predicate, this can nonetheless be easily done on the formal level. Given certain assumptions, it may even be shown that this “predicate” will have to be “ $(\exists x) (x = a)$ ” (for “*a* exists”—literally, “There exists an *x* such that *x* is *a*”) or something equivalent. Furthermore, the logical peculiarities of this predicate seem to explain amply philosophers’ apparent denial of its reality.

The interest in the notion of existence is connected with the question of what entities a theory commits its holder to or what its “ontology” is. The “predicate of existence” just mentioned recalls Quine’s criterion of ontological commitment: “To be is to be a value of a bound variable”—*i.e.*, of the *x* in $(\forall x)$ or in $(\exists x)$. According to Quine, a theory is committed to those and only those entities that in the last analysis serve as the values of its bound variables. Thus ordinary first-order theory commits one to an ontology only of individuals (particulars), whereas higher order logic commits one to the existence of sets—*i.e.*, of collections of definite and distinct entities (or, alternatively, of properties and relations). Likewise, if

Entities
to which a
theory is
committed

Possible
worlds
and
truth-
values

bound first-order variables are assumed to range over sets (as they do in set theory), a commitment to the existence of these sets is incurred.

The doctrine that an ontology of individuals is all that is needed is known as (the modern version of) nominalism. The opposite view is known as (logical) realism. Even those philosophers who profess sympathy with nominalism find it hard, however, to maintain that mathematics could be built on a consistently nominalistic foundation.

The precise import of Quine's criterion of ontological commitment, however, is not completely clear. Nor is it clear in what other sense one is perhaps committed by a theory to those entities that are named or otherwise referred to in it but not quantified over in it. Questions can also be raised concerning the very distinction between what in modern logic are usually called individuals ("particulars" would be a more traditional designation) and such universals as their properties and relations; and these questions can be combined with others concerning the "tie" that binds particulars and universals together in predication.

An interesting approach to these problems is the distinction made by Gottlob Frege, a pioneer of mathematical logic in the late 19th century, between individuals—he called them objects—and what he called functions (which in his view include concepts) and his doctrine of the unsaturated character of the latter, according to which a function (as it were) contains a gap, which can be filled by an object. Another approach is the "picture theory of language" of Wittgenstein's *Tractatus Logico-Philosophicus*, according to which a simple sentence presents a person with an isomorphic representation (a "picture") of reality as it would be if the sentence were true. According to this view (which was later given up by Wittgenstein), "a sentence [or proposition, *Satz*] is a model of reality such as we think of it as being."

Alternative logics. The natures of most of the so-called nonclassical logics can be understood against the background of what has here been said. Some of them are simply extensions of the "classical" first-order logic—e.g., modal logics and many versions of intensional logic. The so-called free logics are simply first-order (or modal) logics without existential presuppositions.

Intuition-
istic
logic

One of the most important nonclassical logics is intuitionistic logic, first formalized by the Dutch mathematician Arend Heyting in 1930. It has been shown that this logic can be interpreted in terms of the same kind of modal logic serving as a system of epistemic logic. In the light of its purpose to consider only the known, this isomorphism is suggestive. The avowed purpose of the intuitionist is to consider only what can actually be established constructively in logic and in mathematics—i.e., what can actually be *known*. Thus, he refuses to consider, for example, "Either A or not-A" as a logical truth, for it does not actually help one in knowing whether A or not-A is the case. This does not close, however, the philosophical problem about intuitionism. Special problems arise from intuitionists' rejection (in effect) of the nonepistemic aspects of logic, as illustrated by the fact that only a part of epistemic logic is needed in this translation of intuitionistic logic into epistemic logic.

Other new logics are obtained by modifying the rules of those games that are involved in the game-theoretical interpretation of first-order logic mentioned above. The logician may reject, for instance, the assumption that he possesses perfect information, an assumption that characterizes classical first-order logic. One may also try to restrict the strategy sets of the players—to recursive strategies, for example.

Many-
valued
logics

Among the oldest kinds of alternative logics are many-valued logics. In them, more truth values than the usual true and false are assumed. The idea seems very natural when considered in abstraction from the actual use of logic. But a philosophically satisfactory interpretation of many-valued logics is not equally straightforward. The interest in finite-valued logics and the applicability of them are sometimes exaggerated. The idea, however, of using the elements of an arbitrary Boolean algebra—a generalized

calculus of classes—as abstract truth-values has provided a powerful tool for systematic logical theory.

LOGIC AND OTHER DISCIPLINES

Technical disciplines. The relations of logic to mathematics, to computer technology, and to the empirical sciences are here considered.

Mathematics. It is usually said that all of mathematics can, in principle, be formulated in a sufficiently theorem-rich system of axiomatic set theory. What the axioms of a set theory that could accomplish this might be, however, and whether they are at all natural is not obvious in every case. (The recent development in abstract algebra known as category theory offers the most conspicuous examples of these problems.) The axioms of set theory may be presumed to hold in virtue of the meanings of the terms set, member of, and so on. Thus, in some loose sense all of pure mathematics falls within the scope of logic in the wider sense. This assertion is not very informative, however, as long as the logician has no ways of analyzing these meanings so as to be able to tell what assumptions (axioms of set theory) should be adopted. The definitions of basic mathematical concepts (such as "number") in logical terms proposed by Gottlob Frege (in 1884), by Bertrand Russell (in 1903), and by their successors do not help in this enterprise. It is not clear that more recent insights in logic help very much, either, in the search for strong set-theoretical assumptions. The relationship of mathematics to logic on this level therefore remains ambiguous.

Notwithstanding these deep problems, virtually all normal mathematical argumentation is carried out in logical terms—mostly in first-order terms, but with a generous sprinkling of second-order reasoning and various principles of set theory. Historically speaking, most specific early examples of nontrivial logical reasoning were taken from mathematics.

Often these examples were set in contrast to logical arguments understood in a narrow traditional sense—in a sense narrower still than the idea of logic as being exhausted by quantification theory. According to this traditional view, logic is equated with syllogistic; i.e., with a part of that part of first-order logic that deals with properties and not with relations. Much of what earlier philosophers said of mathematical reasoning must, thus, be understood as applying to relational (first-order) reasoning. The present-day philosophy of logic is therefore as much an heir to traditional philosophy of mathematics as to traditional philosophy of logic.

Specific logical results are applicable in several parts of mathematics, especially in algebra, and various concepts and techniques used by logicians have often been borrowed from mathematics. (Thus one can even speak of "the mathematics of metamathematics.")

Computers. It has already been indicated that recursive function theory is, in effect, the study of certain idealized automata (computers). It is, in fact, a matter of indifference whether this theory belongs to logic or to computer science. The idealized assumption of a potentially infinite computer tape, however, is not a trivial one: Turing machines typically need plenty of tape in their calculations. Hence the step from Turing machines to finite automata (which are not assumed to have access to an infinite tape) is an important one.

Turing machines and the infinite tape

This limitation does not dissociate computer science from logic, however, for other parts of logic are also relevant to computer science and are constantly employed there. Propositional logic may be thought of as the "logic" of certain simple types of switching circuits. There are also close connections between automata theory and the logical and algebraic study of formal languages. An interesting topic on the borderline of logic and computer science is mechanical theorem proving, which derives some of its interest from being a clear-cut instance of the problems of artificial intelligence, especially of the problems of realizing various heuristic modes of thinking on computers. In theoretical discussions in this area, it is nevertheless not always understood how much textbook logic is basically trivial and where the distinctively nontrivial truths of logic (including first-order logic) lie.

Methodology of the empirical sciences. The quest for theoretical self-awareness in the empirical sciences has led to interest in methodological and foundational problems as well as to attempts to axiomatize different empirical theories. Moreover, general methodological problems, such as the nature of scientific explanations, have been discussed intensively among philosophers of science. In all of these endeavours, logic plays an important role.

By and large, there are here three different lines of thought. (1) Often, only the simplest parts of logic—e.g., propositional logic—are appealed to (over and above the mere use of logical notation). Sometimes, claims regarding the usefulness of logic in the methodology of the empirical sciences are, in effect, restricted to such rudimentary applications. This restriction is misleading, however, for most of the interesting and promising connections between methodology and logic lie on a higher level, especially in the area of model theory. In econometrics, for instance, a special case of the logicians' problems of definability plays an important role under the title "identification problem." On a more general level, logicians have been able to clarify the concept of a model as it is used in the empirical sciences.

In addition to those employing simple logic, two other contrasting types of theorists can be distinguished: (2) philosophers of science, who rely mostly on first-order formulations, and (3) methodologists (e.g., Patrick Suppes, a U.S. philosopher and behavioral scientist), who want to use the full power of set theory and of the mathematics based on it. Both approaches have advantages. Usually realistic axiomatizations and other reconstructions of actual scientific theories are possible only in terms of set theoretical and other strong mathematical conceptualizations (theories conceived of as "set-theoretical predicates"). In spite of the oversimplification that first-order formulations often entail, however, they can yield theoretical insights because first-order logic (including its model theory) is mastered by logicians much more thoroughly than is set theory.

Many empirical sciences, especially the social sciences, use mathematical tools borrowed from probability theory and statistics, together with such outgrowths of these as decision theory, game theory, utility theory, and operations research. A modest but not uninteresting beginning in the study of their foundations has been made in modern inductive logic.

Human disciplines. The relations of logic to linguistics, psychology, law, and education are here considered.

Linguistics. The revival of interest in semantics among theoretical linguists in the late 1960s awakened their interest in the interrelations of logic and linguistic theory as well. It was also discovered that certain grammatical problems are closely related to logicians' concepts and theories. A near-identity of linguistics and "natural logic" has been claimed by the U.S. linguist George Lakoff. Among the many conflicting and controversial developments in this area, special mention may perhaps be made of attempts by Jerrold J. Katz, a U.S. grammarian-philosopher, and others to give a linguistic characterization of such fundamental logical notions as analyticity; the sketch by Montague of a "universal grammar" based on his intensional logic; and the suggestion (by several logicians and linguists) that what linguists call "deep structure" is to be identified with logical form. Of a much less controversial nature is the extensive and fruitful use of recursive function theory and related areas of logic in formal grammars and in the formal models of language users.

Psychology. Although the "laws of thought" studied in logic are not the empirical generalizations of a psychologist, they can serve as a conceptual framework for psychological theorizing. Probably the best known recent example of such theorizing is the large-scale attempt made in the mid-20th century by Jean Piaget, a Swiss psychologist, to characterize the developmental stages of a child's thought by reference to the logical structures that he can master.

Elsewhere in psychology, logic is employed mostly as an ingredient of various models using mathematical ideas or ideas drawn from such areas as automata or information theory. Large-scale direct uses are rare, however, partly

because of the problems mentioned above in the section on logic and information.

Law. Of the great variety of kinds of argumentation used in the law, some are persuasive rather than strictly logical, and others exemplify different procedures in applied logic rather than the formulas of pure logic. Examinations of "Lawiers Logike"—as the subject was called in 1588—have also uncovered a variety of arguments belonging to the various departments of logic mentioned above. Such inquiries do not seem to catch the most characteristic kinds of legal conceptualization, however—with one exception, viz., a theory developed by Wesley Newcomb Hohfeld, a pre-World War I U.S. legal scholar, of what he called the fundamental legal conceptions. Although originally presented in informal terms, this theory is closely related to recent deontic logic (in some cases in combination with suitable causal notions). Even some of the apparent difficulties are shared by the two approaches: the deontic logician's notion of permission, for example, which is often thought of as being unduly weak, is to all practical purposes a generalization of Hohfeld's concept of privilege.

Education. After having been one of the main ingredients of the general school curriculum for centuries, logic virtually disappeared from liberal education during the first half of the 20th century. It has made major inroads back into school curricula, however, as a part of the new mathematical curriculum that came into fairly general use in the 1960s, which normally includes the elements of propositional logic and of set theory. Logic is also easily adapted to being taught by computers and has been used in experiments with computer-based education.

logic

The nature of mathematics

A chief point of interest that has emerged from modern attempts to characterize philosophy is the importance of distinguishing dialectical or analytical inquiries about meaning from empirical inquiries about fact. A primary, traditional task of the philosopher has been to present things in such a light that human feelings may be reasonably grounded. The need for this is especially obvious in the case of the moral philosopher or the aesthetician, whose work treats explicitly of subjective concerns. But the need remains the same in all philosophical inquiries, including even discussions of the foundations of mathematics. For it is obvious to a careful observer that persons who put forward theses about the nature of mathematics are involved not just intellectually but also emotionally in their pursuits; while it must be supposed that in some cases this involvement stems from or inevitably leads to intellectual confusion, it must also be allowed that a certain emotional commitment may perhaps be a necessary condition for the making of discoveries. Thus it can scarcely be an accident that no great mathematician has ever accepted the conventionalist view according to which mathematical truths are man-made.

The inquiry into the nature, underlying assumptions, and scope of mathematics has emerged in the 20th century as a subdiscipline of mathematics itself, known as the study of foundations. For a full historical treatment of this field, see the *Macropædia* article MATHEMATICS, THE FOUNDATIONS OF. The material below, edited from an article originally written by Alfred North Whitehead for the 11th edition of the *Encyclopædia Britannica*, treats mathematics itself as an object of philosophical investigation.

It has been usual to define mathematics as "the science of discrete and continuous magnitude." Even Leibnitz, who initiated a more modern point of view, follows the tradition in thus confining the scope of mathematics properly so called, while apparently conceiving it as a department of a yet wider science of reasoning. A short consideration of some leading topics of the science will exemplify both the plausibility and inadequacy of the above definition. Arithmetic, algebra, and the infinitesimal calculus, are sciences directly concerned with integral numbers, rational (or fractional) numbers, and real numbers generally, which include incommensurable numbers. It would seem that

matics

Use of
first-order
versus
set-
theoretical
formula-
tions

"the general theory of discrete and continuous quantity" is the exact description of the topics of these sciences. Furthermore, can we not complete the circle of the mathematical sciences by adding geometry? Now geometry deals with points, lines, planes, and cubic contents. Of these all except points are quantities. Also, as the Cartesian geometry shows, all the relations between points are expressible in terms of geometric quantities. Accordingly, at first sight it seems reasonable to define geometry in some such way as "the science of dimensional quantity." Thus every subdivision of mathematical science would appear to deal with quantity, and the definition of mathematics as "the science of quantity" would appear to be justified. We have now to see why the definition is inadequate.

CRITICAL QUESTIONS

Types relating to numbers. What are numbers? We can talk of five apples and 10 pears. But what are "five" and "10" apart from the apples and pears? Also in addition to the cardinal numbers there are the ordinal numbers: the fifth apple and the 10th pear claim thought. What is the relation of "the fifth" and "10th" to "five" and "10"? "The first rose of summer" and "the last rose of summer" are parallel phrases, yet one explicitly introduces an ordinal number and the other does not. Again, "half a foot" and "half a pound" are easily defined. But in what sense is there "a half," which is the same for "half a foot" as "half a pound"? Furthermore, incommensurable numbers are defined as the limits arrived at as the result of certain procedures with rational numbers. But how do we know that there is anything to reach? We must know that $\sqrt{2}$ exists before we can prove that any procedure will reach it.

Types relating to geometry. Also in geometry, what is a point? The straightness of a straight line and the planeness of a plane require consideration. Furthermore, "congruence" is a difficulty. For when a triangle "moves," the points do not move with it. So what is it that keeps unaltered in the moving triangle? Thus the whole method of measurement in geometry as described in the elementary textbooks and the older treatises is obscure to the last degree. Lastly, what are "dimensions"? All these topics require thorough discussion before we can rest content with the definition of mathematics as the general science of magnitude; and by the time they are discussed the definition has evaporated. An outline of the modern answers to questions such as the above will now be given. A critical defense of them would require a volume.

Nature of cardinal numbers. A one-one relation between the members of two classes α and β is any method of correlating all the members of α to all the members of β , so that any member of α has one and only one correlate in β , and any member of β has one and only one correlate in α . Two classes between which a one-one relation exists have the same cardinal number and are called cardinally similar; and the cardinal number of the class α is a certain class whose members are themselves classes—namely, it is the class composed of all those classes for which a one-one correlation with α exists. Thus the cardinal number of α is itself a class, and furthermore α is a member of it. For a one-one relation can be established between the members of α and α by the simple process of correlating each member of α with itself. Thus the cardinal number one is the class of unit classes, the cardinal number two is the class of doublets, and so on. Also a unit class is any class with the property that it possesses a member x such that, if y is any member of the class, then x and y are identical. A doublet is any class which possesses a member x such that the modified class formed by all the other members except x is a unit class. And so on for all the finite cardinals, which are thus defined successively. The cardinal number zero is the class of classes with no members; but there is only one such class, namely—the null class. Thus this cardinal number has only one member. The operations of addition and multiplication of two given cardinal numbers can be defined by taking two classes α and β , satisfying the conditions (1) that their cardinal numbers are respectively the given numbers, and (2) that they contain no member in common, and then by defining by reference to α and β two other suitable classes whose cardinal numbers are

defined to be respectively the required sum and product of the cardinal numbers in question.

With these definitions it is now possible to *prove* the following six premises applying to finite cardinal numbers, from which Peano has shown that all arithmetic can be deduced:—

i. Cardinal numbers form a class. ii. Zero is a cardinal number. iii. If a is a cardinal number, $a + 1$ is a cardinal number. iv. If s is any class and zero is a member of it, also if when x is a cardinal number and a member of s , also $x + 1$ is a member of s , then the whole class of cardinal numbers is contained in s . v. If a and b are cardinal numbers, and $a + 1 = b + 1$, then $a = b$. vi. If a is a cardinal number, then $a + 1 \neq 0$.

It may be noticed that (iv.) is the familiar principle of mathematical induction. Peano in a historical note refers its first explicit employment, although without a general enunciation, to Maurolycus in his work, *Arithmeticonum libri duo* (Venice, 1575).

But now the difficulty of confining mathematics to being the science of number and quantity is immediately apparent. For there is no self-contained science of cardinal numbers. The proof of the six premises requires an elaborate investigation into the general properties of classes and relations that can be deduced by the strictest reasoning from our ultimate logical principles. Also it is purely arbitrary to erect the consequences of these six principles into a separate science. They are excellent principles of the highest value, but they are in no sense the necessary premises that must be proved before any other propositions of cardinal numbers can be established. On the contrary, the premises of arithmetic can be put in other forms, and, furthermore, an indefinite number of propositions of arithmetic can be proved directly from logical principles without mentioning them. Thus, while arithmetic may be defined as that branch of deductive reasoning concerning classes and relations that is concerned with the establishment of propositions concerning cardinal numbers, the introduction of cardinal numbers makes no great break in this general science. It is merely a subdivision in a general theory.

Nature of ordinal numbers. We must first understand what is meant by "order," that is, by "serial arrangement." An order of a set of things is to be sought in that relation holding between members of the set that constitutes that order. The set viewed as a class has many orders. Thus the telegraph posts along a certain road have a space-order very obvious to our senses; but they have also a time-order according to dates of erection, perhaps more important to the postal authorities who replace them after fixed intervals. A set of cardinal numbers has an order of magnitude, often called *the* order of the set because of its insistent obviousness to us; if they are the numbers drawn in a lottery, their time-order of occurrence in that drawing also ranges them in an order of some importance. Thus the order is defined by the "serial" relation. A relation (R) is serial when (1) it implies diversity, so that, if x has the relation R to y , x is diverse from y ; (2) it is transitive, so that if x has the relation R to y , and y to z , then x has the relation R to z ; (3) it has the property of connexity, so that if x and y are things to which any things bear the relation R , or which bear the relation R to any things, then *either* x is identical with y , *or* x has the relation R to y , *or* y has the relation R to x . These conditions are necessary and sufficient to secure that our ordinary ideas of "preceding" and "succeeding" hold in respect to the relation R . The "field" of the relation R is the class of things ranged in order by it. Two relations R and R' are said to be ordinally similar, if a one-one relation holds between the members of the two fields of R and R' , such that if x and y are any two members of the field of R , such that x has the relation R to y , and if x' and y' are the correlates in the field of R' of x and y , then in all such cases x' has the relation R' to y' , and conversely, interchanging the dashes on the letters; i.e., R and R' , x and x' , etc. It is evident that the ordinal similarity of two relations implies the cardinal similarity of their fields, but not conversely. Also, two relations need not be serial in order to be ordinally similar; but if one is serial, so is the other.

Cardinal
numbers as
classes

Serial
relations

The relationship-number of a relation is the class whose members are all those relations that are ordinarily similar to it. This class will include the original relation itself. The relation-number of a relation should be compared with the cardinal number of a class. When a relation is serial its relation-number is often called its serial type. The addition and multiplication of two relation-numbers is defined by taking two relations R and S , such that (1) their fields have no terms in common; (2) their relation-numbers are the two relation-numbers in question, and then by defining by reference to R and S two other suitable relations whose relation-numbers are defined to be respectively the sum and product of the relation-numbers in question. We need not consider the details of this process. Now if n be any finite cardinal number, it can be proved that the class of those serial relations, which have a field whose cardinal number is n , is a relation-number. This relation-number is the ordinal number corresponding to n ; let it be symbolized by n . Thus, corresponding to the cardinal numbers 2, 3, 4, ... there are the ordinal numbers 2, 3, 4, ... The definition of the ordinal number 1 requires some little ingenuity owing to the fact that no serial relation can have a field whose cardinal number is 1; but we must omit here the explanation of the process. The ordinal number 0 is the class whose sole member is the null relation—that is, the relation that never holds between any pair of entities. The definitions of the finite ordinals can be expressed without use of the corresponding cardinals, so there is no essential priority of cardinals to ordinals. Here also it can be seen that the science of the finite ordinals is merely a subdivision of the general theory of classes and relations.

Cantor's infinite numbers. Owing to the correspondence between the finite cardinals and the finite ordinals, the propositions of cardinal arithmetic and ordinal arithmetic correspond point by point. But the definition of the cardinal number of a class applies when the class is not finite, and it can be proved that there are different infinite cardinal numbers, and that there is a least infinite cardinal, now usually denoted by \aleph_0 , where \aleph is the Hebrew letter aleph. Similarly, a class of serial relations, called *well-ordered* serial relations, can be defined, such that their corresponding relation-numbers include the ordinary finite ordinals, but also include relation-numbers which have many properties like those of the finite ordinals, though the fields of the relations belonging to them are not finite. These relation-numbers are the infinite ordinal numbers. The arithmetic of the infinite cardinals does not correspond to that of the infinite ordinals. It will suffice to mention here that Peano's fourth premise of arithmetic does not hold for infinite cardinals or for infinite ordinals. Contrasting the above definitions of number, cardinals and ordinals, with the alternative theory that number is an ultimate idea incapable of definition, we find that our procedure exacts greater attention and less credulity.

The data of analysis. Rational numbers and real numbers in general can now be defined according to the same general method. If m and n are finite cardinal numbers, the rational number m/n is the relation that any finite cardinal number x bears to any finite cardinal number y when $n \times x = m \times y$. Thus the rational number one, which we will denote by 1_r , is not the cardinal number 1; for 1, is the relation $1/1$ as defined above, and is thus a relation holding between certain pairs of cardinals. Similarly, the other rational integers must be distinguished from the corresponding cardinals. The arithmetic of rational numbers is now established by means of appropriate definitions, which indicate the entities meant by the operations of addition and multiplication. But in order to obtain general enunciations of theorems without exceptional cases, mathematicians employ entities of ever-ascending types of elaboration. These entities are not created but are employed by mathematicians, and their definitions should show the construction of the new entities in terms of the old. The real numbers, including irrational numbers, have now to be defined. Consider the serial arrangement of the rationals in their order of magnitude. A real number is a class (α , say) of rational numbers that satisfies the condition that it is the same as the class of those rationals

each of which precedes at least one member of α . Thus, consider the class of rationals less than 2_r ; any member of this class precedes some other members of the class—thus $1/2$ precedes $4/3$, $3/2$ and so on; also the class of predecessors of predecessors of 2_r is itself the class of predecessors of 2_r . Accordingly this class is a real number; it will be called the real number 2_r . Note that the class of rationals less than or equal to 2_r is not a real number. For 2_r is not a predecessor of some member of the class. In the above example 2_r is an integral real number, which is distinct from a rational integer, and from a cardinal number. Similarly, any rational real number is distinct from the corresponding rational number. But now the irrational real numbers have all made their appearance. For example, the class of rationals whose squares are less than 2_r satisfies the definition of a real number; it is the real number $\sqrt{2}$. The arithmetic of real numbers follows from appropriate definitions of the operations of addition and multiplication. Except for the immediate purposes of an explanation, such as the above, it is unnecessary for mathematicians to have separate symbols, such as 2 , 2_r and 2_{rr} , or $2/3$ and $(2/3)_r$. Real numbers with signs (+ or -) are now defined. If a is a real number, $+a$ is defined to be the relation that any real number of the form $x + a$ bears to the real number x , and $-a$ is the relation that any real number x bears to the real number $x + a$. The addition and multiplication of these "signed" real numbers is suitably defined, and it is proved that the usual arithmetic of such numbers follows. Finally, we reach a complex number of the n th order. Such a number is a "one-many" relation which relates n signed real numbers (or n algebraic complex numbers when they are already defined by this procedure) to the n cardinal numbers $1, 2, \dots, n$ respectively. If such a complex number is written (as usual) in the form $x_1e_1 + x_2e_2 + \dots + x_ne_n$, then this particular complex number relates x_1 to 1 , x_2 to 2 , ... x_n to n . Also the "unit" e_1 (or e_3) considered as a number of the system is merely a shortened form for the complex number $(+1)e_1 + 0e_2 + \dots + 0e_n$. This last number exemplifies the fact that one signed real number, such as 0, may be correlated to many of the n cardinals, such as $2 \dots n$ in the example, but that each cardinal is only correlated with one signed number. Hence the relation has been called above "one-many." The sum of two complex numbers $x_1e_1 + x_2e_2 + \dots + x_ne_n$ and $y_1e_1 + y_2e_2 + \dots + y_ne_n$ is always defined to be the complex number $(x_1 + y_1)e_1 + (x_2 + y_2)e_2 + \dots + (x_n + y_n)e_n$. But an indefinite number of definitions of the product of two complex numbers yield interesting results. Each definition gives rise to a corresponding algebra of higher complex numbers. We will confine ourselves here to algebraic complex numbers—that is, to complex numbers of the second order taken in connection with that definition of multiplication that leads to ordinary algebra. The product of two complex numbers of the second order—namely, $x_1e_1 + x_2e_2$ and $y_1e_1 + y_2e_2$, is in this case defined to mean the complex $(x_1y_1 + x_2y_2)e_1 + (x_1y_2 + x_2y_1)e_2$. Thus $e_1 \times e_1 = e_1$, $e_2 \times e_2 = -e_1$, $e_1 \times e_2 = e_2 \times e_1 = e_2$. With this definition it is usual to omit the first symbol e_1 , and to write i or $\sqrt{-1}$ instead of e_2 . Accordingly, the typical form for such a complex number is $x + yi$, and then with this notation the above-mentioned definition of multiplication is invariably adopted. The importance of this algebra arises from the fact that in terms of such complex numbers with this definition of multiplication the utmost generality of expression, to the exclusion of exceptional cases, can be obtained for theorems that occur in analogous forms, but complicated with exceptional cases, in the algebras of real numbers and of signed real numbers. This is exactly the same reason as that which has led mathematicians to work with signed real numbers in preference to real numbers, and with real numbers in preference to rational numbers.

DEFINITION OF MATHEMATICS

It has now become apparent that the traditional field of mathematics in the province of discrete and continuous number can only be separated from the general abstract theory of classes and relations by a wavering and inde-

terminate line. Of course a discussion as to the mere application of a word degenerates into the most fruitless logomachy. But on the assumption that "mathematics" is to denote a science well marked out by its subject matter and its methods, and that at least it is to include all topics habitually assigned to it, "mathematics" is employed in the general sense of the "science concerned with the logical deduction of consequences from the general premises of all reasoning."

Kinds of
mathe-
matical
proposi-
tions

Geometry. The typical mathematical proposition is: "If $x, y, z \dots$ satisfy such and such conditions, then such and such other conditions hold with respect to them." By taking fixed conditions for the hypothesis of such a proposition a definite department of mathematics is marked out. For example, geometry is such a department. The "axioms" of geometry are the fixed conditions that occur in the hypotheses of the geometrical propositions. It is sufficient to observe here that they are concerned with special types of classes of classes and of classes of relations, and that the connection of geometry with number and magnitude is in no way an essential part of the foundation of the science.

Classes and relations. We now must deduce the general properties of classes and relations from the ultimate logical premises. In the course of this process, some contradictions have become apparent. That first discovered is known as Burali-Forti's contradiction and consists in the proof that there both is and is not a greatest infinite ordinal number. But these contradictions do not depend upon any theory of number, for Russell's contradiction does not involve number in any form. This contradiction arises from considering the class possessing as members all classes that are not members of themselves. Call this class w ; then to say that x is a w is equivalent to saying that x is not an x . Accordingly, to say that w is a w is equivalent to saying that w is not a w . An analogous contradiction can be found for relations. It follows that a careful scrutiny of the very idea of classes and relations is required. Note that classes are here required in extension, so that the class of human beings and the class of rational featherless bipeds are identical; similarly for relations, which are to be determined by the entities related. Now a class in respect to its components is many. In what sense then can it be one? This problem of "the one and the many" has been discussed continuously by the philosophers. All the contradictions can be avoided, and yet the use of classes and relations can be preserved as required by mathematics, and indeed by common sense, by a theory that denies to a class—or relation—existence or being in any sense in which the entities composing it—or related by it—exist. Thus, to say that a pen is an entity and the class of pens is an entity is merely a play upon the word "entity"; the second sense of "entity" (if any) is indeed derived from the first but has a more complex significance. Consider an incomplete proposition, incomplete in the sense that some entity that ought to be involved in it is represented by an undetermined x , which may stand for any entity. Call it a propositional function; and, if ϕx be a propositional function, the undetermined variable x is the argument. Two propositional functions ϕx and ψx are "extensionally identical" if any determination of x in ϕx that converts ϕx into a true proposition also converts ψx into a true proposition, and conversely for ψ and ϕ . Now consider a propositional function Fx in which the variable argument x is itself a propositional function. If Fx is true when, and only when, x is determined to be either ϕ or some other propositional function extensionally equivalent to ϕ , then the proposition $F\phi$ is of the form which is ordinarily recognized as being about the class determined by ϕx taken in extension—that is, the class of entities for which ϕx is a true proposition when x is determined to be any one of them. A similar theory holds for relations that arise from the consideration of propositional functions with two or more variable arguments. It is then possible to define by a parallel elaboration what is meant by classes of classes, classes of relations, relations between classes, and so on. Accordingly, the number of a class of relations can be defined, or of a class of classes, and so on. This theory is

Classes of
classes and
of relations

in effect a theory of the *use* of classes and relations and does not decide the philosophic question as to the sense (if any) in which a class in extension is one entity. It does indeed deny that it is an entity in the sense in which one of its members is an entity. Accordingly, it is a fallacy for any determination of x to consider " x is an x " or " x is not an x " as having the meaning of propositions. Note that for any determination of x , " x is an x " and " x is not an x " are neither of them fallacies but are both meaningless, according to this theory. Thus Russell's contradiction vanishes, and the other contradictions vanish also.

APPLIED MATHEMATICS

Selection of topics. The selection of the topics of mathematical inquiry among the infinite variety open to it has been guided by the useful applications, and indeed the abstract theory has only recently been disentangled from the empirical elements connected with these applications. For example, the application of the theory of cardinal numbers to classes of physical entities involves in practice some process of counting. It is only recently that the *succession* of processes that is involved in any act of counting has been seen to be irrelevant to the idea of number. Indeed, it is only by experience that we can know that any definite process of counting will give the true cardinal number of some class of entities. It is perfectly possible to imagine a universe in which any act of counting by a being in it annihilates some members of the class counted during the time and only during the time of its continuance. A legend of the Council of Nicaea illustrates this point: "When the Bishops took their places on their thrones, they were 318; when they rose up to be called over, it appeared that they were 319; so that they never could make the number come right, and whenever they approached the last of the series, he immediately turned into the likeness of his next neighbour." Such a story cannot be disproved by deductive reasoning from the premises of abstract logic. We can only assert that a universe in which such things are liable to happen on a large scale is unfitted for the practical application of the theory of cardinal numbers. The application of the theory of real numbers to physical quantities involves analogous considerations. In the first place, some physical process of addition is presupposed, involving some inductively inferred law of permanence during that process. Thus in the theory of masses we must know that two pounds of lead when put together will counterbalance in the scales two pounds of sugar, or a pound of lead and a pound of sugar. Furthermore, the sort of continuity of the series (in order of magnitude) of rational numbers is known to be different from that of the series of real numbers. Indeed, mathematicians now reserve "continuity" as the term for the latter kind of continuity; the mere property of having an infinite number of terms between any two terms is called "compactness." The compactness of the series of rational numbers is consistent with quasi-gaps in it—that is, with the possible absence of limits to classes in it. Thus the class of rational numbers whose squares are less than 2 has no upper limit among the rational numbers. But among the real numbers all classes have limits. Now, owing to the necessary inexactness of measurement, it is impossible to discriminate directly whether any kind of continuous physical quantity possesses the compactness of the series of rationals or the continuity of the series of real numbers. In calculations the latter hypothesis is made because of its mathematical simplicity. But the assumption has certainly no *a priori* grounds in its favour, and it is not very easy to see how to base it upon experience. For example, the continuity of space apparently rests upon sheer assumption unsupported by any *a priori* or experimental grounds. Thus the current application of mathematics to the analysis of phenomena can be justified by no *a priori* necessity.

Existence of applied mathematics. In one sense there is no science of applied mathematics. When once the fixed conditions that any hypothetical group of entities are to satisfy have been precisely formulated, the deduction of the further propositions, which also will hold respecting them, can proceed in complete independence of the question as to whether or not any such group of entities

Relation of
theory and
physical
reality

can be found in the world of phenomena. Thus rational mechanics, based on the Newtonian Laws and viewed as mathematics, is independent of its supposed application, and hydrodynamics remains a coherent and respected science though it is extremely improbable that any perfect fluid exists in the physical world. But this unbendingly logical point of view cannot be the last word upon the matter. For no one can doubt the essential difference between characteristic treatises upon "pure" and "applied" mathematics. The difference is a difference in method. In pure mathematics the hypotheses that a set of entities are to satisfy are given, and a group of interesting deductions are sought. In "applied mathematics" the "deductions" are given in the shape of the experimental evidence of natural science, and the hypotheses from which the "deductions" can be deduced are sought. Accordingly, every treatise on applied mathematics, properly so-called, is directed to the criticism of the "laws" from which the reasoning starts, or to a suggestion of results that experiment may hope to find. Thus if it calculates the result of some experiment, it is not the experimentalist's well-attested results that are on their trial but the basis of the calculation. (A.N.W.)

Western philosophy of law

Philosophy of law is concerned with the formulation of concepts and theories to aid in understanding the nature of law, the sources of its authority, and its role in society. In English-speaking countries the term "jurisprudence" is often used synonymously and is invariably used in reference to particular subdivisions of the field.

To the extent that it implies some necessary link or coincidence with general philosophy, the phrase "philosophy of law" may be somewhat misleading, for philosophy of law is mostly untouched by the conflicts of different philosophical schools, and its practitioners may without incongruity draw on diverse philosophical outlooks—on Logical Positivism for some analytical problem of the structure of legal orders and, simultaneously, on Existentialism for a problem of sociological jurisprudence or justice, for example—without commitment in any such instance to an entire philosophical outlook.

Nor can one treat philosophy of law as a specialized branch of philosophy such as ethical or political philosophy, epistemology, or logic, for in philosophy of law all these branches may make contributions. Ideas that may illumine jurisprudential problems must indeed be sought not only in philosophy but in all systematic bodies of thought. Only if "philosophy" is interpreted in its least technical and broadest sense does "philosophy of law" cease to be a misnomer.

PROBLEMS OF THE PHILOSOPHY OF LAW

Various approaches. For practical reasons, such as to avoid overlappings, it is convenient to organize jurisprudence into three principal branches only: analytical jurisprudence, sociological jurisprudence, and the theory of justice.

Analytical jurisprudence. The analytical questions in jurisprudence are concerned with articulating the axioms, defining the terms, and prescribing the methods that best enable one to view the legal order (or part of it) as a self-consistent system and that maximize awareness of its logical structure. Perhaps the most rigorous solutions are those which, like that of Hans Kelsen, a contemporary Austrian-American legal philosopher, attempt to identify structural or relational features as being necessarily entailed in the meaning of legal norms or in lawyers' intellectual operations with them (see below *Pure theory of law*). Alternatively, the basis for logical structuring may be found in some imputed attribute of law not itself inherently structural. The 19th-century English legal philosopher John Austin, for example, thought it an essential preliminary to his quest for a logical system in law to clarify what was involved in his assumption that law always consists of "commands." This clarification is important, but the claim that such a clarified version of a common assumption necessarily amounts to an analytical model of law seems unwarranted.

On more modest levels, the analyst may seek to infuse clarity and orderliness into some particular branch of a legal system or even into the applications of some particular rule. Such work shades over, on the one hand, into ordinary legal analysis and, on the other, into jurisprudential efforts to clarify the meaning of particular legal terms. Analysis of a particular word or even a particular branch of law will usually, by necessity, be particularist in the sense that it works upon legal materials found only in one particular legal system. In between particularism and universalism lie what are sometimes called comparative approaches, in which analytical jurisprudence is applied to materials drawn from more than one (but not from all) legal systems.

Sociological jurisprudence. The sociological questions in jurisprudence are concerned with the actual effects of the law upon the complex of attitudes, behaviour, organization, environment, skills, and powers involved in the maintenance of a particular society. Conversely, sociological jurisprudence is also concerned with the effects of social phenomena on both the substantive and procedural aspects of law, as well as on the legislative, judicial, and other means of forming, operating, changing, and disrupting the legal order. The fact that men in a given time and place hold particular ideas and values, including ideals of justice, is itself a fact the relation of which to law must be studied; but the focus is sharply different from that in the study of theories of justice. Its focus is descriptive, not normative; it is concerned with what is or with what goes on, not with what ought to be or ought to go on.

The theory of justice. The theory of justice is concerned with the evaluation and criticism of law in terms of the ideals or goals postulated for it. This involves the identification and articulation of the values that the legal order seeks to realize. This aspect of jurisprudence is inextricably interwoven with ethical and political philosophy, and theories of justice thus tend to parallel the full range of ethical and political philosophies.

Law, morality, and natural law. A consideration of fundamental importance in the philosophy of law is that of the distinction between law and morality. The importance of the distinction is illustrated by the main questions to which it gives rise: (1) How far and in what sense should the law of a community seek to give effect to its morality? (2) Is there a moral duty to obey the law even when it does not embody morality, and, if so, are there any limits to this duty? (3) When a legal rule directs conduct that morality forbids, which should the citizen obey? (4) Is there ever (and, if so, when is there) a duty to overthrow an entire legal system because of its conflict with morality?

In all these questions the word "law" refers to the specialized form of social control familiar in modern, secular, politically organized societies. The word "morality" in the four questions may, however, refer to any of the following: (1) the community's relevant factual behaviour patterns (its mores); (2) its socially approved behaviour patterns, as sanctified by some widely held rational or religious ideal, whether observed in practice or not (social morality); or (3) the moral ideals accepted by each individual as binding on himself and on others, whether or not those others agree (individual morality). All these, like law, are means of controlling human conduct by setting normative standards; and all three have a constantly changing interaction with each other, as well as with law.

The fact that legal and moral norms vary from place to place and from one historical period to another lies in part behind a persistent theme in the philosophy of law: the search for unchanging norms that are universally valid. Clearly, the most certain way of establishing such norms would be to base them on widely observed facts, such as man's social propensities or the ubiquitous importance of kinship in social organization, which supposedly reveal something fundamental about the nature of man and his adjustment to the world. The attempt to base norms on some such category of facts has for two millennia been associated with the concept of natural law. This concept has many versions, the principal of which are outlined in the historical survey below, but the significance of the topic merits some separate preliminary discussions.

Aristotle's
conception
of natural
law

It has always been possible to trace a mainstream of natural-law thought, flowing from Aristotle's premise that the "nature" of any creature, from which obligations must be derived, is what it will be in its fullest and most perfect development. For man, this means what he is when the powers and qualities distinguishing him from other creatures, namely, his reason and his impulse to social living, are fully developed. Natural law embodies those obligations that will appear if mankind's reason and sociality are fully unfolded.

A major difficulty presented by this attempt to develop normative standards appears to be that it is very difficult to demonstrate, let alone create a sense of obligation toward, values that are only immanent. All theories of natural law, moreover, have found it necessary to rely on what are essentially intuitions or preconceptions as to what man's true nature is. All such theories acknowledge, for instance, that the full development or fulfillment of an entity is not the same as its mere continued existence, that there may be a "warping" or "impeding" of the natural tendencies, so that what exists may then "be said to be unsound or incorrect." Thus, mere factuality is not a sufficient source of obligation. Similarly, St. Thomas Aquinas himself, in identifying the "inclinations" from which men may learn natural law, found it necessary to order these in grades of inclination, so that those inclinations most closely related to reason and sociality take priority over those concerned (for example) with procreation and self-preservation. The criteria by which such a hierarchy is ordered must be drawn from sources other than the factual inclinations themselves. The "lower" grades (such as self-preservation) may well be based on something like instinct; but the question arises at the higher grades whether there is any comparable instinct by which men seek to find moral precepts binding all of them in common. Aquinas here appealed to *synderesis*, a kind of sympathetic understanding found in men, a disposition (*habitus*) of the practical intellect inclining them to the good and murmuring against evil.

To derive from this *synderesis* a universal natural law, however, it would be necessary to demonstrate some "universal conscience" of all mankind. But natural lawyers faced with the fact that men's consciences do not coincide explain that conscience may err and reason be corrupt. Invocation of *synderesis* is in fact helpful not as an account of how one may arrive at factually based normative standards but as an illustration of the psychological tendency of men to assert values.

HISTORICAL SURVEY OF LEGAL THEORIES

The ancient world. *Greek thought.* The major contribution of Greece was a body of philosophical and cosmological ideals about justice, more apt for orators' appeals to popular assemblies than for preceptual application to day-to-day life situations.

Early Greek cosmologies, embedded in some of the earliest myths, had seen the individual as held within a kind of transcending harmony of the universe, emanating from the divine law (*logos*) and expressed in relation to human life in the law (*nomos*) of the polis, the city-state. The later Sophists, however, who examined critically all assumptions relating to life in the city-state, pointed to the wide disparities in human law and morals and rejected the claim that this human law (*nomos*) necessarily reflected any universal law (*logos*). Taking man as "the measure of all things," they rejected any claims of his law (*nomos*) to absolute value and saw law and justice and values generally as created by men's reasons, in their multitudes and generations, in all their individuated, relativistic, and historically changing dimensions.

In the restless intellectual and political climate of 5th-century Athens, Plato was concerned to redefine the nature of justice by relating it to something far more permanent and absolute than the *nomos* of the city-state. He assigned "reality" to the unchanging archetypal forms—i.e., the ideas—of things rather than to the ephemeral phenomena as superficially and confusedly perceived by individual men unenlightened by philosophy. In the utopia described in *The Republic*, Plato defines justice in an architectonic sense: justice prevails when the state is ordered in accor-

dance with the ideal forms ascertained by its philosopher-kings and is thus unrelated to the *nomos* of the city-state. There is no need for human law, since transcendental knowledge rules. In his later thought, however, as revealed in *Politicus* (the "Statesman") and the *Laws*, when he is concerned to describe a more practicable but nevertheless "second best" state, Plato assigns to law a role almost as important as that of knowledge in *The Republic*. A famous classification of states given in *Politicus* is indeed based on the criterion of whether or not they are ruled by law. The law as Plato here conceived it, however, was not mere convention or the imperfect individual judgments of men but a reflection of the common human reason in its full development. To this extent the rule of law might approximate the ideal rule of knowledge envisaged in *The Republic*, for in the inherited law of men is crystallized that much wisdom of which they are capable.

And yet it was difficult for Plato to find justification for such an argument in his basic philosophical position, with its emphasis on the contrast between the mere opinion of ordinary men and the transcendental knowledge of the philosopher. Aristotle, who in common with Plato held a view of nature or reality that transcended the variability of things as perceived by the senses, was, however, able more successfully to defend the validity of a law resulting from the practice of ordinary men. For Aristotle's transcendental reality is more firmly related to things as they are: it comprises that which they will become as their potentialities unfold in nature toward the end that is theirs in nature. Man, in his nature, is moral, rational, and social, and his law may be judged by the extent to which it facilitates the development of these innate qualities.

The Greek conception of natural law underwent further refinement by the Stoic school of philosophy, which became active toward the end of the 4th century BC. The Stoics posited the existence of a natural law, the *jus naturale*, which was an emanation of the *lex aeterna*, the law of reason of the cosmos. The existence of an innate reason in men linked everyone with the cosmic order and subjected all to a universally valid moral law. This latter concept thoroughly infused Roman thinking, largely as a result of the influence of Stoic philosophy on Rome.

Roman thought. Greek law scarcely survived as a system, because it never developed a class of legal specialists or abandoned its lay administrators or its popular tribunals of grotesque size. Roman law, on the other hand, developed through the efforts of expert juriconsults (learned lawyers) and praetors (magistrates) into a permanent heritage of Western society. By its adoption into works such as Cicero's *De republica* as well as in the work of the great juriconsults, Stoic speculation concerning reason and nature was brought onto the level of precepts for concrete problem solving. The crude, tribal *jus civile* ("civil law") of the Romans was thus transformed into a natural-law-based *jus gentium* (law applying to all people), a set of principles common to all nations and appropriate, therefore, for application to foreigners as well as Romans.

Hebrew thought. In the Talmud there is an assertion that "Whatever decision of a mature scholar in the presence of his teacher will yet derive from the Law (Torah) that was already spoken to Moses on Mt. Sinai." In theory, this presupposed that the Oral Law must respect every jot and tittle of the revealed written law. Yet the richness, ambivalences, and silences of what was written, in relation to a changing world, still left the widest freedom to the scholarly reason of the rabbinical exegetes into whose care both the written law and the Oral Law finally came.

The operations of the rabbinical schools and courts over many creative centuries, especially during and following the first Babylonian Exile, resembled those of the great Roman juriconsults and the great judges of the common-law tradition. One Talmudic story tells of a doctrinal rift between the majority of a rabbinical court led by a great rabbi and a dissenting but no less great rabbi, in which the dissenter successfully summoned the authentic voice of God onto his side of the argument. To this intervention the majority of the court responded: "The law is not in heaven, the law has been handed down to us on earth from Mt. Sinai, and we no longer take notice of

heavenly voices. . . .” And the story relates that, at that point, God said with a smile to Elijah the prophet, with whom he was walking: “My children have defeated me, my children have defeated me.” But this was an indulgent ratification, not an implacably cruel wrath such as the Greek god brought down on the head of Prometheus. Thus, even against divine intervention, the learned stood their ground, relying for the interpretation of the law on their own wisdom and reason.

The Middle Ages. *Augustine.* St. Augustine of Hippo, in attempting to refute the pagan assertion that Christianity was responsible for the decline of Roman power, reintroduced Stoic philosophy alongside Judeo-Christian thought into the stream of modern jurisprudential speculation. He placed God’s reason beside God’s will as the highest source of the unchangeable, eternal, divine law binding directly on man and all other creatures. The divine law was thus accessible to both man’s reason and his faith and was not, as St. Paul had largely concluded, the product of his will alone and hence not rational in terms of human as opposed to divine reason.

At a second level, Augustine placed the no less unchangeable natural law, being the divine law as man is given the reason, heart, and soul to understand it. The third level, of temporal, or positive, law (for him, the Roman law of the Christian Roman Empire), was warranted by the eternal divine law, even though it changed from time to time and from place to place, so long as it respected the limits laid down by the divine and natural law. This rationale of secular power, some have thought, preserved the idea of government under law through the disintegration of the ancient world, for recultivation in the revival of learning of the 12th and 13th centuries.

Scholasticism. Aquinas, like Augustine long before, succeeded in quieting momentarily the competing claims of the will against the reason of God, the struggle between “voluntarism” and “rationalism,” as the underlying basis of the eternal and natural law. Aquinas, like Augustine, gave a plausible place to both natural law and temporal (or positive) law under the eternal law. Human, or positive, law is a creation of human reason for the common good, within limits that natural law prescribes, so that even this proceeds from right reason and therefore from the eternal law. Such positive law as violated the natural and thus the eternal law “was not law” or merely was not binding “in conscience.”

The tendency to make reason prevail over will (as in Plato’s call for philosophers to be kings or the Arab Averroës’ call for philosophers to interpret what is revealed) was challenged by a voluntarist countermovement at Paris and Oxford in the quarter of a century after Aquinas’ death in 1274. A Franciscan, John Duns Scotus, insisted on the uniqueness of all beings as finally traceable to the uniqueness of God’s will. All precepts, even of the divine law, depend on the single precept “Love God,” and, since not reason but will gives access to this, there is no natural law accessible to man’s reason. All that can be required of human, or positive, law is that it must be “consonant” with the precept “Love God,” or with any other precept willed by God.

The Renaissance period to the 18th century. *Machiavelli.* Machiavelli presented himself (on one interpretation, at least) as seeking to escape from both transcendent will and transcendent reason into the empirical, into life as it is, observed through the eyes of a worldly man whose mind is uncluttered with philosophical and theological preconceptions. He can be understood, in his own words, to be seeking “what a principality is, the variety of such States, how they are won, how they are held, how they are lost.” This conception was the more remarkable in 1513, since such an approach had then barely been promulgated for study of the physical world. It had still, indeed, to await its major manifesto in that sphere until Francis Bacon’s *Advancement of Learning* at the end of the century.

Even on the more favourable view of Machiavelli’s aim—i.e., as describing, rather than prescribing, political behaviour—it remains true that he saw this description as ancillary to the art of maintaining the state and its ruler, so that this maintenance is a kind of end in itself. The omnipotence—unrestrained by law or morality—that he both

ascribes and prescribes to the prince is thus a product not so much of his scientific detachment as of his tendency to view political power as a value, as an end in itself.

Natural law and social-contract theory. The supremacy of the human lawgiver, as posited by Machiavelli and in their diverse ways also by the French and English political theorists Jean Bodin and Thomas Hobbes and others, interwove in the following centuries with continued insistence by Grotius and others on the dominance of the divine reason and man’s participation in it, by which he has access to the natural law.

The Dutch political and legal philosopher Hugo Grotius, amid the political expediences and anarchy of the Thirty Years’ War (1618–48), sought to introduce a degree of normative restraint among the monarchical rulers of the newly emerged sovereign states of Europe and to establish a basis in natural law for a rejection of *raison d’état* as a just cause for war, as well as for legal limits on the means and modes of violence in war. Even if the wills of sovereign states form the basis of the international order, Grotius argued, “the totality of the relations between States” is still “governed by law.” That law he found in an updated version of the Stoic natural law, as naturalized into Roman law and Christian theology.

With Grotius, as with the Stoics, the normative or moral power of the natural law derives from the fact that man’s innate nature (itself part of the nature of the cosmos) and his propensities are viewed as ideal or inherently good. In Grotius’ own time, however, there arose a skepticism toward such unfounded optimism, a skepticism that underlies the thought of Hobbes.

With Hobbes (1588–1679), as with the Greek Sophists, the nature of man is not the ideal nature of Grotius and the Stoics. It is rather man’s supposed actual nature, before sociality and authority have tempered it. Man, in a state of nature, is motivated by desires and aversions and most of all by the desire to preserve his biological existence. This need for security is best met by all men vesting their rights of self-help in a sovereign, whether that sovereign be a single man or an assembly of men, and subjecting themselves to the laws of that sovereign, or “great Leviathan.”

The reason why men must obey the law of the sovereign state, which is the only institution capable of protecting men against each other, is thus based firmly in Hobbes’s conception of man’s nature, albeit a very different conception from the idealist premises of earlier theories of natural law. Natural-law theorizing after Hobbes is thus divided into these two major streams.

Judicial supremacy. By the beginning of the 17th century the idea of applying natural law as a test of the validity of the positive law (the law of the particular human jurisdiction) had passed from the province of speculative writers to courts of law. The English jurist Lord Coke, in Bonham’s case in 1610, was already referring to the tradition that “when an act of Parliament is against common right or reason or repugnant or impossible to be performed, the common law will control it, and adjudge such act to be void.” About a century before that, an English treatise known as “St. Germain, Doctor and Student” had already presented a three-tier hierarchy of the law of God, natural law (the law of reason), and human (positive) law, obviously deriving from Augustine and Aquinas.

In the United States in the next century, constitutional theory became highly infused with ideas of natural rights. The Declaration of Independence, with its assertion of the self-evident rights of life, liberty, and the pursuit of happiness, marked the beginning of a continuing natural-law influence on American constitutional development. The power of the judiciary to “review” legislation for consistency with a written constitution was taken in the United States to import the power to declare it void, constitutional law being analogized to natural law. Indeed, American judicial statements of 1814, 1822, and 1831 asserted the power of the judiciary to strike down statutes for violation not only of explicit constitutional restraints but also of “eternal principles of justice which no government has a right to disregard.” The analogy of constitutional and natural law did not necessarily require that the power to

strike down legislation should be a judicial power: this was not so in ancient Rome, nor is it always so in modern civil-law countries. It is arguable that such a judicial repository of the power of final review is unavoidable, since the legislature cannot be expected to annul its own acts; and the executive, even if it were not a party to such acts, is scarcely equipped for the tasks of objective interpretation involved. Yet there are real difficulties of policy and principle raised by giving the judiciary the final word. A distinction must first of all be made among diverse constitutional restraints. Safeguards for such rights as free speech and assembly and access to courts, which help to assure the responsibility of rulers and to prevent the fall of democracy into tyranny or demagoguery, may well be placed in the final custody of judges. But, beyond this point, others have argued, judicial supremacy, in enforcing restraints laid down by the Founding Fathers of an earlier generation, may clearly constitute an obstacle to the implementation by the courts of a society's present convictions.

Decline of natural law. If man is the measure of all things, as the Sophists taught, then a given society of men is the measure of its culture, including its moral and legal standards. In the modern period the French jurist and political philosopher Montesquieu's *De l'esprit des lois* (1748) and *Lettres persanes* (1721) offered the thesis that a people's law and justice are determined by the particular factors and environment that operate upon them. They thus could not, as the natural-law theory of the time held, be unchanging from age to age and from people to people. The French sociologist Auguste Comte's *Système de philosophie positive* (1851–54), which set out to explain positive laws, like other social facts, by reference to verified hypotheses concerning cause and effect and interaction, was similarly antithetical to natural-law theory as it had so far developed. To Comte, metaphysical concepts about such abstractions as ideal essences belonged to a past stage in man's intellectual development. And Darwin's *On the Origin of Species by Means of Natural Selection* (1859), the English philosopher Herbert Spencer's positivism, and other related thinking of the period provided a biological model of self-development of organisms and institutions through a struggle in which survival was a function of challenge and response in the given environment. Change and adaptation, rather than constancy and inviolability, were thus at the heart of their system.

Under the leadership of anthropologists, analyses of man's internal process of response to the exigencies of existence within a particular culture—to conscious and subconscious psychic drives and motivations—deeply affected the jurisprudential study of law and society and helped to bring natural-law thinking to a 19th-century nadir. In the anthropologist Bronislaw Malinowski's most mature statement on the matter, he distinguished four major meanings of the word law as important in understanding the growth of civilization. They included "laws of nature" in the scientific sense of rules governing men's conscious adaptations to the environment; rules of "efficiency" and "convenience" according to which the group lives; rules for conflict adjustment; and rules about enforcement of the last two. No conception of natural law, which had engaged earlier thinkers for two millennia and more, was included.

"Idealism" and justice. Another line of thought, which was also divorced from natural-law concepts, was contained in the Idealist philosophy of Immanuel Kant. Fundamental to Kant's ethical and jurisprudential reasoning is the premise that all moral concepts have their basis wholly in a priori thought, that they can be arrived at by reason alone, without reference to experience or recourse to intuition of rules alleged immanent in experience. Man, furthermore, is a free agent whose actions are determined by aims that he is at liberty to select. From such premises Kant deduced the nature of an ideal law, in which is implicit a theory or criterion of justice. This ideal law comprises the conditions under which all members of society can enjoy the maximum freedom from subjection to the arbitrary will of others.

But Kant's supposedly a priori concepts are in fact as

transcendental as anything natural lawyers have offered. It is thus not surprising that later thinkers, such as Johann Fichte, Kant's Idealist successor, had little difficulty in putting the new Kantian wine into natural-law bottles.

The 20th century saw a fresh attempt at the Kantian approach in the work of the German legal philosopher Rudolf Stammler. Adopting the Kantian position that knowledge is independent of sensory experience, Stammler set out to discover pre-experiential categories, or "pure forms," of thinking about law. Stammler arrived at a social ideal of a "community of free-willing men," an ideal that he claimed to have universal validity because of its supposed a priori basis. Having thus arrived at a "pure" ideal of society, untainted by empirical content deriving from sense perception, he felt able to formulate equally pure principles for just law that would regulate his ideal society. Stammler's pure idea of society comprised the harmony of individual and common purposes: his pure idea of just law thus comprised those principles conducive to such harmony—the mutual respect of individuals for each other's purposes and the participation of all in the achievement of the common purposes.

The different stream of Idealism flowing from Hegel's philosophy of history was fed into jurisprudence by Josef Kohler, Stammler's close predecessor in that subject in the Berlin University. His work is still another effort to relate social facts and the norms of justice by exposing the immanence of values in facts—in "civilization" in Kohler's case.

In perspective, these idealisms, despite their formal or philosophical antagonism to "rationalism" and natural-law thinking, seem to have reinforced in the age of the Industrial Revolution the individualist and libertarian trends that natural law had built up successively against medieval church and empire, the shackles of medieval social, political, and economic organization, and 18th-century despotism.

The 19th and 20th centuries. *Analytical Positivism.* The early 19th century witnessed a reaction against both Kantian Idealism and iusnaturalism (natural-law theorizing). The scientific temper of the age, reflected in the practical achievements of the early decades of the Industrial Revolution, was not conducive to deductive reasoning from a priori hypotheses, which appeared an impractical method of solving the problems of complex societies. Such problems might better be approached via a thorough analysis of existing law and institutions. This new climate of opinion came to be known as Positivism.

Among the chief meanings of Positivism in the legal-analytical sphere are the separation of law as it is and law as it ought to be, stress on the analysis of legal concepts, reliance on logical reasoning in the search for applicable law, and denial that moral judgments can be based on observation and rational proof. Anglo-Saxon analytical Positivism has directed itself mainly to the logical dissection, appraisal, and clarification of the precept element of law, ignoring the elements consisting of lawyers' traditional techniques and received ideals. By the nature of its tasks, analytical jurisprudence does not concern itself with either the facts surrounding or the consequences flowing from legal precepts or with their ethical evaluation, though particular analysts may also be interested in those matters.

Analytical Positivism in England began with the work of the philosopher and legal reformer Jeremy Bentham. His work influenced John Austin, the most outstanding figure in English jurisprudence, who set out to analyze the notions pervading English law. In order to delimit his subject, he defined positive law as the commands of a sovereign addressed to political inferiors and backed by threats of evil in the event of disobedience. Positive law might well be derived from moral precepts and other sources, but such precepts become law only when commanded by a sovereign.

The analytical-Positivist attitude has continued to influence thinkers, although the particular approach of Austin is now of historical interest only. Logical analysis is clearly a tool that may be employed in many spheres of jurisprudence, and its importance thus transcends the limits of any one school. Analysis means little in itself; its value

Montesquieu and early social science

Kant's ideal law

Meaning of Positivism in jurisprudence

depends largely on the validity of the premises from which the argument is made and on the relevance of the subject matter that is chosen for analysis. The paramountcy for the analytical Positivist of questions of logical order and consistency represents a permissible deviation, yet still a deviation, from the wider concerns of ordinary lawyers and students of law and society generally. This is not to say that there is a necessary conflict between the requirements of justice among changing social facts and those of logical consistency of precepts. It means only that there is surely no necessary (nor indeed usual) coincidence between them.

Historical Positivism. In discarding speculative cosmology, the *a priori*, and the self-evident, 19th-century historical jurisprudence opened the way for the search for the realities of law through empirical observation—for a sociodescriptive rather than a logico-analytical-Positivist jurisprudence.

The leading figure in the historical school was the German jurist Friedrich Karl von Savigny, who confronted the natural-law aspiration for a universal human code with the singularity of the law of particular peoples resulting from their unique sociocultural experiences.

For Savigny, law rests on the *Volksgeist*, or innate popular consciousness; law *par excellence* is customary law. He recognized, of course, that the details of a developed legal system do not spring from simple group intuition. With maturity, both life and law become more specialized and artificial, creating a dualism in more mature law. Part of such a system still rests directly on the popular consciousness and way of life (“the political element”); but this becomes elaborated by jurists, be they Roman jurisconsults or common-law judges, who in this respect represent the community (“the technical element”).

Savigny’s emphasis on the need of legal change to respect the continuity of the *Volksgeist* offers a pre-Darwinian concept of juristic evolution. The *Volksgeist* corresponds to modern notions of social rather than biological inheritance. Savigny’s sense of the impotence of legislatures in the face of the restraints imposed by the *Volksgeist* foreshadows modern recognition of the social and psychological limits of effective legal action.

The English legal historian Sir Henry Maine’s dual academic concern with both English law and Roman law challenged him to explain their independent yet often parallel growths and may well have redeemed him from Savigny-like overemphasis of national uniqueness. His concern led him to a comparative historical jurisprudence seeking hypothetical “laws” of development controlling all legal systems. He saw changes in substantive law and in the machinery and modes of legal enforcement and growth as moving in pace with certain recognizable stages in social growth, from primitive, kin-organized society to the mature, complex commercial and industrial societies of Europe.

Maine’s experience in India after the publication of his *Ancient Law* in 1861 broadened his interests so that he embraced less well known and less developed systems, such as the Brehon, Hindu, Welsh, Germanic, Anglo-Saxon, and Hebrew. His breadth of interest matched the concurrent growth in anthropological study of primitive peoples.

Maine’s work shows the strong combined influence of the analogy of biological to social evolution and of the Hegelian philosophy of history. The consequent, somewhat mechanistic tenor of his interpretations resulted in his being accused by many anthropologists and legal historians of making false assumptions concerning the pattern and sequence of social development.

Economic interpretations. Certain residues of the Marxist economic interpretation of history have won a central place in sociological jurisprudence (see below *Sociological jurisprudence*), as indeed in most branches of social science. One such persistent trend of thought is the close interrelatedness of legal, ethical, economic, and psychological inquiries; another is the pre-eminence among these of economic factors. According to Marxist doctrine, the political and judicial systems—the state and the law—represent the superstructure of society, their nature being determined by the economic base—the mode of produc-

tion and exchange. The state and its repressive law are but instruments of class domination, becoming redundant under Communism, which has no need of coercion. During the transition to full Communism, they would “wither away.” There were, of course, softenings of this bold doctrine in its original authors, with admissions that the ethical or legal superstructure should not be seen as a merely passive effect; and Lenin himself pressed to extremes both the passion of the original thesis and its qualifications. Lenin, indeed, saw state power as an essential weapon of the proletarian dictatorship until the movement to a full Communist society should be completed.

The first half-century of the Soviet Union, with its steady consolidation of state power and its attendant law, has imposed the severest strains on the withering-away prediction. The general tenor of explanation is that the “law” the disappearance of which is prophesied refers only to the kind of coercive order manifest in such instrumentalities as the courts, police, and jails of capitalist countries.

Within these sweeping theses of Marxist thinking, more modest subtheses have played a valuable part. The Socialist jurist Karl Renner, for example, in his *Rechts-institute des Privatrechts und ihre soziale Funktion* (1929), was concerned to show that the legal conception of ownership, formulated in early economies, had profound new effects when continued as an institution of the 19th-century economy. It then, through the law of property and contract, alienated into private hands great segments of what should be in the public domain.

Even more notable are the German sociologist Max Weber’s studies of the correlations of socioeconomic and ethicojuristic change, freed of the straitjacket of economic determinism. In these, the impact of unique factors or combinations of factors in particular civilizations is taken into account, including the existence of accepted systems of values, immediate and ultimate, which may (and in Weber’s view did) have a decisive effect on the emergence of the Western capitalist system.

Sociological jurisprudence. The historical jurisprudence of the earlier part of the 19th century became subject to the influence of the developing social sciences, which attempted to explain law in its social context. The result was the emergence of a sociological school of jurisprudence.

The early decades of sociological jurisprudence combined 19th-century faith in progress, social evolution, rationalism, humanitarianism, and political pluralism with a sanguine belief that the Newtonian model of natural science would also hold for the social sciences. It was affected by questions of whether the social sciences are truly sciences, what their mutual boundaries are, and whether they can be integrated or somehow transcended by some subject such as sociology or anthropology.

An outstanding figure of the early sociological school was a German, Rudolf von Jhering, who in the 1860s contributed to the intellectual stream a theory of justice predicated on a view of law as a social phenomenon. He saw law as an outcome of the struggle of men to fulfill their purposes and of the force that they marshal behind this. Another historical jurist, the German Otto von Gierke, stirred a related interest with his emphasis on the importance of the inner life and activities of groups and associations as sources of binding social norms. This opened up jurisprudence to some psychological issues. Gierke’s work also contributed to the later American Neorealism through its influence on Oliver Wendell Holmes, Jr., and to the theory of the “living law” of the Austrian jurist Eugen Ehrlich, in the first decade of the 20th century. Ehrlich insisted on the profuse norm-creating activities of the countless associations in which men are involved.

At the beginning of the 20th century a great variety of psychological hypotheses were brought to bear on law. A theory of dynamic psychic drives, for example, was propounded by an American sociologist, Lester F. Ward, who argued that such drives could be utilized in social planning. Freud’s exploration of psychic activity on a subconscious level, as well as studies of the nonrational and the irrational in the social process by the Italian and German sociologists Vilfredo Pareto and Max Weber, were also profoundly influential.

Early 20th-century views

The Marxist conception of law

Revival of natural-law theories. Iusnaturalism, in the sense of the assertion of an order of norms for human conduct transcending human will, to which the validity of positive law is subjected, has certainly experienced a 20th-century revival. The massive human delinquencies of the century, such as those of the Nazis, have been important in stimulating these modern natural-law yearnings. The revival, indeed, has rarely overthrown dominant Positivist positions, but it has certainly reopened some questions that Positivists have not adequately faced.

Contributions to this re-emergence have come from varied directions, rather than from a single intellectual movement. They have often avoided explicit reference to natural law and have even expressed hostility or ridicule toward it. The German Stammler and the French jurist François Gény were certainly among its pioneers. Gény's *Méthode d'interprétation* (1899) displayed the inescapably creative (or lawmaking) role of the judiciary even under a comprehensive code such as the Code Napoléon. It led him to the questions of what are "the sources of law" and where does the legislator's prescription fall short. Answers to such questions must be based on the facts of each particular situation to be adjusted—the legislator cannot impose his view on the court. This line of thinking foreshadowed a variety of doctrines about "the nature of things" or "the nature of facts," all of which shared the idea that the decisive nature of a situation has its base in the facts for which men seek governing law. The properties and circumstances of these facts themselves afford immediate guidelines for just regulation. The fact situation, if only its essence will be perceived, has the superior applicable norms immanent within it.

In his *Lehre von dem richtigen Recht* (1902), Stammler sought, as described above, the a priori social principles of just law concerning respect for and participation by all members. His call for "natural law with a changing content" based on these a priori principles quickly became a 20th-century slogan.

Even as this express reinvocation of natural law was proceeding, the French public lawyer Léon Duguit was expressly denouncing it. Duguit's concern was to place law and lawyers within what he saw to be the correct frame. This he found in Émile Durkheim's Positivist sociology. This led him, with some paradox for a contemner of natural law, to insist that law is but "*le produit spontané des faits*" ("the immediate result of the facts"). The observed "facts" of social solidarity arising from economic specialization of functions generated, Duguit argued, the society's norms. Breach of these norms causes social disorder and a spontaneous movement toward readjustment. Even a supreme legislator was bound (Duguit affirmed) by this objective "rule of law," so that his acts violating it are void, even apart from any other constitutional restraint. All this bears the clear iusnaturalist mark of the assumed immanence in observed facts of a transcending and overriding order. It pays cryptic homage to a natural law, fealty to which Duguit denied.

The German legal philosopher Gustav Radbruch's turn toward natural law at the end of a life of great contributions to democratic legal relativism and Positivism was very different. Positivism, Radbruch argued, had encouraged German lawyers to stand by at Nazi barbarism, declaring "*Gesetz ist Gesetz*" ("Law is Law"). Nor was Radbruch's turn to natural law in any way cryptic. He came to declare quite openly that:

where justice is not even striven for, where equality which is the core of justice is constantly denied in the enactment of positive law, there the law is not only "unjust law" but lacks the nature of law altogether.

The linkage with the revived natural law of the legal institutionalism of the French legal philosopher Maurice Hauriou and the writer and historian Georges Renard is different again. As with Duguit, the linkage is not proclaimed, but no overt hostility disguised their obvious sympathy for Thomist positions. There is a Catholic version of institutionalism (which regards social institutions such as the family or the corporation as expressing the social reality underlying the law). The natural-law assumptions are apparent in the insistence on "the principles of

organization," the "communion" of members in realizing "durable ideals," and the placing of men's powers of organization into the service of such ideals, as essential elements of any institution. For them, as for Duguit, the principles of justice were principles of social organization, immanent and self-evident.

It has been tempting for many to seek kinships between natural law and Existentialism, as was attempted by the German legal philosopher Werner Maihofer. Such efforts seem, however, destined to denature either Existentialism or natural law itself. Even in all their varieties, Existentialist positions approach no nearer to natural law than to assert that the traumas, anxieties, and demands of mere "existence" confront men with fateful value choices. Yet this is far short of asserting that any transcending principles of harmony may be discoverable.

Abstract symbols such as "social solidarity," "the principles of social organization," or "immanence in the facts of social life" are by virtue of their ambiguity susceptible to misappropriation by absolutist governments. The same may be said of Savigny's *Volksgeist* notion, as witness its affinity to the racialism of Nazi law. Thus, while the modern revival of natural law has been in part a revulsion from totalitarianism, it can also be exploited to rationalize totalitarianism.

There is another paradox also: The growth of the social sciences has invited restatement of natural-law traditions in terms of social ideals. Yet the very complexity of the social and economic orders and of their attendant sciences has placed forbidding barriers before the aspiration to base justice or other values on "objective" knowledge. Some have been tempted to hope that natural law may somehow overleap such barriers.

Pure theory of law. In part, at least, the influence of the distinguished legal philosopher Hans Kelsen's "pure theory of law" reflects early 20th-century skepticism about natural law and sociology, to both of which Kelsen opposed his claimed purity of method; i.e., a method free from contamination by values of any sort.

He asserted, first, that legal theory was properly a science in the sense of an uncommitted, value-free, methodical concern with a determined object of knowledge. Second, he argued, legal theory must be isolated from psychological, sociological, and ethical matters. Third, purity of method permits the analyst to see that every legal system is in essence a hierarchy of norms in which every proposition is dependent for its validity on another proposition. The justification for describing any particular rule as law thus depends on whether there is some other proposition standing behind it, imparting to it the quality of law. This regression is continued until the *Grundnorm*, or "basic norm," is arrived at. The basic norm derives its validity from the fact that it has been accepted by some sufficient minimum number of people in the community.

Kelsen's assertion that norms can spring only from other norms seems but another way of stating his rejection of the relevance of facts to values and, therefore, of iusnaturalism and sociology to his pure science of law. Yet finally it has seemed to many dubious whether the Kelsenite theory itself escaped the *liaison fatale* between facts and norms; for, if all legal norms must finally hang on the basic norm, then whatever it is that the basic norm hangs on must be nonlaw. And whether the basic norm hangs on "habitual obedience to determinate persons," as the English legal philosopher John Austin in effect proposed a century before, or on "efficaciousness," as Kelsen proposed, what it hangs on is fact rather than norm. Critics have complained that, at most points in the creation of norms in Kelsen's system, what is decisive is the intervention of acts of will of persons endowed by higher norms with norm-making authority. The determination whether such acts of will have occurred is a factual inquiry, to the decisiveness of which Kelsen's pure theory gave little weight.

Modern schools of realism. The American jurist Oliver Wendell Holmes's description of law in 1897 as "what the courts will do in fact" and of the "real ground" of decisions as resting often in some "inarticulate major premise" rather than in expressed reasons gave 20th-century legal realism its central theme.

Law in
Positivist
sociology

Kelsen's
hierarchy
of norms

Certain features are common to the "realist" jurists. They include (besides the above-mentioned concern with "the law in action") stress on the social purposiveness of law, on the endless flux in both society and law, on the need to divorce the "is" and the "ought" for purposes of study and to question all orthodox assumptions made by lawyers, and in particular on the need to substitute more realistic working categories for current lawyers' generalities. Among the orthodoxies thus challenged, these writers tended to include the works of early sociological jurisprudence. Yet it is clear, from the present perspective, that the concerns common to the realists and the more orthodox sociological jurists were far more important than the ephemeral if bitter conflicts that at first flared up between them. The American realists in their important surviving contributions have for the most part reinforced, clarified, and elaborated a number of main insights, notably about rule uncertainty and fact uncertainty, which they shared with sociological jurisprudence.

Scandinavian realism

Scandinavian realists, while temperamentally akin to their American colleagues, were rather different in intellectual concerns. Methodologically, they invoked a somewhat gross empiricism, leading them to deny that the law could be the subject of scientific inquiry at all, since its concepts and principles are not founded on spatial and temporal data of experience. Taking lawyers' talk of the will of the sovereign very literally, they were concerned to show that there is no such will of common content and that even legislators who enact a code are merely rubber stamping what others drafted.

The Swedish jurist Axel Hagerström insisted that the idea of rules of law as commands is an idea not corresponding with facts. His disciple Karl Olivecrona added that this false idea results from the syntactical imperative form used in modern legislation. Such rules, he urged, were commands only in a depersonalized sense. He preferred to describe them as "independent imperatives." Such "imperative statements about imaginary actions, rights, duties" may not be directed to any particular persons. Yet, even if some legal rules are directed "so to say, into the air," others are certainly directed to particular persons. If any form of imperative notion is to be preserved, it should be one that accommodates both situations.

Some of the problems that these writings address are rather tied to the special experience of their authors' own legal cultures. Others reach out independently toward truths already reached earlier in Anglo-American jurisprudential scholarship, especially as to the merely noetic and conceptual (rather than physical or psychological) nature of rights, duties, and liabilities.

THE STATUS OF CONTEMPORARY PHILOSOPHY OF LAW

By the middle of the 20th century, serious scholars no longer argued for or against the exclusive imperium of either the analytical-logical, the justice-ethical, or the sociological approach. Whether jurisprudence is a single field in some scientific sense or whether its unity lies in the need to serve the intellectual needs of those concerned with making, applying, improving, or generally understanding law, all the above areas are included within it.

A characteristic feature of contemporary jurisprudence is what has come to be known as "the revolt against formalism"; that is, against preoccupation with the technical and logical aspects of law. It can be traced back to Savigny's early 19th-century reaction against natural law, to Jhering's attacks on the German Pandectists (commentators on Roman law), and to Maine and the work of the anthropologists and early sociological jurists. Its early pressure was toward broader and deeper history, toward recognition of the organic nature of the processes of cultural growth, and toward problems of social action and the value choices therein entailed.

In the United States the legal philosopher Morton White identified five later contributing strains of thought, including the pragmatism of John Dewey; the economist Thorstein Veblen's institutionalism, rejecting both the abstractions of classical political economy and the fatalism of the Marxist interpretation of history; the revolt within jurisprudence of the American legal realists already de-

scribed; and the approach to history as no mere chronicle of kings and battles but rather as a product of underlying economic forces and a guide to present and future civilizations.

The sometimes-overhasty iconoclasm of this revolt have proved less important than its positive affirmations. It has affirmed, for example, that the evaluating activities of justice must somehow move alongside the describing activities of sociological jurisprudence, that the choices of ethics, social policy, and justice still remain to be made when all the empirics of social science are done. The central question includes not merely what are the facts but also what should be done about the facts. These affirmations reject any regression to simple amorism, stirring new temptations to return to natural law or other intuitive absolutes.

There are important advantages in the drive, characteristic of much contemporary social science, for overall cognition of the social and legal orders and the identification of key points for social action within them. But there are also dangers, for, especially with subject matters such as the law, systematic theory and overall cognition can rarely be of aid save in the rather long run, for which present decision makers cannot usually wait.

Growth of the sociological school. The most eminent pioneers and champions of modern sociological jurisprudence were Roscoe Pound in the United States and Hermann Kantorowicz in Europe. For both, the task of sociological jurisprudence, though orientated mainly to practical administrative or legislative problems, included that of framing hypotheses (as to the limits of effective legal action, for example) on which to base general laws of the operation of law in society.

As with the social sciences, the principal methods available to sociological jurisprudence are those of survey, statistical analysis, comparative observation, and experimentation. The controls and corrections available usually fall far short of those of the natural-science models. Much work in sociological jurisprudence has merely brought to bear upon the law relevant findings from other social sciences. But it may also generate its own findings, as it has done in relation to traffic laws, control of moneylending, credit unions, bankruptcy laws, the effect of antitrust practices or of poverty on legal rights, the theory of appellate judicial decision making, and a host of other matters. Examinations of the prehistory and aftercareers of convicted criminals and of persons on probation or parole, probings of family and environmental influences bearing on potential deviance, and attempts to identify decisive factors predictive of future deviance are among the staples of sociological jurisprudence.

Sociological jurisprudence is confronted by the questions whether (and, if so, how and how far) it is possible through empirical methods to approach central issues of social action that involve value judgments. The fact that lawyers are necessarily involved with ideas of obligation, values, and norms sharpens this confrontation. A second group of problems arises from the high level of individuality of men, groups, and societies, from the unending variety of their emotions, roles, and expectations, and from the feedback effects on human behaviour that the empirical observation and testing of that behaviour brings about.

These problems give central importance to efforts to develop frames of social knowledge that give due place to both facts and values. Such inquiries show the great complexities of values held and their intricate and dynamic relation to the physical and cultural environments.

The study of law in society thus shares with anthropology and other social sciences a central interest in roles and functions as basic meaningful categories and in certain mechanisms and channels whereby conduct is thought to become socially meaningful. These notions are thought to permit the analysis of complex social situations into more refined terms, such as constituent goals, tasks, expectations, and allocated rights, powers, and duties.

As to the mechanisms or channels through which conduct becomes socially meaningful, earlier thought tended to explain social norms as built up from individual instances through group usages and mores that then crystallize in in-

Methodology of sociological jurisprudence

The "revolt against formalism"

stitutions such as law. Insofar as this suggests a cumulative movement or process, current thought would regard it as oversimplified. The growth of socio-ethical convictions is rather to be seen in terms of symbolic interaction between individuals. A particular society may be seen, in this light, as a collection of individuals with a culture that has been learned by symbolic communication from other individuals back through time, enabling members to gauge their behaviour to each other and to the society as a whole.

The future of sociological jurisprudence. In his famous program of 1911–12, Pound formulated a series of rather practical objectives for the movement, including making studies of the law in action, of the means of more effective legislation and law enforcement (by creation of ministries of justice, for example), of legal and judicial reasoning, of legal history in its social context, and of the role of the legal profession. An early quip against the sociological school was that it was like a great orchestra constantly tuning its instruments but never actually playing. Yet many practical tasks have been performed, and the school continued to show a gathering momentum and a widening range of concerns.

The maladjustments and inadequacies of the law gave to early sociological jurisprudence an intensely activist drive, directed to ad hoc remedies, and a great deal of the relevant work is still of this nature. Especially since 1945, however, juristic work on the relations of law and society has come into more fruitful contact with other social sciences, leading in turn to greater stress on cognition of the social and economic orders in their complex unity. Whatever the difficulties of designs for an overall analysis of the social system, some adjustment toward them is inevitable for sociological jurisprudence. This is in part, no doubt, a result of the waning of interest in many of the kinds of ad hoc problems with which it was initially concerned. But the interest in sociological theory also results from growing awareness that some problems require to be approached on a wider basis. This has created new stirrings of the turn-of-the-century ambition that the study of law in society become a specific branch of social science, concerned with framing and testing general laws governing law as a social phenomenon. (Ju.S.)

Philosophy of education

Different conceptions of the philosophy of education

Philosophy of education is a field of inquiry, speculation, and application in which philosophical methods are applied to the study of a problem, topic, or issue in education. Characteristic of these methods is the attempt to think as accurately, clearly, coherently, and systematically as possible. Analytical philosophers would say that philosophy of education should end with the attempt to clarify and justify educational statements and arguments. In practice, however, the field includes much more than that. It considers as relevant material much that has been written on education by influential philosophers of the past. There is, therefore, much overlap with the field of history of education, and ultimately no clear demarcation can be drawn between the two fields, which nourish and illuminate each other in their interconnectedness (see EDUCATION, HISTORY OF). Many philosophers of education also go beyond analysis in being concerned with establishing a commitment to value judgments and substantive positions. They take pains to attempt to clarify and justify those judgments and positions on the grounds that clear and substantiated judgments have greater probability of being sound.

The philosophy of education has a special concern with the *applications* of knowledge and theories. Thus, many philosophers of education are especially interested in the relationship between theory and practice. Moreover, they are often concerned with the ways in which philosophy relates to other fields of study in the attempt to shed light on educational problems and issues. This gives them a wide-angled approach to education, which some philosophers have called “educational theory” to distinguish it from a more narrowly analytical form of philosophy of education.

With regard to the term “education,” there is a similar spectrum of views ranging from the narrow view of educa-

tion as that which goes on in schools and universities to a definition of education as all those experiences that affect the growth and development of a person throughout life. The former view has tended to give way, with increased recognition of the crucially important part that informal experiences and relationships play in determining what and how an individual learns.

COMMON ASSUMPTIONS ABOUT HUMAN LEARNING

Symbolization. First, it is to be noted that human learning is largely dominated by symbolic processes. Much of the learning that man acquires during his lifetime is gained through his growing ability to understand and manipulate symbols—verbal, mathematical, artistic, musical, and so on. This symbolic emphasis gives human learning much of its power. It brings power because symbols enable man to deal abstractly and at a high level of generality with words, data, and ideas. Thus, he can learn to think rapidly, to link varied items in fruitful ways, and to create shortcuts to new knowledge.

The symbolic emphasis also brings dangers. It can trap man into circling around at a high level of generality without ever feeling the need to tie his abstractions to concrete applications. Schooling thus can become an apparently self-justifying cycle, which in fact fails to pay off in terms of improving men's lives. Moreover, since learners assimilate and master these symbolic processes at different rates, it is tempting for educators to identify all education with symbol manipulation, to classify those who take longer to master the process as inferior, and to reserve the privileges of higher schooling for those who master this particular process rapidly. This is to mistake a part for the whole and leads to enormous losses of human power and development.

Human motivation. Motivations to learning are more variable in man than in subhuman species. In other animals learning patterns develop largely through instinctual motivations. This means that lower animals need less training than humans before they are independent and self-reliant. Human beings are the most dependent of creatures when young, and they take longest to educate for independent activity. It is precisely this long period of dependence and education that constitutes man's superiority over lower animals, for it is in this period that the growing human being absorbs much of his culture and develops the skills and knowledge that enable him to build on the work of his predecessors. His lower degree of reliance on innate mechanisms also means that man is more flexible in his responses and is capable of adjusting those responses in the light of previous experiences. Thus, he is not condemned to repeat previous patterns of living and thinking but can create change, both in himself and in his culture.

Educators have often acted as if man were a lower animal, for schooling has often resembled training, with emphasis upon imitation, obedience, repetition, drill, and control, more than it has resembled education, with emphasis upon initiative, creativity, choice, decision making, and freedom. As a result, schooling has been more successful in improving man's skill in mechanical and repetitive activities at the lower end of his capacity scale than in developing higher qualities of intellect, feeling, and will that constitute his peculiar humanness.

Human capacity to learn. So far there have been discovered no limits to man's capacity to learn. From earliest times, however, men in positions of power or influence have suggested that the learning capacity of certain individuals or groups is severely limited and that they should not be expected to profit greatly, if at all, from education. These “ineducable” individuals have usually been members of minority or disadvantaged groups. But, repeatedly, when their cultural disadvantages have been removed, these groups have shown that their previous failure to learn has been due not to incapacity but to lack of fully realized opportunity.

These findings have led educators to be much more modest and less hasty in their labelling and classifying procedures. It has been realized that labels affixed to children tend to become self-fulfilling prophecies, that those

Dangers of abstraction

Categorizing learners

who are expected to learn usually do so, and those who are expected to fail to learn also usually do so. Hence, when educators resort to classifying children at all, they increasingly tend to use their labels as temporary rather than permanent, as saying something only about a quality of the child rather than about his person, and as something to be abandoned as soon as the child's performance proves the label wrong.

Similarly, no one has been able to confirm any certain limits to the speed with which man can learn. Schools and universities have usually been organized as if to suggest that all students learn at about the same rather plodding and regular speed. But, whenever the actual rates at which different people learn have been tested, nothing has been found to justify such an organization. Not only do individuals learn at vastly different speeds and in different ways, but man seems capable of astonishing feats of rapid learning when the attendant circumstances are favourable. It seems that, in customary educational settings, one habitually uses only a tiny fraction of one's learning capacities.

Complexity of human learning. Human learning is complex rather than simple. Learners are apt to learn more than one thing at a time. Sometimes this process is conscious, as when one simultaneously or rapidly assimilates many specific items of a whole. More often, the process is entirely or partly unconscious, as when the student learns some "content" consciously but at the same time absorbs unwittingly a great deal more from interrelationships, tones of voice, and so on.

Educators are therefore becoming increasingly concerned with these concomitant learnings. They are aware that the long-term significance of the arithmetical skill that the student consciously learns may be nugatory compared with the importance of what he learns about himself as a learner, about his capacities and limits, about his relationship with his teacher, about power and authority, about his relationships with his fellow students, about equality, collaboration, competition, and friendship. As educators become more knowledgeable about the importance of learning climates, they are impelled to abandon simplified techniques of teaching in favour of a more complex approach that views learning in the context of a matrix of relationships and forces that act upon the student, the teacher, the school, and the community.

Intellectual-emotional-physical-volitional integrity of learning. Human learning concerns the whole person. The intellect is not the only agent of learning. This activity is shared by the body, the emotions, and the will. Moreover, the process cannot be limited to any one of these domains without affecting the others. Educators are most conscious of intellectual learnings, which tend to play the largest part in their plans and intentions. But there is increasing evidence that makes clear the folly of attempting to confine education to the training of intellects. If the teacher does so, he is destined to fare badly, for the child who is emotionally frozen or whose stomach is empty or who is determined to thwart the teacher will not perform intellectually as the teacher intends.

Educators are also becoming more aware of the other side of this coin—that is, that the learner's powers are vastly enhanced when not only is his intellect stimulated but also his feelings are respected, his body is nurtured, and his will to learn is strengthened. Effective education, therefore, is found when the learner is regarded as a person to be respected, nurtured, strengthened, and stimulated, rather than as an intellect to be trained.

DIFFERING CONCEPTIONS OF EDUCATION

Model theories of the educated person. In different historical eras and in different cultures a variety of conceptions has been put forward concerning the nature of mind, of truth, of knowledge, of moral goodness, of aesthetic beauty, and of the purposes of life. These views carry implications for the purpose and nature of the educational process, the ends toward which one should educate, the means by which one can best achieve those ends, the degree of consistency between the ends and the means, and the model, if any, of the ideally educated person that one has in mind when engaging in the educational

process. These relate to some of the perennial questions that concern the philosopher of education. The following represent some of the most influential models that have been presented of the educated person.

Platonic view. The first great attempt to create a philosophically coherent model of the educated person was that of Plato. Reacting against the turbulence and chaos of his own times, Plato envisaged in *The Republic* and the *Laws* a permanent, stable, hierarchical society in which those most adept at education would rule, those moderately adept would become warriors and carry out the orders of the rulers or guardians, and those least adept at education would fill the lowliest worker functions in society. The education that would thus order and segregate the different groups in society would be based upon the ability to understand the perennial, ideal Forms that, Plato maintained, underlie the transient, concrete manifestations of those Forms in everyday life. Since, supposedly, not all people could surmount the difficulties of such an intellectually demanding program of study, it would be justifiable to select, classify, segregate, and reject students at the various stages of the educational process.

The Platonic scheme has been enormously influential, especially in the Western world, during the last 25 centuries. Most educational programs in the West have consistently reflected this hierarchical pattern. Schooling has usually been a process of selection and rejection, with great effort and ingenuity expended on testing, measuring, classifying, and segregating in accordance with the best available knowledge. Similarly, Plato's concept of mind has exerted lasting influence on Western education. Patterns of schooling have reflected the greater prestige accorded to the study of ideas and abstractions and the lower prestige given to practical studies and manual work. There has persisted a dichotomy between the so-called liberal arts, which have been considered suitable educational fare for potential leaders of society, and so-called vocational studies, which have been considered more suitable for potential followers. This pattern has lasted to the present day, not only in Europe and North America, but also in those parts of Asia, Africa, and Latin America greatly influenced by European culture. Thus, one finds in many former colonial societies that students often strongly prefer to follow "liberal" studies, even though the choice may condemn them to genteel unemployment in a society whose economy cries out for people with technological, practical, and manual skills.

Thomist view. In the 13th century, St. Thomas Aquinas made a monumental attempt to reconcile the two great streams of the Western tradition. In his teaching at the University of Paris and in his writings—particularly the *Summa theologiae* and the *Summa contra gentiles*—Aquinas tried to synthesize reason and faith, philosophy and theology, university and monastery, activity and contemplation. In his writings, however, faith and theology ultimately took precedence over reason and philosophy because the former were presumed to give access to truths that were not available through rational inquiry. Hence, Aquinas started with assumptions based on divine revelation and went on to a philosophical explication of man and nature. The model of the educated man that emerged from this process was the Scholastic, a man whose rational intelligence had been vigorously disciplined for the pursuit of moral excellence and whose highest happiness was found in contemplation of the Christian God.

This Scholastic model has greatly affected the development of Western education, especially in fostering the notion of intellectual discipline. Aquinas' theological-philosophical doctrine has been a powerful intellectual force throughout the West and has constituted the official basis of Catholic theology since 1879. Although Aquinas made an important place in his hierarchy of values for the practical uses of reason, later Thomists have often been more exclusively intellectual in their educational emphasis. For Aquinas, the primary agent of education was the learner, and his model was, thus, a person capable of self-education. Intellectually autonomous, he should be able to conduct his own process of research and discovery. The Roman Catholic Church, however, has usually put

Intellectually segregated education

Correlative learning

the learner firmly under the authoritative superordination of the teacher.

Lockean view. John Locke, the 17th-century English philosopher, has been credited with formulating the classical liberal defense of individual freedom against the authorities of state and church. Opposed both to what he deemed the stagnation of unreflective tradition and the perils of enthusiastic radicalism, Locke saw science, reason, and experience as the best safeguards against these dangers. Responding to the rise of the new bourgeoisie and the new science, he became the principal spokesman for the increasingly powerful middle class, who were predominantly skeptical and practical in their intellectual temper. The model of the gentleman had traditionally been the English ideal of the educated person. Locke's achievement was to take this ideal and modify it to a form acceptable to the new bourgeoisie. Originally an aristocratic model, the gentleman ideal became infused, under Locke's influence, with democratic, Puritan, and practical characteristics.

Locke's notion of the mind at birth as a *tabula rasa*, a "blank tablet" devoid of innate ideas, gave enormous importance to the role of experience and sense perception in the educational process. In *Some Thoughts Concerning Education* (1693) and the *Conduct of the Understanding* (1706), Locke outlined the heavily experiential education that would be appropriate for a gentleman. His four cardinal aims of education, in order of importance, were virtue, wisdom, breeding, and learning. Some critics have insisted that the order has remained important to the present day in English education, that learning must always be lightly worn and never ostentatious. Not only was Locke's thinking influential in shaping the subsequent development of English educational thought, but his Puritan individualism also had a considerable effect on the growth of American educational ideals. Locke's failure to recognize the possibilities of the uses of institutional power and legislation for interventions that would enhance rather than restrict freedom was an omission that has often bedeviled American educational thinking.

Naturalistic view. Most movements in philosophy and education have seemed to engender their own opposition. Hence, the rationalism and scientific objectivity of the Enlightenment found a reaction in the subjectivity and emotional spontaneity of romantic naturalism, the principal spokesman of which was Jean-Jacques Rousseau. In particular, Rousseau reacted against the excessive formalism and rationalism of 18th-century France. Out of this reaction there came a model of the educated person as the natural man, a figure presented in contrast to what Rousseau saw as the pathetic products of contemporary civilization. Against civilized values like rationalism, conscious reflection, control, complexity, and objectivity, Rousseau offered his own values of romanticism, intuitive spontaneity, freedom, simplicity, and subjectivity.

In *Émile* (1762), one of the most influential books on education ever written, Rousseau argued that one should protect the child from the corruptions of civilization and carefully nurture his natural, spontaneous impulses, which were always healthy. It was important, he maintained, to avoid premature intellectualization of emotion so that the child's intellectual powers could develop without distortion. Feeling should precede thinking, and the child should be controlled only by things, not by adults' wills. In these ideas lay some of the germs of progressive education, which spread throughout the world during the 19th and 20th centuries. Constantly in tension with the classical demands of reason, discipline, authority, and scholarship, the romantic naturalism of the progressive-education movement has continued to remind educators that their ultimate concern should be the growth of the unique, ultimately unfathomable child.

Marxist view. Probably the most influential writer of recent times was Karl Marx, whose writings, mostly in collaboration with Friedrich Engels, altered the course of history and continue to affect the lives of millions of people in all parts of the world. A central concern of Marx and Engels was to cure the alienation and dehumanization of man caused by what they saw as the exploitative forces of capitalism. In Marx's writings, the material dimension

of history appeared as primary. Economic production was deemed the basis of life, and the prevailing ideas (religious, educational, and political) of a society were seen as being determined by its economic structure. The dominant ideas of an epoch or society were considered to be the ideas of its ruling class—that is, the class that controlled the means of material production. In order to find the hidden interest behind an idea, Marx argued, one had to examine its social function rather than its intellectual content. Marx saw the need for a proletarian revolution in order to bring about Communism. Under Communism, he argued, the opposition between the individual and the group would disappear; each man's interests would be seen to be identical with the interests of all, and alienation would be banished.

In Marx's view, what was needed for man's growth toward maturity was genuine community; that is, the voluntary drawing together of autonomous and socially responsible persons. The model of the educated person that Marx put forward was not the irresponsible individualist nor the coerced collectivist but the accountable communal man, who attained his freedom not by fleeing from social relationship but through social relationships. Individual freedom required social authority.

Marx's and Engels' writings, particularly *Das Kapital* (1867–94), *The German Ideology* (London ed., 1938) and *The Communist Manifesto* (1848), have reshaped the world. Millions have been inspired by their vision of unalienated work and education. Unfortunately, like many influential ideas, they have been abused and distorted. Several states have tried to bring about a Communist utopia through collectivist coercion and social manipulation in a distortion of Marx's arguments. There is a need for state intervention to remove gross inequalities and to expand opportunities, in Marx's view, but ultimately human regeneration is a task for each individual.

Pragmatist view. Out of the America that was created by immigration, urbanization, and industrialization in the second half of the 19th century came the philosophy of Pragmatism. Associated with such thinkers as C.S. Peirce, William James, and John Dewey, Pragmatism, as the dominant American philosophy, exerted a strong influence on the shape of education in the United States, and affected educational ideas and practices in Europe and Japan. In the hands of Dewey, Pragmatism evolved into a philosophy that saw man as formed through interaction with his natural and social environment. The educated person was always viewed by Dewey in a social context. Neither the individual nor society had any meaning without the other. Dewey created a model of the educated person as the reflective man, one who was critical of the authority of custom and tradition as the determinant of belief and action and who preferred the method of science, of "organized intelligence" as the best way to solve his problems.

In *My Pedagogic Creed* (1897), *How We Think* (1910), *Democracy and Education* (1916), *Human Nature and Conduct* (1922), and a stream of other philosophical and pedagogic writings, Dewey formulated a viewpoint that constituted a rigorous intellectual core of the progressive-education movement, although he criticized many of the manifestations of progressive pedagogy in practice. For example, he viewed the child's interests as vitally important and to be neither repressed nor humoured. To repress them was to commit the fault of much traditional education by ignoring the child's unique bent. But to humour them was to commit the fault of some progressive education by failing to discover the underlying power below the passing whim. Subject matter, Dewey argued, should consist of activities that enabled the child to reflect upon his social experiences. When subject matter preceded or was unrelated to the child's experiences, it was largely meaningless. It gained meaning through being made the medium for continued reflection upon, and reconstruction of, experience.

Behaviourist view. In the 20th century, the use of science has been extended to the study of virtually all aspects of human affairs. The possibilities of scientific control of men and events have brought profound changes in

needs

philosophy and education. By studying only the behavioral aspects of man, science has been able to predict and control in ways that have powerful and sometimes frightening implications. The behaviourist view has been most notably represented by the American psychologist B.F. Skinner. In his writings, including the utopian novel, *Walden Two* (1948), *Science and Human Behavior* (1953), and *Beyond Freedom and Dignity* (1971), he has firmly rejected the conventional model of man as a free agent who acts in accordance with the decisions of an inner self that is neither fully explicable nor fully controllable by scientific means. Instead, Skinner envisages the use of scientific knowledge about the control of human behaviour to create a planned man, one who will be conditioned to behave in the way best calculated to achieve society's goals. Behavioral engineering will have removed all of his antisocial tendencies, and he will want only what is good for himself and his society.

Pro-
grammed
learning
and
behavioral
develop-
ment

Behaviourism in general and Skinner in particular have exerted considerable influence on Western, and especially American, education through developments that range from the invention of programmed instruction (or the so-called "teaching machine") to the widespread emphasis on behavioral objectives in educational programs. The philosophy of Behaviourism compels one to examine carefully the issue of control in education. Skinner wants to use scientific control to bring about a society in which it will be easy to be good and to bring about an educational process through which it will be easy to be excellent. There is no alternative to control, in his view. It is simply a matter of *who* is to control. One does not grant the child "freedom" merely by leaving him alone. To refuse to use scientific control to shape human behaviour is, for the Behaviourist, a failure in responsibility.

Existentialist view. The application of science to ever more aspects of the study of man has been particularly marked in the West; but, in reaction to this trend, there has developed some criticism of the scientific way of viewing man as an object to be categorized, studied objectively, or subsumed under a generalization. Prominent in this reaction have been Existentialist philosophers, among whom the Jewish philosopher, Martin Buber, played an outstanding role in deepening contemporary understanding of man and education. In such books as *I and Thou* (1923) and *Between Man and Man* (1947), Buber's model of the educated person appeared as one whose life was shaped by existential decision making. Such a person did not determine choices in advance of existential situations. He used principles and traditions only as checks or reminders, not as infallible guides. His values were created in the concrete here and now and were manifested as he related to other men. Thus, each man was seen as a unique person rather than as a member of a category.

Rela-
tionship
between
learning
and life

A vital concept for Buber was responsibility, viewed in terms of one's response to another. Thus, the dialogue became a central focus in his educational philosophy. The educated person was one who could listen as well as talk. And since genuine dialogue depended upon authenticity, upon *being* rather than *seeming*, one needed the courage to be oneself in relationships. Buber also urged the recognition of a continuity between learning and life, rather than the encouragement of knowledge for its own sake. He insisted that learning be related to consequent action. Thus, for Buber, the educated person was not one who merely had had his cognitive faculties trained but one whose inmost spirit had been infused by what he had learned.

Areas of disagreement among educational theorists. *Conceptions of what constitutes knowledge.* Although there is wide agreement that the assimilation of knowledge by the learner is a principal goal of education, this agreement is more apparent than real, because there is much disagreement about what constitutes knowledge. Clearly, if one person identifies knowledge with information, his pedagogic approach is likely to differ from that of one who identifies knowledge with a process of thinking. Some philosophers have attempted to clarify a distinction between "knowing that" (something is true or false) and

"knowing how" (to do or learn to discover something). The former emphasis is common in educational programs that focus on the product—that is, on the information that the learner has amassed and can reproduce at the end of his program. The latter emphasis is common in programs that focus on the process—that is, on the skills and attitudes that the learner has adopted that enable him to learn more.

Conceptions of how knowledge should be communicated. Throughout history, the commonest way for knowledge to be communicated has been through what can be loosely called apprenticeship. The one who does not know (the apprentice) watches the one who does (the master); he imitates the master, probably fails, watches again, tries again, and so on until he knows what the master knows. This is primarily the way young people learn role identity, for example—what it means to be a husband or wife, a father or mother, a male or female. It is not an effective method for stimulating the growth of new knowledge. A second method, one that has been time-honoured in institutions of formal schooling, is telling. The one who knows (the teacher) tells the one who does not (the student). The student listens, tries to remember, and is usually required to reproduce his memorizations at some stage so that the teacher can judge whether or not the knowledge has been assimilated. This method is a much less effective way of communicating knowledge than would be guessed from its prevalence as an educational practice. Other methods try to remove the difficulties of human relationships from the act of communication by removing one party from the scene. For example, the apprentice can watch the master on film or videotape. Or the teacher can write his lectures in a book, which the student can then read. Another method is that of the dialogue. Unlike the previous methods, which imply superiority-inferiority relationships, this method implies equality between the members of the dialogue. All may at different moments be teachers or learners. The method assumes that all have some knowledge to give and that all need to learn.

Appren-
ticeship,
telling,
and
dialogue

Conceptions of the purpose of education. One of the commonest areas of disagreement among educational theorists concerns what education should be for. Two broad divisions of opinion can be identified. They are, first, that education should serve the needs of the individual and second, that it should serve the needs of society. In industrialized nations it is common for both of these goals to be held but for different classes of the population. For the elite, the needs of the individual tend to prevail, and thus upper-class schooling often tolerates diversity and encourages idiosyncrasy. For the masses, the needs of society tend to dominate, and schooling usually serves to prepare children to become obedient, well-drilled, uncomplaining workers in industry and agriculture. In addition to this dichotomy, there are many national and cultural variations. In France and Germany, for example, there is a strong tendency to see the primary purpose of education as some form of intellectual development, with the French *lycée* and the German *Gymnasium* serving as characteristic institutions. In England, education has usually been seen as primarily serving the purpose of character building. The English public school is sometimes taken as an epitome of this emphasis. In Roman Catholic and Communist countries, moral or religious training is usually the primary purpose of education. Hence, every subject is imbued with religious (or, if it is Marxism-Leninism, quasi-religious) content, and there is a constant attempt to draw moral lessons from educational material. In the United States, where large-scale immigration once brought the fear of social disintegration, preparation for citizenship and development of national consciousness have tended to be emphasized. Even today, nationalistic rituals such as displaying flags and reciting the "Pledge of Allegiance" in classrooms distinguish American schools from those in most other countries.

Needs of
the
individual
and of
society

Conceptions of uniform versus differential grouping. One of the controversies that most consistently divides educational theorists is whether students should be clustered together with similar students for instruction or whether

Means of
segregat-
ing
students

instructional groups should be made deliberately diverse. The criteria that are employed for differentiating students are manifold. They include chronological age, mental age, IQ, skin colour, sex, social class, geographical location, parental income, performance ability on various tests, and so on. Some of these criteria, such as skin colour, are used "officially" in some countries, such as South Africa, and "unofficially" in others, such as the United States. Other criteria, such as parental income, are used overtly in some schools (expensive, private schools) and covertly in others (public schools located in expensive suburbs). Some criteria, such as mental age, IQ, and performance ability, often have the effect of separating rich from poor or elites from cultural minorities because of the cultural content of the tests used. The customary arguments used in favour of homogeneous grouping tend to emphasize speed and efficiency in instruction and learning. Arguments in favour of heterogeneous grouping tend to emphasize social outcomes, such as an enhanced understanding of others and tolerance of diversity.

Conceptions of control and discipline. When education is viewed as a transaction between superior (the teacher) and inferior (the student), questions of control invariably arise; e.g., can students be relied upon to do what is best if they are not controlled by teachers? Answers to this question refer back to assumptions about the nature of man as learner. Those theorists who tend to see man as basically untrustworthy will tend to find justification for a regimen of strict control over students, in order to prevent their natural impulses from harming themselves and others. Theorists who view man as basically trustworthy will tend to justify more lenient, loose, and permissive systems of control. Most theorists would agree that an important goal of discipline would be for the student to develop self-discipline. But disagreement arises over whether one best learns self-discipline through practice in obeying others or through practice in commanding oneself.

Conceptions of the need for competition and collaboration. In most cultures of the world, children from an early age seek to compete against and to surpass their fellows. Whether this competitive spirit is innate or whether it is acquired through the culture is at present unverifiable. The question that divides education theorists, however, is whether these existing competitive strivings should be encouraged or reduced. Some argue that, since competition is endemic in the culture and since schooling should assimilate the child to the culture, the school should encourage individual competition and help children to develop the strengths necessary to compete successfully. On the other hand, others argue that competitiveness in the culture is pernicious and that schooling should not serve to adjust children to harmful aspects of the culture but should foster cultural progress. Usually, the school is in conflict over these two attitudes and gives mixed messages to students. As a result, the students often suffer the double strain of trying to compete successfully but to do so without appearing to compete.

Conceptions of the boundaries of formal education. Considerable disagreement exists over what should legitimately be studied in formal institutions of learning. Usually some topics or subjects are considered taboo. These taboos may come about through interpretations of the law, as in the case of the exclusion of religious teaching from public schools in the United States. Or they may come about as a result of pressure from interest groups, as in the attempts to exclude sex education, teaching about Communism, and sensitivity training from American schools. The major considerations are that young children are not well equipped to resist heavy bias in teaching and that they are usually compelled by law to attend school and thus constitute a captive audience. It is sometimes argued, therefore, that they should be protected against religious and political propaganda and against material or experiences that require greater maturity to be handled creatively. On the other side, the danger in such arguments is that they can be used to keep all controversy out of schools and to render them places characterized by dull uniformity of thought.

(Pa.N.)

BIBLIOGRAPHY

Philosophy of science: ERNEST NAGEL, *The Structure of Science* (1961); and M.W. WARTOFSKY, *Conceptual Foundations of Scientific Thought* (1968), together cover the main approaches to the philosophy of science as a general field of study; whereas ARTHUR DANTO and SIDNEY MORGENBESSER (eds.), *Philosophy of Science* (1962), provides a useful anthology of classic papers on the subject; and SAMUEL B. RAPPORT and HELEN WRIGHT (eds.), *Science: Method and Meaning* (1964), is a stimulating anthology of nontechnical papers. W.V. QUINE, *Theories and Things* (1981), is a collection of papers by an eminent philosopher, on topics of ontology, logic, semantics, epistemology, philosophy of mathematics, identity, existence, etc.; W.H. NEWTON-SMITH, *The Rationality of Science* (1981), is an analysis of interpretations of science; V.V. NALIMOV, *Faces of Science* (1981), is a collection of essays on the nature of science, which originally were published in Soviet philosophical journals; LOREN R. GRAHAM, *Between Science and Values* (1981), is an examination of the relationship of science to values; JEREMY CAMPBELL, *Grammatical Man: Information, Entropy, Language, and Life* (1982), is a study of philosophical aspects of information theory.

The origins and development of natural science and the attitudes of philosophers toward scientific explanation in antiquity and the Middle Ages are well treated in SAMUEL SAMBORSKY, *The Physical World of the Greeks*, 2nd ed. (1962; orig. pub. in Hebrew, 1954); and *The Physical World of Late Antiquity* (1962); JOHN H. RANDALL, JR., *Aristotle* (1960); and in ALISTAIR C. CROMBIE, *Medieval and Early Modern Science*, 2nd ed., 2 vol. (1963). For the 17th and 18th centuries, see EDWIN A. BURTT, *The Metaphysical Foundations of Modern Physical Science*, 2nd ed. (1932); ALEXANDRE KOYRE, *Newtonian Studies* (1965); HERBERT BUTTERFIELD, *The Origins of Modern Science: 1300-1800*, rev. ed. (1965); I. BERNARD COHEN, *Franklin and Newton* (1956); and GOTTFRIED MARTIN, *Immanuel Kant: Ontologie und Wissenschaftstheorie* (1951; Eng. trans., *Kant's Metaphysics and Theory of Science*, 1955). For the 19th century, the most significant contributions have come from scientists writing as philosophers: CLAUDE BERNARD, *Introduction à l'étude de la médecine expérimentale* (1865; Eng. trans., *An Introduction to the Study of Experimental Medicine*, 1927, reprinted 1961); HERMANN VON HELMHOLTZ, *Popular Scientific Lectures* (1962; reprint of a selection of lectures from *Popular Lectures on Scientific Subjects*, 1st and 2nd series, 1881); T.H. HUXLEY, *Science and Culture, and Other Essays* (1882); and WILLIAM WHEWELL, *The Philosophy of the Inductive Sciences, Founded upon Their History*, 2nd ed. (1847, reprinted 1966). RYAN D. TWENEY, MICHAEL E. DOHERTY, and CLIFFORD R. MYNATT (eds.), *On Scientific Thinking* (1981), consists of selections from the writings of Bacon, Newton, Descartes, Darwin, and Einstein; EDWARD GRANT, *Much Ado About Nothing: Theories of Space and Vacuum from the Middle Ages to the Scientific Revolution* (1981), is a study of the origins of modern science and scientific thinking; MORRIS BERMAN, *The Reenchantment of the World* (1981), is a controversial analysis of scientific tradition with alternative suggestions for understanding the modern world.

The background to the 20th-century debate in the philosophy of science, as it developed between 1890 and 1920, can be reconstructed from ERNST MACH, *Die Mechanik in ihrer Entwicklung historisch-kritisch dargestellt*, 9th ed. (1933; Eng. trans., *The Science of Mechanics*, 1960); and *Die Analyse der Empfindungen und das Verhältnis des Physischen zum Psychischen*, 5th ed. (1906; Eng. trans., *The Analysis of Sensations and the Relation of the Physical to the Psychical*, 1959); KARL PEARSON, *The Grammar of Science*, 3rd ed. (1960); PIERRE DUHÉM, *La Théorie physique: son objet et sa structure* (1906; Eng. trans., *The Aim and Structure of Physical Theory*, 1954); HENRI POINCARÉ, *La Science et l'hypothèse* (1903; Eng. trans., *Science and Hypothesis*, 1905); and HEINRICH HERTZ, *Die Prinzipien der Mechanik* (1895; Eng. trans., *The Principles of Mechanics*, 1889, reprinted 1956), especially the Introduction. The subsequent course of the debate, between 1920 and 1960, is illustrated in CARL G. HEMPEL, *Aspects of Scientific Explanation, and Other Essays in the Philosophy of Science* (1965); RUDOLF CARNAP, *Logical Foundations of Probability*, 2nd ed. (1962); KARL R. POPPER, *Logik der Forschung* (1935; 2nd ed., 1966; Eng. trans., *The Logic of Scientific Discovery*, 1959); ROBIN G. COLLINGWOOD, *An Essay on Metaphysics* (1940); NORMAN R. CAMPBELL, *What Is Science?* (1921); and WILLIAM H. WATSON, *On Understanding Physics* (1959). Two significant side-views of the debate from very different formal standpoints may be found in WILLIAM V. QUINE, *From a Logical Point of View*, 2nd ed. rev. (1961); and RONALD A. FISHER, *Statistical Methods for Research Workers*, 14th ed. (1970). PETER ACHINSTEIN and STEPHEN F. BARKER (eds.), *The Legacy of Logical Positivism* (1969), is a first attempt at an historical appraisal of the period. PAUL K. FEYERABEND, *Philosophical Papers*, 2 vol. (1981), is a brilliant examination of historical and philosophical evidence of rationality of science; RICHARD L. GREGORY, *Mind in Science:*

Conflict
of aims in
school

A History of Explanations in Psychology and Physics (1981), is a study of philosophical ideas generated in different historical periods; MANFRED EIGEN and RUTHILD WINKLER, *Laws of the Game: How the Principles of Nature Govern Chance* (1981; trans. from the German), is a discussion of scientific topics from evolution to information theory; LIEBE F. CAVALIERI, *The Double-Edged Helix: Science in the Real World* (1981), deals with sociophilosophical traits of science and technology.

The current debates about conceptual change and the rationale of discovery in science are central topics in KARL R. POPPER, *Conjectures and Refutations*, 2nd rev. ed. (1965); NORWOOD R. HANSON, *Patterns of Discovery* (1958); STEPHEN TOULMIN, *Human Understanding*, vol. 1 (1972); THOMAS S. KUHN, *The Structure of Scientific Revolutions*, 2nd ed. rev. (1970); IMRE LAKATOS and ALAN MUSGRAVE, *Criticism and the Growth of Knowledge* (1970); and MICHAEL POLANYI, *Personal Knowledge* (1958). For broader cultural aspects of the contemporary debate about science, see C.H. WADDINGTON, *The Scientific Attitude*, new ed. (1968); JACOB BRONOWSKI, *Science and Human Values*, rev. ed. (1965); THEODORE ROSZAK, *The Making of a Counter Culture* (1969); and LEWIS MUMFORD, *The Myth of the Machine* (1967). See also PETER B. MEDAWAR, *Pluto's Republic* (1982), a discussion of the relationship between scientists and society; JOHN W. HARRINGTON, *Dance of the Continents* (1983), an explanation of the processes of interpretive scientific thinking; HANS-GEORG GADAMER, *Reason in the Age of Science* (1982; trans. from the German), a collection of essays on hermeneutic philosophy; FRITJOF CAPRA, *The Turning Point: Science, Society, and the Rising Culture* (1982), suggesting a new vision of scientific reality; RICHARD HEALEY (ed.), *Reduction, Time, and Reality: Studies in the Philosophy of the Natural Sciences* (1981), a collection of articles by eminent philosophers; and PETER SMITH, *Realism and the Progress of Science* (1982), examining philosophical foundations of the progress of science.

Philosophy of physics: R. HARRE, "Philosophical Aspects of Cosmology," and W. DAVIDSON, "Philosophical Aspects of Cosmology," *Br. J. Phil. Sci.*, 13:104-119, 120-129 (1962); OTHMAR SPANN, *Naturphilosophie*, 2nd ed. (1963); IVOR LECLERC, *The Nature of Physical Existence* (1972); PASCUAL JORDAN, *Albert Einstein: Sein Lebenswerk und die Zukunft der Physik* (1969), and *Atom und Weltall: Einführung in den Gedankeninhalt der modernen Physik*, 2nd ed. (1960); E.T. WHITTAKER, *From Euclid to Eddington: A Study of Conceptions of the External World* (1949); JACQUES MERLEAU-PONTY and BRUNO MORANDO, *Les Trois Étapes de la cosmologie* (1971; Eng. trans., *The Rebirth of Cosmology*, 1975); LOUIS DE BROGLIE, *La Physique nouvelle et les quanta* (1937; Eng. trans., *The Revolution in Physics*, 1953, reprinted 1969); R.G. COLLINGWOOD, *The Idea of Nature* (1945, reprinted 1960); P.K. FEYERABEND, "Philosophie de la nature," in M.F. SCIACCA (ed.), *Les Grands Courants de la pensée mondiale contemporaine*, part. 2, vol. 2, pp. 901-927 (1961); ERROL E. HARRIS, *The Foundations of Metaphysics in Science* (1965); JAGJIT SINGH, *Great Ideas and Theories of Modern Cosmology*, rev. and enlarged ed. (1970); P.A. SCHILPP (ed.), *Albert Einstein: Philosopher-Scientist*, 2 vol. (1959); PHILIPP FRANK, *Philosophy of Science* (1957); ALFRED NORTH WHITEHEAD, *Process and Reality* (1929, corrected ed. 1978), and *The Concept of Nature* (1920, reprinted 1964); MARY B. HESSE, *Forces and Fields* (1961); CARL FRIEDRICH VON WEIZSAECKER, *Zum Weltbild der Physik*, 12th ed. (1976); ADOLPH GRUENBAUM, *Philosophical Problems of Space and Time*, 2nd enlarged ed. (1973); WERNER HEISENBERG, *Physics and Philosophy* (1958); A.S. EDDINGTON, *The Nature of the Physical World* (1928, reprinted 1958); HENRI POINCARÉ, *La Science et l'hypothèse* (1903; Eng. trans., *Science and Hypothesis*, 1905); HENRY MARGENAU, *The Nature of Physical Reality* (1950, reprinted 1977), and *Physics and Philosophy* (1978); KARL R. POPPER, *Realism and the Aim of Science* (1983), *The Open Universe: An Argument for Indeterminism* (1982), and *Quantum Theory and the Schism in Physics* (1982), comprise the work of one of the greatest philosophers of the 20th century, who challenges most of the traditional assumptions in modern physics; JEREMY BERNSTEIN, *Science Observed: Essays of My Mind* (1982), is a collection of essays on the process of science; ROGER S. JONES, *Physics as Metaphor* (1982) is an original personal commentary on the nature of physical science; HEINZ R. PAGELS, *The Cosmic Code: Quantum Physics as the Language of Nature* (1982), is a very up-to-date review of modern physics; see also FRITJOF CAPRA, *The Tao of Physics: An Exploration of the Parallels Between Modern Physics and Eastern Mysticism*, 2nd rev. ed. (1983); BENJAMIN GAL-OR, *Cosmology, Physics, and Philosophy* (1983); EDWARD M. MACKINNON, *Scientific Explanation and Atomic Physics* (1982); and P.C.W. DAVIES, *The Accidental Universe* (1982).

Philosophy of biology: FRANCISCO JOSÉ AYALA and THEODOSIUS DOBZHANSKY (eds.), *Studies in the Philosophy of Biology: Reduction and Related Problems* (1974), a collection of conference papers that discuss definitions and the implications of

reductionism; M.O. BECKNER, "Biology," in *The Encyclopedia of Philosophy*, vol. 1, pp. 310-318 (1967), an excellent review of some of the basic philosophical problems in biology; LUDWIG VON BERTALANFFY, *General System Theory* (1968), an attempt to unify the disparate aspects of biology and formulate general principles; BARRY COMMONER, "In Defense of Biology," *Science*, 133:1745-1748 (1961), an argument for the autonomy of biology decrying the emphasis on molecular biology to the neglect of general biology; FRANCIS CRICK, *Of Molecules and Men* (1966), a work that expresses the attitudes and positions taken by many molecular biologists in defense of reductionism; W.M. ELSASSER, *The Chief Abstractions of Biology* (1975), a refutation of reductionist analysis in the life sciences; A.G.N. FLEW, *Evolutionary Ethics* (1967), a significant attempt to relate evolutionary theory to ethics. T.A. GOUDGE, *The Ascent of Life* (1961), a work devoted solely to philosophical problems of evolutionary theory; MARJORIE GRENE, *Approaches to a Philosophical Biology* (1968), a review of the European viewpoints on the philosophy of nature (*Naturphilosophie*); THOMAS H. and JULIAN HUXLEY, *Touchstone for Ethics, 1893-1943* (British title, *Evolution and Ethics, 1893-1943*; 1947, reprinted 1969), opposing views on the same theme by two famous biologists; HANS JONAS, *The Phenomenon of Life: Toward a Philosophical Biology* (1966, reprinted 1979), a collection of essays presenting an existential interpretation of biology in the tradition of *Naturphilosophie*; JACQUES MONOD, *Le Hasard et la nécessité: essai sur la philosophie naturelle de la biologie moderne* (1970; Eng. trans., *Chance and Necessity: An Essay on the Natural Philosophy of Modern Biology*, 1971), a significant addition to the biological literature by a Nobel Prize-winning biologist; ASHLEY MONTAGU (ed.), *Man and Aggression*, 2nd ed. (1973), a collection of essays and reviews critical of the notion of innate aggressiveness as expounded by Konrad Lorenz and Robert Ardrey; RONALD MUNSON (ed.), *Man and Nature: Philosophical Issues in Biology* (1971), a collection of writings that provides an excellent introduction to current thinking in biophilosophy, with incisive commentary by the editor; JEAN PIAGET, *Biologie et connaissance* (1967; Eng. trans., *Biology and Knowledge*, 1971), concerned primarily with the evolution of mental faculties; V.R. POTTER, *Bioethics* (1971), a collection of articles dealing with the influence of biology on practical moral problems. BERNHARD RENSCH, *Biophilosophie auf erkenntnistheoretischer Grundlage* (1968; Eng. trans., *Biophilosophy*, 1971), a work emphasizing the rise and nature of consciousness within the framework of the evolutionary process; MICHAEL A. SIMON, *The Matter of Life* (1971), a good review of the current approaches to the philosophy of biology; GEORGE GAYLORD SIMPSON, *This View of Life: The World of an Evolutionist* (1964), a collection of essays by a renowned scholar, some of which have shaped the direction of philosophical biology today, and the especially pertinent chapter, "Man's Place in Nature," in his *Meaning of Evolution*, pp. 281-294, rev. ed. (1967); PIERRE TEILHARD DE CHARDIN, *Le Phénomène humain* (1956; Eng. trans., *The Phenomenon of Man*, 1959), a controversial attempt to meld science and religion by presenting a mystical viewpoint of cosmic evolution; C.H. WADDINGTON, *The Ethical Animal* (1960), a defense of the claim that biological facts can provide grounds for moral principles. STEVEN ROSE (ed.), *Against Biological Determinism* (1982) and *Towards a Liberatory Biology* (1982), are two volumes of essays collected by the DIALECTICS OF BIOLOGY GROUP, based on proceedings of meetings of philosophers and biologists and exploring alternatives in modern life science; CHARLES BIRCH and JOHN B. COBB, *The Liberation of Life: From the Cell to the Community* (1982), is a survey of philosophical interpretations of problems of ecology; JOHN C. GREENE, *Science, Ideology, and World View: Essays in the History of Evolutionary Ideas* (1981), is a discussion of the role of philosophy of evolution in Western intellectual history; C. LEON HARRIS, *Evolution: Genesis and Revelations: With Reading from Empedocles and Wilson* (1981), is a survey of the history of evolutionary thought; and U.J. JENSEN and R. HARRÉ (eds.), *The Philosophy of Evolution* (1981), is a collection of essays on evolutionary concepts in different fields; see also ERNST MAYR, *The Growth of Biological Thought: Diversity, Evolution, and Inheritance* (1982).

Philosophy of history: ROBIN G. COLLINGWOOD, *The Idea of History* (1946), a classical contribution to the critical theory of history; KARL R. POPPER, *The Poverty of Historicism* (1957), an influential critique of types of historical speculation; WILLIAM H. WALSH, *An Introduction to Philosophy of History* (1951), a lucid, general account; PATRICK L. GARDINER, *The Nature of Historical Explanation*, 3rd ed. (1967); WILLIAM H. DRAY, *Laws and Explanation in History* (1957); PETER WINCH, *The Idea of a Social Science and Its Relation to Philosophy* (1958); and MORTON G. WHITE, *Foundations of Historical Knowledge* (1965), four analytical discussions relating to historical knowledge and understanding; FRANK E. MANUEL, *Shapes of Philosophical History* (1965), a brief but reliable survey of the development

of speculative theories. WILLIAM DRAY, *Perspectives in History* (1980), is an explorative collection of essays on particular theorists of history by a prominent contemporary philosopher; ANTHONY GIDDENS, *A Contemporary Critique of Historical Materialism: Power, Property, and the State* (1982), is a work by a leading British sociologist in which he offers an alternative interpretation of history based upon contemporary anthropological research; HILARY PUTNAM, *Reason, Truth and History* (1981), is a discussion of the nature of truth, knowledge, and order, especially the dichotomy between objective and subjective views of truth; LAWRENCE STONE, *The Past and the Present* (1981), is an examination of historiographic methodology; JOHN W. MILLER, *The Philosophy of History with Reflections and Aphorisms* (1981), is an original personal reflection on history as a human science; see also discussions of special issues in MARK BLITZ, *Heidegger's Being and Time and the Possibility of Political Philosophy* (1981); ALFRED SCHMIDT, *History and Structure: An Essay on Hegelian-Marxist and Structuralist Theories of History* (1982; originally published in German, 1971); EDMUND E. JACOBITTI, *Revolutionary Humanism and Historicism in Modern Italy* (1981); EUGENE WEBB, *Eric Voegelin: Philosopher of History* (1981).

Philosophy of religion: General introductions include H.D. LEWIS, *Philosophy of Religion* ("Teach Yourself Book") (1965); and J. HICK, *Philosophy of Religion* (1963). Introductory books that range over a somewhat narrower field include J.L. GOODALL, *An Introduction to the Philosophy of Religion* (1966); I.T. RAMSEY, *Religious Language* (1957 and 1963); and THOMAS FAWCETT, *The Symbolic Language of Religion* (1971). NINIAN SMART, *Philosophers and Religious Truth*, 2nd ed. (1969), centres discussion of some salient issues around particular philosophers. NINIAN SMART, *The Religious Experience of Mankind* (1969); and EDWARD GEOFFREY PARRINDER, *Comparative Religion* (1962), provide general introductions to the comparative study of religions. In *World Religions* (1966), H.D. LEWIS and R.L. SLATER consider issues in the world religions that are highlighted by contemporary approaches in the philosophy of religion and the comparative study of religions respectively. In the psychology of religion, the classic work of WILLIAM JAMES, *The Varieties of Religious Experience* (1902, reprinted 1952), is probably still the best introduction that might then be followed by a comprehensive survey of the contemporary field, such as L.W. GRENSTED, *The Psychology of Religion* (1952). Most of these books contain excellent bibliographies for further reading. NINIAN SMART, *Historical Selections in the Philosophy of Religion* (1962); and I.T. RAMSEY, *Words About God* (1971), are useful sourcebooks for some classic discussions of topics in the philosophy of religion; an excellent survey of recent thought is given in JOHN MACQUARRIE, *Twentieth-Century Religious Thought: The Frontiers of Philosophy and Theology, 1900–1960* (1963). F.R. TENNANT, *Philosophical Theology*, 2 vol. (1928–30); H.H. FARMER, *The World and God: A Study of Prayer, Providence and Miracle in Christian Experience* (1935); and H.D. LEWIS, *Our Experience of God* (1959), represent different general treatments of the subject. WILFRED C. SMITH, *Towards a World Theology: Faith and the Comparative History of Religion* (1980), is an introduction to analysis of the interrelationship of various religious traditions; JOHN B. COBB and W. WIDICK SCHROEDER (eds.), *Process Philosophy and Social Thought* (1981), is a collection of essays on reshaping of social and political thinking; MICHAEL D. CLARK, *Worldly Theologians: The Persistence of Religion in Nineteenth Century American Thought* (1981), is an examination of the relationship between religion and secular thought; SEYYED HOSSEIN NASR, *Knowledge and the Sacred* (1982), is an exposition of neo-traditionalism in philosophy and religion; FREDERICK COPLESTON, *Religion and the One: Philosophies East and West* (1982), is a comparison of various world philosophies in their treatment of human religious experience. For discussion of particular religious philosophers see TERENCE J. GERMAN, *Hamann on Language and Religion* (1982); ROBERT J. VANDEN BURGT, *The Religious Philosophy of William James* (1981); HENRY S. LEVINSON, *The Religious Investigations of William James* (1981); JEFFREY STOUT, *The Flight from Authority: Religion, Morality, and the Quest for Autonomy* (1981).

Books dealing with specific problems of religious belief are: PETER R. BAEZ, *Prayer and Providence* (1968); J. HICK, *Evil and the God of Love* (1966); A. FARRER, *Love Almighty and Ills Unlimited* (1966); I.T. RAMSEY, *The Problem of Evil* (1972); W.T. STACE, *Mysticism and Philosophy* (1960); JOHN HICK, *God Has Many Names* (1982); LESZEK KOLAKOWSKI, *Religion: If There Is No God: On God, the Devil, Sin, and Other Worries of the So-Called Philosophy of Religion* (1982); HARRY J. AUSMUS, *The Polite Escape: On the Myth of Secularization* (1982); and CHARLES F. KEYES and E. VALENTINE DANIEL (eds.), *Karma: An Anthropological Inquiry* (1983).

Philosophy of art: PAUL ZIFF, "The Task of Defining a Work of Art," *Phil. Rev.*, 62:58–78 (1953); DEWITT PARKER, *The*

Analysis of Art (1926); SUSANNE K. LANGER, *Feeling and Form* (1953); JOHN DEWEY, *Art As Experience* (1934); WARREN E. STEINKRAUS, *Philosophy of Art*, rev. ed. (1984); V.A. HOWARD, *Artistry: The Work of Artists* (1982); R.A. SHARPE, *Contemporary Aesthetics: A Philosophical Analysis* (1983); PATRICIA H. WERHANE (ed.), *Philosophical Issues in Art* (1984); and HAROLD ROSENBERG, *The De-definition of Art* (1983).

For a discussion of intention in art interpretation see first the classic attack on intention by WILLIAM K. WIMSATT and MONROE C. BEARDSLEY, "The Intentional Fallacy," in *The Verbal Icon* (1954); for an opposed view see LESLIE A. FIEDLER, "Archetype and Signature: A Study of the Relationship Between Biography and Poetry," *Sewanee Rev.*, 60: 253–273 (1952); and HENRY D. AIKEN, "The Aesthetic Relevance of the Artist's Intentions," *J. Phil.*, 52:742–753 (1955). Classic sources on art as imitation (representation) are ARISTOTLE, *Poetics*, and LONGINUS, *On the Sublime*. Recent works include WALTER ABELL, *Representation and Form* (1936), particularly in visual art; THEODORE M. GREENE, *The Arts and the Art of Criticism* (1940); and STEPHEN C. PEPPER, *The Work of Art* (1955). See also RICHARD KUHN, *Psychoanalytic Theory of Art: A Philosophy of Art on Developmental Principles* (1983); and HOWARD J. SMAGULA, *Currents, Contemporary Directions in the Visual Arts* (1983).

A classic source on art as expression is LEO TOLSTOY's *What Is Art?* (1898; Aylmer Maude translation in "Oxford World's Classic Library," 1930, reprinted 1960); defense of forms of expression theory are ROBIN G. COLLINGWOOD, *The Principles of Art* (1938); and CURT J. DUCASSE, *The Philosophy of Art*, rev. ed. (1966). An anthology of readings on artistic expression is JOHN HOSPERS (ed.), *Artistic Expression* (1971). Later monographs include R.L. HELD, *Endless Innovations: Frederick Kiesler's Theory and Scenic Design* (1982); and MARCIA MUELDER EATON, *Art and Nonart* (1983).

For a defense of art as form, see CLIVE BELL, *Art* (1914, reprinted 1958); ROGER FRY, *Transformations* (1927); EDUARD HANSLICK, *Vom Musikalisch-Schönen*, 7th ed. rev. (1885; Eng. trans., *The Beautiful in Music*, 1891, reprinted 1957). Moral and societal aspects of the subject are treated in GEORGE SANTAYANA, *Reason in Art* (1910). ROGER TAYLOR, *Beyond Art: What Art Is and Might Become If Freed from Cultural Elitism* (1981), is a discussion of art as an integral part of life; ARTHUR C. DANTO, *The Transfiguration of the Commonplace: A Philosophy of Art* (1981), is an examination of the relationship between philosophy and art, and of the distinction between art works and commonplace objects. DENNIS DUTTON (ed.), *The Forger's Art: Forgery and the Philosophy of Art* (1983), is a collection of original essays on this special topic.

Histories of the subject include ALBERT HOFSTADTER and RICHARD KUHN (eds.), *Philosophies of Art and Beauty* (1964); ALEXANDER SESONSKE (ed.), *What Is Art?* (1965); and MONROE C. BEARDSLEY, *Aesthetics from Classical Greece to the Present* (1966). See also EUGENIO TRIÁS, *The Artist and the City* (1982; originally published in Spanish, 1976); MICHAEL F. PALMER, *Paul Tillich's Philosophy of Art* (1984); MIKEL DUFRÉNNE, *Main Trends in Aesthetics and the Science of Art* (1979); and STEPHEN DAVID ROSS (ed.), *Art and Its Significance: An Anthology of Aesthetic Theory* (1984).

Philosophy of logic: W.V. QUINE, *Philosophy of Logic* (1970), is the best compact introductory exposition. HILARY PUTNAM, *Philosophy of Logic* (1971), is useful as a complement to Quine. Much of the important recent literature, however, is in the form of brief papers rather than monographs. The most successful anthologies of such papers are perhaps L.W. SUMNER and JOHN WOODS (eds.), *Necessary Truth* (1969), on logical truth and analyticity; and LEONARD LINSKY (ed.), *Reference and Modality* (1971), on modal concepts and intensional logic. RAYMOND KLIBANSKY (ed.), *Contemporary Philosophy*, vol. 1 (1968), contains several survey articles covering thoroughly the whole field. Still central are the classical writings of the great modern philosophers of logic: PETER GEACH and MAX BLACK (eds.), *Translations from the Philosophical writings of Gottlob Frege*, 2nd ed. (1960); BERTRAND RUSSELL, *Logic and Knowledge* (1956); LUDWIG WITTGENSTEIN, *Tractatus logico-philosophicus* (Eng. trans., 1922) and *Philosophical Investigations* (Eng. trans., 1953); ALFRED TARSKI, *Logic, Semantics, and Metamathematics* (1956); and RUDOLF CARNAP, *Meaning and Necessity* (1947). The period 1879–1931 is also covered in a magnificent volume by JEAN VAN HEIJENOORT (ed.), *From Frege to Gödel: A Source Book in Mathematical Logic, 1879–1931* (1967), which contains valuable introductions to the different selections and comments on them. Of recent literature, especially noteworthy are the writings of Strawson and Quine: P.F. STRAWSON, *Logico-Linguistic Papers* (1971); W.V. QUINE, *From a Logical Point of View* (1953), *Word and Object* (1960), and *Ontological Relativity and Other Essays* (1969). Quine's ideas are discussed critically in DONALD DAVIDSON and JAAKKO HINTIKKA (eds.), *Words and Objections* (1969). A broad spectrum of new work on the borderline of philosophical logic and

linguistics is represented in DONALD DAVIDSON and GILBERT HARMAN (eds.), *Semantics of Natural Language* (1972). Several problems mentioned above are discussed in JAAKKO HINTIKKA, *Logic, Language-Games, and Information* (1972); and in J.W. DAVIS, D.J. HOCKNEY, and W.K. WILSON (eds.), *Philosophical Logic* (1969). Later monographs include JOHN MARENBO, *From the Circle of Alcuin to the School of Auxerre: Logic, Theology, and Philosophy in the Early Middle Ages* (1981), an examination of the progress of medieval philosophical logic; RUDY RUCKER, *Infinity and the Mind: The Science and Philosophy of the Infinite* (1982), a book on the interface of philosophy and computer science; GEORGE BEALER, *Quality and Concept* (1982), an appraisal of elementary symbolic logic; and OSWALD HANFLING, *Logical Positivism* (1981), a treatment of the philosophical movement.

Philosophy of law: Leading treatises in English include A. ROSS, *Om ret og retfaerdighed* (1953; Eng. trans., *On Law and Justice*, 1958); W. FRIEDMANN, *Legal Theory*, 5th ed. (1967); H. Kelsen, *General Theory of Law and State* (1945); G.W. PATON, *A Text-Book of Jurisprudence*, 3rd ed. by D.P. DERHAM (1964); R. POUND, *Jurisprudence*, 5 vol. (1959); J. STONE, *Legal System and Lawyers' Reasonings* (1964); *Human Law and Human Justice* (1965); *Social Dimensions of Law and Justice* (1966); LEV S. JAWITSCH, *The General Theory of Law: Social and Philosophical Problems* (1981; trans. from the Russian); ROBERT S. SUMMERS, *Instrumentalism and American Legal Theory* (1982). NEIL MACCORMICK, *H.L.A. Hart* (1981), is an analysis of the legal philosophy of the prominent jurist.

Notable works on the history of philosophy of law include E. WOLF, *Griechisches Rechtsdenken*, 3 vol. (1950–54); A. VERDROSS, *Abendländische Rechtsphilosophie*, 2nd ed. (1963); R. MARCIC, *Geschichte der Rechtsphilosophie* (1971); G. FASSO, *Storia della filosofia del diritto*, 2 vol. (1966–68; 2nd ed., vol. 1, 1970). DAVID MILLER, *Philosophy and Ideology in Hume's Political Thought* (1981), is a comprehensive survey of Hume's thought on judgment, justice, political power, and government.

Basic works in the main areas include: *Analytical jurisprudence*: J. AUSTIN, *Lectures on Jurisprudence* (1832); H.L.A. HART, *The Concept of Law* (1961); W.N. HOHFELD, *Fundamental Legal Conceptions As Applied to Judicial Reasoning* (1923); H. Kelsen, *Reine Rechtslehre*, 2nd ed. (1960; Eng. trans., *Pure Theory of Law*, 1967); A. KOCOUREK, *Jural Relations*, 2nd ed. (1928); I. TAMMELO, *Outlines of Modern Legal Logic* (1969). *Ethical jurisprudence*: C.K. ALLEN, *Aspects of Justice* (1958); J. BENTHAM, *Introduction to the Principles of Morals and Legislation* (1780); E. BODENHEIMER, *Treatise on Justice* (1967); H. Kelsen, *What is Justice?* (1957); C. PERELMAN, *Justice* (1967); G. RADBRUCH, "Legal Philosophy," in K. WILK (ed.), *The Legal Philosophies of Lask, Radbruch and Dabin*, pp. 47–226 (1950). *(Sociological jurisprudence, including historical jurisprudence)*: W. AUBERT (ed.), *Sociology of Law* (1969); E. EHRLICH, *Grundlegung der Soziologie des Rechts* (1913; Eng. trans., *Fundamental Principles of the Sociology of Law*, 1936); L.M. FRIEDMAN and A.S. MACAULAY (eds.), *Law and Behavioral Sciences* (1969); G.

GURVITCH, *Sociology of Law* (1942); K.N. LLEWELLYN, *Jurisprudence* (1962); H. MAINE, *Ancient Law* (1861); F. VON SAVIGNY, *Vom Berufunsrer Zeit für Gesetzgebung und Rechtswissenschaft* (1830; Eng. trans., *Of the Vocation of Our Age for Legislation and Jurisprudence*, 1831); E.M. SCHUR, *Law and Society* (1968); J. STONE, *Law and the Social Sciences in the Second Half-Century* (1966). See also DONALD DAVIDSON, *Essays on Actions and Events* (1980); HANNU TAPANI KLAMI, *Anti-Legalism* (1980); M.A. STEWART (ed.), *Law, Morality, and Rights* (1983); JOHN D. HODSON, *The Ethics of Legal Coercion* (1983); ANTHONY ALLOTT, *The Limits of Law* (1980); B.R. KRISHNA IYER, *Law Versus Justice* (1981).

Philosophy of education: For an excellent example of the analytical approach to philosophy of education, see ISRAEL SCHEFFLER (ed.), *Philosophy and Education*, 2nd ed. (1966). A representative British example is P.H. HIRST and R.S. PETERS, *The Logic of Education* (1970). Several scholars have attempted to group philosophies of education into schools of thought. The best collections are JOHN PAUL STRAIN (comp.), *Modern Philosophies of Education* (1971); and THEODORE B.H. BRAMELD, *Patterns of Educational Philosophy: Divergence and Convergence in Culturological Perspective* (1971). For examples of attempts to focus on a single problem or issue and to combine clarity and commitment, see PAUL NASH, *Authority and Freedom in Education: An Introduction to the Philosophy of Education* (1966); KENNETH D. BENNE, *Education in the Quest for Identity and Community* (1962); and ROBERT ULICH, *The Human Career: A Philosophy of Self-Transcendence* (1955). A good collection of Existentialist statements on education may be found in MAXINE GREENE (comp.), *Existential Encounters for Teachers* (1967). For selections from the classics on conceptions of the educated person, see PAUL NASH (ed.), *Models of Man: Explorations in the Western Educational Tradition* (1968); and ROBERT ULICH (ed.), *Three Thousand Years of Educational Wisdom*, 2nd ed. enl. (1954). Original essays on all of these major figures may be found in PAUL NASH, ANDREAS M. KAZAMIAS, and HENRY J. PERKINSON (eds.), *The Educated Man: Studies in the History of Educational Thought* (1965). Contemporary problems are treated in BRENDA COHEN, *Education and the Individual* (1982), exploring the concept of freedom of education; MORTIMER J. ADLER, *The Paideia Proposal: An Educational Manifesto* (1982); HENRY A. GIROUX, *Ideology, Culture, and the Process of Schooling* (1981), espousing radical Marxist thought; LLOYD DUCK, *Teaching with Charisma* (1981), analyzing psychology of teaching behaviours; R.F. HOLLAND, *Against Empiricism: On Education, Epistemology, and Value* (1980), a collection of essays of broad concern; LAWRENCE KOHLBERG, *The Philosophy of Moral Development: Moral Stages and the Idea of Justice* (1981), stressing an interdisciplinary approach in education; MICHAEL R. MATTHEWS, *The Marxist Theory of Schooling: A Study of Epistemology and Education* (1981); and DAVID NYBERG, *Power Over Power: What Power Means in Ordinary Life, How It Is Related To Acting Freely, and What It Can Contribute to a Renovated Ethics of Education* (1981).

The History of Western Philosophy

This article has three basic purposes: (1) to provide an overview of the history of philosophy in the West; (2) to relate philosophical ideas and movements to their historical background and to the cultural history of their time; and (3) to trace the changing conception of the definition, the function, and the task of philosophy.

The article is divided into the following sections:

Nature of philosophy and the writing of its history	733
Philosophy in the Western tradition	733
General considerations	734
The writing of the history of philosophy	
Shifts in the focus and concern of philosophy	
Ancient Greek and Roman philosophy	735
The Pre-Socratic philosophers	735
Cosmology and the metaphysic of matter	
Epistemology of appearance	
Metaphysic of number	
Anthropology and relativism	
The seminal thinkers of Greek philosophy	738
Socrates	
Plato	
Aristotle	
Hellenistic and Roman philosophy	740
Stoics	
Epicureans	
Skeptics	
Neo-Pythagoreans and Neoplatonists	
Medieval philosophy	742
Early medieval philosophy	742
Transition to Scholasticism	743
The age of the schoolmen	744
Philosophy in the late Middle Ages	745
Modern philosophy	746
The Renaissance and early modern period	746
Dominant strands of Renaissance philosophy	
Rise of Empiricism and Rationalism	
Literary forms and sociological conditions	
The Enlightenment	751
Classical British Empiricism and its basic tasks	
Nonepistemological movements in the Enlightenment	
Critical examination of reason in Kant	
Literary forms	
The 19th century	754
German Idealism of Fichte, Schelling, and Hegel	
Positivism and social theory in Comte, Mill, and Marx	
Independent and irrationalist movements	
The 20th century	757
Individual philosophies of Bergson, Dewey, and Whitehead	
Marxist thought	
Analytic philosophy	
Continental philosophy	
Concluding comments	
Bibliography	759

Nature of philosophy and the writing of its history

PHILOSOPHY IN THE WESTERN TRADITION

It is a paradox faced by all of those who attempt to write the history of philosophy that the "philosophy" whose history they write probably would not have been defined exactly alike by any two of the major figures whom they judge it fitting to include in their accounts. For throughout its long and varied history in the West, "philosophy" has meant many different things. Some of these have been a search for the wisdom of life (the meaning closest to the Greek words from which the term is derived); an attempt to understand the universe as a whole; an examination of man's moral responsibilities and social obligations; an effort to fathom the divine intentions and man's place with reference to them; an effort to ground the enterprise

of natural science; a rigorous examination of the origin, extent, and validity of men's ideas; an exploration of the place of will or consciousness in the universe; an examination of the values of truth, goodness, and beauty; an effort to codify the rules of human thought in order to promote rationality and the extension of clear thinking. Even these do not exhaust the meanings that have been attached to the philosophical enterprise, but they give some idea of its extreme complexity and many-sidedness.

It is difficult to determine whether any common element can be found within this diversity and whether any core meaning can be discovered for philosophy that could serve as a universal and all-inclusive definition. But a first attempt in this direction might be to define philosophy either as "a reflection upon the varieties of human experience" or as "the rational, methodical, and systematic consideration of those topics that are of greatest concern to man." Vague and indefinite as such definitions are, they do suggest two important facts about philosophizing: (1) that it is a reflective, or meditative, activity and (2) that it has no explicitly designated subject matter of its own but is a method or type of mental operation (like science or like history) that can take any area or subject matter or type of experience as its object. Thus, although there are a few single-term divisions of philosophy of long standing—such as logic, ethics, epistemology (the theory of knowledge), or metaphysics (theory of the nature of Being)—its divisions are probably best expressed by phrases that contain the preposition "of"—such as philosophy of nature, philosophy of mind, philosophy of law, or philosophy of art.

Part of what makes it difficult to find a consensus among philosophers about the definition of their discipline is precisely that they have frequently come to it from different fields, with different interests and concerns, and that they therefore have different areas of experience upon which they find it especially necessary or meaningful to reflect. St. Thomas Aquinas (a Dominican friar of the 13th century), George Berkeley (a bishop of the Irish Church in the 18th century), and Søren Kierkegaard (a Danish divinity student in the 19th century) all saw philosophy as a means to assert the truths of religion and to dispel the Materialistic or Rationalistic errors that, in their opinion, had led to its decline. Pythagoras in ancient south Italy, René Descartes in the late Renaissance, and Bertrand Russell in the 20th century have been primarily mathematicians whose views of the universe and of human knowledge have been vastly influenced by the concept of number and by the method of deductive thinking. Some philosophers, such as Plato or the British philosophers Thomas Hobbes and John Stuart Mill, have been obsessed by problems of political arrangement and social living, so that whatever else they have done in philosophy has been stimulated by a desire to understand and, ultimately, to change the social and political behaviour of men. And still others—such as the Milesians (the first philosophers of Greece); Francis Bacon, an Elizabethan philosopher; and, in the 20th century, Alfred North Whitehead, a process metaphysician—have begun with an interest in the physical composition of the natural world, so that their philosophies resemble more closely the generalizations of physical science than those of religion or sociology.

The history of Western philosophy reveals in detail the concentrated activity of a multitude of serious and able men reflecting upon, reasoning about, and considering deeply the nature of their experience. But throughout this diversity certain characteristic oppositions habitually recur, such as the division between monists, dualists, and pluralists in metaphysics; between Materialists and Idealists in cosmological theory; between Nominalists and Realists in the theory of signification; between Rational-

Characteristic oppositions in philosophy

Various conceptions of what philosophy is

ists and Empiricists in the theory of knowledge; between Utilitarians, self-realizationists, and proponents of duty in moral theory; and between partisans of logic and partisans of emotion in the search for a responsible guide to the wisdom of life.

Many of these fundamental oppositions among philosophers will be treated in the article that follows. But if any single opposition is taken as central throughout the history of Western philosophy at every level and in every field, it is probably that between the critical and the speculative impulses. These two divergent motivations tend to express themselves in two divergent methods: that of analysis and that of synthesis. Plato's *Politeia* (*The Republic*) is an example of the second. The *Principia Ethica* (1903) of G.E. Moore, a founder of linguistic philosophy, is an example of the first. Beginning with a simple question about justice, *Politeia* in its discursiveness slowly but progressively brings more and more areas into the discussion: first ethics, then politics, then educational theory, then theory of knowledge, and finally metaphysics. Starting with one specific question, Plato finally managed to make his discussion as broad as the world. *Principia Ethica* does just the opposite. Beginning with a general question—What is good?—it progressively breaks up this question into a whole series of subordinate questions, analyzing meanings ever more minutely, growing narrower and narrower but always with the utmost modesty and sincerity, striving for increasing simplicity and exactitude.

The analytic, or critical, impulse treats any subject matter or topic by concentrating upon the part, by taking it apart in the service of clarity and precision. It was essentially the method of Aristotle and of Peter Abelard, a medieval Scholastic; of David Hume, a Scottish Skeptic, and of Rudolf Carnap, a 20th-century semantic Positivist; and of Russell and Moore. The synthetic, or speculative, impulse operates by seeking to comprehend the whole, by putting it all together in the service of unity and completeness. It is essentially the method of Parmenides, a Pre-Socratic monist, and of Plato; of St. Thomas and of Benedict de Spinoza, a modern Jewish Rationalist; of G.W.F. Hegel, a German Idealist, and of Whitehead. Throughout philosophy's history, each of the two traditions has made its insistent claim.

There is one philosophical tradition—that of Positivism—that sees philosophy as originating in the obscure mists of religion and coming finally to rest in the pure sunshine of scientific clarity. This represents a necessary progress, because Positivism considers it a scandal when philosophers speak a language that is not accessible to "verification"; it holds that bold and adventuresome philosophical speculation is at best mere self-indulgence, a passing state occurring when philosophical problems are raised prematurely—that is, at a time when philosophy does not possess the means to solve them.

Though Positivism represents a partisan view that it is not necessary to hold, it does express indirectly a basic truth—that the philosophical enterprise has always hovered uncertainly between the lure of religious seriousness and that of scientific exactitude. In the earliest philosophers of Greece it is impossible to separate ideas of divinity and the human soul from ideas about the mystery of being and the genesis of material change, and in the Middle Ages philosophy was acknowledged to be "the handmaiden of theology." But the increased secularization of modern culture has largely reversed this trend, and the Enlightenment emphasis upon the separation of nature from its divine creator has increasingly placed philosophical resources at the disposal of those interested in creating a philosophy of science.

Yet philosophy's continuing search for philosophical truth leads it to hope, but at the same time to profoundly doubt, that its problems are objectively solvable. With respect to a total description of Being or a definitive account of the nature of values, only individual solutions now seem possible; and the optimistic hope for objective answers that secure universal agreement must be given up.

In this respect, philosophy seems less like science than like art and the philosopher more like an artist than a scientist, for his philosophical solutions bear the stamp of

his own personality, and his choice of arguments reveals as much about himself as his chosen problem. As a work of art is a portion of the world seen through a temperament, so a philosophical system is a vision of the world subjectively assembled. Plato and Descartes, Immanuel Kant, an 18th-century German Idealist, and John Dewey, a U.S. Pragmatist, have given to their systems many of the quaint trappings of their own personalities.

But if philosophy is not true in the same sense as science, it is not false in the same sense either; and this gives to the history of philosophy a living significance, which the history of science does not enjoy. In science, the present confronts the past as truth confronts error; thus, for science, the past, even when important at all, is important only out of historical interest. In philosophy it is different. Philosophical systems are never definitively proved false; they are simply discarded or put aside for future use. And this means that the history of philosophy consists not simply of dead museum pieces but of ever-living classics—comprising a permanent repository of ideas, doctrines, and arguments and a continuing source of philosophical inspiration and suggestiveness to those who philosophize in any succeeding age. It is for this reason that any attempt to separate philosophizing from the history of philosophy is both a provincial act and an unnecessary impoverishment of its rich natural resources.

GENERAL CONSIDERATIONS

The writing of the history of philosophy. The writing of the history of philosophy is itself controlled by a series of cultural habits or conventions.

Ways of ordering the history. The ensuing article on the history of Western philosophy is divided into three sections—ancient, medieval, and modern—and this division is so pervasive today that it is difficult to remember that the threefold distinction is only as old as the end of the 17th century. This distinction—first employed in the writing of European history proper by Georg Horn of Leiden in his *Arca Noae: Sive Historia Imperiorum et Regnorum a Conditio Orbe ad Nostra Tempora* (1666; "Noah's Ark; or, The History of Empires and Kingdoms from the Beginning of the World to Our Times") and a generation later by Christophorus Cellarius, a German historian, in 1696—slowly spread to historical writing in all fields and was given definitive influence in philosophical writing through the series of lectures on *Philosophiegeschichte* ("History of Philosophy") that Hegel delivered first at Jena, then at Heidelberg, and finally at Berlin between 1805 and 1830. Since Hegel, it has been taken for granted as standard practice, although a host of cultural assumptions is implied by its use.

Treatment of the total field of the history of philosophy has been traditionally subject to two types of ordering, according to whether it was conceived (1) as primarily a history of ideas or (2) as a history of the intellectual products of men. In the first ordering, certain ideas, or concepts, are viewed as archetypal (such as matter or mind or doubt); and the condensations occurring within the flow of thought tend to consist of basic types or schools. This ordering has characterized such works as Friedrich Lange's *Geschichte des Materialismus* . . . (1866; *The History of Materialism*), A.C. Ewing's compilation *The Idealist Tradition: From Berkeley to Blanshard* (1957), or Richard H. Popkin's *History of Skepticism from Erasmus to Descartes* (1960). In the second type of ordering, the historian, impressed by the producers of ideas as much as by the ideas themselves—that is, with philosophers as agents—reviews the succession of great philosophical personalities in their rational achievement. This ordering has produced the more customary histories such as Émile Bréhier's *Histoire de la philosophie* (1926–32), Bertrand Russell's *History of Western Philosophy* (1945), and Karl Jaspers' *Die grossen Philosophen* (1957; *The Great Philosophers*).

These two different types of ordering depend for their validity upon an appeal to two different principles about the nature of ideas, but their incidental use may also be influenced by social or cultural factors. Thus the biographers and compilers of late antiquity (among them, Plutarch, Sextus Empiricus, Philostratus, and Clement of Alexan-

Comparison with art: living classics

Stress on ideas versus stress on men

dria), impressed by the religious pluralism of the age in which they lived, thought of philosophers, too, as falling into different sects and wrote histories of the Sophists, the Skeptics, the Epicureans, and other such schools; whereas almost 2,000 years later, Hegel—living in a period of Romantic historiography dominated by the concept of the great man in history—deliberately described the history of philosophy as “a succession of noble minds, a gallery of heroes of thought.”

Moving between these two ordering principles, the article below will be eclectic (as has come to be the custom), devoting chief attention to outstanding major figures, while joining more minor figures, wherever possible, into the schools or tendencies that they exemplify.

Factors in writing the history of philosophy. The type of ordering suggested above also has some relationship to the more general problems of method in the writing of the history of philosophy. Here there are at least three factors that must be taken into account: (1) the historian must understand how (at least in part) any philosopher's doctrines depend upon those of his predecessors; (2) he must understand that a man's philosophy occurs at a certain point in history and, thus, how it expresses the effects of certain social and cultural circumstances; and (3) he must understand how in part it stems from the philosopher's own personality and situation in life. This is only to say that the history of philosophy, to be at all comprehensive and adequate, must deal with the mutual interplay of ideas, of cultural contexts, and of agents.

Logical,
socio-
logical,
and
individual
factors

The first factor may be called logical because a given philosophy is, in part, the intellectual response to the doctrines of its forerunners, taking as central the problems given by the current climate of controversy. Thus, many of the details of Aristotle's ethical, political, and metaphysical systems arise in arguments directed against statements and principles of Plato; much of *An Essay Concerning Human Understanding* (1690) by John Locke, an initiator of the Enlightenment, is directed against current Cartesian presuppositions; and the *Nouveaux essais sur l'entendement humain* (1704; *New Essays Concerning Human Understanding*) by Gottfried Wilhelm Leibniz, a broadly learned Rationalist, is, in turn, specifically directed against Locke.

The second factor may be called sociological because it considers philosophy, at least in part, as a direct form of social expression, arising at a certain moment in history, dated and marked by the peculiar problems and crises of the society in which it flourishes. From this perspective, the philosophy of Plato may be viewed as the response of an aristocratic elitism to the immediate threat of democracy and the leveling of values in 5th-century Athens—its social theory and even its metaphysics servicing the thrust toward an aristocratic restoration in the Greek world. Thus, the philosophy of St. Thomas Aquinas may be viewed as an effort toward doctrinal clarification in support of the institution of the medieval Roman Church, as the saint spent his life obediently fulfilling the philosophical tasks set for him by his superiors in the church and the Dominican order. Thus, the philosophy of Kant, with all of its technical vocabulary and rigid systematization, may be viewed as an expression of the new professionalism in philosophy, a clear product of the rebirth of the German universities during the 18th-century Enlightenment.

The third factor may be called biographical, or individual, because, with Hegel, it recognizes that philosophies are generally produced by men of unusual or independent personality, whose systems usually bear the mark of their creators. And what is meant here by the individuality of the philosopher lies less in the facts of his biography (such as the wealth or poverty, the married state or bachelorhood that he shares with other men) than in the essential form and style of his philosophizing. The cool intensity of Spinoza's geometric search for wisdom, the unswerving (if opaque) discursiveness of Hegel's quest for completeness or totality, the relentless and minute analytic search for distinctions and shades of meaning that marks Moore's master passion (“to be accurate—to get everything exactly right”), these qualities mark the philosophical writings of Spinoza, Hegel, and Moore with an unmistakably individual and original character.

Shifts in the focus and concern of philosophy. Any adequate treatment of individual figures in the history of philosophy tries to utilize this threefold division of logical, sociological, and individual factors; but in a synoptic view of the history of philosophy in the West, one is particularly aware of the various shifts of focus and concern that philosophy has sustained and, indeed, of the often profound differences in the way that it defines itself or visualizes its task from age to age or from generation to generation.

Philosophy among the Greeks slowly emerged out of religious awe into wonder about the principles and elements of the natural world. But as the Greek populations more and more left the land to become concentrated in their cities, interest shifted from nature to social living; questions of law and convention and civic values became paramount. Cosmological speculation partly gave way to moral and political theorizing, and the preliminary and somewhat fragmentary questionings of Socrates and the Sophists turned into the great positive constructions of Plato and Aristotle. With the political and social fragmentation of the succeeding centuries, however, philosophizing once again shifted from the norm of civic involvement to problems of salvation and survival in a chaotic world.

The dawn of Christianity brought to philosophy new tasks. Augustine, the philosophical bishop of Hippo, and the Church Fathers used such resources of the Greek tradition as remained (chiefly Platonism) to deal with problems of the creation, of faith and reason, and of truth. New translations in the 12th century made much of Aristotle's philosophy available and prepared the way for the great theological constructions of the 13th century, chiefly those of the Scholastic philosophers Bonaventure, Albertus Magnus, Thomas Aquinas, Roger Bacon, and Duns Scotus. The end of the Middle Ages saw a new flowering of the opposite tendencies in the Nominalist William of Ockham and the mystic Meister Eckhart.

Medieval
and
modern
history

The Middle Ages gave way to the Renaissance. Universalism was replaced by nationalism. Philosophy became secularized. The great new theme was that of the mystery and immensity of the natural world. The best philosophical minds of the 17th century turned to the task of exploring the foundations of physical science, and the symbol of their success—the great system of Newton's physics—turned the philosophers of the Enlightenment to epistemology and to the examination of the human mind that had produced so brilliant a scientific creation. The 19th century, a time of great philosophical diversity, discovered the irrational and in so doing prepared the way for the oppositions between Analysis and Phenomenology and between Positivism and Existentialism that characterize 20th-century philosophy.

Although the foregoing capsule presentation of the history of philosophy in the West follows a strict chronology, it does not do justice to the constant occurrence and recurrence of dominant strands in the history of thought. It would also be possible to write the philosophical history of the Middle Ages simply by noting the complicated occurrence of Platonic and Aristotelian doctrines, of the Renaissance according to the reappearance of Greek Materialism, Stoicism, and Skepticism, and of the 18th century in terms of the competing claims of Rationalist and Empiricist principles. Thus, chronology and the interweaving of philosophical systems cooperate in a history of philosophy. (A.W.L.)

Ancient Greek and Roman philosophy

THE PRE-SOCRATIC PHILOSOPHERS

Cosmology and the metaphysics of matter. Because the earliest Greek philosophers focused their attention upon the origin and nature of the physical world, they are often called cosmologists or naturalists. Though monistic views (which trace the origins of the world to a single substance) prevailed at first, they were soon followed by several pluralistic theories (which trace it to several ultimate substances).

Monistic cosmologies. There is a consensus, dating back at least to the 4th century BC and continuing to the present, that the first Greek philosopher was Thales of

Thales of
Miletus

Miletus, who flourished in the first half of the 6th century BC. At that time the word *philosopher* ("lover of wisdom") had not yet been coined. Thales was counted, however, among the Seven Wise Men (Sophoi), whose name derives from a term that then designated inventiveness and practical wisdom rather than speculative insight. Thales showed these qualities by trying to give the mathematical knowledge that he derived from the Babylonians a more exact foundation and by using it for the solution of practical problems—such as the determination of the distance of a ship as seen from the shore or of the height of the Pyramids. Though he was also credited with predicting an eclipse of the Sun, it is likely that he merely gave a natural explanation of one on the basis of Babylonian astronomical knowledge.

Thales was considered the first Greek philosopher because he was the first to give a purely natural explanation of the origin of the world, free from all mythological ingredients. He upheld that everything had come out of water—an explanation based on the discovery of fossil sea animals far inland. His tendency (and that of his immediate successors) to give nonmythological explanations of the origin of the world was undoubtedly prompted by the fact that all of them lived on the coast of Asia Minor surrounded by a number of nations whose civilizations were much farther advanced than that of the Greeks and whose mythological explanations differed greatly both among themselves and from those of the Greeks. It appeared necessary, therefore, to make a fresh start on the basis of what a person could observe and figure out by looking at the world as it presented itself. This procedure naturally resulted in a tendency to make sweeping generalizations on the basis of rather restricted but carefully checked observations.

Thales' disciple and successor, Anaximander of Miletus (mid-6th century), tried to give a more elaborate account of the origin and development of the ordered world (the cosmos). According to him, it developed out of the *apeiron*, something both infinite and indefinite (without distinguishable qualities). Within this *apeiron* something arose to produce the opposites of hot and cold. These at once began to struggle with each other and produced the cosmos. The cold (and wet) partly dried up (becoming solid earth), partly remained (as water), and—by means of the hot—partly evaporated (becoming air and mist), its evaporating part (by expansion) splitting up the hot into fiery rings, which surround the whole cosmos. Because these rings are enveloped by mist, however, there remain only certain breathing holes that are visible to men, appearing to them as Sun, Moon, and stars. Anaximander was the first to realize that upward and downward are not absolute but that downward means toward the middle of the Earth and upward away from it, so that the Earth had no need to be supported (as Thales had believed) by anything. Starting from Thales' observations, Anaximander tried to reconstruct the development of life in more detail. Life, being closely bound up with moisture, originated in the sea. All land animals, he held, are descendants of sea animals; because the first humans as newborn infants could not have survived without parents, Anaximander believed that they were born within an animal of another kind—specifically, a sea animal in which they were nurtured until they could fend for themselves. Gradually, however, the moisture will be partly evaporated, until in the end all things will have returned into the undifferentiated *apeiron*, "in order to pay the penalty for their injustice"—that of having struggled against one another.

Anaximander's successor, Anaximenes of Miletus (second half of the 6th century), taught that air was the origin of all things. His position was for a long time thought to have been a step backward because, like Thales, he placed a special kind of matter at the beginning of the development of the world. But this criticism missed the point. Neither Thales nor Anaximander appear to have specified the way in which the other things arose out of the water or *apeiron*. Anaximenes, however, declared that the other types of matter arose out of air by condensation and rarefaction. In this way, what to Thales had been merely a beginning became a fundamental principle that remained essentially the same through all of its transmuta-

tions. Thus, the term *arche*, which originally simply meant "beginning," acquired the new meaning of "principle," a term that henceforth played an enormous role in philosophy down to the present. This concept of a principle that remains the same through many transmutations is, furthermore, the presupposition of the idea that nothing can come out of nothing and that all of the comings to be and passings away that men observe are nothing but transmutations of something that essentially remains the same eternally. In this way it also lies at the bottom of all of the conservation laws—those of the conservation of matter, of force, and of energy—that have been basic in the development of physics. Though Anaximenes of course did not realize all of the implications of his idea, its importance can hardly be exaggerated.

The first three Greek philosophers have often been called *hylozoists* because they seemed to believe in a kind of living matter. But this is hardly an adequate characterization. It is, rather, characteristic of them that they did not clearly distinguish between kinds of matter, forces, and qualities nor between physical and emotional qualities. The same entity is sometimes called fire and sometimes the hot. Heat appears sometimes as a force and sometimes as a quality, and again there is no clear distinction between warm and cold as physical qualities and the warmth of love and the cold of hate. To realize these ambiguities is important to an understanding of certain later developments in Greek philosophy.

Xenophanes of Colophon (born c. 560 BC), a rhapsodist and philosophical thinker who emigrated from Asia Minor to Elea in southern Italy, was the first to bring out more clearly what was implied in Anaximenes' philosophy. He criticized the popular notions of the gods, saying that men made their gods in their own image. But, more importantly, he argued that there could be only one God, the ruler of the universe, who must be eternal. For, being the strongest of all beings, he could not have come out of something less strong, nor could he be overcome or superseded by something else, because nothing could arise that is stronger than the strongest. The argument clearly rested on the axiom that nothing can come out of nothing and that nothing that is can really vanish.

This axiom was made more explicit and carried to its extreme consequences by Parmenides of Elea (first half of the 5th century BC), the founder of the so-called school of Eleaticism, of whom Xenophanes has been regarded as the teacher and forerunner. In a philosophical poem Parmenides insisted that "what is" cannot have come into being and cannot pass away because it would have to have come out of nothing or to become nothing, whereas nothing by its very nature does not exist. There can be no motion either; for it would have to be a motion into something that is—which is not possible since it would be blocked—or a motion into something that is not—which is equally impossible since what is not does not exist. Hence everything is solid immobile being. The familiar world, in which things move around, come into being, and pass away, is a world of mere belief (*doxa*). In a second part of the poem, however, Parmenides tried to give an analytical account of this world of belief, showing that it rested on constant distinctions between what is believed to be positive—i.e., to have real being, such as light and warmth—and what is negative—i.e., the absence of positive being, such as darkness and cold.

It is significant that Heraclitus of Ephesus, a contemporary of Parmenides, whose philosophy was later considered to be the very opposite of Parmenides' philosophy of immobile being, came, in some fragments of his work, near to what Parmenides tried to show: the positive and the negative, he said, are merely different views of the same thing; death and life, day and night, or light and darkness are really one.

Pluralistic cosmologies. Parmenides had an enormous influence on the further development of philosophy. Most of the philosophers of the following two generations tried to find a way to reconcile his thesis that nothing comes into being nor passes away with the evidence presented to men by their senses. Empedocles of Acragas (mid-5th century) declared that there are four material elements

Xenophanes and Parmenides

Anaximander of Miletus

(he called them roots of everything) and two forces, love and hate, that did not come into being and would never pass away or increase or diminish. But the elements are constantly mixed with one another by love and again separated by hate. Thus, through mixture and decomposition composite things come into being and pass away. Because he conceived of love and hate as blind forces, Empedocles had to explain how through random motion living beings could emerge. This he achieved by means of a somewhat crude anticipation of the theory of the survival of the fittest. In the process of mixture and decomposition the limbs and parts of various animals would be formed by chance. But they could not survive. Only when by chance they had come together in such a way that they were able to support and reproduce themselves would they survive. It was in this way that the various species were produced and continued to exist.

Anaxagoras of Clazomenae, a 5th-century pluralist, believed that because nothing can really come into being, everything must be contained in everything, but in the form of infinitely small parts. In the beginning all of these particles had been mixed in an even mixture, in which nothing could be distinguished, much like the indefinite apeiron of Anaximander. But then nous, or intelligence, began at one point to set these particles into a whirling motion, foreseeing that in this way they would become separated from one another and then recombine in the most various ways so as to produce gradually the world in which men live. In contrast to the forces assumed by Empedocles, the nous of Anaxagoras is not blind but foresees and intends the production of the cosmos, including living and intelligent beings; but it does not interfere with the process after having started the whirling motion. This is a strange combination of a mechanical and a nonmechanical explanation of the world.

Leucippus
and
Democritus

By far of greatest importance for the later development of philosophy and physical science was an attempt by the Atomists Leucippus (mid-5th century) and (in the following generation) Democritus to solve the Parmenidean problem. Leucippus found the solution in the assumption that, contrary to Parmenides' argument, the nothing *does* in a way exist, viz., as empty space. There are then, however, only two fundamental principles of the physical world, empty space and filled space—the latter consisting of atoms that, in contrast to those of modern physics, are real atoms; that is, they are absolutely indivisible because nothing can penetrate to split them. On these foundations, laid by Leucippus, Democritus appears to have built a whole system, aiming at a complete explanation of the varied phenomena of the visible world by means of an analysis of its atomic structure. This system begins with elementary physical problems, such as that of why a hard body can be lighter than a softer one. The explanation is that, although the heavier body contains more atoms, they are equally distributed and of round shape; the lighter body, however, has fewer atoms, most of which have hooks by which they form rigid gratings. The system ends with educational and ethical questions. A sound and cheerful man, useful to his fellowmen, is literally well composed. Although destructive passions involve violent long-distance atomic motions, education can help to contain them, creating a better composure. Democritus also developed a theory of the evolution of culture, which influenced later thinkers. Civilization, he thought, is produced by the needs of life, which compel man to work and to make inventions. When life becomes too easy because all needs are met, there is a danger that civilization will decay as men become unruly and negligent.

Epistemology of appearance. All of the post-Parmenidean philosophers, like Parmenides himself, presupposed that the real world is different from the one that men perceive. Thus the problems of epistemology, or theory of knowledge, arose. According to Anaxagoras, everything is contained in everything. But this is not what people perceive. He solved this problem, however, by assuming that, if there is a much greater amount of one kind of particle in a thing than of all other kinds, the latter are not perceived at all. The observation was then made that sometimes different persons or kinds of animals have

different perceptions of the same things. He explained this phenomenon by assuming that like is perceived by like. If, therefore, in the sense organ of one person there is less of one kind of stuff than of another, he will perceive the former less keenly than the latter. This reasoning was also used to explain why some animals see better by night and others by daylight. According to Democritus, the atoms have no sensual qualities such as tastes, smells, or colours at all. Thus, he tried to reduce all of them to tactile qualities (explaining a bright white colour, for instance, as sharp atoms hitting the eye like needles), and he made a most elaborate attempt to reconstruct the atomic structure of things on the basis of their apparent sensual qualities.

Also of very great importance in the history of epistemology was Zeno of Elea (mid-5th century), a younger friend of Parmenides. Parmenides had, of course, been severely criticized because of the strange consequences of his doctrine that in reality there is no motion and no plurality either because there is just one solid being. To support him, however, Zeno tried to show that the assumption that there is motion and plurality leads to consequences that are no less strange. This he did by means of his famous paradoxes, saying that the flying arrow rests since it can neither move in the place in which it is nor in a place in which it is not and that Achilles cannot outrun a turtle because when he has reached its starting point, the turtle will have moved to a further point, and so on ad infinitum—that, in fact, he cannot even start running, for, before traversing the stretch to the starting point of the turtle, he will have to traverse half of it and again half of that and so on ad infinitum. All of these paradoxes are derived from the problem of the continuum. Although they have often been dismissed as logical nonsense, many attempts have also been made to dispose of them by means of mathematical theorems, such as the theory of convergent series or the theory of sets. In the end, however, the difficulties inherent in his arguments have always come back with a vengeance, for the human mind is so constructed that it can look at a continuum in two ways that are not quite reconcilable.

Zeno of
Elea

Metaphysic of number. All of the philosophies mentioned so far are in various ways historically akin to one another. Toward the end of the 6th century, however, there arose quite independently another kind of philosophy, which only later entered into interrelation with the developments just mentioned: the philosophy of Pythagoras of Samos. Pythagoras traveled extensively in the East and in Egypt and, after his return to Samos, emigrated to southern Italy because of his dislike of the tyranny of Polycrates. At Croton and Metapontum he founded a philosophical society with strict rules and soon gained considerable political influence. He appears to have brought his doctrine of the transmigration of souls from the East. Much more important for the history of philosophy and science, however, was his doctrine that "all things are numbers," which means that the essences and structures of all things can be determined by finding the numerical relations contained in them. Originally, this, too, was a very broad generalization made on the basis of comparatively few observations: for instance, that the same harmonies can be produced with different instruments—strings, pipes, disks, etc.—by means of the same numerical ratios—1:2, 2:3, 3:4—in one-dimensional extensions; the observation that certain regularities exist in the movements of the celestial bodies; and the discovery that the form of a triangle is determined by the ratio of the lengths of its sides. But because the followers of Pythagoras tried to apply their principle everywhere with the greatest of accuracy, one of them—Hippasus of Metapontum—about 450 BC made one of the most fundamental discoveries of the entire history of science, that of incommensurability, viz., that the quantitative relation between the side and diagonal of such simple figures as the square and the regular pentagon cannot be expressed as a ratio of integers. At first sight this discovery seemed to destroy the very basis of the Pythagorean philosophy, and the school thus split into two sections, one of which engaged in rather abstruse numerical speculations while the other succeeded in overcoming the difficulty by ingenious mathematical inven-

Pythagoras of
Samos

tions and laid the foundations of all quantitative science. Pythagorean philosophy also exerted a great influence on the development of Plato's thought in his later years.

The speculations described so far constitute in many ways the most important part of the history of Greek philosophy because all of the most fundamental problems of Western philosophy turned up here for the first time and one finds here the formation of a great many concepts that have continued to dominate Western philosophy and science to the present day.

Anthropology and relativism. In the middle of the 5th century BC, Greek thinking took a somewhat different turn through the advent of the Sophists. The name is derived from the verb *sophizesthai*, "making a profession of being inventive and clever," and aptly described the Sophists, who, in contrast to the philosophers mentioned so far, asked money for their instruction. Philosophically they were, in a way, the leaders of a rebellion against the preceding development, which more and more had resulted in the belief that the real world is quite different from the phenomenal world. "What is the sense of such speculations?" they asked, since men do not live in these so-called real worlds. This is the meaning of the pronouncement of Protagoras of Abdera (mid-5th century) that "Man is the measure of all things, of those which are that they are and of those which are not that they are not." For man the world is what it appears to him to be, not something else; and, though he meant man in general, he illustrated it by pointing out that even in regard to an individual man it makes no sense to tell him that it is really warm when he is shivering with cold, because for him it is cold—for him, the cold exists, is there.

His younger contemporary Gorgias of Leontini, famous for his treatise on the art of oratory, made fun of the philosophers in a book *Peri tou mē ontos ē peri physeōs* ("On that which is not, or on Nature"), in which—referring to the "truly existing world," also called "the nature of things"—he tried to prove (1) that nothing exists, (2) that if something existed, man could have no knowledge of it, and (3) that if nevertheless somebody knew it, he could not communicate his knowledge to others.

The Sophists were not only skeptical of what had by then become a philosophical tradition but also of other traditions. On the basis of the observation that different nations have different rules of conduct even in regard to things considered most sacred—such as the relations between the sexes, marriage, and burial—they concluded that most rules of conduct are conventions. What is really important is to be successful in life and to gain influence on others. This they promised to teach. Gorgias was proud of the fact that, having no knowledge of medicine, he was more successful in persuading a patient to undergo a necessary operation than his brother, a physician, who knew when an operation was necessary. The older Sophists, however, were far from openly preaching immoralism. They, nevertheless, gradually came under suspicion because of their sly ways of arguing. One of the later Sophists, however, Thrasymachus of Chalcedon (late 5th century), was bold enough to declare openly that "right is what is beneficial for the stronger or better one"; that is, for the one able to win the power to bend others to his will.

THE SEMINAL THINKERS OF GREEK PHILOSOPHY

Socrates. By many of his contemporaries, Socrates (5th century BC) was also considered to be a Sophist because of his tricky arguments, though he did not teach for money and his aims were entirely different from theirs. Although there is a late tradition according to which Pythagoras invented the word *philosopher*, it was certainly through Socrates—who insisted that he possessed no wisdom but was striving for it—that the term came into general use and was later applied to all earlier serious thinkers. In fact, all of the records of his life and activity left by his numerous adherents and disciples indicate that he never tried to teach anything directly. But he constantly engaged in conversations with everybody—old and young, high and low—trying to bring into the open by his questions the inconsistencies in their opinions and actions. Though he never taught directly, his whole activity rested on two

unshakable premises: (1) the principle never to do wrong nor to participate, even indirectly, in any wrongdoing and (2) the conviction that nobody who really knows what is good and right could act against it. He demonstrated his unshakable adherence to the first principle on various occasions and under different regimes. When, after the Battle of Arginusae, the majority of the Athenian popular assembly demanded death without trial for the admirals, Socrates, who on that day happened to be president of the assembly (an office changing daily), refused to put the proposal to the vote because it was wrong to condemn anyone without a fair trial. He refused to do so even though the people threatened him, shouting that it would be terrible if the sovereign people could not do as they pleased.

When, after the overthrow of democracy, the so-called Thirty Tyrants, who tried to involve everybody in their wrongdoings, ordered him to arrest an innocent citizen whose money they coveted, he simply disobeyed. This he did although at that time such disobedience was still more dangerous than disobeying the sovereign people had been at the time of unrestricted democracy. Likewise, in the time of the democracy he pointed out by his questions the inconsistency of allowing oneself to be swayed by the oratory of a good speaker instead of first inquiring into his capability as a statesman, whereas in private life a sensible citizen would not listen to the oratory of a quack but would try to find the best doctor. When, after the overthrow of democracy, the Thirty Tyrants had many people arbitrarily executed, he asked everybody whether a man was a good shepherd who diminished the number of the sheep instead of increasing it and did not cease doing so when Critias, the leader of the Thirty, warned him to take heed not to diminish the number of the sheep by his own, Socrates', person. But the most fundamental inconsistency that he tried to show up everywhere was that most people by their actions showed that they considered what they found to be good, wonderful, and beautiful in others—such as, for instance, doing right at great danger to oneself—not to be good for themselves, and considered to be good for themselves what they despised and condemned in others. Though all of these stands won him the most fervent admiration of many, especially among the young of all classes, it caused also great resentment among leading politicians, whose inconsistencies were shown up publicly by him and his adherents. Though Socrates had survived unharmed through the regime of the Thirty—partly because it did not last long, partly because he was supported by some close relatives of their leader Critias—it was under the restored democracy that he was accused of impiety and of corrupting the youth and finally condemned to death, largely also in consequence of his intransigent attitude during the trial.

After Socrates' death his influence became a dominating one through the greater part of Greek and Roman philosophy down to the end of antiquity and was more or less noticeable even in all of the rest. Many of his adherents—among them Xenophon, a military man and a historian, and Aeschines of Sphettus, one of those present at his death—tried to preserve his philosophical method by writing Socratic dialogues. Some founded schools or sects that perpetuated themselves over long periods of time, Euclides of Megara emphasizing the theoretical aspects of Socrates' thought, and Antisthenes stressing the independence of the true philosopher from material wants. The latter, through his disciple Diogenes of Sinope, who carried voluntary poverty to the extreme and emphasized freedom from all conventions, became the founder of the sect of the Cynics. Aristippus of Cyrene, traditional founder of the Cyrenaic school, stressed man's independence from material needs in a somewhat different way, declaring that there is no reason why a philosopher should not enjoy material goods as long as he is completely indifferent to their loss. Though Aristippus renounced his son because he led a dissolute life, the school that he founded (through his daughter and his grandson) was hedonistic, holding pleasure to be the good.

Plato. By far the most important disciple of Socrates, however, was Plato, a scion of one of the most noble Athenian families, who could trace his ancestry back to

The
Sophists

Founding
of schools
and sects

the last king of Athens and to Solon, the great social and political reformer.

Life. As a very young man Plato became a fervent admirer of Socrates in spite of the latter's plebeian origin. Contrary to his master, however, who always concerned himself with the attitudes of individuals, he believed in the importance of political institutions. In his early youth he had observed that the Athenian masses, listening to the glorious projects of ambitious politicians, had engaged in foolhardy adventures of conquest, which led in the end to total defeat in the Peloponnesian War. When, in consequence of the disaster, democracy was abolished, Plato at first set great hopes in the Thirty Tyrants—especially since their leader, Critias, was a close relative. But he soon discovered that—to use his own words—the despised democracy had been gold in comparison with the new terror. When the oligarchy was overthrown and the restored democracy, in 399, adopted a new law code—in fact, a kind of written constitution containing safeguards against rash political decisions—Plato again had considerable hope and was even inclined to view the execution of Socrates as an unfortunate incident rather than a logical consequence of the new regime. It was only some years later, when demagogy appeared to raise its head again, that he “despaired and was forced to say that things would not become better in politics unless the philosophers would become rulers or the rulers philosophers.” He wrote a dialogue, the *Gorgias*, violently denouncing political oratory and propaganda and then traveled to southern Italy in order to study political conditions there. Again, however, he found the much vaunted dolce vita of the Greeks there, in which the rich lived in luxury exploiting the poor, much worse than the democracy at Athens. But at Syracuse he met a young man, Dion, brother-in-law of the ruling tyrant, Dionysius I, who listened eagerly to his political ideas and promised to work for their realization if any occasion should arise. On his return to Athens, Plato founded the Academy, an institution for the education of philosophers, and in the following years elaborated, besides other dialogues, his great work, *Politeia* (*The Republic*), in which he drew the outlines of an ideal state. Because it is the passions and desires of men that cause all disturbances in society, the state must be ruled by an elite governed exclusively by reason and supported by a class of warriors entirely obedient to them. Both ruling classes must have no individual possessions and no families and lead an extremely austere life, receiving the necessities of life from the working population, which alone is permitted to own private property. The elite receives a rigid education to fit it for its task. At the death of Dionysius I, Dion induced Plato to come to Syracuse again to try to persuade Dionysius' successor to renounce his power in favour of a realization of Plato's ideals. But the attempt failed, and in his later political works, the *Politicus* (*Statesman*) and the *Nomoi* (*Laws*), Plato tried to show that only a god could be entrusted with the absolute powers of the philosopher-rulers of his *Politeia*. Human rulers must be controlled by rigid laws, he held—though all laws are inevitably imperfect because life is too varied to be governed adequately by general rules. But the *Nomoi* still placed strict restrictions on the ownership of property.

Philosophy. In the field of theoretical philosophy, Plato's most influential contribution was undoubtedly his theory of Ideas, which he derived from Socrates' method in the following way: Socrates, in trying to bring out the inconsistencies in his interlocutors' opinions and actions, had often asked what it is that makes men say that a certain thing or action is good or beautiful or pious or brave; and he had asked what people are looking at when they make such statements. Plato sometimes made Socrates ask what is the Eidos, or the Idea—i.e., the image—that a person has before him when he calls something “good.” A definite answer is never given, however, because no abstract definition would be adequate, the purpose being rather to make the interlocutor aware of the fact that he somehow does look at something undefinable when making such statements.

What was at first simply a way of somehow expressing something that is difficult to express developed into a

definite theory of Ideas when Plato made the discovery that something similar could be observed in the field of mathematics. No two things in the visible world are perfectly equal, just as there is nothing that is perfectly good or perfectly beautiful. Yet equality is one of the most fundamental concepts not only in mathematics but also in everyday life—the foundation of all measurement. Hence, like the notion of the good and the beautiful, it appears to come from a different world, a world beyond that of the senses, a world that Plato then called the world of Ideas. Further intimations of such a realm beyond the immediate realm of the senses may be found in the fact that men, in construing a system of knowledge, constantly prefer what is more perfect to what is less perfect; i.e., what is formed and thus recognizable to what is not, what is true to what is false, a sound logical conclusion to a logical fallacy, even an elegant scientific demonstration to a clumsy one, without considering the former as good and the latter as bad.

According to Plato, all of the things that men perceive with their senses appear to be but very imperfect copies of the eternal Ideas. The most important and fundamental one of these is the Idea of the Good. It is “beyond being and knowledge,” yet it is the foundation of both. “Being” in this connection does not mean existence, but being something specific—a man, a lion, or a house—being recognizable by its quality or shape.

Knowledge begins with a perception of these earthly shapes, but it ascends from there to the higher realm of Ideas, which is approachable to the human mind. In the famous myth of the cave in the seventh book of *Politeia*, Plato likened the ordinary person to a man sitting in a cave looking at a wall on which he sees nothing but the shadows of the real things that are behind his back, and he likened the philosopher to a man who has got out in the open and seen the real world of the Ideas. Coming back, he may be less able to distinguish the shades because he has been blinded by the light outside; but he is the only one who knows reality, and he conducts his life accordingly.

In his later thinking, in *Theaetetus*, Plato criticized a sensualist theory of knowledge, anticipating the explanations of the 17th-century English sensualists, such as Thomas Hobbes. In the *Timaeus*, he tried to build up a complete system of physics, partly employing Pythagorean ideas. Most modern Positivists do not take Plato seriously any longer. But one of the greatest physicists of the 20th century, Werner Heisenberg, has insisted that the modern physicist still has to learn a good deal from Plato concerning the foundation of his science.

Aristotle. After Plato's death the Academy continued to exist for many centuries under various heads. When Plato's nephew, Speusippus, was elected as his successor, his greatest disciple, Aristotle, left to go first to Assus and then to the island of Lesbos, where he met Theophrastus, who became his most gifted disciple. But soon thereafter he was called to the Macedonian court at Pella to become the educator of the crown prince, who was later to become Alexander the Great. After the latter had become king, Aristotle returned to Athens and opened there a school of his own, whose members became known as the Peripatetics.

Philosophy. Aristotle had become a member of the Academy at the age of 17, in the year 367 (during Plato's absence in Sicily), under the acting chairmanship of Eudoxus of Cnidus, a great mathematician and geographer. It is a controversial question as to how far Aristotle, during the 20 years of his membership in the Academy, developed a philosophy of his own differing from that of his master. But two things can be considered as certain: (1) that he soon raised certain objections to Plato's theory of Ideas, for one of the arguments against it attributed to him is discussed in Plato's dialogue *Parmenides*, which Plato must have written soon after his return from Sicily, and (2) that it was during his membership in the Academy that Aristotle began and (to a considerable extent) elaborated his theoretical and formal analysis of the arguments used in various Socratic discussions—an enterprise that (when completed) resulted in the corpus of his works on logic,

Theory of
Ideas

a new science, which Aristotle himself claimed to have originated and about which (until rather recent times) it used to be said that he completed it in such a way that hardly anything could be added.

Certainly quite some time before his return to Athens to open a school of his own, Aristotle declared that it is not necessary to assume the existence of a separate realm of transcendent Ideas of which the individual things that men perceive with their senses are but imperfect copies; that the world of perceived things is the real world; and that it is necessary merely to be able to say that something is generally true of certain types or groups of things in order to build up a system of knowledge about them. Thus, it would be wrong to say that, having abandoned the theory of Ideas, Aristotle was left with a completely contingent world. The last chapters of his *Analytica posteriora* (*Posterior Analytics*) show, on the contrary, that he merely replaced Plato's transcendent Ideas with something (*katholou*) corresponding to them that the human mind can grasp in individual things.

Teleology
and
perfection

Aristotle retained another important element of the theory of Ideas in his teleology, or doctrine of purposiveness. According to Plato, individual things are imperfect copies of perfect Ideas. Aristotle pointed out, however, that all living beings develop from an imperfect state (from the seed, the semen, through the germinating plant, or embryo, to the child and young adult), to the more perfect state of the fully developed plant or the full grown mature animal or man—after which they again decay and finally die, having reproduced themselves. But not all individuals reach the same degree of relative perfection. Many of them die before reaching it; others are retarded or crippled or maimed in various ways in the process. It is, therefore, of the utmost importance for man to find out what the best conditions are for reaching the most perfect state possible. This is what the gardener tries to do for the plants; but it is even more important for man to do it in regard to himself. The first question, then, is what kind of perfection a human being as human can reach. In answering this question Aristotle observed that man, being the social animal par excellence, can reach as an individual only some of the perfections possible for man as such. Cats are more or less all alike in their functions; thus each can fend for itself. With bees and termites, however, it is different. They are by nature divided into worker bees, drones, and queen bees or worker termites, soldier termites, and queens. With human beings the differentiation of functions is much more subtle and varied. Men can lead satisfactory lives only on the basis of a division of labour and distribution of functions. Some human individuals are born with very great talents and inclinations for special kinds of activity. They will be happy and will make their best possible contribution to the life of the community only if they are permitted to follow this inclination. Others are less one-sidedly gifted and more easily adaptable to a variety of functions. These people can be happy shifting from one activity to another. That this is so is an enormous advantage the human species has over all other animals because it enables it to adapt to all sorts of circumstances. But the advantage is paid for by the fact that no human individual is able to develop all of the perfections that are possible for the race as a whole.

There is another possible and, in its consequences, real disadvantage to such adaptability; the other animals, tightly confined to the limits set by nature, are crippled almost exclusively by external factors; but man, in consequence of the freedom of choice granted to him through the variety of his gifts, can and very often does cripple and harm himself. All human activities are directed toward the end of a good and satisfactory life. But there are many subordinate aims that are sensible ends only as far as they serve a superior end. There is, for example, no sense in producing or acquiring more shoes than can possibly be worn. This is self-evident. With regard to money, however, which has become exchangeable against everything, the illusion arises that it is good to accumulate it without limit. By doing so, man harms both the community and himself because, concentrating on such a narrow aim, he deprives his soul and spirit of larger and more rewarding

experiences. Similarly, an individual especially gifted for large-scale planning needs power to give orders to those capable of executing his plans. Used for such purposes, power is good. But coveted for its own sake, it becomes oppressive to those subdued by it and harmful to the oppressor because he thus incurs the hatred of the oppressed. Because of his imperfection man is not able to engage in serious and fruitful activities without interruption. He needs relaxation and play, or amusement. Because the necessities of life frequently force man to work beyond the limit within which working is pleasant, the illusion arises that a life of constant amusement would be the most pleasant and joyful. In reality nothing is more tedious.

Aristotle's teleology seems to be based entirely on empirical observation. It has nothing to do with a belief in divine providence and is not, as some modern critics believe, at variance with the law of causality. It forms the foundation, however, of Aristotle's ethics and political theory. Aristotle was an avid collector of empirical evidence. He induced his students, for instance, to make collections of the laws and political institutions (and their historical developments) of all known cities and nations in order to find out how they worked and at what points their initiators had been mistaken regarding the way in which they would work. In later times, Aristotle came to be considered (and by many is still considered) a dogmatic philosopher because the results of his inquiries were accepted as absolutely authoritative. In reality, however, he was one of the greatest Empiricists of all times.

Disciples and commentators. After Aristotle's death his immediate disciples carried on the same kind of work, especially in the historical field: Theophrastus wrote a history of philosophy and works on botany and on mineralogy, Eudemus of Rhodes wrote histories of mathematics and of astronomy, Meno a history of medicine, and Dicaearchus of Messene a history of civilization and a book on types of political constitutions. The next two generations of Peripatetics spread out in two different directions: literary history, in the form of histories of types of poetry, epic, tragedy, and comedy, and of biographies of famous writers, and physical science, Straton of Lampsacus creating a new kind of physics based on experiments, and the great astronomer Aristarchus of Samos inventing the heliocentric system. The school then went for some time into eclipse until, in the 1st century AD, after the rediscovery of Aristotle's lecture manuscripts, there arose a great school of commentators on his works, which had an enormous influence on medieval philosophy.

HELLENISTIC AND ROMAN PHILOSOPHY

The period after the death of Aristotle was characterized by the decay of the Greek city-states, which then became pawns in the power game of the Hellenistic kings who succeeded Alexander. Life became troubled and insecure. It was in this environment that two dogmatic philosophical systems came into being, the Stoic and the Epicurean, which were destined to give their adherents something to hold onto and to make them independent of the external world.

Stoics. The Stoic system was created by a Syrian, Zeno of Citium (about the turn of the 3rd century BC), who went to Athens as a merchant but lost his fortune at sea. Zeno was consoled by the Cynic philosopher Crates, who taught him that material possessions were of no importance whatsoever for a man's happiness. He therefore stayed at Athens, heard the lectures of various philosophers, and—after he had elaborated his own philosophy—began to teach in a public hall, the Stoa Poikile (hence the name Stoicism).

Zeno of
Citium

Zeno's thought comprised, essentially, a dogmatized Socratic philosophy, with added ingredients derived from Heraclitus. The basis of human happiness, he said, is to live "in agreement" (with oneself), a statement that was later replaced by the formula "to live in agreement with nature." The only real good for man is the possession of virtue; everything else (wealth or poverty, health or illness, life or death) is completely indifferent. All virtues are based exclusively on right knowledge—self-control (*sōphrosynē*) being the knowledge of the right

choice, fortitude the knowledge of what must be endured and what must not, and justice the right knowledge “in distribution.” The passions, which are the cause of all evil, are the result of error in judging what is a real good and what is not. Because it is difficult to see, however, why murder, fraud, and theft should be considered evil if life and possessions are of no value, the doctrine was later modified by making among the “indifferent things” distinctions between “preferable things,” such as having the necessities of life and health; “completely indifferent things”; and “anti-preferable things,” such as lacking the necessities of life or being ill—while insisting still that the happiness of the truly wise man could not be impaired by illness, pain, hunger, or any deprivation of external goods. In the beginning, Zeno also insisted that either a man is completely wise, in which case he would never do anything wrong and would be completely happy, or he is a fool. Later he made the concession, however, that there are men not completely wise but progressing toward wisdom. Though the latter might even have true insight, they are not certain that they have it, whereas the truly wise man is also certain of having true insight. The world is governed by divine Logos—a word originally meaning “word” or “speech,” then (with Heracleitus) also a speech that expresses the laws of the universe, and, finally, “reason.” This Logos keeps the world in perfect order. Man can deviate from or rebel against this order, but by doing so he cannot disturb it but can only do harm to himself.

Develop-
ment of
Zeno's
philosophy

Zeno's philosophy was further developed by Cleanthes, the second head of the school, and by Chrysippus, its third head. Chrysippus elaborated a new kind of logic, which did not receive much attention, however, outside the Stoic school until in recent times (under the name of “propositional logic”) it has been hailed by some logicians as superior to the “conceptual logic” of Aristotle. In the mid-2nd century BC, Panaetius of Rhodes adapted Stoic philosophy to the needs of the Roman aristocracy (whose members were then governing the known world) and made a great impression on some of the leading men of the time, who tried to follow his moral precepts. In the following century, in the time of the decay of the Roman Republic, of civil war, and of slave rebellions, Poseidonius of Apamea, who was also one of the most brilliant historians of all times, taught that the Stoic takes a position above the rest of mankind, looking down on men's struggles as on a spectacle. In the periods of the rising monarchy and of its established rule, Stoicism became the religion of the republican opposition. The most famous Stoic was the younger Cato, who committed suicide after the victory of Julius Caesar. It was also the guiding philosophy of Seneca the Younger, the educator and (for a long time) the adviser of Nero, who tried to keep Nero on the path of virtue but failed and finally had to commit suicide on the orders of the Emperor. In spite of the oddities of Zeno's original doctrine, Stoicism gave consolation, composure, and fortitude in times of trouble to many proud men to the end of antiquity and beyond.

Epicurus

Epicureans. The thought of Zeno's contemporary Epicurus also comprised a philosophy of defense in a troubled world. It has been (and still is) considered—in many respects justly—the opposite of Zeno's. Whereas Zeno had proclaimed that the wise man would try to learn from everybody and would always acknowledge his debt to earlier philosophers, Epicurus insisted that everything he taught was the result of his own thinking, though it is obvious that his physical explanation of the universe is a simplification of Democritus' Atomism. And whereas the Stoics had taught that pleasure and pain are of no importance for a man's happiness, Epicurus made pleasure the very essence of a happy life. Moreover, the Stoics from the beginning had acted as advisers of kings and statesmen. Epicurus, on the other hand, lived in the retirement of his famous Garden, cultivating intimate friendships with his adherents but warning against participation in public life. The Stoics believed in divine providence; Epicurus taught that the gods pay no attention whatsoever to human beings. Yet in spite of these contrasts, the two philosophies had some essential factors in common. Though Epicurus made pleasure the criterion of a good life, he was far from

advocating a dissolute life and debauchery; he insisted that it was the simple pleasures that made life happy. When in his old age he suffered terrible pains from prostatitis, he asserted that philosophizing and the memory and love of his distant friends made pleasure prevail even in the grips of such pain. Nor was Epicurus an atheist. His Roman admirer, the poet Lucretius Carus (c. 95–55 BC), in his poem *De rerum natura* (*On the Nature of Things*), praised Epicurus enthusiastically as the liberator of mankind from all religious fears; and Epicurus himself had affirmed that this had been one of the aims of his philosophy. But although he taught that the gods are much too superior to trouble themselves with paying attention to mortals, he said—and, as his language clearly shows, sincerely believed—that it is important for human beings to look at the gods as perfect beings, since only in this way could men approach perfection. It was only in Roman times that people began to misunderstand Epicureanism, holding it to be an atheistic philosophy justifying a dissolute life, so that a man could be called “a swine from the herd of Epicurus.” Seneca recognized the true nature of Epicureanism, however, and in his *Epistulae morales* (*Moral Letters*) deliberately interspersed through his Stoic exhortations maxims from Epicurus.

Lucretius
Carus

Skeptics. There was still another Hellenistic school of philosophy, the Skeptic school initiated by another of Zeno's contemporaries—Pyrrhon of Elis—a school that was destined to become of great importance for the preservation of a detailed knowledge of Hellenistic philosophy in general. Pyrrhon had come to the conviction that no man can know anything for certain nor ever be certain that the things he perceives with his senses are real and not illusory. He is said to have carried the practical consequences of his conviction so far that, when walking in the streets, he paid no attention to the vehicles and other obstacles, so that his faithful disciples always had to accompany him to see that he came to no harm. Pyrrhon's importance for the history of philosophy lies in the fact that one of the later adherents of his doctrine, Sextus Empiricus (2nd–3rd century AD), wrote a large work, *Pros dogmatikous* (“Against the Dogmatists”), in which he tried to refute all of the philosophers who had a more positive philosophy, and in so doing he quoted extensively from their works, thus preserving much that would otherwise have been lost. It is a noteworthy fact that the British sensualists of the 18th century, such as David Hume, and also Immanuel Kant derived most of their knowledge of ancient philosophy from Sextus.

Pyrrhon of
Elis and
Sextus
Empiricus

Neo-Pythagoreans and Neoplatonists. All of the philosophical schools and sects of Athens that had originated in the 4th century BC continued into late antiquity, most of them until the emperor Justinian I ordered all of them closed in AD 529 because of their pagan character. Within that whole period of nearly 1,000 years only two new schools were added; even these, however—the Neo-Pythagorean and the Neoplatonic schools—drew their inspiration from early Greek philosophy, though only the latter was of importance for the history of philosophy. Neoplatonism began with Ammonius Saccas (first half of the 3rd century AD), who had been brought up as a Christian but had abandoned his religion for the study of Plato and developed his own kind of Platonic philosophy. Because he wrote nothing, his philosophy is known only through his famous disciple, Plotinus. But Plotinus did not publish anything either. His philosophy is known, however, through the *Enneads*, a collection of his writings arranged by his disciple Porphyry, who also wrote a biography of Plotinus.

The philosophy of Plotinus (and Ammonius) was derived from the study of Plato. It, moreover, used many philosophical terms first coined by Aristotle and adopted some elements of Stoic philosophy as well. Yet it is essentially a new philosophy, agreeing with the religious and mystical tendencies of its time. Plotinus assumed the existence of several levels of Being, the highest being that of the One, or the Good, which are identical but indescribable and indefinable in human language. The next lower level is that of the nous, or pure intellect or reason; the third is that of the soul or souls. There then follows the world

Plotinus
and
Iamblichus

perceivable by the senses and, finally, at the lowest level there is matter, which is the cause of all evil. The highest bliss for man is union with the One, or Good, attained by contemplation and purification. That this is not a lasting state attained once for all—like the status of the Stoic wise man, who was supposed never to lose his wisdom again—is shown by the fact that Porphyry, in his *Vita Plotini*, said that Plotinus had experienced this supreme bliss seven times in his life, whereas he, Porphyry, had experienced it only once.

The further history of Neoplatonism is extremely complicated. While Porphyry had emphasized the ethical element in Plotinus' philosophy, his disciple Iamblichus of Chalcis in Syria (died c. AD 330), founder of a Syrian branch of the sect, mingled Neoplatonism with Neo-Pythagoreanism, writing on the Pythagorean way of life and on number theory. Above all, he multiplied the levels of being, or the emanations from the One, which enabled him to incorporate the traditional Greek gods into his system. Another branch of the school was founded in Pergamum, in western Asia Minor, by his disciple Aedesius, who with his disciple Maximus tried to revive the ancient Greek mystery religions, such as Orphism. All of these developments became of great importance in the 4th century when the emperor Julian attempted to revive paganism. In the following century the Athenian school reached a new high point when Proclus combined ideas of his predecessors into one comprehensive system. When in 529 Justinian closed all of the philosophical schools in Athens, however, a branch continued to exist in Alexandria. The Athenian Neoplatonists found refuge at the court of the Persian king Khosrow, and in 535 they were permitted to return to Athens. But gradually pagan philosophy as such died out, though it continued to exist as an influence in the development of Christian philosophy and theology.

(K.v.Fr.)

Medieval philosophy

Medieval philosophy designates the philosophical speculation that occurred in western Europe during the Middle Ages; i.e., from the fall of the Roman Empire in the 4th and 5th centuries AD to the Renaissance of the 15th century. Philosophy of the medieval period remained in close conjunction with Christian thought, particularly theology, and the chief philosophers of the period were churchmen, particularly churchmen who were teachers. Philosophers who strayed from the close relation were chided by their superiors. Greek philosophy ceased to be creative after Plotinus in the 3rd century AD. A century later Christian thinkers such as Ambrose, Victorinus, and Augustine began to assimilate Neoplatonism into Christian doctrine in order to give a rational interpretation of Christian faith. Thus, medieval philosophy was born of the confluence of Greek (and to a lesser extent of Roman) philosophy and Christianity. Plotinus' philosophy was already deeply religious, having come under the influence of Middle Eastern religion. Medieval philosophy continued to be characterized by this religious orientation. Its methods were at first those of Plotinus and later those of Aristotle. But it developed within faith as a means of throwing light on the truths and mysteries of faith. Thus, religion and philosophy fruitfully cooperated in the Middle Ages. Philosophy, as the handmaiden of theology, made possible a rational understanding of faith. Faith, for its part, inspired Christian thinkers to develop new philosophical ideas, some of which became part of the philosophical heritage of the West.

Toward the end of the Middle Ages, this beneficial interplay of faith and reason started to break down. Philosophy began to be cultivated for its own sake, apart from, and even in contradiction to, Christian religion. This divorce of reason from faith, made definitive in the 17th century by Francis Bacon and René Descartes, marked the birth of modern philosophy.

EARLY MEDIEVAL PHILOSOPHY

The early medieval period, which extended to the 12th century, saw the barbarian invasions of the Roman Empire,

the collapse of its civilization, and the gradual building of a new, Christian culture in western Europe. Philosophy in these troubled and darkened times was cultivated by late Roman thinkers such as Augustine (354–430) and Boethius (c. 480–c. 525), then by monks such as Anselm (1033–1109). The monasteries became the main centres of learning and education and retained their preeminence until the founding of the cathedral schools and universities in the 11th and 12th centuries.

Augustine. During these centuries philosophy was heavily influenced by Neoplatonism; Stoicism and Aristotelianism played only a minor role. Augustine was awakened to the philosophical life by reading Cicero, but the Neoplatonists most decisively shaped his philosophical methods and ideas. To them he owed his conviction that beyond the world of the senses there is a spiritual, eternal realm of truth that is the object of the human mind and the goal of all man's striving. This truth he identified with the God of Christianity. Man encounters this divine world of truth and beauty not through his senses but by turning inward to his mind, and above his mind to the intelligible light, in which he sees the truth. The Augustinian demonstration of the existence of God coincides with the proof of the existence of necessary, immutable Truth. Augustine considered the truths of both mathematics and ethics to be necessary, immutable, and eternal. These truths cannot come from the world of contingent, changing, and temporal things, nor from the mind itself, which is also contingent, mutable, and temporal. They are due to the illuminating presence in man's mind of eternal and immutable Truth, or God. Any doubt that man knows the truth with certainty was dispelled for Augustine by the certitude that even if he is deceived in many cases, man cannot doubt that he exists and knows and loves.

Augustine conceived of man as a composite of two substances, body and soul, of which the soul is by far the superior. The body, nevertheless, is not to be excluded from human nature, and its eventual resurrection from the dead is assured by Christian faith. The soul's immortality is proved by its possession of eternal and unchangeable Truth.

Augustine's *Confessions* (c. 400) and *De Trinitate* (400–416; *On the Trinity*) abound with penetrating psychological analyses of knowledge, perception, memory, and love. His *De civitate Dei* (413–426; *The City of God*) presents the whole drama of human history as a progressive movement of humanity, redeemed by God, to its final repose in its Creator.

Boethius. One of the most important channels by which Greek philosophy was transmitted to the Middle Ages was Boethius. He began to translate into Latin all the philosophical works of the Greeks, but his imprisonment and death by order of Theodoric, king of the Ostrogoths, cut short this project. He translated only the logical writings of Porphyry (a 3rd-century-AD Neoplatonist) and Aristotle. These translations and his commentaries on them brought to the thinkers of the Middle Ages the rudiments of Aristotelian logic. They also raised important philosophical questions, such as the nature of universals (terms that can be applied to more than one particular thing). Are universals real or only mental concepts? If real, are they corporeal or incorporeal; if incorporeal, do they exist in the sensible world or apart from it? Medieval philosophers debated at length these and other problems relating to universals. In his logical works Boethius presents the Aristotelian doctrine of universals, that they are only mental abstractions. In his *De consolazione philosophiae* (c. 525; *Concerning the Consolation of Philosophy*), however, he adopts the Platonic notion that they are innate ideas and their origin is in the remembering of knowledge in a previous existence. This book was extremely popular and influential in the Middle Ages. It contains not only a Platonic view of knowledge and reality but also a lively treatment of providence, divine foreknowledge, chance, fate, and human happiness.

Greek Fathers of the Church and Origen. Another stream from which Greek philosophy, especially Neoplatonic thought, flowed into the Middle Ages was the Greek Fathers of the Church, notably Origen (c. 185–c. 254),

The question of the nature of universals

Gregory of Nyssa (c. 335–c. 394), Nemesis (c. 400), Pseudo-Dionysius the Areopagite (c. 500), and Maximus the Confessor (c. 580–662). In the 9th century, John Scotus, called Erigena (“belonging to the people of Erin”) because he was born in Ireland, a master at the Carolingian court of Charles the Bald, translated into Latin some of the writings of these Greek theologians, and his own major work, *De divisione naturae* (862–866; *On the Division of Nature*), is a vast synthesis of Christian thought organized along Neoplatonic lines. For him, God is the primal unity, unknowable and unnameable in himself, from which the multiplicity of creatures flows. He so far transcends his creatures that he is most appropriately called supernatural and supergood. Creation is the process of division whereby the many derive from the One. The One descends into the manifold of creation and reveals himself in it. By the reverse process the multiplicity of creatures will return to their unitary source at the end of time, when everything will be absorbed in God.

Anselm. After the breakdown of the Carolingian Empire in the 10th century, intellectual speculation was at a low ebb in western Europe. In the next century some political stability was achieved by Otto I, who reestablished the empire, and Benedictine monasteries were revitalized by reformers such as Peter Damian. Like Tertullian, a Christian writer of the 2nd and 3rd centuries, Damian mistrusted secular learning and philosophy as harmful to the faith. Other monks showed a keen interest in dialectic and philosophy. Among the latter was Anselm, an Italian who became abbot of the French monastery of Bec and later archbishop of Canterbury.

Like Augustine, Anselm used both faith and reason in his search for truth. Faith comes first, in his view, but reason should follow, giving reasons for what men believe. Anselm’s monks asked him to write a model meditation on God in which everything would be proved by reason and nothing on the authority of Scripture. He replied with his *Monologium* (1077; “Monologue”; Eng. trans., *Monologium*), the original title of which was “A Meditation on the Reasonableness of Faith.” It contains three proofs of the existence of God, all of which are based on Neoplatonic thought. The first proof moves from the awareness of a multiplicity of good things to the recognition that they all share or participate more or less in one and the same Good, which is supremely Good in itself, and this is God. The second and third proofs are similar: beginning with their awareness of a multiplicity of beings that have more or less of being, and more or less of perfection, men recognize that they share in One who is supremely Being and perfect.

Anselm’s later work, the *Proslogium* (1077/78; “Allocution” or “Address”; Eng. trans., *Proslogium*), also entitled “Faith Seeking Understanding,” contains his most famous proof of the existence of God. This begins with a datum of faith: men believe God to be the being than which none greater can be thought. Some, like the fool in the Psalms, say there is no God; but even the fool, on hearing these words, understands them, and what he understands exists in his intellect, even though he does not grant that such a being exists in reality. But it is greater to exist in reality and in the understanding than to exist in the understanding alone. Therefore it is contradictory to hold that God exists only in the intellect, for then the being than which none greater can be thought is one than which a greater can be thought, namely, one that exists both in reality and in the understanding. Philosophers still debate the meaning and value of this so-called ontological argument for God’s existence.

Bernard of Clairvaux and Abelard. Anselm’s inquiry into the existence and nature of God, as also his discussion of truth, love, and human liberty, aimed at fostering monastic contemplation. Other monks, such as the Cistercian Bernard of Clairvaux (1090–1153), were suspicious of the use of secular learning and philosophy in matters of faith. Bernard complained of the excessive indulgence in dialectic displayed by contemporaries such as Peter Abelard (1079–1142) and Gilbert de La Porrée. He himself developed a doctrine of mystical love, the influence of which lasted through the centuries. The monks of the

Parisian Abbey of Saint-Victor were no less intent on fostering mystical contemplation, but they cultivated the liberal arts and philosophy as an aid to it. In this spirit, Hugh of Saint-Victor wrote his *Didascalicon* (c. 1127; “Teaching”; Eng. trans., *Didascalicon*), a monumental treatise on the theoretical and practical sciences and the trivium (grammar, rhetoric, dialectic) and the quadrivium (arithmetic, music, geometry, astronomy). During the same period the School of Chartres, attached to the famous cathedral near Paris, was the focus of Christian Neoplatonism and humanism.

Urban development in the 12th century shifted the centre of learning and education from the monasteries to the towns. Abelard founded several urban schools near Paris and taught in them. A passionate logician, he pioneered a method in theology that contributed to the later Scholastic method. His *Sic et non* (1115–17; *Yes and No*) cites the best authorities on both sides of theological questions in order to reach their correct solution. In philosophy his main interest was logic. On the question of universals he agreed with neither the Nominalists nor the Realists of his day. His Nominalist teacher Roscelin held that universals, such as “man” and “animal,” are nothing but words, or names (*flatus vocis*). Abelard argued that this does not take into account the fact that names have meaning. His Realist teacher William of Champeaux taught that universals are realities apart from the mind. For Abelard, only individuals are real; universals are indeed names or mental concepts, but they have meaning because they refer to individuals. They do not signify an essence common to individuals, as the Realists maintained (e.g., the essence “humanity” shared by all men), but signify instead the individuals in their common condition, or status, of being in a certain species, which results from God’s creating them according to the same divine idea.

TRANSITION TO SCHOLASTICISM

In the 12th century a cultural revolution took place that influenced the whole subsequent history of Western philosophy. The old style of education, based on the liberal arts and emphasizing grammar and the reading of the Latin classics, was replaced by new methods stressing logic, dialectic, and all the scientific disciplines known at the time. John of Salisbury, of the School of Chartres, witnessed this radical change:

Behold, everything was being renovated: grammar was being made over, logic was being remodeled, rhetoric was being despised. Discarding the rules of their predecessors, [the masters] were teaching the quadrivium with new methods taken from the very depths of philosophy.

In philosophy itself, there was a decline in Platonism and a growing interest in Aristotelianism. This change was occasioned by the translation into Latin of the works of Aristotle in the late 12th and early 13th centuries. Until then, only a few of his minor logical treatises were known. Now his *Topica*, *Analytica priora*, and *Analytica posteriora* were rendered into Latin, giving the schoolmen (the teachers of Western Christian philosophy in the 13th and 14th centuries) access to the Aristotelian methods of disputation and science, which became their own techniques of discussion and inquiry. Many other philosophical and scientific works of Greek and Arabic origin were translated at this time, creating a “knowledge explosion” in western Europe.

Arabic thought. Among the translations from Arabic were some of the writings of Avicenna (980–1037). This Islāmic philosopher had an extraordinary impact on the medieval schoolmen. His interpretation of Aristotle’s notion of metaphysics as the science of *ens qua ens* (“being as being”), his analysis of many metaphysical terms, such as “being,” “essence,” “existence,” and his metaphysical proof of the existence of God were often quoted, with approval or disapproval, in Christian circles. Also influential were his psychology, logic, and natural philosophy. His *al-Qānūn fī al-ṭibb* (*Canon of Medicine*) was an authority on the subject until modern times. The *Maqāṣid al-Falāsifah* (1094; “The Aims of the Philosophers”) of the Arabic theologian al-Ghazālī, known in Latin as Algazel (died c. 1111), an exposition of Avicenna’s philosophy written in

Growing interest in Aristotelianism

Anselm’s proofs of the existence of God

order to criticize it, was read as a complement of Avicenna's works. The anonymous *Liber de causis* ("Book of Causes") was also translated into Latin from Arabic. This work, excerpted from Proclus' *Stoicheiōsis theōlogikē* (*Elements of Theology*), was often ascribed to Aristotle, and it gave a Neoplatonic cast to his philosophy until its true origin was discovered by Thomas Aquinas.

The commentaries of the Arabic philosopher Averroës were translated along with Aristotle's works. As Aristotle was called "the Philosopher" by the medieval philosophers, Averroës was dubbed "the Commentator." These two taught the Scholastics philosophy as a purely rational discipline, divorced from revealed religion. The Christian schoolmen often attacked Averroës as the archenemy of Christianity for his rationalism and his doctrines of the eternity of the world and the unity of the intellect for all men; i.e., the doctrine that intellect is a single, undifferentiated form with which men become reunited at death. This was anathema to the Christian schoolmen because it contravened the Christian doctrine of individual immortality.

Jewish thought. Of considerably less influence on the Scholastics was medieval Jewish thought. Ibn Gabirol, known to the Scholastics as Avicbron or Avencebrol, was thought to be an Arab or Christian, though in fact he was a Spanish Jew. His chief philosophical work, written in Arabic and preserved only in a Latin translation entitled *Fons vitae* (c. 1050; *Fountain of Life*), stresses the unity and simplicity of God. All creatures are composed of form and matter, either the gross corporeal matter of the sensible world or the spiritual matter of angels and human souls. Some of the schoolmen were attracted to the notion of spiritual matter and also to Ibn Gabirol's analysis of a plurality of forms in creatures, according to which every corporeal being receives a variety of forms by which it is given its place in the hierarchy of being—for example, a dog has the forms of a corporeal thing, a living thing, an animal, a dog.

Maimonides, or Moses ben Maimon, was known to Christians of the Middle Ages as Rabbi Moses. His *Dalālat al-hā'irīn* (c. 1190; *Guide of the Perplexed*) helped them to reconcile Greek philosophy with revealed religion. For Maimonides there can be no conflict between reason and faith because both come from God; an apparent contradiction is due to a misinterpretation of either the Bible or the philosophers. Thus, he showed that creation is reconcilable with philosophical principles and that the Aristotelian arguments for an eternal world are not conclusive because they ignore the omnipotence of God, who can create a world of either finite or infinite duration.

While Western scholars were assimilating the new treasures of Greek, Islāmic, and Jewish thought, universities that became the centres of Scholasticism were being founded. Of these the most important were Paris and Oxford (formed 1150–70 and 1168, respectively). Scholasticism is the name given to the theological and philosophical teachings of the schoolmen in the universities. There was no one Scholastic doctrine; each of the Scholastics developed his own, which was often in disagreement with that of his fellow teachers. They had in common a respect for the great writers of old, such as the Fathers of the Church, Aristotle, Plato, Boethius, the Pseudo-Dionysius, and Avicenna. These they called "authorities." Their interpretation and evaluation of the authorities, however, frequently differed. They also shared a common style and method that developed out of the teaching practices in the universities. Teaching was done by lecture and disputation (a formal debate). A lecture consisted of the reading of a prescribed text followed by the teacher's commentary on it. Masters also held disputations in which the affirmative and negative sides of a question were thoroughly argued by students and teacher, before the latter resolved the problem.

THE AGE OF THE SCHOOLMEN

Robert Grosseteste and Roger Bacon. The newly translated Greek and Arabic treatises had an immediate effect on the University of Oxford. Its first chancellor, Robert Grosseteste (c. 1168–1253), commented on some of Aristotle's works and translated the *Ethica Nichomachea*

(*Nicomachean Ethics*) from Greek to Latin. He was deeply interested in scientific method, which he described as both inductive and deductive. By the observation of individual events in nature, man advances to a general law, called a "universal experimental principle," that accounts for these events. Experimentation either verifies or falsifies a theory by testing its empirical consequences. For Grosseteste the study of nature is impossible without mathematics. He cultivated the science of optics (*perspectiva*), which measures the behaviour of light by mathematical means. His studies of the rainbow and comets employ both observation and mathematics. His treatise *De luce* (1215–20; *On Light*) embodies a metaphysics of light, presenting light as the basic form of all things and God as the primal uncreated light.

Grosseteste's pupil Roger Bacon (c. 1220–c. 1292) made the mathematical and experimental methods the key to natural science. The term experimental science was popularized in the West through his writings. For him, man acquires knowledge through reasoning and experience, but without the latter he can have no certitude. Man gains experience through the senses and also through an interior divine illumination that culminates in mystical experience. Bacon was critical of the methods of Parisian theologians such as Albertus Magnus and Thomas Aquinas. He strove to create a universal wisdom embracing all the sciences and organized by theology. He also proposed the formation of a single worldwide society, or "Christian republic," that would unite all men under the leadership of the pope.

William of Auvergne. At the University of Paris, William of Auvergne (c. 1180–1249) was one of the first to feel the impact of the philosophies of Aristotle and Avicenna. As a teacher, and then as bishop of Paris, he was concerned with the threat of pagan and Islāmic thought to the Christian faith. He opposed the Aristotelian doctrine of the eternity of the world as contrary to the Christian notion of creation. His critique of Avicenna centred around the latter's conception of God and creation. The God of Avicenna, who creates the universe eternally and necessarily, through the mediation of 10 Intelligences, was opposed by William of Auvergne with the Christian notion of a God who creates the world freely and directly. Creatures are radically contingent and dependent on God's creative will. Unlike God, they do not exist necessarily; indeed, their existence is distinct from their essence and accidental to it. God has no essence distinct from his existence; he is pure existence. In stressing the essential instability and noneternity of the world, he attributed true existence and causality to God alone. William of Auvergne was a follower of Augustine, but, like others at the time, he was compelled to rethink the older Augustinian notions in terms of the newer Aristotelian and Avicennian philosophies.

Bonaventure. The Franciscan friar Bonaventure (c. 1217–74) reacted similarly to the growing popularity of Aristotle and his Arabic commentators. He admired Aristotle as a natural scientist, but he preferred Plato and Plotinus, and, above all, Augustine, as metaphysicians. His main criticism of Aristotle and his followers was that they denied the existence of divine ideas. As a result, Aristotle was ignorant of exemplarism (that is, God's creation of the world according to ideas in his mind) and also of divine providence and government of the world. This involved Aristotle in a threefold blindness: he taught that the world is eternal, that all men share one agent intellect (the active principle of understanding in man), and that there are no rewards or punishments after death. Plato and Plotinus avoided these mistakes, but, because they lacked Christian faith, they could not see the whole truth. For Bonaventure, faith alone enables men to avoid error in these important matters.

Bonaventure did not confuse philosophy with theology. Philosophy is the knowledge of the things of nature and the soul innate in man or acquired by his own efforts, whereas theology is the knowledge of heavenly things based on faith and divine revelation. Bonaventure, however, rejected the practical separation of philosophy from theology. Philosophy needs the guidance of faith; far from being self-sufficient, it is but a stage toward the higher knowledge that culminates in the vision of God.

Opposition
to Aristotelianism

The
universities
and
Scholasticism

For Bonaventure, every creature to some degree bears the mark of its Creator. The soul has been made in the very image of God. Thus, the universe is like a book in which the triune God is revealed. His *Itinerarium mentis in Deum* (1259; *The Soul's Journey into God*) follows Augustine's path to God, from the external world to the interior world of the mind, and then above the mind from the temporal to the eternal. Throughout this journey, men are aided by a moral and intellectual divine illumination. The mind has been created with an innate idea of God, so that, as Anselm pointed out, man cannot think that God does not exist. In a terse reformulation of the Anselmian argument for God's existence, Bonaventure states that if God is God, he exists.

Albertus Magnus. The achievement of the Dominican friar Albertus Magnus (c. 1200–80) was of vital importance for the development of medieval philosophy. A man of immense erudition and intellectual curiosity, he was one of the first to recognize the true value of the newly translated Greco-Arabic scientific and philosophical literature. Everything he considered valuable in it, he included in his encyclopaedic writings. He set out to teach this literature to his contemporaries and in particular to make the philosophy of Aristotle, whom he considered to be the greatest philosopher, understandable to them. He also proposed to write original works in order to complete what was lacking in the Aristotelian system. In no small measure, the triumph of Aristotelianism in the 13th century can be attributed to him.

Albertus' observations and discoveries in the natural sciences advanced botany, zoology, and mineralogy. In philosophy he was less original and creative than his famous pupil Thomas Aquinas. Albertus produced a synthesis of Aristotelianism and Neoplatonism, blending together the philosophies of Aristotle, Avicenna, and Ibn Gabirol, and, among Christians, Augustine and Pseudo-Dionysius.

Thomas Aquinas. Albertus Magnus' Dominican confrere and pupil Thomas Aquinas (1224/25–1274) shared his master's great esteem for the ancient philosophers, especially Aristotle, and also for the more recent Arabic and Jewish thinkers. He welcomed truth wherever he found it and used it for the enrichment of Christian thought. For him reason and faith cannot contradict each other because they come from the same divine source. In his day conservative theologians and philosophers regarded Aristotle with suspicion and leaned toward the more traditional Christian Neoplatonism. Thomas realized that their suspicion was due, in part, to the fact that Aristotle's philosophy had been distorted by his Arabic commentators; so he wrote his own commentaries on Aristotle to show the essential soundness of his system and to convince contemporaries of its value for Christian theology.

Thomas' own philosophical views are best expressed in his theological works, especially his *Summa theologiae* (1265/66–1273; Eng. trans., *Summa theologiae*) and *Summa contra gentiles* (1258–64; *Summa Against the Gentiles*). In these works he clearly distinguishes between the domains and methods of philosophy and theology. The philosopher seeks the first causes of things, beginning with data furnished by the senses; the subject of the theologian's inquiry is God as revealed in sacred Scripture. In theology, appeal to authority carries most weight; in philosophy, it carries least.

Thomas found Aristotelianism and, to a lesser extent, Platonism useful instruments for Christian thought and communication; but he transformed and deepened everything he borrowed from them. For example, he took over Aristotle's proof of the existence of a primary unmoved mover, but the primary mover at which Thomas arrives is very different from that of Aristotle; it is in fact the God of Judaism and Christianity. He also adopted Aristotle's teaching that the soul is man's form and the body is his matter, but for Aquinas this does not entail, as it does for the Aristotelians, the denial of the immortality of the soul or the ultimate value of the individual. Thomas never compromised Christian doctrine by bringing it into line with the current Aristotelianism; rather, he modified and corrected the latter whenever it clashed with Christian belief. The harmony he established between Aristotelianism

and Christianity was not forced but achieved by a new understanding of philosophical principles, especially the notion of being, which he conceived as the act of existing (*esse*). For him, God is pure being, or the act of existing. Creatures participate in being according to their essence; for example, man participates in being, or the act of existing, to the extent that his humanity, or essence, permits. The fundamental distinction between God and creatures is that creatures have a real composition of essence and existence, whereas God's essence is his existence.

Averroists. A group of masters in the Faculty of Arts at Paris welcomed Aristotle's philosophy and taught it in disregard of its possible opposition to the Christian faith. They wanted to be philosophers, not theologians, and to them this meant following the Aristotelian system. Because Averroës was the recognized commentator on Aristotle, they generally interpreted his thought in an Averroistic way. Hence, in their own day they were known as "Averroists"; today they are often called "Latin Averroists" because they taught in Latin. Their leader, Siger de Brabant, taught as rationally demonstrated certain Aristotelian doctrines that contradicted the faith, such as the eternity of the world and the oneness of the intellect for all men. They were accused of holding a "double truth"—of maintaining the existence of two contradictory truths: one commanded by faith, the other taught by reason. Although Siger never proposed as true philosophical conclusions contrary to faith, other members of this group upheld the right and duty of the philosopher to follow human reason to its natural conclusions, even when they contradicted the truths of faith.

This growing rationalism confirmed the belief of theologians of a traditionalist cast that the pagan and Muslim philosophies would destroy the Christian faith. They attacked these philosophies in treatises such as Giles of Rome's *Errores philosophorum* (1270; *The Errors of the Philosophers*). In 1277 the Bishop of Paris condemned 219 propositions based on the new trend toward rationalism and naturalism. These included even some of Thomas' Aristotelian doctrines. The same year, the Archbishop of Canterbury made a similar condemnation at Oxford. These reactions to the novel trends in philosophy did not prevent the Averroists from treating philosophical questions apart from religious considerations. Theologians, on their part, were increasingly suspicious of the philosophers and less optimistic about the ultimate reconciliation of philosophy and theology.

PHILOSOPHY IN THE LATE MIDDLE AGES

In the late Middle Ages earlier ways of philosophizing were continued and formalized into definite schools of thought. In the Dominican order, Thomism (theology and philosophy of Thomas Aquinas) was made the official teaching, though the Dominicans did not always adhere to it rigorously. Averroism, cultivated by philosophers such as John of Jandun (died c. 1328), remained a live, though sterile, movement into the Renaissance. In the Franciscan order, the Englishmen John Duns Scotus and William of Ockham developed new styles of theology and philosophy that vied with Thomism throughout the late Middle Ages.

Duns Scotus. John Duns Scotus (c. 1265–1308) opposed the rationalists' contention that philosophy is self-sufficient and adequate to satisfy man's desire for knowledge. In fact, he claimed, a pure philosopher, such as Aristotle, could not truly understand the human condition because he was ignorant of the Fall of man and his need for grace and redemption. Unenlightened by Christian revelation, Aristotle mistook man's present fallen state, in which all his knowledge comes through the senses, for his natural condition, in which the object of his knowledge would be coextensive with all being, including the being of God. The limitation of Aristotle's philosophy is apparent to Duns Scotus in the Aristotelian proof of the existence of God as the primary mover of the universe. More adequate than this physical proof, he contended, is his own very intricate metaphysical demonstration of the existence of God as the absolutely primary, unique, and infinite being. He incorporated the Anselmian argument into this demonstration. For Duns Scotus, the notion of

Triumph
of Aristo-
telianism

nation of
Aristo-
telian
doctrines

infinite being, not that of primary mover or being itself, is man's most perfect concept of God.

Defense
of the
doctrine of
God's will

In opposition to the Greco-Arabic view of the government of the universe from above by necessary causes, Duns Scotus stressed the contingency of the universe and its total dependence on God's infinite creative will. He adopted the traditional Franciscan voluntarism, elevating the will above the intellect in man.

Duns Scotus' doctrine of universals justly earned him the title "Doctor Subtilis." Universals, in his view, exist only as abstract concepts, but they are based on common natures, such as humanity, which exist, or can exist, in many individuals. Common natures are real, and they have a real unity of their own distinct from the unity of the individuals in which they exist. The individuality of each individual is due to an added positive reality that makes the common nature to be this individual; for example, humanity to be Socrates. Duns Scotus calls such a reality an "individual difference," or "thisness" (*haecceitas*). It is an original development of the earlier medieval realism of universals.

William of Ockham. In the late 14th century, Thomism and Scotism were called the "old way" (*via antiqua*) of philosophizing in contrast to the "modern way" (*via moderna*) begun by such men as William of Ockham (c. 1285–1347). Ockham, no less than Duns Scotus, wanted to defend the Christian doctrine of the freedom and omnipotence of God and the contingency of creatures against the necessitarianism of Greco-Arabic philosophy. But for him the freedom of God is incompatible with the existence of divine ideas as positive models of creation. God does not use preconceived ideas when he creates, as Duns Scotus maintained, but he fashions the universe as he wishes. As a result, creatures have no natures or essences in common. There are no realities but individual things, and these have nothing in common. They are more or less like each other, however, and on this basis men can form universal concepts of them and talk about them in general terms.

The absolute freedom of God was often used by Ockham as a principle of philosophical and theological explanation. Because the order of nature has been freely created by God, it could have been different: fire, for example, could cool, as it now heats. If he wishes, he can give us the sight, or "intuitive knowledge," of a star without the reality of the star. The moral order could also have been different. God could have made hating him meritorious instead of loving him. It was typical of Ockham not to put too much trust in the power of human reason to reach the truth. For him, philosophy must often be content with probable arguments, for example, in establishing the existence of the Christian God. Faith alone gives certitude in this and in other vital matters. Another principle invoked by Ockham is that a plurality is not to be posited without necessity. This principle of the economy of thought, later stated as beings are not to be multiplied without necessity, is called "Ockham's razor."

Ockhamism was censured by a papal commission at Avignon, Fr., in 1326, and in 1474 it was forbidden to be taught at Paris: it spread widely in the late Middle Ages, nevertheless, and rivaled Thomism and Scotism in popularity. Other Scholastics in the 14th century shared Ockham's basic principles and contributed with him to skepticism and probabilism in philosophy. John of Mirecourt (c. 1345) stressed the absolute power of God and the divine will to the point of making him the cause of man's sin. Nicholas of Autrecourt (c. 1347) adopted a skeptical attitude regarding such matters as man's ability to prove the existence of God and the reality of substance and causality. Rejecting Aristotelianism as inimical to the Christian faith, he advocated a return to the Atomism of the ancient Greeks as a more adequate explanation of the universe.

Trend
away from
Aristo-
telianism

Meister Eckehart. The trend away from Aristotelianism was accentuated by the German Dominican Meister Eckehart (c. 1260–1327/28), who developed a speculative mysticism of both Christian and Neoplatonic inspiration. Eckehart depicts the ascent of the soul to God in Neoplatonic terms: by gradually purifying itself from the body, the soul transcends being and knowledge until it is ab-

sorbed in the One. The soul is then united with God at its highest point, or "citadel." God himself transcends being and knowledge. Sometimes Eckehart describes God as the being of all things. This language, which was also used by Erigena and other Christian Neoplatonists, leaves him open to the charge of pantheism (the doctrine that the being of creatures is identical with that of God); but for Eckehart there is an infinite gulf between creatures and God. Eckehart means that creatures have no existence of their own but are given existence by God, as the body is made to exist and is contained by the soul. Eckehart's profound influence can be seen in the flowering of mysticism in the German Rhineland in the late Middle Ages.

Nicholas of Cusa. Nicholas of Cusa (1401–64) also preferred the Neoplatonists to the Aristotelians. To him, the philosophy of Aristotle is an obstacle to the mind in its ascent to God because its primary rule is the principle of contradiction, which denies the compatibility of contradictories. But God is the "coincidence of opposites." Because he is infinite, he embraces all things in perfect unity; he is at once the maximum and the minimum. Nicholas uses mathematical symbols to illustrate how, in infinity, contradictories coincide. If a circle is enlarged, the curve of its circumference becomes less; if a circle is infinite, its circumference is a straight line. As for man's knowledge of the infinite God, he must be content with conjecture or approximation to the truth. The absolute truth escapes man; his proper attitude is "learned ignorance."

For Nicholas, God alone is absolutely infinite. The universe reflects this divine perfection and is relatively infinite. It has no circumference, for it is limited by nothing outside of itself. Neither has it a centre; the Earth is neither at the centre of the universe nor is it completely at rest. Place and motion are not absolute but relative to the observer. This new, non-Aristotelian conception of the universe anticipated some of the features of modern theories.

Thus, at the end of the Middle Ages, some of the most creative minds were abandoning Aristotelianism and turning to newer ways of thought. The philosophy of Aristotle, in its various interpretations, continued to be taught in the universities, but it had lost its vitality and creativity. Christian philosophers were once again finding inspiration in Neoplatonism. The Platonism of the Renaissance was in direct continuity with the Platonism of the Middle Ages.

(A.A.Ma.)

Modern philosophy

THE RENAISSANCE AND EARLY MODERN PERIOD

The philosophy of a period arises as a response to social need, and the development of philosophy in the history of Western civilization since the Renaissance has, thus, reflected the process in which creative philosophers have responded to the unique challenge of each stage in the development of Western culture itself.

The career of philosophy—how it views its tasks and functions, how it defines itself, the special methods it invents for the achievement of philosophical knowledge, the literary forms it adopts and utilizes, its conception of the scope of its subject matter, and its changing criteria of meaning and truth—hinges on the mode of its successive responses to the challenges of the social structure within which it arises. Thus, Western philosophy in the Middle Ages was primarily a Christian philosophy, complementing the divine revelation, reflecting the feudal order in its cosmology, devoting itself in no small measure to the institutional tasks of the Roman Catholic Church. It was no accident that the major philosophical achievements of the 13th and 14th centuries were the work of churchmen who also happened to be professors of theology at the universities of Oxford and Paris.

The Renaissance of the late 15th and 16th centuries presented a different set of problems and therefore suggested different lines of philosophical endeavour. What is called the European Renaissance followed upon the introduction of three novel mechanical inventions from the East: gunpowder, block printing from movable type, and the compass. The first was used to explode the massive fortifications of the feudal order and thus became an

Cultural
impact
of new
inventions
and
nations

agent of the new spirit of nationalism that threatened the rule of churchmen—and, indeed, the universalist emphasis of the church itself—with a competing secular power. The second, printing, made the propagation of knowledge widespread, secularized learning, reduced the intellectual monopoly of an ecclesiastical elite, and restored the literary and philosophical classics of Greece and Rome. The third, the compass, increased the safety and scope of navigation, produced the voyages of discovery that opened up the Western Hemisphere, and symbolized a new spirit of physical adventure and a new scientific interest in the structure of the natural world.

Each of these inventions with its wider cultural consequences presented new intellectual problems and novel philosophical tasks within a changed political and social environment. For, as the power of a single religious authority was slowly eroded under the influence of the Protestant Reformation and as the prestige of the universal Latin language gave way to vernacular tongues, philosophers became less and less identified with their positions in the ecclesiastical hierarchy and more and more identified with their national origins. The works of Albertus Magnus, St. Thomas Aquinas, St. Bonaventure, and John Duns Scotus had been basically unrelated to the countries of their birth; but the philosophy of Niccolò Machiavelli was directly related to Italian experience, that of Sir Francis Bacon and Thomas Hobbes was English to the core, and that of René Descartes set the standard and tone of French intellectual life for 200 years.

Dominant strands of Renaissance philosophy. Knowledge in the contemporary world is conventionally divided between the natural sciences, the social sciences, and the humanities. In the Renaissance, however, fields of learning had not yet become so sharply departmentalized: in fact, each of these divisions arose in the comprehensive and broadly inclusive area of Renaissance philosophy. For, as the Renaissance mounted its revolt against the reign of religion and therefore reacted against the church, against authority, against Scholasticism, and against Aristotle, there was a sudden blossoming of interest in problems centring on civil society, man, and nature. These three interests found exact representation in the three dominant strands of Renaissance philosophy: (1) political theory, (2) humanism, and (3) the philosophy of nature.

Political theory. As secular authority replaced ecclesiastical authority and as the dominant interest of the age shifted from religion to politics, it was natural that the rivalries of the national states and their persistent crises of internal order should raise with renewed urgency philosophical problems, practically dormant since pre-Christian times, about the nature and the moral status of political power. This new preoccupation with national unity, internal security, state power, and international justice stimulated the growth of political philosophy in Italy, France, England, and Holland.

In early 16th-century Italy, Niccolò Machiavelli, sometime state secretary of the Florentine republic, explored in *Il principe* (written 1512–13; *The Prince*) and in his *Discorsi sopra la prima deca di Tito Livio* (completed by 1521; “Discourses on the First Ten Books of Livy” in *Discourses*) the techniques for the seizure and retention of power in ways that seemed to exalt “reasons of state” above morality and codified the actual practices of Renaissance diplomacy for the next 100 years. In fact, Machiavelli was motivated by patriotic hopes for the ultimate unification of Italy and by the conviction that the low estate of Italian Renaissance morality needed to be elevated by restoring the ancient Roman virtues. More than half a century later in France, Jean Bodin, magistrate of Laon and a member of the Estates-General, insisted that the state must possess a single, unified, and absolute power; he thus developed in detail the doctrine of national sovereignty in all of its administrative consequences and in its role as the source of all legal legitimacy.

In the 17th century in England, Thomas Hobbes, who was to become tutor to the future Charles II, developed the fiction that in the “state of nature” that preceded civilization life was “nasty, brutish, and short” with “every man’s hand raised against every other,” and that a “social

contract” was thus agreed upon to convey all private rights to a single sovereign in return for general protection and for the institution of a reign of law. Because law is simply “the command of the sovereign,” Hobbes at once turned justice into a by-product of power and denied any right of rebellion except when the sovereign becomes too weak to protect the commonwealth and hold it united.

In Holland, a prosperous and tolerant commercial republic in the 17th century, the issues of political philosophy took a different form. Thus, when the Dutch East India Company commissioned a great jurist, Hugo Grotius (1583–1645), to provide a defense of their trade rights and of their free access to the seas, the resulting two treatises, *Mare Liberum* (1609; *The Freedom of the Seas*) and *De Jure Belli ac Pacis* (1625; *On the Law of War and Peace*), were the first significant codifications of international law. Their philosophical originality lay, however, in the fact that, in defending the rights of a small, militarily weak nation against the powerful absolutisms of England, France, and Spain, Grotius was led to a preliminary investigation of the sources and validity of the concept of “natural law”—the notion that inherent in human reason and immutable even against the willfulness of sovereign states are imperative considerations of natural justice and moral responsibility, which must serve as a check against the arbitrary exercise of vast political power.

In general, the political philosophy of the Renaissance was dualistic: it was haunted, even confused, by the conflict between political necessity and general moral responsibility. Machiavelli, Bodin, and Hobbes asserted claims that justified the actions of Italian despotism and the absolutisms of the Bourbon and Stuart dynasties. Yet Machiavelli was obsessed with the problem of human virtue; Bodin insisted that even the sovereign ought to obey the law of nature—that is, to govern in accordance with the dictates of natural justice; and Hobbes himself found in natural law the rational motivation that causes a man to seek for security and peace. In the end, though Renaissance political necessity required that the philosophical doctrines of Thrasymachus (who held that right is what is in the interest of the strong) be implemented, it could never finally escape a twinge of Socratic conscience.

Humanism. The Renaissance was characterized by the renewed study of mathematics, medicine, and classical literature. The first two sparked the scientific revolution of the 16th and 17th centuries; the last became the foundation of the philosophy of Renaissance humanism. From its origin, humanism—suspicious of science and generally indifferent to religion—emphasized anew the centrality of man in the universe, his supreme value and importance. Characteristic of this emphasis was the famous *Oratio de hominis dignitate* (written 1486; *Oration on the Dignity of Man*) of a late 15th-century Platonist, Pico della Mirandola, a leading member of Lorenzo de’ Medici’s Platonic Academy of Florence. But the new emphasis upon man’s personal responsibility and on the possibility of his self-creation as a work of art was in no small part a consequence of the rediscovery of a series of crucial classical texts, which served to reverse the trends of medieval learning. Renaissance humanism was predicated upon the victory of rhetoric over dialectic and of Plato over Aristotle, as Quintilian and Cicero had triumphed over Abelard and as the cramped format of Scholastic philosophical method gave way to a Platonic discursiveness.

Much of this had been prepared by Italian scholarly initiative in the early 15th century. The recently discovered manuscript of Quintilian was used by Lorenzo Valla, an antiauthoritarian humanist, for the creation of modern rhetoric and the principles of textual criticism. But even more important was the rebirth of an enthusiasm for the philosophy of Plato in Medicean Florence and at the cultivated court of Urbino, a dukedom east of Florence. Precisely to service this enthusiasm, Marsilio Ficino, head of the Platonic Academy, had translated the entire Platonic corpus into Latin by the end of the century.

Except for Pico and Giordano Bruno, a late 16th-century Italian philosopher, the direct influence of Platonism upon Renaissance metaphysics is difficult to trace. The Platonic account of the moral virtues, however, was admirably

Ambivalence of political philosophers

Enthusiasm for Plato

Machiavelli and power

adapted to the requirements of Renaissance education and gave new support to the Renaissance ideal of the courtier and the gentleman. But Plato also represented the philosophical importance of mathematics and the Pythagorean attempt to discover the secrets of the heavens, the earth, and the world of nature in terms of number and exact calculation; and this aspect of Platonism spilled over from humanism into the domain of Renaissance science. The scientists Nicolaus Copernicus, Johannes Kepler, and Galileo owe more to the general climate of Pythagorean confidence in the explanatory power of number than does Renaissance metaphysics.

But Platonism also had the effect of influencing the literary form in which Renaissance philosophy was written. Although the very early medieval Platonists St. Augustine and John Scotus Erigena occasionally had used the dialogue form, later Scholasticism had abandoned it in favour of the formal treatise, of which the great "Summas" of Alexander of Hales and St. Thomas Aquinas are pristine examples. The Renaissance rediscovery of the Platonic dialogues suggested the literary charm of this conversational method to humanists, scientists, and political theorists alike. The humanist philosopher Bruno put forth his central insights in a dialogue, *De la causa, principio e uno* (1584; *Concerning the Cause, Principle, and One*); Galileo presented his novel mechanics in his *Dialogo sopra i due massimi sistemi del mondo, tolemaico e copernicano* (1632; *Dialogue Concerning the Two Chief World Systems—Ptolemaic and Copernican*); and even the politician Machiavelli wrote *Dell'arte della guerra* (1521; *The Art of War*) as a genteel conversation taking place in a quiet Florentine garden.

Renaissance humanism was primarily a moral and a literary, rather than a narrowly philosophical, movement. And it flowered in figures with broadly philosophical interests, such as Erasmus of Rotterdam, the erudite citizen of the world; Sir Thomas More, the learned but unfortunate chancellor of Henry VIII; and, in the next generation, in the great French essayist and mayor of Bordeaux, Michel de Montaigne. But the recovery of the Greek and Latin classics, which was the work of humanism, had profound effects upon the entire field of Renaissance philosophy and science through the ancient schools of philosophy to which it once more directed attention. In addition to Platonism, the most notable of these were Greek Atomistic Materialism, Greek Skepticism, and Roman Stoicism. The discovery of the manuscript of Lucretius (and the Atomistic doctrines of Democritus) finally came to influence Galileo, Bruno, and, later, Pierre Gassendi, a modern Epicurean, through the insights into nature reflected in this work. The recovery of the manuscript of Sextus Empiricus, with its carefully argued Skepticism presented in a printed text in 1562, produced "a skeptical crisis" in French philosophy, which dominated the period from Montaigne to René Descartes. And the Stoicism of Seneca and Epictetus became almost the official ethics of the Renaissance—to appear prominently in the *Essais* (1580–88) of Montaigne, in the letters that Descartes wrote to the princess Elizabeth of Bohemia and to Queen Christina of Sweden, and in the later sections of the *Ethics* (first published 1675) of the Rationalist Benedict de Spinoza.

Philosophy of nature. Philosophy in the modern world is a self-conscious discipline. It has managed to define itself narrowly, so as to differentiate itself on the one hand from religion and on the other from exact science. But this narrowing of focus came about very late in its history—certainly not before the 18th century. The earliest philosophers of Greece were theorists of the physical world; Pythagoras and Plato were at once philosophers and mathematicians; and in Aristotle no clear distinction between philosophy and natural science can be maintained. The Renaissance continued this breadth of conception characteristic of the Greeks. Galileo and Descartes were mathematicians, physicists, and philosophers at once; and physics retained the name of "natural philosophy" at least until the death of Sir Isaac Newton in 1727.

Had the Renaissance been painstakingly self-aware in the matter of definition (which it was not), it might have defined philosophy, on the basis of its actual practice, as

"the rational, methodical, and systematic consideration of man, civil society, and the natural world." The areas of its interests would in no case have been in doubt. But exactly what constitutes "rational, methodical, and systematic consideration" would have been extremely controversial. For knowledge advances through the discovery and advocacy of new philosophical methods; and, because the diverse methods advocated depend for their validity upon the acceptance of different philosophical criteria of truth, meaning, and importance, the crucial philosophical quarrels of the 16th and 17th centuries were at bottom quarrels in the advocacy of methods. It is this issue rather than any disagreement over subject matter or areas of attention that separated the greatest Renaissance philosophers—such as Francis Bacon, René Descartes, and Thomas Hobbes.

The great new fact that confronted the Renaissance was the immediacy, the immensity, and the uniformity of the natural world. But what was of primary importance was the new perspective in which this fact was interpreted. To the Middle Ages the universe was hierarchical, organic, and God-ordained. To the Renaissance it was pluralistic, machinelike, and mathematically ordered. In the Middle Ages scholars thought in terms of purposes, of ends, of divine intentions; in the Renaissance they thought in terms of forces, mechanical agencies, and physical causes. All of this had become clear by the end of the 15th century. Within the early pages of the *Notebooks* of Leonardo da Vinci, the great Florentine artist, scientist, humanist, and mechanical genius, occur the following three propositions:

Leonardo's
three
theses

- (1) Since experience has been the mistress of whoever has written well, I take her as my mistress, and to her on all points make my appeal.
- (2) Instrumental or mechanical science is the noblest and above all others the most useful, seeing that by means of it all animated bodies which have movement perform all their actions.
- (3) There is no certainty where one can neither apply any of the mathematical sciences, nor any of those which are based upon the mathematical sciences.

Here are enunciated respectively: (1) the principle of Empiricism, (2) the advocacy of mechanistic science, and (3) the faith in mathematical explanation; and it is upon these three formulations, as upon a rock, that the science and philosophy of the Renaissance built their foundations. From each of Leonardo's theses descended one of the great streams of Renaissance philosophy: from the empirical principle the work of Francis Bacon; from mechanism the work of Thomas Hobbes; and from mathematical explanation that of René Descartes.

Any adequate philosophical treatment of scientific method surely contains both an empirical principle and a faith in mathematical explanation; and, in Leonardo's thinking, as in scientific procedure generally, there need be no conflict between them. Yet they do represent two poles of emphasis, each capable of excluding the other. Moreover, the peculiar accidents of Renaissance scientific achievement did present some evidence for their mistaken separation: for the revival of medical studies on the one hand and the novel blooming of mathematical physics on the other emphasized opposite virtues in scientific methodology. This polarity was represented by the opposing figures of Vesalius and Galileo.

In the mid-16th century Andreas Vesalius, a Belgian physician, was astounding all of Europe with the unbelievable precision of his anatomical dissections and drawings. Having invented new tools for this precise purpose, he successively laid bare the vascular, the neural, and the musculature systems of the human body; and this procedure seemed to demonstrate the virtues of empirical method, of physiological experiment, and of the precision and disciplined skill in sensory observation that made his demonstrations classics of inductive procedure.

Only slightly later the Italian physicist Galileo, following in the tradition already established by Copernicus and Kepler, founders of modern astronomy (but without their more mystical and metaphysical eccentricities), attempted to do for terrestrial and sidereal movements what Vesalius had managed for the structure of the human body—creating his experiential dynamics, however, with the help

schools

of hypotheses supplied by the quantitative calculations of mathematics. In Galileo's work all of the most original scientific directions of the Renaissance came to a head: the revival of Alexandrian mathematics, the experimental use of new instruments, like the lens and the telescope, the search for certainty in physics based upon the undoubted applicability of mathematical theory, and the underlying faith that the search for absolute certainty in science was reasonable because matter in motion accorded with a model of mathematical simplicity. Galileo's work also deals with some of the recurrent themes of 16th- and 17th-century philosophy: an atomism that relates changes in the relations of physical bodies to the corpuscular motion of their parts, the reduction of all qualitative differences to quantitative reasons, and the resultant important distinction between "primary" and "secondary" qualities. The former—including shape, extension, and specific gravity—were considered to be in fact a constituent part of nature and therefore "real." The latter—such as colour, odour, taste, and relative position—were taken to be simply the effect of bodily movements upon perceiving minds and therefore ephemeral, "subjective," and essentially irrelevant to the nature of physical reality.

Rise of Empiricism and Rationalism. The scientific contrast between Vesalius' rigorous observational techniques and Galileo's reliance upon mathematical theory received further expression in the contrast between the respective philosophies of Francis Bacon and René Descartes. And, indeed, in its more abstract formulation as the contrast between Rationalism and Empiricism, it was to dominate the philosophical controversies of the 17th and 18th centuries and to present a dilemma hardly to be resolved before the advent of Immanuel Kant.

The Empiricism of Francis Bacon. Flourishing about the turn of the 17th century, Sir Francis Bacon (1561–1626) was the outstanding apostle of Renaissance Empiricism. Less an original metaphysician or cosmologist than the advocate of a vast new program for the advancement of learning and the reformation of scientific method, Bacon conceived of philosophy as a new technique of reasoning that should reestablish natural science upon a firm foundation. In the *Advancement of Learning* (1605) he charted the map of knowledge: history, which depends upon the human faculty of memory; poetry, upon that of imagination; and philosophy, upon man's reason. To reason, however, Bacon assigned a completely experiential function. Fifteen years later, in his *Novum Organum*, he made this clear: because, he said, "we have as yet no natural philosophy which is pure, . . . the true business of philosophy must be . . . to apply the understanding . . . to a fresh examination of particulars." A technique for "the fresh examination of particulars" thus constituted his chief claim to philosophical distinction.

Bacon's hope for a new birth of science hinged not only upon vastly more numerous and varied experiments but chiefly upon "an entirely different method, order, and process for advancing experience." This method consisted in the construction of what he called "tables of discovery." He distinguished three kinds: tables of presence, of absence, and of degree (*i.e.*, in the case of any two properties, such as heat and friction, instances in which they appeared together, instances in which one appeared without the other, and instances in which their amounts varied proportionately); and the ultimate purpose of these tables was to order facts in such a way that the true causes of phenomena (the subject of physics) and the true "forms" of things (the subject of metaphysics—the study of the nature of Being) could be inductively established.

Bacon's was no raw Empiricism; his profound sense of fact and his belief in the primacy of observation led him to elicit laws and generalizations. Also, his conception of forms was quite un-Platonic: a form for him was not an essence but a permanent geometric or mechanical structure. His enduring place in the history of philosophy lies, however, in his single-minded advocacy of experience as the only source of valid knowledge and in his profound enthusiasm for the perfection of natural science. It is in this sense that "the Baconian spirit" continued as a source of inspiration: his elaborate classification of the sciences

inspiring the French Encyclopaedists of the 18th century and his Empiricism inspiring the English philosophers of science of the 19th century.

The Materialism of Thomas Hobbes. The English political philosopher Thomas Hobbes (1588–1679) was acquainted with both Bacon and Galileo. With the first he shared a strong concern for philosophical method, with the second an overwhelming interest in matter in motion. His philosophical efforts, however, were more inclusive and more complete than those of either of these contemporaries. He was a comprehensive thinker within the scope of an exceedingly narrow set of presuppositions, and he produced one of the most systematic philosophies of the early modern period—an almost completely consistent description of nature, man, and civil society according to the tenets of mechanistic Materialism.

Hobbes's account of what philosophy is and ought to be clearly distinguished between content and method. As method, philosophy is simply reasoning or calculating by the use of words as to the causes of phenomena. When a man reasons forward from causes to effects, he reasons synthetically, and, when he reasons from effects backward to causes, he does so analytically. (His strong deductive and geometric bias favoured the former.) Hobbes's dogmatic metaphysical presupposition was that the basic reality is matter in motion. The real world is a corporeal universe in constant movement, and the phenomena, the causes and effects of which it is the business of philosophy to lay bare, are either the mutual action of bodies or the quaint effects of bodies upon minds. From this assumption follows Hobbes's classification of the fields that form the content of philosophy: (1) physics, (2) moral philosophy, and (3) civil philosophy. Physics is the science of the motions and actions of natural bodies conceived in terms of cause and effect. Moral philosophy (or, more accurately, psychology) is the detailed study of "the passions and perturbations of the mind"—that is, how minds are "moved" by desire, aversion, appetite, fear, anger, and envy. And civil philosophy concerns the concerted actions of men in a commonwealth—how in detail the wayward wills of men are constrained by power (force) in the prevention of civil disorder and the maintenance of peace.

Hobbes's philosophy was a bold Renaissance restatement of Greek Atomistic Materialism with applications to the realities of Renaissance politics that would have seemed strange to its ancient originators. But there are also elements in it that make it characteristically English. For Hobbes's conventionalist account of language led him to a nominalistic position—that is, to a position denying the reality of universals (general or common concepts)—in much the same fashion as did Bacon's exaggerated emphasis on particulars. Moreover, Bacon's general emphasis upon experience also had its analogue in Hobbes's sensationalist theory of knowledge: the notion that all knowledge has its origin in sense impressions and that all sensations are caused by the action of external bodies upon the organs of sense. Empiricism has been a basic and recurrent expression of British mentality, and its nominalistic and sensationalist roots were already clearly evident in both Bacon and Hobbes.

Rationalism of Descartes. But it was not their philosophy that was to dominate the last half of the 17th century but rather that of René Descartes (1596–1650), a French gentleman who signed himself "Lord of Perron" and who lived the 20 most productive years of his life in the tolerant and hospitable Dutch republic. Descartes, a crucial figure in the history of philosophy, combined (however unconsciously or even unwillingly) the influences of the past into a synthesis that was striking in its originality and yet congenial to the scientific temper of the age. In the minds of all later historians he counts as the progenitor of the modern spirit in philosophy.

From the past there seeped into the Cartesian synthesis doctrines about God from Anselm and Aquinas, a theory of the will from Augustine, a deep sympathy with the Stoicism of the Romans, and a skeptical method taken indirectly from the ancient Skeptics Pyrrho and Sextus Empiricus. But Descartes was also a great mathematician, who invented analytic geometry, who made many physical

Examination of particulars in tables of discovery

Synthesis of past and present thought

and anatomical experiments, who knew and profoundly respected the work of Galileo, and who withdrew from publication his own cosmological treatise *Le Monde* ("The World") after Galileo's condemnation by the Inquisition in 1633.

Each of the maxims of Leonardo, which constitute the Renaissance worldview, found its place in Descartes: the Empiricism of his physiological researches described in his *Discours de la méthode* (1637; *Discourse on Method*), the mechanistic interpretations of the physical world and human action detailed in the *Principia Philosophiae* (1644; *Principles of Philosophy*) and *Les Passions de l'âme* (1649; *The Passions of the Soul*), and the mathematical bias that dominates his theory of method in the *Regulae ad Directionem Ingenii* (published 1701; *Rules for the Direction of the Mind*) and his metaphysics in the *Meditationes de Prima Philosophia* (2nd ed. 1642; *Meditations on the First Philosophy*). But of these three, it is the mathematical strain that clearly predominates.

Bacon and Descartes, the founders of modern Empiricism and Rationalism, respectively, shared two pervasive Renaissance tenets: an enormous enthusiasm for physical science; and the belief that knowledge means power—that the ultimate purpose of theoretical science is to serve the practical needs of men.

In his *Principia* Descartes defined philosophy as "the study of wisdom" or "the perfect knowledge of all one can know." Its chief utility is "for the conduct of life" (morals), "the conservation of health" (medicine), and "the invention of all the arts" (mechanics). He expressed the relation of philosophy as theoretical inquiry to practical consequences in the famous metaphor of the tree of philosophy whose root is metaphysics, whose trunk is physics, and whose branches are, respectively, morals, medicine, and mechanics. The metaphor is revealing for it indicates that, for Descartes (as for Bacon and Galileo), the major concern was for the trunk (physics) and that he busied himself with the roots only in order to provide a firm foundation for the trunk. Thus the *Discours de la méthode*, which provides a synoptic view of the Cartesian philosophy, shows it to be not (as with Aristotle or Whitehead) a metaphysics founded upon physics but rather—that more characteristic product of the 17th century—a physics founded upon metaphysics.

Descartes's mathematical bias was expressed in his determination to ground natural science not in sensation and probability (as did Bacon) but in a principle of absolute certainty. Thus his metaphysics in essence consisted of three principles:

1. To employ the procedure of complete and systematic doubt to eliminate every belief that does not pass the test of indubitability (skepticism);
2. To accept no idea as certain that is not clear, distinct, and free of contradiction (mathematicism);
3. To found all knowledge upon the bedrock certainty of self-consciousness, so that "I think, therefore I am" becomes the only innate idea unshakable by doubt (subjectivism).

From the indubitability of the self, Descartes deduced the existence of a perfect God; and, from the fact that a perfect being is incapable of falsification or deception, he made the inference that those ideas about the corporeal world that he has implanted within man must be true. The achievement of certainty about the natural world was thus guaranteed by the perfection of God and by the clear and distinct ideas that are his gift.

The Cartesian metaphysics is the fountainhead of Rationalism in modern philosophy, for it suggests that the mathematical criteria of clarity, distinctness, and absence of contradiction among ideas are the ultimate test of meaningfulness and truth. This stance is profoundly antiempirical. Bacon, who had said that "reasoners resemble spiders who make cobwebs out of their own substance," might well have said so of Descartes, for the Cartesian self is just such a substance from which the idea of God originates and with which all deductive reasoning begins. Yet for Descartes the understanding is vastly superior to the senses, and, in the question of what constitutes truth in science, only man's reason can ultimately decide.

Cartesianism was to dominate the intellectual life of the Continent until the end of the 17th century. It was a fashionable philosophy, appealing alike to learned gentlemen and highborn ladies; and it was one of the few philosophical alternatives to the decadent Scholasticism still being taught in the universities. Precisely for this reason it constituted a serious threat to established religious authority. In 1663 the Roman Catholic Church placed Descartes's works on the Index of Forbidden Books, and the University of Oxford forbade the teaching of his doctrines. Only in the liberal Dutch universities, such as Groningen and Utrecht, did Cartesianism make serious headway.

Certain features of the Cartesian philosophy made it an important starting point for subsequent philosophical speculation. Being the meeting ground of the medieval and the modern worldviews, it accepted the doctrines of Renaissance science while attempting to ground them metaphysically in the medieval notions of God and the human mind. Thus a certain dualism between God the Creator and the mechanistic world of his creation and between mind as a spiritual principle and matter as mere spatial extension was inherent in the Cartesian position; and a whole generation of French Cartesians (among them Arnold Geulincx, Nicolas Malebranche, and Pierre Bayle) wrestled with the resulting problems of the interaction and reconciliation between the counterposed entities.

Rationalism of Spinoza and Leibniz. Two philosophers of genius carried on the tradition of continental Rationalism: the Dutch Jew Benedict de Spinoza (1632–77) and his younger contemporary Gottfried Wilhelm Leibniz (1646–1716), a Leipzig scholar and polymath. Bacon's philosophy had been a search for method in science, and Descartes's basic aim had been the achievement of scientific certainty; but Hobbes and Spinoza provided the most comprehensively worked out speculative systems of the early modern period. In certain respects they had much in common: a mechanistic picture of the world, with its events guided by a strict determinism, and even a political philosophy in each case looking for political stability based upon centralized power. Yet Spinoza introduced a conception of philosophizing that was new to the Renaissance: Philosophy became a personal and moral quest for the wisdom of life and for the achievement of human perfection.

In conducting this search, Spinoza borrowed much of the basic apparatus of Descartes: the aim at a rational understanding of principles, the terminology of "substance" and of "clear and distinct ideas," and a mathematical method that seeks to convert philosophical knowledge into a complete deductive system using the geometric model of Euclid's *Elements*. Spinoza viewed the universe pantheistically as a single infinite substance, which he called "God," with the dual attributes (or aspects) of thought and extension, and which he differentiated into plural "modes" (or particular things); and he attributed to this world as a whole the properties of a timeless logical system—of a complex of completely determined causes and effects. In so doing Spinoza was simply seeking for man the series of "adequate" ideas that furnish the intellect and constitute human freedom. For ultimately, for Spinoza, the wisdom that philosophy seeks is achieved when one perceives the universe in its wholeness, through the "intellectual love of God," which merges the finite individual with the eternal unity and provides the mind with the pure joy that is the final achievement of its search.

Whereas the basic elements of the Spinozistic worldview are given in his one great work, the *Ethics*, Leibniz' philosophy has to be pieced together from numerous brief expositions or fragments, which seem to be mere intermissions, or philosophical interludes, in an otherwise busy life. But the philosophical form is deceptive. Leibniz was a mathematician and jurist (inventor of the infinitesimal calculus and codifier of the laws of Mainz), diplomat, historian to royalty, and court librarian in a princely house; yet he was also one of the most original philosophers of the early modern period. His chief contributions were in the fields of logic, in which he was a truly brilliant innovator, and metaphysics, in which he provided a third alternative to the Rationalist constructions of Spinoza and Descartes. Leibniz saw logic as a mathematical calculus.

Cartesianism after Descartes

Spinoza's aim, terminology, and method

Elements in Cartesian synthesis

A plu-
rality of
monads

He was the first to distinguish "truths of reason" from "truths of fact" and to contrast the "necessary" propositions of logic and mathematics (which express identities), which hold for all possible worlds, with the "contingent" (or empirical) propositions of science, which hold only for certain existential conditions; and he saw clearly that, as "the principle of contradiction" controls the first, so "the principle of sufficient reason" governs the second.

In metaphysics Leibniz espoused pluralism (as opposed to the dualism of Descartes's thought and extension and the monism of Spinoza's single substance, which is God). There were for him an infinite number of spiritual substances (which he called "monads"), each different, each a percipient of the universe around it, and each mirroring that universe from its own point of view. The chief significance of Leibniz, however, lies not in his differences from Descartes and Spinoza but in the extreme Rationalism that all three shared. In the *Principes de la nature et de la grâce fondés en raison* (1714; "Principles of Nature and of Grace Founded in Reason"), he stated the maxim that can stand for the entire school:

True reasoning depends upon necessary or eternal truths, such as those of logic, numbers, geometry, which establish an indubitable connection of ideas and unailing consequences.

Literary forms and sociological conditions. The literary forms in which philosophical exposition was couched in the early modern period ranged from the scientific aphorisms of Bacon and the autobiographical meditations of Descartes to the systematic prose of Hobbes and the episodic propositional format of Leibniz. Two basic tendencies, however, can be discerned:

1. The early Renaissance commitment to the dialogue form (already noted), inspired by the rediscovery of the Platonic dialogues;

2. The later prevalence of the systematically ordered treatise, undoubtedly influenced by the enormous prestige of deductive mathematics.

The concept of serial order stressed by geometry, in which the reasoner passes from more universal axioms to more specific derivative propositions, influenced in turn the style of Hobbes, Descartes, and Spinoza. The order of presentation in Hobbes's *Leviathan* and in Descartes's *Principia Philosophiae* reflects this serial concern, while Spinoza's *Ethics* utilizes the Euclidean method so formalistically as almost to constitute an impenetrable barrier to the basic lucidity of his thought.

Medieval philosophy with its texts, readings, learned authorities, Disputed Questions, Quodlibetal Questions (brief academic discussions), and its Summas was characteristically associated with the medieval university. It is a singular fact, therefore, that from the birth of Bacon in 1561 to the death of Hume in 1776—i.e., for 200 years—not one first-rate philosophical mind in Europe was permanently associated with a university.

The fact is that, as the age of the saint passed into that of the gentleman, philosophers too reflected this profound change in their titles, their social status, and their economic situation. Sir Francis Bacon was a lawyer, judge, and attendant upon the royal court. Thomas Hobbes was the tutor and companion of young noblemen. René Descartes, son of a noble family, traveled and studied at leisure, retiring to Holland to live out his life on inherited income. Gottfried Wilhelm Leibniz, courtier, diplomat, and scholar, became a privy councillor and baron of the Holy Roman Empire. Thus philosophers often belonged to the lesser nobility or were closely associated with the nobility, to whom—like poets—they dedicated their works; and they lived not by philosophy but for it—either independently, by pensions, gifts, inherited income, or in the households of the nobility.

Thus, philosophy in the 16th and 17th centuries was clearly the preoccupation of a widely scattered elite; and this meant that, despite the printed essay, much philosophical communication took place within a small but at the same time loose and informal circle. Treatises were circulated in manuscript; comments and objections were solicited; and a vast polemical correspondence was built up. Prior to its publication, Descartes prudently sent

his *Meditationes* to the theologians of the Sorbonne for comment; and, after its publication, his friend Mersenne sent it to Hobbes, Antoine Arnauld, and Pierre Gassendi, among others, who returned formal "objections," to which Descartes in turn replied. In addition, the 17th century possessed a rich repository of philosophical correspondence, such as the letters that passed between Descartes and the scientist Christiaan Huygens, between Spinoza and Henry Oldenburg (one of the first secretaries of the Royal Society), and between Leibniz and Arnauld. But philosophers were also familiar with the great monarchs and administrators of the age: Descartes gave philosophical instruction to Queen Christina of Sweden, Leibniz was an intimate of Queen Sophia Charlotte of Prussia, and Spinoza enjoyed the personal friendship of the Dutch politician Johan de Witt.

The chief fact, however, remains the sharp separation of creative philosophers from the formal centres of learning: Hobbes expressed extreme contempt for the decadent Aristotelianism of Oxford; Descartes, despite his prudence, scorned the medievalists of the Sorbonne; and Spinoza refused the offer of a professorship of philosophy at Heidelberg with polite aversion. It was to be another 100 years before philosophy returned to the universities.

THE ENLIGHTENMENT

Although they both lived and worked in the late 17th century, Sir Isaac Newton and John Locke were the true fathers of the Enlightenment. Newton was the last of the scientific geniuses of the age, and his great *Philosophiæ Naturalis Principia Mathematica* (1687; *Mathematical Principles of Natural Philosophy*) was the culmination of the entire movement that had begun with Copernicus and Galileo—the first great physical synthesis based upon the application of mathematics to nature in every detail. The basic idea of the authority and autonomy of reason, which dominated all philosophizing in the 18th century, was, at bottom, the consequence of Newton's work.

Copernicus, Kepler, Bacon, Galileo, and Descartes—scientists and methodologists of science—performed like men urgently attempting to persuade nature to reveal her secrets. Newton's comprehensive mechanistic system made it seem as if at last she had done so. It is impossible to exaggerate the enormous enthusiasm that this assumption kindled in all of the major thinkers of the 18th century from Locke to Kant. The new enthusiasm for reason that they all instinctively shared was based not upon the mere advocacy of propagandists like Descartes and Leibniz but upon the conviction that for the intellectual conquest of the natural world reason had really worked.

Classical British Empiricism and its basic tasks. Two major philosophical problems remained: to account for the genetic origins of the reason that had proved so successful and to shift its application from external nature to man. John Locke's *Essay Concerning Human Understanding* (1690) was devoted to the first; and David Hume's *Treatise of Human Nature* (1739–40), "being an attempt to apply the method of experimental reasoning to moral subjects," was devoted to the second.

These two basic tasks reflect a shift away from the direction in which philosophizing had moved in the late Renaissance. The Renaissance preoccupation with the natural world had represented a certain "realistic" bias. Hobbes and Spinoza had each produced a metaphysics. They had been interested in the real constitution of the physical world. Moreover, the Renaissance bias in favour of mathematics had generated the profound interest in rational principles, necessary propositions, and innate ideas that was so prevalent in the philosophies of Leibniz and Descartes. On the other hand, the Enlightenment, in turning from the realities of nature to account for the structure of the mind that knows it so successfully and in attempting an experiential account of the furnishings of that mind, settled on the sensory components of knowledge rather than on the merely mathematical. Thus the school of so-called British Empiricism (John Locke, George Berkeley, and David Hume) dominated the perspective of Enlightenment philosophy until the time of Kant. And this school philosophized in terms of ideas rather than things

logical and
Empiricist
philosophy

and of experience rather than innate necessary principles. Whereas the philosophy of the late Renaissance had been metaphysical and Rationalistic, that of the Enlightenment was epistemological and Empiricist.

Origin and nature of reason in Locke and Berkeley. Locke's *Essay Concerning Human Understanding* thus marked a decisively new direction for modern philosophizing because it proposed what amounts to a new criterion of truth. The design of his essay was "to inquire into the origin, certainty, and extent of human knowledge," which involved three tasks:

1. To discover the origin of men's ideas;
2. To exhibit their certainty and evidential value;
3. To examine the claims of all knowledge that is less than certain.

What was crucial for Locke, however, was that the second task is dependent upon the first. Following the general Renaissance custom, Locke defined an "idea" as a mental content, as "whatever is the object of the understanding when a man thinks"; but, whereas for Descartes and the entire Rationalistic school the certainty of ideas had been a function of their self-evidence—i.e., of their clarity and distinctness—for Locke their validity hinged expressly upon the mode and manner of their origin. A genetic criterion of truth and validity replaced an intrinsic one.

Locke's exhaustive survey of mental contents is useful, if elaborate. Though he distinguished between ideas of sensation and ideas of reflection, the whole thrust of his efforts and those of his Empiricist followers was to reduce the latter to the former, to minimize the originative power of the mind in favour of its passive receptivity to the sensory impressions received from without. Locke's classification of ideas into simple and complex was an attempt to distinguish mental contents such as blueness or solidity, which come from a single sense like sight or touch, and those such as figure, space, extension, rest, and motion, which are the product of several senses combined, on the one hand, from those complicated and compounded (complex) ideas of universals such as triangle or gratitude, of substances, and of relations such as identity, diversity, and cause and effect, on the other.

Locke's *Essay* was a dogged attempt to produce the total world of man's conceptual experience out of a set of elementary sensory building blocks, moving always from sensation toward thought and from the simple to the complex. The basic outcome of his epistemology was therefore:

1. That the ultimate source of men's ideas is sensation;
2. That all mental operations are a combining and compounding of simple sensory materials into complex conceptual tools.

It was a theory of knowledge based upon a kind of sensory atomism, which sees the mind as an agency of discovery rather than of creation and views its ideas as "like" the objects that are the sources of the sensations it receives. But it sees also that an important distinction must still be made between those "primary qualities" such as solidity, figure, extension, motion, and rest, which are the actual characteristics of objects themselves, and those "secondary qualities" such as colour, taste, and smell, which are simply the internal consequences of how the mind is affected by them. This important Lockean distinction (already found in Galileo) was only a mirroring in the theory of knowledge of the physics of Sir Isaac Newton, which was its contemporary.

It was precisely this dualism presupposed by the science of the time between primary qualities, which belong to matter, and secondary qualities, which belong to mind, that Locke's successor George Berkeley (1685–1753) sought to overcome. Though Berkeley was a bishop in the Anglican Church who wanted to combat "atheistic Materialism" and to sustain the power of God and spirituality, his importance for the theory of knowledge lies rather in the way in which he demonstrated that, in the end, primary qualities are reducible to secondary qualities. His Empiricism led to a denial of abstract ideas because he believed that general notions are simply fictions of the mind and vehemently denied that one may validly distinguish between objects and the sensory impressions that repose in the mind. Science, he argued, can easily dispense with

the concept of matter: nature is simply that which men perceive by their senses, and this means that sense data can be considered as "objects for the mind" rather than as "qualities adhering in a substance." A thing is simply a recurrent group of sense qualities. With this important reduction of substance to quality, Berkeley thus became the true father of the epistemological position known as phenomenalism, which has remained an important influence in British philosophizing to the present day.

Basic science of man in Hume. The third, and in many ways the most famous, of the British Empiricists was the Skeptic David Hume (1711–76). Hume's philosophical intention was to reap, humanistically, the harvest sowed by Newtonian physics, to apply the method of natural science to human nature, and to create a basic science of man. The paradoxical result of this admirable purpose, however, was to create a skeptical crisis more devastating than that of the early French Renaissance and to reduce human certainty once more to the state that it was in before Descartes had reached the dogmatic halting point in his procedure of methodical doubt.

Hume followed Locke and Berkeley in approaching the problem of knowledge from a psychological perspective. He too found the origin of knowledge in sense impressions. But whereas Locke had found a certain trustworthy order in the compounding power of the mind, and Berkeley had found mentality itself expressive of a certain spiritual power, Hume's relentless analysis discovered as much contingency in mind as in the external world. All uniformity in perceptual experience, he held, comes from "an associating quality of the mind." The "association of ideas" is a fact, but the relations of resemblance, contiguity, and cause and effect that it produces have no intrinsic validity because they are the product of an inexplicable "mental habit." Thus the causal principle upon which all knowledge rests indicates no necessary connections between things but is simply the accident of their constant conjunction in men's minds. Moreover, the mind itself, far from being an independent power, is simply "a bundle of perceptions" without unity or cohesive quality. Hume's denial of a necessary order of nature on the one hand and of a substantial or unified self on the other precipitated a philosophical crisis from which Enlightenment philosophy was not to be definitely rescued until the work of Kant.

Nonepistemological movements in the Enlightenment. Though the school of British Empiricism represented the mainstream of Enlightenment philosophy until the time of Kant, it was by no means the only type of philosophy that the 18th century produced. The Enlightenment, which was based upon a few great fundamental ideas—such as the dedication to reason, the belief in intellectual progress, the confidence in nature as a source of inspiration and value, and the search for tolerance and freedom in political and social institutions—produced many cross-currents of intellectual and philosophical expression.

Materialism and scientific discovery. The profound influence of Locke spread to France, where it not only produced the skeptical Empiricism of Voltaire but also united with the mechanistic side of the teachings of Descartes to create an entire school devoted to a sensationalistic Materialism. Julien de La Mettrie in *L'Homme-machine* (1747; *Man a Machine*), Étienne de Condillac in his *Traité des sensations* (1754; *Treatise on the Sensations*), and Paul, baron d'Holbach, in his *Système de la nature* (1770; *The System of Nature*) represented a limited worldview in which matter in motion is the only reality, determining the functioning of the human brain and its sensations according to ironclad and necessary laws. This position even found its way into many of the articles of the great French encyclopaedia edited by Denis Diderot and Jean d'Alembert, which was almost a complete compendium of the scientific and humanistic accomplishments of 18th-century intellectual life.

Though the Middle Ages and the Renaissance had not referred to themselves by these names, the 18th century called itself "the Enlightenment" with self-conscious enthusiasm and pride. It was an age of optimism with a sense of new beginnings. Great strides were made in chemistry and biological science. Jean-Baptiste, chevalier

Sense impressions and association of ideas

Locke's effort to build a total world

Optimism and the beginning of many disciplines

de Lamarck, Georges Cuvier, and Georges-Louis Leclerc, comte de Buffon, were perfecting a system of animal classification. And, in the eight years between 1766 and 1774, Henry Cavendish discovered hydrogen; Daniel Rutherford, nitrogen; and Joseph Priestley, oxygen. It was the period when foundations were being laid in psychology and the social sciences and in ethics and aesthetics. Anne-Robert-Jacques Turgot, the marquis de Condorcet, and Montesquieu in France, Giambattista Vico in Italy, and Adam Smith in England marked the beginning of history, economics, sociology, and jurisprudence as sciences. Hume, Jeremy Bentham, and the British moral sense philosophers were turning ethics into a specialized field of philosophical inquiry; and Anthony Ashley, 3rd earl of Shaftesbury, Edmund Burke, Johann Gottsched, and Alexander Baumgarten were laying the foundations for a systematic aesthetics.

Social and political philosophy. But, outside of the theory of knowledge, the most significant contribution of the Enlightenment came in the field of social and political philosophy, as Locke's *Two Treatises of Civil Government* (1690) and Jean-Jacques Rousseau's *Du contrat social* (1762; *The Social Contract*) proposed a justification of political association grounded in the newer political requirements of the age. The Renaissance political philosophies of Machiavelli, Bodin, and Hobbes had centred on the absolute power of kings and rulers. But the Enlightenment theories of Locke and Rousseau turned instead to the freedom and equality of citizens. It was a natural historical transformation. The 16th and 17th centuries had constituted the age of absolutism; the political problem had been largely that of internal order, and political theory had been presented in the language of national sovereignty. But the 18th century was the age of the democratic revolutions (including the French Revolution); the political problem was that of freedom and the revolt against injustice, and political theory was expressed in the idiom of natural and inalienable rights.

Locke's political theory was an express denial of the divine right of kings and the absolute power of the sovereign as contained in the doctrines of Hobbes. Instead, he insisted that all men have a natural right to freedom and equality. The state of nature in which men originally live is not, as in Hobbes, intolerable, but it has certain inconveniences. Therefore men band together to form society, as Aristotle had taught, "not simply to live, but to live well." Political power can never be exercised apart from its ultimate purpose, which is the common good; for men enter the political contract in order to preserve life, liberty, and property.

Locke thus stated one of the fundamental principles of the liberal tradition: that there can be no subjection to power without consent, although once political society has been founded, there is an obligation to submit to the decisions of the majority. It is the legislature that makes these decisions, although the ultimate power of choosing the legislature rests with the people; and even the powers of the legislature are not absolute, because the laws of nature remain as a permanent standard and as principles of protection against any arbitrary authority.

Rousseau's more radical political doctrines were built upon Lockean foundations. For him, too, the convention of the social contract formed the basis of all legitimate authority among men, although his conception of citizenship was much more organic and much less individualistic than Locke's. The surrender of natural liberty for civil liberty means that all individual rights (among them property rights) become subordinate to the general will. For Rousseau the state is a moral person whose life is the union of its members, whose laws are acts of the general will, and whose end is the liberty and equality of the citizens. It follows that, when any government usurps the power of the people, the social compact is broken; and not only are the citizens no longer compelled to obey but they also have an obligation to rebel. Rousseau's defiant collectivism was clearly a revolt against Locke's systematic individualism; for him the fundamental category is not "natural person" but "citizen." Nevertheless, however much they differed, in these two social theorists of the

Enlightenment is to be found the germ of all modern liberalism: its faith in representative democracy, in civil liberties, and in the basic dignity of man.

Professionalization of philosophy. In his *Éléments de philosophie* (1759; "Elements of Philosophy"), Jean d'Alembert, an 18th-century French mathematician and Encyclopaedist, wrote:

Our century is the century of philosophy par excellence. If one considers without bias the present state of our knowledge, one cannot deny that philosophy among us has shown progress.

D'Alembert was calling attention to that reflective self-examination for which the 18th century is famous, and he was undoubtedly referring to the activities of mathematicians like himself, jurists, economists, and amateur moralists rather than to narrow philosophical specialists. But the 18th century was clearly the "century of philosophy par excellence" in a more technical sense also. For it was the period in which philosophizing first began to pass from the hands of gentlemen and amateurs into those of true professionals. The chief sign of this shift was the return of reputable philosophy to the universities.

This transformation first occurred in Germany and is chiefly associated with the University of Halle (founded 1694). In the time of the generation that lies between Leibniz (died 1716) and Kant (born 1724), the philosophical climate changed profoundly. The chief representative of this change was Christian Wolff, who taught philosophy at Halle and was the intermediary between the ideas of Leibniz and those of Kant and the profoundly different conceptions of philosophizing for which they stood.

Kant later called Wolff "the real originator of the spirit of thoroughness in Germany"; and Wolff was indeed a pioneer in those techniques that transform philosophy into a professional discipline—the self-conscious adoption of a systematic approach and the creation of a specialized philosophical vocabulary. Wolff carefully distinguished the various fields of philosophy; wrote textbooks in each of them, which were used in the German universities for many years; and created many of the specialized philosophical terms that have survived to the present day.

The German Enlightenment was the first modern period to produce "specialists in philosophy." In England philosophizing in the universities did not become serious until well after the time of Hume, but already philosophical fields had been sufficiently distinguished to be represented by distinct professorships. The titles professor of mental or moral or metaphysical philosophy, as they arose at Oxford and Cambridge, were the product of the late 18th and early 19th centuries.

Two additional factors of the German Enlightenment are relevant: (1) the founding of the first professional journals and (2) the rising concern of philosophy with its own history. The learned journal, like the scientific society, was an innovation of the 17th century. But what had begun as a general intellectual endeavour became in 18th-century Germany a specifically philosophical enterprise. Journals were published in great numbers; e.g., *Acta Philosophorum* (Halle, 1715–26), *Der Philosophische Büchersaal* (Leipzig, 1741–44; "The Philosophical Book Room"), and the short-lived *Neues philosophisches Magazin* (Leipzig, 1789–91), devoted exclusively to the philosophy of Kant.

More interesting still is the flowering of voluminous German histories of philosophy after 1740. By the 18th century there was already a vast accumulation of historical materials, and the self-conscious feeling that philosophy constitutes a specific field the past of which is worth examination and careful ordering combined with the German spirit of thoroughness to produce a series of massive histories such as Johann Brucker's *Historia Critica Philosophiae*, 6 vol. (1742–44; *The History of Philosophy*); Johann Buhle's *Lehrbuch der Geschichte der Philosophie*, 8 vol. (1796–1804; "Textbook on the History of Philosophy"); Dietrich Tiedemann's *Geist der spekulativen Philosophie von Thales bis Berkeley*, 6 vol. (1791–97; "The Spirit of Speculative Philosophy from Thales to Berkeley"); and Gottlieb Tennemann's *Geschichte der Philosophie*, 11 vol. (1789–1819; excerpted in *A Manual of the History of Philosophy*).

Freedom, equality, justice, rights

Critical examination of reason in Kant. All of these developments led directly to Immanuel Kant (1724–1804), professor at Königsberg, the greatest philosopher of the modern period, whose works mark the true culmination of the philosophy of the Enlightenment. Historically speaking, Kant's great substantive contribution was to relate both the sensory and the a priori elements in knowledge and thus to mend the breach between the extreme Rationalism of Leibniz and the extreme Empiricism of Hume. But in addition to the brilliant content of his philosophical doctrines, Kant was responsible for three crucial philosophical innovations: (1) a new definition of philosophy, (2) a new conception of philosophical method, and (3) a new structural model for the writing of philosophy.

Kant's definition of philosophy culminated the Enlightenment, for it took reason to be the very heart of the philosophical enterprise. Philosophy's sole task, in his view, is to determine what reason can and cannot do. Philosophy, he said, "is the science of the relation of all knowledge to the essential ends of human reason"; and its true aim is both constructive ("to outline the system of all knowledge arising from pure reason") and critical ("to expose the illusions of a reason that forgets its limits"). Philosophy is thus a calling of great dignity, for its aim is wisdom, and its practitioners are themselves "lawgivers of reason." But in order for philosophy to be "the science of the highest maxims of reason," the philosopher must be able to determine the source, the extent, and the validity of human knowledge and the ultimate limits of reason. And these tasks require a special philosophical method.

Sometimes Kant called this the "transcendental method," but more often the "critical method"; for his purpose was to reject the dogmatic assumptions of the Rationalist school, and his wish was to return to the semiskeptical position with which Descartes had begun before his dogmatic pretensions to certainty took hold. Kant's method was to conduct a critical examination of the powers of an a priori judging reason and to inquire what reason can achieve when all experience is removed. The method was based upon a doctrine that he himself called "a Copernican revolution" in philosophy (by analogy with the change from geocentric to heliocentric cosmology): the assumption not that man's knowledge must conform to objects but that objects must conform to man's apparatus of knowing. The question then became: What is the exact nature of that knowing apparatus?

Unlike Descartes, Kant could not question that knowledge exists. Mathematics and Newtonian physics were too real for any Enlightenment mentality to entertain this doubt. Kant's methodological question was rather: How is mathematical and physical knowledge possible? What must be the structure of man's knowing process to have made these sciences secure? The attempt to answer these questions was the task of Kant's great *Kritik der reinen Vernunft* (1781; *Critique of Pure Reason*).

But Kant's great aim was to examine reason not merely in one of its domains but in each of its employments, according to the threefold structure of the human mind that he had taken over from Wolff. Thus the critical examination of reason in thinking (science) is undertaken in the *Kritik der reinen Vernunft*, that of reason in willing (ethics) in the *Kritik der praktischen Vernunft* (1788; *Critique of Practical Reason*), and that of reason in feeling (aesthetics) in *Kritik der Urteilkraft* (1790; *Critique of Judgment*).

Literary forms. The literary format of Enlightenment philosophizing was essentially simple and straightforward. Except for an occasional reversion to the dialogue form, as in Berkeley's *Three Dialogues Between Hylas and Philonous* (1713) and in Hume's *Dialogues Concerning Natural Religion* (1779), it consisted of inquiries, discourses, treatises, dissertations, and essays, generally well written in clear, relatively nontechnical prose. But Kant not only introduced a formidable technical philosophical terminology into his works but was, in fact, the originator of a new philosophical form—the "critique" or "critical examination"—which had its own special architectonics. Each of Kant's three critiques consists of the same division into three parts: (1) an "Analytic," or analysis of reason's right functioning; (2) a "Dialectic," or logic of error,

showing the pitfalls into which a careless reason falls; and (3) a "Methodology," which is an arrangement of rules for practice. It is a form that was unique to Kant, but it raised certain problems of "oppositional" thinking, to which 19th-century philosophers such as Hegel, Schopenhauer, and Kierkegaard were subsequently to turn.

THE 19TH CENTURY

Kant's death in 1804 formally marked the end of the Enlightenment. The 19th century ushered in new philosophical problems and new conceptions of what philosophy ought to do. It was a century of great philosophical diversity. In the Renaissance the chief intellectual fact had been the rise of mathematics and natural science, and the tasks that this fact imposed upon philosophy determined its direction for two centuries. In the Enlightenment attention had turned to the character of the mind that had so successfully mastered the natural world, and Rationalists and Empiricists had contended for mastery until the Kantian synthesis. As for the 19th century, however, if one single feature of its thought could be singled out for emphasis, it might be called the discovery of the irrational. But many philosophical schools were present, and they contended, one with another, in a series of distinct and powerful oppositions: Pragmatism against Idealism; Positivism against irrationalism; Marxism against liberalism.

Politically the 19th century began with the consulate of Napoleon and ended with the Golden Jubilee of Queen Victoria; but it is the intellectual and social changes that fell in between that have philosophical consequences. These changes were chiefly the Romantic movement of the early 19th century, which was a poetic revolt against reason in favour of feeling; the maturation of the Industrial Revolution, which caused untold misery within society and called forth a multitude of philosophies of social reform; the Revolution of 1848 in Paris, Germany, and Vienna, which symbolized class divisions and first implanted in the European consciousness the concepts of "the bourgeoisie" and "the proletariat"; and, finally, the great surge in biological science with Darwin and the publicizing of the idea of biological evolution. Romanticism influenced both German Idealism and philosophers of irrationalism. Experiences of economic discord and social unrest produced the ameliorative social philosophy of English Utilitarianism and the revolutionary doctrines of Karl Marx. And the developmental ideas of Darwin provided the prerequisites for American Pragmatism.

A synoptic view of philosophy in the 19th century reveals an interesting chronology. The early century was dominated by the German school of absolute Idealism (Johann Fichte, Friedrich Schelling, and G.W.F. Hegel). The mid-century was marked by a rebirth of interest in science and its methods (Auguste Comte in France and John Stuart Mill in England) and by liberal (Mill) and radical (Marx) social theory. The late century saw a second flowering of Idealism, this time in England (T.H. Green, F.H. Bradley, and Bernard Bosanquet) and, with Charles Sanders Peirce and William James, the rise of American Pragmatism. The new philosophies of the irrational in the highly individual thinkers Søren Kierkegaard, Arthur Schopenhauer, and Friedrich Nietzsche ran through the century in its entirety.

German Idealism of Fichte, Schelling, and Hegel. The Enlightenment, inspired by the example of natural science, had accepted certain bounds to the possibility of knowledge; that is, it had recognized certain limits to reason's ability to penetrate ultimate reality because that would require methods that surpass the boundaries of scientific method. In this particular modesty, the philosophies of Hume and Kant were much alike. But the early 19th century marked a resurgence of the metaphysical spirit at its most ambitious and extravagant extreme. German Idealism reinstated the speculative pretensions of Leibniz and Spinoza at their height. This turn was partly a consequence of the Romantic influence but, more importantly, of a new alliance of philosophy not with science but with religion. It was not accidental that all of the great German Idealists were university professors whose fathers were Protestant pastors or who had themselves studied theology: Fichte at Jena and Leipzig (1780–84); Schelling

The end of the Enlightenment

The transcendental, or critical, method of examining reason

Resurgence of religiously inspired metaphysics

and Hegel at the Tübingen seminary (1788–95). And it is probably this circumstance that gave to German Idealism its intensely serious, its quasi-religious, and its dedicated character.

The consequence of this religious alignment was that philosophical interest shifted from Kant's *Critique of Pure Reason* (in which he had attempted to account for natural science and denied the possibility of certainty in metaphysics) to his *Critique of Practical Reason* (in which he had explored the nature of the moral self) and his *Critique of Judgment* (in which he had treated of the purposiveness of the universe as a whole). For absolute Idealism was based upon three premises:

1. That the chief datum of philosophy is the human self and its self-consciousness;
2. That the world as a whole is spiritual through and through, that it is, in fact, something like a cosmic Self;
3. That, in both the self and the world, it is not primarily the intellectual element that counts but, rather, the volitional and the moral.

Thus, to understand the self, self-consciousness, and the spiritual universe became for Idealistic metaphysics the task of philosophy.

From the point of view of doctrine, Fichte, Schelling, and Hegel had much in common. Fichte (1762–1814), professor of philosophy at the newly founded University of Berlin (1809–14) and a great symbol of German patriotism through the Napoleonic Wars, combined in a workable unity the subjectivism of Descartes, the cosmic monism of Spinoza, and the moral intensity of Kant. He saw human self-consciousness as the primary metaphysical fact through the analysis of which the philosopher finds his way to the cosmic totality that is “the Absolute.” And, just as the moral will is the chief characteristic of the self, so also is it the activating principle of the world. Thus Fichte provided a new definition of philosophizing that made it central in dignity in the intellectual world. The sole task of philosophy is “the clarification of consciousness.” And the highest degree of self-consciousness is achieved by the philosopher because he alone recognizes “Mind,” or “Spirit,” as the central principle of reality.

Hegel:
“the
rational is
the real”

This line of thought was carried further by Georg Wilhelm Friedrich Hegel (1770–1831), Fichte's successor at Berlin and perhaps the single most comprehensive and influential thinker of the 19th century. Kant's problem had been the critical examination of reason's role in human experience. For Hegel, too, the function of philosophy is to discover the place of reason in nature, in experience, and in reality; to understand the laws according to which reason operates in the world. But whereas Kant had found reason to be the form that mind imposes upon the world, Hegel found it to be constitutive of the world itself—not something that mind imposes but that it discovers. As Fichte had projected consciousness from mind into reality, so Hegel projected reason; and the resultant Hegelian dictates—that “the rational is the real” and that “the truth is the whole”—although they express an organic and a totalitarian theory of truth and reality, tend to blur the usual distinctions that previous philosophers had made between logic and metaphysics, between subject and object, and between thought and existence. For the basic tenet of Idealism, that reality is spiritual, generates just such a vague inclusiveness.

To the Fichtean foundations, however, Hegel added one crucial corollary: that the Absolute, or Whole, which is a concrete universal entity, is not static but undergoes a crucial development in time. Hegel called this evolution “the dialectical process.” By stressing it, Hegel accomplished two things: (1) he indicated that reason itself is not eternal but “historical,” and (2) he thereby gave new meaning and relevance to the changing conditions of human society in history—which added to the philosophical task a cultural dimension that it had not possessed before.

The philosopher's vocation, in Hegel's view, was to approach the Absolute through consciousness, to recognize it as Spirit expressing and developing itself (“realizing itself” was his own phrase) in all of the manifold facets of human life. For struggle is the essence of spiritual existence, and self-enlargement is its goal. For these reasons the various

branches of intellect and culture become stages in the unfolding of the World-Spirit:

1. The psychological characteristics of man (habit, appetite, judgment) representing “Subjective Spirit”;
2. His laws, social arrangements, and political institutions (the family, civil society, the state) expressing “Objective Spirit”;
3. His art, religion, and philosophy embodying “Absolute Spirit.”

What began, therefore, in Hegel as a metaphysics of the Absolute ended by becoming a total philosophy of human culture.

Positivism and social theory in Comte, Mill, and Marx.

The absolute Idealists wrote as if the Renaissance methodologists of the sciences had never existed. But if in Germany the Empirical and scientific tradition in philosophy lay dormant, in France and in England in the middle of the 19th century it was very much alive. In France, Auguste Comte (1798–1857) wrote his great philosophical history of science, *Cours de philosophie positive* (1830–42; *The Positive Philosophy of Auguste Comte* [abridged]) in six volumes. Influenced by Bacon and the entire school of British Empiricism, by the doctrine of progress put forward by Turgot and Condorcet during the 18th century, and by the very original social reformer Henri de Saint-Simon, Comte called his philosophy “Positivism,” by which he meant a philosophy of science so narrow that it denied any validity whatsoever to “knowledge” not derived through the accepted methods of science. But the *Cours de philosophie positive* made its point not by dialectic but by an appeal to the history of thought, and here Comte presented his two basic ideas:

Comte's
Philosophie positive

1. The notion that the sciences have emerged as sciences in strict order, beginning with mathematics and astronomy, followed by physics, chemistry, and biology in that order, and culminating in the new science of sociology, to which Comte was the first to ascribe the name;

2. The so-called “law of the three stages,” which views thought in every field as passing progressively from superstition to science by first being (a) religious, then (b) abstract, or metaphysical, and finally (c) positive, or scientific. Comte's permanent contribution was to initiate an antireligious and an antimetaphysical bias in the philosophy of science that has passed into the 20th century.

In mid-19th-century England the chief representative of the Empirical tradition from Bacon to Hume was John Stuart Mill (1806–73). Mill's theory of knowledge, best presented in his *Examination of Sir William Hamilton's Philosophy* (1865), was not particularly original but rather a judicious combination of the doctrines of Berkeley and Hume; but it symbolized his mistrust of vague metaphysics, his denial of the a priori element in knowledge, and his determined opposition to any form of intuitionism. It is in his enormously influential *System of Logic* (1843), however, that Mill's chief theoretical ideas are to be found.

This work, as part of its subtitle, *the Principles of Evidence and the Methods of Scientific Investigation*, shows, was concerned less with formal logic than with scientific methodology. Mill made here the fundamental distinction between deduction and induction, defined induction as the process by which men discover and prove general propositions, and presented his “four methods of experimental inquiry” as the heart of the inductive method. These methods were, in fact, only an enlarged and refined version of Francis Bacon's “tables of discovery.” But the most significant section of *A System of Logic* was its conclusion: book 6, “On the Logic of the Moral Sciences.”

Mill had taken men's experience of the uniformity of nature as the warrant of induction. Here he reaffirmed the belief of Hume that it is possible to apply the principle of causation and the methods of physical science to moral and social phenomena. These may be so complex as to yield only “conditional predictions,” but in this sense there are “social laws.” Thus Comte and Mill agreed upon the possibility of a true social science.

Mill's *Logic* was extremely influential, and it continued to be taught at Oxford and Cambridge well into the 20th century; but in the end his importance lay less in logic and

Mill's
political
liberalism
and ethics

theory of knowledge than in ethics and political theory. For Mill was the great apostle of political liberalism in the 19th century, a true follower of John Locke. And, just as Locke and Rousseau had represented the liberal and the radical wings of social theory in the early modern period, so Mill and Karl Marx represented the liberal and the radical approaches to social reform 100 years later.

Raised by social reformers (his father, James Mill, and Jeremy Bentham) to be a social reformer himself, Mill's social theory was an attempt, by gradual means arrived at democratically, to combat the evils of the Industrial Revolution. His ethics, expressed in his *Utilitarianism* (1861), followed the formulations of Bentham in finding the end of society to consist in the production of the greatest quantity of happiness for its members, but he gave to Bentham's cruder (but more consistent) doctrines a humanistic and individualistic slant. Thus, the moral self-development of the individual becomes the ultimate value in Mill's ethics.

This trend was also expressed in his essay *On Liberty* (1859) and *Considerations on Representative Government* (1861). In the former he stated the case for the freedom of the individual against "the tyranny of the majority," presented strong arguments in favour of complete freedom of thought and discussion, and argued that no state or society has the right to prevent the free development of human individuality. In the latter he provided a classic defense for the principle of representative democracy, asked for the adequate representation of minorities, urged renewed public participation in political action for necessary social reforms, and pointed up the dangers of class-oriented or special-interest legislation.

Marx and
social
revolution

A radical counterbalance to Mill's liberal ideas was provided by Karl Marx (1818–83), a German philosopher, social revolutionary, and political economist. Taking over from Hegel the idea of estrangement (which Hegel had used in a metaphysical sense), Marx used this notion prior to 1848 to indicate the alienation of the worker from the enjoyment of the products of his work, the crass treatment of human labour as a mere commodity (and man as a thing), and, in fact, the general dehumanization of man in a selfish, profit-seeking capitalist society.

In the famous *Communist Manifesto* (1848), Marx, yielding to the revolutionary temper of the times, called (as Rousseau had done before the French Revolution) for the violent overthrow of the established order. All of history, Marx said, is the struggle between exploiting minorities and the underlying population, that is, between bourgeois and proletarians; and he advocated the formation of a Communist Party to stimulate proletarian class consciousness toward the seizure of power and the institution of a just and democratically managed Socialist society.

Marx's revolutionary fervour may have tended to dampen his philosophical reputation in the West, and his philosophical achievement remains a controversial point; but certain of his ideas (some Hegelian in inspiration, some original) have endured. Among these are the ideas:

1. That society is a moving balance (dialectic) of antithetical forces that produce social change;
2. That there is no conflict between a rigid economic determinism and a program of revolutionary action;
3. That ideas (including philosophical theories) are not purely rational and thus independent of external circumstance but depend upon the nature of the social order in which they arise.

Independent and irrationalist movements. The end of the 19th century saw a flowering of many independent philosophical movements. After Hegel was almost forgotten in Germany, his influence migrated to England, where T.H. Green, F.H. Bradley, and Bernard Bosanquet initiated a new Hegelian renaissance. Bradley's *Appearance and Reality* (1893) constituted the high-water mark of the rediscovery of Hegel's dialectical method. In America a strong reaction against Idealism led to the beginnings of the Pragmatic movement initiated by Charles Sanders Peirce and William James. Peirce was an exact logician who recognized that the function of all inquiry is to eradicate doubt and that the meaning of a concept consists in the practical consequences that the concept might be said

to have. James transformed Peirce's pragmatic theory of meaning into a pragmatic theory of truth and, in his *Will to Believe* (1897), asserted that men have a right to believe even in the face of inconclusive evidence and that, because knowledge is an instrument for the sake of life, the true test of a belief is the practical consequences that it entails. Meanwhile, in Austria, Franz Brentano, who taught at Vienna from 1874 to 1895, and Alexius Meinong, who taught at Graz, were developing an empirical psychology and a theory of objects, which were to have considerable influence upon the new philosophy of Phenomenology.

It was not, however, any of these late 19th-century developments but, rather, the emphasis upon the irrational, which started almost at the century's beginning, that gave the philosophy of the period its peculiar flavour. Hegel, despite his commitment to systematic metaphysics, had, nonetheless, carried on the Enlightenment tradition of faith in human rationality. But soon his influence was challenged from two different directions. The Danish Christian thinker Søren Kierkegaard (1813–55) challenged the logical pretensions of the Hegelian system; and one of his contemporaries, Arthur Schopenhauer (1788–1860), himself a German Idealist and constructor of a bold and imaginative system, contradicted Hegel by asserting that the irrational is the truly real.

Kierkegaard's criticism of Hegel was an appeal to the concrete as against the abstract. He satirized Hegelian Rationalism as a perfect example of "the academic in philosophy"—of detached, objective, abstract theorizing and system building, blind to the realities of human existence, to its subjective, living, emotional character. What a man requires in life, said Kierkegaard, is not infinite inquiry but the boldness of resolute decision and commitment. Man's essence is not contained in thinking but in the existential conditions of his emotional life, in his anxiety and despair. The titles of three of Kierkegaard's books—*Frygt og baeven* (1843; *Fear and Trembling*), *Begrebet angst* (1844; *The Concept of Dread*), *Sygdommen til døden* (1849; *The Sickness unto Death*)—indicate his preoccupation with states of consciousness quite unlike the usual philosophical concentration on cognition and the validity of knowledge.

Schopenhauer, even though, for a short time, he competed unsuccessfully with Hegel at the University of Berlin, soon withdrew and thereafter waged a lifelong battle against academic philosophy. His own system, though orderly and carefully worked out, was written in a vivid and engaging style. Schopenhauer agreed with Kant that the world of appearances, of phenomena, is governed by the conditions of space, time, and causality. But he held that science, which investigates this world, cannot itself penetrate the real world behind appearances, which is dominated by a strong, blind, striving, universal cosmic Will that expresses itself in the vagaries of human instinct, in sexual striving, and in the wild uncertainties of all animal behaviour. Everywhere in nature one sees strife, conflict, and inarticulate impulse; and these, rather than rational processes or intellectual clarity, are man's true contacts with ultimate reality.

Schopenhauer's great work *Die Welt als Wille und Vorstellung* (*The World As Will and Idea*) was published in 1819, and Kierkegaard's uneven masterpieces appeared between 1843 and 1849. But Friedrich Nietzsche (1844–1900), the third of the irrationalist triumvirate, wrote between 1872 and 1889. A prolific but unsystematic writer, presenting his patchwork of ideas in swift atoms of thought, Nietzsche saw the task of the philosopher as that of a man who destroys old values, creates new ideals, and through them a new civilization. He agreed with Schopenhauer that mind is an instrument of instinct to be used in the service of life and power, and he held that illusion is as necessary to man as truth. Nietzsche spent much time in the analysis of such states as resentment, guilt, bad conscience, and self-contempt.

Kierkegaard, Schopenhauer, and Nietzsche provided for the 19th century a new, nonrational conception of human nature, and they viewed the mind not with the rational clarity of Locke and Hume but as something dark, obscure, hidden, deep. But, above all, they initiated a new

Irrational-
ism in
Kierke-
gaard and
Schopen-
hauer

Nietzsche's
Dionysian
irrational-
ism

style of philosophizing. Schopenhauer wrote like an 18th-century essayist; Kierkegaard was a master of the methods of irony and paradox; and Nietzsche used aphorism and epigram with conscious literary intention. For these three, the philosopher should be less a crabbed academician than a man of letters.

THE 20TH CENTURY

Despite the tradition of philosophical "professionalism" established during the Enlightenment by Wolff and Kant, philosophy in the 19th century was still largely created by men outside of the universities. Comte, Mill, Marx, Kierkegaard, and Schopenhauer were not professors. Only the German Idealist school was rooted in academic life. Today, however, it is difficult to find one first-rate philosophical mind outside of the academy. (George Santayana after his early years and Jean-Paul Sartre are the notable exceptions.) The agencies of professionalism—the philosophical congress, the national philosophical societies, the narrowly specialized journals—have become increasingly important. Philosophers more and more employ a technical vocabulary and deal with specialized problems, and they write not for a broad intellectual public but for one another.

Professionalism also has sharpened the divisions between philosophical schools and made the definition of what philosophy is and ought to be, a matter of the sharpest controversy. Philosophy has become extremely self-conscious about its own method and nature. Intellectual competitiveness, moreover, has been further sharpened by geographical and political considerations. The tradition of clear analysis, inaugurated by Locke and Hume, still dominates the Anglo-Saxon world; the Hegelian tradition of speculative metaphysics and the Nietzschean tradition of bold psychological generalization still dominate the Continent. And the special framework of thinking established by Karl Marx still dominates philosophy in the Socialist world.

Individual philosophies of Bergson, Dewey, and Whitehead. Except, then, for philosophical Marxism and a few individual philosophers such as Henri Bergson, John Dewey, and A.N. Whitehead, who evade easy classification, the main currents of contemporary philosophy are (1) Analytic philosophy with its two chief branches, (a) Logical Positivism and (b) Linguistic Analysis; and (2) Continental philosophy with its two branches, (a) Existentialism and (b) Phenomenology.

Henri Bergson (1859–1941), John Dewey (1859–1952), and Alfred North Whitehead (1861–1947) have been called the three most important speculative philosophers of the first half of the 20th century. The French Bergson and the American Dewey shared an instrumental theory of mind; that is, influenced by Darwinism, they both held that mind has emerged in the course of biological evolution as an instrument of man's adaptation to his environment and, therefore, that man's mental functions are chiefly utilitarian agencies of action. Bergson and the English Whitehead were both adherents of a process philosophy; that is, each held that actuality is, like a river, fluent, that ultimate reality is mobile and dynamic. Yet, in fact, each of the three defined philosophy differently and saw it as performing a uniquely different task. Bergson's vision of philosophy was intuitionist, Whitehead's was speculative, and Dewey's was pragmatic.

Bergson, in the *Introduction à la métaphysique* (1903; *An Introduction to Metaphysics*) and in his masterpiece, *L'Évolution créatrice* (1907; *Creative Evolution*), distinguished between two profoundly different ways of knowing: the method of analysis, which is that of science; and the method of intuition, which is just that intellectual sympathy by which men enter into objects and persons and identify with them. All basic metaphysical truths, Bergson held, are grasped by philosophical intuition. This is how men know their deepest selves, the duration, which is the essence of all living things, and the vital spirit, which is the mysterious creative agency in the world.

For Whitehead, philosophy was primarily metaphysics (or "speculative philosophy"), the effort "to frame a coherent, logical, necessary system of general ideas in terms of which every element of our experience can be inter-

preted." Whitehead's philosophy was, thus, an attempt to survey the world with a large generality of understanding, an end toward which his great trilogy, *Science and the Modern World* (1925), *Process and Reality* (1929), and *Adventures of Ideas* (1933), was directed.

While Bergson and Whitehead were principally metaphysicians and philosophers of culture, Dewey was an all-around philosopher who dominated the fields of ethics, metaphysics, and methodology in the United States for many years and who stressed the unity, interrelationship, and organicity of all forms of philosophical knowledge. He is chiefly notable, however, because his notion of philosophy stressed so powerfully the conceptions of practicality and moral purpose. One of the guiding aims of Dewey's philosophizing was the effort to find the same warranted assertibility for ethical and political as for scientific judgments. Philosophy, he said, should be oriented not to professional pride but to human need.

The social thought of Mill and Marx presented opposed solutions to the social problems of the 19th century; that of Dewey and Lenin presented opposed solutions to the problems of the 20th century. Not revolution but the continuous application of intelligence to social affairs was Dewey's answer. He believed in social planning, in conscious intelligent intervention to produce desirable social change; and he proposed a new "experimentalism" in social affairs as the guide to enlightened public action to promote the aims of a democratic community. His pragmatic social theory is the major social philosophy that liberal democracy has produced in the modern world.

Marxist thought. The framework of 19th-century Marxist thought, augmented by the philosophical suggestions of Vladimir Ilich Lenin, still serves as the starting point of all philosophizing in the Socialist countries of eastern Europe. To Marx's conception of the dialectic (that the social world progresses through the rise and fall of oppositions), Lenin added a strong tinge of metaphysical Materialism (material things and their systems of relations exist independently of mind, and the laws of nature are objective) and a naively Realist theory of knowledge (ideas and sensations are true copies of independently existing things). But much of Lenin's thinking was also devoted to rather practical issues, like the tactics of violence and the role of the Communist Party in bringing about and consolidating the proletarian revolution.

Later Marxism has continued this concern with practical issues, because it represents the basic Marxist conception of what philosophy is and ought to be. For Marxism (like Pragmatism) tries to assimilate theoretical issues to practical needs. It asserts the basic unity of theory and practice by finding that the function of the former is to serve the latter. Marx and Lenin both held that theory is always in fact expressive of class interests; consequently, they wished philosophy to be transformed into a tool for furthering the class struggle: not abstractly to discover the truth but concretely to forge the intellectual weapons of the proletariat is philosophy's dominant task. Thus philosophy becomes inseparable from ideology.

Since the discovery and publication in 1927 and 1932 of some of Marx's early writings, many have sensed a breath of fresh air in Marxist philosophizing outside the Soviet Union. For the concern of the young Marx with alienation, with a theory of the nature of man, and with moral values has given Marxism a new humanistic dimension and has inspired some notable revisionist thinking in Poland, Hungary, and particularly Yugoslavia.

Analytic philosophy. *Logical Positivism.* Logical Positivism, or Logical Empiricism, the earliest branch of modern Analytic philosophy, was jointly inspired by Hume and by the new logic of Russell and Whitehead, authors of the *Principia Mathematica* (3 vol.; 1910–13). The school, formally instituted at the University of Vienna in a seminar of Moritz Schlick in 1923, continued there as the Vienna Circle until 1938. Its great period began in 1926 when Rudolf Carnap, who became a leading semanticist and philosopher of science, arrived at the University. Its manifesto of 1929, *Wissenschaftliche Weltauffassung: Der Wiener Kreis* ("Scientific Conception of the World: The Vienna Circle"), and its journal *Erkenntnis* ("Know-

Unity of theory and practice in Marxism

Bergson's two ways of knowing

edge”), founded a year later, marked its self-consciousness as a philosophical movement.

Logical Positivism’s basic contribution has been a profound alteration in the conception of the role that philosophy itself must play. Philosophy, it claimed, must henceforth be scientific. It should seek less a content than a function: it should produce not complicated pictures of the world but clear thinking. This was best stated by Ludwig Wittgenstein in his *Tractatus Logico-Philosophicus* (1922), first published as *Logische-philosophische Abhandlung* (1921):

The object of philosophy is the logical clarification of thoughts. Philosophy is not a theory but an activity. A philosophical work consists essentially of elucidations. The result of philosophy is not a number of “philosophical propositions,” but to make propositions clear.

Despite this emphasis upon philosophy as a pure activity, Logical Positivism did propound, at the same time, a series of revolutionary theses:

1. All meaningful discourse consists either of (a) the formal sentences of logic and mathematics or (b) the factual propositions of the special sciences;

2. Any assertion that claims to be factual has meaning only if it is possible to say how it might be verified;

3. Metaphysical assertions, coming under neither of the two classes of (1), are meaningless;

4. All statements about moral, aesthetic, or religious values are scientifically unverifiable and meaningless.

Logical Positivism’s radical denial of the meaningfulness of metaphysics and of assertions of value at first produced something of a philosophical scandal. But meanwhile Bertrand Russell and his student Wittgenstein (who had emigrated from Austria) were propounding similar doctrines in England; and, after the Nazis overran Austria and Carnap, Hans Reichenbach (a Berlin Positivist), and many others from the Vienna Circle moved to America, this philosophy proved remarkably influential in the Anglo-American world. The Logical Positivists were mainly interested in three basic themes: logic, language, and perception. Whereas Russell began with logic, turned to problems of perception, and ended with semantics, Carnap, having begun with perception in *Der logische Aufbau der Welt* (1928; *The Logical Structure of the World*), turned to problems of semantics in *Logische Syntax der Sprache* (1934; *The Logical Syntax of Language*) and ended with logic in *Meaning and Necessity* (1947). But of these three themes it was that of language that proved most enduring. This emphasis Logical Positivism shared with its successor, Linguistic Analysis.

Linguistic Analysis. Sometimes called “ordinary language” Analysis or even “Oxford philosophy” from its later stronghold, this movement was, in fact, largely the product of two philosophers of the first half of the 20th century who were associated with the University of Cambridge, G.E. Moore (1873–1958) and Ludwig Wittgenstein (1889–1951). Moore made the examination of the assertions of other men philosophically popular—i.e., the practice of directing the philosopher’s critical energies to the mistakes of his contemporaries. The major subjects of his interest were ethics and the theory of knowledge; his thought was always Realistic and commonsensical, and he introduced into philosophy an unbelievably precise and closely applied analytical method. It was Moore’s passion for clarity and his infinite pains “to get everything *exactly* right” that served as moral inspiration to a succeeding generation of younger men who had attended his Cambridge lectures over a span of 30 years.

Wittgenstein had begun as a kind of adjunct to the Vienna Circle. There was a time when his philosophical position was much like that of Russell and Carnap; but as he later became more skeptical of the foundations of mathematics and logic, his interest turned from logic and artificial language systems toward a critical examination of ordinary natural language. This change was principally registered in his *Philosophical Investigations*, posthumously published in 1953, which has become the true bible of Linguistic Analysis. For it is here that Wittgenstein showed how a man’s entire world is constituted by his linguistic experience and suggested that “all philoso-

phy is critique of language.” Wittgenstein thought that to ask “Why do we use this particular word or expression?” was the crucial philosophical question since a focusing of philosophy not upon the world but upon the mechanisms of linguistic use would solve most of the perplexities that have plagued philosophizing. Thus Linguistic philosophy was to perform a therapeutic function.

Wittgenstein’s example found many followers in the United States and, particularly, in England. There philosophers Gilbert Ryle, J.L. Austin, and P.F. Strawson have examined “category mistakes,” “systematically misleading expressions,” “mental-conduct concepts” (such as “other minds”), and all of the major “perception words” such as “looking,” “seeing,” “sensing,” “feeling,” and the like. The effect of this concentration not upon things or ideas but upon words has, for members of this school, turned the customary works on ethics, aesthetics, or the philosophy of religion into treatises entitled “The Language of Ethics” or “The Language of Aesthetics” or “The Language of Religion.” And these efforts are all, in Wittgenstein’s terms, “a battle against the bewitchment of our intelligence by means of language.”

Continental philosophy. The Analytic philosophy that by the mid-1970s had come to dominate Anglo-American philosophical thinking for almost half a century has had comparatively little influence on the continent of Europe. There the metaphysical and speculative traditions have remained strong; and in the 1950s and 1960s the interest in both, but particularly in Phenomenology, posed an increasing threat to philosophical Analysis in Britain and the United States. Continental philosophy may be divided into Phenomenology and Existentialism, but the division is not sharp. Thinkers such as Martin Heidegger, Jean-Paul Sartre, and Maurice Merleau-Ponty combine the two strands. And the phenomenological method has been one of the formative forces in Existentialism.

Phenomenology of Husserl and others. Edmund Husserl (1859–1939), a German mathematician turned philosopher, was the true father of Phenomenology. He was an extremely complicated and technical thinker whose views changed considerably over the years. His chief contributions were the phenomenological method, developed early, and the concept of the life-world, appearing only in his later writings. Husserl proposed the phenomenological method as a technique for conducting phenomenological analyses—that is, for making possible “a descriptive account of the essential structures of the directly given.” The emphasis here is upon the immediacy of experience, the attempt to isolate it and set it off from all assumptions of existence or causal influence and to lay bare its actual intrinsic structure; for it is this structure that constitutes its essence. Phenomenology restricts the philosopher’s attention to the pure data of consciousness uncontaminated by metaphysical theories or scientific assumptions. Husserl’s concept of the life-world expressed this same idea of immediacy. It is the individual’s personal world as directly experienced, with the ego at the centre and with all of its vital and emotional colourings.

With the appearance of the *Jahrbuch für Philosophie und Phänomenologische Forschung* (1913–30; “Annual for Philosophical and Phenomenological Research”), under Husserl’s chief editorship, his personal philosophizing flowered into an international movement. Its two most notable adherents were Max Scheler, a scholar of life-philosophy, whose *Formalismus in der Ethik und die materiale Wertethik* (“Formalism in Ethics and the Material Value-Ethics”) was published in the *Jahrbuch* (1913–16), and the ontological Existentialist Martin Heidegger (1889–1976), whose famous *Sein und Zeit* (*Being and Time*) appeared in the *Jahrbuch* in 1927. Despite the differences in their individual philosophies their work showed clearly the influence of the phenomenological method: in Scheler’s careful explorations of the role that emotion plays in men’s moral values and in his descriptive analyses of the human attitudes of resentment, sympathy, and love; and in Heidegger’s startlingly original investigations of human existence with its unique dimensions of being-in-the-world, dread, care, and being toward death. In all of these painstaking and enormously detailed inquiries, however,

Husserl’s phenomenological method and life-world

Scheler, Heidegger, and Merleau-Ponty

Seminal influence of Moore and Wittgenstein

both Scheler and Heidegger held to the phenomenological principle that philosophy is not empirical but is the strictly self-evident insight into the structure of experience. Later, Maurice Merleau-Ponty, a French student of philosophical psychology, in his *Phénoménologie de la perception* (1945; *The Phenomenology of Perception*), took over Husserl's conception of the life-world and used the notions of the lived body and its facticity to build up a hierarchical order of man's lived experience.

Existentialism of Jaspers and Sartre. Continental Existentialism, true to its roots in Kierkegaard and Nietzsche, is oriented toward two major themes: (1) the analysis of human Being and (2) the centrality of human choice. Thus its chief theoretical energies are devoted to ontology and decision. Existentialism as a philosophy of human existence found its best spokesman in the German Karl Jaspers, who came to philosophy from medicine and psychology. As a philosophy of human decision, its spokesman was the French philosopher and playwright Jean-Paul Sartre. These two preoccupations of Existentialism lead to two different conceptions of philosophy's function.

Human
existence
and choice
in Jaspers
and Sartre

For Jaspers (1883–1969), as for Dewey, the aim of philosophy is practical; for Dewey, however, it guides human doing, whereas for Jaspers its purpose is the achievement of human Being. Philosophizing is an inner activity by which the individual finds and becomes himself: it is a revelation of Being. It is an attempt to answer the question of what man is and what he can become; and this activity, wholly unlike that of science, is one of mere thought, through the “inwardness” of which a man becomes aware of the deepest levels of Being.

But if, for Jaspers, philosophy is devoted to “the illumination of existence,” that illumination is achieved when a person recognizes that human existence is revealed most profoundly in his experience of those “extreme” situations that define the human condition—conflict, guilt, suffering, and death. It is in man's confrontation with these extremes that he achieves his existential humanity.

Sartre (1905–80), too, has some concern for man's Being and his dread before the threat of Nothingness. But Sartre finds the essence of this Being in man's liberty—in his duty of self-determination and his freedom of choice—and therefore spends much time in describing the human tendency toward “bad faith”—reflected in man's perverse attempts to deny his own responsibility and to flee from the truth of his inescapable freedom. Sartre, like Schopenhauer and Nietzsche, considered himself less an academic philosopher than a man of letters and also wrote novels and plays that assert the Existential dogma of human freedom and explore the inexhaustible mechanisms of bad faith. It is not that Sartre overlooks the legitimate series of obstacles to freedom a human being has to face in the givens of place, past, environment, fellowmen, and death; but his Existentialist bias demands that man surmount these limitations by acts of conscious decision. For only in acts of freedom does human existence achieve authenticity.

Concluding comments. It seems clear that, in the 50 years around the mid-20th century, philosophizing has become uncommonly concerned with problems of language, symbolism, and communication. Renaissance philosophy was primarily preoccupied with nature, with an external physical world and the objects contained within it. The Enlightenment turned to the mind that knows the world; its philosophy spoke of the genesis of ideas, the relation of concepts, the quality of appearances. But 20th-century philosophizing largely states its problems in terms of symbolic manipulation and the characteristics of words.

Nor is this merely the preoccupation of Analytical philosophy: Dewey was interested in social communication; Whitehead wrote a little volume on *Symbolism: Its Meaning and Effect* (1927); Heidegger turned to poetry and the etymology of words for the revelation of Being; Ernst Cassirer, a German Neo-Kantian, produced a “philosophy of symbolic forms”; and Jaspers tried to decipher the meanings reflected in human speech and gesture.

Apart from this underlying tendency there seems little prospect for philosophical unification. The scientific and the metaphysical tempers still pursue their opposite

courses, and the subjectivity of Existentialism and the objectivity of Logical Positivism still express their opposition in mutual contempt. Thus, in the contemporary philosophical universe, multiplicity and division still reign.

(A.W.L.)

(1901, reissued 1979; originally published in German, 1892), a problems approach, particularly good on Kant and German Idealism; ALFRED WEBER, *History of Philosophy*, rev. ed. (1925; originally published in French, 5th ed. rev., 1892), with supplement by RALPH BARTON PERRY, “Philosophy Since 1860”; FRANK THILLY, *A History of Philosophy*, 3rd ed. rev. by LEDGER WOOD (1957); EMILE BRÉHIER, *Histoire de la philosophie*, new ed., 3 vol. (1981), particularly good on French thinkers, less so on English; JULIÁN MARÍAS, *History of Philosophy* (1967; originally published in Spanish, 22nd ed., 1966); BERTRAND RUSSELL, *A History of Western Philosophy . . .* (1945); WILLIAM T. JONES, *A History of Western Philosophy*, 2nd ed., 5 vol. in 6 (1969–75); FREDERICK C. COPELSTON, *A History of Philosophy*, 9 vol. (1946–74); and JOHN HERMAN RANDALL, *The Career of Philosophy*, 2 vol. (1962–65), an informed, comprehensive, and judicious treatment. The best sources for bibliographic information in philosophy are TERRENCE N. TICE and THOMAS P. SLAVENS, *Research Guide to Philosophy* (1983); and *Répertoire bibliographique de la philosophie* (quarterly), which the Institut Supérieur de Philosophie at Louvain began publishing in 1949. R.J. HOLLINGDALE, *Western Philosophy: An Introduction* (1966, reissued 1983), is for the neophyte.

Ancient Greek and Roman philosophy: (Studies): Detailed histories on the whole course of Greek and Roman philosophy can be found in EDUARD ZELLER, *Die Philosophie der Griechen*, 3 vol. in 2 (1844–52), also available in the following translations from parts of various editions: *A History of Greek Philosophy from the Earliest Period to the Time of Socrates*, trans. by SARAH F. ALLEYNE (1881), *Socrates and the Socratic Schools*, trans. by OSWALD REICHEL, 3rd rev. ed. (1885), *Plato and the Older Academy*, trans. by SARAH F. ALLEYNE and ALFRED GOODWIN, new ed. (1888), *Aristotle and the Earlier Peripatetics*, trans. by B.F.C. COSTELLOE and J.H. MUIRHEAD (1897), and *A History of Eclecticism in Greek Philosophy*, trans. by SARAH F. ALLEYNE (1883). Equally thorough and up to date is the great work by W.K.C. GUTHRIE, *A History of Greek Philosophy*, 6 vol. (1962–81). For short introductions to Greek philosophy in English, see MARGARET E.J. TAYLOR, *Greek Philosophy* (1921, reissued 1945); REX WARNER, *The Greek Philosophers* (1958); and the excellent one by W.K.C. GUTHRIE, *The Greek Philosophers: From Thales to Aristotle* (1950, reissued 1975). (*Collections of fragments and works*): An influential source from perhaps the 3rd century AD is LAERTIUS DIOGENES, *Lives of Eminent Philosophers*, trans. from the Greek by R.D. HICKS, 2 vol. (1925, reprinted 1979–80). The best comprehensive collection of the fragments of the pre-Socratic philosophers is still HERMANN DIELS and WALTHER KRANZ, *Die Fragmente der Vorsokratiker*, 11th ed. edited by WALTHER KRANZ, 3 vol. (1951–52, reprinted 1972–73), made more readily accessible for English-speaking readers by KATHLEEN FREEMAN, *Ancilla to the Pre-Socratic Philosophers: A Complete Translation of the Fragments . . .* (1948, reprinted 1983). A good selection of texts from the whole history is CORNELIA J. DE VOGEL, *Greek Philosophy: A Collection of Texts Selected and Supplied with Some Notes and Explanations*, 3rd ed., 3 vol. (1963–67). (*Bibliographies*): The most detailed bibliography to 1925 is in FRIEDRICH UEBERWEG, *Grundriss der Geschichte der Philosophie*, vol. 1, *Die Philosophie des Altertums*, ed. by KARL PRAECHTER, 13th ed. (1953); the most complete bibliography from 1926 to 1963 is WILHELM TOTOK, *Handbuch der Geschichte der Philosophie*, vol. 1, *Altertum* (1964), 353 pages of bibliography, including ancient Indian philosophy.

Medieval philosophy: ETIENNE GILSON, *History of Christian Philosophy in the Middle Ages* (1955, reissued 1980), is the best account of medieval philosophy. AIMÉ FOREST, FERNAND VAN STEENBERGHEN, and MAURICE DE GANDILLAC, *Le Mouvement doctrinal du IX^e au XIV^e siècle* (1951, reissued 1956), traces doctrinal developments from the 9th to the 14th century. FERNAND VAN STEENBERGHEN, *La Philosophie au XIII^e siècle* (1966), gives a different interpretation of 13th-century philosophy from that of Gilson, and his *Aristotle in the West*, 2nd ed. (1970), is a valuable account of the introduction of Aristotle's works into western Europe. DAVID KNOWLES, *The Evolution of Medieval Thought* (1962, reissued 1964), is the work of an

eminent historian of medieval religion. ARMAND A. MAURER, *Medieval Philosophy*, 2nd ed. (1982), sketches medieval philosophy from Augustine to the Renaissance; while NORMAN KRETZMANN, ANTHONY KENNY, and JAN PINBORG (eds.), *The Cambridge History of Later Medieval Philosophy* (1982), covers the period from the rediscovery of Aristotle to the decline of Scholasticism (1100–1600). The following are short accounts of philosophy in the Middle Ages: JOHN MARENBO, *Early Medieval Philosophy (480–1150): An Introduction* (1983); GORDON LEFF, *Medieval Thought: St. Augustine to Ockham* (1958, reissued 1980); PAUL VIGNAUX, *Philosophy in the Middle Ages* (1959, reissued 1975; originally published in French, 3rd ed., 1958); and JULIUS R. WEINBERG, *A Short History of Medieval Philosophy* (1964, reprinted 1974). Useful information about medieval Arab and Jewish philosophy is contained in T.J. DE BOER, *The History of Philosophy in Islam* (1903, reprinted 1970; originally published in German, 1901); GOFFREDO QUADRI, *La filosofia degli arabi nel suo fiore*, 2 vol. (1939); ISAAC HUSIK, *A History of Mediaeval Jewish Philosophy* (1916, reissued 1974); and GEORGES VAJDA, *Introduction à la pensée juive du Moyen Âge* (1947). Collections of translated texts include RICHARD MCKEON (ed.), *Selections from Medieval Philosophers*, 2 vol. (1928, reissued 1958); HERMAN SHAPIRO, *Medieval Philosophy: Selected Readings from Augustine to Buridan* (1964); ARTHUR HYMAN and JAMES J. WALSH (eds.), *Philosophy in the Middle Ages: The Christian, Islamic, and Jewish Traditions*, 2nd ed. (1983); and JOHN F. WIPPEL and ALLAN B. WOLTER (eds.), *Medieval Philosophy: From St. Augustine to Nicholas of Cusa* (1969). See also TIMOTHY C. POTTS (ed.), *Conscience in Medieval Philosophy* (1980), a study of many theories of conscience.

Modern and contemporary philosophy: (Comprehensive classical studies): JOHANN EDUARD ERDMANN, *A History of Philosophy*, 3 vol., 6th ed. (1915; originally published in German, 2 vol., 1878); KUNO FISCHER, *History of Modern Philosophy: Descartes and His School* (1887, reprinted 1890; originally published as vol. 1 in his *Geschichte der Neuern Philosophie*, 11 vol., 1878); and HARALD HØFFDING, *A History of Modern Phi-*

losophy, 2 vol. (1900, reprinted 1958; trans. from the 1895–96 German ed.; originally published in Danish, 1894–95). (Contemporary works): RAYMOND KLIBANSKY (ed.), *Philosophy in the Mid-Century: A Survey*, 4 vol. (1958–59, reissued 1976), and *Contemporary Philosophy: A Survey*, 4 vol. (1968–71), broad coverage in essays by leading scholars; ALBERT WILLIAM LEVI, *Philosophy and the Modern World* (1959, reissued 1977), a broad treatment, and *Philosophy as Social Expression* (1974); WOLFGANG STEGMÜLLER, *Main Currents in Contemporary German, British, and American Philosophy* (1969, reissued 1970; originally published in German, 4th ed., 1969), narrower, more technical treatment; WALTER KAUFMANN (ed.), *Existentialism from Dostoevsky to Sartre*, rev. ed. (1975), selections with introductions; and MARVIN FARBER (ed.), *Philosophic Thought in France and the United States: Essays Representing Major Trends in Contemporary French and American Philosophy*, 2nd ed. (1968; originally published in French, 1950). (Chiefly Anglo-American): JOHN PASSMORE, *A Hundred Years of Philosophy*, 2nd ed. (1966, reissued 1984), and its supplement, *Recent Philosophers* (1985); G.J. WARNOCK, *English Philosophy Since 1900*, 2nd ed. (1969, reprinted 1982); and HERBERT W. SCHNEIDER, *A History of American Philosophy*, 2nd ed. (1963), standard reference work with excellent bibliographies. (Chiefly continental): I.M. BOCHEŃSKI, *Contemporary European Philosophy* (1956, reprinted 1982; originally published in German, 2nd rev. ed., 1951); MICHELE FEDERICO SCIACCA, *Philosophical Trends in the Contemporary World* (1964; originally published in Italian, 3rd ed., 2 vol., 1958); HERMANN NOACK, *Die Philosophie Westeuropas*, 2nd rev. ed. (1976); HERBERT SPIEGELBERG, *The Phenomenological Movement: A Historical Introduction*, 3rd rev. ed. (1982); and ANNA-TERESA TYMIENIECKA, *Phenomenology and Science in Contemporary European Thought* (1962). See also ROGER SCRUTON, *From Descartes to Wittgenstein: A Short History of Modern Philosophy* (1981, reissued as *A Short History of Modern Philosophy: From Descartes to Wittgenstein*, 1984).

Photography

Photography (from the Greek *photos* ["light"] and *graphos* ["writing"]) is the recording of visible images by light action on light-sensitive materials. The term usually refers to the formation of optical images projected by a lens in a camera onto a film or other material carrying a layer of light-sensitive silver salts and the duplication and reproduction of such images by light action (printing); in an extended sense it also includes the formation of images by certain invisible radiations (ultraviolet and infrared rays) and images recorded in other sensitive materials not containing silver by means of chemical or physical processes or both. Related processes include the

recording of images by X rays, electron beams, and nuclear radiations (radiography) and the recording and transmission of light images in the form of electromagnetic signals (television and videotape).

This article treats the historical, technical, and aesthetic aspects of still photography. For a similar treatment of motion-picture photography, or cinematography, see **MOTION PICTURES**.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 628 and 735, and the *Index*.

The history and art of photography

Immediacy
of the
photograph

As a means of visual communication and expression, photography has marked aesthetic capabilities. In order to understand them, the characteristics of the process itself must first be understood. Of these the first is immediacy. Usually, but not necessarily, the image that is recorded is formed by a lens in a camera. Upon exposure to the light forming the image, the sensitive material undergoes changes in its structure; a latent image is formed, which becomes visible by development and permanent by fixing. With modern materials, the processing may take place immediately or may be delayed for weeks or months. But, either way, the elements of the final image are determined at the time of exposure. This characteristic is unique to photography and sets it apart from other ways of picture

making. Although the photographer can control the character of the original image he captured upon film by the way he develops the negative and prints it, he cannot alter it except by manual interference.

A second characteristic of the photograph is that it can contain more than the photographer intended it to. The first daguerreotypes, shown to an astounded public in Paris in the winter of 1838–39 by the inventor Louis-Jacques-Mandé Daguerre, were praised because of the amount of detail recorded by them; looking at one with a magnifying glass, it was said, was like looking at nature with a telescope. The rival inventor of photography, William Henry Fox Talbot, after noting this characteristic, commented:

It frequently happens, moreover—and this is one of the charms of photography—that the operator himself discovers on examination, perhaps long afterwards, that he has de-

picted many things he had no notion of at the time. Sometimes inscriptions and dates are found upon the buildings, or printed placards most irrelevant, are discovered upon their walls: sometimes a distant dial-plate is seen, and upon it—unconsciously recorded—the hour of the day at which the view was taken.

As technological advances have improved photographic equipment, materials, and techniques, the scope of photography has expanded enormously. High-speed photography has made visible certain aspects of motion never before seen; with material sensitive to invisible radiation, hidden aspects of nature can be revealed; and, by a combination of photographic, electronic, and space technology, even the planets can be observed in new ways. Photography pervades every sphere of activity in modern civilization. Its thousandfold applications have made it indispensable in daily life. Photography disseminates information about humanity and nature, records the visible world, and extends human knowledge into areas the eye cannot penetrate. Next to the printed word the image drawn by light is the most important means of communication, and for this reason photography has been aptly called the most important invention since the printing press.

Authenticity of the photograph

The seemingly automatic recording of an image by photography has given the process a sense of authenticity shared by no other picture-making technique. The fact that the photograph can show more than the eye can see and that the image is not filtered through the brain of a man and put down by the skill of his hand has given it value as evidence. The photograph has become, in the popular mind, so much a substitute for reality and of such apparent accuracy that the adage "The camera does not lie" has become a cliché.

This intrinsic characteristic is of such strength that it has dominated the evaluation of photography's role in the arts. In the past photography was sometimes belittled as a mechanical art because of its dependence on technology. It has also been used over and over again as a foil by art critics to denounce paintings that rely heavily upon exact representation of subject matter. Indeed, after reviewing the daguerreotype process, the painter and art expert Paul Delaroche, who served on the committee that advised the French government to purchase the rights to the new process, declared: "From today painting is dead."

In truth, photography is not the automatic process that is implied by the use of a camera. A fully automatic camera can produce a correctly exposed and sharp negative, but it cannot distinguish between a banal snapshot and a well-composed picture. The ability to make such a distinction rests solely with the person behind the camera. The creative photographer perceives the essential qualities of the

subject and interprets it according to his judgment, taste, and involvement. The mechanical photographer merely reproduces what he sees.

Although the camera does limit the photographer to depicting existing objects rather than imaginary or interpretive views, the skilled photographer has at his command a wide variety of controls that can be used to overcome the constraints of literalness and to introduce creativity into the mechanical reproduction process. The image can be modified by different lenses and filters. The type of sensitive material used to record the image is a further control, and the contrast between highlight and shadow can be changed by variations in development. In printing the negative, the photographer has a wide choice in the physical surface of the paper, the tonal contrast, and the image colour.

Technical controls

The most important control is, of course, the photographer's vision. He chooses the vantage point and the exact moment of exposure. Through experience he knows how the camera will record what he sees. He learns to pre-visualize the final print. If he has visual imagination and perception, he can make more than a passive record. He can express universal qualities. He can extend the vision of the viewer.

So facile a medium is photography that it is difficult to grasp its aesthetic capabilities and accomplishments. Of the billions of photographs that are taken every year, only a relatively small number can be considered art. Few camera users are deliberately concerned with the production of photographs to be judged as art. A far greater number look upon photography as a means of communication. While the aim of the commercial photographer, the photojournalist, and the scientist may not primarily be aesthetic, it is significant and remarkably characteristic of the medium that often in their work can be found memorable pictures that reach beyond the particular to the universal. Recognition plays an overwhelming role in photography: recognition by the creative photographer of the picture possibilities presented to him and recognition by the viewer of aesthetic qualities in photographs that he sees.

THE PIONEERS

The forerunner of the camera was the camera obscura, a dark chamber or room with a hole (later a lens) in one wall through which images of objects outside the room were projected on the opposite wall. The principle was probably known to Aristotle more than 2,000 years ago. The Italian scientist and writer Giambattista della Porta, late in the 16th century, demonstrated and described in detail the use of a camera obscura with a lens. By the 18th

century artists commonly used various types of camera obscura to trace accurate images from nature. These devices still depended on the artist's drawing skills, however, and the search for a method to reproduce images completely mechanically continued.

In 1727 the German professor of anatomy Johann Heinrich Schulze proved that the darkening of silver salts, known since the 16th century, and possibly earlier, was caused by light and not heat. He demonstrated the fact by using sunlight to record words on the salts, but he made no attempt to preserve the images permanently. His discovery, in combination with the camera obscura, provided the basic technology necessary for photography. It was not until the early 19th century, however, that photography actually came into being, largely through the artistic aspirations of two Frenchmen, Nicéphore Niepce and Louis-Jacques-Mandé Daguerre, and two Englishmen, Thomas Wedgwood and William Henry Fox Talbot.
