Pre-Columbian Civilizations

Pre-Columbian civilization refers to the aboriginal American Indian cultures that evolved in Meso-America (part of Mexico and Central America) and the Andean region (western South America) prior to Spanish exploration and conquest in the 16th century. The pre-Columbian civilizations were extraordinary developments in human society and culture, ranking with the early civilizations of Egypt, Mesopotamia, and China. Like the ancient civilizations of the Old World, those in the New World were characterized by kingdoms and empires, great monuments and cities, and refinements in the arts, metallurgy, and writing; the ancient civilizations of the Americas also display in their histories similar cyclical patterns of growth and decline, unity and disunity.

In the New World the roots of civilization lay in a native agricultural way of life. These agricultural beginnings go back several millennia, to early post-Pleistocene times (c. 7000 BC) and to the first experimentations by the early Americans with plant cultivation. The domestication of successful food plants proved to be a long, slow process, and it was not until much later that a condition of permanent village farming life was achieved in the tropical latitudes of the two continents.

Sedentary village farming in Meso-America came into being by about 1500 BC. Corn (maize), beans, squashes, chili peppers, and cotton were the most important crops. These early villagers wove cloth, made pottery, and practiced other typical Neolithic skills. It appears that such villages were economically self-contained and politically autonomous, with an egalitarian social order. But rather quickly after this—between about 1200 and 900 BC—the building of large earthen pyramids and platforms and the carving of monumental stone sculptures signaled significant changes in this heretofore simple social and political order. These changes first appeared in the southern Gulf coast region of what is now Mexico; and the sculptures, rendered in a style now called Olmec, are presumed to depict chiefs or rulers. From these and other archaeological indications it has been inferred that a class-structured and politically centralized society developed. There appeared subsequently other large capital towns and cities in neighbouring regions that also displayed a similar Olmec art style. This Olmec horizon (*i.e.*, a cultural diffusion that is contemporaneous at widely scattered sites) represents the first climax, or era of “unification,” in the history of Meso-American civilization.

After about 500 BC the Olmec “unification” gave way to an era (consisting of the Late Formative and Classic periods) of separate regional styles and kingdoms. These lasted until c. AD 700–900. Among these are the well-known Maya, Zapotec, Totonac, and Teotihuacán civilizations. While sharing a common Olmec heritage, they also displayed many differences. For example, the Maya excelled in the intellectual pursuits of hieroglyphic writing, calendar making, and mathematics, while the Teotihuacán civilization placed its emphasis on political and commercial power. Teotihuacán, in the Valley of Mexico, was an urban centre of some 150,000 people, and the influence of its civilization eventually radiated over much of Meso-America. As such, Teotihuacán constituted a second grand civilizational climax or “unification” (AD 400–600). Teotihuacán power waned after about 600, and a “time of troubles” ensued, during which a number of states and nascent empires competed for supremacy. Among these competitors were the Toltecs of Tula, in central Mexico, who held sway from perhaps 900 to 1200 (the Early Postclassic Period). After their decline (in the Late Postclassic Period), another interregnum of warring states lasted until 1428, when the Aztec defeated the rival city of Azcapotzalco and emerged as the dominant force in central Mexico. This last native Meso-American em-

pire was conquered by Hernán Cortés (or Cortéz) and the Spaniards in 1521.

In the Andean area, the threshold of a successful village agricultural economy can be placed at c. 2500 BC, or somewhat earlier than was the case in Meso-America. The oldest primary food crops there were the lima bean and the potato, which had long histories of domestication in the area, although corn appeared soon after the beginnings of settled village life. Indications of a more complex sociopolitical order—huge platform mounds and densely populated centres—occurred very soon after this (c. 1800 BC); however, these early Andean civilizations continued for almost a millennium before they participated in a shared stylistic “unification.” This has become known as the Chavín horizon, and Chavín sculptural art has been found throughout the northern part of the area.

The Chavín horizon disappeared after about 500 BC, and it was replaced by regional styles and cultures that lasted until about AD 600. This period of regionalization (called the Early Intermediate Period) saw the florescence of a number of large kingdoms both on the Pacific coast and in the Andean highlands; among them were the Mochica, Early Lima, Nazca, Recuay, and Early Tiahuanaco. The period was brought to an end by the Tiahuanaco–Huari horizon (Middle Horizon) (600–1000), which was generated from the highland cities of Tiahuanaco (in modern northern Bolivia) and Huari (in central highland Peru). There is evidence—such as the construction of new centres and cities—that this Tiahuanaco–Huari phenomenon, at least in many regions, was a tightly controlled political empire. The horizon and its influences, as registered in ceramics and textiles, died away rather gradually in the ensuing centuries, and it was replaced by the several regional styles and kingdoms of what has become known as the Late Intermediate Period (1000–1438).

The terminal date of the Late Intermediate Period marked the beginning of the Inca horizon and of the Inca conquests, which spread from the Inca capital, Cuzco, in the southern highlands of modern Peru. By 1533, when Francisco Pizarro and his cohorts took over the empire, it extended from what is now the Ecuador–Colombia border to central Chile.

The synchronicity of horizon unifications and alternating regionalizations in Meso-America and the Andean region is striking and prompts the question of communication between these two areas of pre-Columbian high civilization. Although it is known that there were contacts—with the result that knowledge of food plants, ceramics, and metallurgy was shared between the two areas—it is also highly unlikely that political or religious ideologies were so spread. Rather, the peoples of each of these major cultural areas appear to have responded to their own internally generated stimuli and to have followed essentially separate courses of development. There are fundamental differences between the two cultural traditions. Thus, in Meso-America there was, from early on, a profound interest in hieroglyphic writing and calendar making. Religious ideology, judged from art and iconography, was more highly developed in Meso-America than in the Andean region. In Meso-America the market was a basic institution; it does not appear to have been so in the Andes, where the redistributive economy of the Inca empire—with such features as its government warehouses and a system of highways—must have had deep roots in the past. On the other hand, in the early development and deployment of metallurgy and in governmental institutions and empire-building, the ancient Peruvians were much more efficient than their Meso-American contemporaries. (G.R.W.)

MESO-AMERICAN CIVILIZATION

The term Meso-America denotes the part of Mexico and Central America that was civilized in pre-Spanish times. In many respects, the American Indians who inhabited Meso-America were the most advanced native peoples in the Western Hemisphere. The northern border of Meso-America runs west from a point on the Gulf coast of Mexico above the modern port of Tampico, then dips south to exclude much of the central desert of highland Mexico, meeting the Pacific coast opposite the tip of Baja (Lower) California. On the southeast, the boundary extends from northwestern Honduras on the Caribbean across to the Pacific shore in El Salvador. Thus, about half of Mexico, all of Guatemala and Belize, and parts of Honduras and El Salvador are included in Meso-America.

Geographically and culturally, Meso-America consists of two strongly contrasted regions: highland and lowland. The Mexican highlands are formed mainly by the two Sierra Madre ranges that sweep down on the east and west. Lying athwart them is a volcanic cordillera stretching from the Atlantic to the Pacific. The high valleys and landlocked basins of Mexico were important centres of pre-Spanish civilization. In the southeastern part of Meso-America lie the partly volcanic Chiapas–Guatemala highlands. The lowlands are primarily coastal. Particularly important was the littoral plain extending south along the Gulf of Mexico, expanding to include the Petén–Yucatán Peninsula, homeland of the Mayan peoples.

Agriculture in Meso-America was advanced and complex. A great many crops were planted, of which corn, beans, and squashes were the most important. In the highlands, hoe cultivation of more or less permanent fields was the rule, with such intensive forms of agriculture as

irrigation and chinampas (the so-called floating gardens reclaimed from lakes or ponds) known in some regions. In contrast, lowland agriculture was frequently of the slash-and-burn variety; a patch of jungle was first selected, felled and burned toward the end of the dry season, and then planted with a digging stick in time for the first rains. After a few years of planting, the field was abandoned to the forest, as competition from weeds and declining soil fertility resulted in diminishing yields. There is good evidence, however, that the slash-and-burn system of cultivation was often supplemented by “raised-field” cultivation in the lowlands; these artificially constructed earthen hillocks built in shallow lakes or marshy areas were not unlike the chinampas of the Mexican highlands. In addition, terraces were constructed and employed for farming in some lowland regions. Nevertheless, the demographic potential for agriculture was probably always greater in the highlands than it was in the lowlands, and this was demonstrated in the more extensive urban developments in the former area.

The extreme diversity of the Meso-American environment produced what has been called symbiosis among its subregions. Interregional exchange of agricultural products, luxury items, and other commodities led to the development of large and well-regulated markets in which cacao beans were used for money. It may have also led to large-scale political unity and even to states and empires. High agricultural productivity resulted in a nonfarming class of artisans who were responsible for an advanced stone architecture, featuring the construction of stepped pyramids, and for highly evolved styles of sculpture, pottery, and painting.

The two
major
regions

Principal sites of Meso-American civilization.

The Meso-American system of thought, recorded in folding-screen books of deerskin or bark paper, was perhaps of even greater importance in setting them off from other New World peoples. This system was ultimately based upon a calendar in which a ritual cycle of 260 (13×20) days intermeshed with a "vague year" of 365 days (18×20 days, plus five "nameless" days), producing a 52-year Calendar Round. The religious life was geared to this cycle, which is unique to them. The Meso-American pantheon was associated with the calendar and featured an old, dual creator god; a god of royal descent and warfare; a sun god and moon goddess; a rain god; a culture hero called the Feathered Serpent; and many other deities. Also characteristic was a layered system of 13 heavens and nine underworlds, each with its presiding god. Much of the system was under the control of a priesthood that also maintained an advanced knowledge of astronomy.

Language groups

As many as 14 language families were found in Meso-America, but most can be grouped into three large "phyla": Uto-Aztecan, Macro-Mayan, and Oto-Manguean. A dominant role was played by Uto-Aztecan, particularly by speakers of the Nahuatl groups of which Náhuatl, official tongue of the Aztec Empire, was the most important. While Macro-Mayan includes Zoquean and Totonacan, its largest member is Mayan, with a number of mutually unintelligible languages, at least some of which were spoken by the inhabitants of the great Maya ceremonial centres. The modern Mexican state of Oaxaca is now the centre of the heterogeneous Oto-Manguean phylum; but the only linguistic groups that played any great part in Meso-American civilization were the Mixtec and Zapotec, both of which had large, powerful kingdoms at the time of the Spanish conquest. Still a linguistic puzzle are such languages as Tarascan, mother tongue of an "empire" in western Mexico that successfully resisted Aztec encroachments; it has no sure relatives, although some linguistic authorities have linked it with the Quechua language of distant Peru. Huavean and Xinca-Lencan are little-known language groups of southeastern Meso-America.

Pre-Classic and Classic periods

EARLY HUNTERS (TO 6500 BC)

The time of the first peopling of Meso-America remains a puzzle, as it does for that of the New World in general. It is widely accepted that groups of Mongoloid peoples en-

tered the hemisphere from northeastern Siberia, perhaps by a land bridge that then existed, at some time in the Late Pleistocene, or Ice Age. There is abundant evidence that, by 11,000 bc, hunting peoples had occupied most of the New World south of the glacial ice cap covering northern North America. These men hunted such large grazing mammals as mammoth, mastodon, horse, and camel, armed with spears to which were attached finely made, bifacially chipped points of stone. Finds in Meso-America, however, confirm the existence of a "prebifacial-point horizon," a stage known to have existed elsewhere in the Americas, and suggest that it is of very great age. In 1967 archaeologists working at the site of Tlapacoya, southeast of Mexico City, uncovered a well-made blade of obsidian associated with a radiocarbon date of about 21,000 bc. Near Puebla, Mex., excavations in the Valsequillo region revealed cultural remains of human groups that were hunting mammoth and other extinct animals, along with unifacially worked points, scrapers, perforators, burins, and knives. A date of about 21,800 bc has been suggested for the Valsequillo finds.

More substantial information on Late Pleistocene occupations of Meso-America comes from excavations near Tepexpan, northeast of Mexico City. The excavated skeletons of two mammoths showed that these beasts had been killed with spears fitted with lancelike stone points and butchered on the spot. A possible date of about 8000 bc has been suggested for the two mammoth kills. In the same geologic layer as the slaughtered mammoths was found a human skeleton; this Tepexpan "man" has been shown to be female and rather a typical American Indian of modern form. While the association with the mammoths was first questioned, fluorine tests have proved them to be contemporary.

Tepexpan finds

The environment of these earliest Meso-Americans was quite different from that existing today, for volcanoes were then extremely active, covering thousands of square miles with ashes. Temperatures were substantially lower, and local glaciers formed on the highest peaks. Conditions were ideal for the large herds of grazing mammals that roamed Meso-America, especially in the highland valleys, much of which consisted of cool, wet grasslands not unlike the plains of the northern United States. All of this changed around 7000 bc, when worldwide temperatures rose and the great ice sheets of northern latitudes began their final retreat. This brought to an end the successful hunting way

of life that had been followed by Meso-Americans, although man probably also played a role in bringing about the extinction of the large game animals.

INCIPIENT AGRICULTURE (6500–1500 BC)

The three
major food
plants

The most crucial event in the prehistory of Meso-America was man's capture of the food energy contained in plants. This process centred on three plants: Indian corn (maize), beans, and squashes. Since about 90 percent of all food calories in the diet of Meso-Americans eventually came from corn, archaeologists for a long time have sought the origins of this plant—which has no wild forms existing today—in order to throw light on the agricultural basis of Meso-American civilization.

The search for Meso-American agricultural origins has been carried forward most successfully through excavations in dry caves and rock shelters in the modern southern Mexican states of Puebla and Oaxaca. Sequences from these archaeological sites show a gradual transition from the Early Hunting to the Incipient Cultivation periods. At the Guila Naquitz cave, in Oaxaca, there are indications that the transition began as early as 8900 bc; finds from caves in the Tehuacán valley of Puebla, however, offer more substantial evidence of the beginnings of plant domestication at a somewhat later time. There, the preservation of plant remains is remarkably good, and from these it is evident that shortly after 6500 bc the inhabitants of the valley were selecting and planting seeds of chili peppers, cotton, and one kind of squash. Most importantly, between 5000 and 3500 bc they were beginning to plant mutant forms of corn that already were showing signs of the husks characteristic of domestic corn.

One of the problems complicating this question of the beginnings of early corn cultivation is related to a debate between paleobotanists on wild versus domesticated strains. One school of thought holds that the domesticated races of the plant developed from a wild ancestor. The other opinion is that there was never such a thing as wild corn, that, instead, corn (*Zea mays*) developed from a related grass, teosinte (*Zea mexicana*, or *Euchlaena mexicana*). In any event, by 5000 bc corn was present and being used as a food, and between 2,000 and 3,000 years after that it had developed rapidly as a food plant. It has been estimated that there is more energy present in a single kernel of some modern races than there was in an ear of this ancient Tehuacán corn. Possibly some of this was popped, but a new element in food preparation is seen in the metates (querns) and manos (handstones) that were used to grind the corn into meal or dough.

Beans appeared after 3500 bc, along with a much improved race of corn. This enormous increase in the amount of plant food available was accompanied by a remarkable shift in settlement pattern. In place of the temporary hunting camps and rock shelters, which were occupied only seasonally by small bands, semipermanent villages of pit houses were constructed on the valley floor. Increasing sedentariness is also to be seen in the remarkable bowls and globular jars painstakingly pecked from stone, for pottery was as yet unknown in Meso-America.

In the centuries between 3500 and 1500 bc, plant domestication began in what had been hunting-gathering contexts, as on the Pacific coast of Chiapas and on the Veracruz Gulf coast and in some lacustrine settings in the Valley of Mexico. It seems probable that early domesticated plants from such places as the Tehuacán valley were carried to these new environmental niches. In many cases, this shift of habitat resulted in genetic improvements in the food plants.

Pottery, which is a good index to the degree of permanence of a settlement (because of its fragility it is difficult to transport), was made in the Tehuacán valley by 2300 bc. Fired clay vessels were made as early as 4000 bc in Ecuador and Colombia, and it is probable that the idea of their manufacture gradually diffused north to the increasingly sedentary peoples of Meso-America.

The picture, then, is one of man's growing control over his environment through the domestication of plants; animals played a very minor role in this process, with only the dog being surely domesticated before 1500 bc. At any rate,

by 1500 bc the stage was set for the adoption of a fully settled life, with many of the sedentary arts already present. The final step was taken only when native agriculture in certain especially favoured subregions became sufficiently effective to allow year-round settlement of villages.

EARLY FORMATIVE PERIOD (1500–900 BC)

Early village life. It is fairly clear that the Mexican highlands were far too dry during the much warmer interval that prevailed from 5000 to 1500 bc for agriculture to supply more than half of a given population's energy needs. This was not the case along the alluvial lowlands of southern Meso-America, and it is no accident that the best evidence for the earliest permanent villages in Meso-America comes from the Pacific littoral of Chiapas (Mexico) and Guatemala, although comparable settlements also have been reported from both the Maya lowlands (Belize) and the Veracruz Gulf coast.

The Barra (c. 1800–1500 bc), Ocós (1500–1200 bc), and Cuadros (1100–900 bc) phases of the Pacific coasts of Chiapas and Guatemala are good examples of early village cultures. The Barra phase appears to have been transitional from earlier preagricultural phases and may not have been primarily dependent upon corn farming; but people of the Ocós and Cuadros phases raised a small-eared corn known as *nal-tel*, which was ground on metates and manos and cooked in globular jars. From the rich lagoons and estuaries in this area, the villagers obtained shellfish, crabs, fish, and turtles. Their villages were small, with perhaps 10 to 12 thatched-roof houses arranged haphazardly.

Ocós pottery is highly developed technically and artistically. Something of the mental life of the times may be seen in the tiny, handmade clay figurines produced by the Ocós villagers. These, as in Formative cultures generally throughout Meso-America, represent nude females and may have had something to do with a fertility cult. The idea of the temple-pyramid may well have taken root by that time, for one Ocós site has produced an earthen mound about 26 feet (eight metres) high that must have supported a perishable building. The implication of the site is that, with increasing prosperity, some differentiation of a ruling class had taken place, for among the later Meso-Americans the ultimate function of a pyramid was as a final resting place for a great leader.

Eventually, effective village farming with nucleated settlements occupied throughout the year appeared in the highlands. But perhaps from the very beginning of Formative life there were different cultural responses directed toward both kinds of environment. In the highlands, divided into a number of mutually contrasting environments no one of which could have provided sufficient resources for the subsistence of a single settlement, villages were presumably linked to each other symbiotically. In the lowlands, particularly in the littoral, one especially favourable environment, such as the lagoon–estuary system, may have been so rich in resources that villages within it would have been entirely self-sufficient. In effect, the former would have resulted in a cultural integration based upon trade, while the latter would have been integrated, if at all, by a unity of likeness. The two kinds of civilization that eventually arose in each region—the highlands definitely urban, the lowlands less so—reflect the same contrast.

Early religious life. Early religious phenomena can only be deduced from archaeological remains. Numerous clay figurines found in tombs afford little evidence of religious beliefs during the agricultural Pre-Classic periods of Zacatenco and Ticomán (roughly 1500 to the 1st century bc). It is possible, however, that terra-cotta statuettes of women were meant to represent an agricultural deity, a goddess of the crops. Two-headed figurines found at Tlatilco, a site of the late Pre-Classic, may portray a supernatural being. Clay idols of a fire god in the form of an old man with an incense burner on his back date from the same period.

The first stone monument on the Mexican plateau is the pyramid of Cuicuilco, near Mexico City. In fact, it is rather a truncated cone, with a stone core; the rest is made of sun-dried brick with a stone facing. It shows the main features of the Mexican pyramids as they were developed in later times. It was doubtless a religious monument,

Barra,
Ocós, and
Cuadros
phases

crowned by a temple built on the terminal platform and surrounded with tombs. The building of such a structure obviously required a protracted and organized effort under the command of the priests.

The final phase of the Pre-Classic cultures of the central highland forms a transition from the village to the city, from rural to urban life. This was a far-reaching social and intellectual revolution, bringing about new religious ideas together with new art forms and theocratic regimes. It is significant that Olmec statuettes have been found at Tlatilco with late Pre-Classic material.

The rise of Olmec civilization. It was once assumed that the Formative stage was characterized only by simple farming villages. It is now realized, however, that coexisting with these peasantlike cultures was a great civilization, the Olmec, that had arisen in the humid lowlands of southern Veracruz and Tabasco, in Mexico.

The Olmec were perhaps the greatest sculptors of ancient Meso-America. Whether carving tiny jade figures or gigantic basalt monuments, they worked with a great artistry that led a number of archaeologists to doubt their considerable antiquity, although radiocarbon dates from the type site of La Venta showed that Olmec civilization was indeed Formative, its beginning dating to at least 1,000 years before the advent of Maya civilization.

San Lorenzo is now established as the oldest known Olmec centre. In fact, excavation has shown it to have taken on the appearance of an Olmec site by 1150 BC and to have been destroyed, perhaps by invaders, around 900 BC. Thus, the Olmec achieved considerable cultural heights within the Early Formative, at a time when the rest of Meso-America was at best on a Neolithic level. The reasons for its precocious rise must have had something to do with its abundant rainfall and the rich alluvial soil deposited along the broad, natural levees that flank the waterways of the southern Gulf coast. Thus, the ecological potential for corn farmers in this counterpart of Mesopotamia's Fertile Crescent was exceptionally high. The levee lands, however, were not limitless, and increasingly dense populations must inevitably have led to competition for their control. Out of such conflicts would have crystallized a dominant landowning class, perhaps a group of well-armed lineages. It was this elite that created the Olmec civilization of San Lorenzo.

In appearance, the San Lorenzo site is a compact plateau rising about 160 feet above the surrounding plains. Cutting into it are deep ravines that were once thought to be natural but that are now known to be man-made, formed by the construction of long ridges that jut out from the plateau on the northwest, west, and south sides. Excavations have proved that at least the top 25 to 35 feet of the site was built by human labour. There are about 200 small mounds on the surface of the site, each of which once supported a dwelling house of pole and thatch, which indicates that it was both a ceremonial centre, with political and religious functions, and a minuscule town.

San Lorenzo is most noted for its extraordinary stone monuments. Many of these, perhaps most, were deliberately smashed or otherwise mutilated about 900 BC and buried in long lines within the ridges and elsewhere at the site. The monuments weighed as much as 44 tons and were carved from basalt from the Cerro Cintepec, a volcanic flow in the Tuxtla Mountains about 50 air miles to the northwest. It is believed that the stones were somehow dragged down to the nearest navigable stream and from there transported on rafts up the Coatzacoalcos River to the San Lorenzo area. The amount of labour involved must have been enormous and so would have the social controls necessary to see the job through to its completion.

Most striking are the "colossal heads," human portraits on a stupendous scale. Several of these are now known from San Lorenzo, the largest of which is nine feet high. The visages are flat-faced, with thickened lips and staring eyes. Each has a headgear resembling a football helmet, and it is entirely possible that these "helmets" were in fact protective coverings in a rubber-ball game that is known from Olmec figurines to have been played at San Lorenzo.

The central theme of the Olmec religion was a pantheon of deities each of which usually was a hybrid between

jaguar and human infant, often crying or snarling with open mouth. This "were-jaguar" is the hallmark of Olmec art, and it was the unity of objects in this style that first suggested to scholars that they were dealing with a new and previously unknown civilization. There is actually a whole spectrum of such were-jaguar forms in Olmec art, ranging from the almost purely feline to the human in which only a trace of jaguar can be seen.

These Olmec monuments were generally carved in the round with great technical prowess, even though the only methods available were pounding and pecking with stone tools. Considerable artistry can also be seen in the pottery figurines of San Lorenzo, which depict nude and sexless individuals with were-jaguar traits.

Exotic raw materials brought into San Lorenzo from distant regions suggest that the early Olmec controlled a large trading network over much of Meso-America. Obsidian, used for blades, flakes, and dart points, was imported from highland Mexico and Guatemala. Most items were obviously for the luxury trade, such as iron ore for mirrors and various fine stones like serpentine employed in the lapidary industry. One material that is conspicuously absent, however, is jade, which does not appear in Olmec sites until after 900 BC and the fall of San Lorenzo.

There is evidence that the Olmec sent groups from their Gulf coast "heartland" into the Meso-American highlands toward the end of the Early Formative, in all likelihood to guarantee that goods bound for San Lorenzo would reach their destination. San Lorenzo-type Olmec ceramics and figurines have been found in burials at several sites in the Valley of Mexico, such as Tlapacoya, and in the state of Morelos. The Olmec involvement with the rest of Meso-America continued into the Middle Formative and probably reached its peak at that time.

San Lorenzo is not the only Olmec centre known for the Early Formative. Laguna de los Cerros, just south of the Cerro Cintepec in Veracruz, appears to have been a large Olmec site with outstanding sculptures. La Venta, just east of the Tabasco border, was another contemporary site, but it reached its height after San Lorenzo had gone into decline.

MIDDLE FORMATIVE PERIOD (900–300 BC)

Horizon markers. Once ceramics had been adopted in Meso-America, techniques of manufacture and styles of shape and decoration tended to spread rapidly and widely across many cultural frontiers. These rapid diffusions, called horizons, enable archaeologists to link different cultures on the same time level. For the Early Formative, colour zones of red pigment set off by incised lines; complex methods of rocker stamping (a mode of impressing the wet clay with the edge of a stick or shell); the *tecomate*, or globular, neckless jar; and Olmec excised pottery are good horizon markers. The beginning of the Middle Formative over much of Meso-America is marked by the diffusion of a very hard, white pottery, decorated with incised lines, and by solid pottery figurines with large, staring eyes formed by a punch. The people who replaced and probably overthrew the Olmec of San Lorenzo in about 900 BC had such pottery and figurines, the ultimate origins of which are still a puzzle.

During the Middle Formative, cultural regionalism increased, although the Olmec presence can be widely detected. The transition to fully settled life had taken place everywhere, and burgeoning populations occupied hamlets, villages, and perhaps even small towns throughout Meso-America, both highland and lowland.

Olmec civilization at La Venta. La Venta was located on an almost inaccessible island, surrounded at that time by the Tonalá River; the river now divides the states of Veracruz and Tabasco. As San Lorenzo's fortunes fell, La Venta's rose, and between 800 and 400 BC it was the most important site in Meso-America.

At the centre of La Venta is a 100-foot-high mound of earth and clay that may well house the tomb of a great Olmec ruler. Immediately north of the Great Mound is a narrow north-south plaza flanked by a pair of long mounds. Beyond the plaza is a ceremonial enclosure surrounded by a "fence" made entirely of upright shafts of

The San Lorenzo site

The "colossal heads"

Olmec trade

columnar basalt. A low, round mound on the north side of the ceremonial enclosure contained several tombs, one of which was surrounded and covered by basalt columns. In this tomb were found the bundled remains of two children, accompanied by magnificent ornaments of jade. Offerings were not only placed with the dead but were also deposited as caches in the site, especially along the north-south axis of the ceremonial centre.

Olmec
mirrors

Among the most beautiful objects manufactured by the Olmec were the concave mirrors of iron ore, which were pierced to be worn around the neck. These could throw pictures on a flat surface and could probably start fires on hot tinder. Olmec leaders at La Venta, whether they were kings or priests, undoubtedly used them to impress the populace with their seemingly supernatural powers. Olmec sculptors continued to produce the basalt monuments, including colossal heads and "altars," that have been found at La Venta. Significantly, an increasing number of monuments were carved in relief, and some of these were stelae with rather elaborate scenes obviously based upon historical or contemporary events.

Olmec colonization in the Middle Formative. From the Middle Formative there are important Olmec sites located along what appears to have been a highland route to the west to obtain the luxury items that seemed to have been so desperately needed by the Olmec elite; e.g., jade, serpentine, iron ore for mirrors, cinnabar, and so forth. Olmec sites in Puebla, the Valley of Mexico, and Morelos are generally located at the ends of valleys near or on major passes; they were perhaps trading stations garrisoned by Olmec troops. The largest of these sites is Chalcatzingo, Morelos, a cult centre located among three denuded volcanic peaks rising from a plain. On a talus slope at the foot of the middle peak are huge boulders on which have been carved Olmec reliefs in La Venta style. The principal relief shows an Olmec woman, richly garbed, seated within the mouth of a cave; above her, cumulus clouds pour down rain.

Similar Olmec reliefs, usually narrative and often depicting warriors brandishing clubs, have been located on the Pacific plain of Chiapas (Mexico) and Guatemala. Since about 1960, spectacular Olmec cave paintings have been found in Guerrero, offering some idea of what the Olmec artists could do when they worked with a large spectrum of pigments and on flat surfaces.

Olmec culture or civilization did not spread eastward from its Veracruz-Tabasco centres into the Maya lowlands, but occasional Olmec artifacts have been found in Formative Maya contexts, such as at Seibal, in southern Petén, Guatemala. Maya Formative Period occupations, represented by settled farming villages and well-made ceramics, date to c. 1000 BC in the lowlands of Guatemala and Belize. It seems reasonably certain, however, that at this early date great ceremonial centres, comparable to those of Olmec San Lorenzo or La Venta, were never constructed in the Maya lowlands.

It was formerly thought that the Olmec worshiped only one god, a rain deity depicted as a were-jaguar, but study has shown that there were at least 10 distinct gods represented in Olmec art. Surely present were several important deities of the later, established Meso-American pantheon, such as the fire god, rain god, corn god, and Feathered Serpent. Other aspects of mental culture are less well-known; some Olmec jades and a monument from La Venta have non-calendrical hieroglyphs, but none of this writing has been deciphered.

To sum up the Olmec achievement, not only was this the first high culture in Meso-America—one that had certainly achieved political statehood—but either it or cultures influenced by it lie at the base of every other Meso-American civilization.

Early Monte Albán. Monte Albán is a prominent series of interconnected hills lying near Oaxaca, Mex. One of these was completely leveled off in Middle Formative times to serve as the base for a site that was to become the Zapotec people's most important capital. Prior to that time, the Early Formative ancestral Zapotec had lived in scattered villages and at least one centre of some importance, San José Mogote. San José Mogote shows

evidence of Olmec trade and contacts dating to the time of San Lorenzo.

At Monte Albán, during the earliest, or Monte Albán I, epoch of that site's history, a peculiar group of reliefs was carved on stone slabs and affixed to the front of a rubble-faced platform mound and around a contiguous court. The reliefs are usually called *danzantes*, a name derived from the notion that they represent human figures in dance postures. Actually, almost all of the *danzante* sculptures show Olmecoid men in strange, rubbery postures as though they were swimming in honey. From their open mouths and closed eyes, it is assumed that they are meant to represent dead persons. On many *danzantes* one or more unreadable hieroglyphs appear near the heads of the figures, most likely standing for the names of the sacrificed lords of groups beaten in combat by the Zapotec. Several slabs also bear calendrical notations, and it can be stated that the Middle Formative elite of Monte Albán were the first in Meso-America to develop writing and the calendar (at least in written form).

The
danzantes
figures

The Valley of Mexico in the Middle Formative. The cultures of central Mexico tended to lag behind those of southern Mexico in the development of political and religious complexity. The presence of Olmec figurines and ceramics in Early Formative burials in the Valley of Mexico has been noted, but the local communities of that time were of a modest village sort, as were those of the succeeding Middle Formative. On the western shores of the great lake filling the Valley of Mexico, for instance, remains of several simple villages have been uncovered that must have been not unlike small settlements that can be found in the Mexican hinterland today. The people who lived at El Arbolillo and Zacatenco had simply terraced off village refuse to make platforms on which their pole-and-thatch houses were built. Metates and manos are plentiful; pottery is relatively plain—featuring the abundant hard, white-slipped ware of the Middle Formative—and small female figurines are present by the thousands. Subsistence was based upon corn farming and upon hunting. In some Middle Formative sites, however, such as Tlatilco, there is evidence of Olmec influence, as in the previous Early Formative Period. There are also indications that ceremonial pyramid construction began in the latter part of the Middle Formative at Cuicuilco, a site in the southern part of the valley, which was to become a major centre in the succeeding Late Formative Period.

The Maya in the Middle Formative. In the Maya highlands, the key archaeological region has always been the broad, fertile Valley of Guatemala around present-day Guatemala City. The earliest occupation is known as the Arevalo phase, a village culture of the Early to Middle Formative. It was followed by Las Charcas, a Middle Formative culture known largely from the contents of bottle-shaped pits found dug into the subsoil on the western edge of the modern city. Extremely fine ceramics have been excavated from them, including red-on-white bowls with animal figures, effigy vessels, three-footed cups, and peculiar three-pronged incense burners. Solid female figurines are also present.

Las
Charcas

The earliest Middle Formative cultures of the Maya lowlands are called, collectively, the Xe horizon. They apparently developed from antecedent Early Formative cultures of the Maya lowlands that have been discussed above. The problem of the origin of the Mayan-speaking people has not been solved. It may be that they were Olmec people who had been forced out of their homeland to the west by the collapse of San Lorenzo. There were already peoples in the Maya lowlands in Early Formative times, however, and if the early Maya were Olmec, they brought little of their Olmec culture with them. Another hypothesis is that the earliest Maya descended to their lowland homelands from the Guatemalan highlands.

In the Maya lowlands the Mamom cultures developed out of those of Xe times. Mamom shares many similarities with the highland Maya at Las Charcas: pottery is almost entirely monochrome—red, orange, black, and white—and figurines are female with the usual punched and appliquéd embellishments. Toward the end of the Middle Formative, or after about 600 BC, Mamom peoples began

building small ceremonial centres and modest-sized pyramidal platforms.

LATE FORMATIVE PERIOD (300 BC-AD 100)

Probably the most significant features of the Late Formative are: (1) the transformation of Olmec civilization in southeastern Meso-America into something approaching the earliest lowland Maya civilization and (2) the abrupt appearance, toward the end of the Late Formative, of fully urban culture at Teotihuacán in the Valley of Mexico. Most of the distinctive cultures that were to become the great Classic civilizations began to take shape at this time. There was no unifying force in the Late Formative comparable to the earlier Olmec; rather, regionalism and local cultural integration were the rule. There were, however, horizon traits, particularly in pottery, that were almost universal. Ceramics became elaborate in shape, often with composite or recurved outlines, hollow, bulbous feet, and flangelike protrusions encircling the vessel. The use of slips of a number of different colours as pottery decoration at times approached the elaborate polychromes of Classic times.

Horizon
traits

The idea of constructing temple-pyramids was probably also a general trait. It was a Meso-American custom to bury a dead person beneath the floor of his own house, which was often then abandoned by the bereaved. As an elite class of noble lineages became distinguished from the mass of the people, the simple house platforms serving as sepulchres might have become transformed into more imposing structures, ending in the huge pyramids of the Late Formative and Classic, which surely had funerary functions. The deceased leader or the gods from which he claimed descent, or both, would then have been worshiped in a "house of god" on the temple summit. These pyramids became the focal point of Meso-American ceremonial life, as well as the centres of settlement.

Valley of Mexico. The Cuicuilco-Ticomán culture succeeded the Middle Formative villages of the valley but retained many of their traits, such as the manufacture of solid handmade figurines. Of considerable interest is the type site of Cuicuilco, located on the southwestern edge of the valley. Lava from a nearby volcano covers all of Cuicuilco, including the lower part of the round "pyramid" for which it is best known. Ceramic analysis and radiocarbon dating have proved that the flow occurred at about the time of Christ. Rising up in four tiers, the Cuicuilco pyramid has a clay-and-rubble core faced with broken lava blocks. The summit was reached by ramps on two sides. Circular temples were traditionally dedicated in Meso-America to Quetzalcóatl, the Feathered Serpent, and he may have been the presiding deity of Cuicuilco.

In the Valley of Teotihuacán, a kind of side pocket on the northeastern margin of the Valley of Mexico, Cuicuilco-Ticomán culture eventually took on a remarkable outline, for there is evidence that by the beginning of the Christian Era a great city had been planned. There is little doubt that by the Proto-Classic stage (AD 100-300) it had become the New World's first urban civilization (see below *Teotihuacán*).

Valley of Oaxaca. Occupation of the Monte Albán site continued uninterrupted, but ceramic evidence for Monte Albán II culture indicates that cultural influences from southeastern Mexico were reaching the Zapotec people. On the southern end of the site's main plaza is a remarkable stone structure called Building J, shaped like an arrow pointing southwest and honeycombed with galleries. Some believe it to have been an astronomical observatory. Incised slabs are fixed to its exterior; these include some older *danzantes* as well as depictions of Zapotec place glyphs from which are suspended the inverted heads of dead chiefs—surely again the vanquished enemies of Monte Albán. Dates are given in the 52-year Calendar Round, with coefficients for days and months expressed by bar-and-dot numerals, a system that is first known for Monte Albán I and that became characteristic of the Classic Maya. Throughout its long Formative and Classic occupation, the dominant ware of Monte Albán is a fine gray pottery, elaborated in Monte Albán II into the usual Late Formative shapes.

Veracruz and Chiapas. La Venta suffered the fate of San Lorenzo, having been destroyed by violence around 400 BC. Olmec civilization subsequently disappeared or was transformed into one or more of the cultures of the southeastern lowlands.

One centre that retained a strong Olmec tradition, however, was Tres Zapotes, near the Tuxtla Mountains in the old Olmec "heartland." Its most famous monument, the fragmentary Stela C, is clearly epi-Olmec on the basis of a jaguar-monster mask carved in relief on its obverse. On the reverse is a column of numerals in the bar-and-dot system, which was read by its discoverer, Matthew W. Stirling, as a date in the Maya calendar corresponding to 31 BC; this is more than a century earlier than any known dated inscription from the Maya area itself. Thus, it is highly probable that this calendrical system, formerly thought to be a Maya invention, was developed in the Late Formative by epi-Olmec peoples living outside the Maya area proper.

Tres
Zapotes

Izapan civilization. Izapa, type site of the Izapan civilization, is a huge temple centre near modern Tapachula, Chiapas, on the hot Pacific coast plain. Its approximately 80 pyramidal mounds were built from earth and clay faced with river boulders. A large number of carved stone stelae have been found at Izapa, almost all of which date to the Late Formative and Proto-Classic. Typically, in front of each stela is a round altar, often crudely shaped like a toad.

These stelae are of extraordinary interest, for they contain a wealth of information on Late Formative religious concepts prevalent on the border of the Maya area. Izapan stelae are carved in relief with narrative scenes derived from mythology and legend; among the depictions are warfare and decapitation, ceremonies connected with the sacred world tree, and meetings of what seem to be tribal elders. Many deities are shown, each of which seems derived from an Olmec prototype.

Sites with Izapan-style sculpture are distributed in a broad arc extending from Tres Zapotes in the former Olmec region, across the Isthmus of Tehuantepec into coastal Chiapas and Guatemala, and up into the Guatemalan highlands. Izapan civilization is clearly the intermediary between Olmec and Classic Maya in time and in cultural content, for the following early Maya traits are foreshadowed by it: (1) the stela-altar complex, (2) long-lipped deities, (3) hieroglyphic writing and Long Count dates on some monuments, (4) such iconographic elements as a U-shaped motif, and (5) a cluttered, baroque, and painterly relief style that emphasizes narrative. An important site pertaining to this Izapan culture is Abaj Takalik, on the Pacific slopes of Guatemala, to the east of Izapa. Three sculptural styles are represented there: Olmec or Olmecoid, Izapan, and Classic Maya. Among the latter is one stela with a date read as AD 126, earlier than any monuments discovered in the Maya lowlands.

Perhaps it was not Izapa itself but the great site of Kaminaljuyu, on the western edge of Guatemala City, that transmitted the torch of Izapan civilization to the lowland Maya. This centre once consisted of more than 200 earth and clay mounds, most of which have been destroyed. The major occupation is ascribed to the Miraflores phase, the Late Formative culture of the Valley of Guatemala. Some of these huge Miraflores mounds contained log tombs of incredible richness. In one, the deceased lord was accompanied by sacrificed followers or captives. As many as 340 objects were placed with him, including jade mosaic masks, jade ear spools and necklaces, bowls of chlorite schist, and pottery vessels of great beauty. Also present in the tombs are peculiar "mushroom stones," which may actually have been used in rites connected with hallucinogenic mushrooms.

Kaminal-
juyu

The earliest Maya civilization of the lowlands. By the Late Formative, the lowland Maya had begun to shape a civilization that was to become the greatest in the New World. The Petén-Yucatán Peninsula lacks many raw materials and has a relatively low agricultural potential. But what it does have in limitless quantities is readily quarried limestone for building purposes and flint for stonework. Cement and plaster could easily be produced by burning limestone or shells.

The heart of the Maya civilization was always northern Petén, in Guatemala, where the oldest dated Maya stelae are found, although this presents something of a problem in cultural-historical interpretation, since the earliest prototypes for these stelae—as mentioned above—have been found in Pacific-littoral and highland Guatemala. The Late Formative culture of Petén is called Chicanel, evidence of which has been found at many Maya centres. Chicanel pottery includes dishes with wide-everted and grooved rims, bowls with composite silhouette, and vessels resembling ice buckets. Figurines are curiously absent.

Architecture was already quite advanced and had taken a form peculiar to the Maya. Temple platforms were built by facing a cemented-rubble core with thick layers of plaster. At the site of Uaxactún, Structure E-VII-sub affords a good idea of a Chicanel temple-platform. It is a four-sided, stucco-covered, stepped pyramid with pairs of stylized god masks flanking stairways on each side. On its summit was a thatched-roof temple. At Tikal, the giant among Maya ceremonial centres, the so-called Acropolis was begun in Chicanel times, and there was a great use of white-stuccoed platforms and stairways, with flanking polychromed masks as at Uaxactún. Most importantly, there is evidence from Tikal that the Maya architects were already building masonry superstructures with the corbel vault principle; *i.e.*, with archlike structures the sides of which extend progressively inward until they meet at the top. The large sizes of Chicanel populations and the degree of political centralization that existed by this time are further attested to by the discovery in the 20th century of the huge site of El Mirador, in the extreme northern part of Petén. The mass of El Mirador construction dwarfs even that of Tikal, although El Mirador was only substantially occupied through the Chicanel phase.

Chicanel-like civilization is also known in Yucatán, where some temple pyramids of enormous size are datable to the Late Formative. An outstanding site is the cave of Loltún in Yucatán, where a relief figure of a standing leader in pure Izapan style is accompanied by a number of unreadable hieroglyphs as well as a notation in the 260-day count. This inscription raises the question of writing and the calendar among the lowland Maya in the Late Formative. On the whole, the evidence is negative and suggests that several important intellectual innovations considered to be typically Mayan were developed beyond the Maya area proper and appeared there only at the close of the Formative. Izapan civilization appears to have played the crucial role in this evolutionary process.

EARLY CLASSIC PERIOD (AD 100–600)

Definition of the Classic. In the study of the Classic stage, there has been a strong bias in favour of the Maya; this is not surprising in view of the fact that the Maya have been studied far longer than any other people in Meso-America. But the concept of a “Classic” period is a case of the Maya tail wagging the Meso-American dog, since the usual span given to that stage—AD 250–900—is the period during which the Maya were erecting dated stone monuments. This brackets the Maya apogee, but for most areas of non-Maya Meso-America only the first half of the period may be accurately called a “golden age.” While the famous and yet mysterious Maya collapse took place at about AD 900, in many other regions this downfall occurred almost three centuries earlier.

Qualitatively, there is little to differentiate the Classic from the Late Formative that preceded it. Various tendencies that were crystallizing in the last centuries before the Christian era reached fulfillment in the Classic. Two cultures stand out beyond all others. One is that of Teotihuacán, which during the Early Classic played a role in Meso-America similar to that which Olmec had performed in the Early Formative. The second is the lowland Maya civilization, which during its six centuries of almost unbroken evolution in the humid forests reached cultural heights never achieved before or since by New World natives. The contrast between the two—one urban and expansionist, the other less urban and non-expansionist—exemplifies well the cultural results of the ecological possibilities offered by highland and lowland Meso-America.

Teotihuacán. Teotihuacán, which was located in the Valley of Teotihuacán, a pocketlike extension of the Valley of Mexico on its northeastern side, was probably the largest city of the New World before the arrival of the Spaniards. At its height, toward the close of the 6th century AD, it covered about eight square miles and may have housed more than 150,000 inhabitants. The city was divided into quarters by two great avenues that crosscut each other at right angles, and the entire city was laid out on a grid plan oriented to these avenues. The Avenue of the Dead, the main north–south artery of the city, is aligned to a point 16° east of true north, which may have had astrological meaning.

Because irrigation plays some part in the present-day agricultural economy of the Valley of Teotihuacán, it has been suggested that the Early Classic city also was based upon this subsistence system. It is almost inconceivable, however, that a city of such proportions could have relied upon the food production of its own valley or even upon the Valley of Mexico, whether irrigated or not.

Planning and construction of Teotihuacán began, according to radiocarbon dates, about the beginning of the Christian Era, in the Tzacualli phase. At this time, the major avenues were laid out and construction of the major ceremonial structures along the Avenue of the Dead began. Figurines and potsherds extracted from fill inside the 200-foot-high Pyramid of the Sun, the most prominent feature of Teotihuacán, prove that this was erected by the end of the Tzacualli phase. The pyramid rises in four great stages, but there is a fifth and much smaller stage between the third and fourth. An impressive stairway rises dramatically on its west side, facing the Avenue of the Dead. Reexamination suggested the presence of a huge tomb at its base, but this has never been excavated.

On the northern end of the Avenue of the Dead is the Pyramid of the Moon, very similar to that of the Sun, but with an additional platform-temple jutting out on the south. This exhibits the *talud-tablero* architectural motif that is typical of Teotihuacán culture: on each body or tier of a stepped pyramid is a rectangular frontal panel (*tablero*) supported by a sloping batter (*talud*). The *tablero* is surrounded by a kind of projecting frame, and the recessed portion of the panel usually bears a polychrome mural applied to the stuccoed surface.

Near the exact centre of the city and just east of the Avenue of the Dead is the Ciudadela (“Citadel”), a kind of sunken court surrounded on all four sides by platforms supporting temples. In the middle of the sunken plaza is the so-called Temple of Quetzalcóatl, which is dated to the second phase of Teotihuacán, Miccaotli. Along the balustrades of its frontal stairway and undulating along the *talud-tablero* bodies of each stage of this stepped pyramid are sculptured representations of Quetzalcóatl, the Feathered Serpent. Alternating with the Feathered Serpents on the *tableros* are heads of another monster that can be identified with the Fire Serpent—bearer of the Sun on its diurnal journey across the sky.

On either side of the Avenue of the Dead are residential palace compounds (probably occupied by noble families), which also conform to the Teotihuacán master plan. Each is a square, 200 feet on a side, and is surrounded by a wall. The pedestrian would have seen only the high walls facing the streets, pierced by inconspicuous doors. Within the compounds, however, luxury was the rule. Roofs were flat, constructed of large cedar beams overlaid by brush and mortar. Interior walls were plastered and magnificently painted with ritual processions of gods and various mythological narratives. Interconnected apartments were arranged around a large, central, open-air court.

These dwellings were the residences of Teotihuacán's elite. Toward the periphery of Teotihuacán, however, the social situation may have been quite different. One excavation on the eastern side of the city disclosed a mazelike complex of much tinier and shoddier apartments that recall the poorer sections of Middle Eastern cities. It may be guessed that there lay the crowded dwellings of the artisans and other labourers who made the city what it was. There is also evidence that certain peripheral sections were reserved for foreigners.

Layout of the city

The Temple of Quetzalcóatl

Early architecture

Manu-
facturing
and trade

Teotihuacán must have been the major manufacturing centre of the Early Classic, for the products of its craftsmen were spread over much of Meso-America. The pottery, particularly during the Xolalpan phase, which represents the culmination of Teotihuacán as a city and empire, is highly distinctive. The hallmark of the city is the cylindrical vessel with three slab legs and cover, often stuccoed and then painted with scenes almost identical to those on the walls of buildings. There are also vessels shaped like modern flower vases and cream pitchers. Thin Orange ware is a special ceramic type produced to Teotihuacán specifications, perhaps in southern Veracruz, and exported by its own traders. Figurines were produced by the tens of thousands in pottery molds.

Among its many commercial specializations, obsidian was probably preeminent, for the Teotihuacanos had gained control of the mines of green obsidian above the present-day city of Pachuca, in Hidalgo. They also had a local but poorer quality source. Millions of obsidian blades, as well as knives, dart points, and scrapers, were turned out by Teotihuacán workshops for export.

The name Teotihuacán meant "City of the Gods" (or, "Where Men Became Gods") in Aztec times, and although the city had been largely deserted since its decline, the Aztec royal house made annual pilgrimages to the site. Teotihuacán culture exerted a profound influence on all contemporary and later Meso-American cultures. Many Aztec gods, such as Tlaloc, his consort Chalchiuhtlicue, and Quetzalcóatl, were worshiped by the Teotihuacanos. Like the Aztec, the Teotihuacanos generally cremated their dead. In fact, there are so many congruences between Teotihuacán practices and those of the later Toltec and Aztec that some authorities believe them to have been speakers of Náhuatl language and the precursors of those people. Some linguistic authorities, however, believe that the Teotihuacanos spoke a Totonac language, similar to what was spoken by the inhabitants of central Veracruz. It is not known whether the people of the city, like the Maya, were literate.

Teotihuacán was the greatest city of Meso-America, indeed, of all pre-Columbian America. Authorities are divided as to whether it was the capital of a great political empire. Some believe that Teotihuacán's expansion was carried by force of arms; others believe its power to have been largely economic and religious. In either case, at its height in the 6th century Teotihuacán was the greatest civilization in Meso-America, with an influence that far outstripped that of the later Aztec empire. For the archaeologist, the universal spread of Teotihuacán ceramic and other traits constitutes an Early Classic horizon.

Cholula. The broad, fertile plains surrounding the colonial city of Puebla, to the southeast of the snowcapped volcanoes that border the Valley of Mexico, were from very ancient times an important centre of pre-Hispanic population. The modern traveler, approaching the city, sees to its west, in the distance, what looks like a sizable hill rising from the plain. This is actually the pyramid of Cholula, the largest single structure in Mexico before the Spanish conquest.

Size and
decoration
of the
Cholula
pyramid

Archaeological exploration of the Cholula pyramid has shown that it was built from adobe in four great construction stages. In its final form, the pyramid measured 1,083 feet by 1,034 feet at the base and was about 82 feet high. By Late Postclassic times the pyramid had been abandoned for so long that the Spaniards who subdued (and massacred) the residents of Cholula considered it a natural prominence. All four superimposed structures within the pyramid were carried out according to strict Teotihuacán architectural ideas. The earliest structure, for instance, has the usual *talud-tablero* motif, with stylized insectlike figures painted in black, yellow, and red appearing in the *tableros*. Similar decoration, also in Teotihuacán style, is to be found in the later structures.

Great quantities of ceramics and pottery figurines have been recovered from the excavations, and these demonstrate a near archaeological identity between Early Classic Teotihuacán and Cholula. Because of the staggering size and importance of its pyramid, it has been suggested that Cholula was some kind of sister city to Teotihuacán.

Cholula was surely part of the Teotihuacán cultural sphere and may well have participated in the administration of its empire. Excavations at the base of the pyramid have produced a previously unsuspected cultural element. Several enormous slabs were uncovered, two of which were a kind of altar, while the third was set upright as a stela. All are rectangular but with borders carved in low relief in the complex interlace motif that is the hallmark of the Classic Central Veracruz style.

Classic Central Veracruz. The Meso-American ball game was played throughout the area and still survives in attenuated form in northwestern Mexico. On the eve of the conquest, games took place in a rectangular court bordered on the long sides by walls with both sloping and vertical rebound surfaces. There were two teams, each composed of a small number of players. The ball was of solid rubber, of substantial size, and traveled with considerable speed around the court. It could not be hit or touched with the open hands or with the feet; most times the player tried to strike it with the hip. Consequently, fairly heavy protective padding was necessary to avoid injuries, which in some cases were fatal. Leather padding was worn over the hips, and pads were placed on the elbows and knees. A heavy belt was tied around the waist built up from wood and leather, while in some parts of the Maya region and in Late Formative Oaxaca, gloves and something resembling jousting helmets were worn.

The Meso-
American
ball game

Peabody Museum, Harvard University

The ball court at Copán, Honduras; Late Classic Maya.

The Classic Central Veracruz style is almost purely devoted to the paraphernalia of the ball game and to the ball courts themselves. At the site of El Tajín, which persisted through the end of the Late Classic, elaborate reliefs on the walls of the courts furnish details on how this equipment was used. *Yugos* ("yokes") were the stone counterparts of the heavy protective belts. During the post-game ceremonies, which may have featured the sacrifice of the captain and other players on the losing side, these U-shaped objects were worn about the waists of the participants. On the front of the *yugo* was placed an upright stone object that may originally have functioned as a ball-court marker and that took two forms: *hachas* ("axes") or thin stone heads, and *palmas* ("palms"). All are carved in an elaborate low-relief style in which life forms are enmeshed in undulating and interlaced scroll designs with raised borders. All of these items, and the style itself, may have evolved out of late Olmec art on the Gulf coast.

Very often the *yugos* represent the marine toad, a huge amphibian with swollen poison glands on the head; in its jaws is a human head. The earliest *hachas*, which were characteristically notched to fit on the *yugos*, were quite thick human heads and may well date to the Late Formative or Proto-Classic. In time, these become very thin and represent human heads wearing animal headgear. *Palmas* are paddle-shaped stone objects with trilobed bases and exhibit a much richer subject matter than either *hachas* or *yugos*, quite often illustrating brutal scenes of sacrifice and death, two concepts that were closely associated with the ball game on the Gulf coast.

Despite the definite presence of the style at Teotihuacán and Cholula, Classic Central Veracruz is focused upon north central Veracruz, where the type site of El Tajín is located, and contiguous parts of Puebla. Today, this region is dominated by speakers of Totonac, a distant relative of Mayan, and the Totonac themselves claim that they built El Tajín. Whether or not Classic Central Veracruz culture was a Totonac achievement, the style persisted through the Classic period and strongly influenced developments in distant regions.

Southern Veracruz. On the southern Gulf coast plain, Olmec traditions seemed to have lasted into the Early Classic and merged with Teotihuacán artistic canons to produce new kinds of art. Cerro de las Mesas, lying in the plains of the Papaloápan River not far from the coast, is one of these hybrid sites. Dozens of earthen mounds are scattered over the surface in a seemingly haphazard manner, and the archaeological sequence is long and complex. The site reached its apogee in the Early Classic, when the stone monuments for which it is best known were carved. Most important are a number of stelae, some of which are carved in a low-relief style recalling Late Formative Tres Zapotes, early lowland Maya, and Cotzumalhuapa (on the Pacific coast of Guatemala).

Cerro de las Mesas pottery

Cerro de las Mesas pottery, deposited in rich burial offerings of the Early Classic, is highly Teotihuacanoid, with slab-legged tripods predominating. At this and other sites in southern Veracruz, potters also fashioned large, hollow, handmade figures of the gods. An especially fine representation of the Old Fire God was found at Cerro de las Mesas. The most spectacular discovery, however, was a cache of some 800 jade objects. Many of the specimens in this treasure trove are of Olmec workmanship, obviously heirlooms from the much earlier Olmec civilization, while some are clearly Early Classic Maya.

The entire coastal plain from Cerro de las Mesas north to the borders of Classic Central Veracruz culture is famed for Remojadas-style pottery figurines, which must have been turned out in incredible quantity for use as burial goods. The Remojadas tradition dates to the Late Formative and lasts until the Early Postclassic. Figurines are hollow and largely mold-made in the Late Classic, while they were fashioned by hand in the Early Classic. The best-known Classic representations are the "smiling figures" of grinning boys and girls wearing loincloths, skirts, or nothing at all. All kinds of genre scenes are represented, including even lovers in swings, as well as more grim activities such as the heart sacrifice of victims tied down in what look like beds.

Classic Monte Albán. The cultural phases designated as Monte Albán III-A and III-B mark the Classic occupation of this major site in the Valley of Oaxaca. There can be little doubt that the people of Monte Albán were Zapotec speakers, who during Classic times had unequalled opportunity to develop their civilization unaffected by the major troubles that disturbed Teotihuacán and the Maya at the close of the Early Classic. Instead of the 18 or 19 sites known for the valley during the Late Formative, there now were more than 200, a testimony to Zapotec prosperity.

Zapotec prosperity

The Monte Albán Classic Period (III-A and III-B) lasted from AD 250 to 700. During the earlier (III-A) part of the period (250–450) the site shows considerable influence from Teotihuacán. The Early Postclassic Period at Monte Albán (IV; 700–1000) was a time of significant cultural change; it is still uncertain, however, whether the Mixtec replaced the Zapotec at that time.

The Classic site of Monte Albán is quite spectacular. Stone-faced platforms are fronted by stairways with flanking balustrades and exhibit a close counterpart of the *tahud-tablero* motif of Teotihuacán. The temple superstructures had colonnaded doorways and flat beam-and-mortar roofs. One of the best-preserved ball courts of Meso-America can be seen at Monte Albán, with a ground plan fashioned in the form of a capital I. Spectators watched the game from stone grandstands above the sloping playing surfaces.

Subsurface tombs were dug in many parts of the site as the last resting places of Monte Albán's elite. The finest are actually miniature replicas of the larger temples on the surface, complete with facade and miniature painted

rooms. The style of the funerary wall paintings is quite close to Teotihuacán, in which areas of flat colour are contained within very finely painted lines in red or black. Teotihuacán presence can also be seen in the finer pottery of Classic Monte Albán, but the manufacture is local as can be proved from the predominance of the fine gray ware that has always typified Monte Albán.

The tradition of literacy dates to Monte Albán I. By Classic times, inscriptions are abundant, appearing on stelae, lintels, slabs used as doors, and wall paintings. The 52-year Calendar Round was the only form of writing dates. The subject matter of these inscriptions can be related to the scenes that they accompany: quite often it is a bound captive standing on a place-glyph, presumably an enemy leader taken in war—an old Monte Albán preoccupation.

The Zapotec of Monte Albán, like the Maya, never exerted much cultural or other pressure on peoples beyond their lands. They did, however, control lands from the Tehuacán Valley in Puebla as far south as the Pacific shore of Oaxaca. Whether they themselves were also controlled by Teotihuacán has not been demonstrated.

The Maya highlands and Pacific coast. Little is known about the Guatemalan highlands between the demise of the Late Formative Miraflores culture and the onset of the Early Classic. But at the ancient site of Kaminaljuyú, on the western side of Guatemala City, a group of invaders from Teotihuacán built a miniature replica of their capital city. This happened about AD 400, when Teotihuacán was at the height of its power.

This implanted Teotihuacán culture is called Esperanza. Mexican architects must have accompanied the elite, for Kaminaljuyú structures copy the older prototypes down to the last detail, including the support of the lower moldings around *tableros* with slate slabs. The abundant volcanic building stone, however, so freely used at Teotihuacán, was not present, so that Esperanza temple platforms are built from clay instead.

Each temple platform was rebuilt several times, the later structures being raised over the earlier. Within the stairways fronting each successive platform a great leader was buried. The rich burial furniture in the tombs is informative, for it included three classes of goods: (1) items such as Thin Orange pottery manufactured in Teotihuacán or in one of its satellite areas, (2) hybrid Teotihuacán-Maya pottery and other objects, probably made in Kaminaljuyú, and (3) pottery imported from Petén and of Early Classic Maya manufacture. Also discovered in one tomb was a slate mirror carved in Classic Central Veracruz style. Jade objects occur in abundance in the Esperanza tombs, and in one structure an enormous boulder was recovered; it had been imported from the Maya source along the Motagua River in the southeastern lowlands. The Esperanza elite were enormously wealthy.

What were they doing in the Maya highlands in the first place? Were they an army of imperial conquest? Or were their interests more in the realm of trade? Or both? It is not possible to be definite in these interpretations; but it is known that among the Aztec of the Late Postclassic there was an institution called the *pochteca*, a hereditary guild of armed merchants who traveled into distant lands looking for luxury goods to bring back to the royal house. Quite often the *pochteca* would seize lands of hostile peoples through which they passed, or they would provoke incidents that led to the intervention of the regular Aztec army.

The *pochteca*

It has been suggested that the Teotihuacanos in Kaminaljuyú were also *pochteca*. They had clear access to the Petén-Yucatán Peninsula and may have exercised political control over it. Kaminaljuyú may have been one of their principal bases of operations in the inclusion of the Maya, both highland and lowland, within the Teotihuacán state.

Within a zone only 75 miles long and 30 miles wide, on the Pacific coast plain of Guatemala, is a cluster of nine compactly built ceremonial centres that together form the Cotzumalhuapa civilization. It forms a puzzle, for there are strong affiliations with most other contemporary civilizations in Meso-America. Stylistic influence from the lowland Maya, Classic Central Veracruz, and Teotihuacán can be detected among others. While Cotzumalhuapa

took form by the Early Classic, it continued into the Late Classic; but there are great problems in dating individual sculptures.

The problem of Cotzumalhuapa has been linked with that of the Pipil, a shadowy people living in the same region on the eve of the Spanish conquest, who spoke Nahuatl rather than Maya. It is possible that these Classic sites were actually Pipil capitals, but the case cannot be proved. There is some hieroglyphic writing on Cotzumalhuapa sculptures, mainly dates within what seems to be a 52-year Calendar Round, the glyphs for days being Mexican rather than Maya. There are no real texts, then, to help with the problem.

Classic civilization in the Maya lowlands: Tzakol phase. Archaeologists have divided the entire area occupied by speakers of Mayan languages into three subregions: (1) the Southern Subregion, essentially the highlands and Pacific Coast of Guatemala, (2) the Central Subregion, which includes the department of Petén in northern Guatemala and the immediately adjacent lowlands to the east and west, and (3) the Northern Subregion, consisting of the Yucatán Peninsula north of Petén proper. Between 250 and 900 the most brilliant civilization ever seen in the New World flourished in the forested lowlands of the Central and Northern subregions.

Lowland Maya civilization falls into two chronological phases or cultures: Tzakol culture, which is Early Classic and began shortly before AD 250, and the Late Classic Tepeu culture, which saw the full florescence of Maya achievements. Tepeu culture began about 600 and ended with the final downfall and abandonment of the Central Subregion about 900. (These dates, based on the correlation of the Long Count system of the Maya calendar with the Gregorian calendar, are the most generally accepted; but there is a slight chance that a rival correlation espoused by the American archaeologist Herbert J. Spinden may be correct, which would make these dates 260 years earlier.)

One of the earliest objects inscribed with the fully developed Maya calendar is the Leiden Plate, a jade plaque, now housed in the National Museum of Ethnology, Leiden, Neth., depicting a richly arrayed Maya lord trampling a captive underfoot. On its reverse side is a Long Count date corresponding to 320. Although it was found in a very late site on the Caribbean coast, stylistic evidence suggests that the Leiden Plate was made at Tikal, in the heart of northern Petén. In the mid-20th century the University of Pennsylvania's ambitious field program at the Tikal site produced Stela 29, erected 28 years before, in 292. Both objects and, in fact, almost all early Tzakol monuments draw heavily upon a heritage from the older Izapán civilization of the Late Formative, with its highly baroque, narrative stylistic content.

Because of the Maya penchant for covering older structures with later ones, Tzakol remains in the Central Subregion have to be laboriously dug out from their towering Late Classic overburdens. Nevertheless, it is clear that at sites like Tikal, Uaxactún, and Holmul, Maya civilization had reached something close to its final form. Enormous ceremonial centres were crowded with masonry temples and "palaces" facing onto spacious plazas covered with white stucco. The use of the corbel vault for spanning rooms—a trait unique to the lowland Maya—was by this time universal. Stelae and altars (a legacy from Izapa) are carved with dates and embellished with the figures of men and perhaps gods. Polychrome pottery, the finest examples of which were sealed in the tombs of honoured personages, emphasizes stylized designs of cranes, flying parrots, gods, and men. These often occur on bowls with a kind of apron or basal flange encircling the lower vessel. Along with these purely Maya ceramics are vessels that show the imprint of distant Teotihuacán: the cylindrical vase supported by three slab legs, the "cream pitcher," and the *florero* ("flower vase").

Wall painting had already reached a high degree of perfection in the Central Subregion, as attested by an extremely fine mural at Uaxactún depicting a palace scene in which two important lords confer with each other. This mural art is quite different from that of Teotihuacán, being very naturalistic instead of formal and including a

definite interest in portraiture. Nonetheless, excavations in Petén sites have shown that Teotihuacán influence was quite pervasive. From Tikal, for example, comes Stela 31, depicting a richly garbed Maya lord, festooned with jade ornaments, standing between two warriors from Teotihuacán. These foreigners carry shields that bear the visage of the Teotihuacán rain god, Tlaloc. It is certain that there was a three-way trading relationship between Tikal, Kaminaljuyú, and Teotihuacán in Early Classic times.

Thus, the Teotihuacán involvement with Tikal and the Central Subregion may have taken, as at Kaminaljuyú, the form of *pochteca* trading colonies that exerted some control over the lowland Maya. The lord on Stela 31 may have been a puppet ruler manipulated by tough merchant-warriors. Teotihuacán as a city and capital of an empire began to weaken toward the close of the 6th century. It could therefore be expected that the disruptions that effectively ended the life of the great Mexican capital would be reflected in the Maya area. This is exactly the case. In the Guatemalan highlands, Kaminaljuyú declined rapidly after AD 600, and the entire Southern Subregion was to play little part in Maya culture until the Late Postclassic. The lowland Maya suffered some temporary reverses; few stelae were erected between 534 and 692, and there is evidence that existing monuments were mutilated.

LATE CLASSIC NON-MAYA MESO-AMERICA (600–900)

The cultural situation in Late Classic Meso-America is the reverse of that prevailing in the Early Classic: Central Mexico now played only a minor role, while the lowland Maya reached their intellectual and artistic heights. In contrast to the old Teotihuacanos, however, the Maya were not expansionistic. It is true that Maya cultural influence has been detected along the Gulf coast and in the states of Morelos and Tlaxcala—as in the painted murals of Cacaxtla in the latter state—but it is unlikely that this was the result of a military takeover. The outcome of this state of affairs, with no one people powerful enough or sufficiently interested in dominating others, was a political and cultural fragmentation of Meso-America after 600. It was not until the great Toltec invasions of the Early Postclassic that anything approaching an empire was to be seen again.

The decline in fortunes of the Valley of Mexico, and especially of Teotihuacán, cannot now be explained. Climatic deterioration, resulting in drier conditions and thus a diminished subsistence potential, may have been a factor.

Nevertheless, Teotihuacán was never completely abandoned, even though its great palaces had been burned to the ground and its major temples abandoned. People continued to live in some sections, but their houses were mere hovels compared to the dwellings of the Early Classic. In general, the Valley of Mexico was a cultural and political vacuum in Late Classic times.

One of the very few centres of the Late Classic in central Mexico that amounted to much was Xochicalco, in Morelos. Strategically located on top of a hill that was completely reworked with artificial terraces and ramparts, Xochicalco was obviously highly defensible, an indication of the unsettled times then prevailing in central Mexico. The site shows a bewildering variety of cultural influences, particularly Maya. The principal structure of Xochicalco is a temple substructure of masonry that is completely carved in relief with undulating Feathered Serpents, indicating that it was dedicated to the cult of Quetzalcóatl. All indications are that Xochicalco was a cosmopolitan and very powerful centre, perhaps the most influential west of Veracruz and northwest of the Maya area. It was literate and civilized at a time when most other parts of central Mexico were in cultural eclipse.

The Late Classic occupation of Oaxaca, especially of the Valley of Oaxaca, is designated as Monte Albán III-B (450–700). The Mixtec invasions of the valley probably began in earnest around 900. The Mixtec occupied the hilly, northern part of Oaxaca; their records, which extend to the 7th century, show them to have been organized into a series of petty states headed by aggressive, warlike kings. By the Postclassic, they had become the dominant force throughout Oaxaca and in part of Puebla.

Ceremonial
centres

Decline
of Teoti-
huacán

The
Pyramid of
the Niches

The tendencies in central Veracruz art and architecture that began in the Late Formative culminated in the Late Classic at the great centre of El Tajín, placed among jungle-covered hills in a region occupied by the Totonac Indians, whose capital this may well have been. Its most imposing structure is the Pyramid of the Niches, named for the approximately 365 recesses on its four sides. In this and other buildings at El Tajín, the dominant architectural motif is the step-and-fret. There are a number of other temple pyramids at the site, as well as palacelike buildings with flat, concrete roofs, a tour de force of Meso-American engineering knowledge. El Tajín's three major ball courts are remarkably important for the reliefs carved on their vertical playing surfaces, for these give valuable information on the religious connotations of the sacred game. Like Xochicalco, El Tajín was in some way linked to the destiny of the lowland Maya, and the collapse of Maya civilization around 900 may have been reflected in the demise of the Veracruz centre.

Further down the Gulf coast plain, the Remojadas tradition of hollow pottery figurines continued to be active in the Late Classic, with a particularly large production of the mysterious smiling figures of dancing boys and girls, which were intended as funerary offerings. But in addition, there was a great deal of pottery and figurines that were fashioned under very strong Maya influence. In fact, much of southern Veracruz at this time was a cultural extension of the lowland Maya. There is no indication, however, that these peoples had any acquaintance with Maya literacy or with Maya building techniques.

LATE CLASSIC LOWLAND MAYA (600–900)

Settlement pattern. There is still controversy over whether the Late Classic sites built by the lowland Maya were actually cities or whether they were relatively empty ceremonial centres staffed only by rulers and their entourages.

The common people built their simple pole-and-thatch dwellings on low earthen mounds to keep them dry during the summer rains. Thus, total mapping of a particular site should always include not only masonry structures but also house mounds as well. So far, only a few Maya sites have been so mapped. The mightiest Maya centre of all, Tikal in northern Petén, has a total of about 3,000 structures ranging from the tiny mounds up to gigantic temple pyramids; these are contained, however, within an area of six square miles. The Tikal population has been estimated from this survey to be 10,000–11,000 people, but perhaps as many as 75,000 within an even wider area could have belonged to Tikal.

This sounds very much like a city, but the evidence actually can be differently interpreted. First, at the time of the conquest the Maya generally buried their dead beneath the floors of houses, which were then abandoned. Thus, an increase in number of house mounds could just as easily indicate a declining population in which the death rate exceeded the birth rate. Second, the appearance of even such a tremendous centre as Tikal is quite different from that of such true cities as Teotihuacán. An ordinary Maya family typically occupied two or three houses arranged around a rectangular open space. These were grouped into unplanned hamlets near good water and rich, well-drained soils. A survey of Petén has shown that for every 50 to 100 dwellings there was a minor ceremonial centre; this unit has been called a zone. Several zones formed a district for which a major centre like Tikal acted as the ceremonial and political nucleus. Neither Tikal nor any other such centre shows signs of town planning or neatly laid out streets.

There are also ecological factors that must have set certain limits upon the potential for urban life in the Maya lowlands. Slash-and-burn cultivation would have made for widely settled populations; and, as has been argued, the uniformity of the lowland Maya environment would have worked against the growth of strong interregional trade, always a factor in urban development. Yet these statements must be qualified. It is known that raised-field, or chinampa-type, farming was used in many places and at many times in the Maya lowlands. This would have

allowed for greater population concentration. It is also known that there was a brisk trade in some commodities from one lowland Maya region to another.

What, then, can be concluded about lowland Maya urbanism? Clearly, the urban form, even at a metropolis such as Tikal, was not as large or as formally developed as it was at highland Teotihuacán. At the same time, a centre whose rulers could draw upon the coordinated efforts of 75,000 people must inevitably have had some of the functions of a true city—in governance, religion, and trade, as well as in the development of the arts and intellectual life.

Major sites. While there are some important differences between the architecture of the Central and Northern subregions during the Late Classic, there are many features shared between them. A major Maya site generally includes several types of masonry buildings, usually constructed by facing a cement-and-rubble core with blocks or thin slabs of limestone. Temple pyramids are the most impressive, rising in a series of great platforms to the temple superstructure above the forests. The rooms, coated with white stucco, are often little more than narrow slots because of the confining nature of the corbeled vaults, but this was probably intentional, to keep esoteric ceremonies from the public.

The so-called palaces of Maya sites differ only from the temple pyramids in that they are lower and contain a great many rooms. Their purpose still eludes discovery; many scholars doubt that they really served as palaces, for the rooms are damp and uncomfortable, and there is little or no evidence of permanent occupation. The temples and palaces are generally arranged around courts, often with inscribed stelae and altars arranged in rows before them. Leading from the central plazas are great stone causeways, the function of which was probably largely ceremonial. Other features of lowland sites (but not universal) are sweat-houses, ball courts, and probably marketplaces.

There are more than 50 known sites that deserve to be called major. Most are in the Central Subregion, with probably the greatest concentration in northern Petén, where Maya civilization had its deepest roots. Tikal is the largest and best-known Classic site of the Central Subregion. It is dominated by six lofty temple pyramids, one of which is some 230 feet high, the tallest structure ever raised by the Meso-American Indians. Lintels of sapodilla wood still span the doorways of the temple superstructures and are carved with reliefs of Maya lords enthroned amid scenes of great splendour. Some extraordinary Late Classic tombs have been discovered at Tikal, the most important of which produced a collection of bone tubes and strips delicately incised with scenes of gods and men. Ten large reservoirs, partly or entirely artificial, supplied the scarce drinking water for the residents of Tikal.

Other important sites of northern Petén include Uaxactún, Naranjo, Nakum, and Holmul, of which only the first has been adequately excavated. To the southeast of Petén are two Maya centres—Copán and Quiriguá—that show notable differences with the Petén sites. Copán is located above a tributary of the Motagua River in western Honduras in a region now rich in tobacco. Its architects and sculptors had a ready supply of a greenish volcanic tuff far superior to the Petén limestone. Thus, Copán architecture is embellished with gloriously baroque figures of gods, and its stelae and other monuments are carved with an extraordinary virtuosity. Copán also has one of the most perfectly preserved ball courts in Meso-America. Quiriguá is a much smaller site 30 miles north of Copán. While its architectural remains are on a minor scale, it is noted for its gigantic stelae and altars carved from sandstone.

The principal watercourse on the western side of the Central Subregion is the Usumacinta River, originating in the Guatemalan highlands and emptying into the Gulf of Mexico. For much of its course the Usumacinta is lined with such great Maya ceremonial centres as Piedras Negras and Yaxchilán. Even more renowned is Bonampak, a satellite of Yaxchilán located on a tributary of the Usumacinta. The discovery in 1946 of the magnificent murals embellishing the rooms of an otherwise modest structure astounded the archaeological world. From floors to vault capstones, its stuccoed walls were covered with

The
Bonampak
murals

highly realistic polychrome scenes of a jungle battle, the arraignment of prisoners, and victory ceremonies. These shed an entirely new light on the nature of Maya society, which up until then had been considered peaceful.

In the hills just above the floodplain of the Usumacinta lies Palenque, the most beautiful of Maya sites. The architects of Palenque designed graceful temple pyramids and "palaces" with mansard-type roofs, embellished with delicate stucco reliefs of rulers, gods, and ceremonies. The principal structure is the Palace, a veritable labyrinth of galleries with interior courts; over it looms a four-story square tower that may have served as both lookout and observatory. A small stream flowing through the site was carried underneath the Palace by a long, corbel-vaulted tunnel. The temples of the Cross, Foliated Cross, and Sun were all built on the same plan, the back room of each temple having a kind of sanctuary designed like the temple of which it was a part. It can be supposed that all three temples served the same cult. The most extraordinary feature of Palenque, however, was the great funerary crypt discovered in 1952 deep within the Temple of the Inscriptions. Within a sarcophagus in the crypt were the remains of an unusually tall ruler, accompanied by the richest offering of jade ever seen in a Maya tomb. Over his face had been fitted a mask of jade mosaic, while a treasure trove of jade adorned his body.

Northward from the Central Subregion, in the drier and flatter environment of the Yucatán Peninsula, the character of lowland Maya civilization changes. Just north of Petén is the Río Bec zone, as yet little explored but noted for temple pyramids and palaces with flanking false towers fronted by unclimbable "stairways" reaching dummy "rooms" with blank entrances. Río Bec structures are carved with fantastic serpents in deep relief, a feature that becomes even more pronounced in the Chenes country to the northwest, in the modern state of Campeche. At Chenes sites, Maya architects constructed frontal portals surrounded by the jaws of sky serpents and faced entire buildings with a riot of baroquely carved grotesques and spirals.

This elaborate ornamentation of buildings is far more restrained and orderly in the style called Puuc, so named from a string of low hills extending up from western Campeche into the state of Yucatán. The Puuc sites were for the Northern Subregion what the Petén sites were for the Central, for they are very numerous and clearly were

the focal point for Maya artistic and intellectual culture. Uxmal is the most important Puuc ceremonial centre and an architectural masterpiece. It has all of the characteristics of the Puuc style: facings of thin squares of limestone veneer over a cement-and-rubble core; bootshaped vault stones; decorated cornices around columns in doorways; engaged or half-columns repeated in long rows; and lavish use of stone mosaics in upper facades, emphasizing sky-serpent faces with long, hook-shaped noses, as well as frets and latticelike designs of crisscrossed elements.

The nearby centre of Kabah, connected to Uxmal by a ceremonial causeway, has an extraordinary palace completely faced with masks of the Sky Serpent. Other major Puuc sites are Sayil, with a multistoried palace, and Labná. The Puuc style reaches east across the Yucatán Peninsula, for at Chichén Itzá, a great site that was to occupy centre stage during the Toltec occupation of the Northern Subregion, there are several buildings strongly Puuc in character.

Puuc sites may be said to represent a lowland Maya "New Empire" in the sense that their apogee occurred in the 9th and 10th centuries, a time during which the great Petén, or Central Subregion, centres were in decline or had collapsed. Just how late Puuc sites remained active, with major constructions being dedicated, remains something of a question. In about 1000 a major change took place in northern Yucatán. It was marked by the construction of a number of Toltec-style temples and palaces at Chichén Itzá, a site that also has many Puuc-style edifices. It is not known if Toltec Chichén Itzá existed contemporaneously with such Puuc sites as Uxmal and Labná, and if so, for how long. Eventually, Chichén Itzá appears to have dominated northern Yucatán, lasting well into the Postclassic Period (about 1250). Questions also surround the bringers of Toltec-style architecture to Chichén Itzá. They may have been either central Mexican Toltecs or Gulf coast peoples who probably were Maya-speakers and who had adopted central-Mexican ways. In this connection, it should be noted that Puuc sites were under several influences from Gulf-coast Mexico, particularly from central Veracruz.

Maya art of the Late Classic. Maya art, at the height of its development, was fundamentally unlike any other in Meso-America, for it was highly narrative, baroque, and often extremely cluttered, unlike the more austere styles found elsewhere. It is essentially a painterly rather than sculptural tradition, and it is quite likely that even stone reliefs were first designed by painters. Much of this art has disappeared for all time because of the ravages of the wet, tropical environment on such perishable materials as wood, painted gourds, feathers, bark, and other substances. There must have been thousands of bark-paper codices, not one of which has survived from Classic times.

Peabody Museum, Harvard University

Ruins of the palace at Sayil, a Puuc site, Yucatán state, Mexico; Late Classic Maya.

Uxmal

Following the downfall of Teotihuacán, Maya artists were free to go their own way. Magnificently carved stelae and accompanying altars are found at most major sites, the greatest achievement in this line being found at Copán, where something approaching three-dimensional carving was the rule. Palenque and Yaxchilán specialized in graceful bas-reliefs placed as tablets or lintels in temple pyramids and palaces. In the Northern Subregion, however, the sculptor's art was definitely inferior in scope and quality and shows strong influence from alien, non-Maya cultures.

Wood
carvings

A few wooden objects have somehow survived. Particularly noteworthy are the massive wooden lintels of Tikal, with scenes of lords and their guardian deities, accompanied by lengthy hieroglyphic texts. In ancient times, wood carvings must have been vastly more common than sculptures. The wet climate has also destroyed innumerable examples of mural art.

Maya pottery can be divided into two groups: (1) the pots and pans of everyday life, usually undecorated but sometimes with geometric designs, and (2) grave offerings. Vessels meant to accompany the honoured dead were usually painted or carved with naturalistic and often macabre scenes. To achieve polychrome effects of great brilliance, the Maya potters painted in semitranslucent slips over a light background, then fired the vessels at a very low temperature. Relief carving was carried out when the vessels were leather-hard, just before firing.

The most precious substance of all to the Maya was jade, to which their craftsmen devoted great artistry. Jade was mainly fashioned into thin plaques, carved in relief, or into beads. In the absence of metal tools, jade was worked by applying abrasives and water with cane or perhaps other pieces of jade.

The Maya calendar and writing system. It is their intellectual life that established the cultural superiority of the Maya over all other American Indians. Much of this was based upon a calendrical system that was partly shared with other Meso-American groups but that they perfected into a tool capable of recording important historical and astronomical information. Most Maya inscriptions that have been interpreted are calendrical inscriptions. Since the late 1950s, it has been learned that the content of Classic Maya inscriptions was far more secular than had been supposed. For many years specialists believed that the inscriptions recorded little more than the passage of time and that, in fact, the Maya were time worshipers; but it has been shown that certain inscriptions recorded the birth, accession, marriage, and military victories of ruling dynasties. One very significant advance in following dynastic histories and plotting political territoriality was the discovery in 1958 of "emblem glyphs," symbols standing for royal lineages and their domains.

Yet it would be misleading to contend that the hurly-burly of Maya court affairs and conquests was all that mattered, for some texts must have been sacred and god-oriented. At Palenque, in the similar temples of the Cross, Foliated Cross, and Sun, the dates inscribed on the tablets in the sanctuaries fall into three groups. The very latest seem to refer to events in the lives of reigning monarchs. An earlier group must deal with distant but real ancestors of those kings, while the very earliest fall in the 4th millennium BC and apparently describe the birth of important gods to whom the respective temples were dedicated and who may have been regarded as the progenitors of Palenque's royal house.

The meaning of many non-calendrical signs and even of complete clauses is not known, but there is a difference between this and assigning an actual Maya word to an ancient glyph or a sentence to a glyphic clause. While it is certain that the language of the Classic inscriptions was Mayan, it is also certain that it was more archaic than any of the Mayan languages spoken at the time of the conquest, six centuries after the Classic downfall. The three extant Maya codices, none dating earlier than 1100, contain a strong phonetic component, in fact a kind of syllabary, which can be successfully read as Yucatec-Maya, but the Classic peoples of the Central Subregion more likely spoke an ancestor of the Cholan branch of

The Maya
codices

Maya. Furthermore, Maya hieroglyphic writing covers the entire span from about AD 250 to the conquest, during which time both the language or languages and the writing system itself must have undergone extensive evolution.

In writing systems in general, there is usually a development from pictographic signs, in which a picture stands for a word or concept, through logographic systems, in which words are still the basic unit but phoneticism is employed to reduce ambiguities (as in Chinese), to phonetic syllabaries, and finally to alphabets. Probably most Classic Maya hieroglyphs are logograms with a mainly ideographic orientation, and it seems that there was a considerable degree of flexibility in how the words and sentences could be written. By the Postclassic, this had been codified into a much more rigid system closely resembling that of Japanese, in which a well-defined syllabary can supplement or even replace logograms. There are approximately 300 to 500 logograms in Classic Maya (the number varies according to how one separates affixes from so-called main signs), but it will probably be many years before the majority of these are satisfactorily deciphered. Great progress, however, may be expected in unraveling their meaning in specific contexts.

(M.D.C./G.R.W.)

Maya mathematics included two outstanding developments: positional numeration and a zero. These may rightly be deemed among the most brilliant achievements of the human mind. The same may also be said of ancient Maya astronomy. The duration of the solar year had been calculated with amazing accuracy, as well as the synodical revolution of Venus. The Dresden Codex contains very precise Venusian and lunar tables and a method of predicting solar eclipses.

Maya chronology consisted of three main elements: a 260-day sacred year (*tzolkin*) formed by the combination of 13 numbers (1 to 13) and 20 day names; a solar year (*haab*), divided into 18 months of 20 days numbered from 0 to 19, followed by a five-day unlucky period (*Uayeb*); and a series of cycles—*uinal* (20 *k'ins*, or days), *tun* (360 days), *katun* (7,200 days), *baktun* (144,000 days), with the highest cycle being the *alautun* of 23,040,000,000 days. All Middle American civilizations used the two first counts, which permitted officials accurately to determine a date within a period defined as the least common multiple of 260 and 365: 18,980 days, or 52 years.

The Classic Maya Long Count inscriptions enumerate the cycles that have elapsed since a zero date in 3114 BC. Thus, "9.6.0.0.0," a *katun*-ending date, means that nine *baktuns* and six *katuns* have elapsed from the zero date to the day 2 Ahau 13 Tzec (May 9, AD 751). To those Initial Series were added the Supplementary Series (information about the lunar month) and the Secondary Series, a calendar-correction formula that brought the conventional date in harmony with the true position of the day in the solar year.

The Long
Count

Both Classic and recent Maya held the *tzolkin* as the most sacred means of divination, enabling the priests to detect the favourable or evil influences attached to every day according to the esoteric significance of the numbers and the day-signs. (Ja.S.)

Classic Maya religion. It has been denied that there was any such thing as a pantheon of deities in Classic times, the idea being that the worship of images was introduced by the Toltec or Itzá invaders, or both, in the Postclassic. Several gods who played significant roles in the Postclassic codices, however, can be identified on earlier Maya monuments. The most important of these is Itzamná, the supreme Maya deity, who functioned as the original creator god, as well as lord of the fire and therefore of the hearth. In his serpent form he appears on the ceremonial bar held in the arms of Maya rulers on Classic stelae. Another ophidian deity recognizable in Classic reliefs is the Feathered Serpent, known to the Maya as Kukulcán (and to the Toltecs and Aztecs as Quetzalcóatl). Probably the most ubiquitous of all is the being known as Bolon Tzacab (first called God K by archaeologists), a deity with a baroque branching nose who is thought to have functioned as a god of royal descent; he is often held as a kind of sceptre in rulers' hands.

The Classic Maya lavished great attention on their royal dead, who almost surely were thought of as descended from the gods and partaking of their divine essence. Many reliefs and all of the pictorial pottery found in tombs deal with the underworld and the dangerous voyage of the soul through that land. Classic Maya funerary ceramics show that this dark land was ruled by a number of gods, including several sinister old men often embellished with jaguar emblems, the jaguar being associated with the night and the nether regions.

Human
sacrifice

The Classic, as well as the Postclassic, Maya practiced human sacrifice, although not on the scale of the Aztecs. The victims were probably captives, including defeated rulers and nobles. Self-sacrifice or self-mutilation was also common; blood drawn by jabbing spines through the ear or penis, or by drawing a thorn-studded cord through the tongue, was spattered on paper or otherwise collected as an offering to the gods. (M.D.C./G.R.W.)

The four main categories of documents that provide knowledge of the Maya civilization and its religion are: archaeological remains; native books in hieroglyphic writing; books in native languages written in Latin script by learned Indians; and early accounts written in Spanish by conquerors or priests.

From surviving temples, tombs, sculpture, wall paintings, pottery, and carved jades, shells, and bone, a significant amount of valuable information can be gained; e.g., representations of godheads and ritual scenes. Perhaps the most important archaeological source, however, is the hieroglyphic texts carved on stone monuments or stone or bone artifacts and painted on pottery. These, insofar as they can be translated, provide descriptions of ceremonies and beliefs.

Three native hieroglyphic books of pre-Columbian date survived the Spanish conquest: the Dresden, Madrid, and Paris codices, named for the cities in which they are now housed. Written on bark paper, they deal with astronomical calculations, divination, and ritual. They appear to be Postclassic copies of earlier Classic originals.

After the Spanish conquest, books were written by learned Indians who transcribed or summarized hieroglyphic records. Such is the case of the *Books of Chilam Balam*, in Yucatec Maya, and of the *Popol Vuh*, in Quiché, a highland Maya language. The former consist of historical chronicles mixed with myth, divination, and prophecy, and the latter (which shows definite central Mexican influences) embodies the mythology and cosmology of the Postclassic Guatemalan Maya. The *Ritual of the Bacabs* covers religious symbolism, medical incantations, and similar matters.

The most important of the early accounts written by the Spanish themselves is Diego de Landa's *Relación de las cosas de Yucatán* ("On the Things of Yucatán"), which dates to about 1566. It describes Postclassic rather than Classic religion, but given the deeply conservative nature of Maya religion, it is highly probable that much of this description is pertinent for the earlier period. Landa's account is also an excellent description of other aspects of Maya life in 16th-century Yucatán.

To these archaeological, ethnohistorical, and historical sources may be added the observations of modern ethnologists about the present-day Maya. Thus, in the Guatemalan highlands, the 260-day calendar still survives, as do ancient prayers to and information about Maya gods.

It is likely that a simpler religion of nature worship prevailed in Early Formative times. This probably began to undergo modification during the Middle Formative, as astronomical knowledge became more precise. Certainly by the Late Formative (300 bc, if not earlier), with the appearance of major centres and pyramid and temple constructions, an elaborate worldview had evolved. Deified heavenly bodies and time periods were added to the earlier-conceived corn and rain gods. Concepts derived from priestly speculation were imposed upon the simpler religious beginnings. Religion became increasingly esoteric, with a complex mythology interpreted by a closely organized priesthood.

Creation. The Maya, like other Middle American Indians, believed that several worlds had been successively

created and destroyed before the present universe had come into being. The Dresden Codex holds that the end of a world will come about by deluge: although the evidence derived from Landa's *Relación* and from the Quiché *Popol Vuh* is not clear, it is likely that four worlds preceded the present one. People were made successively of earth (who, being mindless, were destroyed), then of wood (who, lacking souls and intelligence and being ungrateful to the gods, were punished by being drowned in a flood or devoured by demons), and finally of a corn gruel (the ancestors of the Maya). The Yucatec Maya worshiped a creator deity called Hunab Ku, "One-God." Itzamná ("Iguana House"), head of the Maya pantheon of the ruling class, was his son, whose wife was Ix Chebel Yax, patroness of weaving.

Four Itzamnas, one assigned to each direction of the universe, were represented by celestial monsters or two-headed, dragonlike iguanas. Four gods, the Bacabs, sustained the sky. Each world direction was associated with a Bacab, a sacred ceiba, or silk cotton tree, a bird, and a colour according to the following scheme: east-red, north-white, west-black, and south-yellow. Green was the colour of the centre.

The main act of creation, as stated in the *Popol Vuh*, was the dawn: the world and humanity were in darkness, but the gods created the Sun and the Moon. According to other traditions, the Sun (male) was the patron of hunting and music, and the Moon (female) was the goddess of weaving and childbirth. Both the Sun and the Moon inhabited the earth originally, but they were translated to the heaven as a result of the Moon's sexual license. Lunar light is less bright than that of the Sun because, it was said, one of her eyes was pulled out by the Sun in punishment for her infidelity.

Because the Maya priests had reached advanced knowledge of astronomical phenomena and a sophisticated concept of time, it appears that their esoteric doctrines differed widely from the popular myths.

Cosmology. The Maya believed that 13 heavens were arranged in layers above the earth, which itself rested on the back of a huge crocodile or reptilian monster floating on the ocean. Under the earth were nine underworlds, also arranged in layers. Thirteen gods, the Oxlahuntiku, presided over the heavens; nine gods, the Bolontiku, ruled the subterranean worlds. These concepts are closely akin to those of the Postclassic Aztec, but archaeological evidence, such as the nine deities sculptured on the walls of a 7th-century crypt at Palenque, shows that they were part of the Classic Maya cosmology.

Time was an all-important element of Maya cosmology. The priest-astronomers viewed time as a majestic succession of cycles without beginning or end. All the time periods were considered as gods; time itself was believed to be divine.

The gods. Among the several deities represented by statues and sculptured panels of the Classic period are such gods as the young corn god, whose gracious statue is to be seen at Copán, the sun god shown at Palenque under the form of the solar disk engraved with anthropomorphic features, the nine gods of darkness (also at Palenque), and a snake god especially prominent at Yaxchilán. Another symbol of the corn god is a foliated cross or life tree represented in two Palenque sanctuaries. The rain god (Chac) has a mask with characteristic protruding fangs, large round eyes, and a proboscis-like nose. Such masks are a common element in Puuc architecture.

The three hieroglyphic manuscripts, especially the Dresden Codex, depict a number of deities whose names are known only through Postclassic documents. Itzamná, lord of the heavens, who ruled over the pantheon, was closely associated with Kinich Ahau, the sun god, and with the moon goddess Ix Chel. Though Itzamná was considered an entirely benevolent god, Ix Chel, often depicted as an evil old woman, had definitely unfavourable aspects.

The Chacs, the rain gods of the peasants, were believed to pour rain by emptying their gourds and to hurl stone axes upon the earth (the lightning). Their companions were frogs (*uo*), whose croakings announced the rains. Earth gods were worshiped in the highlands, and wind gods were of minor importance in Maya territory.

The corn god, a youthful deity with an ear of corn in his headdress, also ruled over vegetation in general. His name is Ah Mun, and he is sometimes shown in combat with the death god, Ah Puch, a skeleton-like being, patron of the sixth day-sign Cimi ("Death") and lord of the ninth hell. Several other deities were associated with death; e.g., Ek Chuah, a war god and god of merchants and cacao growers, and Ixtab, patron goddess of the suicides.

In Postclassic times, central Mexican influences were introduced; e.g., the Toltec Feathered Serpent (Quetzalcóatl), called Kukulcán in Yucatán and Gucumatz in the Guatemalan highlands.

The ancient Maya's attitude toward the gods was one of humble supplication, since the gods could bestow health, good crops, and plentiful game or send illness and hunger. Prayers and offerings of food, drink, and incense (*pom*) were used to placate the gods. A strong sense of sin and a belief in predestination pervaded the Maya consciousness. Man had to submit to the forces of the universe. The priests, because of their astronomical and divinatory knowledge, determined favourable days for such undertakings as building houses and hunting.

Death. As was noted above, the Classic Maya buried the dead under the floors of their houses. High priests or powerful lords were laid to rest in elaborate underground vaults. The dead were believed to descend to the nine underworlds, called Mitnal in Yucatán and Xibalba by the Quiché. There is no evidence of a belief among the Maya in a heavenly paradise, such as that which prevailed in central Mexico. The modern Lacandón, however, believe that the dead live forever without work or worry in a land of plenty located somewhere above the earth.

Eschatology. The present world, the Maya believed, is doomed to end in cataclysms as the other worlds have done previously. According to the priestly concept of time, cycles repeat themselves. Therefore, prediction was made possible by probing first into the past and then into the future: hence the calculations, bearing on many millennia, carved on temples and stelae. Evil influences were held to mark most of the *katun* endings. The *Chilam Balam* books are full of predictions of a markedly direful character. The priests probably believed that the present world would come to a sudden end, but that a new world would be created so that the eternal succession of cycles should remain unbroken.

Sacrifice. Sacrifices made in return for divine favour were numerous: animals, birds, insects, fish, agricultural products, flowers, rubber, jade, and blood drawn from the tongue, ears, arms, legs, and genitals. Evidence of human sacrifice in Classic times includes two Piedras Negras stelae, an incised drawing at Tikal, the murals at Bonampak,

various painted ceramic vessels, and some scenes in native manuscripts. Only in the Postclassic era did this practice become as frequent as in central Mexico. Toltec-Maya art shows many instances of human sacrifice: removal of the heart, arrow shooting, or beheading. At Chichén Itzá, in order to obtain rain, victims were hurled into a deep natural well (cenote) together with copper, gold, and jade offerings. Prayers for material benefits (which were usually recited in a squatting or standing position), fasting and continence (often for 260 days), and the drawing of blood from one's body often preceded important ceremonies and sacrifices.

These practices had become so deeply rooted that, even after the Spanish conquest, Christian-pagan ceremonies occasionally took place in which humans were sacrificed by heart removal or crucifixion. The last recorded case occurred in 1868 among the Chamula of Chiapas.

The priesthood. Bejeweled, feather-adorned priests are often represented in Classic sculpture. The high priests of each province taught in priestly schools such subjects as history, divination, and glyph writing. The priesthood, as described by Landa, was hereditary. *Ahkin*, "he of the sun," was the priests' general title. Specialized functions were performed by the *nacoms*, who split open the victims' breasts, the *chacs* who held their arms and legs, the *chilans* who interpreted the sacred books and predicted the future. Some priests used hallucinatory drugs in their roles as prophets and diviners.

Rites. Ritual activities, held on selected favourable days, were complex and intense. Performers submitted to preliminary fasting and sexual abstinence. Features common to most rites were: offerings of incense (*pom*), of balche (an intoxicating drink brewed from honey and a tree bark), bloodletting from ears and tongues, sacrifices of animals (human sacrifices in later times), and dances. Special ceremonies took place on New Year's Day, 0 Pop, in honour of the "Year-Bearer"; i.e., the *tzolkin* sign of that day. Pottery, clothes, and other belongings were renewed. The second month, Uo, was devoted to Itzamná, Tzec (fifth month) to the Bacabs, Xul (sixth) to Kukulcán, Yax (10th) to the planet Venus, Mac (13th) to the rain gods, and Muan (15th) to the cocoa-tree god. New idols were made during the eighth and ninth months, Mol and Ch'en, respectively.

Both the Classic and Postclassic Maya practiced a typically Middle American ritual ball game, as evidenced by numerous grandiose ball courts at Tikal, Copán, and Chichén Itzá. No court, however, has been found at Mayapán, and Landa does not mention that game. It appears, therefore, that the Yucatec had ceased to play it, while it remained of the utmost importance in central Mexico.

Archaeological remains at Uxmal and Chichén Itzá point to phallic rites, doubtless imported into the Yucatán from the Gulf coast. The *Chilam Balam* books strongly condemn the Mexican immigrants' sexual practices, which were quite alien to Maya tradition.

Sorcery. *Ahmen*, "he who knows," was the name given to sorcerers and medicine men, who were both prophets and inflictors or healers of disease. They made use of a mixture of magic formulas, chants, and prayers and of traditional healing methods, such as administering medicinal herbs or bleeding. Belief in witchcraft is widespread among present-day Maya Indians, as it most probably was in pre-Columbian times.

The evolution of Maya religion parallels that of Mexican religions from the Classic to the Postclassic era, with the sun worship and human sacrifice complex gaining importance as it did in Mexico proper.

The profoundly original feature of Maya religious thought, in comparison with that of other pre-Columbian civilizations, is the extraordinary refinement of mathematical and astronomical knowledge, inextricably mixed with mythological concepts. Even the most learned Aztec priests never reached the intellectual level of their Maya counterparts of the 1st millennium, nor did they conceive of the eternity of time and of its "bearers," the divinized time periods. The ancient Maya may be said to have been among the very few people in history (along with the Zurvanites of Iran) who worshiped time.

The ritual ball game

The end of the world

Forms of sacrifice

The simple, naturalistic religion of the corn-growing peasants, however, subsisted apart from the priesthood's abstract speculations and has partly survived to this day among the Christianized Maya Indians or the unevangelized Lacandón. (Ja.S./G.R.W.)

Society and political life. There is a vast gap between the lavishly stocked tombs of the Maya elite who ran the ceremonial centres and the simple graves of the peasantry. Careful measurements of the skeletons found in tombs and graves have also revealed that persons of the Maya ruling class were much taller than the tillers of the soil who provided them tribute. It is likely that this gulf was unspannable, for throughout Meso-America the rulers and nobility were believed to have been created separately from commoners.

The most revealing testimony to this royal cult is the temple pyramid itself, for almost every one explored has a great tomb hidden in its base. On death, each ruler might have been the object of ancestor worship by members of his lineage, the departed leader having become one with the god from whom he claimed descent. Ancestor worship, in fact, seems to be at the heart of ancient and modern society and religion among the Maya.

The ordinary folk may have participated in the ceremonies of even the greatest Maya centres. The modern highland Maya have a complex ceremonial life in which a man advances through a series of *cargos*, or "burdens," each one of which brings him greater prestige, costs him a great deal of money, and requires that he reside in the otherwise nearly empty centre for a year at a time carrying out his religious duties. The same may have prevailed in Classic times, though all activities were then under the direction of a hereditary and divine elite class, long since destroyed by the Spaniards.

Warfare

Warfare apparently was a continuing preoccupation of the Maya lords. Translations of hieroglyphic inscriptions show that in some cases such warfare led to territorial aggrandizement and the domination of one centre or polity by another; however, the principal purpose of war appears to have been to gain captives for slavery and sacrifice.

It has often been said that the Maya realm was a theocracy, with all power in the hands of the priests. That this is a misconception is apparent from the monuments themselves, which show kings, queens, heirs, and war prisoners, but no figures surely identifiable as priests. In 16th-century Yucatán, the priesthood was hereditary, and it is reported that younger sons of lords often took on that vocation. Quite probably such a class was also to be found among the Late Classic Maya, but neither for the Maya nor for any other Classic civilization of Meso-America can the term theocracy be justified.

The collapse of Classic Maya civilization. In the last century of the Classic period, Maya civilization went into a decline from which it never recovered. Beginning about 790 in the western edge of the Central Subregion, such ceremonial activity as the erection of stelae virtually came to a standstill. During the next 40 years this cultural paralysis spread gradually eastward, by which time the great Classic civilization of the Maya had all but atrophied. A date in the Maya calendar corresponding to 889 is inscribed on the last dated monuments in the Central Subregion; soon after the close of the 9th century it is clear that almost all of this region was abandoned.

For this event, which must have been one of the greatest human tragedies of all time, there are few convincing explanations. It now seems that the Classic Maya civilization in the region of its greatest development went out "not with a bang but a whimper." Massive foreign invasions can be discounted as a factor, but non-Maya elements did appear in the west at the same time as ceremonial activity terminated. These became the inheritors of whatever was left of the old civilization of the Central Subregion after AD 900, having established trading colonies and even a few minor ceremonial centres on its peripheries.

Whatever incursions did take place from the west were piecemeal and probably the result of the general decline, rather than its cause. Similarly, there is little reason to believe that there were peasant revolts on a general scale. The only real fact is that most of the inhabitants of the

Central Subregion went elsewhere. Probably some were absorbed by such still flourishing ceremonial centres of the Northern Subregion as Uxmal and Kabah, while others might have migrated up into the congenial highlands of Chiapas and Guatemala. Although a population explosion and severe ecological abuse of the land must have played their role in the tragedy, the full story of the decline and fall of this brilliant aboriginal civilization remains to be told. (M.D.C./G.R.W.)

Postclassic Period (900–1519)

DEFINITION OF THE POSTCLASSIC

The final period of pre-Columbian Meso-American history is referred to as the Postclassic. Its beginning is usually placed at 900, and it terminates with the arrival of the Spanish conquistador Hernán Cortés in 1519 or with his conquest of the Aztec in 1521. The 900 date is based on two considerations: first, the 10th century was the period of the catastrophic collapse of the lowland Maya civilization and the cessation of the custom of erecting monuments dated by the Long Count; second, 900 was also the approximate date of the founding of the city of Tula in central Mexico and the rise of a people called the Toltec, who, according to the historical annals, built the first great empire in Meso-America. At one time it was thought that the date marked the collapse of all of the regional Classic civilizations of the area as the result of massive population dislocation. But it now appears that some Classic civilizations declined as early as 750, whereas others persisted until as late as 1200. The period is usually divided into two phases: Early Postclassic (900–1200) and Late Postclassic (1200–1519), the former equivalent with the period of the Toltec, the latter with that of the Aztec. The Postclassic civilizations of Meso-America came to an abrupt end with the coming of the Spanish in the early 16th century. For an account of the Spanish conquest, see the article LATIN AMERICA, THE HISTORY OF.

The two
Postclassic
phases

The Postclassic Period as a whole has also been distinguished from the Classic on the basis of assumed major changes in Meso-American political, economic, and social institutions. It has been asserted, for example, that the Classic period was one of relatively peaceful contact between polities, of the absence of large imperialistic states and empires (and of the militaristic élan and organization that accompanies such states). The Classic has been further characterized by the absence of true cities, by theocratic rather than secular government, and by an overall superiority of arts and crafts, with the exception of metallurgy, which appears for the first time in the Postclassic Period. In contrast, the Postclassic was characterized as a period of intense warfare and highly organized military organization, of empires and cities, of secular government, and of overall artistic decline.

Subsequent research, however, has cast considerable doubt on these conclusions. Many of the contrasts were drawn from events in the lowland Maya area and applied to the entire culture area; others were concluded essentially by a comparison of the Classic Maya of the lowland tropical forest of northern Guatemala and the Yucatán Peninsula with the Postclassic Aztec living in central Mexico in a dry mountain basin 7,000 feet above sea level. The differences, in part, are the product of separate culture evolution, conditioned by ecological factors. Cities and large states comparable to those built by the Toltec and Aztec were present in Early Classic times at Teotihuacán in central Mexico and probably at Monte Albán in Oaxaca. Militarism was at least significant enough to be a major artistic theme throughout the Classic period, even among the lowland Maya. One could also question the criterion of artistic decline, since a number of Postclassic crafts were highly developed, such as Aztec sculpture, Mixtec ceramics and metallurgy, and Zapotec architecture.

The separation between Postclassic and Classic is therefore little more than a convenient way of splitting up the long chronicle of Meso-American cultural development into manageable units for discussion and analysis. The Postclassic is a period also in which historical traditions combine with archaeological data, whereas the Classic

either lacks a written history or, in the case of the lowland Maya, provides little more than cryptic biographies of kings. Perhaps this is the best rationale for definition of the period.

At the time of the Spanish conquest, Meso-America was occupied by a number of peoples speaking languages as distinct from each other as English is from Chinese. On the central Gulf coast and adjacent escarpment were the Totonac; in Oaxaca and adjacent portions of Puebla and Guerrero two major ethnic groups, the Mixtec and the Zapotec, shared the western and eastern portions of the area, respectively; and in Michoacán lived the Tarascan. Various peoples of the Maya linguistic family occupied most of Guatemala, the Yucatán Peninsula, eastern Tabasco, and highland Chiapas; a detached group, the Huastec (Huastec), occupied the north Gulf coast. An equally widespread family, the Nahua (to which the Aztec belonged) occupied most of the Central Plateau, a huge area in the northwest frontier, portions of Guerrero, the Pacific coast of Chiapas and Guatemala (where they were known as the Pipil), and the Gulf coast. Some detached groups had spread beyond the frontier of Meso-America into Nicaragua and Panama. The linguistic family to which the Nahua belong (the Uto-Aztecan) is the only Meso-American family with affinities to languages north of the Rio Grande, including those of such western U.S. Indians as the Hopi, Paiute, and Shoshoni.

One of the Nahua-speaking nations, the Mexica, or Tenochca (or the Aztec, as they are commonly called), were the dominant people in Meso-America in 1519, having created by conquest an empire estimated as covering some 80,000 square miles (207,000 square kilometres) and having a population of 5,000,000 to 6,000,000 people.

All of these diverse ethnic groups shared a common cultural tradition, but separate historical origins and environmental factors had also produced a substantial degree of regional differentiation. Most of the cultural characteristics of the area go back at least to the beginning of the Postclassic, and many appeared in Classic times. The various regional cultures and languages have great time depths and undoubtedly were present during the Classic period. Common institutional characteristics included organization into centralized polities, including populations minimally in the tens of thousands, with a formal government, supported by a highly organized taxation system; stratification into social classes (including slave and serf classes); occupational specialization—in some areas full time with a guildlike organization; highly organized local and inter-regional trade involving professional merchants and regularly meeting markets; and a professional priesthood.

The technological base of this elaborate institutional structure seems weak by western European standards, since the primary technology (*i.e.*, the tools used to manufacture other technology) was based on chipped and ground stone, metal being reserved primarily for ornaments. Since draft animals were absent, all power was based on human energy. The economic base of the civilization was a highly productive agriculture, but the basic tools were primitive—stone axes for clearing vegetation and a number of wooden digging tools for working the soil. The crop complex was rich, with corn (maize) serving as the staple food and beans an important source of protein. But the list of secondary crops was large: chili peppers, tomatoes, squashes, sweet potatoes, cassava (manioc), cotton, tobacco, cacao, pineapples, papayas, maguey, nopals (prickly pears), sapotes (zapotes), peanuts (groundnuts), avocados, amates (paper figs), and many others.

Many crops were limited to particular environmental zones, thus acting as a major stimulus to trade. In many areas, particularly the tropical lowlands, the slash-and-burn, or swidden, system of farming was employed: forests were cleared, planted for up to three years, and rested for longer periods to restore fertility and eliminate the more difficult weeds. This regular rotation of fields resulted in high production per capita but had low demographic potential because in any given year most of the land lay fallow. In some lowland areas permanent grain and orchard cropping were practiced. In the drier highlands a number of specialized techniques were used, and agricul-

ture generally was more intensive. Particularly important were terracing, irrigation, and swamp reclamation. The per capita productivity of highland agriculture was probably less (because of the higher labour input), but the demographic capacity was considerably greater than that in the lowlands. As a result of these highly effective approaches to farming, the population was dense when compared to western Europe in the 16th century. Population estimates for the conquest period have varied from 3,000,000 to 30,000,000; a reasonable estimate is between 12,000,000 and 15,000,000.

The diet of the average Meso-American was relatively uniform throughout the area. Dried corn was boiled in lime-impregnated water to soften the hull, ground into a dough on milling stones (*manos* and *metates*), and then either made into tortillas or mixed with water and drunk as a gruel called *posol*. The tortillas were eaten with sauces prepared from chili peppers and tomatoes, along with boiled beans. This was essentially the diet of the peasant, with the addition of pulque, the fermented sap of the maguey, at higher altitudes. To this were added the other crops in minor quantities and combinations depending on the specific local environment. Luxury foods included cocoa drinks, meats (from game or from the only two domestic animals of significance, the hairless dog and the turkey), and fish. The diet of the peasant, as is the case even today, was low in animal protein; but apparently the quantity of vegetable protein ingested made up for this deficiency.

Major Postclassic Meso-American crafts were weaving of cotton and maguey fibre; ceramics for pottery vessels, figurines, and musical instruments; stone sculpture; featherwork used for personal and architectural ornament; lapidary work (jadeite, jade, serpentine, and turquoise); metalwork (using gold, copper, and, more rarely, silver) for ornaments and a few tools; woodworking, the products including large dugout canoes, sculpture, magnificently made drums, stools, and a great variety of household items; baskets for containers and mats; painting; and, most particularly, stone and lime concrete masonry architecture.

On the intellectual, ideological, and religious levels, although some diversity and certain elaborations occurred in some regions, there was a fundamental unity to the Meso-American area, the product of centuries of political and economic ties. The religion was polytheistic, with numerous gods specialized along the lines of human activities. There were gods for basic activities such as war, reproduction, and agriculture; cosmogenic gods who created the universe and invented human culture; and gods of craft groups, social classes, political systems, and their subdivisions. Gods were all-powerful and had to be constantly propitiated with offerings and sacrifices, a concept reaching its peak in personal bloodletting and human sacrifice. Certain gods, such as the god of rain (called Tlaloc in central Mexico), were found throughout the area. A fundamental concept was that of a quadripartite multilevel universe that, by 1519, had gone through five creations and four destructions. Meso-American religion heavily emphasized the astral bodies, particularly the Sun, the Moon, and Venus, and the observations of the movement of these bodies by the astronomer-priests were extraordinarily detailed and accurate. The major purpose of these observations was astrological, and the Meso-American priests had developed a number of time counts, or calendrical rounds, based in part on these observations. Two basic calendars, a 260-day divinatory calendar and one based on the solar year of 365 days, were found throughout the area.

One of the great intellectual achievements of Meso-American civilization was writing; in Postclassic times books were made from the inner bark of the paper-fig tree and used to record calendars, astronomical tables, dynastic history, taxes, and court records.

Religion was a pervasive force in Meso-American life, as the art demonstrates; and considerable surplus energy was devoted to it (*e.g.*, temple construction, support of a numerous professional priesthood). Many writers have stated that the major focus of Meso-American culture was in this sphere. In fact, the contrast between Postclassic and

The Nahua peoples

Post-classic technology

Post-classic arts and crafts

Classic was in part based on the presumed even greater emphasis on religion in the art and architecture of the latter period.

THE HISTORICAL ANNALS

The rise of the Aztec. A major characteristic of the Postclassic, in contrast to the Classic, is the abundant historical documentation. The Aztec record is particularly rich, and much of it is undoubtedly genuine, although there is always the possibility that records were rewritten or tampered with for political reasons. One of the functions of Meso-American writing was to record the succession and achievements of dynastic lines, and consequently it served as a validation of power. Virtually all of the dynasties of the local states recorded their history. A problem in the utilization of these documents, other than the low number of survivals, is the fact that many of them have strong mythological overtones. The Aztec themselves, for example, as creators of a great empire, explained their rise in part to the fact that they were the chosen people of the sun god Huitzilopochtli and were the sustainers of the sun god Tonatiuh. They started their history as a poor, nomadic tribe from the north, who entered the Basin of Mexico, led by a magician-priest, and ultimately settled on the lake islands because of a series of astrological predictions and signs. They lived for a while as a subject people and then embarked on their destined role as conquerors and priests of the sun god. Virtually all historical traditions of local groups begin with a migration, a period of trials, and ultimate success—and some records even claim that the people were hunters and gatherers during the early part of their history.

On the northern frontier of Meso-America, in the arid Mexican Plateau, true hunters and gatherers, referred to as the "Chichimeca" by the civilized peoples, did actually reside in 1519. The name Chichimeca was frequently applied to the migrant groups. It is difficult to see how hunting and gathering bands could successfully invade areas of dense civilized populations; but agricultural groups, during periods of dynastic weakness, undoubtedly could. In fact, the term Chichimeca was also applied to agricultural but less civilized peoples (such as the Otomí in central Mexico) and thus connoted a lack of polish or a rustic life-style. Since the northwestern portion of Meso-America was occupied by such people and since they were Nahuatl in speech, the legends of periodic north-south migrations of invaders, though they may have a factual basis, probably refer to movements of agricultural rather than hunting and gathering peoples.

The histories of these invading groups take on a more convincing historical character after the legends of migration. In the Aztec case they record the founding of Tenochtitlán in 1325. By 1376 the Aztec had increased in numbers and prestige sufficiently to obtain a member of the ruling family of Culhuacan, a neighbouring state, to rule as their *tlatoani*, or king. His name was Acamapichtli. The Aztec at this time were paying tribute to another state, Azcapotzalco, on the lake shore; and they remained under this obligation through the reigns of his two successors, Huitzilhuilitl (c. 1390–1415) and Chimalpopoca (1415–26). During the reign of Chimalpopoca, Maxtla, the ruler of Azcapotzalco, attempted to secure tighter control over subject states by replacing their *tlatoanis* with his own men. He succeeded in arranging the assassination of Chimalpopoca and the exile of Nezahualcōyotl, ruler of Texcoco, a state on the east shore of Lake Texcoco. In response to these acts, a coalition was formed between Nezahualcōyotl, Itzcōatl (Chimalpopoca's successor), and another small state (Tlacopan), and the power of Azcapotzalco was broken.

A triple alliance was then formed between Tenochtitlán, Texcoco, and Tlacopan, which by 1519 resulted in the dominance of Aztec Tenochtitlán. Under the Aztec rulers Itzcōatl (1428–40), Montezuma I (1440–69), Axayacatl (1469–81), Tizoc (1481–86), Ahuitzotl (1486–1502), and Montezuma II (1502–20), and the two Texcocan rulers—Nezahualcōyotl (1431–72) and Nezahualpilli (1472–1516)—the triple alliance succeeded in conquering the vast domain described above. Tlacopan seems to have

been relegated to an inferior political role early in the history. The records of the Aztec and neighbouring states in the Basin of Mexico between 1300 and 1519 are relatively free from mythological tales and have sufficient cross-referencing to present a reasonably clear picture of military events, dynastic succession, institutional changes, and economic development. The period from 1200 to 1300 is essentially one of migration legends of the dynasties of the various states, the historical traditions of which are discussed below.

The question of the Toltec. The historical traditions also state that these migrations were responsible, along with a series of natural disasters, for the collapse of a great empire ruled by a people called the Toltec from their capital of Tollan, or Tula. Many dynasties of the conquest period, not only in central Mexico but even as far afield as highland Guatemala and the Yucatán Peninsula, claimed descent from the Toltec, apparently as a result of their dispersion after the fall of Tula.

The traditions describe the Toltec as the first civilizers, the first city builders, and the originators of craft skills and astrological knowledge. The major questions are: Did the Toltec really exist as a people? Where was Tula? Did these people actually play the extraordinary political and cultural role ascribed to them? To begin with, the annals themselves are in fundamental disagreement with respect to dates and the lists of Toltec kings. There are at least three major chronologies of the Toltec Empire (see Table 1). The dates by Ixtlilxōchitl, a learned mestizo of the post-conquest period, place the Toltec well within the Classic period of Meso-American archaeology, but the others correlate them with the early portion of the Postclassic. Most writers favour the later dates, but this would mean that the Toltec were not the first civilized peoples in central Mexico, as they claim.

Table 1: Chronologies of the Toltec Empire

Ixtlilxōchitl		<i>Anales de Cuauhtitlán</i>		Codex Ramírez
Chalchiuhtlanetzin	510–562	Huetzin	896–?	
Ixtlilcuechahuac	562–614	Totepeuh	?–887	Mixcoatl 900–947
Huetzin	614–666	Ihuital	887–923	
Totepeuh	666–718	Topiltzin	923–947	980–999
Nacoxoc	718–770	Matlaxochitl	947–983	1000–34
Mitl-tlacomihua	770–829	Nauhyotzin	983–997	1034–49
Xihuiqueitzan	829–833	Matlaccoatzin	997–1025	1049–77
Iztaccaltzin	833–885	Tilcoatzin	1025–46	1077–98
Topiltzin	885–959	Huemac	1047–1122	1098–1168

Adding further doubt to the veracity of the Toltec history is the admixture of myth and magic in the annals, not only at the beginning (which, like the histories of later dynasties, begins with a migration under a magician priest) but throughout the narrative. The ruler Topiltzin, for example, is also called Quetzalcōatl (the Nahuatl name for the Feathered Serpent god); he is opposed by Tezcatlipoca (also an Aztec god) and is driven out of Tula. He flees with his followers to the Gulf of Mexico and embarks on a raft of serpents. The story sounds like a duplicate of the cosmic myth or conflict between the two gods (see below *Cosmogony and eschatology*). Notably, the Maya in Yucatán had a tradition of a landing on the west coast made by foreigners, under a leader named Kukulcán (which is the Maya word for Feathered Serpent), who founded a city at Chichén Itzá and ruled over the Maya.

In spite of all the objections, the traditions of a great empire and of the city of Tula are so persistent that they must refer to some historical event and, indeed, have some archaeological support.

ARCHAEOLOGICAL REMAINS OF POSTCLASSIC CIVILIZATION

The early Postclassic period (900–1200) in central Mexico is associated with three major sites, all of which began in Classic times: Cholula in Puebla, Xochicalco in Morelos, and Tula in Hidalgo. Cholula was a major centre as far back as Early Classic times, probably as a political dependency of Teotihuacán. It reached its maximum growth in Late Classic times, following the collapse of Teotihuacán, when the largest structure ever built by Meso-Americans was erected (see above *Cholula*).

In Postclassic times Cholula continued as a major religious and cultural centre. Xochicalco probably was of minor significance in Early Classic times; but it went through a phase of explosive growth in the Late Classic and was probably abandoned by 1200, possibly earlier. Tula, on the other hand, a small centre in the Late Classic, went through a rapid growth during the period 900–1200 and then declined to a provincial centre in the Late Postclassic. There is a strong suggestion that the demise of Classic Teotihuacán was in part related to the emergence of one or all of these major centres.

Tula. The location of the Toltec capital of Tollan, or Tula, is not certain. The archaeological site located on a low ridge near the modern town of Tula has been the persistent choice of all historians since the conquest, in part because of the coincidence of place-names. There is further support for this identification in that the annals provide a great number of place-names near the modern Tula that have persisted since the conquest. There is also support for the identification in that the glyph Ce Acatl, the birthday and birth name of the great Toltec leader Topiltzin, has been found carved on a hill near Tula. Moreover, the sculpture from the site is heavily loaded with symbolism that relates to the Quetzalcóatl cosmology and cosmogony. It clearly was the city of the god Quetzalcóatl. The confusion between the god and the ruler can be ascribed to the fact that the name Quetzalcóatl may have served as a title of office carried by all Toltec rulers. The archaeological dates are in agreement with the *Anales de Cuauhtitlán* and the Codex Ramírez (see below *The nature of the sources*).

The major factors that have made some researchers reluctant to accept this identification lie in the claim that Tula was the capital of a great pan-Meso-American empire and that the Toltec were the first civilizers in central Mexico. Archaeologically, it is quite clear that Tula was preceded by the great Classic centre of Teotihuacán. Tula as a site does not really approach the earlier Teotihuacán or the later Tenochtitlán in size, in the number of public buildings, or in estimated population, although studies indicate that Tula had a population of between 30,000 and 60,000. Furthermore, although some basic stylistic elements of the art and architecture of Tula are widespread, the style, in an integrated specific sense, is limited (with one notable exception) to a small area in central Mexico. These facts make it difficult to accept Tula as the capital of a great empire. But archaeological evidence of even the Aztec empire is skimpy. In both cases, this may mean that the expansion was a rapid, explosive one that failed to last long enough to register these effects. But at least in the case of Tenochtitlán it did result in the rapid growth of a truly gigantic urban centre.

Because of these objections and because Teotihuacán fits better the description of the Toltec as the builders of the first truly civilized society in central Mexico, that site must still be considered a possible candidate.

The art and architecture of Tula shows a striking similarity to the later art and architecture of Tenochtitlán, and the themes represented in the art indicate a close approximation in religious ideology and behaviour. The symbols

of sun sacrifice and the marching predators represented in sculpture both suggest that the concept that the Aztec had of themselves as the warrior-priests of the sun god was directly borrowed from the people of Tula.

On the basis of the symbolism represented in the carvings on a temple pyramid at Tula called Structure B, it has been concluded that the pyramid was dedicated to the god Quetzalcóatl, lending further support to the identification of the site as the Toltec capital.

Chichén Itzá. Also in support of the identification of Tula as the Toltec capital are the architectural characteristics and stylistic features of the sculpture of a large site in northern Yucatán called Chichén Itzá. The resemblance between the two sites is extraordinarily close. At Chichén are found flat beam and masonry roofs (contrasting sharply with the typical Maya corbeled vault), serpent columns, colonnaded halls attached to the bases of temples, altars with Atlantean figures, sculptured representations of skulls and crossbones, marching felines, canines and raptorial birds devouring human hearts, and depictions of warriors with typical Toltec accoutrements. Furthermore, there are even scenes showing Toltec and Maya warriors in combat. The Temple of the Warriors at Chichén Itzá looks like an attempt to duplicate Structure B at Tula.

One of the puzzling aspects of the relationship between the two sites is that the public architecture of Chichén Itzá is actually more monumental than that at Tula, leading at least one Meso-American specialist to believe that Tula's style was derived from Chichén. Many of the stylistic features themselves, however, have prototypes in Classic Teotihuacán, whereas there is little in Classic Maya culture that could be considered as the source. What is more probable—and this agrees with the Toltec version of the relationship—is that the Toltec state in Yucatán was politically independent from Tula and was larger in area and population. The presence of rival states in central Mexico such as Xochicalco and Cholula may have kept the core of the Toltec polity relatively restricted in space. The much larger area and population controlled by the Toltec state at Chichén would explain the differences in the scale of architecture. The superior military organization and equipment of the Toltec perhaps explains their apparent success in Yucatán.

Archaeological unity of the Postclassic. The Postclassic period of Meso-American archaeology generally is a period characterized by considerable regionalism combined with a certain degree of uniformity. To a great extent, the latter was the product of the large states and extensive trade networks centred in the central plateau region. The Early Postclassic in some areas may be described as a continuation of the Late Classic; on the Gulf coast, for example, sites like El Tajín continued to be occupied, while in the Valley of Oaxaca (although Monte Albán was abandoned) the Zapotec tradition continued with the new centre at Mitla. In other areas, new styles either began or reached their climactic development, such as the Mixteca-Puebla style in painting, ceramics, and metallurgy, which evolved either in western Oaxaca or, more probably, at Cholula in Puebla. On the Guatemalan Pacific piedmont and in Tabasco, two specialized ceramic traditions (both of which

Tula and Chichén Itzá compared

Ceramic traditions

The question of Tula's existence

began in Late Classic times) evolved: (1) plumbate (so called because of its slip, which had an unusually high iron content in the natural clay that fired to a lead-colour glaze); and (2) Fine Orange (so called because of its fine-grained, temperless paste). Wares of these two styles were widely traded.

The unity of the Postclassic consisted primarily of the diffusion of religious ideology, particularly the sun god-warfare-sacrificial complex and of the related institutional development such as the military orders (the latter probably originated at Classic Teotihuacán). This ideology clearly originated in central Mexico, at either Cholula or Tula or both. The specific artistic style of representation of the themes in painting and sculpture spread as well. Along with this was diffused a specific style of representation of the social calendar and writing generally and much greater emphasis on the 52-year cycle. The specific style most probably originated at Cholula.

In the highland areas of Meso-America the Late Postclassic was a period of maximum population growth. The Early Postclassic was, however, the period of maximum expansion of sedentary peoples on the northern frontier, probably the product of minor changes in climate as a result of increased rainfall. This frontier retracted substantially in Late Postclassic times, possibly because the rainfall decreased. This was perhaps the major factor in the precipitate arrival of barbarous tribes into the plateau, as the annals state.

The Postclassic, over large areas of the lowlands, on the other hand, was strikingly different. One of the most intriguing problems of Meso-American archaeology is the peculiar sequence of events in the lowland Maya area. At the time of European contact much of the northern portion of Yucatán was well settled. A narrow band of densely settled country also extended along the east coast south to modern Belize City and along the entire length of the west coast (where it joined another area of substantial settlement in the south Gulf coast). Most of the heart of the peninsula, the department of Petén in Guatemala, and large portions of the states of Campeche and Quintana Roo in Mexico (the most densely settled portion of the Classic Maya territory) were virtually abandoned.

Reasons
for the
decline in
population

One of the major problems of Meso-American archaeology is the explanation of this massive population decline. The immediate causes are clear: it must have been the product of migrations out of the area or a set of internal factors that caused a decline in situ or both. Various hypotheses as to processes and causes have been suggested. These may be grouped in the following categories: natural disasters (earthquakes, famines, epidemics, and hurricanes have all been suggested); ecological processes (primarily the deterioration of the natural environment by overintensification of land use in response to population

pressure); and sociopolitical processes (internal warfare, invasion from outside, peasant revolts, breakdown of critical trade networks). Some of these hypotheses are clearly derivations from others or are not explanations but rather are descriptions of events that were produced by other processes. It seems certain that the causes were multiple and in some way related. Of great interest is the fact that at least one other lowland area, the Pacific Coastal Plain of Guatemala, experienced a comparable Postclassic decline. (W.T.Sa.)

AZTEC CULTURE TO THE TIME OF THE SPANISH CONQUEST

The nature of the sources. At the time of the Spanish conquest the dominant people of Meso-America were the Aztec. This description is based primarily on written documents from the 16th century but also includes some archaeological data. The literature, both published and unpublished, of the 16th century is enormous and takes in all aspects of Aztec culture. Much of it covers the period within a few decades after the conquest, and it is uncertain how much change had occurred because of the introduction of Spanish culture. Some Aztec institutions, such as the military orders, were immediately abolished by the Spaniards; and the sources, therefore, give only the barest outline of their organization. This information, however, combined with archaeological data, gives a fairly detailed picture of Aztec culture at the time of the Spanish conquest. The sources can be classified by content and purpose into five categories, each of which is described below.

Accounts written by the conquistadores. Eyewitness accounts of Aztec culture on the eve of the conquest are, of course, the most directly pertinent sources because they describe Aztec culture before it became transformed by the Spanish conquest. Important among these are the *Cartas de Relación* ("Letters of Information"), sent by Hernán Cortés to the Holy Roman emperor Charles V, and the *Historia verdadera de la conquista de la Nueva España* (1632; *The True History of the Conquest of New Spain*) by Bernal Díaz del Castillo. Religious rites and ceremonies, temples, and paraphernalia of the cults are often described in these accounts. Their value, however, is lessened by the writers' ignorance of Náhuatl (the Aztec language at the time of the conquest), their lack of understanding of the Indian way of thinking, and their deep hostility to the native religion, which they considered to be inspired by the devil. These documents, therefore, have been interpreted with utmost caution.

Roman Catholic missionaries also wrote accounts of the Aztec. Paradoxically, the priests generally showed more understanding and tolerance than did the laymen. Thanks to their training and theological knowledge, they were able to analyze the Indian mind and to gain insight into the

Aztec farmers (left) planting and (right) cultivating corn with the assistance of a wooden digging tool; illustrations from the Florentine Codex, a version, in Náhuatl, of the *Historia general de las cosas de Nueva España* by Bernardino de Sahagún, 16th century.

meaning of the myths and ritual. The missionaries, as a rule, learned the native languages, especially Náhuatl.

Postconquest histories of the Aztec written in Spanish. Within a few decades of the conquest, a series of histories had been written in the Spanish language, based in part on Aztec books and in part on information supplied by the upper class. Among the most detailed of these is the three-part *Historia de las Indias de la Nueva España e Islas de Tierra Firme* ("History of the Indies of New Spain"), written in about 1580 by the Dominican friar Diego Durán.

Postconquest ethnographic accounts written in Spanish and Náhuatl. These works are comparable in methodology and subject matter to the kinds of studies of native peoples conducted by present-day anthropologists. Probably the finest of them was written by Bernardino de Sahagún. Sahagún was a Franciscan priest who arrived in Mexico very early (1529), learned the Náhuatl tongue, and spent his life building a wonderful monument, a real encyclopaedia called the *Historia general de las cosas de Nueva España* ("General History of the Things of New Spain"). His work covers virtually all aspects of Aztec culture. It contains particularly detailed accounts of religion, ethnobotany, folk medicine, and economics, dictated to him in Náhuatl by Aztec noblemen and priests. As a source, it has the added value of being written in both Náhuatl and Spanish. One of the most complete versions of this work, written in Náhuatl, is called the Florentine Codex.

The codices. Aztec sacred books and works, which were kept in the temples, and other native books have become known in Western scholarship as codices. Sacred books were written (or rather, painted) on deerskin or agave-fibre paper by scribes (*tlacuiloanime*), who used a combination of pictography, ideograms, and phonetic symbols and dealt with the ritual calendar, divination, ceremonies, and speculations on the gods and the universe. Because of their religious content only a small fraction of these escaped destruction by the Spaniards; the few specimens that have survived—such as the Codex Borbonicus, the Codex Borgia, the Codex Fejérváry-Mayer, and the Codex Cospi—usually come accompanied by Spanish notations. These sources are limited in scope and subject matter but nevertheless are valuable documents. Their interpretation is far from easy. Only a few of them, such as the Borbonicus, are truly Aztec, while others, such as the Borgia, seem to emanate from the priestly colleges of the "Mexica-Puebla" area, between the central highlands and the Oaxaca Mountains.

Other native books, either pre-Cortesian or post-Cortesian, also afford valuable material. Examples include such manuscripts as the Codex Telleriano-Remensis, the Azcatitlan, and the Codex of 1576, which describe the history of the Aztec tribe and state and occasionally depict religious scenes and events; the Codex Badianus, an herbal with magnificent drawings of medicinal plants; and the Codex Mendoza and the *Matrícula de tributos*, both tax documents of the Aztec empire. A number of books were written in the Latin alphabet—either in Náhuatl or in Spanish—by learned Aztec chroniclers, who used ancient pictographic manuscripts as their basis. Among those that were prepared in central Mexico are the Codex Chimalpopoca (also called the *Anales de Cuauhtitlán*; "Annals of Cuauhtitlán"), in Náhuatl, and the Codex Ramírez (also called the *Historia de los mexicanos por sus pinturas*; "History of the Mexicans Through Their Paintings"), in Spanish; both are anonymous compilations.

Official ecclesiastical and government records. Much of this literature is unpublished. Its purpose was administrative rather than intellectual, but it has provided an extraordinarily rich source of information for all 16th-century ethnic groups. The documents vary from tax lists, censuses, and marriage and baptismal records to broad geographic-economic surveys. Among the most valuable of the last type are the *Relaciones geográficas* of 1579–85, a series of surveys ordered by Philip II of his overseas possessions. Formal questionnaires were drawn up that demanded information from each town in the empire on virtually all aspects of Meso-American life: questions on the natural environment and resources, crops, population

history, settlement patterns, taxes paid, markets and trade, the language, native history and customs, and progress of the missionization program. (W.T.Sa./Ja.S.)

Agriculture. The homeland of the Aztec, from which they ruled their vast domain, was a large (about 3,000 square miles), mountain-rimmed basin with a floor at approximately 7,000 feet above sea level. The surrounding ranges reached a maximum elevation of 18,000 feet in the volcano of Popocatepetl. The annual rainfall varied from 20 to 35 inches (500 to 900 millimetres) in the valley floor to a maximum of 50 inches on the southern escarpment. Approximately 80 percent of the rain fell between May 1 and October 1. Because of the high elevation, the area suffered from severe winter frosts that normally began in mid-October and lasted until the end of March. Normally, the rainfall was adequate for corn, even in the drier portions of the basin, but a major problem was the timing of the rains and the frosts. A delay of the rainfall to mid- or late June, accompanied by early autumn frosts, could produce crop disasters.

Another major problem for the pre-Hispanic cultivator was the paucity of level land. Much of the land surface is sloping, and the problem of soil erosion was acute. Furthermore, of the 1,600 square miles of relatively level land, 400 square miles were occupied by a chain of lakes; and much of the immediate lakeshore plain was waterlogged.

Because of the effect of elevation on the growing season, the areas above 8,300 feet were also unsuitable for cultivation, removing an additional 400 square miles from the agricultural resource. Even within zones of cultivation, the presence of steep slopes and thin soil further reduced the area of cultivation. It is doubtful that more than 50 percent of the basin was suitable for labour-intensive methods of cultivation. Yet in 1519 it supported a population of 1,000,000 to 1,500,000; i.e., a density of 500 people per square mile (200 per square kilometre), the densest population in Meso-American history. This was achieved by an extraordinarily intensive system of farming that involved a number of specialized techniques. Soil fertility was maintained by plant and animal fertilizers, by short-cycle fallowing, and by irrigation. In gently sloping terrain, erosion was controlled by earth and maguey terraces, in steeper areas by stone terracing. The problem of humidity was solved by canal irrigation of both the floodwater and permanent type. Much of the irrigation was done just before planting in April and May in order to give crops a head start and hence avoid the autumn frosts. Terracing functioned also as a method of conserving moisture. There is also evidence that dry-farming techniques were applied to store moisture in the soil. The most significant achievement of Aztec agriculture, however, was that of swamp reclamation, even including colonization of the lakes. This system of farming, called chinampa, was first applied to Lake Chalco. The lake covered approximately 60 square miles and apparently varied in its character from swamps to ponds of fairly deep, open water. By a process varying from digging drainage ditches to artificial construction of land from lake mud and vegetation, most of the lake was converted to highly productive agricultural land. A series of masonry causeway dikes were constructed across the lake to control flooding. By a system of dikes and sluice gates the Aztec even managed to convert a portion of saline Lake Texcoco, the largest and lowest lake in the basin, to a freshwater bay for further chinampa colonization.

The total area colonized was probably in the neighbourhood of 30,000 acres, and Tenochtitlán, the Aztec capital, depended on these lands for much of its food. By a comparable method, much of the waterlogged lakeshore plain was also converted into agricultural land. Particularly notable is the fact that all of these techniques of food production were achieved by human power and simple hand tools.

Aside from agriculture, the basin had a number of major resources, some of which were exploited not only for local consumption but also to supply other areas of Meso-America. Obsidian, natural glass of volcanic origin, was a superb material for a great variety of stone tools; and the northeastern ranges of the basin contained one of Meso-

Factors
limiting
cultivation

The work
of Sahagún

The
codices

Other
resources
of the
basin area

America's major deposits. Basalt for manos and metates (milling stones) was also abundant. Lake Texcoco was a major source of salt, and the lakes generally provided waterfowl, fish, and other aquatic foodstuffs. The great pine forests above the limits of agriculture were a major source of lumber. On the other hand, the basin, because of its high elevation, was unsuitable for a great variety of tropical products, including cotton, paper, tropical roots and fruits, tobacco, copal incense, rubber, cacao, honey, precious feathers and skins, and such prized goods as metal, jade, and turquoise. The major motivation of Aztec conquest was to obtain control of these resources.

Social and political organization. Aztec technology differed little from that of other Meso-American groups. One of its distinctive aspects was differentiation by status levels. The use of most of the extra-local resources noted above was limited to a small upper and middle class; and there were striking differences in dress, housing, and diet by social class. Commoners, for example, wore clothing woven from maguey fibre, while the upper classes wore cotton garments. The use of imported foods, at least on a regular basis, was limited to the upper and middle classes. Commoners lived in small adobe or stone and mud huts, the upper and middle class in large multiroomed palatial houses of cut stone, lime plaster, and concrete.

Aztec social and political organization can be divided into a number of levels of increasing size and complexity of organization. The nuclear family—that is, a pair of cohabiting adults and their unmarried children—formed the lowest level of organization. The nuclear family functioned in procreation, education of children, and as a unit of food preparation and consumption, with a well-defined division of labour between husband and wife. Among the Aztec, however, a number of nuclear families usually resided together in a single cooperating household, or extended family. Such a family usually consisted of a man, his married sons or brothers, and their families. The average peasant household of this type was small. Up to three nuclear families occupied a small multiroom house divided into apartments for each family. The houses were usually placed within a courtyard fenced with organ cactus or adobe walls, forming a compound. The extended family household probably functioned as a unit of land use and food production. In the towns, however, some households could be considerably larger, and the household of Montezuma II included several thousand people.

A number of households, varying from a few score to several hundred, were organized into an internally complex corporate group referred to as a *calpulli* by the Aztec and translated as *barrio* ("ward") by the Spaniards. Questions about the structure and function of this level of Aztec organization have caused a great deal of debate among Meso-American specialists. It is clear, however, that it was a physical and territorial unit as well as a socially organized one. It was a unit of land tenure. *Calpulli* lands were owned communally but were distributed among various households. The household retained the right of usufruct, but only the *calpulli* as a whole could sell or rent lands.

The *calpulli* rural communities varied considerably in physical appearance. Some were isolated, tightly nucleated physical settlements surrounded by their agricultural land, whereas in others houses were dispersed through the land holdings. In a few cases, they were physically attached as wards to one or more other *calpulli*. These differences corresponded to ecological, economic, and political factors. Rural, dispersed settlements were found on terraced hillsides in which houses were tightly integrated with the terrace; in the chinampa area, each house was placed on its chinampa holding. On the other hand, nucleated, isolated *calpulli* were found in areas of level land, and the ward type was usually found in the towns and cities. In the latter case, many lost their agricultural character and became units of craft specialization. The *calpulli* was a unit of political administration within the larger unit that will be referred to here as the state. It was ruled by a council of household heads presided over by a chief selected by the council from within a particular lineage. The *calpulli* functioned as a unit of taxation to the central government, as a unit of *corvée* labour, and as a military regiment.

The structure of the *calpulli* is open to question. Some sources call it a kin group, "a lineage" with a common ancestor; and as a result some anthropologists have referred to it as a clan, or sib. There is no evidence, however, of either exogamy or unilineal descent; in fact, marriage records from the post-conquest period show a strong tendency toward endogamy. There is some evidence of internal ranking and significant status differentiation, another non-clanlike feature. The sources also mention smaller territorial subdivisions, referred to as *barrios pequeños*, or "little wards." If these are descent lines, then the *calpulli* resembled quite closely a type of kin group called by anthropologists a *ramage*, or a conical clan. This is a group with a myth of common descent, divided into ranked senior and junior lineages based on the seniority of older versus younger brother in the group genealogy. In support of this reconstruction is the statement that the *calpulli* god was a deified ancestor.

The *calpulli* also functioned as a unit of education, for each possessed a school for young men—the *telpuchcalli*—primarily for military and moral instruction.

Above the level of the *calpulli* was the state. With the exception of those historical periods when larger polities, such as the Aztec empire, emerged, such states in Meso-America, including the Basin of Mexico, were small. Just prior to the Aztec expansion there were 50 or 60 such states in the basin, with an average size of about 50 to 60 square miles. In 1519 these once independent domains had an average population of 25,000 to 30,000 people. In less densely settled areas, the territories were larger and populations smaller. The range of size was from a few thousand up to 100,000.

The average small state included a central town with a population of several thousand, the balance of the population consisting of the rural *calpulli*. The central town was divided into wards that corresponded in size and to a certain degree in structure to the rural *calpulli* but were clearly different in function; they in turn were divided into *barrios pequeños*. At the head of the state was an official called the *tlatoani*, to whom all household heads owed allegiance, respect, and tax obligations. The *tlatoani*'s position was fixed within a particular lineage, the particular choice varying from state to state. In some areas, succession passed from father to son; in others, the succession went through a series of brothers and then passed to the eldest son of the eldest brother. In still other states, the office was elective, but the choice was limited to sons or brothers of the deceased ruler. The office was accompanied by all of the trappings and sumptuary behaviour typical of despotic states. The ruler resided in a large, multiroom masonry palace inhabited by a great number of wives, servants, and professional craftsmen. He was carried in a sedan chair in public and treated with exaggerated respect by his subordinates. The *tlatoani* held considerable power: he appointed all lesser bureaucrats, promoted men to higher military status, organized military campaigns, and was the distributor of booty and tribute; he collected taxes in labour, military service, and goods from his supporters; he owned private estates manned by serfs; he was the final court of appeal in judicial cases; and he was titular head of the religious cult and head of the town market.

Many of these functions were delegated to a large staff of professional administrators: priests, market supervisors, military leaders, judges, tax collectors, and accountants. The tax collectors, or *calpixque*, were especially important administrators because they acted as the rulers' agents in collecting goods and services from the *calpulli* chiefs.

Most of these positions were appointed and selected from two classes—the *pipiltin* (plural of *pilli*), and the professional warriors. Society was divided into three well-defined castes. At the top were the *pipiltin*, nobles by birth and members of the royal lineage. Below them was the *macehual* class, the commoners who made up the bulk of the population. At the base of the social structure were the *mayerques*, or serfs, attached to private or state-owned rural estates. Within these three castes, a number of social classes could be differentiated, according to wealth, occupation, and political office. The Aztec system made a distinction between ascribed and achieved status. By a

social
castes

system of promotions, usually as a reward for military deeds, commoners were appointed to such political offices as *calpixque* and judges. Many *pipiltin* held no political office and, unless they had inherited private estates, were forced to live off the largess of the ruler. Commoners who had captured four enemy warriors in combat were promoted to the rank of *tecuhli*, entered one of the military orders, were assigned a private estate with serfs for their maintenance, and acted as an elite professional army. The children of both *pipiltin* and *tecuhli* could enroll in the religious college, or *calmecac*, where they could be trained as priests or political administrators. The *calmecac* apparently was also open to certain other commoners, such as wealthy and influential merchants and craftsmen.

Aside from the commoner-warriors, the *macehual* class was further differentiated into class levels. Certain occupations were accorded higher prestige than others (merchants, lapidarians, goldsmiths, and featherworkers are mentioned, and the list probably included stone sculptors); and all urban occupations were assigned higher status as compared with rural farming. Since occupations were restricted to *calpulli* membership and since the *calpulli* were kin groups, it follows that crafts tended to be hereditary. In small towns the craft specializing group would have to be the *barrio pequeño*. In the cities it was definitely the larger unit, but in either case crafts would be found within hereditary corporate groups.

The system of social stratification emphasized ascribed status but also permitted considerable vertical mobility. The land-tenure system was an important aspect in maintaining both processes, as could be expected in a basically agrarian society. Although most of the land was held in common by the *calpulli*, private estates with serfs helped to maintain the prestige of the *pilli* class and similar estates assigned to political office; and the *tecuhli* positions freed able commoners from the necessity of subsistence procurement.

The taxation system also helped to maintain the social system. All heads of households owed military service to the *tlatoani*. For the *pipiltin* and *tecuhli*, this was the only tribute demanded. Urban craftsmen also paid tribute in their craft products but were exempt from *corvée* labour. That obligation, plus taxes in agricultural products, were the burdens of the rural peasants, and the *mayeques* owed their labour and agricultural produce to their overlord.

Two other elements in the Aztec social system were pawns and slaves. The former were poor men who could sell themselves or members of their household for a specified period of time. Their rights were carefully defended by Aztec law, and they were not slaves but more like indentured servants. True slaves did exist and in some parts of Meso-America were used as workers or servants. Among the Aztec, the *mayeques* were their counterpart. Slaves were bought in lowland markets and used primarily for human sacrifice.

The high development of craft specialization—much of it full-time—in Aztec towns has been noted above. But many rural communities also had part-time specialties, a feature due in part to the heterogeneity of the highland environment, with its highly local distribution of resources. Foreign goods were brought into the Aztec homeland by great caravans of professional merchants called *pochteca*, who frequently undertook journeys exceeding a year in length. As a group the merchants enjoyed very high prestige and even had their own tribunals. Various merchant wards of a great number of towns and cities in central Mexico were organized into one great trading guild that had its centre at Tenochtitlán. They also organized and administered the town markets, another highly evolved aspect of Aztec institutions. These markets were held in great open plazas—in smaller towns every fifth day, in larger towns and cities daily, although in the latter case the market population reached a peak every fifth day.

The centres and the political organization of large states such as the Aztec empire were fundamentally similar in character to small ones; but the vast differences in size (Tenochtitlán, the Aztec capital, may have had 140,000 to 200,000 inhabitants in 1519) demanded some changes. Generally, when one central Mexican state conquered an-

other, the ruler of the conquering town extorted an annual tribute, but there was little attempt at political integration. In the case of the Aztec, this policy was generally maintained, but many conquered states were given Aztec governors. Furthermore, conquest was usually accompanied by an exchange of women from the two ruling lineages (conqueror and conquered), and successors to the throne of the conquered states were through these women, from the royal lineage of Tenochtitlán. As a result, the ruling class gradually tended toward a single kin group. Because of the great number of states conquered by the Aztec (400 to 500), some form of intermediate-level territorial and administrative organization became imperative. The states conquered by the Aztec were grouped into 38 provinces. One town in each province served as capital, and an Aztec tax collector-governor was placed there to supervise the collection, storage, and disposition of the tribute. In many provinces, the Aztec established garrisons. These consisted of warriors and their families culled from all of the towns of the Valley of Mexico, and they were assigned lands in the conquered province. Since they supported themselves, they were colonists as well as troops. The planting of colonists, combined with such factors as the merchant guild and royal family intermarriage, suggests that the Aztec elite were attempting to integrate more closely the population of the Valley of Mexico as a kind of core nationality for the empire. Other indications that the Aztec were in the process of achieving further political integration are statements in several *relaciones* that the tax collectors served as courts of appeals in serious judicial cases and also that the Aztec introduced the cult of their national god Huitzilopochtli to conquered provinces.

Tenochtitlán. Tenochtitlán itself was a huge metropolis covering more than five square miles. It was originally located on two small islands in Lake Texcoco; but it gradually spread into the surrounding lake by a process, first of chinampa construction, then of consolidation. It was connected to the mainland by several causeway dikes that terminated in smaller lakeside urban communities. The lake around the city was also partly covered with chinampas with numerous rural settlements. Together, the complex of settlements—the city, the chinampa villages, and the settlements along the lakeshore plain—must have appeared from the air as one gigantic settlement. The population in 1519 was in the neighbourhood of 400,000 people, the largest and densest concentration in Meso-American history.

The majority of the people in the city were non-food-producing specialists; *i.e.*, craftsmen, merchants, priests, warriors, and administrators. In Tenochtitlán, as in other larger towns, the larger *calpulli* formed craft guilds. Guild organization was internally complex, an economic development related to the higher level of political integration and the greatly expanded trade and tax base that accrued from it. The great market in the *barrio* of Tlatelolco was reported by the Spaniards to have had 60,000 buyers and sellers on the main market day. The Spaniards also described the enormous canoe traffic on the lake moving goods to the market. There is even evidence that many chinampa cultivators, in response to the expanded market, were shifting from the production of staple crops to truck gardening.

The Aztec capital was originally two separate cities, Tlatelolco and Tenochtitlán, which merged into one through the conquest of Tlatelolco. The division was maintained for administrative purposes, however, and with further growth it became necessary to divide Tenochtitlán into four great wards (also referred to as *calpulli*). Each ward contained 12 to 15 *calpulli*, some 50 to 60 in all. Tlatelolco must have had 10 to 20 *calpulli* as well, bringing the total up to perhaps 80.

With this enormously expanded tax base, the central government became internally complex. The Spaniards described the palace of Montezuma II as containing 300 rooms grouped around three courts. Land titles dating from after the conquest give it an area of 10 acres. Aside from the private apartments of the king, the palace included libraries, storehouses, workshops for royal craftsmen, great halls for justice and other councils, and offices

Organiza-
tion of the
provinces

Pawns and
slaves

Montezu-
ma's palace

for an army of accountants. The sources even describe a royal zoo and aviary and a number of country retreats. The internal organization of the taxation, military, and judicial departments must have been far more complex than in small states; but precise data is lacking.

Within the city there were literally hundreds of temples and related religious structures. There were at least two large complexes, religious centres of the dual cities of Tenochtitlán and Tlatelolco. Each of the four great wards of Tenochtitlán, as well as each calpulli, had smaller temple complexes, so that the total number must have run into the hundreds. The great temple complex of Tenochtitlán consisted of three large pyramid temples (the principal temple platform, dedicated to Huitzilopochtli and Tlaloc, was 100 feet high and measured 300 feet on a side at its base). There were also six small pyramid temples, three calmecac buildings (dormitories and colleges for priests), a ball court, a great wooden rack for the skulls of sacrificed victims, a sacred pool, a sacred grove, and several large open courts. All of these structures were placed within a vast walled enclosure, 1,200 feet on a side. The temple complex at Tlatelolco was at least half as large.

Aztec religion. Perhaps the most highly elaborated aspect of Aztec culture was the religious system. The Aztec derived much of their religious ideology from the earlier cultures of Meso-America or from their contemporaries. This was particularly true during the final phase of their history, when their foreign contacts broadened. Indeed, much confusion about Aztec religious ideology stems, in part, from the fact that Aztec civilization was still in a process of assimilation and reorganization of these varied religious traditions. Moreover, as the empire expanded and Tenochtitlán evolved into a heterogeneous community, the religious needs correspondingly changed from those of a simple agrarian society. The ruling class, particularly, demanded a more intellectual and philosophical ideology.

The great
ceremonial
rites

The Aztec approach to contact with the supernatural was through a complex calendar of great ceremonies, which were held at the temples and were performed by a professional priesthood that acted as the intermediary between the gods and human beings. Many of these were public in the sense that the populace played the role of spectators. Elements in all the ceremonies were very similar and included ritual ablutions to prepare the priests for the contact; offerings and sacrifices to gain the gods' favour; and theatrical dramas of myths by masked performers in the form of dances, songs, and processions. Each god had his special ceremony that, considering the richness of the pantheon, must have filled the calendar. These ceremonies must have played a significant recreative function, as do ceremonies held in honour of patron saints in present-day Mexico.

Aztec religion heavily emphasized sacrifice and ascetic behaviour as the necessary preconditions for approaching the supernatural. Priests were celibate and were required to live a simple, spartan life. They performed constant self-sacrifice in the form of bloodletting as penitence (by passing barbed cords through the tongue and ears). This pattern of worship reached its climax in the practice of human sacrifice; it was in this aspect of Aztec culture that religion, war, and politics became closely related. Ideologically at least, Aztec warfare was waged for the purpose of obtaining sacrificial victims. The tribute lists, of course, demonstrate that there was a more mundane purpose as well, and it would be a serious mistake to think of Aztec warfare as functioning primarily in the religious sphere.

The
priesthood

The cult of the gods required a large professional priesthood. Spanish documents indicate that the priesthood was one of the most elaborate of Aztec institutions. Each temple and god had its attendant priestly order. At Tenochtitlán the high priests of Tlaloc and Huitzilopochtli served as heads of the entire priestly organization. Within the orders were priests in charge of ceremonies, of the education of novices, of astrology, and of the temple lands. (These consisted of specific rural communities assigned by the state to particular temples.) Furthermore, there were several grades of priests. As noted above, the priests maintained a number of schools, or calmecacs, where sons of the nobility and certain commoners were given instruc-

tion. Most of the novices ultimately left the priesthood and carried out economic and political functions; others remained, joined the priesthood on a permanent basis, and lived at the calmecac.

Much of Aztec religion probably was practiced at home at special household altars. Common archaeological artifacts are small baked-clay idols or figurines, representing specific gods apparently used in these household ceremonies, along with incense burners. (W.T.Sa.)

Cosmogony and eschatology. The Aztec believed that four worlds had existed before the present universe. Those worlds, or "suns," had been destroyed by catastrophes. Humankind had been entirely wiped out at the end of each sun. The present world was the fifth sun, and the Aztec thought of themselves as "the People of the Sun." Their divine duty was to wage cosmic war in order to provide the sun with his *tlaxcaltiliztli* ("nourishment"). Without it the sun would disappear from the heavens. Thus the welfare and the very survival of the universe depended upon the offerings of blood and hearts to the sun, a notion that the Aztec extended to all the deities of their pantheon.

The first sun was called Nahui-Ocelotl, "Four-Jaguar," a date of the ritual calendar. Humankind was first destroyed by jaguars. The animal was considered by the Aztec as the *nahualli* ("animal disguise") of the creator god Tezcatlipoca.

At the end of the second sun, Nahui-Ehécatl, "Four-Wind," a magical hurricane transformed all people into monkeys. That disaster was caused by Quetzalcóatl (the Feathered Serpent) in the form of Ehécatl, the wind god.

A rain of fire had put an end to the third sun, Nahuiahuitl, "Four-Rain." Tlaloc as the god of thunder and lightning presided over that period.

The fourth sun, Nahui-Atl, "Four-Water," ended in a gigantic flood that lasted for 52 years. Only one man and one woman survived, sheltered in a huge cypress. But they were changed into dogs by Tezcatlipoca, whose orders they had disobeyed.

Present humanity was created by Quetzalcóatl. The Feathered Serpent, with the help of his twin, Xólotl, the dog-headed god, succeeded in reviving the dried bones of the old dead by sprinkling them with his own blood. The present sun was called Nahui-Ollin, "Four-Earthquake," and was doomed to disappear in a tremendous earthquake. The skeleton-like monsters of the west, the *tzitzimime*, would then appear and kill all people.

Two deeply rooted concepts are revealed by these myths. One was the belief that the universe was unstable, that death and destruction continually threatened it. The other emphasized the necessity of the sacrifice of the gods. Thanks to Quetzalcóatl's self-sacrifice, the ancient bones of Mictlan, "the Place of Death," gave birth to men. In the same way, the sun and moon were created: the gods, assembled in the darkness at Teotihuacán, built a huge fire; two of them, Nanahuatzin, a small deity covered with ulcers, and Tecciztécatl, a richly jeweled god, threw themselves into the flames, from which the former emerged as the sun and the latter as the moon. Then the sun refused to move unless the other gods gave him their blood; they were compelled to sacrifice themselves to feed the sun.

Cosmology. According to the Aztec cosmological ideas, the earth had the general shape of a great disk divided into four sections oriented to the four cardinal directions. To each of the four world directions were attached five of the 20 day-signs, one of them being a Year-Bearer (east, *acatl*, "reed"; west, *calli*, "house"; north, *tecpatl*, "flint knife"; south, *tochtli*, "rabbit"), a colour (east, red or green; west, white; north, black; south, blue), and certain gods. The fifth cardinal point, the centre, was attributed to the fire god Huehuetéotl, because the hearth stood at the centre of the house.

Above the earth, which was surrounded by the "heavenly water" (*ilhuicáatl*) of the ocean, were 13 heavens, the uppermost of which, "where the air is delicate and frozen," was the abode of the Supreme Couple. Under the "divine earth," *teotlalli*, were the nine hells of Mictlan, with nine rivers that the souls of the dead had to cross. Thirteen was

The myth
of the
"suns"

considered a favourable number, nine extremely unlucky.

All of the heavenly bodies and constellations were divinized, such as the Great Bear (Tezcatlipoca), Venus (Quetzalcóatl), the stars of the north (Centzon Mimixcoa, "the 400 Cloud-Serpents"), the stars of the south (Centzon Huitznáua, "the 400 Southerners"). The solar disk, Tonatiuh, was supposed to be borne on a litter from the east to the zenith, surrounded by the souls of dead warriors, and from the zenith to the west among a retinue of divinized women, the Cihuateteo. When the night began on the earth, day dawned in Mictlan, the abode of the dead.

Deities. The ancient tribes of central Mexico had worshiped fertility gods for many centuries when the Aztec invaded the valley. The cult of these gods remained extremely important in Aztec religion. Tlaloc, the giver of rain but also the wrathful deity of lightning, was the leader of a group of rain gods, the Tlaloques, who dwelt on mountaintops. Chalchiuhtlicue ("One Who Wears a Jade Skirt") presided over fresh waters, Huixtocihuatl over salt waters and the sea. Numerous earth goddesses were associated with the fertility of the soil and with the fecundity of women, as Teteoinnan ("Mother of the Gods"), Coatlicue ("One Who Wears a Snake Skirt"), Cihuacóatl ("Serpent-Woman"), and Itzpápálotl ("Obsidian-Butterfly"). Their significance was twofold: as fertility deities, they gave birth to the young gods of corn, Centéotl, and of flowers, Xochipilli; as symbols of the earth that devoured the bodies and drank the blood, they appeared as warlike godheads. Tlazoltéotl, a Huastec goddess, presided over carnal love and over the confession of sins.

Xipe Totec, borrowed from the faraway Yopi people, was a god of the spring, of the renewal of vegetation, and at the same time the god of the corporation of goldsmiths. Human victims were killed and flayed to honour him.

The concept of a supreme couple played an important role in the religion of the old sedentary peoples such as the Otomí. Among the Aztec it took the form of Intonan, Intota ("Our Mother, Our Father"), the earth and the sun. But the fire god Huehuetéotl was also associated with the earth. In addition, Ometecuhtli ("Lord of the Duality") and Omecihuatl ("Lady of the Duality") were held to abide in the 13th heaven: they decided on which date a human being would be born, thus determining his destiny.

Among the fertility gods are to be counted the "400 Rabbits" (Centzon Totochtin), little gods of the crops, among which are Ometochtli, the god of *octli* (a fermented drink), and Tepoztécatl, the god of drunkenness.

The Aztec brought with them the cult of their sun and war god, Huitzilopochtli, "the Hummingbird of the Left," who was considered "the reincarnated Warrior of the South," the conquering sun of midday. According to a legend probably borrowed from the Toltec, he was born near Tula. His mother, the earth goddess Coatlicue, had already given birth to the 400 Southerners and to the night goddess Coyolxauhqui, whom the newborn god exterminated with his *xiuhcoatl* ("turquoise serpent").

Tezcatlipoca, god of the night sky, was the protector of the young warriors. Quetzalcóatl, the ancient Teotihuacán deity of vegetation and fertility, had been "astralized" and transformed into a god of the morning star. He was also revered as a wind god and as the ancient priest-king of the Toltec golden age: the discoveries of writing, the calendar, and the arts were attributed to him.

Mythology of death and afterlife. The beliefs of the Aztec concerning the other world and life after death showed the same syncretism. The old paradise of the rain god Tlaloc, depicted in the Teotihuacán frescoes, opened its gardens to those who died by drowning, lightning, or as a result of leprosy, dropsy, gout, or lung diseases. He was supposed to have caused their death and to have sent their souls to paradise.

Two categories of dead persons went up to the heavens as companions of the sun: the Quauhteca ("Eagle People"), who comprised the warriors who died on the battlefield or on the sacrificial stone, and the merchants who were killed while traveling in faraway places; and the women who died while giving birth to their first child and thus became Cihuateteo, "Divine Women."

All the other dead went down to Mictlan, under the northern deserts, the abode of Mictlantecuhtli, the skeleton-masked god of death. There they traveled for four years until they arrived at the ninth hell, where they disappeared altogether.

Offerings were made to the dead 80 days after the funeral, then one year, two, three, and four years later. Then all link between the dead and the living was severed. But the warriors who crossed the heavens in the retinue of the sun were thought to come back to earth after four years as hummingbirds. The Cihuateteo were said to appear at night at the crossroads and strike the passersby with palsy.

Worldview. The world vision of the Aztec conceded only a small part to man in the scheme of things. His destiny was submitted to the all-powerful *tonalpohualli* (the calendrical round); his life in the other world did not result from any moral judgment. His duty was to fight and die for the gods and for the preservation of the world order. Moreover, witchcraft, omens, and portents dominated everyday life. That such a pessimistic outlook should have coexisted with the wonderful dynamism of Aztec civilization is in itself a remarkable achievement.

Aztec ritual calendar. *Tonalpohualli*, an Aztec term meaning "the count of days," was the name of the ritual calendar of 260 days. It ran parallel to the solar calendar of 365 days, which was divided into 18 months of 20 days and five supplementary unlucky days. The word *tonalli* means both "day" and "destiny": the 260-day calendar was mainly used for purposes of divination. The days were named by the combination of 20 signs—natural phenomena such as wind and earthquake, animals like rabbit and jaguar, plants such as reeds, and objects like flint knife and house—with the numbers 1 to 13. Thus the calendrical round included 20 series of 13 days.

Specialized priests called *tonalpouhque* interpreted the signs and numbers on such occasions as birth, marriage, departure of traders to faraway lands, and election of rulers. Each day and each 13-day series were deemed lucky, unlucky, or indifferent according to the deities presiding over them. Thus Ce-Coatl ("One-Snake") was held as favourable to the traders, Chicome-Xochitl ("Seven-Flower") to the scribes and the weavers, and Nahui-Ehécatl ("Four-Wind") to the magicians. The men who were born during the Ce-Ocelotl ("One-Jaguar") series would die on the sacrificial stone, those whose birth took place on the day Ometochtli ("Two-Rabbit") would be drunkards, and so on. The *tonalpohualli* dominated every aspect of public and private life. (Ja.S.)

ANDEAN CIVILIZATION

For several thousand years before the Spanish invasion of Peru in 1532 a wide variety of high mountain and desert coastal kingdoms developed in western South America. The extraordinary artistic and technological achievements of these people, along with their historical continuity across centuries, have encouraged modern observers to refer to them as a single, Andean civilization.

A look at a modern map reveals that no single South American state encompasses all of the territories controlled by the Inca (Inka) before the coming of the Spanish; rather these territories were spread over parts of Ecuador,

Peru, Bolivia, Chile, and Argentina, and in 1532 they were all part of a single Inca state called Tawantinsuyu, the "Realm of the Four Parts." Earlier, local hegemonies—some coastal, others centred in the mountains, and still others bridging these geographic barriers—had risen, expanded, and eventually collapsed.

The Inca of Cuzco (Cusco) were themselves newcomers to most of the regions that they came to dominate. Such rapid expansion did not allow for complete consolidation; and the Spanish were able to take advantage of what had been a recent incorporation of numerous regional ethnic

Principal sites of Andean civilization.

groups and the resentments that the Inca victory had created among the ethnic lords. Some of these, like Don Francisco Cusichaq, lord of Xauxa, the earliest colonial capital, lived long enough after 1532 to testify before a Spanish court of inquiry that he regretted having opened the country to the Europeans. For 30 years his bookkeepers had recorded on their knotted quipu (*kipu*) accounts not only everything the Spanish had received from Xauxa warehouses but also, on separate knot-strings, everything that had been considered stolen.

The outsider visiting the Andes perceives two overwhelming geographic realities: the Pacific coastal desert stretching for thousands of miles and the high Andes rising parallel to the coast. These contrasting regions—utter desert on the coast and high, looming mountains to the east (where the bulk of the pre-Columbian population lived above 10,000 feet [3,000 metres])—could, and at several times in Andean history did, coalesce into a single political entity. Thus it is possible to speak of a single Andean civilization, even if at times, early and late, there was no political integration. One indicator of this social unity is extant even now: Quechua, one of the Andean languages, is still spoken by some 10,000,000 people from northern Ecuador to northern Argentina, a distance of thousands of miles.

The nature of Andean civilization

The coastal desert was inhabited for millennia by fishermen, and many of their settlements have been studied by

archaeologists. The people in these communities were familiar with the sea and depended heavily on its products, but from very early times they also used and possibly cultivated native varieties of cotton. Textiles have been the major art form in the Andes for thousands of years. It is known that these textiles—found preserved in the coastal sands—have woven into them a wealth of information on Andean peoples; and, while the information in the textiles still cannot be read, it is believed that they will eventually be as revealing as have been the Meso-American codices.

In modern Peru irrigation eventually may permit the cultivation of the lower reaches of most rivers. Still, it is useful to note that of some 50 rivers descending from the Andean glaciers to the Peruvian coast, only three have water flowing through them year-round. Such an ambitious irrigation scheme would be most productive only if the waters were tapped quite high on the western slope and if several rivers were connected through canals high in the Andes, thus allowing the scarce waters of three or four valleys to be pooled into a single one as needed. Rumours of such a project reached the first Spaniards in Peru: in the final decade before the invasion, the Inca were said to be planning to bore through a mountain in what today is northern Chile, so that water from the Amazonic watershed would flow westward to the deserts and thus alter the continental divide.

Archaeologists, particularly non-Peruvian scholars, have concentrated on the study of coastal peoples: they have found that sites are more accessible along the Pan-American Highway; that the hot and dry climate presents none of

The coastal desert

the challenges of the high altitudes; and that the remains, mummified in the desert sands, are immediately rewarding. Pottery finds have portrayed such things as fishing or warfare, diseases, weapons, cultivated plants, and differences in rank and in sexual habits among the Andeans. Usually this evidence has been recovered by professional grave looters but sometimes also by archaeologists themselves. One of the most remarkable of the latter type of finds is the grave of a Moche leader that was discovered near the village of Sipan on the northern coast of Peru in the mid-1980s. Since the mid-20th century architectural studies of ceremonial and political centres have allowed researchers to follow changes in the location and the architectural features of important Andean cities. Distance from the sea and the degree of dependence on maritime products, the proximity to irrigation waters from the highlands, and the repeated efforts to control militarily more than a single irrigated valley have all received attention from archaeologists.

A major question remains: did these coastal polities extend upward to the Andean highlands to control areas beyond the slopes where the irrigation works tapped the rivers? The Peruvian historian María Rostworowski has pointed to similarities, found in colonial administrative papers, between coastal places-names and personal names in the Cajamarca Highlands, an area due east and above the coastal political entities. The colonial papers have not explained the presence of such distant colonies, but they have introduced a topic fundamental to understanding Andean success: given the apparently inhospitable environments of both the desert coast and the nearby high Andes, how could so many separate societies have fed such enormous populations and constructed highways, palaces, and temples in what were clearly urban centres for so many centuries?

AGRICULTURAL ADAPTATION

One answer to this question was suggested in the 1930s by the German geographer Carl Troll. His solution took into account a unique aspect of Andean ecology: the greatest population concentration (more than 1,000,000 people) and the highest agricultural productivity occurred around Lake Titicaca, which is some 12,500 feet above sea level. Nowhere else in the world—not even in Tibet or Nepal—has cultivation been so successful at such a high altitude. The effort to understand the ramifications of this paradox is far from complete, but Troll's insights have proved fertile: (1) The fields and terraces clustered around the lake were located just a few degrees south of the Equator, where daytime temperatures are truly tropical. (2) At this altitude climatic contrasts are not so much seasonal as diurnal, *i.e.*, summer by day and winter by night. Contrasts of 55° to 70° F (30° to 40° C) within a single 24-hour period are not uncommon, and nearly 300 nights of frost per year have been recorded on the high, windy plateau (puna) surrounding the lake. (3) Populations settled in such circumstances seem to have endured as others have survived in the Arctic, the Kalahari, and the Gobi, but it is clear that in the Andes a far denser population fared much better than have groups in other environmentally harsh regions, acquiring with time an intimate familiarity with the agricultural and pastoral possibilities of high altitude.

These peoples cultivated many varieties of tubers, of which only the potato has achieved widespread use in the world. But since the soils at this altitude were easily exhausted, "second- and third-year" tubers had to be domesticated to take advantage of the nutrients left unused in the soil. Then, as now, it was usual to allow the ground to rest—for six, eight, or even 10 years—after which some of the "rested" acreage was returned to cultivation annually, a rotation pattern that is still familiar to the local people.

The upper elevation limit of cultivation has varied throughout the centuries, as the climate has fluctuated. Thus, considerable effort was invested in the development of ever more frost-resistant varieties of tubers. Modern observers have noted that tubers grown close to and above about 13,000 feet were mostly of the pentaploid varieties, bitter hybrids resulting from selection and crossing by the grower. Although they usually required additional nurture

and processing that were beyond the procedures familiar today, the bitter varieties represented a gain in total productivity.

A significant improvement in agriculture was the construction of massive terraces, which not only extended the cultivated area but also created protected microclimates where particular varieties could flourish. It has been suggested that an "amphitheatre" found in the Cuzco region was actually an experimental field where the concentric terraces reproduced tiny variations in the upland environment. When the use of highland irrigation and raised-ridged fields are taken into account, it becomes clear that these upland populations were highly familiar with, and respectful of, the potential for high-altitude agriculture and were intent on gaining additional acreage in circumstances that elsewhere would not have seemed worth the effort.

Another incentive for settlement at high altitudes was the presence of glacier-fed pastures for alpaca herds. The llama—it and the alpaca were the two camelids domesticated by the Andean peoples—could live at altitudes ranging from sea-level to those in the high mountains. The alpaca's habitat, however, was much narrower; it did best above 13,000 feet, and its preference for a swampy range was catered to by pastoralists. It has been found that even today alpaca-herding is a full-time occupation, almost impossible to combine with agriculture. While Andean herders did belong to wider ethnic groups, they tended to be specialists, relying for their food staples on their kinsmen closer to Lake Titicaca.

Present-day distribution and use of these animals (known collectively as camelids) tends to mask their importance in pre-Columbian times. A European inspector, reporting in the 1560s on the camelid wealth of a single Aymara chiefdom near Lake Titicaca, claimed, "I have heard of an Indian who is not even a lord, one don Juan Alanoca of Chucuito, who has more than 50,000 head." Such control of vast herds, combined with the hundreds of varieties of high-altitude tubers and grains, helps to explain the density of Andean populations.

THE COLD AS A RESOURCE

Beyond such skilled manipulation of the natural geography there lay an awareness of frost. As noted above, in the high Andes frost can occur almost every night of the year. Elsewhere people have endured the cold; in the Andes the cold was transformed into a positive and even creative factor.

It is not known when this step was taken. For at least 1,000 years people in the Andes have been aware that the sharp alternation between tropical noon and arctic midnight can be utilized. Any animal or vegetable tissue exposed to this daily contrast can be processed into nutritive products that keep for decades, and the process can be achieved either at the household or the state level.

Chuño is the name popularly used for processed tubers, but a rich vocabulary for tubers exists in the Quechuan (Andean) languages: there is a separate term for each plant and for each mode of preparation. Chuño cannot be made where a diurnal temperature extreme is absent; thus, north of modern Cajamarca in northern Peru no chuño is prepared, since nocturnal frosts are rare or absent. Animal tissues also can be handled in this manner. After 1532 European meats were added to those of local birds, fish, and camelids. The name for these preserved meats is charqui, or jerky (*ch'arki* in Quechua), the one Andean word that has made its way into common English usage.

Such food reserves allowed both the peasants and the state to compensate for natural and man-made calamities. They filled thousands of warehouses—many of which are still extant—that were built in ways and places so as to use the tiny differences of exposure to the sun, winds, and humidity. Those built by the state or by the ethnic lords along the more than 15,500 miles of roads provided food for both human and camelid porters, for the armies, and for priests traveling to the many shrines.

The presence of such large stores made possible the incredible forays of Spaniards like Diego de Almagro, who reached Chile from Cuzco across thousands of miles of deserts and snow-covered mountains. As late as 1547, 15

Terracing

Food preservation and storage

Tuber cultivation

years after the Spanish invasion, one Spaniard, Polo de Ondegardo, reported that he had fed 2,000 soldiers for seven weeks with the food still stored above Xauxa, which had been the first European capital. A detailed archaeological study of an Inca storage system was made by the American anthropologist Craig Morris, who found almost 500 warehouses at Huánuco Pampa. There were some 1,000 warehouses at Xauxa and many more near Cuzco, the Inca capital.

THE HIGHLANDS AND THE LOW COUNTRIES

The cultivators of high-altitude tubers and lowland crops—the plants of which seem botanically far apart at first glance—were actually in continuous contact. This point was stressed by the pioneer Peruvian archaeologist Julio C. Tello and was later verified by foreign scholars. The inhabitants all along the Andean highlands were aware of the diverse populations and climates of the Pacific coastal deserts to the west and of the Amazon lowlands to the east. The Chilean researcher Lautaro Núñez has traced the several societies who inhabited a single valley: products and settlement patterns changed through the centuries, but at all times each successive ethnic group accumulated resources from diverse ecological niches into a single system.

By adding written Spanish sources to the information provided by archaeologists, it is possible to explain further the density of the Andean population and its great productivity. Throughout the Andes, south of Cajamarca, political units large and small were characterized by a dispersed settlement pattern. The preferred location of the seat of power frequently was at very high altitudes, almost at the upper limit of cultivation, and kinsmen of these highlanders were settled permanently at three, five, or even 10 days' walk from the political centres. The German anthropologist Jürgen Golte has stressed that the agricultural calendar permitted such absences, since crops matured at different dates according to altitude; but many outliers were too far away from the political and demographic nucleus to permit seasonal migrations. The outlier communities could be large or small and could be established on the dry Pacific shore or in wet Amazonic enclaves. The Lupaca (Lupaqa), an Aymara-speaking polity whose political centre was located on the puna on the shores of Lake Titicaca, controlled outliers on both slopes.

Other ethnic groups reached in only one direction. For example, the two lords of the Karanga (Caranga), on what today is the highest part of the Bolivian High Plateau, do not seem to have controlled any outliers of their own on the Amazonic slope. Their main puna farms and most of their subjects lived above 12,000 feet, and their camelid herds were pastured even higher. The Karanqa also controlled corn (maize) fields at less lofty altitudes in what today is Chilean territory, several days' walk away. Farther west and closer to the coast were their fruit and coca-leaf gardens. Finally, even farther north, across the Atacama Desert near the modern city of Arica, the Karanqa had their "own" fishers.

One unexpected feature of such outliers is that they were usually multiethnic: several political centres shared settlements of salt miners, fishers and seaweed gatherers, cultivators of hot peppers and coca leaves, and timber cutters and honey gatherers. The political mechanisms by which conflicting groups could reach truces, even if temporary, or the means by which caravans moved with safety when connecting the central settlements with their multiple outliers are still not known.

This diverse pattern of settlement and political control and of pooling dispersed resources and populations has been named "Andean ecological complementarity," or the "vertical archipelago." Such complementarity went beyond the efficient control of the nocturnal cold and of the high altitude. Even if many details of how it worked still escape understanding, it is obvious that each ethnic group was able to diversify the risks that would have existed if each had been concentrated in any of the separate Andean ecological tiers. Beyond defensive strategies, in ecological complementarity it is possible to detect new opportunities that would permit massive storage of a wide range of foods going beyond those grown locally. Eventually

there emerged dense populations and large polities like the Inca. It is notable that the foci of Andean civilizations across the centuries—Chavín, Huari (Wari), Tiahuanaco (Tiawanaku), Cuzco—were all located on the high puna.

The pre-Inca periods

The names the several prehistoric populations called themselves are not known, and archaeologists have come to distinguish the various peoples and civilizations by descriptive terms—the Late Preceramic, the Initial (or Lower Formative) Period, the Early Horizon, the Early Intermediate Period, the Middle Horizon, the Late Intermediate Period, and the Late Horizon (also called the Upper Formative, or Inca, Period). Each of the periods lasted for centuries, some for millennia. These designations stress the differences between the peoples who inhabited the coast and those who lived in the highlands, although contacts between the two areas were frequent at all times in prehistory. What have been termed "horizons" in Andean studies were much shorter periods of time when wide areas of the central Andes were united culturally and politically with one another and with sections of the Pacific coast.

THE LATE PRECERAMIC

There is ample evidence of human occupation by 3500 BC, at which time there was already considerable diversity along the Pacific. In the central and northern coastal areas lived people who cultivated beans, squash, cotton, and chili peppers and who exploited the sea, catching fish with cotton nets and shell or composite hooks, collecting shellfish, and hunting sea mammals. One group at Chilca, south of modern Lima, built conical huts of cane thatched with sedge. The dead were buried wrapped in twined-sedge mats and the skins of the guanaco, a wild camelid. Some people camped in winter on the lomas, patches of vegetation outside the valleys that were watered at that season by fogs. In summer, when the lomas dried up, they built camps along the shore. The lomas provided wild seeds, tubers, and large snails; deer, camelids (probably guanaco), owls, and foxes were hunted. The lomas had long been shrinking, and the winter camps were abandoned (c. 2500 BC) in favour of permanent fishing villages. Nowhere are the deposits thick enough to show stratification, but they have been arranged in chronological order by comparing the implement types and noting their distribution within the shrinking patches of vegetation. Some small patches still survive.

In the far south, the lomas were and still are more extensive than in the centre, and projectile points are abundant in them and in caves in the valleys. Deer can still be seen on the lomas, and it appears that hunting of them and of guanaco was the main activity in Late Preceramic times.

In the far north, in the Talara region and extending north into Ecuador, are stone tools and mangrove-dwelling mollusks, left by people who enjoyed a wetter climate than that now prevailing, and one inland site at El Estero, provisionally dated somewhat earlier (c. 5000 BC), has well-made polished stone axes and mortars that indicate the exploitation of forests and grasslands yielding seeds.

Much longer periods of occupation have been postulated for the highlands: the American scholar Richard S. MacNeish has suggested a human presence as early as 15,000 BC in the Ayacucho Basin, which would correspond to the traditional "first wave" of immigrants into the New World. Since there has been much less research in the highlands than on the coast, little is known of the highland Late Preceramic. The caves at Lauricocha at about 13,000 feet in the central Andes, which had been occupied by deer and camelid hunters since nearly 8000 BC, were still used, at least as summer camps, by hunters who employed small leaf-shaped points. Gourds, squash, cotton, and lucuma, with seed plants such as quinoa and amaranth, were cultivated in the Ayacucho Basin before 3000 BC; corn and beans came within the next millennium. There were also ground stone implements for milling seeds. It has been claimed that llamas and guinea pigs long had been domesticated.

After about 2500 BC came a great increase in the speed

Archaeological periods

Dispersed settlement pattern

Population
growth

of development, which is best known on the coast. Population increased, and stable settlements were established in many places. By 2000 BC there were perhaps 100 villages on the coast with populations of 50 to 500 people, with a few of up to 1,000, indicating a total population of about 50,000. This was a far cry from the thinly scattered bands and occasional villages of about 1,000 years before. Considerable variation has been observed from place to place, but most sites have shown a predominance of seafood, including fish, shellfish, sea lions, and sea birds.

On the north central coast, the stretch between the Casma and Huarmey rivers was heavily populated. One site, at Culebras, was a large village on a terraced hillside, with semi-subterranean houses whose underground parts were lined with basalt blocks and whose upper parts were built of lighter materials such as adobe blocks. They originally had hard clay floors, and some had guinea-pig hutchers consisting of stone-lined tunnels connecting two rooms at floor level. The guinea pig, normally vegetarian, appears to have been taught to feed on small fish. A site at Huarmey has provided the earliest known instance of corn on the coast, and it also occurred in the top Preceramic levels at Culebras.

Burials at Culebras were tightly flexed, wrapped in twined mats and cotton cloth, and accompanied by gourd vessels and beads and pendants of stone, shell, or bone. The skulls of these people were deformed by having been bound to cradleboards in infancy. There was a cemetery, but many burials were under house floors. No ceremonial buildings are known in this area.

Farther north, at the mouth of the Chicama River, is Huaca Prieta, which was the first Preceramic site to be excavated. A thick midden, it contains some subterranean houses lined with cobblestones and roofed with earth supported by whalebones and wooden beams. The twined textiles found there were the vehicle for a peculiar art style, showing highly stylized crabs, double-headed snakes, birds, and human beings, expressed by warp manipulation designed to bring groups of warps of one colour to one face. The dyes have faded, and the only way to recover the designs is by examination under a microscope. Such textiles were not confined to this area, but they have been more fully studied there. Woven textiles were rare, and weaving was combined with twining in a way that shows that a loom was not used.

Ceremo-
nial archi-
tecture

Unlike the area farther north, sites along the central coast had ceremonial buildings, of which the most remarkable is El Paraíso in the Chillón Valley. This is an imposing stone-built structure on an artificial mound, with a central stairway leading up to a group of rectangular rooms. The central block, which occupied a commanding position in a side valley, has been partly reconstructed, but there were extensive wings that may have been residential, though they now appear as little more than piles of stones. Flood-water farming may have been practiced there, but definite signs of it have been obliterated by modern cultivation. At Río Seco, a few miles to the north, are two pyramids, constructed by filling a group of preexisting rooms with boulders, building adobe-walled rooms on top of them, and finally filling these up also.

Apart from one site, Kotosh, near modern Huánuco in the central Andes, little is known of the highland final Preceramic. A Japanese research team has found structures of undressed stone chosen to present flat wall surfaces, set in mud, covering an area of at least 200 by 100 yards (180 by 90 metres), in some parts of which was a succession of buildings piled up to a considerable height. Among these were two superimposed temples, the lower being a rectangular structure on a stepped platform about 26 feet high. The floor was surrounded by a broad, low bench, and each outside wall had two or three rectangular niches. The walls and floor were covered with two coats of mud plaster, and beneath the central niche at one end was a pair of crossed forearms modeled in the same material. This temple was later buried in boulders surrounded by a retaining wall and covered by a new floor on which a second temple was built, of which little remains. The burial of the first temple to act as a raised foundation for the second recalls the construction at Río Seco.

THE INITIAL PERIOD

The next epoch, called the Initial Period by the American scholar John H. Rowe, and the Lower Formative by the Peruvian archaeologist Luis G. Lumbreras, began with the introduction of pottery. The earliest ceramics have yielded radiocarbon dates of about 1800 BC, although Rowe has suggested that even a date of 2100 BC is plausible. Ceramics from this period have been found on the central coast between Las Haldas, in the Casma-Huarmey region, and Lima. These are considerably later than the earliest pottery finds at Puerto Hormiga on the northern coast of Colombia near Panama (before 3000 BC) and Valdivia in Ecuador (c. 2700 BC). The period ends with the spread of the Chavín cult (also called the Early Horizon; see below).

Lumbreras has stressed agriculture as a more telling indicator: while no single starting date has been cited for this achievement, beans may have been cultivated for centuries if not millennia before the date of the earliest pottery. Bottle gourds and squashes were other cultivated species. Potatoes and other tubers, so important in later times, did not keep well in highland circumstances; but some researchers believe that Andean peoples were reliant on wild tubers and rhizomes 10,000 years ago, although these groups had not yet domesticated them. It has been demonstrated that on the coast virtually all the crops that were important in 1532 (with the notable exception of corn) were already known and in daily use during the Initial Period.

The introduction of pottery at first made little difference to the general pattern of life; cooking continued to be done by roasting on hot stones. On the coast, there was a gradual increase in the consumption of cultivated plants, grown mainly in the lower reaches of the valleys; but the basic reliance on seafood continued. An important innovation was the development, or possibly the introduction, of the heddle loom, but, if it was introduced, its origin is not known. At first it seems only to have been used for making plain-weave cotton cloth. Village life and temple buildings spread over the country, except to the far south, where conditions favoured the continuance of hunting and gathering. Corn spread from the centre over most of the coast, and cassava, or manioc (an edible root), and peanuts (groundnuts) appeared there for the first time, their ultimate source being the Amazonian lowlands.

New ceremonial centres showed considerable diversity. Examples include La Florida, a huge pyramid in Lima that formed the nucleus of a yet-unmapped building complex. The Tank site at Ancón consists of a series of stone-faced platforms on a hill. Las Haldas has a platform and three plazas; two smaller similar sites are also known. The old centres at El Paraíso and Río Seco had been abandoned, but, in the highlands, Kotosh continued to be occupied. Any constructions at Yarinacocha in a wet, stoneless area would have been of wood or other perishable materials.

The variety of the pottery suggests that it was derived from several different sources. In the Lima area, the earliest examples are neckless jars and incurved bowls with thickened rims and rounded bottoms, very uneven in shape. Some later types are pebble polished and the jars thinner. Other later types include bottles with straight spouts, which may have simple incised or applied decoration, and open bowls. Finally, as the period drew to a close, tan-coloured decorated wares, with punctate or red-painted areas outlined by incised lines, as well as orange ware with black stripes, were produced. A type found on the south coast is a small, double-spouted bottle with simple negative-painted decoration, the first appearance of a form long-lived in that area and of a decorative technique that later spread widely over the country.

In the highlands, the earliest pottery at Kotosh consists predominantly of simple bowls with somewhat constricted mouths, and bowls with gently rounded bases meeting the vertical to outsloping concave walls at a sharp angle. There are rare double-spout-and-bridge bottles, closed vessels with two tubular spouts connected by a solid bridge. The ware is mainly dark gray, black, or dark brown to sombre red, and it may have a red slip. The decoration—which was either applied to a broad zone covering most of the walls or, on the neckless jars, formed a ring around

Techno-
logical
advances
in the
Initial
Period

the mouth—consists of linear incision, hatching, stamped circles, punctation, or excision. Postfired painting in red, yellow, and white frequently covers excised, hatched, and stamped areas. Despite the fact that Kotosh was on the eastern side of the Andean watershed, its pottery had little in common with that of Yarinacocha, save some similar decorations and the double-spout-and-bridge bottle.

The first known pottery of Yarinacocha is far from primitive. It consists mainly of bowls, mostly with complex outlines. Large open bowls with a broad labial flange, concave sides, and in some cases a second flange where side meets base, could have been cooking pots. Small bowls with inward-sloping sides meeting the rounded base at a sharp angle could have served for drinking; and a shallow bowl, with rounded base meeting the low, slightly outslipping concave sides at a lesser angle, may have been a plate for solid food. There are shards from large urns that may have served for brewing cassava beer. Decoration of finely hatched or cross-hatched geometrical areas, outlined by broad incised lines, occurs on most vessels, and one has a similarly executed feline face. In spite of severe weathering, postfired red paint, later so characteristic of the south coast, is found on some vessels.

THE EARLY HORIZON

The Early Horizon emerged after the appearance and rapid spread of the Chavín art style, ending the regional isolation of the Initial Period. The Chavín art style derives its name from the ruined temple complex of Chavín de Huántar in the Andean highlands of central Peru. The dates suggested for the emergence of the style beyond the environs of the temple, however, vary among scholars. Rowe dated it from 1400 BC, while Lumbreras suggested 850 BC; and the very designation of Chavín as a horizon has been challenged. But even those who have most favoured dropping the concept of horizon for this period have noted that in about 1000 BC there was an invasion of highlanders into the coastal Casma Valley who brought with them radically different architectural styles, ceramics, and food plants and animals that supplanted those in the valley; such a penetration was clearly a unification of the coast and the highlands into a single polity.

Beginnings of a unified art style Chavín came to cover most of the north and centre of Peru, and its influence affected a good part of the south coast, excluding only the southern highlands. The art style, which is regarded as the expression of a cult, is expressed in painted textiles (of which few have survived), in pottery, and chiefly in stone carvings. Archaeologists at one time generally agreed that the chief object of worship was a cat, probably the jaguar, but this has been questioned, although many natural bird, animal, and human forms had feline mouths and other attributes. Feline representations were widespread, whereas some unquestioned deities were confined to the immediate neighbourhood of Chavín.

The temple at Chavín Most Chavín temples seem to have been ceremonial centres without people living around them, although the complex at Chavín itself seems to have been accompanied by a considerable town. The remainder appear to have been focuses for scattered settlements. The most elaborate temple known is that at Chavín, which lies at an elevation of 10,530 feet on a tributary of the Marañón River, east of the Callejón de Huaylas district of the Santa River. The temple consists of a group of stone platforms formed of rubble faced by walls of coursed masonry in which two thin courses alternate with one thick one. They are honeycombed with galleries running parallel to the walls at different levels and ventilated by shafts. The oldest part of the temple is a U-shaped structure, with the open top of the U facing east; the rectangular central arm contains a cruciform gallery, at the crossing of which stands a remarkable prismatic shaft of white granite, some 15 feet high, carved in low relief to represent a standing human figure with snakes typifying the hair and a pair of great fangs in the upper jaw.

This figure, which has variously been called El Lanzón, the Great Image, and the Smiling God, is thought to have been the chief object of worship in the original temple. The southern arm of the temple was subsequently twice widened by rectangular additions, into which some of the

original galleries were prolonged. After the second addition, the two were joined by a freestanding facade having a central portal with a lintel supported on two cylindrical columns. The lintel bears 14 eagles in low relief, supplied with feline jaws with prominent fangs behind the beak, and each column is entirely covered by a mythical bird bristling with feline fangs and faces. These have been interpreted as attendants of the god worshiped in that part of the temple, who had perhaps superseded the Smiling God and could have been the god shown on the Raimondi Stone, now in Lima. The stone shows the Staff God, a standing semihuman figure having claws, a feline face with crossed fangs, and a staff in each hand. Above his head, occupying two-thirds of the stone, is a towering, pillarlike structure fringed with snakes and emerging from a double-fanged face, which Rowe interpreted as a symbolic treatment of his hair as a tongue coming out of a mouth. Unlike the Smiling God, this figure has been found in areas as far from Chavín as the northern and southern coasts of Peru. Except for the columns, which are of black slate, the stones of the facade are light in colour on the south side and dark on the north. East of the facade is a small sunken court of the same period, which contained a number of slabs with carvings in low relief, and to the east of this is a much larger court surrounded by platforms. Within this court is a square, slightly sunken area, in which was found the Tello obelisk, a rectangular pillar carved in low relief to represent a caiman and covered with Chavín symbolic carvings, such as bands of teeth and animal heads. This is considered to be an object of worship like the Smiling God and Staff God. Carvings found on and around the temple include a cornice of projecting slabs, on the underside of which are carved jaguars, eagles, and snakes, and a number of tenoned heads of men and the Smiling God; they are thought to be decorations or the attendants of gods rather than objects of worship.

On the coast, the temples were built mostly of adobe. In the Nepeña Valley, two temples—Cerro Blanco and Punkurí—differ so much that they must also differ in age, but it is not known which is the earlier. Cerro Blanco is a massive platform of conical adobes and stones, supporting rooms with walls bearing Chavín decoration, including eyes and feline fangs, modeled in mud plaster in low relief and painted red and greenish yellow. Punkurí has a low, terraced platform with a wide stairway on which stands a feline head and paws, modeled from stone and mud, and painted. By the paws was buried a woman, believed to have been sacrificed. At Moxeke and Palca in the Casma Valley to the south, there are terraced, stone-faced pyramids with stone stairways. The first has niches containing clay-plastered reliefs of mud, stone, and conical adobes, showing felines, snakes, and human beings of Chavinoid character painted in polychrome. Also in Casma is a temple at Cerro Sechín, consisting of a series of superimposed platforms with a central stair, on either side of which, at the bottom level, stands a row of irregularly shaped flat stones with incised designs showing standing men carrying clubs, severed heads, and other designs. Lacking Chavín characteristics, these have been interpreted variously as ancestral Chavín or derived from it, the latter being the more plausible. There is a Chavín ceremonial centre at Garagay in the Chillón Valley but none to the south.

Chavín pottery is best known from the decorated types found in the galleries in the temple at Chavín and in graves on the northern coast, where it is called Cupisnique. Until the end of the period, the ware was monochrome—dull red, brown, or gray—and hard and stonelike. Vessels were massive and heavy, especially in the early part of the period. The main forms are open bowls with vertical or slightly expanding sides and flat or gently rounded bases, flasks, and stirrup-spouted bottles. The surface may be modeled in relief or decorated by incision, stamping, brushing, rouletting, or dentate rocker-stamping, all of which may be applied to particular zones in contrast with other smooth ones. Some bowls have deeply incised designs on both the inside and outside faces. Many of the forms and decorative features, apart from specifically Chavinoid designs (particularly feline fangs), were already present at Kotosh in the previous phase.

Chavín
pottery

Considerable time changes are represented in Chavín pottery; for example, the earliest stirrup spouts were relatively small and very thick and heavy, and the spout had a thick flange. As time went on, the stirrups became lighter and the spouts longer; the flange was reduced and finally disappeared. The necks of the flasks underwent similar changes. The decoration on some of these is extremely striking; one has incised flower designs, and another has a roughened surface in which there are a number of concave circular depressions with a notably high polish. The Cupisnique stirrup-spouted vessels, some of which were modeled in the form of human beings, animals, or fruits, were the beginning of a north-coast tradition of naturalistic modeling, which persisted throughout its history. Toward the end of the period, a bichrome (dark red on cream) pottery came into use.

There is a considerable area on the south Peruvian coast with its focus in the Ica Valley, where strong influences from Chavín have been found in the Paracas pottery style, and two painted textiles in pure Chavín style have survived from the same valley. Paracas pottery was very different from that of Chavín, but various motifs have enabled the two to be correlated closely. Paracas began at practically the same time as Chavín, about 1000 bc, and lasted throughout its span and beyond it, perhaps to about 200 bc. The most characteristic form of Paracas pottery was a closed globular vessel with a somewhat flattened base, which had two narrow spouts connected by a flat bridge, or more frequently, with one spout replaced by a human or bird head. Simple round-based bowls were very common. The ware was most commonly black or very dark brownish, and much of the surface was covered with decoration outlined by incision and painted in polychrome with hard, shiny, resinous colours after firing. A panel bearing a feline face on one end of a spout-and-bridge vessel was one of the most frequent forms of decoration. Paracas is also distinguished for its gorgeous embroidered textiles, generally found in the mummy bundles of the important dead. Embroidery had a popularity at this time that it afterward lost, but a surprisingly wide range of weaving techniques were also used in various parts of the coast.

THE EARLY INTERMEDIATE PERIOD

The Early Horizon was succeeded by what has been termed the Early Intermediate Period. The onset of the Early Intermediate marked the decline of Chavín's cultural influence and the attainment of artistic and technological peaks in a number of centres, both on the coast and in the highlands.

The southern coast. The beginning of the period is best determined by the evolution of the Paracas pottery style into that of the Nazca (Nasca) area on the southern coast; this is traditionally estimated to have occurred about 200 bc, but Rowe's date of 400 bc is probably more reliable, since this is the area where his detailed succession was worked out. Nazca ware is marked by the introduction of slip painting applied before firing, which took the place of the resin painting applied afterward; but the style evolved continuously, and the polychrome tradition continued. The most common forms were bowls and beakers, all with rounded bases, but double-spout or head-and-spout jars were also characteristic. In contrast to the Moche area on the northern coast, figure modeling played a very minor role. Designs were painted in up to eight colours and fell into two main groups: one characterized by stylized but recognizable life forms, such as birds, fish, or fruits, with some humans; the other depicting mythical subjects such as complex demons. Between approximately middle and late Nazca, mythical figures became increasingly angular and elongated and developed a tangled mass of appendages. Trophy-head representations, which were modeled as complete vessels as well as painted in profile on simple vessels, increased greatly at the same time. Because Nazca art was less realistic than that of Moche, little can be learned of the appearance and life of the people.

In the time of the Nazca style what has been described as a small city was located in each of the south-coast valleys of Pisco, Ica, Nazca, and Acari. At Cahuachi, in

Nazca, this included a ceremonial centre consisting of six pyramids, which were terraced and adobe-faced natural hills associated with courts. Tambo Viejo in Acari was fortified, which supports inferences drawn with some difficulty from late Nazca art that a concern with warfare developed at that time.

The northern coast. A cultural peak was reached in the valleys of Pacasmayo, Chicama, and Moche on the northern Peruvian coast. A large proportion of this area has been grouped by archaeologists into a Moche culture, although some of the territory encompassed by these valleys was not part of the polity called Moche. The Japanese archaeologist Izumi Shimada has referred to this kind of control as "horizontally discontinuous territoriality." The coast-highland "vertical" type of polity described above appears to have emerged later in coastal history. Thus, this "horizontal discontinuity" may have been related to coastal trade, as products were sought north of the desert coast, while at a later time it may have coexisted with "verticality."

The Moche culture is distinguished by a ceremonial pottery style, commonly covered with a white or red-and-white slip, which may have had decoration painted on it, chiefly in red on the white parts. Some pots are molded in forms that include figures, animals, plants, and weapons; and some have molded designs in low relief. Molding and painting both convey highly realistic impressions of the people, things, and scenes they represent and are a vivid source of information about the life and activities of the people, though some important aspects, such as agricultural processes, are not represented. Moche pottery has been divided into five phases that were originally defined mainly by differences in the stirrup-spouted jars, but this has been extended to other forms—for example, bell-shaped bowls, double vessels, and jars with collars. The prevalence of stirrup spouts and the quality of the modeling connect Moche much more closely with Chavín-Cupisnique than with the intermediate styles, in which features such as the spout-and-bridge vessels suggest intrusive influences from the south. Among Moche buildings are adobe pyramids, like the enormous Huaca del Sol in the Moche Valley, palaces with large rooms (on terraces in the case of the Huaca de la Luna near the Sol), and fortified structures perched on the sides of valleys. These structures reinforce the evidence, provided by warriors and enthroned dignitaries depicted on pots, for the existence of an aggressive hierarchical state, and it may be inferred that this grew up as the result of dependence on highly developed irrigation systems in the restricted areas available in the valleys.

There were no towns in the northern valleys. Dispersed communities, built in places where they would not use the valuable irrigated agricultural lands seem to have been situated in ways suggesting dependence on one of the ceremonial centres.

The north highlands. In the north highlands, the remarkable pottery style of Recuay has been found in the Callejón de Huaylas region. This pottery is related to the negative-painted representative of Gallinazo in the Santa Valley and is painted with black negative designs over white and red, one of the most characteristic being a feline in profile with a comb on the head. There is a good deal of lively modeling, but it is much less naturalistic than that of Moche. A typical feature is a broad, nearly horizontal flange surrounding the mouth of a jar, and many jars also have a horizontal spout below the flange. Most of this pottery has come from stone-lined graves, and some stone buildings of two or three stories may have belonged to the people who made it.

The Cajamarca Basin is the site of a pottery style (called *cursive*) that was entirely independent of known outside influences and that spanned at least the Early Intermediate Period and the Middle Horizon. It has lightly painted running-scroll designs, which vaguely recall writing (whence the name *cursive*), as well as small animals and faces, in brownish black or red on a cream background, mostly on open bowls with ring bases. It was traded widely in the north, and south as far as Huari, during the Middle Horizon.

The Moche culture

Recuay pottery

Nazca pottery

Pucará

The south highlands. Large urban and ceremonial centres emerged at this time near the shores of Lake Titicaca. One site, Pucará, includes a well-built, horseshoe-shaped sanctuary of concentric walls of red sandstone enclosing a slightly sunken terrace lined with white-sandstone slabs. Within the terrace is a sunken court some 50 feet square and seven feet below the surface, also lined with white sandstone and reached by a stairway. This court contains two stone-lined grave chambers, and the outer horseshoe wall has small chambers, each containing one or two altarlike slabs in its thickness. There are also squat stone statues of men carrying trophy heads and stelae (upright sculptured slabs of stone) bearing recessed geometrical carvings and snakes. The pottery includes a reddish-buff micaceous ware painted in red, black, and yellow; cats, human or bird heads, and geometrical figures are all outlined by incision. The faces have the eyes divided vertically, one half of each eye black, the other half the natural colour of the ware. Pucará occurred early in the period, before the main development of Tiahuanaco, and it may have taken shape about 400 BC. It appears to have controlled an area between the site and Lake Titicaca or farther.

Tiahuanaco

Tiahuanaco is a well-known ceremonial centre whose stone remains are now a tourist attraction in the Andes second in popularity only to the ruins of Machu Picchu. The occupation of the ceremonial centre is believed to have begun very early in the period, since some of the earliest pottery shows similarity to that found at Pucará. The ceremonial buildings—whose exact age is uncertain—include a large stepped pyramid or platform called Acapana (Akapaná), with foundations of buildings on the top; a semi-subterranean temple with stone heads tenoned into the walls; and a low rectangular platform called Calasasaya (Kalasasaya), enclosed by a retaining wall of upright stones alternating with smaller rectangular blocks. In one corner of the platform stands a great monolithic doorway, not in its original position, cut from a large block of lava. At the top of the doorway is carved a central low-relief figure attended by three rows of smaller winged figures that appear to run inward toward him. The central figure, carrying staves that may represent a spear thrower and darts, has been likened to the Chavín Staff God and for convenience may be called the Doorway, or Gateway, God. Versions of the Doorway God and his attendants are found almost everywhere within the range of Tiahuanaco influence in the subsequent Middle Horizon. Another feature of the site is a number of large and finely finished stone blocks with niches, doorways, and recessed geometrical decorations. Tiahuanaco masonry is sometimes held together by accurately cut notches, sometimes by copper clamps set in either straight or T-shaped grooves. Several massive monolithic statues have been found in and around Tiahuanaco, the largest being 24 feet high. They resemble pillars bearing relief designs and some carry beakers.

Decorated Tiahuanaco pottery is a finely polished polychrome, which commonly has a red slip with designs painted in various colours. Felines and hawks in profile, with eyes divided vertically into black and white halves, are common designs, as are geometric figures such as triangles and steps. Like all Tiahuanaco art, the designs are stiff and formal. The shapes include a tall, graceful, hollow-sided beaker, or *kero*, and various types of bottles and hollow-sided bowls with flat bases, including a form bearing a jaguar head and tail on the rim.

THE MIDDLE HORIZON

Both Pucará and Tiahuanaco were early forms of what became known as the Middle Horizon, an expansion of multiple-valley political rule that had two centres: one in the southern altiplano, the other centred on Huari (Wari), near the modern Peruvian city of Ayacucho. This development is usually dated around AD 600. Some Tiahuanaco effigy vessels have been discovered at Huari, but otherwise they seem to have been independent entities. Subsequent research has located parallel occupations near each other in the vicinity of the modern city of Moquegua.

Huari

The American archaeologist William H. Isbell has argued that Huari was a true state which displayed archaeological manifestations of administrative recording, had storage

facilities on a scale suggesting major revenues, contained status tombs and palaces, and had other symbols and ornaments of a ruling class. Huari colonies and control also have been detected in the evidence. Attempts to explain what Huari and Tiahuanaco were doing outside the areas of their immediate control have pointed toward religious proselytism, as well as to trade. It has also been suggested that, although these polities employed an extensive form of control, they did not attempt to rule all of the intervening territories.

After a period of consolidation, the expansion was intensified, eventually reaching Cajamarca and the Chicama Valley in the north and the Ocoña Valley on the far southern coast, by about 800. The growth of the empire and its nature is shown by a number of features. One was the spread of Huari pottery styles and local copies of them, some bearing the Doorway God and other religious figures but many with neutral or secular motifs such as bands of chevrons. These generally were polychrome wares, and figures appearing on them—mythological, human, or animal—may have the eyes divided vertically into black and white halves, as at Tiahuanaco. A result of the increasing dominance of Huari styles was the obliteration of the old pottery styles over the whole coast from Nazca to Moche. The southern burial custom of huddled, cloth-wrapped mummies spread northward along the coast, displacing the older fashion of extended burial. The presence of large groups of storage buildings at Piquillacta in the Cuzco Valley and at Viracochapampa, near Huamachuco far to the north, suggests military activity like that of the later Incas. On the coast, some great cities in the north—of which Chan Chan, near modern Trujillo, is the best-known—originated at this time, apparently under southern influence, and the rectangular Great Enclosure Compounds in the Virú Valley may be an expression of the same phenomenon. All these changes, taken together, point strongly to military conquest.

Tiahuanaco designs, derived through Huari, are seen on coastal textiles as well as on pottery, and they are found particularly on tapestry. Besides recognizable figures like the Doorway God and his attendants, there are many examples, perhaps somewhat later in date, on which only the divided eyes—in black and white or other combinations of colours—can be inferred to belong to human or animal figures.

Pachacamac, on the central coast, which survived until Inca times as a great temple and oracle, was established as a ceremonial centre by the beginning of the Middle Horizon. At that time it also became a considerable town, with a degree of independence in the Huari empire, as is demonstrated by the presence of its own local variety of coastal Huari pottery—distinguished by the frequent depiction of a creature, sometimes called a griffin, with a winged feline body, human hands, and an eagle head, or sometimes the head alone—from Pachacamac north to Chicama, south to Nazca, and inland to Huancayo. Its influence may have been more religious than political, as in Inca times.

The Moche pottery style disappeared from the Chicama and neighbouring valleys under Huari pressure, but it is unlikely to have become entirely extinct because many features of it reappeared later on Chimú pottery. It probably survived, along with a remnant of the Moche state, in some valleys farther north (including perhaps Lambayeque), but the succession there has not been sufficiently worked out to demonstrate this.

When the Huari Empire reached its maximum extent, at about 800, it collapsed at the centre. Huari was abandoned, as it appears was Cajamarquilla, a large urban centre near Lima. Also at this time, it appears that construction peaked at Tiahuanaco—which is estimated to have had 5,000 to 10,000 inhabitants—although the city's influence on the region continued. Thereafter, few signs of urban life occur in the south, except at Pachacamac, until Inca times. Curiously, the decline of the cities in the south appears to have coincided with the beginnings of urban settlement on the northern coast at Chan Chan, Pacatnamú, and other places.

After Huari fell, signs of new influences from there dis-

The fall
of Huari

appeared in the provinces, but various changes evolved in local pottery styles. Among these was the development of a new style on the north-central coast. One of the most distinctive products of this style was a face-collar jar, in many cases oval, decorated in pressed relief with cats and other Huari-derived designs and painted in washy black, white, and orange on a buff ground (Huari Norteño B). Other examples are the Epigonal styles of Nazca and Ica, characterized by bowls and flasks with occasional Huari motifs, such as animal heads, carried out in what has been described as "a slovenly, rounded and hasty" manner.

THE LATE INTERMEDIATE PERIOD

The Chimú state. The Late Intermediate Period began about 1000 (Rowe has said 900) with the dying out of the signs of unity imposed by Huari. The seeds of the Chimú state were probably sown at the same time, but they are not recognizable until considerably later. Elsewhere there were small independent states, which on the central and southern coasts were in most cases no bigger than a single valley, to judge from the distribution of the distinct pottery styles.

There were few new advances in techniques, and perhaps the most notable was the spread of bronze to the Peruvian coast from northwest Argentina and Bolivia, where tin ore was found and where the manufacture of bronze appears to have originated during the Middle Horizon. A hard alloy of copper and arsenic had been used previously in the centre and north. Pottery improved in quality in most areas, though its artistic character was not equal, for instance, to the earlier products of Moche and Nazca. There was a tendency toward standardization and toward reduction in the number of colours, which went with a degree of mass production. The modeling tradition of the north coast revived, but it was dull and lifeless by comparison with that of Moche times and was generally executed in black ware. In other parts, entirely new styles evolved. That of Chiclaya, on the central coast, was thin, dull red or cream in colour, with rather a dusty-looking cream slip and painted decoration in black. A common shape was an egg-shaped jar with a flaring collar and a pair of small loop handles, which were sometimes turned into a figure by modeling a face on the collar and adding ill-shaped limbs. Bowls and beakers with slightly bowed, almost vertical sides, were other common shapes. The porosity of the ware and the flaky nature of the slip made this pottery inferior in quality to that of other coastal areas. In the south, pottery of an attractive style was made in the Ica Valley. It was hard, well-burnished buff or red ware, covered with painted, textile-derived patterns in black, white, and red, although some vessels also depicted small birds and fish. Highly characteristic are bowls with a rounded base meeting the inward-sloping sides at a sharp angle and a thickened rim of triangular section.

It is difficult to determine whether any new textile techniques were adopted, but it is unlikely since the extreme versatility of the Peruvian weavers appears already to have covered most of the imaginable varieties at one time or another. On the other hand, fashions varied, and a relevant instance is the use of tapestry. Tapestry was known in the Early Horizon, suffered something of an eclipse in the Early Intermediate Period, and grew greatly in popularity in the Middle Horizon, when notable examples were produced. During the Late Intermediate Period its popularity waned again, although it was used for the finest garments on into the Inca Period; but in Chimú textiles it was generally confined to borders and other small areas. Textiles were similar over the whole coast, and to distinguish between those of different areas is a task for specialists. Some of the most characteristic types were garments adorned with regular rows, horizontal or diagonal, of stylized birds or fish, executed in brocade or double cloth.

In most of the northern valleys, irrigation systems reached their maximum extent; and the Virú Valley—which has been the most thoroughly studied—is deceptive in this respect, because much of the land went out of cultivation, possibly owing to removal of part of the population to other valleys by the Chimú rulers. In some cases, the systems of more than one river were connected, and water

was taken, for instance, from the Chicama Valley to that of Moche, where Chan Chan was situated.

The legendary Chimú ruler Nançen Pinco, who began to expand the state, is thought to have begun his reign about 1370, and the names of two predecessors are known; so it is a fair guess that the state was taking shape in the first half of the 14th century, when distinctively Chimú pottery forms appeared. Various rather exotic pottery styles dating before this time have been found in the northern area, but insufficient work has been done on their distribution in time and space. An early type consisted of bottles on a ring base with a loop handle and a narrow, tapering spout, decorated with geometric designs and cursive scrolls in black on a red-and-white ground. There were double whistling vessels, with modeled figures on one vessel connected to a tapering spout on the other by a flat, arched bridge; some early examples were of orange ware with a few dark-red stripes on the spout and bridge, but later ones were black. Carinated whistling vessels of black ware with hornlike projections above the ears on a ring base, with a tapering spout connected to a figure by a bridge, also have been found at an early stage. Similar vessels with two spouts connected by a bridge had a considerable range in time. Another form was a bottle, of black ware, with a tapering spout emerging from a modeled figure or head. These vessels had a strap handle and ring base of variable height. Many of the later blackware vessels had panels in pressed relief, a form of decoration that continued through Chimú times; these bore designs such as men holding staves, moons, or cats on a background of raised dots.

The overwhelming majority of Chimú vessels were of black ware. There was a revival of stirrup spouts, either on modeled vessels such as human figures or reed balsas, or on plain ones with or without pressed relief panels, and these normally had a monkey sitting on the stirrup at the base of the spout. Double vessels, often with a bird head to balance the spout and pressed relief panels on the bodies, continued. Many vessels were lentil-shaped. Jugs with strap handles and pressed relief panels sometimes took on a flattened section to become canteens. These are only a few of the forms that have been found, some resembling immediate predecessors, some new, and some, especially the stirrup spout, revivals of earlier types.

Nançen Pinco is believed to have conquered the coast from the Saña River, just south of Lambayeque, south to Santa. After him came six rulers before Minchancaman, who conquered the remainder of the coast from at least as far north as Piura and possibly to Tumbes, south almost to Lima. His triumph was short-lived since he himself was conquered by the Inca in the early 1460s.

The Chimú state originated in the Moche Valley, where its capital, Chan Chan, lay. There were other cities at Farfán and Pacatnamú in the Pacasmayo Valley and at Purgatorio and Apurí in the Leche and Motupe valleys, respectively, which shared some features with Chan Chan. All included large walled compounds. Apart from the cities, there were defensive settlements, such as one in the narrow part of the Moche Valley, up which it straggled for five miles, occupying terraced hillsides and side valleys and commanding three of the main canals. A third type of settlement consisted of scattered compounds in the midst of large irrigated areas, one example of which was found in the Chicama Valley alongside an irrigation canal that took water to Chan Chan. Chan Chan covered an area of about 14 square miles (36 square kilometres), with a central area of about 2.5 square miles containing 10 or more large rectangular enclosures sometimes called *ciudadelas* ("citadels"). These were surrounded by tapering adobe walls, 10 feet thick at the base and about 30 feet high. They ranged in size from about 400 by 200 yards to 650 by 400 yards.

At least six of these citadels have similar plans, and one has been studied in detail. It has a narrow opening at the north end and is divided into three parts by high walls. The northern part contains a large entry court, flanked by a kitchen area and several smaller courts, leading to a densely built area of small courts, some of which have a U-shaped structure at one end, while others are filled

Chimú
pottery

Chan Chan

Chimú
textiles

with small rooms. The U-shaped structures, which do not appear to have been roofed, may have been shrines, and the courts that contain them may have had walls covered with mud-plaster reliefs, such as bands of animals, birds, or fish, scrolls or step frets, arranged in a manner reminiscent of Chimú textiles. The central part has a somewhat smaller entrance court leading to several courts occupied by rooms, perhaps storerooms, although nothing was found in them. Another feature of this area is a great burial platform with rows of chambers arranged in three levels. All these features are connected by narrow and tortuous passages. The southern part is an open area, containing one or more *pukios* (rectangular areas where the ground has been lowered to the water table, either to supply water or to grow plants). In the spaces between the enclosures, and elsewhere in the city, are large areas of dwellings, irrigated areas, and cemeteries.

It is now thought that the *ciudadelas* may have been the dwellings of the ruling classes and their immediate retainers, and it has even been suggested that they were the palaces of successive rulers, maintained by their descendants in the way that those of deceased Inca were maintained in Cuzco. The number of recognizable *ciudadelas* agrees with the number (10) of known Chimú rulers. This intriguing suggestion is further supported by the belief that the Inca learned a great deal from the Chimú after they conquered them, for, not content with carrying Minchancaman off to Cuzco, they established a colony of north-coast workmen there, and Topa Inca Yupanqui (Thupa 'Inka Yupanki) appears to have worked out the political organization of the empire at the same time, basing it largely on the Chimú system.

Roads between the valleys were always necessary to coastal states and were vital to the Chimú, and the Inca may have learned something in this connection also. There are almost continuous traces of a road from just north of Lambayeque to the Chao Valley just south of Virú, with remains even farther south in Santa, Nepeña, and Casma. The remains differ in elaboration and tend to be wider and more imposing near the cities; in the deserts between valleys they were tracks marked by posts or bordered by low walls, but in the valleys the simplest type is a leveled surface 15 to 25 feet wide, with walls of stone or adobe about three feet high and with the surface of the road sometimes being raised.

Although the Chimú had a powerful, aggressive, organized state, their dependence on elaborate irrigation systems for the maintenance of concentrated populations rendered them vulnerable to attack, which was one of the main factors that enabled the Inca to take them over comparatively easily. (G.H.S.B./J.V.M.)

The Chincha. The growth and expansion of Chimú were paralleled on the southern coast by Chincha, which was a similarly well-organized polity. Comparison between them has been difficult because of the very different evidence available. Whereas Chimú has become familiar through extensive archaeological research, data on the Chincha has come primarily from the study of historical sources.

In the first few years of Spanish rule, the Holy Roman emperor Charles V complained that he had not received any of the newly conquered lands as a personal fief. The conquistador Francisco Pizarro and his brother Gonzalo hurried to assign him three ethnic groups: (1) The Ayмара kingdom of the Lupaqa, listed on the Inca quipu at 20,000 households; (2) the tropical island of Puná, in the Gulf of Guayaquil in modern Ecuador, with an unknown aboriginal population; and (3) the coastal Chincha polity, allegedly with 30,000 households. Unfortunately for the Chincha, their population vanished within the first three decades of the Spanish invasion; the royal affiliation and proximity to Lima did not help protect the Chincha.

Belonging to the crown, however, did promote account keeping and administrative reports to the Spanish court. The unusual feature about Chincha was its considerable orientation to the sea. Several thousand households were listed as high-seas fishers and sailors, and thousands more were engaged in long-distance trade with lands to the north. Because the waters off the Chilean and Peruvian coast were cold, there was a long-standing interest in the

warm waters off the Ecuadorean coast, more than 1,000 miles away, where the Antarctic current was no longer present. The details of these exchanges are not known, but one feature was paramount in Andean eyes: throughout the central and southern Andes, wherever puna dwellers were the dominant population, there was a demand for the spiny oyster (*Spondylus*), the shells of which were believed to encourage rainmaking. The one Quechua literary text available lists the spiny oyster as the favourite food of the gods, although it was inedible for humans.

While there has been a long-standing archaeological interest in the shells of this mollusk, the extent and the organization of the shell traffic has not been verified archaeologically. One of the witnesses of the invasion, Pedro Pizarro (a cousin of Francisco), reported being told that the Chincha lord had 100,000 rafts on the "Southern Sea." The number need not be accurate: even 1,000 oceangoing rafts, with keels and sails, would imply a major economic operation.

Chimú and Chincha have received considerable attention from non-Peruvian scholars; understanding of the contemporaries of these peoples in the highlands, however, has remained sketchy. The oral tradition reported by the early European observers claimed that before the expansion of Tawantinsuyu, the Inca state, there were many polities large and small, all ruled by traditional lords and frequently at war with one another. To what extent the notions of ecological complementarity or the vertical archipelago were attempts to bridge these conflicts or their consequences cannot be stated with any certainty.

The 17th-century Andean writer Felipe Guamán Poma de Ayala (Waman Puma) reported the oral tradition that he had learned from his forebears, who were minor ethnic lords in the Huánuco region. In the century before the Inca conquest people had lived in the "epoch of the soldiers." During this period,

they began to fight and there was much war and death . . . one lord against the other . . . bloodshed and taking of prisoners. And they also grabbed their wives and sons and took their fields and irrigation waters and pastures. And they were very cruel and stole each other's property, cloth, gold, copper, even their millstones. . . . And so they went and settled on the heights where they built walls and houses inside . . . and wells to draw water.

Poma de Ayala's description of Late Intermediate settlement patterns on mountaintops, at the very edge of and even beyond puna cultivation, has been confirmed by field research undertaken near Lake Titicaca by the American archaeologist John Hyslop. He found dozens of walled-in enclosures of 50 to 100 acres and larger. During the Late Horizon—which corresponds to the century of Inca rule—these populations were moved to the lakeshore, along the royal road.

The Inca

Forty years had elapsed since Columbus' landfall when in 1532 fewer than 200 Spaniards brought down the Inca (Inka) state. Ever since then, historians have been pondering the reasons for this sudden collapse. The evidence seems to favour internal subversion. Don Francisco Cusichaq, lord of the Huanca in central Peru, opened the country to alien rule; he wanted to destroy his hereditary enemies, the Inca. The Andean pattern of many dispersed regional polities that frequently were at war with one another—a situation that the Inca had manipulated but had not eliminated—and the diverse archipelago-like string of the communities may also have facilitated the relatively effortless Spanish victory.

By 1532 Tawantinsuyu, the Inca state, had incorporated dozens of coastal and highland ethnic groups stretching from what is now the northern border of Ecuador to Mendoza in west-central Argentina and the Maule River in central Chile—a distance roughly equal to that between New York City and the Panama Canal. By conservative estimates the Inca ruled more than 12,000,000 people, who spoke at least 20 different languages. A century earlier, during the wars of the Late Intermediate, they had controlled little beyond the villages of their own Cuzco

Table 2: Inca Rulers and Royal Corporations

Inca name	Spanish spelling	panaca (royal corporation)
Manco Qhapaq	Manco Capac	Chima
Zinchi Roq'a	Sinchi Roca	Rawra
Lloq'e Yupanki	Lloque Yupanqui	'Awayni
Mayta Qhapaq	Mayta Capac	'Uska Mayta
Qhapaq Yupanki	Capac Yupanqui	'Apu Mayta
'Inka Roq'a 'Inka	Inca Roca	Wika-k'iraw
Yawar Waqaa	Yahuar Huacac	'Awqaylli
Wiraqocha 'Inka	Viracocha Inca	Zukzu
'Inka 'Urqon	Inca Urcon	none
Pachakuti 'Inka Yupanki (1438-71)	Pachacuti Inca Yupanqui	'Inaqa
Thupa 'Inka Yupanki (1471-93)	Topa Inca Yupanqui	Qhapaq
Wayna Qhapaq (1493-1525)	Huayna Capac	Tumipampa
Washkar 'Inka (1525-32)	Huascar	Washkar
'Ataw Wallpa 'Inka (1532-33)	Atahualpa	none
Thupa Wallpa (1533)	Topa Huallpa	none
Manco 'Inka Yupanki (1533-45)	Manco Inca Yupanqui	none (?)

Valley. While forming their state they subordinated more than 100 independent ethnic groups; how much of this achievement corresponded to political experience gained during the Middle Horizon cannot be told. It is likely that the memory of that multiethnic expansion was alive in the ruling families of the major polities.

THE ORIGINS AND EXPANSION OF THE INCA STATE

Inca origins and early history are largely shrouded in legends that may be more mythical than factual. Their later history, particularly from the reign of Pachacuti Inca Yupanqui (Pachakuti 'Inka Yupanki) onward, is largely based on fact, even though it presents what the Inca wanted people to know. Whether these historical traditions are true, in the sense that they accurately related what happened, is not so important as the fact that the Inca used them to justify their various imperial conquests.

Bookkeeper (right) rendering accounts to the Inca ruler Topa Inca Yupanqui. The contents of the storehouses (foreground and background) are recorded on the bookkeeper's quipu of knotted strings. Drawing by Felipe Guamán Poma de Ayala from *El primer nueva coronica y buen gobierno*.

The nature of the sources. The Inca kept detailed accounts of their dynastic history, knotted onto the quipu records kept by professional accountants. The major local ethnic lords also kept records. As mentioned above, Don Francisco Cusichaq kept records of Spanish exactions, which were offered to and accepted in evidence by Spanish administrators. Through the study of Cusichaq's quipu, modern researchers have learned that there was both a quantitative and a historical dimension to Andean records. Cusichaq's quipu refers to more than 20 separate events—all recorded in perfect historical sequence—but the way in which these events were recorded has not been fathomed. The quantitative record, which was easier to decipher, lists counts of men and women on the first two cords, followed by the number of domestic animals (llamas being separated from alpacas). Cloth, the most valuable commodity according to Andean reckoning, comes first among the goods listed, followed by food and household items. The quipu could incorporate strings for new, Spanish items. Thus, in Cusichaq's records Spanish sandals are itemized separately from Andean footwear, and eggs and imported hens have their own strings.

The quipu records

The Cuzco bookkeeping records were used by the Spanish in the early days of their rule in order to divide the country and its population among the invaders. The accuracy of the information about distant places and peoples available to the Inca rulers astonished the Spanish observers. Some among them transcribed what they were told; these accounts became the source of the fragmentary information available to modern researchers. In 1549 and again in the 1570s systematic efforts were made by the Spanish to investigate the Andean past. Some of the interviewers were excellent ethnographers who noted discrepancies between separate oral traditions and contradictions from one set of claims to another. Just as in Mexico, where there were true ethnographers like Bernardino de Sahagún, so in the Andes a young soldier, Pedro de Cieza de León, was a remarkable interviewer, who constantly checked what he had been told by the members of one royal lineage against alternate versions.

Thus, the present knowledge of Inca society has been derived from a combination of archaeological studies and the written accounts sent to Spain by the early Spanish observers. Some of these accounts reached a wide public: within two years of the fall of the Inca, two quite different versions of what happened at Cajamarca (the place where Pizarro first met and kidnapped the Inca ruler Atahualpa) were already in print in Europe. One of these was the official version of the Pizarro brothers, while the other criticized their actions. At a time when printing was still a rare skill and censorship was severe, such ample coverage of the invasion is notable.

The first serious study of the Andean peoples was written by Cieza de León, who had reached the Americas as a 14-year-old soldier and had settled in what today is Colombia. A decade or so later he drifted by horse to what is now Peru; he then rode for some 1,300 miles, traveling as far south as the mines at Potosí, in present-day Bolivia. Cieza de León was encouraged by the clergy, many of them partisans and correspondents of the Dominican missionary and historian Bartolomé de Las Casas, to interview both Spanish and Andean participants of the invasion and of the wars that some Andean factions had fought against one another.

Work of Cieza de León

The most widely read source during the colonial period was the work of Garcilaso de la Vega, also called El Inca—the son of an Inca royal woman and a Spanish nobleman (whose name the son adopted when he "returned" to his father's estate in Spain). He lived in Spain nearly 60 years, leading the life of a gentleman, reading, translating love poetry, editing the memoirs of one of the early invaders of Florida, and, finally, writing a vast account of his mother's ancestors, *The Royal Commentaries of the Inca*.

Guamán Poma de Ayala (Waman Puma) was one of the few Andean writers whose work is available. He wrote a 1,200-page "letter" to Philip III of Spain, consisting of two books combined into one. The first book was a "new chronicle," describing Andean achievements and history; the second, much larger part advised the king on how to

achieve a “good government.” The second included 400 pages of pen-and-ink drawings, which have remained a major contribution to the modern understanding of Andean society. The manuscript somehow reached the Danish Royal Library in Copenhagen, where it was discovered in 1908 and where it still resides.

Settlement in the Cuzco Valley. Several of the modern Andean peoples trace their ancestries to mythical figures who emerged from holes in the ground. These places of origin, or *paqarina*, were regarded as shrines, where religious ceremonies had to be performed. The Inca *paqarina* was located at Paqari-tampu (Paccari Tampu), about 15 miles south of Cuzco. There are three caves at Paqari-tampu, and the founders of the Inca dynasty—Manco Capac (Manqo Qhapaq), his three brothers, and his four sisters—supposedly emerged from the middle cave. They assumed leadership over 10 groups of people, or *ayllus*, that emerged from the caves on either side and led them on a journey lasting an unknown number of years.

During this period the Inca and their followers moved from village to village in search of enough fertile land to sustain themselves. Manco Capac succeeded in disposing of his three brothers. One of his sisters, Mama Ocllo, bore him a son named Sinchi Roca (Zinchi Roq’a). Eventually, the Inca arrived at the fertile area around Cuzco, where they attacked the local residents and drove them from the land. They then established themselves in Cuzco and gradually began to meddle in the affairs of their neighbours, forcing them to pay tribute in order to retain their freedom.

By this time Manco Capac was quite old and close to death. In order to ensure that all he had accomplished would be preserved for posterity, he named his eldest son, Sinchi Roca, to succeed him to the throne. He then directed his next eldest son to shelter and care for all of his other children and their descendants, who composed the Chima *panaca*. The traditions say little about Sinchi Roca, the second emperor, but apparently he was a peaceful man who made no military campaigns to add lands to the Inca domain. It is not clear whether or not Sinchi Roca married his sister, as his father had done. It is clear, however, that he did not follow his father’s lead in naming his eldest son as his successor, for the third emperor, Lloque Yupanqui (Lloq’e Yupanki), had an older brother. Lloque Yupanqui, like his father, was not warlike and added no lands to the Inca domain.

The demand for additional lands and, more importantly, the resources they could provide first became apparent during the reign of the fourth emperor, Mayta Capac (Mayta Qhapaq). The reasons for the appearance of this need in the 14th century are undoubtedly complex, and any single-factor explanation is probably insufficient. But one possible explanation may lie in the fact that rainfall began to diminish very slightly about this time throughout the central Andes. In an area like the Cuzco Valley, this would imply that some of the marginal farmlands were either abandoned because they could not be watered adequately or were less productive than they had been earlier. Given this situation, if the Inca attempted to maintain their old standard of living, they might have placed some pressure on their food resources. One way of alleviating the problem would have been to acquire additional land and sources of water in an adjacent part of the valley. This is apparently what Mayta Capac did.

Mayta Capac is described in the chronicles as a large, aggressive youth who began fighting with boys from a neighbouring group when he was very young. Pedro de Cieza de León and Pedro Sarmiento de Gamboa (who also was one of the more reliable Spanish chroniclers) indicate that the quarrel began because the Inca were taking water from this group, although they differ on the details concerning who actually took the water. By the time Mayta Capac became emperor, this quarrel had grown into a full-scale war, which the Inca won. They looted the homes of their enemies, took some of their lands, and probably imposed some sort of tribute payment on them.

The beginnings of external expansion. The fifth emperor, Capac Yupanqui (Qhapaq Yupanki), was appointed ruler by his father before he died. He was apparently not

the eldest son but was named emperor because his older brother was considered ugly. Capac Yupanqui was the first Inca ruler to conquer lands outside the Cuzco Valley, although these were only about a dozen miles away. Inca Roca (Inka Roq’a Inka) succeeded his father and subjugated some groups that lived about 12 miles southeast of Cuzco. He is mostly remembered in the chronicles for the fact that he fathered a large number of sons, one of whom, Yahuar Huacac (Yawar Waqac), was kidnapped by a neighbouring group when he was about eight years old. The boy’s mother, Mama Mikay, was a Huayllaca (Wayllaqa) woman who had been promised to the leader of another group called the Ayarmaca (Ayarmaka). When the promise was broken and Mama Mikay married Inca Roca, the Ayarmaca went to war with the Huayllaca and were defeating them. As a peace offering, the Huayllaca agreed to deliver Mama Mikay’s son to the Ayarmaca. This tale says a great deal about the way war was waged around the Cuzco Valley at this time; the fact that the Ayarmaca held the boy for several years before returning him to his father suggests that the Inca were no more powerful than several other groups in the area.

Two years before his death, Inca Roca named Yahuar Huacac as the seventh emperor, ensuring a peaceful succession to the throne. Yahuar Huacac was never very healthy and apparently spent most of his time in Cuzco. His brothers Vicaquirao (Wika-k’iraw) and Apo Mayta (Apu Mayta) were able military leaders and incorporated lands south and east of Cuzco into the Inca domain. Yahuar Huacac’s principal wife was apparently an Ayarmaca, indicating that at that time sister marriage was not the rule (see below *Civil war on the eve of the Spanish conquest*). She bore him three sons, and he attempted to follow his father’s example by naming her second son as the next emperor; the son was murdered through the intrigues of another of his wives, who wanted her own son named to the throne. The Emperor himself was apparently killed shortly thereafter, and the elders chose Viracocha Inca (Wiraqocha Inka) as his successor.

The Inca conquest began during the reign of Viracocha Inca in the early part of the 15th century. Up to this time, neighbouring ethnic groups were conquered and their lands taken, but no garrisons or Inca officials were placed among them. They were left undisturbed until the Inca felt it necessary to attack them again. This pattern of raiding and plundering changed during Viracocha Inca’s reign. He planned to establish permanent rule over these groups and was ably assisted by his uncles, Vicaquirao and Apo Mayta, who developed military tactics that made permanent conquest possible. Their victory over the Ayarmaca kingdom in the southern Cuzco Valley provided a model for many subsequent campaigns. They first conquered lands in the upper part of the Urubamba Valley that lay behind the Ayarmaca territory. They then successfully attacked the Ayarmaca from two directions—one force coming from Cuzco and the other from the Urubamba Valley.

This was a relatively small-scale campaign, but it made the Inca a political power in the Urubamba Valley, an important passageway between Cuzco and the Lake Titicaca Basin. As a result of their conquest, the Inca were invited to interfere in a conflict between two Aymara-speaking kingdoms, the Colla and the Lupaca, in the northern part of the Titicaca Basin. The Inca allied themselves with the Lupaca, probably because the Colla were located between themselves and the Lupaca. But before the Inca could attack, the Colla attacked the Lupaca and were defeated. The battle was over by the time the Inca arrived; they joined in a victory celebration with the Lupaca but did not share in the booty.

During the early 15th century a group called the Chanca was emerging as a political power in the area west of the Inca territory. Presumably, they, too, may have been feeling the effects of diminishing food resources and were trying to maintain their standard of living by acquiring land outside their home territory. They moved from their place of origin in Huancavelica and conquered the Quechua (K’ichuwa), a large group whose lands lay immediately west of those controlled by the Inca. In about

ning of
permanent
conquests

Rise of the
Chanca

1438 the Chanca attacked the Inca. One of the major effects of the Chanca invasion was to foment a civil war among the Inca.

Pachacuti Inca Yupanqui. For some time there had been palace intrigue in Cuzco over who would succeed Viracocha Inca to the throne. The Emperor chose Inca Urcon ('Inka 'Urqon) as his successor, but the two generals Vicaquirao and Apo Mayta preferred another son, Cusi Inca Yupanqui (Kusi 'Inka Yupanki). As the Chanca approached Cuzco, Viracocha Inca and Inca Urcon withdrew to a fort near Calca, while Cusi Inca Yupanqui, the two generals, and a few nobles remained to defend the city. They defended it successfully, and after their allies joined them they inflicted two heavy defeats on the Chanca. Cusi Inca Yupanqui then attempted to resolve the differences between his faction and that of his father; but the negotiations failed, and he set himself up as emperor, taking the title of Pachacuti (Pachakuti). At this point, there were two Inca states, one in Cuzco, headed by Pachacuti Inca Yupanqui, and the other in Calca, headed by Viracocha Inca. As the power and prestige of the Cuzco group increased, many people left the Calca faction to join Pachacuti Inca Yupanqui.

Pachacuti Inca Yupanqui had to deal simultaneously with two enemies—the Chanca and his father's forces. The Cuzco faction had made some gains during their two encounters with the Chanca; they took some Quechua lands from the Chanca and formed an alliance with the Quechua, who supported them against the Chanca. They then entered into an agreement with the Chanca that permitted either group to make independent military advances or gains as long as the other was not attacked. At this point, the Cuzco faction moved its army eastward to the edge of the tropical rain forest, thereby encircling the lands controlled by the Calca faction. By this maneuver, the Cuzco faction prevented the possibility of attack coming simultaneously from two directions. Viracocha Inca died about this time, leaving Inca Urcon as leader of the Calca faction. The latter was killed shortly thereafter in a skirmish with the Cuzco group. As a result, the differences between the two factions were resolved, and the Inca were reunited under a single leader.

The Inca forces crossed the Quechua territory and attacked the provinces of Vilcas and Soras, southwest of the area controlled by the Chanca. In about 1445, Pachacuti Inca Yupanqui sent his brother Capac Yupanqui (Qhapaq Yupanki) to explore the south coast, marking the first time the Inca reached the ocean. Returning to Cuzco, Capac Yupanqui passed through Chanca territory and captured a few of their villages. The Chanca retaliated by outflanking the Inca and conquering the Colla in the Lake Titicaca Basin.

The Chanca's action increased the tension between the Inca and the Chanca, but no fighting broke out. Instead, they decided to undertake a joint invasion of the area north of Vilcas. Pachacuti Inca Yupanqui appointed Capac Yupanqui to lead the Inca contingent, warning him of Chanca treachery and instructing him to go no farther than Yanamayo. As the expedition moved northward, the Chanca distinguished themselves in battle, to the embar-

assment of the Inca. When Pachacuti Inca Yupanqui heard of this, he feared that the Chanca contingent might revolt and ordered his brother to kill the Chanca leaders. The Chanca, learning of this command, fled to the tropical rain forest near the headwaters of the Huallaga River before the order could be carried out.

Capac Yupanqui pursued the Chanca well beyond the Yanamayo, the limit set by his brother, before giving up the chase. Seeing that his forces were considerably overextended, he turned northward toward the rich province of Cajamarca, which was an ally of the powerful kingdom of Chimú on the north coast. Capac Yupanqui stormed and captured Cajamarca and left a small garrison there as he set out for Cuzco.

Pachacuti Inca Yupanqui was furious at this turn of events. His orders had been blatantly disobeyed, and he was apprehensive about his brother's intentions. Perhaps fearing that Capac Yupanqui would usurp the throne, Pachacuti Inca Yupanqui had him killed before he arrived in Cuzco. The Inca still had to contend with the Chanca and with the possibility of attacks from hostile groups in the north, including the kingdom of Chimú, which had set out on a campaign of conquest.

To alleviate this situation, Pachacuti Inca Yupanqui organized two expeditions: one to conquer the peoples of the Titicaca Basin and protect their exposed southern flank and the other to subdue the area to the north. According to Sarmiento de Gamboa, the Titicaca campaign was led by two of his older sons. They had subjugated the Colla earlier and now turned their attention to the Lupaca and their allies. When the campaign was over, the Inca controlled all of the territory between Cuzco and the southern end of the lake basin.

The northern expedition was led by another son, Topa Inca Yupanqui (Thupa 'Inka Yupanki), who subjected the territories of the Quechua and the Chanca. Topa Inca Yupanqui marched north through the highlands toward Cajamarca, subduing and pacifying the country as he went. After relieving the garrison at Cajamarca, which was being threatened by the kingdom of Chimú, he conquered as far north as Quito (Ecuador) in an attempt to outflank the Chimú armies. Frustrated during this drive by his ignorance of the geography of the region, he came out of the Ecuadorian mountains near Manta, north of the Gulf of Guayaquil; the local residents told him that he could not proceed southward along the coast because the mountains came down to the sea. So he returned to the highlands and sent a small force along the shores of the Gulf of Guayaquil toward the northern border of Chimú. As a result, the Inca were still able to attack the Chimú armies simultaneously from several different directions. After a brief but bitter battle, the Inca sacked the Chimú capital at Chan Chan and then advanced southward along the coast as far as Pachacamac, bringing the area under Inca control.

Topa Inca Yupanqui returned to Cuzco, secure in the knowledge that Inca power could not be challenged. The rapid expansion of the empire, however, created a number of problems concerned with sustaining themselves and governing a large number of diverse ethnic groups.

Pachacuti Inca Yupanqui and Topa Inca Yupanqui were imaginative and made several important innovations in Inca institutions.

Pachacuti Inca Yupanqui began rebuilding Cuzco, the political and religious capital of the empire. Considerable effort was put into enlarging Sacsahuamán, the huge fortress built on a hill overlooking the city. At the same time he undertook a vast agricultural project over the entire upper end of the Cuzco Valley; rivers were channeled, the valley floor was leveled, and agricultural terraces were built on the surrounding hillsides. This reclamation project undoubtedly increased the agricultural productivity of the area and involved moving many of the original inhabitants of this part of the valley to other localities for several years while the work was being completed.

Pachacuti Inca Yupanqui also turned his attention to social problems. He decreed that no ruler could inherit property from his predecessor; instead, the property of a dead ruler was to pass to his other descendants, who could then support themselves from his lands and the labour taxes owed him. Consequently, each new emperor had to acquire land and labour to support his corporation and government. Pachacuti Inca Yupanqui thus ensured that the corporations of his eight predecessors had estates in the area around Cuzco so their members could support themselves adequately, attend certain ceremonies, and perform ceremonial obligations. Pachacuti Inca Yupanqui and his successors to the Inca throne formed corporations that had lands and estates scattered throughout the empire as well as in the Cuzco Valley itself.

Policy of
mitma

He probably also began the policy of forced resettlement, or *mitma*, about this time, in order to ensure both loyalty to the state and better utilization of land resources, at least from the perspective of the Inca. This practice involved moving some members of an ethnic group from their home territory to distant lands. When a new area was conquered, loyal settlers were brought in from a province that had been under Inca rule long enough so that its residents knew how the Inca system of government worked. They were replaced in their home territories by recalcitrant groups from the newly conquered province. The policy had three important consequences: first, it broke up the size and power of an ethnic group by dispersing its members throughout the empire; second, it weakened the ability of an ethnic group to be self-sufficient; and, finally, it made it more difficult for the inhabitants of an area to revolt successfully.

Pachacuti Inca Yupanqui invented a state religion based on the worship of a creator-god called Viracocha, who had been worshiped since pre-Inca times. Priests were appointed, ceremonies were planned, prayers were prepared, and temples were built throughout the empire. He also expounded the view that the Inca had a divine mission to bring this true religion to other peoples, so that the Inca armies conquered in the name of the creator god. His doctrine was a relatively tolerant one. Conquered groups did not have to give up their own religious beliefs; they merely had to worship the Inca god and provide him and his servants with food, land, and labour.

Topa Inca Yupanqui. About 1471, Pachacuti Inca Yupanqui abdicated in favour of his son Topa Inca Yupanqui, thereby ensuring the peaceful succession to the throne. Topa Inca Yupanqui was a great conqueror who was to bring most of the Central Andes region under Inca rule. Yet his first military campaign as emperor, an invasion of the tropical rain forest near the Tono River, was not particularly successful. The Inca were always fascinated with the rain forest and its products but never got used to military operations in this type of environment. This campaign did, however, establish trade relations with the area and secured a contingent of archers in return for a few bronze tools. The Emperor soon abandoned the campaign because of a revolt that had broken out in the Titicaca Basin. The rebellion was led by the Colla and Lupaca and was fanned by the rumour that Topa Inca Yupanqui had been killed during his expedition into the jungle.

The Colla's mountaintop forts around Pucará fell one by one as the Inca attacked them. After subduing the Colla, the Inca moved against the Lupaca, who had retreated to

the southwest corner of the Titicaca Basin, where they had allied themselves with another Aymara-speaking group, the Pacasa. The Inca armies were again victorious, and the revolt was ended. Topa Inca Yupanqui then turned southward, conquering all of highland Bolivia, northern Chile, and most of northwestern Argentina. He set the boundary markers of the Inca Empire at the Maule River in central Chile.

At this point, the southern coast of Peru still had not been incorporated into the Inca state. The area, however, was now surrounded by the Inca on three sides, and in about 1476 Topa Inca Yupanqui launched a campaign against this region. Each valley, beginning with those in the south, was attacked separately. Most valleys submitted peacefully or put up only minimal resistance; the inhabitants of the Cañete Valley, however, put up a stubborn fight; and it took the Inca nearly three years to subdue them.

During the remainder of his reign, Topa Inca Yupanqui concerned himself with the administration of the empire. He spent much of his time traveling throughout his territories, making assignments of land and establishing local administrations. He introduced a system of classifying the adult male population into units of 100, 500, 1,000, 5,000, and 10,000, which formed a basis for labour assignments and military conscription. He also instituted a system of tribute in which each province provided Chosen Women (Aqllakuna) to serve as temple maidens in state shrines or to become the brides of soldiers who had distinguished themselves in combat.

Huayna Capac. Topa Inca Yupanqui's unexpected death in about 1493 precipitated a struggle for the succession. It appears that Topa Inca Yupanqui had originally favoured the succession of Huayna Capac (Wayna Qhapaq), the youngest son of his principal wife and sister. Shortly before his death, he changed his mind and named as his successor Capac Huari (Qhapaq Wari), the son of another wife. Capac Huari, however, never became emperor. The claims of his mother and her relatives were suppressed by the supporters of Huayna Capac. This group was led by Huaman Achachi (Waman 'Achachi), the child's uncle and presumably the brother of the Emperor's principal wife. A regent named Hualpaya (Walpaya) was appointed from this group to tutor Huayna Capac in the ways of government until the child was old enough to rule in his own name. Hualpaya, however, tried to assert the claims of his own son to the throne and, as a result, was killed by Huaman Achachi. Huayna Capac's reign was mostly peaceful; he devoted much of his time to traveling, administering the empire, and suppressing small-scale revolts. He did extend the empire by conquering Chachapoyas, a mountainous country in northeastern Peru, and later northern Ecuador. After conquering Chachapoyas, he recruited part of his bodyguard from the warlike inhabitants of the area. The conquest of northern Ecuador occupied the last years of his life and took place shortly before the Spaniards arrived. During these campaigns, he pushed the frontiers of the Inca Empire to the Ancasmayo River, the present-day boundary between Ecuador and Colombia.

While he was fighting in northern Ecuador, Huayna Capac received word that the Bolivian frontier had been invaded by the Chiriguano, a Guaraní-speaking group that periodically crossed the Gran Chaco from Argentina to raid Inca frontier settlements for bronze tools and ornaments made of precious metals. The Chiriguano were more of a nuisance than an actual threat to the empire, but Huayna Capac dispatched a general named Yasca (Yaska) to drive them from the area and to build forts along the frontier.

Meanwhile, he undertook another expedition in northern Ecuador to wipe out isolated pockets of resistance. During this campaign, he learned that an epidemic was sweeping Cuzco and the surrounding countryside. He left immediately for Quito, on the highroad to Cuzco, to deal with this crisis and arrived there about the same time the epidemic did. The pestilence had spread rapidly from Bolivia and, judging by its description, was either smallpox or measles, both of which were European diseases introduced into South America by the Spanish settlers at La Plata. The disease was probably communicated to the

Conquest
of northern
Ecuador

Andean area by the Chiriguano, who had been in contact with the Spanish at La Plata. Whatever the ailment was, Huayna Capac contracted it and died about 1525, without naming a successor in the appropriate manner. This set off another struggle over the throne.

Civil war on the eve of the Spanish conquest. Huayna Capac's father had begun the custom of marrying a full sister in order to keep the royal bloodline pure and, more importantly, to prevent conflict over succession. According to this custom, one sister became the principal wife of the emperor, and one of their sons became the next ruler. As noted above, this system had failed at Huayna Capac's succession. Nor did it work at Huayna Capac's death because his principal wife had been childless. In this situation, the emperor could appoint any one of his sons as his successor, as long as one of them had "divine" approval registered on the lungs of a sacrificed llama. There were several candidates for the throne: Ninan Cuyuchi who was in Tumipampas with his father; Atahualpa ('Ataw Wallpa), who was also in the north; Huascar (Washkar), who was apparently in Cuzco; Manco Inca (Manqo 'Inka), whose mother belonged to 'Iñaca (the royal corporation of Pachacuti Inca Yupanqui); Topa Huallpa (Thupa Wallpa); and Paullu Topa (Pawllu Thupa).

Huayna Capac, aware of imminent death, asked the priest to perform the divination ceremony to determine whether or not he should name Ninan Cuyuchi as his successor; if the signs were not favourable, then Huascar was to be the next candidate to be tested. The Emperor apparently died before the ceremony was performed. The priest then notified Ninan Cuyuchi that he was to be the next ruler, but the latter had contracted the same disease as his father and died shortly thereafter. The priest then named Huascar as the new emperor; this was highly irregular, because the priest apparently followed the old ruler's wishes without performing the required ceremony. The other candidates for the throne were not pleased with the situation.

The priest brought Huayna Capac's body back to Cuzco, while Atahualpa remained in Quito. Huascar was so furious with the priest for leaving a rival for the throne in the north with a large army that he had him killed. This created animosity against Huascar among the members of the priest's royal corporation. Huascar then demanded that Atahualpa return to Cuzco, but the latter ignored him and undertook a campaign to suppress a revolt around the Gulf of Guayaquil. While he was involved in this expedition, Huascar sent an officer to remove Atahualpa's wives and insignias. Atahualpa killed the officer and had a drum made out of him, which he sent to Huascar. This insult completed the breach between the two rivals, and a civil war resulted.

At this point, Huascar controlled the southern part of the empire, while Atahualpa controlled Ecuador and parts of northern Peru. Atahualpa won the first battle of the war, fought at Riobamba in Ecuador, and advanced to Tumipampas. There he lost to Huascar's army and was taken prisoner. He later escaped, rallied his forces, and drove his brother's army from the Cañari territory around Tumipampas. He then devastated the Cañari lands because he thought they had supported his brother's faction during his imprisonment. Apparently, the Cañari wanted little to do with either Inca faction and offered minimal support to whichever group controlled Tumipampas at the moment. After their lands were destroyed, they wanted nothing at all to do with the Inca, and later they became close allies of the Spaniards.

Atahualpa's armies, led by the able generals Quisquis (Kizkiz) and Challcuchima (Challku-chima), marched south and won a series of decisive victories at Cajamarca, Bombon, and Ayacucho. As they moved southward, Huascar formed another army to defend Cuzco from the invaders. His forces were defeated, and he was captured a few miles from Cuzco in April 1532. The generals killed his entire family and fastened them to poles along a highway leading from the capital. They also killed a number of people in Topa Inca Yupanqui's corporation because they had supported Huascar during the civil war; and they burned the mummy of the deceased ruler, which was venerated by the members of this group. Atahualpa

was in the north, setting up his administration, when he learned of the victory. He ordered Challcuchima to bring Huascar to the north so he could insult him properly before being crowned.

The Spanish conquest. Meanwhile, the Spaniards had landed at Tumbes on the northern coast of Peru early in 1532 and were seeking an interview with Atahualpa so that they could kidnap him. It is clear that they understood the nature of the Inca civil war and were dealing with emissaries from both factions. Their actions, however, must have seemed puzzling to Atahualpa. On the one hand, Pizarro and his men were deposing and executing leaders who were loyal to him, and, on the other hand, they were sending messages that recognized him as the legitimate ruler of Tawantinsuyu. As the Spaniards moved toward Cajamarca, he sent them a message indicating that he was now the sole ruler of his father's domain. Furthermore, he reminded the Spaniards that they were far from their base of supply and in a land controlled by his armies. The Spaniards replied to this veiled threat by indicating that they would come to his aid against any group that opposed his rule. Atahualpa clearly wanted the Spaniards as allies but continually misinterpreted their intentions and underestimated their abilities—even after he was kidnapped in Cajamarca on Nov. 16, 1532.

Atahualpa was allowed to meet with his advisers while the Spaniards held him prisoner, and he arranged to have the ransom they demanded paid. An enormous ransom was raised, but Pizarro did not free him because it would have been too dangerous for the Spaniards. While he was in prison, Atahualpa decided that the Spaniards were indifferent to the idea of having his brother slain and ordered Huascar's death. The Spaniards, of course, wanted all pretenders to authority removed but later used this act to justify their execution of the Inca ruler. Realizing that Atahualpa's death was a mistake because it weakened their position, they approved the coronation of Topa Huallpa, a candidate whom they thought would be acceptable to both Inca factions. But the Spaniards miscalculated. Topa Huallpa had not supported Atahualpa and, in fact, had been in hiding as long as the latter was alive. He was supported by Huascar's group and was opposed by Atahualpa's following, who believed that the legitimate heir was the deceased ruler's son in Lima. With this act, the Spaniards suddenly found themselves closely allied with Huascar's faction and were so viewed by both Inca groups.

Topa Huallpa died within a few months—poisoned, according to Huascar's supporters. At this point, the Spaniards reaffirmed their alliance with Huascar's following, placing Huascar's brother, Manco Inca, on the throne and assisting him in dispersing the remnants of Atahualpa's army. The real Spanish conquest of Peru occurred during the next few years, when they prevented Manco Inca from reestablishing control over the coast and the north, much of which was still loyal to Atahualpa or under no control at all. By 1535 the Inca ruler realized that the Spaniards were more dangerous than any threat posed by the remnants of Atahualpa's followers. But it was too late. His attacks on the Spanish settlements were beaten back, and he was eventually driven into a remote mountainous area called Vitcos, where he established an independent Inca state that lasted until 1572.

INCA CULTURE AT THE TIME OF THE CONQUEST

The rapid incorporation of so many mountain and coastal desert polities before 1532 calls for explanation. It is tempting to view such expansion in the context of the instantaneous breakup in 1532, when some of the same forces were likely to have been at work: dispersed territories, interlocked with some belonging to other powers in the region, and multiethnic and polyglot agglomerations in neighbouring valleys. Each political unit—as eventually was the case with the Inca state itself—was likely to share pastures, cultivated terraces, and beach installations; hegemonies shifted according to local and regional circumstances. The Early, Middle, and Late Horizons were temporary concatenations, and none lasted for very long. The Spanish invasion interrupted these alternations: a

Rule of

player had entered the field who ignored the local rules and who did not fathom the true sources of Andean wealth, which was not silver but an intimate familiarity with local conditions and possibilities and the ability to pool vastly different geographic and ecological tiers into single polities.

Social and political structure. According to the incomplete evidence provided by the Spanish eyewitnesses, the Inca themselves considered the term Inca applicable only to the descendants of the 12 individuals who traditionally are said to have ruled from Cuzco. Of the 12, only four or five can be documented to have been actual historical personages. The others may have been products of later efforts to legitimate and enhance the royal genealogy. There is also the possibility that some of the “earlier” names were actually a parallel line of personalities, possibly with different functions that may have been considered “heathen” by the Spanish. This hypothesis cannot be verified with the sources now available.

In addition to the 12 lineages, the ranks of “Inca by decree” or “as a privilege” are also mentioned by some of the Spanish sources. Their origins and functions were just as nebulous as those of the royals: one of the few Andean sources, Poma da Ayala, claims that some of the inhabitants of the Cuzco basin who were conquered early during the expansion of the Late Horizon were “granted” or “promoted to” Inca status. They were “improved,” according to Poma da Ayala, although his own case is weakened by his claim that his ancestors, who lived many hundreds of miles north of Cuzco, had benefited from such social mobility.

The administrative organization of Tawantinsuyu is poorly understood, although its origins are known to lie in the earlier ethnic subdivisions. Claims have been made that authority was left in the hands of traditional lords who simply had to demonstrate their fealty. Other Spanish sources make reference to an administrative reorganization, in which all of the conquered groups were shoehorned into a decimal system. There is some evidence that decimal subdivisions were present in the Cajamarca region of northern Peru; and at the time of the conquest the decimal vocabulary apparently was in the process of being imposed on the rest of the country, presumably to rationalize the multiplicity of local and divided loyalties. The administrative papers available for a part of the Huánuco region allow the identification of a “hundred-households” unit with five actual hamlets, all of which were near each other. Since these records were kept house by house, it has been possible to test the significance of the decimal vocabulary at its lowest level. What is meant when the records speak of “lords of 10,000 households,” however, cannot now be fathomed.

A clearer picture has emerged of the ethnic lords incorporated by the Inca into their realm. Some had ruled only small units—a few hundred households; others, like the Huanca or the Lupaca claimed to have had 20,000 domestic units. There is no record of the size of the coastal Chimú polity, which must have been quite large. The Chincha claimed 30,000 “fires,” and the Chimú may well have been even larger before their defeat by Cuzco.

Usually, two lords ruled each ethnic group—which has been one of the arguments for considering as plausible a dual rule in Cuzco as well. The best evidence of the duties of the ethnic lords has come from the Aymara kingdom

of the Lupaca: at one point in Inca history they rose in rebellion against Cuzco rule, and in the decades immediately prior to the arrival of the Europeans they were busy leading “6,000 soldiers” on faraway battlefields in what is now Ecuador. The testimony of the Lupaca, collected in 1567, claims that on such adventures they did not return to their lands for the harvest but devoted most of their energies to war, and in return they were exempted from farming, road building, and other state chores.

There was no tribute system in Inca statecraft, just as there had been no contributions in kind in earlier Andean polities. The peasantry owed only their energy, which was delivered through the well-understood *mit'a* system. Led by their traditional leaders, the people appeared for their obligations, lineage by lineage. The best quipu record of these obligations has come from a group who lived in the Huánuco area. Just as they had provided energy for their own lords, under Inca rule this group sent dozens of couples to labour on public works or to produce the grain that, as beer, was “fed” to the mummies of deceased Inca kings. Others became soldiers or helped fill the warehouses; some carried loads along the Inca highway system, while still others were soldiers under the command of their traditional lords. Using this quipu, it has been possible to test the claim that there was no tribute system: of its 26 cords only two deal with articles submitted in kind, wild honey and tropical feathers, both of which were lowland commodities that were gathered and not cultivated.

The absence of tribute was closely connected to the absence of markets. Just as all households owed some of their energies to their ethnic lords, to the shrines, and to Cuzco, so too their household needs were satisfied by the claims they could make to the reciprocal services of their kinfolk or their ethnic peers or to the administrative services of their ethnic authorities. It is probable that with the growth of the Inca state over time, this formula was breached, particularly in the case of prisoners of war and other populations moved from their traditional areas for state purposes.

The most elaborate example of the structural changes that emerged from the need to create new state revenues was the expansion and reorganization of corn production for military purposes in the Cochabamba Valley. This region was the largest single corn-producing area in the highlands. One of the later kings removed the native population and set up a large state enterprise (more than 2,000 warehouses), to which some 25 highland groups were sent on rotation, lineage by lineage. Each ethnic group was responsible for particular strips that were traced across the valley by Cuzco surveyors. In 1575 the Spanish viceroy Francisco de Toledo used this Inca precedent to establish the repartimiento system that provided labour for the silver mines at Potosí.

Inca technology and intellectual life. The intellectual tradition of the Inca emerged from their detailed and efficient knowledge and use of an extremely challenging environment. No system of writing, in the European sense, has been discovered, and the question remains as to how long-distance communication was achieved.

Beyond oral transmission, the most promising domain for research is in textiles. In the highlands very few have been preserved because of the humidity, but on the coastal desert many burial cloths from widely different periods have been located and studied. Their artistic qualities have

Terminology

Administrative organization

Textiles

fomented grave robbing on a very large scale; museums throughout the world have dozens if not hundreds of such cloths, each of great beauty and enormous sophistication.

Fibre technology went beyond burial or sacrificial textiles: Viceroy Toledo wrote to Philip II that he was sending four gigantic cloths on which maps of his Andean realm had been painted. While the letter was carefully filed in the Archives of the Indies, at Seville, the maps have never been located. Other uses of textiles included the quipu used for bookkeeping and possibly also for historical recording; suspension bridges, some of which are still maintained on a regular basis by particular villages responsible for reweaving; and calendars and ceremonial accounting.

While in the field, Inca armies were rewarded with corn and cloth. One European observer was told that soldiers would rebel if they did not receive their issues of textiles and corn beer. A major manufacturing centre employing "a thousand" full-time weavers was established on the northeastern shore of Lake Titicaca. The craftspeople there were men, but every administrative centre along the Inca highway is said to have housed a group of secluded women weavers (Chosen Women); one such house, at Huánuco Pampa (administrative centre of the Huánuco region), has been located and excavated. The storehouses, full of thousands of textiles, were one of the wonders frequently mentioned by the early Spaniards in their letters.

As Tawantinsuyu grew and involved peoples of many different environments and cultures, techniques originating in any particular ethnic group were spread across the land. Prior to the Inca expansion, metals—gold, silver, copper, and their alloys—were used mainly for ornaments; and tools were made from wood and stone. Bronze tools—crowbars, chisels, axes, knives, and clubheads, to name only a few—became exceedingly common after the Inca conquest.

The remarkable Inca highway system was also noted by the earliest Spanish eyewitnesses, since these roads were in constant use, even by horses. Research since the 1950s has provided fresh insights into the engineering methods and geographic location of two parallel roads—one in the highlands, the other on the coast—the whole system adding up to at least 15,500 miles. While some of these roads may have been built first during the Middle Horizon and even earlier, it was during Inca times that the roads were maintained and unified into a single political and economic system. Travel units, adjusted to the pace of a loaded llama or human carrier, can still be detected along the Qhapaq Ñan, the main north-south royal road in the highlands. At the end of each day the caravan stopped at a tambo, a way station, which, although smaller than an administrative centre, was complete with warehouses and barracks. The maintenance of the road segment and the filling of storehouses was part of the *mit'a* responsibilities of neighbouring groups.

Measurement of both distance and surface area was done by units called *tupu*, since the Andean concern was with units of human energy expended. Somehow, two measurements that belonged to very different European systems of reckoning were part of a single Andean concern. Units of land measurement, called *papakancha*, also differed: where the land was in continuous cultivation, as in corn country, one unit was used; another unit was in use for highland-tuber cultivation, where fallowing and rotation was the dominant crop pattern. As one "measurer" explained to the viceroy's envoy, the *papakancha* was of one size when it was at a protected, lower altitude, but it could be up to seven times that size on the high, cold puna.

(T.C.P./J.V.M.)

Inca religion. Inca religion—an admixture of complex ceremonies, practices, animistic beliefs, varied forms of belief in objects having magical powers, and nature worship—culminated in the worship of the sun, which was presided over by the priests of the last native pre-Columbian conquerors of the Andean regions of South America. Though there was an Inca state religion of the sun, the substrata religious beliefs and practices of the pre-Inca peoples exerted an influence on the Andean region prior to and after the conquest of most of South America by the Spaniards in the 16th century.

Inca gods. The creator god of the Inca and of pre-Inca peoples was Viracocha, who was also a culture hero. Creator of earth, man, and animals, Viracocha had a long list of titles, including Lord Instructor of the World, the Ancient One, and the Old Man of the Sky. Some have said that he also was the creator of the Tiahuanaco civilizations, of which the Inca were the cultural heirs. Viracocha went through several transmogrifications (often with grotesque or humorous effects). He made peoples, destroyed them, and re-created them of stone; and when they were re-created, he dispersed mankind in four directions. As a culture hero he taught people various techniques and skills. He journeyed widely until he came to the shores of Manta (Ecuador), where he set off into the Pacific—some say in a boat made of his cloak, others that he walked on the water. This part of the myth has been seized upon by modern mythmakers, and, as Kon-Tiki, Viracocha was said to have brought Inca culture to Polynesia.

Viracocha was the divine protector of the Inca ruler Pachacuti Inca Yupanqui; he appeared to Pachacuti in a dream when the Inca forces were being besieged by the Chanca. Upon victory, Pachacuti raised a temple to Viracocha in Cuzco. He was represented by a gold figure "about the size of a 10-year-old child."

Inti, the sun god, was the ranking deity in the Inca pantheon. His warmth embraced the Andean earth and matured crops; and as such he was beloved by farmers. Inti was represented with a human face on a ray-splayed disk. He was considered to be the divine ancestor of the Inca: "my father" was a title given to Inti by one Inca ruler.

Apu Illapu, the rain giver, was an agricultural deity to whom the common man addressed his prayers for rain. Temples to Illapu were usually on high structures; in times of drought, pilgrimages were made to them and prayers were accompanied by sacrifices—often human, if the crisis was sufficient. The people believed that Illapu's shadow was in the Milky Way, from whence he drew the water that he poured down as rain.

Mama-Kilya, wife of the sun god, was the Moon Mother, and the regulator of women's menstrual cycles. The waxing and waning of the moon was used to calculate monthly cycles, from which the time periods for Inca festivals were set. Silver was considered to be tears of the moon. The stars had minor functions. The constellation of Lyra, which was believed to have the appearance of a llama, was entreated for protection. The constellation Scorpio was believed to have the shape of a cat; the Pleiades were called "little mothers," and festivals were celebrated on their reappearance in the sky. Earth was called Paca-Mama, or "Earth Mother." The sea, which was relatively remote to the Inca until after 1450, was called Mama Qoca, the Sea Mother.

Temples and shrines. Temples and shrines housing fetishes of the cult were occupied by priests, their attendants, and the Chosen Women. In general, temples were not intended to shelter the celebrants, since most ceremonies were held outside the temple proper. The ruins of the Temple of Viracocha at San Pedro Cacha (Peru), however, had a ground plan that measured 330 by 87 feet, which indicates that it was designed for use other than the storage of priestly regalia.

The Sun Temple in Cuzco is the best-known of the Inca temples. Another, at Vilcashuman (which was regarded as the geographic centre of the empire), has a large temple still existing. Near Mount Aconcagua in Argentina, at the southern limit of the Inca Empire, "there was a temple . . . an ancient oracle held in high regard where they made their sacrifices," and on Titicaca Island, one of the largest of several islands in Lake Titicaca, there was a temple of the sun.

As the Inca conquered new territories, temples were erected in the new lands. In Caranqui, Ecuador, one such temple was described by a chronicler as being filled with great vessels of gold and silver. At Latacunga (Llactacunga) in Ecuador there was a sun temple where sacrifices were made; part of the temple was still visible when the German explorer and geographer Alexander von Humboldt sketched the ruins in 1801.

The Sun Temple in Cuzco, built with stones "all matched

The Inca highway system

Inti, the sun god

The Sun Temple

and joined," had a circumference of more than 1,200 feet. A fragment of the wall still extant is testimony to the accuracy of the chronicler's description. Within the temple was an image of the sun "of great size," and in another precinct, the Golden Enclosure (Corincancha), were gold models of cornstalks, llamas, and lumps of earth. Portions of the land, which supported the temples, the priests, and the Chosen Women, were allotted to the sun and administered for the priests.

Along with the shrines and temples, huacas (sacred sites) were widespread. A huaca could be a man-made temple, mountain, hill, or bridge, such as the great *huacachaca* across the Apurímac River. A huaca also might be a mummy bundle, especially if it was that of a lord-Inca. On high points of passage in the Andes, propitiatory cairns (*apacheta*, "piles of stones") were made, to which, in passing, each person would add a small stone and pray that his journey be lightened. The idea of huaca was intimately bound up with religion, combining the magical and the charm-bearing.

The priesthood. Priests resided at all important shrines and temples. A chronicler suggests that a priest's title was *umu*, but in usage his title was geared to his functions as diviner of lungs, sorcerer, confessor, and curer. The title of the chief priest in Cuzco, who was of noble lineage, was *villac umu*. He held his post for life, was married, and competed in authority with the Inca. He had power over all shrines and temples and could appoint and remove priests. Presumably, priests were chosen young, brought up by the more experienced, and acquired with practice the richly developed ceremonialism.

Divination. Divination was the prerequisite to all action. Nothing of importance was undertaken without recourse to divination. It was used to diagnose illness, to predict the outcome of battles, and to ferret out crimes, thus giving it a judiciary function. Divination was also used to determine what sacrifice should be made to what god. Life was believed to be controlled by the all-pervading unseen powers, and to determine these portents the priests had recourse to the supernatural. Oracles were considered to be the most important and direct means of access to the wayward gods. One oracle of a huaca close to the Huaca-Chaca Bridge, across the Apurímac River near Cuzco, was described by a chronicler as a wooden beam as thick as a fat man, with a girdle of gold about it with two large golden breasts like a woman. These and other idols were bloodspattered from sacrifices—animal and human. "Through this large idol," a chronicler wrote, "the demon of the river used to speak to them." Another well-known oracle was housed in a temple in the large adobe complex of Pachacamac near Lima.

Divination also was accomplished by watching the meandering of spiders and the arrangement that coca leaves took in a shallow dish. Another method of divination was to drink *ayahuasca*, a narcotic that had profound effects on the central nervous system. This was believed to enable one to communicate with the supernatural powers.

Fire also was believed to provide spiritual contact. The flames were blown to red heat through metal tubes, after which a practitioner (*yacarca*) who had narcotized himself by chewing coca leaves summoned the spirits with fiery conjuration to speak—"which they did," wrote a chronicler, by "ventriloquism." Divination by studying the lungs of a sacrificed white llama was considered to be efficacious. The lungs were inflated by blowing into the dissected trachea (there is an Inca ceramic showing this), and the future was foretold by priests who minutely observed the conformance of the veins. On the reading of this augury, political or military action was taken.

Confession was part of the priestly ritual of divination. Should rain not fall or a water conduit break without cause, it was believed that such an occurrence could arise from someone's failure to observe the strictly observed ceremonies. This was called *hocha*, a ritual error. The *ayllu*, a basic social unit identified with communally held land, was wounded by individual misdeeds. Crimes had to be confessed and expiated by penitence so as not to call down the divine wrath.

Sacrifice. Sacrifice, human or animal, was offered on

every important occasion; guinea pigs (more properly *cui*), llamas, certain foods, coca leaves, and *chicha* (an intoxicant corn beverage) were all used in sacrifices. Many sacrifices were daily occurrences for the ritual of the sun's appearance. A fire was kindled, and corn was thrown on the coals and toasted. "Eat this, Lord Sun," was the oblation of officiating priests, "so that you will know that we are your children." On the first day of every lunar month 100 pure-white llamas were driven into the Great Square, Huayaca Pata in Cuzco; they were moved about to the various images of the gods and then assigned to 30 priestly attendants, each representing a day of the month. The llamas were then sacrificed; chunks of flesh were thrown onto the fire, and the bones were powdered for ritual use. Ponchos of excellent weave or miniature vestments were burned in the offering. The Inca ruler wore his poncho only once: it was ceremoniously sacrificed in fire each day.

Humans also were sacrificed; when the need was extreme, 200 children might be immolated, such as when a new Inca ruler assumed the royal fringe. Defeats, famine, and pestilence all called for human blood. Even a Chosen Woman from the Sun Temple might be taken out for sacrifice. Children, before being sacrificed, were feasted "so that they would not enter the presence of the gods hungry and crying." It was important in human sacrifice that the sacrificed person be without blemish. Many were chosen from the conquered provinces as part of regular taxation; "blood money" was scarcely a metaphor.

Festivals. The 30-day calendar was religious, and each month had its own festival. The religious calendar is explained in considerable detail by Guamán Poma de Ayala (see Table 3). In his letter to Philip II he offered two different versions, one centring on state ceremonies and sacrifices performed at Cuzco and the other describing the agricultural practices at the local level in the highlands. Quite different calendars prevailed on the irrigated coast, but surviving sources do not record them in any detail.

(V.W.v.H./J.V.M.)

Table 3: Months and Celebrations of the Inca Calendar

Gregorian months	Andean months	approximate translation
December	Capac Raimi, Capac Quilla	the lord festival; the month of rest
January	Zarap Tuta Cavai Mitán	the time to watch the growing corn
February	Paucar Varai	the time to wear loin cloths
March	Pacha Pucuy Quilla	the month of the land's maturation
April	Camai Quilla [Inti Raymi in state calendar]	the month of harvest and rest
May	Zara Muchuy Quilla Aymoray Quilla	dry corn to be stored
June	Papa Allai Mitán Pacha Haucai Cusqui	potato harvest rest from harvesting
July	Chacra Conaqui Quilla	the month of redistributing lands
August	Chacra Yapuy Quilla Hailly	the month to open lands coming into cultivation with songs of triumph
September	Zara Tarpuy Quilla Coia Raymi Quilla	the month for planting; also, the Festival of the Queen
October	Chacramanta Pisco Carcoy	the time to scare birds out of newly planted fields
November	Chacra Parcay	the time to irrigate fields

BIBLIOGRAPHY. GORDON R. WILLEY, *An Introduction to American Archaeology*, 2 vol. (1966–71); and GORDON R. WILLEY and JEREMY A. SABLOFF, *A History of American Archaeology*, 2nd ed. (1980), provide overviews of all of New World prehistory and place the Mesoamerican and Andean civilizations into the larger cultural-historical setting. See also LESLIE BETHELL (ed.), *The Cambridge History of Latin America*, vol. 1 (1984).

Meso-American civilization: (General works): The comprehensive, multivolume series "Handbook of Middle American Indians," especially vol. 2–3, GORDON R. WILLEY (ed.), *Archaeology of Southern Mesoamerica* (1965), and vol. 10–11, GORDON F. EKHOLM and IGNACIO BERNAL (eds.), *Archaeology of Northern Mesoamerica* (1971), is indispensable. Summaries of more recent developments are found in JEREMY A. SABLOFF (ed.), *Archaeology* (1981), vol. 1 in the series "Supplement to the Handbook of Middle American Indians." STARK and BARBARA VOORHIES (eds.), *Prehistoric Coastal Adaptations: The Economy and Ecology of Maritime Middle America* (1978). General introductions include WILLIAM T. SANDERS and BARBARA J. PRICE, *Mesoamerica: The Evolution of a Civilization* (1968); RICHARD E.W. ADAMS, *Prehistoric Mesoamerica* (1977); ERIC R. WOLF, *Sons of the Shaking Earth* (1959, reprinted 1974); and MARY W. HELMS, *Middle America: A Culture History of Heartland and Frontiers* (1975, reprinted 1982). For a coordination of regional chronologies within the area, see R.E. TAYLOR and CLEMENT W. MEIGHAN (eds.), *Chronologies in New World Archaeology* (1978). Books dealing with Olmec civilization include MICHAEL D. COE and RICHARD A. DIEHL, *In the Land of the Olmec*, 2 vol. (1980); MICHAEL D. COE, DAVID GROVE, and ELIZABETH P. BENSON (eds.), *The Olmec & Their Neighbors* (1981); and IGNACIO BERNAL, *The Olmec World* (1969; originally published in Spanish, 1968). For other cultures of the period, see the general works cited above.

(*Late Classic Period*): General books on the Maya include J. ERIC S. THOMPSON, *The Rise and Fall of Maya Civilization*, 2nd enl. ed. (1966, reprinted 1977); MICHAEL D. COE, *The Maya*, 4th rev. ed. (1987); NORMAN HAMMOND, *Ancient Maya Civilization* (1982); and SYLVANUS G. MORLEY and GEORGE W. BRAINERD, *The Ancient Maya*, 4th ed., rev. by ROBERT J. SHARER (1983). The rise and decline of Maya civilization are discussed in RICHARD E.W. ADAMS (ed.), *The Origins of Maya Civilization* (1977); and T. PATRICK CULBERT (ed.), *The Classic Maya Collapse* (1973, reprinted 1983). See also JOHN S. HENDERSON, *The World of the Ancient Maya* (1981), an ethnohistory. The transition from Maya Classic to Postclassic culture is examined in JEREMY A. SABLOFF and E. WYLLIS ANDREWS V (eds.), *Late Lowland Maya Civilization: Classic to Postclassic* (1986). A basic work on Maya hieroglyphic writing is J. ERIC S. THOMPSON, *Maya Hieroglyphic Writing: An Introduction*, 3rd ed. (1971). For later research in the field, see DAVID HUMISTON KELLEY, *Deciphering the Maya Script* (1976); ELIZABETH P. BENSON (ed.), *Mesoamerican Writing Systems* (1973); and LINDA SCHELE and MARY ELLEN MILLER, *The Blood of Kings: Dynasty and Ritual in Maya Art* (1986). For the complex subject of ancient Maya religion, J. ERIC S. THOMPSON, *Maya History and Religion* (1970), is an indispensable introductory guide. Native and early historical sources include DANIEL G. BRINTON (ed. and trans.), *The Maya Chronicles* (1882, reprinted 1969), and *The Annals of the Cakchiquels* (1885, reprinted 1969); *Popol Vuh: The Sacred Book of the Ancient Quiché Maya*, trans. from the Spanish work of ADRIÁN RECINOS by DELIA GOETZ and SYLVANUS G. MORLEY (1950, reprinted 1978); RALPH L. ROYS (trans.), *The Book of Chilam Balam of Chumayel* (1933, reprinted 1967); DIEGO DE LANDA, *Landa's Relación de las cosas de Yucatán*, trans. into English and ed. by ALFRED M. TOZZER (1941, reprinted 1978); and MUNRO S. EDMONSON (trans. and ed.), *The Ancient Future of the Itza: The Book of Chilam Balam of Tizimin* (1982). JACQUES SOUSTELLE, *Mexico*, trans. from French (1967), deals with the relation of Maya and other ancient Mesoamerican religions. Economic and demographic features are treated in PETER D. HARRISON and B.L. TURNER II, *Pre-Hispanic Maya Agriculture* (1978); and WENDY ASHMORE (ed.), *Lowland Maya Settlement Patterns* (1981). See also HENRI STIERLIN, *Art of the Maya: From the Olmecs to the Toltec-Maya* (1981; originally published in French, 1981).

(*Postclassic Period*): BERNARDINO DE SAHAGÚN, *General History of the Things of New Spain: Florentine Codex*, trans. from Náhuatl and ed. by ARTHUR J.O. ANDERSON and CHARLES E. DIBBLE, 13 vol. in 12 (1950–82), is the first full translation of this 16th-century Spanish writer of Aztec culture and is

particularly informative on Aztec religion. J. ERIC S. THOMPSON, *Mexico Before Cortez: An Account of the Daily Life, Religion, and Ritual of the Aztecs and Kindred Peoples* (1933), is a shorter survey. See also JACQUES SOUSTELLE, *The Daily Life of the Aztecs: On the Eve of the Spanish Conquest* (1962, reissued 1970; originally published in French, 1955); RICHARD A. DIEHL, *Tula: The Toltec Capital of Ancient Mexico* (1983); NIGEL DAVIES, *The Toltecs, Until the Fall of Tula* (1977), and *The Toltec Heritage: From the Fall of Tula to the Rise of Tenochtitlán* (1980); and BURR CARTWRIGHT BRUNDAGE, *The Fifth Sun: Aztec Gods, Aztec World* (1979), and *The Phoenix of the Western World: Quetzalcoatl and the Sky Religion* (1982).

Andean civilization: (General works): A comprehensive and still useful survey is provided by the articles in *The Andean Civilizations*, vol. 2 of JULIAN H. STEWARD (ed.), *Handbook of South American Indians*, 7 vol. (1946–59, reprinted 1963). Introductions include JOHN HOWLAND ROWE and DOROTHY MENZEL (eds.), *Peruvian Archaeology: Selected Readings* (1967); LUIS G. LUMBRERAS, *The People and Cultures of Ancient Peru* (1974; originally published in Spanish, 1969); and RICHARD W. KEATINGE (ed.), *Peruvian Prehistory* (1988). Important research by Andean authors is presented in RAMIRO CONDARCO MORALES, *El escenario andino y el hombre* (1971); and SEGUNDO MORENO YAÑEZ and UDO OBEREM, *Contribución a la etnohistoria ecuatoriana* (1981). See also JOHN A. MASON, *The Ancient Civilizations of Peru* (1968, reprinted 1979); JOHN V. MURRA, NATHAN WACHTEL, and JACQUES REVEL (eds.), *Anthropological History of Andean Politics* (1986; originally published in French in issues 5–6 of *Annales, Economies, Sociétés, Civilizations*, vol. 33, 1978); and SHOZO MASUDA, IZUMI SHIMADA, and CRAIG MORRIS (eds.), *Andean Ecology and Civilization: An Interdisciplinary Perspective on Andean Ecological Complementarity* (1985). For the material culture admired by the Spanish observers from the first days of the invasion, see CHRISTOPHER B. DONNAN (ed.), *Early Ceremonial Architecture in the Andes* (1985); HEATHER LECHTMAN and ANA MARÍA SOLDI (eds.), *La tecnología en el mundo andino: subsistencia y mensuración* (1981); and ANN POLLARD ROWE (ed.), *The Junius B. Bird Conference on Andean Textiles, April 7–8, 1984* (1986).

(*Pre-Inca periods*): Surveys of these civilizations include WENDELL C. BENNETT and JUNIUS B. BIRD, *Andean Culture History*, 2nd rev. ed. (1960, reissued 1964); GEOFFREY H.S. BUSHNELL, *Peru*, rev. ed. (1963); EDWARD P. LANNING, *Peru Before the Incas* (1967); DONALD W. LATHRAP, *The Upper Amazon* (1970); and JONATHAN HAAS, SHELIA POZORSKI, and THOMAS POZORSKI (eds.), *The Origins and Development of the Andean State* (1987).

(*The Inca*): The works of the chroniclers are available in modern English translations or in modern critical editions: PEDRO DE CIEZA DE LEÓN, *The Incas*, trans. by HARRIET DE ONIS, ed. by VICTOR WOLFGANG VON HAGEN (1959, reprinted 1967); GARCILASO DE LA VEGA, *The Incas: The Royal Commentaries of the Inca, Garcilaso de la Vega, 1539–1616*, trans. by MARIA JOLAS from the critical annotated French edition of ALAIN GHEERBRANT (1961, reissued 1971; originally published in French, 1959); and FELIPE GUAMÁN POMA DE AYALA, *El primer nueva crónica y buen gobierno*, trans. from Quechua by JORGE L. URIOSTE, ed. by JOHN V. MURRA and ROLENA ADORNO, 3 vol. (1980). Comprehensive histories include ALFRED MÉTRAUX, *The History of the Incas* (1969; originally published in French, 1963); GEORGE A. Prehistoric Peoples and Cultures

This article provides a general account of man's cultural-historical development during the Pleistocene Ice Age and the early Holocene, or Recent, Epoch. During these approximately 500,000 years of prehistoric human development, the climates and environments of the world fluctuated considerably, and there were, of course, no national boundaries or ethnological regions that conformed in any meaningful way to those of the present. It would be impossible to maintain, on the basis of the

archaeological evidence, that the inhabitants of what is now France were already Frenchmen 25,000 years ago or that the inhabitants of what is now Zimbabwe were already Bantu-speaking peoples 250,000 years ago. Hence, the approach of this article is one of an overview of vast regions and of the great, general steps forward that human culture made from earliest times until the civilizations of the conventional ancient historians were initiated. The article is divided into the following sections:

CULTURAL HISTORY OF THE STONE AGES

Paleolithic archaeology is concerned with the origins and development of early human culture between the first appearance of man as a tool-using mammal, which is believed to have occurred about 600,000 or 700,000 years ago, and the beginning of the Recent geologic era, about 8000 BC. It is included in the time span of the Pleistocene, or Glacial, Epoch—an interval of about 1,000,000 years. Although it cannot be proved, modern evidence suggests that the earliest protohuman forms had diverged from the ancestral primate stock by the beginning of the Pleistocene. In any case, the oldest recognizable tools are found in horizons of Lower Pleistocene Age. During the Pleistocene a series of momentous climatic events occurred. The northern latitudes and mountainous areas were subjected on four successive occasions to the advances and retreats of ice sheets (known as Günz, Mindel, Riss, and Würm in the Alps), river valleys and terraces were formed, the present coastlines were established, and great changes were induced in the fauna and flora of the globe. In large measure, the development of culture during Paleolithic

times seems to have been profoundly influenced by the environmental factors that characterize the successive stages of the Pleistocene Epoch.

Throughout the Paleolithic, man was a food gatherer, depending for his subsistence on hunting wild animals and birds, fishing, and collecting wild fruits, nuts, and berries. The artifactual record of this exceedingly long interval is very incomplete; it can be studied from such imperishable objects of now-extinct cultures as were made of flint, stone, bone, and antler. These alone have withstood the ravages of time, and, together with the remains of contemporary animals hunted by our prehistoric forerunners, they are all that scholars have to guide them in attempting to reconstruct human activity throughout this vast interval—approximately 98 percent of the time span since the appearance of the first true hominid stock. In general, these materials develop gradually from single, all-purpose tools to an assemblage of varied and highly specialized types of artifacts, each designed to serve in connection with a specific function. Indeed, it is a process of increasingly

Environmental factors

more complex technologies, each founded on a specific tradition, that characterizes the cultural development of Paleolithic times. In other words, the trend was from simple to complex, from a stage of nonspecialization to stages of relatively high degrees of specialization, just as has been the case during historic times.

In the manufacture of stone implements, four fundamental traditions were developed by the Paleolithic ancestors: (1) pebble-tool traditions; (2) bifacial-tool, or hand-ax, traditions; (3) flake-tool traditions; and (4) blade-tool traditions. Only rarely are any of these found in "pure" form, and this fact has led to mistaken notions in many instances concerning the significance of various assemblages. Indeed, though a certain tradition might be superseded in a given region by a more advanced method of producing tools, the older technique persisted as long as it was needed for a given purpose. In general, however, there is an overall trend in the order as given above, starting with simple pebble tools that have a single edge sharpened for cutting or chopping. But no true pebble-tool horizons had yet, by the late 20th century, been recognized in Europe. In southern and eastern Asia, on the other hand, pebble tools of primitive type continued in use throughout Paleolithic times.

French place-names have long been used to designate the various Paleolithic subdivisions, since many of the earliest discoveries were made in France. This terminology has been widely applied in other countries, notwithstanding the very great regional differences that do in fact exist. But the French sequence still serves as the foundation of Paleolithic studies in other parts of the Old World.

(H.L.Ms./Ed.)

The Recent
(Holocene)
Era

There is reasonable agreement that the Paleolithic ended with the beginning of the Recent (Holocene) geologic and climatic era about 8000 B.C. It is also increasingly clear that a developmental bifurcation in man's culture history took place at about this time. In most of the world, especially in the temperate and tropical woodland environments or along the southern fringes of Arctic tundra, the older Upper Paleolithic traditions of life were simply readapted toward more or less increasingly intensified levels of food collection. These cultural readaptations of older food procedures to the variety and succession of post-Pleistocene environments are generally referred to as occurring in the Mesolithic Period. But also by 8000 B.C. (if not even somewhat earlier) in certain semi-arid environments of the world's middle latitudes, traces of a quite different course of development began to appear. These traces indicate a movement toward incipient agriculture and (in one or two instances) animal domestication. In the case of southwestern Asia, this movement had already culminated in a level of effective village-farming communities by 7000 B.C. In Meso-America, a comparable development—somewhat different in its details and without animal domestication—was taking place almost as early. It may thus be maintained that in the environmentally favourable portions of southwestern Asia, Meso-America, the coastal slopes below the Andes, and perhaps in southeastern Asia (for which little evidence is available), little if any trace of the Mesolithic stage need be anticipated. The general level of culture probably shifted directly from that of the Upper Paleolithic to that of incipient cultivation and domestication.

The picture presented by the culture history of the earlier portion of the Recent period is thus one of two generalized developmental patterns: (1) the cultural readaptations to post-Pleistocene environments on a more or less intensified level of food collection; and (2) the appearance and development of an effective level of food production. It is generally agreed that this latter appearance and development was achieved quite independently in various localities in both the Old and New Worlds. As the procedures and the plant or animal domesticates of this new food-producing level gained effectiveness and flexibility to adapt to new environments, the new level expanded at the expense of the older, more conservative one. Finally, it is only within the matrix of a level of food production that any of the world's civilizations have been achieved.

(R.J.Br./Ed.)

Europe

PALEOLITHIC

Three major subdivisions—Lower, Middle, and Upper Paleolithic—are recognized in Europe. Although the dividing line between the Lower and Middle stages is not so clearly defined as that separating the Middle and Upper subdivisions, this system is still used by most workers.

Lower Paleolithic. On the basis of the very rich materials from the Somme Valley in the north of France and the Thames Valley in the south of England, two main Lower Paleolithic traditions have been recognized in western Europe. These are as follows: (1) bifacial-tool, or hand-ax, traditions (Abbevillian and Acheulean); and (2) flake-tool traditions (Clactonian and Levalloisian).

The type tools of the Abbevillian (formerly Chellean), which takes its name from the town of Abbeville, France, on the 45-metre (150-foot) terrace of the Somme Valley, consist of pointed, bifacial implements, or hand axes. Their forms vary, and the flaking is generally irregular; it is probable that they were manufactured either with a stone hammer or on a stone anvil. Associated with these crude types of hand axes, simple flake tools are found, but they lack definite form. The Abbevillian has been reported from deposits of lower Pleistocene (First Interglacial) age.

Abbevillian
industry

The Acheulean, which begins in the Second Interglacial and persists to the close of the Third Interglacial, covers by far the longest time span of any of the Paleolithic traditions found in western Europe. The type site is on the 30-metre terrace of the Somme Valley at St. Acheul, near Amiens, in northern France. Acheulean hand axes, which display a marked technological refinement over their Abbevillian precursors, were apparently made by employing a wooden or bone billet rather than the more primitive stone-on-stone technique. But, except at the very end of the Acheulean cycle of development, there is very little typological difference in the types of hand axes found in the various layers.

The Micoquian, or Final (Upper) Acheulean, is characterized by elongated hand axes that exhibit very straight and finely chipped edges, in marked contrast with the Lower Acheulean, in which ovate forms predominate. Flake tools occur in all Acheulean levels, the side scrapers being the predominant type. Many of these tools were made from trimming flakes produced during the process of hand-ax manufacture. In general, flake tools, including points with a triangular cross section, are found in greater quantities in Micoquian deposits than in the older horizons.

The evidence from Clacton-on-Sea, Essex, and Swanscombe, Kent, in the Thames Valley of southeastern England clearly shows that the main development of the Clactonian occurred during early Second Interglacial times. The type artifacts are flakes, although core tools—single-edged choppers and chopping tools—do in fact occur. The flakes, which have large, high-angle (greater than 90°), plain striking platforms, as well as prominent bulbs of percussion, were detached from roughly prepared, discoidal cores by the stone-hammer or stone-anvil technique. Actual retouching or secondary working of the edge is found in some instances, but for the most part it is crude, and edge chipping resulting from use is far more characteristic.

Named after a locality at Levallois, a suburb of Paris, the Levalloisian is primarily a flake tradition, although hand axes are found in certain of the Middle and Upper Levalloisian stages. It first appears in deposits of the late Second Interglacial in association with hand axes of Middle Acheulean type and persists into Fourth Glacial (Würm) times. It is characterized by a new and improved method of producing flakes, which previously had been obtained in a more or less haphazard manner. This involves the careful shaping of the core by the removal of centrally directed flakes, and the preparation of an extremity for the detachment of a symmetrical oval flake. Since unstruck cores of this type exhibit a plano-convex section suggesting the form of a tortoise, they are known as tortoise cores. On the striking platforms of typical levallois flakes, small vertical flake scars, called facets, may be observed, and the scars of the converging core-preparation flakes are present

Leval-
loisian
tradition

on the upper surface. The use of this technique resulted in the production not only of symmetrical flakes but also of larger ones in proportion to the size of the core. In the Middle and Upper Levalloisian a variation of this same basic technique was developed whereby it was possible to produce either triangular flakes (or points) or rectangular flakes (or flake blades) by modifying the method of core preparation.

Middle Paleolithic. The Middle Paleolithic comprises the Mousterian, a portion of the Levalloisian, and the Tayacian, all of which are complexes based on the production of flakes, although survivals of the old hand-ax tradition are manifest in many instances. These Middle Paleolithic assemblages first appear in deposits of the third interglacial and persist during the first major oscillation of the Fourth Glacial (Würm) stage. Associated with the Tayacian, in which the artifacts consist of very crude flakes, remains of modern man (*Homo sapiens*) have been found. Mousterian man, on the other hand, is of the Neanderthal race. By the 1960s no human remains had yet been found associated with the Levalloisian. It is in the Mousterian levels of the caves and rock shelters of central and southern France that the earliest evidence of the use of fire and the first definite burials have been discovered in western Europe. The cave of Le Moustier, near Les Eyzies in the classic Dordogne region of France, is the type site of the Mousterian. The typology of the artifacts is complex; it consists of three distinct increments: (1) the prepared striking-platform-tortoise-core (Levalloisian) tradition; (2) the plain striking-platform-discoidal-core technique of ultimate Clactonian tradition; and (3) a persistence of the bifacial core tool, or Acheulean tradition. The type artifacts from the Mousterian consist of points and side scrapers, in addition to a few hand axes (especially heart- or triangular-shaped forms), and the secondary working is coarse. A crude bone industry appears here for the first time. Judging by what is known concerning modern hunting groups, small bands or tribes of people already had developed simple social institutions, even at this early level of development.

Upper Paleolithic. The Upper Paleolithic, which occupies only approximately one-tenth of the time span of the period as a whole, first appears in horizons referable to the Würm I-II interstadial, and it persists to the very end of late Glacial times. Early man made his greatest cultural progress at this time. The hand axes and flake tools of the earlier assemblages were replaced by diversified and specialized tools made on blades struck from specially prepared cores. Many important inventions appeared, such as needles and thread, skin clothing, hafted stone and bone tools, the harpoon, the spear thrower, and special fishing equipment. Bone, ivory, and antler, in addition to flint, were extensively used. The earliest man-made dwellings are found, consisting of semisubterranean pit houses. Of prime importance and interest is the beginning of the basic techniques of drawing, modelling, sculpture, and painting,

as well as the earliest manifestations of dancing, music, the use of masks, ceremonies, and the organization of society into patterns that were apparently fairly complex. Indeed, the location of certain settlements suggests a more complex social life, including perhaps collective hunting. There is evidence for fertility magic, private property, and possible social stratification. Furthermore, primitive types of early man disappeared, and the remains of men of modern type (*Homo sapiens*) alone are found in Upper Paleolithic sites.

The chronology of this interval in western Europe shows a succession of cultures known as Lower Périgordian (or Châtelperronian; formerly Lower Aurignacian), Aurignacian, Upper Périgordian (or Gravettian; formerly Upper Aurignacian), Solutrean, and Magdalenian, each characterized by its distinctive types of artifacts. These latter occur, together with gravers (or burins), end scrapers, points, etc., which are common to all levels. The graver itself is a very important tool, for its invention made possible the extensive working of bone and facilitated the development of art. The climate of the Upper Paleolithic varied from cold steppe, or even Arctic tundra, to north temperate (taiga), similar to parts of Siberia and Canada of the present day.

Périgordian. In the Périgordian, named after a region in south central France, blades with steeply retouched backs are typical. The Lower Périgordian is characterized by large curved points with blunted backs that are known as Châtelperron points. These first appear, together with other types of blade tools, in horizons immediately overlying Upper Mousterian levels. It is believed that the straight points with blunted backs, called Gravette points and characteristic of the Upper Périgordian, were evolved from the Châtelperron type. In the final stage of the Upper Périgordian, tanged Font Robert points and diminutive multiangle gravers, known as the Noailles burin, are found. A number of small sculptured human torsos depicting the female form have been found at Upper Périgordian sites.

Aurignacian. The type site of the Aurignacian is near the village of Aurignac (Haute-Garonne) in southern France. At many sites it is found intervening between horizons referable to the Lower and the Upper Périgordian, a fact that is considered to indicate that more than one cultural element was present in western Europe at the beginning of Upper Paleolithic times. The tool types include various kinds of steep-ended scrapers, nose scrapers, blades with heavy marginal retouch, strangulated blades, busked gravers (or burins), and split-base bone points. Bone was extensively used, mainly for javelin points, chisels, perforators, and *bâtons de commandement*, or arrow straighteners. Articles of personal adornment, probably worn as necklaces, such as pierced teeth and shells, as well as decorated bits of bone and ivory, appear for the first time in the Aurignacian.

The oldest manifestations of art were produced during the Aurignacian, and the development continued during Upper Périgordian times. In general, Upper Paleolithic art falls into two closely related categories: mural art and portable art. The former includes finger tracings, paintings, engravings, bas-reliefs, and sculptures on the walls of caves and rock shelters; the latter is characterized by small engravings and sculptures on stone and bone found in the occupation layers. The whole development almost certainly owes its inspiration to the magico-religious idea, especially the custom of hunting magic as practiced today by living primitive peoples.

Solutrean. The Solutrean, which is named after the site of Solutré, near Mâcon (Saône-et-Loire), is noted for the beautifully made, symmetrical, bifacially flaked, laurel-leaf, and shouldered points, the finest examples of flint workmanship of the Paleolithic in western Europe. In addition, the usual types of gravers, end scrapers, points, perforators, etc., are present. Examples of Solutrean art are comparatively rare; they consist of sculpture in low relief and incised stone slabs. The fauna indicates that this culture flourished in a relatively cold climate.

Magdalenian. The rock shelter of La Madeleine, near Les Eyzies (Dordogne), is the type Magdalenian locality. This final culture of the Upper Paleolithic is noted for the

dominance of bone and antler tools over those of flint and stone and for the very remarkable works of art that were produced at this time. The wide variety of bone tools include javelin points, barbed bone points (or harpoons), eyed needles, *bâtons de commandement* (often elaborately decorated), perforators, spear throwers, chisels, etc. The flint and stone tools include a variety of special forms, among which small geometric forms, denticulated blades, scrapers with steeply retouched edges, and the parrot-beak graver are especially distinctive. The six phases of the Magdalenian have been established stratigraphically and are characterized mainly by the contained bone and antler implements. But the heights attained by the people responsible for this culture can best be evaluated on the basis of the art objects they produced. Magdalenian sites have yielded countless fine examples of both mural and portable art. Animals of the period, the usual subject matter, are portrayed in paintings (often polychrome), engravings, and sculptures. The fauna from the various Magdalenian horizons demonstrates that cold conditions prevailed in western Europe at the end of Paleolithic times.

Mural and portable art

MESOLITHIC

In the Upper Paleolithic of Europe, certain evidence exists for what must have already been well-organized collective-hunting activities, such as the horse-stampede traces of Solutré, France, and the great concentrations of mammoth bones of the Gravettian hut settlements of Czechoslovakia and Russia. Cultural adaptations appear to have been made to restricted local areas or niches and to the fluctuations of climate and environment during the changing phases at the end of the Pleistocene range of time. In fact, it could be maintained generally that Upper Paleolithic traditions flowed rather smoothly into the Mesolithic, with no more significant indication of cultural development than further environmental readaptations. The people of the Mesolithic stage, or level of development, can be said to have "changed just enough so that they would not have to change."

The cultures. *The Maglemosian.* The level of intensified food-collecting cultures of the early Recent period in the Old World is best known from northwestern Europe, and it is with regard to this area that the term Mesolithic has greatest currency to denominate archaeological traces. A classic example of such traces comes from the Maglemose bog site of Denmark, although there are comparable materials ranging from England to the eastern Baltic lands. These bogs were probably more or less swampy lakes in Mesolithic times. At about 6000 BC, when the Maglemosian culture flourished, traces of primitive huts with bark-covered floors have been found. Flint axes for felling trees and adzes for working wood have appeared, as well as a variety of smaller flint tools, including a great number of microlithic scale. These were mounted as points or barbs in arrows and harpoons and were also used in other composite tools. There were adzes and chisels of antler or bone, besides needles and pins, fish-hooks, harpoons, and several-pronged fish spears. Some larger tools, of ground stone (e.g., club heads) have appeared. Wooden implements also have survived because of the unusually favourable preservative qualities of the bogs; bows, arrow shafts, ax handles, paddles, and even a dugout canoe have been discovered. Fishnets were made of bark fibre. There is good evidence that the Maglemosian sites were only seasonally occupied. Deer were successfully hunted, and fish and waterfowl were taken, and it appears possible that several varieties of marsh plants were utilized. At Star Carr, in northern England, there are indications that four or five huts existed in the settlement, with a population of about 25 people.

This description of the Maglemosian must suffice to represent a considerable variety of European manifestations of the level of intensified post-Pleistocene food collecting. The catalogs of the Azilian and Tardenoisian industries of western Europe, of the Ahrensburgian of northern Ger-

J. Vertut—Ziolo

many, of the Asturian of Spain, etc., would each differ in detail, but all would point in the same general direction as regards cultural–historical interpretation.

The Nachikufan. As a further and far-distant example, the Nachikufan culture of southern Zimbabwe might be cited. Here again, microlithic flint bladelet tools, with certain types mounted as projectile points or in composite tools, existed. The Nachikufan cave walls show a few seminaturalistic drawings, and the caves also contain “pencils” of red and black pigment. Ground-stone axes and adzes, bored stones (digging-stick weights?), and normalized chopping and scraping tools of chipped stone also occurred. Grindstones of various types indicate a degree of dependence on collected vegetable foods, and the animal bones suggest specialization in the hunting of zebras,

wildebeeste, hartebeeste, and wild pig. These Nachikufan materials date back to at least 4500 BC. Again, an intensified level of food collecting is implied.

The general picture. Though there are vast gaps in our knowledge of the Recent period in many parts of the Old World, enough is known to see the general cultural level of this range of time. Outside of the regions where food production was establishing itself, the period was one of a gradual settling-in and of an increasingly intensive utilization of all the resources of restricted regional niches. At first, the level seems nowhere to have achieved a climax of artistic expression, such as that for example, of Upper Périgordian–Magdalenian times. But, as time went on, certain climaxes within the matrix of an intensified level of food collection did occur. An often-cited example might be the complex art and social organization of the cultures of the northwest coast of British Columbia.

More often, however, as the culture history of the Recent period proceeded, cultures at the level of intensified food collecting were “captured” by being absorbed within an expanding matrix of the new elements, procedures, and traditions of food production or—subsequent to its appearance—by the expansion of civilized societies.

(R.J.Br./Ed.)

NEOLITHIC

The origins and history of European Neolithic culture are closely connected with the post-glacial climate and forest development. The increasing temperature after the late Dryas period during the Pre-Boreal and the Boreal (c. 8000–5500 BC, determined by radiocarbon dating) caused a remarkable change in late glacial flora and fauna. Thus, the Mediterranean zone became the centre of the first cultural modifications leading from the last hunters and food gatherers to the earliest farmers. This was established by some important excavations in the mid-20th century in the Middle East, which unearthed the first stages of early agriculture and stock breeding (7th and 6th millennia BC) with wheat, barley, dogs, sheep, and goats. In a deep sounding in the Argissa Magula near Larissa (Thessaly, Greece), there have been early prepottery Neolithic finds (probably 6th millennium BC), while excavations in Lepenski Vir (Yugoslavia) have brought to light some sculptures of the same period. The independent origin of European Neolithic was established, and it was thought highly probable that the cradle of farming in the Middle East had not been the only one: there were others in Europe, too.

The zones. Neolithic farming in Europe developed on its own lines in the four different ecological zones. These are: the Mediterranean zone of evergreen forest and winter rains; north of the Pyrenees, the Alps, and the Balkans, the temperate zone of deciduous forest and evenly distributed annual rainfall; still farther north the circumpolar taiga, or coniferous forest (the only zone to remain free of agriculture and stock breeding); and to the southeast the western end of the Eurasian Steppe. Each zone itself is subdivided into natural regions by physiographic boundaries and peculiarities of climate or soil. Only the three major divisions of the temperate zone are not obvious from every map. We may distinguish: western Europe, from the Atlantic to the Vosges and Alps and including the British Isles; the loesslands of central Europe, including the Ukraine and limited by the Balkans and the Harz; and the northern province, that portion of the Eurasian plain lying between the Rhine and the Vistula and including Denmark and southern Sweden. The substantial Neolithic communities that arose by 6000 BC must have been largely recruited from indigenous Mesolithic hunters and fishers, attested to so abundantly in western and northern Europe by various remains. (Some communities indeed seem to be composed entirely of such Mesolithic stocks, though they had adopted a Neolithic equipment from immigrant farmers; such are sometimes termed Secondary Neolithic. From these Mesolithic survivors, too, must be derived much of the science and equipment applied in Neolithic times to adapting societies to European environments. Upon the resultant distinctively European technology and economy was reared a no less original ideological superstructure expressed in distinctive sepulchral monuments, styles of ceramic decoration, and fashions in personal ornaments.

Cultural elements. Rural economy. In each of the above-mentioned provinces, the archaeological record begins with the early stages of farming, as in Thessaly. In the Mediterranean zone, this early farming is connected with the cardium pottery (decorated by shell impressions of *Cardium edule*), cultivation of the land having been proved by pollen-analytical methods in France, as elsewhere in temperate Europe, while northern Germany and

southern Scandinavia revealed grain prints in pots (Ertebølle-Ellebek). The process of cultural formation and modification during the Neolithic may be studied with the help of the different kinds of pottery and stone artifacts.

Save in the taiga, where a Mesolithic economy persisted until the end of the Bronze Age, the basis of life everywhere was subsistence farming, supplemented by some measure of hunting and fishing—fish being a source of food curiously neglected in western and central Europe during the earlier phases of the Neolithic. Everywhere the same cereals were cultivated, together with beans, peas, and lentils. In the Mediterranean zone, orchard husbandry may already have begun, while around the Alps, apples were eventually cultivated and utilized for the preparation of a sort of cider. The balance between cultivation and stock breeding varied. Throughout the temperate zone, sheep, though bred even in Britain and Denmark, were at first rare. The damp temperate forests were uncongenial to these animals, and only toward the end of the Neolithic Period, when the greater dryness of the subboreal climatic phase and incipient clearing for plow cultivation were leaving their mark on the landscape, did flocks begin to multiply. On the loesslands, in early Neolithic times, animal husbandry may have played a subordinate role as compared with agriculture. But in the sequel, cattle raising combined with hunting proved to be the most productive pursuit among the deciduous forests with a Neolithic equipment; cultivation was relegated to an increasingly secondary place, until in the late Bronze Age more efficient tools for clearing land became generally available. The rural economy permitted the continuous occupation of permanent villages around the Aegean and in the Balkan Peninsula, perhaps also in southern Italy and the Iberian Peninsula. In the temperate zone, shifting cultivation may have been based on slash-and-burn clearance. Under this extravagant system, plots were presumably tilled with hoes, as in parts of Africa today. But by the beginning of the Bronze Age, the ox-drawn plow was beginning to replace the hoe.

Houses. Dwelling houses in Greece, Sicily, and the Iberian Peninsula were built, as in the Middle East, of pisé, or mud brick, on stone foundations. But in the Balkans and throughout the temperate zone, wood was used for the construction of gabled houses, stout posts serving to support the ridgepole and the walls of split saplings or wattle and daub. The earliest houses on the loessland of central Europe were very large, up to 42 metres (135 feet) in length and large enough to accommodate a whole lineage or small clan together with stalled cattle and grain stores. In the sequel these communal houses gave place to smaller two-roomed dwellings, 7.5 to 10 metres (24½ to 33 feet) long but still entered through one end. Finally in late Neolithic times clusters of one-roomed huts became the most widespread fashion. Around the Alps such two-roomed houses and, less often, one-roomed huts were raised on piles above the shores of lakes or on platforms laid on peat mosses. These are the world-famous Swiss "lake-dwellings" (*Uferrandsiedlungen*) that have yielded such precious collections of the organic substances from wood to bread that are otherwise missing from the archaeological record. In northern Europe, too, the earliest villages consisted of two parallel, long communal houses, but these were subdivided by cross walls into 20 or more apartments, each with a separate door. But here again the communal houses eventually broke up into free-standing one-roomed huts. Finally, Skara Brae on the treeless island of Orkney illustrates an ingenious adaptation of the one-roomed wooden hut to an inhospitable environment but shows how commodiously such huts must always have been furnished.

Stone tools. Carpenters used celts (ax or adz heads) edged by grinding and polishing of fine-grained rock or of flint where that material was available in large nodules. In Greece and the Balkans, all over central Europe and the Ukraine, and throughout the taiga, adzes were used exclusively, as in the earlier Baltic Mesolithic; in northern and western Europe axes were preferred. In the Iberian Peninsula axes and adzes occur in equal numbers in early Neolithic graves, but the proportion of axes in-

creased later. Often in western Europe, and occasionally in Greece and Cyprus, celts were mounted with the aid of antler sleeves inserted between the stone head and the wooden handle—a device that was already employed in the northern European Mesolithic. In Spain, the British Isles, and northern Europe axheads were simply stuck into or through straight wooden shafts, but adz heads must always have been mounted on a knee shaft (a crooked stick), a method regularly used for axheads, too, by the Bronze Age. Axheads like those in modern use, with a hole for the shaft, were rarely used for tools, but the Danubian peasants on the loesslands may sometimes have mounted adzes in this manner. They certainly knew how to perforate stone, using a tubular borer (a reed or bone with sand as an abrasive). From them the technique was adopted by various secondary Neolithic tribes in northern Europe for the manufacture of so-called battle-axes. The latter seem to derive their form from Mesolithic weapons

of antler, but their splayed blades disclose the influence of metal forms.

Ax factories and flint mines. Celts, or axes, were manufactured in factories where specially suitable rock outcrops occurred, and they were traded over great distances. Products of the factories at Graig Lwyd, Penmaenmawr, North Wales, were transported to Wiltshire and Anglesey, those of Tievebulliagh on the Antrim coast to Limerick, Kent, Aberdeen, and the Hebrides. Similarly, large nodules of good flint were secured by mining in Poland, Denmark, The Netherlands, England, Belgium, France, Portugal, and Sicily. The mine shafts, which were cut through solid chalk sometimes to a depth of six metres (20 feet) with the aid only of antler picks and bone shovels, may be simple pits, but often regular galleries branching from them follow the seams of big nodules. Although the ancient miners appreciated the necessity of leaving pillars to support the roof, skeletons of workers killed by falls have been discovered at Cissbury, Spiennes, and elsewhere. In the British Isles and Denmark, at least, there is evidence that the ax factories and flint mines were exploited and the products distributed by trade, for example, to the northern parts of Sweden. Still, the operators and distributors need nowhere be regarded as full-time specialists.

Art. Neolithic art, except among the hunter-fishers of the taiga, was geometric and not representational. It is best illustrated by the decoration of pottery. Pots, which were always handmade, were painted in southeastern Europe, southern Italy, and Sicily; elsewhere they were adorned with incised, impressed, or stamped patterns. Many designs are skeuomorphic—i.e., they enhance the pot's similarity to vessels of basketry, skin, or other material. But on the loesslands of central Europe and the Ukraine and in the Balkans, spirals and meanders were favourite motifs.

Trade. While Neolithic societies could be completely self-sufficient, growing their own food and making all essential equipment from local materials, luxury objects were transmitted quite long distances by some sort of trade. So ornaments made of the shells of the Mediterranean mussel, *Spondylus gaederopus*, are found all across

the Balkans, up the Danube Valley, and even on the Saale and the Main. Products of factories and flint mines were, as stated, traded widely throughout a single province, such as the British Isles, and some especially valued raw materials—the yellow flint of Grand-Pressigny (France), the obsidian of Melos and the Lipari Islands—became objects of “international trade” as much as shells. But the most prized object of such commerce was the amber of Jutland and East Prussia, whose electrical properties seemed evidence of potent mana.

(Ri.P./Ed.)

Asia

PALEOLITHIC

During the Paleolithic, two major culture provinces can be recognized in Asia, each of which has yielded a distinctive sequence. The first of these includes the Middle East, Russian Turkistan, central Siberia, and India; throughout this vast region a developmental sequence has been reported that, in all its essential respects, is related to that of Europe as well as to that of Africa in the early stages. The second of these provinces is in the south and east, and it embraces Pakistan, Burma, Java, Malaya, Thailand, and China. There the characteristic implement types consist of choppers and chopping tools that are often made on pebbles.

Hand-ax industries of Abbeville-Acheulean type are missing in southern and eastern Asia, together with the intimately associated prepared striking-platform-tortoise-core, or Levallois, technique. There the pebble-tool tradition persisted to the very end of Paleolithic times uninfluenced by contemporary innovations characteristic of the western portion of the continent.

Middle East. In this area, especially in Israel, Jordan, Lebanon, and Syria, a Lower Paleolithic development closely paralleling that of Europe is indicated by the widespread distribution of hand axes of Abbevillian and Acheulean type. Unfortunately, the majority of these finds are from open-air, unstratified sites that cannot be dated. A crude flake industry, reminiscent of the Tayacian of western Europe, has been reported from several cave sites. This is followed by a typical Upper Acheulean horizon in which there occur many developed hand axes of Micoquian type, a wide variety of flake implements, and the prepared striking-platform-tortoise-core technique. The Levallois-Mousterian found in the next-younger horizon

is associated with a series of Neanderthaloid burials at one of the Mt. Carmel Caves of Israel and at Shanidar Cave in northern Iraq. Next in the sequence comes an early Upper Paleolithic development, which is characterized by various types of blade and flake-blade tools, including points that recall the Châtelperron type. This is overlain by the Antelian (formerly Middle Aurignacian), which in turn is followed by the Atlitian and the Kebarian. These assemblages, together with the recently discovered Baradostian of northern Iraq, constitute specialized late Upper Paleolithic industries that preceded various Mesolithic developments in the Middle East.

Central Asia. In the central Asiatic parts of the U.S.S.R. (formerly Russian Turkistan), few investigations of Paleolithic sites have been conducted. Surface finds of Acheulean-type hand axes have been reported from the Turkmen Republic, and several Mousterian localities have been excavated in the southeastern Uzbek Republic. At the most important of these sites—the cave of Teshik-Tash—the burial of a Neanderthal child who was surrounded by horns of a Siberian mountain goat has been discovered. No convincing evidence has been reported showing that this region was occupied during Upper Paleolithic times.

South Asia. Certain of the Paleolithic assemblages from India and Pakistan demonstrate that during Pleistocene times the region played an intermediate role between western Asia and the Far East. In the Punjab province of Pakistan, assemblages of implements that are characteristic of both the chopper-chopping-tool and the hand-ax-Levallois-flake complexes have been found. The former, which is called the Sohanian, or Sohan, has been reported from five successive horizons, each of which yields pebble tools that are associated with flake implements. Massive and crude in the earliest phases of the Sohanian, these reveal a progressive refinement in the younger horizons, where the evolved pebble tools are associated with flakes produced by the prepared striking-platform-tortoise-core technique. In part contemporary with the Early Sohanian is a series of hand axes of Abbeville-Acheulean affinities, which occur in profusion at many sites in India from the Gujarât region in the north to the Madras in the south. These sites yield hand axes, cleavers, and flake tools that are very reminiscent of assemblages from southern and eastern Africa. As in the latter areas, the oldest materials are of Abbevillian type, and this is followed by the entire Acheulean cycle of development, just as in the case of the Stellenbosch of the Vaal Valley. The occurrence of choppers and chopping tools of Sohanian affinities and made on pebbles throughout peninsular India in deposits of Middle Pleistocene Age suggests the probability that Lower Pleistocene horizons will ultimately be found in this area containing only pebble tools, as in the case of Africa.

No convincing evidence has been reported to indicate that a blade-burin complex was introduced into India before the close of Paleolithic times.

Far East. Pebble tools, including choppers and chopping tools, are found in the Pleistocene terrace deposits of the Irrawaddy Valley of upper Burma. This complex is known as the Anyathian. The Early Anyathian is characterized by single-edged core implements made on natural fragments of fossil wood and silicified tuff, and these are associated with crude flake implements. In the Late Anyathian, a direct development from the earlier stage, smaller and better made core and flake artifacts are found. No hand axes or flakes produced by the prepared striking-platform-tortoise-core technique have been found in Burma.

Elsewhere in the Far East, pebble tools have been reported from deposits apparently of Middle Pleistocene Age in western Thailand, for which the name Fingnoian has been proposed. In northern Malaya a large series of choppers and chopping tools made on quartzite pebbles and found in Middle Pleistocene tin-bearing gravels have been referred to collectively as the Tampanian, since they come from a place called Kota Tampan in Perak. Still another late Middle Pleistocene assemblage, called the Patjitanian, is known from a very prolific site in south central Java.

Neanderthaloid burials

The Patjitanian assemblage

In both the Tampanian and Patjitanian the main types of implements consist of single-edged choppers and chopping tools that occur in association with primitive flakes with unprepared, high-angle striking platforms. Also in both assemblages is an interesting series of pointed, bifacial implements that have been described as crude hand axes. Since these tools are very rare in each instance and are absent in Burma, it is probable that they were developed in southeastern Asia independently of influences from the West. Several sites of Upper Pleistocene age in central Java have produced artifacts made on small- to medium-sized flakes and flake blades. Antler and bone implements belong to this complex, known as the Ngandongian, which has also been reported from the Celebes and from the Philippines.

The
Choukoutienian
assemblage

One of the oldest Lower Paleolithic occupation sites ever discovered is near the village of Chou-k'ou-tien, about 48 kilometres (30 miles) southwest of Peking in northern China. Associated with the remains of Peking man (*Homo erectus pekinensis*, formerly *Sinanthropus pekinensis*), pebble tools, together with quartz-flake implements, occur in quantity. This assemblage, known as the Choukoutienian, is of Middle Pleistocene age; it forms an integral part of the chopper-chopping tool tradition of the Far East.

Also in northern China several Upper Paleolithic sites are known in the provinces of Shansi, Shensi, and northern Kansu, in the region encompassed by the great bend of the Yellow River (Huang Ho). Collectively known as the Ordosian, these materials are of Upper Pleistocene age. Typical of the Ordosian are blade implements of various types, points and scrapers of Mousterian-like appearance, and pebble tools of Choukoutienian tradition. Originally classified as Mousterio-Aurignacian, it later became apparent that this development had much in common with that of the Yenisey-Baikal region to the north in central Siberia.

Siberia. The archaeological materials from the loess sites of Siberia between the Yenisey Valley and the Lake Baikal area is an interesting mixture of (1) blade tools, together with antler, bone, and ivory artifacts of classic Upper Paleolithic type; (2) points and scrapers made on flakes of Mousterian aspect; and (3) pebble tools representing a survival of the ancient chopper-chopping tool tradition of eastern Asia. Remains of semi-subterranean dwellings with centrally located hearths occur at certain of these stations, together with female statuettes in bone. One of the most striking features of this Siberian Upper Paleolithic is the fact of its comparatively late survival: in terms of the European sequence, it seems to have persisted as late as Early Mesolithic times. Indeed, in several instances it actually occurs in the uppermost layer of loess immediately below a horizon of humus containing Neolithic campsites. The problems of the Siberian Upper Paleolithic are of obvious importance to students of New World archaeology, since they have an intimate and direct bearing on the question of the peopling of the Americas. (H.L.Ms.)

MESOLITHIC-NEOLITHIC:

THE RISE OF VILLAGE-FARMING COMMUNITIES

Middle East. There is little question that a level of an effective food-producing, village-farming-community way of life had been achieved in certain portions of southwestern Asia by at least 7000 BC. Furthermore, increasing evidence indicated that the effective village-farming level was preceded by one of cultivation and animal domestication and that this incipient level was at least under way by about 9000 BC.

Incipient cultivation and domestication. The level of incipient cultivation and domestication was essentially restricted to the piedmont and intermontane valley zone that flanks the Zagros-Taurus-Lebanon chain of highlands about the great basin of the upper Tigris-Euphrates and Karkheh-Karun rivers and their tributaries. There are even hints that the zone extended to parts of the Iranian and Anatolian plateaus and that it may possibly have fingered northwest toward European Thrace. The significant point is that the zone appears to have formed a natural habitat for the cluster of plants and animals that were potentially domesticable. Most of these subsequent

domesticates—wheat, barley, sheep, goats, cattle, and pigs, plus a possible wolf dog—still exist in their wild state in those parts of the zone that have been examined by prehistoric archaeologists and natural scientists.

The level of incipient cultivation and domestication is best manifested by the archaeological materials of the Natufian group in the Palestine-Syro-Lebanese littoral and parts of its hinterland, and by the Karim Shahr group in Iraqi and Iranian Kurdistan. The possibility of a continuation of the level into the northern Syrian and southern Turkish portions of the natural-habitat zone has been essentially untested by modern field research. Both of the available complexes of materials, the Natufian and the Karim Shahr, appear to have been established by about 9000 BC.

The Natufian and Karim Shahr. In both, there are clear indications of open settlements that were of modest size, and there are some traces of round huts, some of which were built on stone foundations, although caves are also known to have still been inhabited. Both groups yield traces of normal developments of flint industries that are based essentially upon local Upper Paleolithic antecedents, and both must have been influenced in their food getting by the already intensified food-collecting practices of their immediate predecessors. It is freely admitted that the postulation of this incipient level rests considerably on a judgment based on the materials of the succeeding level of effective village-farming communities. Nevertheless, it has been demonstrated that sheep were already being used at the incipient level; and there are such hints as flint sickles, ground-stone mullers, mortars and pestles, and probable hoe blades to suggest that food plants were also receiving marked attention. Claims for the domesticated dog in the Natufian are not universally accepted, however. It has been rightly stressed that the materials of this level will be exceedingly difficult to interpret, since the earliest plant and animal domesticates will show little morphological difference from their wild contemporaries and since the procedures and artifacts of the new food-getting and food-preparation techniques will have taken considerable time to develop.

The effective village-farming community. The next level, that of the effective village-farming community, yields, even in its earliest available phase (e.g., at Jarmo, in Iraqi Kurdistan, c. 7000 BC), materials that leave little doubt about the presence of food production. In the Jarmo phase, wheat, barley, a pea, goats, sheep, and—before the phase is completed—pigs and probably dogs all appear. The Jarmo settlement suggests a permanent village of about 20 rectangular several-roomed huts, which probably had a population of at least 150 people. Several other variants of the Jarmo phase have been excavated or at least located in Kurdistan. One of these, Sarab, near Bakhtarān (formerly Kermanshah) in Iran, suggests a seasonal encampment of herdsmen. Sarab yields pottery throughout its shallow deposit; at Jarmo itself, similar pottery appeared only in the upper third of a much thicker deposit.

"Pre-ceramic" village sites have been recovered in the Dead Sea Valley, along the Syro-Palestinian littoral, on Cyprus, in the southwestern Turkish highlands, and even in Thessalian Greece. Controversy exists regarding the very spectacular architectural remains of the Dead Sea Valley site of Tall as-Sultān (reputedly also the site of the later Jericho), with disagreements about its "town" or even "urban" nature in view of the normal small-object assemblage there, the radiocarbon determinations now available for it, and the relative lack of firm evidence for cultivation. These disagreements will certainly be resolved as more sites in the time range of about 9000 to 6000 BC are excavated in the Syro-Palestinian littoral and in parts of its hinterland.

Fully established village sequences in the Middle East. By, or soon after, 6000 BC, a variety of more or less complete regional cultural sequences developed in the Middle East. In Iran, two sequences appeared. That beginning at the site of Sialk developed most characteristically in the northern and northeastern parts of the country and evidently extended into the Turkmen Soviet Socialist Republic and northern Baluchistan and perhaps beyond to

Evidence
of
settlements

the Indus. A somewhat different tradition developed in southwestern and southern Iran, early traces of which may be seen at Ja'farabad in Susiana (Elam) and at Bakun B near Persepolis. This tradition exhibited a closer proximity to the earlier sites in Iraq; its eastern extension may also be traced as far as Baluchistan, if not beyond into the Indus Valley.

The
Hassunan
assemblage

The earliest full-bodied assemblage in northern Iraq, following that of Jarmo, is the Hassunan of the Mosul-Kirkuk piedmont. Next—either as elements in the developed Hassunan phases or alone at the mid-Euphrates site of Baghouz or at the mid-Tigris site of Samarra—comes the Samarran phase. Then, with further overlap, comes the Halafian phase of the upper (Syro-Turkish-Iraqi) piedmont. The overlapping of these three assemblages is indicated by the availability of a radiocarbon determination for an early Halafian level, which is as early as either of the two determinations of the Hassunan—about 5750 bc. The beginning of the food-producing sequence in classic southern Mesopotamia comes after this time and is, perhaps, partly an amalgam of (1) a southward extension of Hassuna-Samarra-Halaf traits; (2) the westward extension of early Susiana traits from southwestern Iran; and (3) the probable presence of indigenous riverine-oriented food collectors.

Another local tradition, at least contemporary with that of Hassuna (and perhaps earlier than that of Sialk), appears to have its focus in the Syro-Cilician corner of the eastern Mediterranean; its preceramic antecedents may be seen in the basal levels of coastal Ras Shamra. Later, this Syro-Cilician tradition appears to have been affected by the Halafian and later inland developments. To the north of Syro-Cilicia the early materials of Hacilar and of Çatal Hüyük must be given place, including the possibility of their implications for the early developments in the Aegean. To the south, the Syro-Cilician tradition merged gradually into a somewhat related coastal Palestinian tradition. But in the more arid reaches of inland Palestine, a somewhat different tradition developed that appears to have culminated in the sites of semi-nomadic traders, such as that at Beersheba.

Food production appears to have reached Egypt (and northern Africa generally) relatively late, perhaps not much before 4500 bc. Such northern Egyptian occurrences as Merimde (on the western flank of the Nile Delta) and the Fayum (Fayyūm) A pit sites might argue for an expansion directly (by boats?) from the Asian coast. But some authorities favour the idea of a way into middle Egypt via the Red Sea and the Wādī Rawḍ 'Aid to account for the available developments there.

General cultural level of the early villages. This very compressed sketch is meant only to suggest the variety of regional variations and adjustments within the general development of the effective village-farming level in the Middle East, from about 6000 to 4500 bc. Wheat and barley were the staple crops; cattle join sheep, goats, and pigs as major food animals, at least by the Halafian phase. Villages—except the Tall as-Sultān fortified establishment—were small; an informed guess would put their limit of population at about 500 people. Again, except for some dubious interpretations of certain rather modest buildings as “shrines,” the architecture appears to be entirely domestic in nature. Aesthetic expression also took the form of an almost bewildering variety of regionalized and successive painted-pottery styles. The modelling of clay figurines—already well attested in the phase of Jarmo and its contemporaries—continues, with both animals and stylized human females being rendered. The latter, especially, may be suspected as having represented some magico-religious aspect of concern with fertility, upon which the livelihood of the communities depended. Flint tools were gradually replaced by copper and, eventually, by bronze implements, and the early trade routes in obsidian (a volcanic glass of restricted occurrence) were doubtless taken over by the metallurgists. Certain artifacts indicate the presence of weaving; in addition to their local utility, woven fabrics may also have served as media of exchange. It would be difficult to maintain that there was a strict subdivision of labour on a full-time scale (except

Evidence
of woven
fabrics

perhaps on a basis of sex or age), but such a trend must have been setting in.

It should be emphasized that the complexity of this picture cannot readily be conceived apart from a system of effective food production. It may also be noted that an older trend was not being reversed. The intensified food collecting at the close of the Pleistocene was apparently accompanied by increasing regional specialization and a tendency toward full utilization of a rather restricted environmental niche. Now—with the establishment and spread of the effective village-farming community, its expansion beyond the confines of the natural-habitat zone, and the beginnings of trade—the horizon began to widen again. The *oikoumenē*, or known world of these first effective village farmers, became an ever-expanding one. Hence, just as it is probably not very fruitful to ask exactly where any particular element was “invented” or first discovered within the level of incipient cultivation and domestication in the natural-habitat zone, it is probably most useful to view the development of the way of life of the effective village-farming community as a general regional phenomenon of cultural interrelationships and stimulations. It might be further suggested that this general development took place over a broad area that had certain localized environmental variables and natural resources. These environmental conditions, however, had been there, just as the natural-habitat zone itself had been, long before incipient and effective food production came into being. The latter were human, cultural achievements; favourable environment, though it enabled them to come into being, did not cause them.

The threshold of town and city life in the Middle East. The end of prehistory and the threshold of urban civilization are first seen in classic southern Mesopotamia about 4500 bc. The materials of the Ubaidian assemblage make their appearance after a still rather poorly delineated phase in the basal levels of the mound of Eridu. Whatever elements combined in the earliest amalgam (northern Iraqi, Susian, or indigenous), the resultant traits of the Ubaidian tradition are revealed in their greatest clarity, consistency, and variety in southern Mesopotamia by 4000 bc.

There are mound accumulations and at least one large cemetery, which suggest a scale of communities well beyond that of the simple village. Buildings sufficiently large, formal in design and size, and monumental in concept and decoration to be judged as temples were present. Great quantities of painted pottery of high quality appear in the excavations. This pottery, by its very uniformity and the somewhat cursive nature of its decoration, may already have been the product of specialized craftsmen. No unquestionable instances of metal tools were available by the early 1960s from Ubaidian contexts in southern Mesopotamia (although metal was available by that time in the north), but quantities of very highly fired clay tools (axes, adzes, sickles) had been found. These were useful for cutting the pithy woods, reeds, and grain of the southern alluvial environment or for dressing sun-baked bricks. The female clay figurines continued, but in a unique and highly characteristic stylization.

General cultural level of the Ubaidian Phase. A Ubaidian town supplied itself from fields of wheat and barley and its animal herds. The agricultural regime in the hot, dry alluvium of southern Mesopotamia depends, however, upon the utilization of the braided lower channels of the Tigris and especially of the Euphrates. Though elaborate irrigation works did not exist, the management of even quite informal ditches, with necessary shifts when the natural channels of the rivers shifted, added a new dimension to the sociopolitical necessities of Ubaidian culture. This system of irrigation may have been one of the factors that contributed to the expansion of society in late prehistoric Mesopotamia. Given the proper management and water, the yield of the rich alluvial soil was magnificent (until salinity became a problem several centuries later). There were also important dietary additions, such as dates from the groves of date palms and fish from the river channels and ditches.

With southern Mesopotamia as its focus, the Ubaidian tradition “exported” some of its elements at least as far as the Mediterranean coast and throughout the great up-

The Indus
Valley

per drainage basin of the Tigris-Euphrates and Karkheh-Kārūn rivers. These exported traits doubtless reflect the growth of another *oikoumenē*, and one much more explicitly southern Mesopotamian in character. In southern Mesopotamia itself, the Ubaidian phase was followed (after a "Warkan" interval) by the proto-Literate period, in which the usual criteria of civilization are manifest.

South and East Asia. It is known that village-farming communities existed in the Indus Valley as early as 3000 BC, if not earlier. The original complexion of their assemblages resembled those of Iran (and perhaps those of the Ubaidian imprint on southwestern Iran), but this complexion gradually changed to something characteristic of the Indus Valley itself and evidently culminated in the Harappan urban civilization. Some degree of contact between the cities of the Indus and of Mesopotamia certainly continued to exist, however. It is becoming evident that the Harappan complex was not restricted to the Indus Valley alluvium but extended into the adjacent semitropical portions of India as well.

Knowledge of the developmental sequence in China is obviously incomplete. Except for a few snatches of typologically more simple materials, the first evidence of food production in China appears to pertain to a well-advanced phase of the effective village-farming-community level. This is the Yangshao complex, focussed in the basin about the confluence of the Yellow River (Huang Ho), the Fen Ho, and the Kuei Shui. Characterized by a handsome painted-pottery style, the Yangshao catalog also includes cultivated millet, rice, kaoling, and possibly soybeans, as well as domesticated pig, cattle, sheep, dog, chicken, and possibly the horse and silkworm. The village houses were built of tamped earth; there was a flourish of "ceremonial" pottery vessels and of elaborately worked objects in jade, as well as flint, bone, and ground-stone objects of daily use. The Yangshao phase is followed by that called Lungshan, after which comes the Yin, or Shang, early dynastic complex of about 1500 BC. The date for the beginning of the Yangshao is unknown; 3500 BC is probably much too early.

Even less is known of southern China and southeastern Asia; the former seems to have been affected by the expansion of the makers of the Lungshan black pottery and perhaps was also stimulated from the south. The rather amorphous Hoabinhian and Bacsonian sequence in Indochina, with ground-stone axes and adzes, appears to be quite late—perhaps of the 1st millennium BC. In Japan, on the other hand, the first appearance of pottery of early Jōmon type (evidently all of the Jōmon development lies before effective cultivation had begun) has several radiocarbon determinations at about 7000 BC, but some authorities suspect contamination of the samples. Positive cultivation (wet rice) appears in Japan about 300 BC, in the Yayoi phase. (R.J.Br./Ed.)

Central Asia and Siberia. The Mesolithic-Neolithic era and the settlement of northern Siberia started in the 7th to 6th millennia BC—the period of climatic optimum in Postglacial times, when forest conditions were introduced. Stratified sites in the Lake Baikal area show a long and gradual transition from the Paleolithic to the Neolithic stage. The Postglacial culture in Siberia was not a true "Neolithic" food-producing, but a "Mesolithic," or "sub-Neolithic," hunter-and-fisher, culture (except in southern Siberia around the Aral Sea) with a microlithic flint industry in western and southern Siberia and with polished-stone tools, pointed- or round-based pottery, and bow and arrow, starting in about the 4th millennium BC in almost all parts of Siberia.

Culturally and racially the territories of this vast area are divisible into two blocks: (1) the southwestern, covering the area from the Caspian Sea to the upper Yenisey, extending over the zones of semidesert, steppe, and forest steppe and (2) the eastern and northern, covering mountainous regions from Lake Baikal to the Pacific Ocean and the taiga (coniferous forest) and tundra belts of northern Siberia. The first is represented by Europoid people, the second by Mongoloid. These two blocks were in conflict until the Mongoloid overflowed the Europoid in several waves.

Europoid block. The earliest Neolithic culture in the steppes and in the oases may reach the 4th millennium or earlier, but its beginnings are not as yet satisfactorily investigated. The small flint industry continued from the earlier Mesolithic times. In the 3rd millennium BC, copper, painted ware, and other elements from the south entered the area. Sheep, cattle, and horses were the chief domesticated animals. Copper knives and stone sledges for mining appeared. Pottery was mostly round-bottomed, decorated with geometric stamped or scratched patterns in rows. Typical burial of the dead was in a contracted position under an earth mound. Excavations in Khwārezm (Khor-ezm, Khiva) revealed large communal houses of oval form. In the region of the Aral Sea (Khwārezm) this culture was given the name Kelteminar, in Altai and the region of Bisk, Krasnodar, and Minusinsk, Afanasievo, although related cultural features are found between southern Russia and the upper Yenisey, the area presumed to be Indo-European homeland. The Afanasievo was replaced by the Okun group of stockbreeders mixed with Mongoloid elements, famous for stone stelae incised with mythical figures, elsewhere in southern Siberia.

Continuous cultural development is seen in the 2nd millennium BC. This culture, named Andronovo, is relatively uniform in this wide area, in spite of some local variations. Agriculture now played an important role. People lived in earth huts and reared cattle, sheep, and horses. Bowl- and flowerpot-shaped vessels were flatbottomed, well smoothed, decorated with geometric patterns, triangles, rhombs, and meanders, pointing to relationship with the painted pottery of the southern regions. Burial in contracted position persisted. The typical elements of a religion of food producers, the fire and sun cult, as well as bread offering, are evidenced. Wooden constructions in rich graves may have designated social differentiation. The Andronovo complex is intimately related to the Timber-Grave (Russian Srubna) group in southern Russia: both represent branches of the Indo-Iranian cultural block.

In the second half of the 2nd millennium BC in the region of Minusinsk, a Sinid group broke in that brought with it a bronze inventory of Ordos (northern China) type. Cemeteries of single graves covering the dead in extended position in stone cists, equipped with round-bottomed pots, appeared. New people mixed with the local Andronovo population. Through this immigration the so-called Karasuk culture originated and spread its influences farther to western Siberia and Russian Turkistan. Trade relations extended to central Russia. Exchange with the centres of the Far Eastern metallurgy introduced a new character of material culture (daggers and knives terminating in animal sculptures, series of ornaments) and stimulated the flourishing of metal industry in a wide area. The regions west of Minusinsk—Altai, Kazakhstan, and Kirghizia—show variations of Karasuk culture with strong local elements with which the persistence of the ancient racial type corresponds. Chronology of this period is based on comparisons with northern Chinese bronzes.

The Karasuk period persisted down to c. 700 BC. From c. 700 to c. 200 BC, culture developed along similar lines. Vital trade contact is traced from northern China and the Baikal region to the Black Sea and the Urals, influencing the uniformity of the culture. A mounted-warrior element occurred, although the agricultural and cattle-breeding elements persisted. In the high Altai, Tien Shan, and Pamirs appeared graves of nomadic warriors with co-burial of horses. Regarding the local facies, or separate political confederations, cultures of this period are called Tagar in the region of Minusinsk, Maiemiric in Altai, Sauromatian (Sarmatian) in western Kazakhstan, Sakian in Tien Shan and Pamirs, and Massagetian in Khwārezm.

The art of the steppe zone from southern and eastern Russia to China developed into specific animal style. The decorative talent is illustrated in the great ingenuity that the artist displayed in filling up with animal figures a shape determined by practical ends. The elk, ram, bird, and cat-animal portrayals of the middle of the 1st millennium BC exhibit a conjunction of the highest verisimilitude with rigorous stylization; later the organic form of the animal was ruled by extreme stylization. The elements of natural-

Burial
practice
and
dwellings

Animal-
style
decorative
arts

ism link this style with the naturalistic animal style of the northern Eurasian forest belt. New motifs in the steppe and forest-steppe belt—portrayal of groups of animals, antithetic and intertwined groups of bodies, curled up animals, beasts, and birds of prey—originated in a borrowing of ideas from the Middle East and China.

Pre-Christian culture, although influenced by the Persian Empire, progressed gradually until the new flow from the east started. The territory between the lower Volga and Altai represents a unit with a common destiny. Chinese and Western sources report that the Sarmatian-Sakian time was followed by the supremacy of the Huns, who dominated the western steppes as far as the Urals and the Volga. Archaeological investigations show that the east-west movement started at a time when the Hun confederation had not yet been consolidated. In eastern Kazakhstan appeared an eastern group of Stone Tombs people not later than the 5th century BC. The main east-west stream ran presumably from Manchuria—upper Lena, along the northern border of the Gobi, into the Lake Balkhash territory, and from there on, avoiding powerful cities in Khwarezm, into the steppes north of the Caspian. For centuries up to the consolidation of the Turkish khanate in the 6th century AD, Mongoloid components were mingling with the local Europoid, which have never been wiped out. The known pre-Turkic tribes—Massageti, Sakians, Usuns, Khakas—all show more or less Europoid traits.

The cultural pattern from Altai to Transbaikalia in the last centuries BC and first centuries AD is largely traced to China of the Han period. Social differentiation is evidenced by princely burials, extraordinarily well preserved in five large burial mounds of Pazyryk and Shibe in the high Altai. Complete burial places were frozen, and even perishable substances were preserved, including human bodies and horses with harness and saddles, textiles, felt and leather objects, clothing, fur coats, false beards, besides jewelry, mirrors, hair plaits, etc. All materials were finished with virtuosity. The art combined animal, plant, geometric, and human designs. Polychromy played an important part. Mummification, tattooing, scalping, and the use of amulets are evidenced.

Meanwhile, in the region of the Aral Sea, the apogee of the Khwarezm civilization was reached in the epoch of the empire of the Kushans. During the 1st and 2nd centuries AD the irrigation system attained its greatest development. Numerous cities were built along the banks of the canals.

Mongoloid block. The Arctic and sub-Arctic zones exhibit a continuous culture belt in a sub-Neolithic stage from Boreal times through several millennia. Making of pottery and polishing of stones, but neither farming nor domestication of animals, except the dog, were known. People lived in small, semi-nomadic communities, in semi-subterranean houses. The Arctic seashores demonstrate sea-hunter cultures. In the north this stage of life has lasted down to the present time. The region of the Amur River in eastern Siberia shows a long-lasting Neolithic, of which the oldest forms resemble certain finds of northern Japan (Proto-Ainu) and China. Cultural continuity is traced from the Neolithic through the stages in which copper smelting and iron were known. In the farthest northeast, archaeological and other data suggest that the Kamchadal, Koryak, and Chukchi entered the area from the west less than 2,000 years ago and found the coastal region occupied by a population related to the Eskimo.

The Ural region was linked with the northern Russian and western Siberian culture on one hand and with the Aral Sea region on the other. Throughout the Neolithic and Bronze Age times, two cultural branches were evident: the middle Ural (or Shigir) and that of the River Ob Basin. During the 3rd and 2nd millennia BC the culture of the middle Ural region is famous for its elk and water-bird sculptures portrayed in wood, found in the peat bogs of Gorbunovo and Shigir, and that of the upper Ob region for its cemeteries in the area of Tomsk, abundant art objects, including bear figurines, and rock carvings. Cultural relationships between the northern Baltic and northwestern Siberia, forming a continuum up to the early historic period, furnish this area with the characteristics of the homelands of the Finno-Ugric-speaking peoples.

The best explored regions are the shores of Lake Baikal, the Angara Valley, the upper Lena, and the lower Selenga. The earliest Neolithic culture shows Siberian Upper Paleolithic traits; the flint tradition of small implements persisted alongside a wood-working and quartzite industry, which developed as a result of adaptation to a taiga environment. Chronological phases are based chiefly on the Angara grave materials by means of stratigraphy and comparisons. The following successive cultures are discerned: (1) Isakovo, showing the earliest appearance of pottery, alongside flint and bone tools (arrowheads, knives, points, half-ground adzes). Pointed-based pots in Isakovo probably were copies of similarly shaped baskets. Art monuments are not numerous here. The period may reach back to c. 4000 BC. (2) Serovo, characterized by thinner pottery, decorated by dentate stamping, boss, pit, and net impressions and by stone inventory of more regular forms; reinforced bows with bone backing and fish effigies of stone appear. A marked increase of population is indicated by settlements covering hundreds of square metres, including storage pits for fish. In cemeteries, women's graves were richly equipped, which may indicate woman's equal rights in Serovo community. Serovo people migrated to the steppe and deserts of Central Asia and Inner Mongolia. The period belongs to the 3rd millennium BC. (3) Kitoi, placed before the middle of the 2nd millennium BC, shows a variety of more developed forms of equipment; the great number of fishhooks found in the graves indicates that subsistence was now based primarily on fishing instead of hunting; sculptures of human faces in stone, stone rings, and nephrite and copper objects appear; close parallels in stone and bone industry, as well as in art style, are found from northern Scandinavia and northern Russia to China. (4) Glazkovo, extending through the middle of the 2nd millennium BC to c. 1300 BC, continues a similar mode of life; novelties include the appearance of burial mounds and burials in stone cists, copper knives and arm rings, nephrite rings and disks.

The first bronze inventory in the region of Lake Baikal is related to the bronzes of the Shang period in northern China and the earliest Ordos bronzes. Life was then of semi-settled character, and cattle breeding was known. Continuity of culture in the Bronze Age stage is traced up to c. 300 BC. The period between c. 700 and 300 BC in Transbaikalia, called Stone Tombs I, exhibits a transition to nomadism and mounted-warrior conditions. Cultural elements held in common with the Scythian steppe zone appear as far in the northeast as the Lena River. South-north and north-south movements are attested in the last centuries BC. The south-north movement is assumed as Yakut migration from the Baikal to the upper Lena region, the north-south movement from Cisbaikalia to Transbaikalia as migration of the taiga group, related to the Tungus of the present day. (M.G.)

Chronological phases

Africa

PALEOLITHIC

The Paleolithic of Africa is characterized by a variety of stone-tool assemblages, some of which represent purely local developments while others are practically identical with materials from corresponding horizons in Europe. Geological investigations of the Late Cenozoic deposits of this continent indicate that, as the result of fluctuations in rainfall, the Pleistocene Epoch throughout most of Africa can be subdivided on the basis of a succession of pluvial and interpluvial stages. The pluvials, known as Kageran, Kamasian, Kanjeran, and Gamblian, are believed to represent the tropical and subtropical equivalents of the four major glacial stages of the Northern Hemisphere, but this has not yet been proved. The archaeological succession is well established in certain areas, although not in the continent as a whole.

North Africa. In this area, very crudely worked pebble tools have been reported from one site in Algeria in direct association with a Lower Pleistocene (Villafranchian) mammalian assemblage. Throughout Tunisia, Algeria, Morocco, and the Sahara region, Lower Paleolithic hand axes of both Abbevillian and Acheulean type, to-

Tool sequences

gether with flake tools, have been found in great numbers. The geological evidence shows that the Sahara region was far less arid during Pleistocene times than it is at present. The Middle Paleolithic of both Levalloisian and Mousterian facies is very widespread in North Africa, and it apparently persisted as late as the second maximum of the Würm glaciation in terms of the European sequence. A specialized Middle Paleolithic development, known as the Aterian, occurred there; it is characterized by tanged points made on flakes and flake blades. This was succeeded by two distinctive blade-tool complexes—the Capsian and Oranian—which are more or less contemporary. Their main development took place during the time span of the European Mesolithic. The Capsian sites are all inland, whereas the Oranian has a coastal distribution. Both are microlithic tool complexes that persisted after the introduction of Neolithic traits into the area.

Egypt. The Pleistocene terrace gravels of the Nile Valley in Egypt have produced a wealth of Paleolithic materials. The 30-metre terrace contains typical Abbevillian and early Acheulean hand axes, including a special form with a triangular section known as the Chalossian type. These are associated with primitive flake implements. In the 15-metre terrace, developed Acheulean has been recorded, while the nine-metre terrace yields large flakes and cores of Levalloisian type. In the low terrace, which occurs at a height of three metres above river level, developed Levalloisian (originally called Mousterian) has been reported. Overlying the low terrace, a local development known as the Sebilian is found. It contains very highly evolved flake implements of Levallois type and, in its later phases, a definite microlithic industry. Of approximately the same age as the Sebilian are several Epi-Levalloisian sites in the Lower Nile drainage, including the Fayyūm Depression and the al-Khārījāh (Kharga) Oasis. In the latter area, where the specialized Levalloisian development is called the Khargan, an Egyptian version of the Aterian has been discovered.

East Africa. In Kenya, Tanzania, and Uganda, very simple types of pebble tools, roughly chipped to an edge on one side only, occur in deposits of Lower Pleistocene age. This development, known as the Kafuan, apparently evolved into an industry characterized by implements made on pebbles chipped to an edge on both sides, called the Oldowan. Overlying the latter are beds containing true Lower Paleolithic hand axes of Abbevillian and Acheulean type, together with flake tools. Associated with the Middle and Late Acheulean are cleavers made on flakes, as well as evidence of the use of the prepared striking-platform-tortoise-core (Levallois) technique in the production of flakes. In the next-younger horizon, two distinct toolmaking traditions are found: the Kenya Stillbay, a Levalloisian derivative characterized by small- to medium-sized, bifacially flaked points or minute hand axes; and the Kenya Fauresmith, basically of Acheulean inspiration and very similar to the true Fauresmith of southern Africa. Carefully shaped round stone balls, believed to have been used as bola weights in hunting, constitute part of the Fauresmith assemblage. In the post-Gamblian dry phase, microlithic tools appear for the first time in an assemblage known as the Magosian. This was followed by the introduction into the area of a true blade technique, called the Kenya Capsian, together with the art of pottery making. More or less contemporary with the localities where the earliest pottery is found in East Africa, a series of sites has been discovered yielding typical microlithic assemblages and referable to the Kenya Wilton, also found in South Africa, Zimbabwe, and Zambia.

Southern Africa. The sequence in southern Africa is well established on the basis of the terrace stratigraphy of the Vaal Valley. Just as in North and East Africa, the succession begins in the basal Pleistocene with the occurrence of simple pebble tools of Kafuan type. These develop into what is called the pre-Stellenbosch, which is found in the oldest gravels of the Vaal and which includes artifacts made on pebbles that recall both the Kafuan and the Oldowan. The true Stellenbosch complex occurs in the next-younger series of deposits; it is simply a southern African version of the Abbevillian and Acheulean

of other parts of Africa and Europe. Typical are hand axes, cleavers, flakes struck from Victoria West cores, and (in its later phases) various sorts of flakes produced by the prepared striking-platform-tortoise-core technique. The Stellenbosch was followed by the Fauresmith, which is characterized by evolved hand axes and Levallois-type flakes. The Stellenbosch and Fauresmith together constitute what is called the South African Older Stone Age, a period roughly corresponding to the Lower and Middle Paleolithic stages of Europe. On the other hand, the South African Middle Stone Age belongs to the later part of the Upper Pleistocene. It is characterized by a series of more or less contemporary flake-tool assemblages, each of which displays local features. These are known as Mossel Bay, Pietersburg, Howieson's Poort, Bambata Cave, Stillbay, etc.; Stillbay, which occurs in Kenya and Uganda, is the only one of these found outside southern Africa. The characteristic tools are made on flakes produced by a developed Levalloisian technique, including slender unifacial and bifacial lances or spear points for stabbing or throwing. In the final stages of the Middle Stone Age, known as the South African Magosian, microlithic elements appear, just as in the case of East Africa. The Later Stone Age cultures of this region—the Smithfield and the Wilton—developed during post-Pleistocene times. These are closely related and, in their later stages, reveal varying degrees of influence as the result of contact with the culture introduced by the Bantu-speaking peoples. Both were extant at the time the first Europeans arrived in southern Africa, and there is little doubt that the Wilton, which is a typical microlithic assemblage, is to be associated with the modern San (Bushman). There are many paintings in the rock shelters and engravings on stones in the open-air sites of southern Africa, the oldest of which belong to the Later Stone Age. The naturalistic style of art revealed at these sites persisted until well into historic times.

Central Africa. The Lower Paleolithic sequence of Central, or Equatorial, Africa is essentially a repetition of what has already been outlined for East and southern Africa. At the beginning of Middle Stone Age times, however, a special development took place known as the Sangoan (formerly Tumbian). This is characterized by picks and adzes made on bifacially flaked cores, the tranchet type of ax, hand axes of developed Acheulean form, massive side scrapers, and many elongated, bifacially flaked points that probably served as lances or spearheads. The Sangoan seems to represent a response to the environmental conditions of this tropical rain-forest region. Its main development took place during Upper Pleistocene times, but it persisted after the introduction of Neolithic traits into the area. (H.L.Ms.)

MESOLITHIC-NEOLITHIC

The Paleolithic was everywhere followed by the Mesolithic, a period when man continued to use stone tools, mostly microlithic, and, while still in the hunting-and-gathering stage, depended less for his food supply on large mammals than on fish and mollusks. In Africa the evidence for the Mesolithic is still scanty. In the Lower Nile Valley, sites have been examined only at Hulwān (Helwan) and Kawm Umbū (Kom Ombo). At the latitude of Khartoum, for a considerable distance to each side of the Nile, have been found sites of a Mesolithic culture in which large, well-fired, unburnished pots decorated with designs impressed with a fish spine to make them resemble baskets were made and barbed bone harpoons were used for fishing. Arrows were mostly armed with stone lunates, and in general the microlithic industry shows relations with the Capsian (of northwestern Africa) and the Wilton (of east central Africa). The fauna indicates a climate much wetter than the present. The upper Kenya Capsian, with traces of similar pottery found at Gamble's Cave, probably represents the Mesolithic of Kenya. Its pottery also copies basketwork. And while it is impossible to say where pottery was invented, the discovery of a prepottery Neolithic in Asia, with the existence of modern mud-lined baskets among the Nilotes, the accidental burning of which could have led to the invention of pottery, suggests that pottery was possibly an African discovery.

Valley sites

Vaal Valley
strati-
graphy

The Neolithic inventions that led to the rise of man above the conditions of the Old Stone Age were made gradually in different places and probably over a long period. Some, such as the domestication of animals, took place more than once. In a famine, a wild animal will sell itself into slavery to man for the food that will preserve its life. Thus, cattle and goats, while certainly domesticated in Asia, may have been independently domesticated in Africa, too. African jackals may have provided one breed of domestic dog, while the donkey and the cat are African. The polishing of stone implements was probably a by-product of the grinding of red ochre, in wide demand for its magic properties since the Paleolithic and extensively used in Africa in the Mesolithic and later. One result of the grinding of ochre was to polish the grindstone, and another, when the upper grindstone was used at an angle, was to develop a sharp edge that, produced accidentally, may have led to the idea of grinding the cutting edge of celts or other tools. Repeated pecking of the flat surfaces of the grindstones that became too smooth to grind ochre efficiently led to perforation of the stone and thus to the development of the disk macehead of the Nile Valley. Archaeology must establish where and when celts were first ground; but the partly polished celts of the Fayum and Khartoum are probably the earliest forms of that tool known. The cultivation of wheat, barley, and flax probably were Asiatic developments that first entered Africa through the Nile Delta. The cultivation of one form of wheat may have originated in Ethiopia, however.

In Egypt, civilization first reached its full development c. 3000 bc, but though it passed through Copper and Bronze ages and introduced copper tools to The Sudan, there is no evidence of either of these ages in the rest of Africa, where a transition from the Stone Age, generally still Mesolithic in type, directly to the Iron Age took place gradually during the last two millennia and in a few places did not take place until the middle of the 20th century. In some localities, an intermediate state, when Neolithic forms were used, occurred (e.g., Zaire and Ghana), but elsewhere (e.g., Kenya) polished-stone celts, or axes, seem so rare that they may have been comparatively late imports from the north.

(Ed.)

The Americas

The prehistoric sequence in the New World shares many essential developmental features with the Old World and provides a test for generalizations about cultural development based upon Old World materials. In the New World there is evidence for an early horizon of primitive food collectors, followed by an increasing specialization of food collecting based primarily upon differences in localized resources. These specialized collectors were followed by a tradition of food production independent of the Old World.

With food production came gradual increases in centres of population; villages were succeeded by towns and finally by centres of urban civilizations, which at the time of European contact were comparable to the ancient civilizations of the Middle East.

The absence of a suitable fossil record and of cultural remains from Early and Middle Pleistocene deposits in the New World have led prehistorians to look to the Old World as the ultimate source of the diverse populations of American Indians found in the Western Hemisphere by the early European explorers. Present knowledge of Pleistocene glaciations and of accompanying alterations in sea level indicates that the most probable route of entry for man from the Old World was via a land bridge between Alaska and Siberia, crossing what is now the Bering Strait. It appears that a dry-land crossing of this area was possible during periods of continental glaciation, until about 10,000 years ago. The subsequent flooding of this region has hidden whatever traces these early migrants may have left of their arrival on the threshold of the American continents, and it is necessary to look to the interior of North America for evidence of their presence. Although these early horizons of American prehistory are little known,

a few sites in central Mexico have cultural remains or other possible evidences of man in a context suggesting occupation as early as 20,000 years ago. At no site in this early context are there any types of implements distinctive enough to be recognized in a context of crudely chipped stone tools from later horizons.

EARLY CULTURES

The earliest well-defined cultures in the New World have been placed by radiocarbon dating at about 9000 to 10,000 bc. At this period, two distinct traditions in North America are known: the Paleo-Indian big-game hunters of the Great Plains and eastern North America, and the Desert-culture peoples of the western basin-range region.

Paleo-Indian tradition. The oldest remains of the Paleo-Indian tradition are found on sites where large Pleistocene mammals were killed and butchered. The most distinctive artifact type of this horizon is the Clovis Fluted projectile point, a lanceolate point of chipped stone that has had one or more longitudinal flakes struck from the base of each flat face. These points are accompanied by side scrapers and, in one instance, by long cylindrical shafts of ivory. They are most frequently associated with mammoth, although associations with extinct species of bison, horse, and camel have also been reported.

A second Paleo-Indian horizon, which seems in part to be contemporary with the Clovis material and partially to postdate it, is the Folsom phase of the central high plains. It is characterized by lanceolate points of more careful manufacture (including broader fluted surfaces) than Clovis, associated with the remains of extinct *Bison antiquus*. The Lindenmeier site, a Folsom campsite in northeastern Colorado, has yielded a wide variety of end and side scrapers, graters, and miscellaneous bone artifacts. Clovis sites have been dated at about 9000 bc by radiocarbon, and Folsom sites at about 500 to 1,000 years later. Fluted points similar to western Clovis specimens have been found over most of the eastern United States south of the limits of the last major glacial advance. A single series of radiocarbon dates from the Debert site in Nova Scotia places the age of points of similar type at about 8500 to 9000 bc in that area. The distribution of this artifact type with respect to glacial events, however, suggests an appearance as early as 11,000 bc and a terminal date about 3,000 years later. In the east, several specialized varieties of fluted points may replace Clovis-type points toward the end of the Paleo-Indian occupation. While there is no instance of the discovery of eastern fluted points in association with an extinct fauna, the similarity of the accompanying assemblages of scrapers and graters to those of the western industries suggests a similar carnivorous economic orientation in the east. Outside of the United States, fluted points have been reported at scattered sites from Alaska to Ecuador, but no certain temporal context has been established for any of these finds, and faunal associations are not clear.

Another variety of Paleo-Indian culture, which appears to be contemporary with the Clovis and Folsom phases, is characterized in its early horizons by rather crudely flaked lanceolate points that have been found associated with the bones of mammoth at two sites near Ixtapan in the Valley of Mexico and between the Clovis and Folsom horizons in a gravel pit near Portales, New Mexico. Similar points in circumstances suggesting comparable age have been found at San Jon, New Mexico, and Lime Creek, Nebraska. It appears that by about 7000 bc the fluted-point industries were replaced by a succession of lanceolate-point-using phases, which continued the Paleo-Indian hunting tradition, concentrating primarily on large, now-extinct species of bison until the onset of the Altithermal dry period about 5000 bc. The eastern limit of these cultures is in the vicinity of the western Great Lakes, while the most intensive occupation was on the western plains.

Desert tradition. The Desert-culture tradition, an adaptation of food-collecting peoples to the impoverished habitats of the basin-range area of western North America, seems to have been established by about 9000 bc. The most extensive knowledge of this way of life comes from cave or rock-shelter sites, such as Danger Cave in western

The Clovis point

Transition from the Stone Age

Utah, in which the desiccated remains of vegetal and animal materials have been discovered along with stone tools. The Desert peoples made intensive use of virtually all aspects of their habitat, specializing in the use of vegetable fibres for a wide variety of implements, including twine, nets, baskets, sandals, and snares. Projectile points appear to have been mostly leaf- or lozenge-shaped or lanceolate in earlier phases, with a greater use of notching for hafting in later phases. An essential feature of Desert assemblages is the milling stone, for use in grinding wild seeds. In earlier sites this is likely to be a small, thin, portable slab of stone used with a small pebble handstone, while later in the sequence, large, basin-shaped milling stones are more characteristic. Large choppers and scrapers are common in Desert sites and appear to have been used for the processing of plant materials.

RISE OF AGRICULTURE

Although the southern limits of the Desert culture are not yet clearly defined, it is known that it extended into Mexico, where, in the state of Tamaulipas, Desert materials have been found associated with the earliest known cultivated plants in the New World. Here, in the Infernillo phase, it appears that native American squash, peppers, and perhaps beans were being cultivated as early as 6500 BC. At this time, domesticates formed only a small portion of the total diet, the bulk of which was derived from wild animals and, to a lesser extent, wild plants. At about 2500 BC a primitive variety of corn (maize) first appeared in the Tamaulipas area in the La Perra phase. It appears, however, that corn was first domesticated elsewhere, possibly in the Puebla area of south central Mexico, where a date of 3600 BC is reported from materials associated with early corn in a cave near the town of Tehuacán. Even in the La Perra phase, cultivated species formed only a small part of the total diet, the majority of foodstuffs being wild plants. It appears that the development of efficient techniques of production of the three major New World domesticates—corn, beans, and squash—was necessary before real sedentary village and town life was possible in most of nuclear America. This level of efficiency seems to have been reached between 2000 and 1500 BC in Meso-America and Peru. Thus, there is evidence in the New World for plant domestication comparable in age to that of the Old World, but for many years this was unattended by the development of village life that closely followed domestication there.

OTHER DEVELOPMENTS

While the earliest cultivation was under way in Middle America, other areas of the New World also show evidence of interesting developments. At the site of Palli Aike, on the Strait of Magellan, the earliest cultural horizon has yielded a radiocarbon date of about 8000 BC, indicating that man reached the southern extremity of the New World well before 10,000 years ago. In the Northern Hemisphere, food-collecting cultures were well adapted to several specialized ways of life by about 4000 BC.

Archaic tradition. In the eastern United States, two basic traditions utilizing the woodland areas appear to have grown from an earlier culture that was present in that area by 6000 or 7000 BC. This early Archaic tradition is best known from the Modoc Rock Shelter in southern Illinois and from Graham Cave in Missouri and Russel Cave in Alabama. It differs from preceding Paleo-Indian horizons in its orientation toward a broad range of resources, including plant foods, as evidenced by the frequent use of milling stones. While some projectile points from these sites suggest Paleo-Indian varieties, the majority are stemmed or notched and differ in flaking technique from contemporary western Paleo-Indian specimens. By 2500 BC the Archaic cultures of eastern North America had separated into several distinct phases. There appears to have been a major division between peoples adapted to a riverine environment in the south and those adapted to the lacustrine resources of the north. Both depended, to a large extent, on the forest resources bordering these aquatic habitats. The Middle Atlantic coastal area appears to have supported another type of Archaic culture, and the boreal

forests of the north yet another. In areas without concentrations of particularly favourable resources, a generalized Archaic culture similar to the earlier pattern seems to have persisted. Most Archaic cultures are characterized by a rather extensive use of ground-stone implements, both woodworking tools and other categories, such as bowls, knives, net sinkers, and elaborate weights for spear throwers. Projectile points vary widely but are usually rather large and crude and are stemmed or broadly notched for hafting. Perhaps the most interesting of the late Archaic manifestations is the Old Copper culture of the northern Great Lakes area. Here, exposures of native copper were quarried and cold-hammered into implements, such as projectile points, knives, awls, and axes; and highly valued copper from this region was traded over much of eastern North America.

Western North America. In western North America, similar developments were under way during this same period. It appears that the more arid regions of the basin-range country were largely depopulated during the Altithe thermal dry period (from about 5600 to 2500 BC) and that in surrounding regions diversification and specialization took place. In the drainages of the major rivers of the northwest, such as the Columbia and the Fraser, the annual abundance of salmon was the basis of a cultural adjustment as early as 7000 BC. Implements of this horizon are similar to those found earlier in the Desert culture, with projectile points, the most diagnostic artifact types, tending to be long and leaf-shaped or slightly stemmed and with a few notched forms also present. Following the Altithe thermal drought, a broad horizon characterized by the use of indented-based points with serrate-edged blades (generally termed "Pinto-like," after the type locality in the Pinto Basin of California) is found over much of the southern portion of western North America. In at least one of the phases representing this horizon, the Chiricahua of southern Arizona and New Mexico, it appears that primitive corn cultivation was practiced. The site of Bat Cave in western New Mexico has produced specimens of a type of primitive corn that is also known from the Flacco phase in Tamaulipas at 2000 BC but that is here in association with a Chiricahua assemblage from which materials have been dated at about 1000 BC.

South and Middle America. By 2500 BC, techniques of cultivation had also reached the northern coast of Peru, where, at such sites as Huaca Prieta at the mouth of the Chicama Valley, there was a mixed dependence upon marine foods such as sea urchins, mollusks, and fish; upon wild plants, mostly tubers and roots; and upon cultivated plants, including beans, peppers, and a different genus of squash than that cultivated in the early horizons in Tamaulipas. Gourds and cotton were also grown, the gourds for use as containers and net floats, the cotton for twined fabric and cordage. The use of stone at Huaca Prieta is interesting in its simplicity. Crude flakes and shattered pebbles compose the entire chipped-stone industry, while pecked and ground-stone artifacts are chiefly perforated net sinkers. In the upper levels of the site are architectural remains consisting of one- or two-room, small cobble-walled subterranean houses. The absence of ceramics at the Huaca Prieta site poses a number of interesting problems. From the Valdivia site in Ecuador, several hundred miles to the north, radiocarbon samples indicate that ceramics may have been present there as early as 2500 BC, and another date from Panama indicates that the ceramics of the Monagrillo phase were manufactured by about 2000 BC. Present knowledge of the northern coast of Peru does not reveal ceramics before about 1200 BC, indicating an isolation of this area from cultural developments to the north. With ceramics, corn and other indications of Middle-American influence appear in Peru.

VILLAGE FARMING AND TOWNS

The appearance of village farming in the upper levels at Huaca Prieta and in the immediately succeeding Guañape phase in surrounding areas is roughly contemporaneous with the first appearance of this way of life in the Valley of Mexico at such sites as Zacatenco and El Arbolillo. Here a relatively sophisticated ceramic tradition (clearly derived

tradition

from elsewhere) appears in the earliest levels. While evidence for architecture is not completely clear, it appears that by about 1500 BC there were small villages of wattle-and-daub huts scattered along the shores of the lakes of the Valley of Mexico, with inhabitants subsisting largely on corn-bean-squash cultivation, supplemented by the meat of game animals and by various aquatic resources.

Earliest evidences for the next cultural advances are apparent by about 800 BC in changes in architecture and settlement pattern in several areas of Middle America and Peru. At this time, fairly extensive public works are represented by temple structures and large sculptured monuments, which occupy a central position in towns and villages. Phases as widely separated as the Olmec of Veracruz and the Cupisnique of coastal Peru appear to be linked not only in time and patterns of basic subsistence but in specific ritual practices involving a jaguar or feline deity. Throughout Middle America and in the Andean area, this appears to have been a time of consolidation and establishment of the basic traditions that dominated the development of high cultures in the New World up to European contact.

Hopewell culture. The spread of cultivation into North America seems to have proceeded along two separate courses, one from northern Mexico into the southwest and the other from an unknown Middle American source into the Mississippi Valley. One of the earliest known phases in eastern North America in which corn cultivation appears to have had a role in subsistence is the Adena, which occupied the middle Ohio River Valley by about 800 BC. The stimulus of the Adena farmers was apparently instrumental in bringing about the spectacular Hopewell culture in the Illinois and Ohio valleys. The success of the Hopewell peoples (400 BC to AD 400) seems to have been due largely to their combining elements of the preceding Archaic cultures with elements of the Adena culture and perhaps with some features of a local cultivating tradition. It is evident that the Hopewell culture included a well-organized village-based society in which surplus resources were used in the construction of elaborate earthworks and were concentrated as wealth in a restricted group of individuals. The most outstanding feature of Hopewell culture is a burial complex that called for the deposition of concentrations of wealth in tombs of one or several deceased individuals. The interment procedure was elaborate and involved the construction of a large log tomb, later burned and covered by an earth mound. Artifacts found within these burial mounds indicate that the Hopewell were able to obtain goods from widespread localities in North America. Obsidian and grizzly-bear teeth were apparently derived from the Rocky Mountain region, copper from the northern Great Lakes, and conch shells and other exotic objects from the southeast and along the coast of the Gulf of Mexico. The ceramics of the Hopewell appear to be based in two major traditions, one derived from northern Asia, which reached eastern North America by about 1000 BC, and the other from Middle America, where the decorative technique of rocker-stamping, characteristic of finer Hopewell pottery, existed several hundred years prior to the earliest appearance of the Hopewell culture. In less favourable areas of eastern North America, a "generalized Woodland" culture paralleled the Hopewell in time, probably based more on collecting than on cultivation.

Mississippi culture. The period of the Hopewell culture was followed by relative decline in social cohesion in the northern Mississippi and Ohio valleys, evidenced by the absence of unifying features comparable to the Hopewell in the succeeding generalized Woodland culture. At about AD 800 a new tradition, with much stronger and more specific Middle American elements, moved up the Mississippi Valley. This Mississippi culture was based on more intensive cultivating techniques than the Hopewell and resulted in impressive concentrations of population in large towns through the southern and central Mississippi Valley and in several areas of the southeastern United States. A central ceremonial plaza provided the nucleus of a Mississippi town, and each settlement had one or more pyramidal or oval earth mounds, surmounted by a temple or chief's residence, grouped around the plaza. This settle-

ment pattern is typical of most of Middle America after about 850 BC but is not found in North America until the Mississippi culture appears. The scale of public works in the culture can be estimated from remains of the largest of the Mississippi earthworks, Monk's Mound near Cahokia, Illinois, which measures 1,000 feet in length, more than 700 feet in width, and is still 100 feet in height. The first European explorers in the southern Mississippi Valley in the early 16th century found the Mississippi culture still flourishing as warring alliances of towns, each ruled through a theocratic system based on kin ties.

Pueblos. In the southwest, the earliest villages of farmers appeared by about 200 BC, and this initial development in southern New Mexico and Arizona was succeeded by a gradual spread of this way of life as far north as southwestern Colorado, east to the Pecos River, and west into the lower valley of the Colorado River. The maximum expansion of the Puebloan culture of the eastern and northern portions of the southwest appears to have taken place by AD 1150 or 1200 and was followed by the gradual abandonment of much of the area by farming peoples. This decline seems to have been due to a combination of factors, including drought, deforestation, and lack of social cohesion within the villages. At the time of historic contact the Puebloan peoples were restricted to the Rio Grande Valley and adjacent localities and to scattered settlements in west central New Mexico and on the Hopi mesas of Arizona. The early explorers encountered other less well-organized farming groups, descended from the Hohokam and Patayan traditions of the southwest, in scattered localities along the Gila, Salt, and Colorado rivers.

South America. In South America, little is known of cultural development outside the Andean area, where, as in Middle America, urban civilization was well under way by the first few centuries AD. From a sequence near the mouth of the Orinoco, it appears that manioc cultivation, which formed the subsistence base for stable villages in the tropical forest, had been developed by about 1000 BC. Peripheral to the Andean area, numerous cultures are known, particularly in Colombia and northern Argentina and Chile, that show marked influence from Andean urban centres and yet preserve distinct local traditions throughout the late prehistoric period.

The general picture. An overall view of the prehistory of the New World prior to the development of urban civilization reveals several general trends. The outline above follows the forefront of cultural development as it took place in several well-known areas. In localities less favourable to primary or intensive cultivation, the level of cultural development tended to stabilize at the point at which maximum food production was possible with the techniques at hand. Thus, in the Arctic and in the boreal forests of the north, as well as through most of southern South America and various other regions unfavourable for cultivation, cultural activity remained at an Archaic food-collecting level through the entire prehistoric period. In the tropical forests of South America and the woodlands of the northeastern United States, farming villages were the apex of cultural development under prehistoric conditions. In relatively favourable areas, such as the Mississippi Valley, the oasis regions of the southwestern United States, and several other regions peripheral to the South and Middle American high-culture centres, temple-centred towns were the climactic development. A general appraisal of cultural complexity reveals a trend from a single or few early cultural phases of uniform composition covering the entire New World, to the extremely diversified cultures of the last two millennia of the prehistoric period. Within the sequence of cultural development, it appears that the greatest diversity is present at the village-farming level, with hundreds of distinct phases indicating essentially locally oriented social groups that gradually united into larger units as communication and political pressures from more successful centres submerged the cultures of the weaker local phases.

When compared with the Old World sequence, a similar succession of cultural levels can be distinguished in the New World, but there are differences in such basic qualities as the lack of economically important domestic ani-

The Adena
phase

Manioc
cultivation

imals in the New World and the much greater diversity of habitats and forms in which the various cultivated plants originated. These factors seem basic in explaining the wide discrepancy in rapidity of cultural development between the Old and the New World once the idea of cultivation was present. It was not until several cultivated crops (corn, beans, and squash for most of the New World) were fully developed and assembled that higher cultural levels were possible. (R.M.As./Ed.)

Oceania

The archaeology of Oceania involves, for the most part, short time perspectives, because migrations within the open Pacific could have occurred only after the development of seagoing canoe navigation in Neolithic times. The exception is the New Guinea–Australia region, where the ancestors of the Australoid- and Negritoid-type peoples evidently arrived in Paleolithic times.

The long-term history of the Oceanic peoples, especially the Polynesians, has been the subject of many theories. Scholars reject ideas involving a lost continent (*e.g.*, Lemuria, Mu) or direct relations with the Middle East (*e.g.*, the Ten Lost Tribes, migrations of Children of the Sun from Egypt), early India (*e.g.*, Indus Valley–Easter Island connections), or Japan (*e.g.*, supposed language relations). They also insist that, while eastern-voyaging Polynesians could well have reached the American continent and some may have found their way back into the islands, none of the various theories claiming that Oceanic peoples had their homelands in North or South America is scientifically credible (*e.g.*, E. Rout's imaginative *Maori Symbolism*, T. Heyerdahl's thesis for the "Kon Tiki" voyage). Similarly, they reject theories explaining the Pre-Columbian civilizations on the American continent in terms of influences by way of the tropical Pacific islands from Asia. Most archaeological as well as racial, linguistic, and ethnological evidence continues to support the long-standing hypothesis of the settlement of Oceania by a succession of migrants from the Southeast Asia region, with at most very minor contacts eastward to America.

The archaeological record begins when early *Homo sapiens* populations, comparable with the fossils of Wadjak in Java, Aitape in New Guinea, and Keilor and others in Australia, were moving eastward. This apparently occurred during the Fourth Glacial Epoch, when sea levels were lower, land pathways perhaps more uplifted, and inter-island channels narrower than now. Early man could migrate with lessened water obstructions from the Asiatic continental platform (Sunda Shelf) through the intermediate Celebes–Molucca–Lesser Sunda zones on to the Australian continental platform (Sahul, or Papuan, Shelf). Some scholars suggest such movements even during the Third Glacial, but this seems dubious. Core tools typologically Paleolithic and sometimes heavily patinated occur in both Southeast Asia and Australia, and crude flake tools often of microlithic size are found in the intermediate zones (*e.g.*, Timor) as well. Yet all these are surface finds or of dubious age when at subsurface levels. Doubtless most early groups moved, in glacial times, near shorelines now inundated, though valleys suitable for inland hunting or locally uplifted coasts might yield finds. The vital western New Guinea region, much of which is swampy and lacking stone, has had little systematic study.

The hypothetical picture has the isolated Australian and Tasmanian populations developing along regional and local lines characteristic of their later archaeological perspectives: generally Paleolithic, but with some Neolithic and also recent Malay trading contacts along the northern coasts. The New Guinea region was penetrated by canoe-migrating peoples carrying Neolithic elements that come to dominate the picture. The evidence suggests that the first comers were "dry" gardeners living in semi-sedentary hamlets, with crude stone tools including adzes and axes of oval cross section; such shifting cultivators are found still from Southeast Asia to the Solomon Islands and Vanuatu (New Hebrides). The Melanesian areas were also penetrated, apparently later and especially along the coasts, by village-living peoples with more sedentary cul-

tivation; stone construction in various forms; finer tools, including quadrilateral cross-section types; stone pestles and mortars; pottery; and other later Neolithic elements. In New Guinea, as shown by A. Riesenfeld, these influences appeared to arrive by way of the northeastern coast from the outer fringe of islands, perhaps the Bismarcks, Admiralties, and others. Unhappily, archaeological work in all these Melanesian zones has been limited to sporadic surface collecting and recording and to occasional tools turned up by garden workers or miners; time-sequence definitions are out of the question except as they may be inferred from Neolithic chronology in Southeast Asia.

By contrast, archaeological work in Polynesia and some zones of Micronesia is considerably more advanced. For northwestern Micronesia a vital clue is a radiocarbon dating of approximately 1527 bc from a stratified deposit excavated in the Marianas. Collateral evidence suggests that occupation may go back to 2000 bc. The Mariana *latte* sites (rows of capped stone pillars, probably posts of important houses), together with stone mortars, pottery, and other artifacts, suggest migrations from the Philippines area in late Neolithic times.

Farther east, the low coral islands of the Carolines, Marshalls, and Gilberts yield limited artifacts of shell, bone, and coral rock capable of some comparative study. The few high islands in this part of Micronesia, however, have extensive stone construction and other more diversified elements. Yap, for example, has stone ceremonial platforms, stepped tombs, "stone money," pottery, etc. Ponape's most spectacular site, the "Venice" called Metalanim, has several acres of stone-faced islands and canals, the principal structure being a rectangular enclosure with double walls up to 40 feet high containing a central stepped tomb and also vault tombs. A much smaller Venice exists on Kosrae (formerly Kusaie), most easterly of the Carolines. Scholars generally attribute such elaborations of the basic stonework elements, in Polynesia as well as Micronesia, to local creativity rather than undemonstrated outside influences.

Micronesia and Polynesia may usefully be treated as a continuous zone. With them, too, may justifiably be placed the Fiji zone of eastern Melanesia, the most easterly limit of the potter's craft. In compiling known data on stonework in this whole area, one may distinguish two great types: one to the west (Micronesia, Fiji, Tonga, Samoa areas), characterized by ceremonial courts, perhaps with god houses, and platform tombs often of stepped types; the other to the east (Societies, Hawaii, New Zealand, and islands eastward to Easter Island), characterized by temple structures, usually with altars, standing stones probably as backrests for gods and priests in the rituals, and cist burials within the structures. From simpler shrines having a few standing stones (*e.g.*, inland Tahiti, New Zealand, small, outlying Hawaiian islands), the Polynesian temple became elaborated into various local forms including usually larger-size and "megalithic" stonework. In Hawaii wooden posts or images generally replaced standing stones. In the Tuamotus huge coralline slabs were often used, and in the Marquesas the stones were sometimes carved in human (or god) form. Some specialists consider that such comparative study solves the "mystery" of the Easter Island statues. Rather than being relics of some lost continent or pre-Polynesian migration, they follow this last pattern of carved figures, standing on altar platforms (called by the standard Polynesian name *ahu*) in which there are cist burials. Apparently a local inventive urge toward large size, combined with the presence of easily worked volcanic tuff, produced this one of the many variants of the Polynesian place of worship.

Such local constructions, however, together with other more spectacular elements, such as widely scattered petroglyphs and a dubiously old "script" on Easter Island, have less significance for historical reconstruction than detailed study of variability in minor artifacts.

Theories of contacts with the American continent must be treated with caution so far as they lean on gross parallels such as stone images or art resemblances; the most concrete evidence has been the presence of the sweet potato, apparently an American plant, in Oceania in prehistoric times. CIVILIZATIONS

It is customary to regard the time span of modern civilization as immensely long, extending back through medieval Europe to the Greco-Roman world and to still earlier Oriental forerunners. But the length of time for this development is probably no greater than that which had elapsed between the prior introduction of agriculture and the rise of the first civilized states. And both of these intervals together probably constitute only about 1 percent or less of the time since two-legged, tool-using creatures made their first appearance. Furthermore, the extensive spread of civilization is much more recent still. Civilizations have prevailed over uncivilized food collectors, nomads, and primitive farmers across most of the world only within recent centuries. Thus, it must be stressed that civilization is a late condition in the human record.

Since at least the days of L.H. Morgan (1818–81), the achievement of civilization has been widely recognized as a major stage in man's social and cultural evolution. Coming ultimately as a consequence of the attainment of settled food production, its main attributes were substantial, qualitative increases in the scale and complexity of the limited number of societies that were its initial representatives. As there is civilization, so there are civilizations. And at least until well after the end of prehistory by any definition, the early civilizations must be regarded as very limited enclaves in a largely uncivilized world.

The earliest civilizations of the Old World occupied the great alluvial valleys of the Middle East by around the year 3000 BC. There is some evidence that Egyptian developments were stimulated by Mesopotamian influences, but the beginnings of civilization in the two areas were nonetheless essentially independent of one another and more or less contemporaneous. Farther to the east, civilization made its appearance in the valley of the Indus River a half millennium or so later. Here it was also essentially independent in at least its stylistic manifestations, but the time lag and the apparently abrupt inception of urban life—abrupt, that is, relative to the development of urban life in Mesopotamia—suggest that stimulus from the latter area played a considerable part in its origin. The civilization of northern China, still farther afield, did not cross the same threshold until perhaps the middle of the 2nd millennium BC, and controversies continue regarding the role of the already well-established Middle Eastern civilizations in its formation. From these four primary centres, lesser and later centres naturally developed across the Eurasian hinterland. This process of consolidation and expansion is, however, a part of the historic, and not the prehistoric, record.

A direct comparison of the Old World sequence with that of the New World is complicated by somewhat different cultural emphases. But while criteria for the identification of early civilization in the two hemispheres are not entirely the same, most authorities would concur in assigning the first appearance of a civilized way of life in the New World to the middle centuries of the 1st millennium BC. In view of the evident delay in this achievement, the possibility that it was prompted by influences from eastern Asiatic centres has long been debated. Apart from a few isolated and somewhat dubious cultural elements, however, the general course of development was sufficiently different in the New World to convince most authorities that it was essentially independent of external stimuli.

Two centres of focusses of early civilization in the New World came into existence roughly at the same time, in Middle America and in the central Andes. Stylistic affinities suggest the possibility of a brief period of interconnection between them at the outset, perhaps the result of the southward spread of an early Meso-American cult. As in the case of Egypt and Mesopotamia, however, the subsequent development of the two major focusses proceeded along substantially independent lines. As late as the time of the Spanish conquest in the 16th century, the powerful Mexican and Inca empires had little or no direct knowledge of one another.

The Urban Revolution

Civilization is of concern in the present context, of course, only as the terminus of the long prehistoric record. In most areas the rise of civilization coincided at least roughly with the development of writing, so that the later courses of civilization are illuminated by historical sources. In the absence of documents, the limitations of purely archaeological sources entail a stress on certain aspects of the rise of early civilizations—primarily those involving formal governmental or religious institutions and the material-technical facets of culture more generally. To be sure, a comparison with civilizations that have left written records or with non-Western civilizations of today suggests many other dimensions in which the early civilized societies must have diverged from their predecessors and noncivilized contemporaries. The U.S. anthropologist Robert Redfield, for example, identified the rise of civilization primarily with the formation of great traditions that systematized and redirected the cultural and moral order as it had been previously conceived in scattered folk communities. But except as indirectly inferred from objects associated with ritual or from tenuous parallels with modern non-Western societies, such a dimension of change as this is virtually irrecoverable by the prehistorian.

The possibility of attaining a civilized way of life rested ultimately on conditions that only intensive agriculture made possible. Among these were storable food supplies permitting permanent residence, agricultural surpluses supporting the proliferation of full-time administrators and specialists freed from primary subsistence activities, and a sufficient intensity of production within a given area to encourage the formation of urban centres. Recognizing these as prerequisites for civilization, V. Gordon Childe formulated the growth of civilization as the consequence of two successive revolutions. The first, or Neolithic, revolution has been dealt with in a preceding section; it encompassed the domestication of the plants and animals essential for an agricultural mode of subsistence, as well as the formation and spread of settled village communities. For the second, the Urban Revolution, a number of criteria have been proposed. Most importantly, these include: (1) cities, or large, dense settlements; (2) the differentiation of the population into specialized occupational groups; (3) social classes, including a ruling stratum exempt from primary subsistence tasks; (4) mechanisms for extracting a "social surplus," such as taxes or tribute; (5) monumental public buildings and other enterprises; and (6) writing.

It is important to note that these two proposed revolutions differ fundamentally in character. The first represented most importantly an advance in man's control of his environment and consisted of a series of discoveries permitting its vastly fuller exploitation. The Urban Revolution, on the other hand, affected man's relation to his environment only secondarily and much more slowly. As agricultural techniques became stabilized, the crucial changes increasingly were those in community size and composition, in the appearance of new institutions, and in the vastly greater complexity of patterns of social organization. These are changes less in man's interaction with his habitat than in that with his fellows. Hence, different interpretive skills are required to elucidate them than to explain the changes which accompanied the beginnings of agriculture, skills rooted more in the social sciences and humanities than in the natural sciences. Moreover, because of the increasing diversity of the social and cultural scene, our understanding of these changes is increasingly subject to distortions arising from the accidents of preservation or the unrepresentativeness of evidence so far obtained. The preoccupation of archaeologists with late prehistoric and protohistoric temple furnishings and architecture, for example, probably has exaggerated the importance of temples and certainly has left us with disappointingly little information on the nature of contemporary secular life in neighbouring precincts of the same towns. By contrast, it

Criteria for
the Urban
Revolution

can be (or, at least, has been) generally assumed that the relative absence of social and cultural differentiation in early villages permits them to be adequately sampled by random small-scale soundings.

If we accept the general descriptive validity of the criteria for civilization given above, the identification of the rise of civilization with the sequence of a Neolithic revolution and an Urban Revolution is still subject to three important qualifications. In the first place, to say that civilization depends on agricultural surpluses is not the same as saying that agricultural surpluses were all that was necessary to bring civilization into being in any given area. There is simply not enough known of the productivity of prehistoric agriculture to indicate whether increasing surpluses might have triggered subsequent changes in other aspects of culture. In fact, on the basis of present evidence it seems at least as likely that it was primarily through changes in social organization that civilizations brought about that there were advances in agricultural productivity. Second, it must be stressed again that the criteria given above are only those that are in some way accessible to the archaeologist. The tendency to regard them as a self-contained list that somehow defines civilization, or even that somehow embraces its primary causes and consequences, must be avoided. Third, the term revolution implies sudden and violent change. Yet, if the rise of civilization was undoubtedly rapid as compared with the hundreds of thousands of years of preagricultural life, it is equally clear that it was spread over many generations and probably never was as apparent to its participants as the Industrial Revolution has been to recent generations. Authorities are not even agreed, moreover, that the Neolithic and Urban revolutions were events separable in time. It remains only a hypothesis that one was consummated before the other began, and an equally plausible hypothesis might see a single, rising tempo of change that began with incipient agriculture and culminated in the appearance of Oriental Bronze Age monarchies.

There remains a further difficulty with the criteria mentioned earlier: they apply most usefully to the earliest, or "type," sequence in Mesopotamia, and elsewhere diverge to a greater or lesser degree from the observed archaeological data. The Maya area of Meso-America, for example, lacked true cities yet exhibits the other elements in the list to such a degree that its status as a civilization seems indisputable. According to some scholars, cities were also absent in Egypt during the Old Kingdom, although the other appurtenances of a civilized state are unusually well represented there. Similarly, the highly organized Inca Empire got along entirely without writing, while in the Mayan and Mexican areas the much earlier invention of writing was only applied to economic and administrative tasks in the centuries immediately preceding the Spanish conquest.

To phrase the problem more broadly, the separate focusses of early civilization tended to crystallize into patterns that in some respects are quite different. Mesopotamia was characterized by extensive irrigation agriculture, by fairly rapid technological progress (though hardly rapid enough to "explain" the more profound social changes that took place concomitantly), by emphasis on urban settlement, and by an early separation between the fundamental economic and administrative units (which were often temples) and the political leaders. In Egypt, one finds irrigation agriculture again and an even more precocious elaboration of a state administrative apparatus, but there is an absence of the trends toward rapid technological advance, urbanization, and secularization that are so evident in Mesopotamia. A further variation on this pattern is found in the Maya area, where agriculture was largely of a nonintensive slash-and-burn variety, where the bureaucracy of a centralized state was entirely absent, and where primary cultural emphasis seems to have been placed on the elaboration of esoteric cults by hierarchies of priests for whom important nonreligious functions in the society are not apparent. Peruvian civilization, on the other hand, was somewhat closer to the Mesopotamian model, except perhaps in its greater emphasis on an ethnically distinguished ruling stratum. In both New World

civilizations, but in neither of those of the Old World, it might be added, there are indications that monumental temple architecture long preceded the other criteria of civilization—and in fact may be as old as the earliest village settlements based on agriculture.

These divergences should not be taken to deny the regularities that are implied by Childe's criteria for the Urban Revolution. Given a sufficient level of abstraction, the early civilizations of both hemispheres shared most of their essential features. And certainly they constitute a distinctive sociocultural type when contrasted with all earlier folk societies. They form the culminating stage of the prehistoric record, and it is worth noting in conclusion that their essential attributes never subsequently disappear. In fact, in one sense the world's written history is the documenting of their spread: gradually and irregularly, based on a succession of different focusses (of which western Europe and the United States are only the most recent), but ultimately irresistible.

(R.M.As./Ed.)

The example of the Middle East

EVOLUTION OF MIDDLE EASTERN CIVILIZATIONS

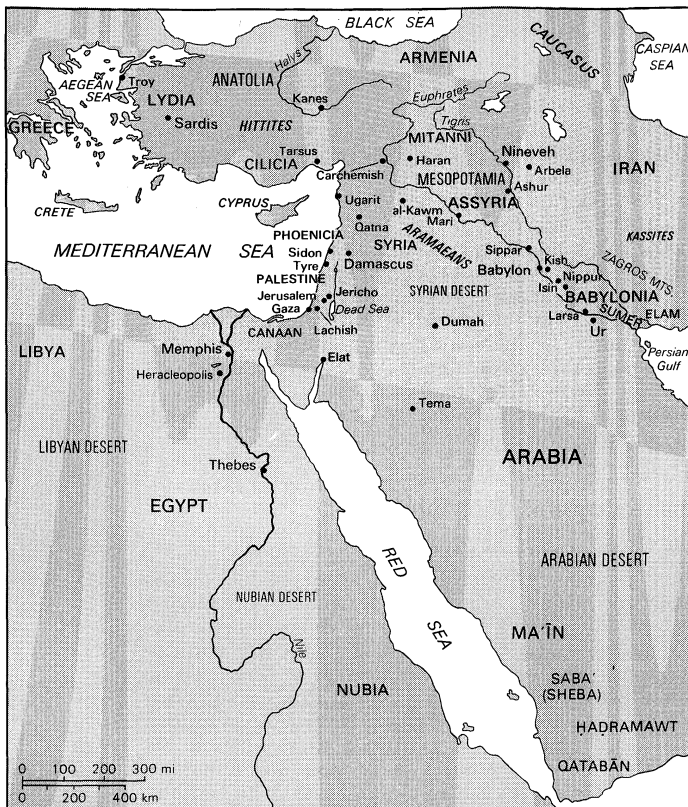

The high antiquity of civilization in the Middle East is largely due to the existence of convenient land bridges and easy sea lanes passable in summer or winter, in dry or wet seasons. Movement of large numbers of people north of the Caspian Sea was virtually impossible in winter, owing to the severity of the climate; central Eurasia was often too dry in summer. Land passage between Asia and Africa was in early times limited to narrow strips of land in the Isthmus of Suez. Large-scale desert travel was limited to special routes in Iran and in North Africa, both east and west of the Nile Valley.

Another reason for the early significance of this area in world history is the fact that the water supply and the climate were ideal for the introduction of agriculture. Several species of grain grew wild, and there were marshes and tributary streams that could easily be drained or dammed in order to sow wild wheat and barley. The seed had only to be strewn over a sufficiently moist surface to ensure some kind of crop under normal conditions. It is therefore not surprising that there is evidence of simple agriculture as far back as the 8th or 9th millennium BC, especially in Palestine, where more excavating has been done in early sites than in any other country of the Middle East. Many bone sickle handles and flint sickle edges dating from between c. 9000 and 7000 BC have been found in Palestinian sites.

In Mesopotamia and Iran remains of this period appear in caves on the lower slopes of the Zagros Mountains between western Iran and Iraq. The date of the systematic introduction of irrigation on a large scale in Mesopotamia is somewhat doubtful because most of the early sites of irrigation culture were covered long ago by accumulation of alluvial soil brought down by the spring floods of the Tigris and Euphrates rivers. Archaeologists once thought that all irrigation originated in the foothills of the Zagros and that the earliest true farmers lived in the plains of Iran. But recent excavations and surface explorations have proved that irrigation around the upper Tigris and Euphrates, as well as their tributaries, dates from the early 6th millennium BC (e.g., at al-Kawm on the Upper Euphrates). Small-scale irrigation was practiced in Palestine (e.g., at Jericho) in the 7th millennium BC.

In northern and eastern Mesopotamia, main streams were soon partly diverted during moderate river floods into canals running more or less parallel to the rivers, which could thus be used to irrigate an extensive area. Such deflector dam irrigation avoided the self-destructive weaknesses of large storage dams, in particular the danger of depositing great masses of refractory mud in the storage basin behind the dam. In the north and east considerable urban installations developed at sites such as Nineveh no later than the 5th millennium BC, when southern Mesopotamia was still mostly swampland like the early Egyptian delta. The Euphrates had a much smaller flow of water than the nearby Tigris. The latter was much swifter,

however, so that it was potentially more important for irrigation, even though much harder to tame.

The Egyptian Nile had a much more predictable water flow than the Mesopotamian rivers because it flowed through hundreds of miles of swamp, where unusually high annual floods spread out, interfering with navigation but averting the danger of the occasional destructive inundations of Mesopotamia.

Mesopotamia and Egypt to c. 1600 BC. The oldest known urban and literate culture in the world was developed by the Sumerians in Mesopotamia beginning in the late 4th millennium BC. About 2300 BC a Semitic leader, Sargon I, conquered all of Babylonia and founded the first dynasty of Akkad (Akkadu), which held power for about a century and a half. Sargon and his successors were the first known rulers in southwest Asia to gain control of the Fertile Crescent as well as of adjacent territories. They sent trading expeditions to central Anatolia, Iran, and as far as India and Egypt. After the fall of the dynasty of Akkad there was a Sumerian revival under the 3rd dynasty of Ur (Ur III: [21st–20th centuries]), followed by another influx of Semites. These people founded the first dynasty of Babylon (19th–16th centuries), whose most important king was Hammurabi. In the 17th century new ethnic groups appeared in both Babylonia and Syria–Palestine: Kassites from the Zagros Mountains, Hurrians from what is now Armenia, and Indo-Europeans from Central Asia. This period marked the end of the formative phase of Mesopotamian civilization.

Shortly after 3000 BC the numerous small states that had arisen in the Nile Valley during the 4th millennium were united under the 1st dynasty of Egypt. At this time the Egyptians had already developed a system of writing. Between c. 2686 and c. 2160 BC, their country was united under a powerful monarchy (the Old Kingdom) served by a complex bureaucracy.

Toward the end of the 3rd millennium there was a period of disunity, followed by reunification under the 12th dynasty (1991–1786).

During these two centuries Egyptian control was established over Nubia, Libya, Palestine, and southern Syria.

Soon after 1800 BC the Egyptian Empire fell apart, and c. 1700 Egypt was overwhelmed by the Asian “Hyksos,” who ruled the country for a century and a half.

New states and peoples. Before the close of the 16th century BC the native 18th dynasty rose in Egypt; it expelled the Hyksos and founded the New Kingdom. The New Kingdom rulers moved back into Syria–Palestine and came into conflict first with the Hurrian state of Mitanni and later with the Anatolian Hittites, who were expanding into Syria from the north in the 14th century BC. The Amarna Letters (diplomatic correspondence written in Babylonian script and language, and discovered in Egypt by archaeologists) are an important source of information on this period. In Mesopotamia the dominant powers were Kassite Babylonia and Assyria (which emerged from subjection to Mitanni in the early 14th century BC). Relations between states were governed by elaborate treaties, which were constantly being broken. After the fall of Mitanni (c. 1350) the Hittites and Babylonians both directed their hostility against Assyria. Kassite Babylonia was subjugated by Assyria c. 1230. This, followed by the fall of the Hittite Empire (c. 1200), ended what has been called the first “International Age” in the civilized world.

The latter part of the 13th century BC saw the irruption of new peoples into the Aegean, Anatolia, and the Fertile Crescent; their appearance coincided with the Trojan War, the collapse of the Hittite Empire, and the destruction of many coastal cities of Greece, Cyprus, and Syria–Palestine. Best known of the new settlers from the west are the Phrygians, who occupied most of the old Hittite heartland, and the Philistines, who moved into Palestine. At the same time, in Transjordan and western Palestine, the Hebrews founded a tribal confederation that was changed into a monarchy by Saul and David (c. 1020–960 BC).

In the east, the Iranian tribes, led by the Medes, were pouring into Iran from Turkistan. From the south and west came the Semitic Aramaeans. The Aramaeans and Medes were to transform the ancient Near East.

The Assyrian state suffered an eclipse in the 11th century BC, when the Aramaeans and related tribes occupied most of its territory. It was not until the late 10th century that the Assyrians began to recover, but by 850 they had conquered much of western Media and southern Armenia as well as Babylonia and Syria. In the following centuries, until just before 630, the empire was greatly expanded. It was also highly organized administratively; its language became Aramaic.

The Canaanite Phoenicians on the Syrian coast re-established their trading communities after the Philistine and Aramaean invasions; in the 10th and 9th centuries they moved out into the Mediterranean, establishing colonies in North Africa and as far west as Spain. Their influence in the western Mediterranean declined after the 6th century. Their Carthaginian colony then took over Phoenician trade in the western and central Mediterranean.

Farther east, the Medes and Chaldeans destroyed the Assyrian Empire at the end of the 7th century. The Chaldean dynasty in Babylonia carried on Assyrian traditions of administration and encouraged commerce; under Nebuchadnezzar II (604–562 BC), their Neo-Babylonian Empire became the most powerful political entity of its time. Its rule extended from the Taurus Mountains in Anatolia to eastern Arabia and deep into southern Iran. This short-lived state made a tremendous impression on contemporaries, especially on the Jews, whose state was destroyed and who were carried into Babylonian Captivity, and on the Greeks, to whom the glory of Babylon became legendary.

The Achaemenian Empire and its successors. In the 6th century the Iranian Persians under Cyrus the Great conquered their Median cousins and established the Achaemenian state (549). This was followed by the conquest of Lydia (546) and the Babylonian Empire (539). Aramaic became the official language of the Persian Empire, and its official religion was Zoroastrianism. Cyrus’ enlightened policy put an end to the Assyro-Babylonian practice of deporting conquered peoples and trying to destroy all local nationalisms.

The
invasions
of the 13th
century BC

The
Sumerians

The
Mace-
donian
conquest

At its height the Achaemenian Empire ruled the whole of the Middle East; Greek resistance prevented it from expanding successfully into Europe.

In 334 BC Alexander of Macedon invaded Anatolia and nine years later completed the conquest of the Persian realm. His vast empire was broken up into Macedonian "successor states" after his death. The Seleucid kings of Syria controlled most of Anatolia, Mesopotamia, and Iran. About 250 BC the still seminomadic Parthians emerged from a small area southeast of the Caspian Sea. Establishing control over Iran, they declared their independence of the Seleucid Empire and in the 2nd century BC expanded westward into Mesopotamia. In the 3rd century AD the semi-Hellenized Parthians were replaced by the Persian Sāsānians. The Sāsānians ruled Iran from AD 224 to 642; they extended its boundaries, reinvigorated its administration and cultural life, and challenged Roman power in the Middle East. In 636 the Sāsānian Empire was conquered by the Muslim Arabs, bringing to an end the last phase of ancient Middle Eastern civilization.

Pre-Islāmic Arabia. Arabia was drawn into the orbit of western Asiatic civilization toward the end of the 3rd millennium BC; caravan trade between south Arabia and the Fertile Crescent began about the middle of the 2nd millennium BC. The domestication of the camel around the 12th century BC made desert travel easier and gave rise to a flourishing society in South Arabia, centred around the state of Saba (Sheba). In eastern Arabia the island of Dilmun (Bahrain) had become a thriving entrepôt between Mesopotamia, South Arabia, and India as early as the 24th century BC.

The discovery by the Mediterranean peoples of the monsoon winds in the Indian Ocean made possible flourishing Roman and Byzantine seaborne trade between the northern Red Sea ports and South Arabia, extending to India and beyond.

In the 5th and 6th centuries AD, successive invasions of the Christian Ethiopians and the counterintervention of the Sāsānian kings disrupted the states of South Arabia. The resulting economic decline made the rapid Muslim conquest of the area an easy task in the 7th century.

ELEMENTS OF CIVILIZED CULTURE

Religion. Middle Eastern religious thought had a strong influence on the ancient Greeks. The cosmogonies of Egypt, Babylonia, Phoenicia, and Anatolia were transmitted in part to the West and formed the basis of much of the cosmogonies of Hesiod and the Orphics before 600 BC, as well as the background for the cosmogonies of Thales and Anaximander in the 6th century BC. There is some influence from the Middle East in Pythagorean and Platonic thinking, but it is often hard to define and still harder to prove in detail. From the early 3rd century BC on, the Middle East began to influence Greek thought increasingly. Babylonian astrology influenced Stoic philosophy, and some Jewish influence on Stoic ethics is likely as well.

Late Egyptian religious speculations were transmitted to the Greeks, especially through the "Physiologists" and Hermetic writers who flourished in Hellenistic Egypt beginning in the 2nd century BC. Astrology and alchemy were transmitted to our time in substantially the forms they received in Hellenistic and Roman Egypt.

Jewish
influence

With the partial Hellenization of Judaism and its Christian offshoot in the 1st century AD, Jewish influence on the West rapidly became dominant. Most of it came through the Pharisees, but such Jewish sects as the Essenes and Baptists were directly involved.

Even such a heterodox Jewish sect as the Samaritans exerted disproportionately great influence. In the first years of the nascent Christian Church a Samaritan diviner named Simon, later called "Magus," founded a new faith known as Gnosticism. The Gnostics spread rapidly over both the Roman and Iranian worlds, and by the end of the 3rd century AD they had subdivided into a multitude of different sects that covered a wide spectrum of possible combinations between Judaism, Christianity, Zoroastrianism, and Greco-Roman paganism.

In four centuries Christianity conquered the entire Roman Empire and many outlying regions, thanks to the

intensity of its faith and the tenacity with which Christians held to their views, following Jewish models, through the bitterest persecutions.

In the East, Zoroastrianism maintained its hold over the Iranians and neighbouring peoples until the Islāmic conquest, when it was replaced by Islām, itself an offshoot of the monotheistic Judeo-Christian stem.

With the Hebrew Bible (which became the Christian Old Testament) almost the whole of traditional Israelite and early Jewish religion passed into Christianity, which was to a great extent an extension of Judaism. What was lost by the surrender of a large part of Jewish ritual law, with its stress on purity, was compensated by the triumph of monotheism over Greco-Roman polytheism and the transformation of ethical and spiritual ideas in the Greco-Roman world. Judaism itself survived to coexist with Christianity and Islām through all the intervening centuries to our own day.

Science and law. During the 3,000 years of urbanized life in Mesopotamia and Egypt tremendous strides were made in various branches of science and technology. The greatest advances were made in Mesopotamia—very possibly because of its constant shift of population and openness to foreign influence, in contrast to the relative isolation of Egypt and the consequent stability of its population. The Egyptians excelled in such applied sciences as medicine, engineering, and surveying; in Mesopotamia greater progress was made in astronomy and mathematics. The development of astronomy seems to have been greatly accelerated by that of astrology, which took the lead among the quasi-sciences involved in divination. The Egyptians remained far behind the Babylonians in developing astronomy, while Babylonian medicine, because of its chiefly magical character, was less advanced than that of Egypt. In engineering and architecture Egyptians took an early lead, owing largely to the stress they laid on the construction of such elaborate monuments as vast pyramids and temples of granite and sandstone. On the other hand, the Babylonians led in the development of such practical arts as irrigation.

Mesopo-
tamian
astronomy
and mathe-
matics

Both sciences and pseudosciences spread from Egypt and Mesopotamia to Phoenicia and Anatolia. The Phoenicians in particular transmitted much of this knowledge to the various lands of the Mediterranean, especially to the Greeks. The direction taken by these influences can be followed from Egypt to Syria, Phoenicia, and Cyprus, thanks to a combination of excavated art forms that prove the direction of movement, as well as to Greek tradition, which lays great stress on what the early Greek philosophers learned from Egypt. Mesopotamian influence can be traced especially through the partial borrowing of Babylonian science and divination by the Hittites and later by the transmission of information through Phoenicia. The Egyptians and Mesopotamians wrote no theoretical treatises; information had to be transmitted piecemeal through personal contacts.

The westward transmission of Babylonian mathematics was associated with that of law. All early Babylonian mathematics was transmitted in case form, introduced by a condition followed by its solution. This model appears first in late Sumerian law: from law it was extended to scientific problems, and the form remained the same until well into the 1st millennium BC. This was true also of such derived systems as Hittite law and the so-called covenant law of Israel, as well as the earliest Greek codes (Draco and Gortyn), all of which are formulated similarly: condition (protasis), secondary condition or conditions, and conclusion (apodosis). The Babylonian Code of Hammurabi provides an example: "If a man accuses another man and brings a charge of murder against him but does not prove it, the accuser shall be executed."

With the spread of case law in such conditional formulation, it was eventually discovered that formulation as generalized propositions or prohibitions was a simpler and more logical means of setting up a coherent code of laws than the case-law formulation (*e.g.*, in the Hebrew Decalogue). The next step was the formulation of generalized geometrical propositions. This was first done by the Ionian Greek Thales (about 600 BC), whose listing of

Logical
thought

mathematical propositions in this generalized form instead of as conditional sentences was quite naturally described later as the “discovery” of mathematical theorems. With Thales logical reasoning made a giant step forward from the age of empirical modes of thought.

The Judeo-Christian concept of ethics and morals in law often prevailed in the Roman law of Christian times. Roman forms of law were ultimately adopted in almost the entire Western world, and through their universal sway many biblical approaches to legal problems became dominant.

The alphabet. Of all the accomplishments of the ancient Middle East, the invention of the alphabet is probably the greatest. While pre-alphabetic systems of writing in the Old World became steadily more phonetic, they were still exceedingly cumbersome, and the syllabic systems that gradually replaced them remained complex and difficult. In the early Hyksos period (17th century BC) the Northwestern Semites living in Egypt adapted hieroglyphic char-

acters—in at least two slightly differing forms of letters—to their own purposes. Thus was developed the earliest known purely consonantal alphabet, imitated in northern Syria, with the addition of two letters to designate vowels used with the glottal catch.

This alphabet spread rapidly and was in quite common use among the Northwestern Semites (Canaanites, Hebrews, Aramaeans, and especially the Phoenicians) soon after its invention. By the 9th century BC the Phoenicians were using it in the western Mediterranean, and the Greeks and Phrygians adopted it in the 8th. The alphabet contributed vastly to the Greek cultural and literary revolution in the immediately following period. From the Greeks it was transmitted to other Western peoples. Since language must always remain the chief mode of communication for *Homo sapiens*, its union with hearing and vision in a uniquely simple phonetic structure has probably revolutionized civilization more than any other invention in history. (W.F.A.)

PREHISTORIC RELIGION

Practices and beliefs

BURIAL CUSTOMS AND CULTS OF THE DEAD

The oldest known burials can be attributed to the Middle Paleolithic Period. The corpses, accompanied by stone tools and parts of animals, were laid in holes in the ground and sometimes the corpses were especially protected. In some cases, the findings give the impression that the dead were to be “held onto.” Whether or not that meant that the dead were to be cared for lovingly or that their return was to be feared, it implies, in any case, a belief in life after death in some form. But it is not necessary to infer a belief in separate souls; rather, it could also indicate the concept of a “living corpse.”

From the Upper Paleolithic Period on, the burials manifest richer grave goods; however, it is not possible to conclude from this that religious concepts had changed. The same holds for the adoption of other burial practices, as, for example, secondary burials, in which the bodies were first allowed to decompose fully and then the bones were buried, or in the burning of bodies (evident from the Neolithic Period). From these facts it is not possible to infer the existence of a definite belief in souls; it is also not possible to determine the advent of such concepts from archaeological evidence. Even the increase in the discoveries of grave goods, occasionally also including other human remains, is evidence not for a change of religious concepts but for increased needs of the dead in the beyond—i.e., needs after death that are dependent on economic and social status in life. Analogies to recent (primitive) phenomena demonstrate that it is not possible to connect particular burial customs with particular notions of the beyond, or to any other religious conceptions. Other than the burial of the whole body, the disposition of the individual parts of the body, and especially the skull, is important. Ritual deposition of skulls is confirmed for the Middle Paleolithic Period. From even earlier periods, however, individual or multiple human skulls and long bones have been found within a single site (for example, associated with Peking man). It is not necessary to interpret these findings as remains of headhunting or developed skull cults; for even today some simple hunting and gathering societies have the custom of preserving such parts of corpses for long periods of time and even of carrying them around on their bodies. The same practice is observed also to have occurred in the Upper Paleolithic and even later periods; but it is not possible to infer an elaborated ancestor cult directly from such prolonged connections of the living with the dead.

The situation is different with findings from permanent settlements of agrarian people, in contrast to constantly shifting hunter-collectors. Evidences for ancestor cult practices dating to the 7th century BC were first discovered at Jericho in Palestine, where several skulls were found to have been deposited in a separate room, some of them

covered with a plastic modelling of faces similar to that found on the ancestral skulls preserved by present-day agrarian peoples of South Asia and Oceania. An elaborated skull cult is usually connected with the veneration of ancestors. An important theme of ancestral cults is the belief in a connection between the dead and the fertility of the land of their descendants.

An especially noteworthy kind of burial is that of the megalithic (huge stone) graves that appear in various areas from the Neolithic Period on. It is probable that in this practice there was also a vital believed link between the living and the dead, and that occasionally sacred areas and gathering places were connected with such graves. The practices of the megalith builders were probably rooted, to a considerable extent, in ideas about the dead and in ancestor cults to which their stones gave a particular durability and a monumental form. It is more difficult to explain the individual erect stones (menhirs), which, of course, could be the symbol or seat of ancestors, especially where they show indications of being sculpted in human form. It surely would be a mistake, however, to look for a uniform interpretation of all megalithic monuments or even to speak of a distinct megalithic religion. The megalithic monuments are rather to be understood as a complex of grandiose manifestations of ideas that could well have been diverse, but among which the cult of the dead, nevertheless, played an important role.

Megalithic graves

CANNIBALISM

In finds belonging to the Paleolithic Period, pieces of human bodies as well as the bones of other animals are found scattered throughout the archaeological layers and are sometimes broken or charred. This is often taken as evidence for cannibalism, but other interpretations are just as likely (e.g., the action of carrion-eating animals [such as hyenas] turning up the bones to the surface and thus causing their burning by later fires at the same place). To be sure, the finds allow the interpretation of cannibalism; however, they do not necessarily or intrinsically require it but rather permit that explanation if one proceeds from the prior conviction that cannibalism already existed at that time. This obsolete conception, still held by some scholars today—i.e., that cannibalism is an especially “primitive” phenomenon and therefore very ancient—must be abandoned. Ethnological studies show clearly that cannibalism appears almost exclusively in the practices of agrarian peoples, that is, in a later cultural stage, and evidently is essentially bound up with religious or magical conceptions in which cultivated plants play a large role. Even if a Paleolithic cannibalism existed on a large scale, it could not be explained by means of concepts that originated in a cultural stage so differently structured.

The situation in later periods, especially in the Neolithic, is different. Here, rather than isolated parts of human skeletons scattered about a settlement, human remains

Implication
of life after
death

Burial of
skulls and
skull cults

occasionally are found in association with remains of food-stuffs in waste pits or in holes and tunnels that served as sacrificial sites. Especially where human skulls have been broken open and the hollow bones split, the interpretation of cannibalism is unavoidable. Since this inferred practice occurred in the realm of agrarian cultures, it is more feasible to make comparisons with present-day cannibalism, where the meaning is generally the acquisition of the powers and other qualities of the victim.

SACRIFICES

Sacrifices (*i.e.*, the presentation of offerings to higher beings or to the dead) appear as early as the Middle Paleolithic Period. Pits with some animal bones have been found in the vicinity of burial sites; thus, it is a likely possibility that they represent offerings to the dead. There is a dispute over the interpretation of the arrangement of the skulls and long bones of bears, since they are deposited in such a manner that it is hardly possible to discern a profane explanation. It is assumed that they had a cultic or magical significance. Most likely, certain parts of the prey, such as the head and the meaty shanks, or at least the bones with brain and marrow, were sacrificed. Even if it cannot be definitely stated who the recipient of these sacrifices was, analogies with present-day "primitive" phenomena make it likely that a part of the prey was offered to a higher being who was believed to dispense nourishment. It could also, however, have been a matter of preserving parts of animals in order to resurrect the entire animal and preserve the species. Furthermore, finds of bones and drawings show that the preservation of skulls with still attached vertebrae, ribs, and front legs of oxen and reindeer played a certain religious or magical role. The sinking of whole reindeer into lakes is hard to explain other than as a sacrifice. This might be traced to the idea that what occupies the centre of attention is not the individual hunted animal but the whole herd; no longer only a part of an animal but a whole animal as part of a herd is sacrificed. The custom also existed in recent times among hunters and herders of central and north Asia. As such finds become more numerous, it seems evident that certain specific animals and parts of their bodies are selected for sacrifice.

It is difficult to differentiate between animal sacrifices and the immediate cultic veneration of an animal at the burial sites of animals. In the Neolithic Period, the sites become especially profuse and are usually found in connection with human burials; nevertheless, there are such burial sites of animals that are not related in this manner and that occur with pronounced frequency, characteristically in particular groups of cultures. In these cases, domestic animals almost exclusively are involved, and among them the dog and the ox predominate.

The question of human sacrifice is of special significance here. Human sacrifices often were related to cannibalism and to the sacrifice of animals. With conspicuous frequency victims discerned in ceremonial remains are females and children, sometimes along with young pigs. This practice is similar to fertility and agricultural rites that are known to have been practiced in the early Mediterranean civilizations. It is also similar to beliefs and practices observed among present-day "primitive" agrarian peoples (in which pigs are often substituted for humans), such as in ceremonies of secret societies, initiation rites, sacrifices, celebrations of feasts of the dead, and notions about fertility, especially in connection with the growing and ripening of cultivated plants.

In comparison, the inclusion of servants or women in the burial sites of highly placed persons can hardly be called sacrifice in a strict sense—that is, an offering to a higher power or deity. Such inclusions most likely reflect the social status of the deceased leader and his need for servants in the afterlife, rather than an offering. It is a sacrifice in the wider sense of respect and awe for the person and status—and all that this conveyed—of the deceased leader. This practice becomes more important only where correspondingly differentiated social conditions are found (such as in the royal graves at Ur in Mesopotamia and in those of the Shang dynasty in China). Sometimes it took on almost unbelievable forms, especially in terms

of the numbers of persons and animals interred with the deceased leader.

The ritual preservation of objects also must be included in the realm of sacrifice (in a wider sense). This can be demonstrated for the first time in the Neolithic Period (for instance, the ritual depositing of axes); in later periods, it plays a large role. In finds from the Bronze Age on, weapons and jewelry frequently are found in wells and springs. In Iron Age finds, such objects are found in almost unbelievable quantities in a number of swamps and other bodies of water. It seems probable that they represent the sacrifice of war booty.

HUNTING RITES AND ANIMAL CULTS

In the oldest known examples of graphic art, the representations of animals play a large part; humans appear rarely and then frequently with animal attributes or as mixed human-animal figures. In the context of the whole situation, the view that these representations were merely ornamental or served a purely artistic need may be dismissed; they are found without boundaries and background on rock walls and are not part of an interrelated scene. It is evident that animals played a predominant role in the mental world of the Upper Paleolithic Period insofar as this role is reflected in the art of the period. What is represented is, first of all, that which is essential to the animal, partly in its relation to the hunt, but also in relation to anthropomorphic figures showing the intermixing of human and animal forms. This indicates a special and intimate relationship between humans and animals that transcends and overcomes the boundaries between different realms of being that modern concepts and understanding require.

This phenomenon is similar to what is still known today as animalism (or nagualism or theriocentrism). It is characterized by close magical and religious ties of humans with animals, especially with wild animals. It is also characterized in terms of otherworldly and superworldly realms and practices, such as placating and begging for forgiveness of the game killed, performing oracles with animal bones, and performing mimic animal dances and fertility rites for animals. Animals were thought to be manlike, to have souls, or to be equipped with magical powers. Animalism thus expresses itself in various conceptions of how animals are regarded as guardian spirits and "alter egos," of the facile and frequent interchangeability between human and animal forms, and also of a theriomorphically (animal-formed) envisioned higher being—one who changes between human and animal forms and unifies them. Higher, often theriomorphic, beings are gods who rule over the animals, the hunters, and the hunting territory, or spirits in the bushland and with the animals. It is obviously not possible to identify special occurrences or forms of such higher beings during the Paleolithic Period, but their general features may be safely assumed.

Animalism is, to a large extent, a basis for totemism, which involves various permanent relationships of individuals or groups to certain animals or other natural objects; hence animalism is occasionally called "protototemism." Individual and cultic totemism, as opposed to group totemism of an almost solely social function, are particularly close to animalism, whereas religious and cultic meanings in group or clan totemism are usually poorly developed. It is not possible to determine to what extent animalism had already assumed the character of true totemism in the Paleolithic Period; the early existence of clan totemism is improbable because it occurs primarily among peoples who are to some extent agrarian, and possibly a certain kind of sedentary life was prerequisite to its development.

Also, special sacrificial traditions were closely connected to game, particularly the custom of preserving the animal skeleton or a part of a skeleton in order to placate the ruler of the animals (see above) and to provide for continuation of the species.

A certain kind of bear ceremonialism is rooted in this conception and is to be recognized in several finds and pictures from the Upper Paleolithic Period on. A skin with attached head was evidently draped over the body of

a bear made out of clay; the skull and long bones of the bear were buried separately (a practice begun in the Middle Paleolithic Period); the bear was shot with arrows and killed by a shot or a thrust into the lungs; the animal or a bearlike figure was surrounded by dancers. Similar phenomena are documented for more recent periods, above all for the hunting cultures of Neolithic Siberia. These observations can be effortlessly fitted into the practice of bear ceremonialism that is still widely distributed in northern Eurasia and North America.

The question of whether animals were the immediate objects of a cult is extremely difficult to judge in each particular case. Nevertheless, with the beginning of the Neolithic Period, animal phenomena appear that probably go beyond functioning merely as a sacrifice and symbol. This applies especially to representations of oxen and bulls and to the symbolism of bull heads and bull horns.

FEMALE FERTILITY DEITIES

Small female figures, the so-called Venus statuettes, appear for the first time in the Upper Paleolithic Period. In some cases they are very schematically formed, and

Dortes—B. Arthaud

Fertility
statuettes

it is often difficult or impossible to recognize female attributes. In other cases, however, they are naturalistic representations of corpulent women whose secondary sexual characteristics (their breasts and buttocks) were given special prominence, though their faces, feet, and arms were almost completely neglected. Such strong emphasis on the anatomical zones that are related to the bearing of children and nourishing them easily conveys to one the idea of female fertility. Nevertheless, it is not necessarily true of all these small figures.

Ethnological analogies with present-day primitive phenomena offer the equally plausible view that such figures were regarded as the representations of the abodes of spirits whose function was to help and protect, and especially during hunting. They also may have been conceived, among other things, as mothers or rulers of the animals, goddesses of the underworld, helpers during hunting and donors of game, and as sovereigns of the land and other regions and of natural forces, including that of fertility.

No known direct continuum connects these earlier Paleolithic figures to similar ones of the early Neolithic and later periods. In settlements and shrines of these later periods are found large numbers of female figurines of widely differing types. They may have been representations of deities and symbols or, perhaps, votive offerings, somehow connected with female fertility. This can be safely assumed for figurines that show an obvious indication of fertility or are connected with children, and even more for shrines containing figures with sculptured pairs of breasts, and figures on the walls of women in childbirth. Not all female figures can, however, be understood merely as fertility symbols; rather, in many cases they are assumed to be house gods or representations of ancestors, and, especially when appearing in graves, as substitutes for the bodies of maids, wives, and concubines. An appearance of a large number of smaller figures suggests a votive or magical usage.

SHAMANISM, SORCERY, AND MAGIC

Shamanism is a rather variable and highly stratified complex of practices and conceptions; characteristic among these are the use of ecstasy, the belief in guardian spirits (who are often in animal form, with the function of helping and guiding the dead on their voyage to the beyond), and beliefs concerning metamorphosis (change of form) and travelling to the beyond. Pictures from the Upper Paleolithic Period indicate the existence at that time of ecstatic practices and of beliefs in protective and helping spirits, which assume the form of birds and other animals. On the other hand, it is doubtful whether shamanism existed in fully developed form at that time. Also, in the course of prehistory, objects appear that may well have belonged to the paraphernalia of shamanism. Noisemaking objects (to drive away evil spirits) are often found in the material remains of the Iron Age and probably are connected with shamanism.

Recent studies stress the religious character of shamanism, though in practice it is related to sorcery and magic. Shamanism is not to be identified with sorcery and magic if they are understood as attempts to manipulate the supernatural through certain human techniques, in contrast with religion, in which man approaches higher beings (gods) in an attitude of supplication. Magic or sorcery thus appears as the opponent of true religion and gains importance when religion declines or is overwhelmed. In fact, magic and sorcery may take over cultic forms and rob them of their religious meaning when this occurs. For these reasons, it is often difficult to decide whether prehistoric phenomena were of religious or magical character.

Magic also can be practiced to a large degree without the use of material objects, and it is, therefore, as hard to grasp archaeologically as true religion. In the interpretation of the art of the Upper Paleolithic, scholars have given great importance to magic because, for example, missiles (spears and arrows) were drawn on the pictures of animals. This has been interpreted to mean that an effort was made to insure and compel the success of hunters through magical action. But this interpretation is highly speculative, and it remains uncertain what these drawings mean. It is just

Belief in
guardian
spirits

as difficult to decide whether or not other pictures, sculptures, abstract symbols, amulets, and similar objects were used to make magic in this and later periods.

Evolutionary development

Religion is always closely related to other realms of life, such as economic activities. These relations are partly direct and partly mediated by social forms. The latter are, on the one hand, at least partially dependent on economic conditions; on the other hand, social structures influence the formation of religious phenomena and often serve as models for their elaboration. In a negative sense, then, it is often possible to eliminate certain religious phenomena as inappropriate to a particular society. It is inconceivable, for example, that the religious conception of simple hunters and gatherers included an elaborately organized hierarchy of gods with detailed division of labour between the individual figures. Similarly, it is a mistake to attribute to hunters and gatherers conceptions that are bound up with agriculture and the fertility of fields. In a positive sense, however, certain economic and social conditions will encourage the development of certain corresponding religious conceptions. Animalistic notions will be especially effective in situations where animals play a large role as partners of humans. Nevertheless, the spiritual ties to animals will be considerably different among hunters or agrarian peoples who still find it necessary to rely heavily on hunting for their meat supply as compared with pastoral peoples. In fully agrarian cultures, on the other hand, ideas about the fertility of fields and cultivated plants play an important part; they are connected with other notions about fertility and influence other spheres of life.

STONE AGE CULTURES

Lower or Early and Middle Paleolithic. The oldest burials that attest to a belief in life after death can be placed in the period between about 50,000 and 30,000 BC. The earliest evidence of human activity in any form, on the other hand, goes back more than 1,000,000 years. Yet, since religious conceptions are not always bound to material objects, and since there is evidence that truly human beings existed even during early Paleolithic times, it is inadmissible to infer that earliest man had no religion from the mere fact that no identifiable religious objects have been found.

A study of very simple hunters and gatherers of recent times shows that several religious conceptions generally considered to be especially "primitive" (e.g., fetishism) hardly play an important part, but rather that, among other things, the supposedly "advanced" conception of a personal creator and preserver of the world does play an important part. Such a belief could never be discovered by examining archaeological sources—the material remains—and hence cannot be ruled out for the Early Paleolithic Period. Whether or not the sacrifices in that era involved divine creators or preservers or other beings can only be a matter of conjecture. Features of animalism, magic, and various other views and practices may have played a role, but probably less so than in later epochs.

Upper Paleolithic and Mesolithic. The animalistic features encountered in the art of the Upper Paleolithic Period were most likely only a part of the religion that existed at that time. Among present-day "primitives" the animalistic realm often occupies only a lower sphere of what can be considered religious, and beyond and above that sphere are still other notions about gods. Practices concerning the resurrection of animals and the preservation of species evidently also played an important part and were closely tied to animalistic conceptions. The corresponding rituals clearly took on a special significance in relation to bears and became the basis for the bear ceremonies that were later widely diffused. Although shamanism may have been initiated somewhat earlier, it was now evident, at least in some of its aspects.

The realm of hunting was primarily a masculine sphere; nevertheless, it also includes in religious phenomena the feminine aspect, as symbols of female fertility (and probably also of female deities) demonstrate.

Proto-Neolithic and Neolithic. The characteristics of early religion were continued but transformed in the proto-Neolithic and Neolithic periods. Shamanism developed, especially among the pastoralists of central and north Asia. Animals, viewed as the hypostases (essences) of higher beings, especially the eagle or falcon and the raven, became highly significant in shamanism. Animalistic conceptions continued and often assumed the proportions of a true animal cult. Hoofed animals, especially sheep and oxen, played an important part as sacrifices and bulls particularly assumed a leading role; they seem to have been relegated to the masculine sphere. Horses appear as domesticated animals and as sacrifices only toward the end of the Neolithic Period. They may have been connected with a heavenly divinity, as later evidence suggests.

In the early period of agriculture, before the full development of the Neolithic Period, deposits of human skulls appear that suggest the presence of ancestor cults. A spiritual identification between humans and plants apparently played a predominant part in conceptions connected with headhunting and cannibalism. The death of a god was often considered a prerequisite to the appearance and prospering of the plants, and this mythical event was repeated through human sacrifice that was either accompanied by or replaced by animal sacrifice.

At an early stage, in addition to an agricultural connection with the earlier feminine aspects, the masculine aspect appears in the form of portrayals of sexual union and, perhaps, of the "holy wedding," or sacred coupling, as well as in portrayals of couples and families. Among the material remains, however, the direct representation of the male element recedes sharply, yet perhaps the symbol of the axe and probably also that of the bull may indicate the male element. This dualism of the masculine and feminine aspects can possibly be interpreted in terms of father sky and mother earth, and in their union as a couple by which they become parents of the world. In the early civilizations, the conception of a supreme being or a heavenly god (which cannot clearly be recognized either in pictures or in other material objects) plays a minor role. That does not mean, however, that such a conception is necessarily of recent origin but rather that it probably existed at an early period in places where there was no literate tradition (predominantly among pastoral cultures).

Dualism of masculine and feminine elements

CIVILIZATIONS

The decisive factors that brought about the early civilizations were the new kinds of economic and social organization, the large-scale exploitation of human energy, the formation of ruling classes, hierarchical organization, and the administrative division of labour. Under such conditions polytheism, which had undoubtedly been nascent before, could develop fully. The social order is mirrored in the conception of city and state gods and of a hierarchically organized "state of gods" with a division of labour. The concentration of power and people in one place, in contrast with the wandering of earlier nomadic cultures, enabled fixed central shrines to become influential. Yet the old traditions continued, and not least among them, that of animalism, in the form of conceptions about a ruler of the animals, animal cults, and similar phenomena. Female fertility figures remain generally prominent, such as the Great Mother and the Earth Mother. (K.J.N./Ed.)

Printing, Typography, and Photoengraving

Printing traditionally has been defined as a technique for applying under pressure a certain quantity of colouring agent onto a specified surface to form a body of text or an illustration. Certain recently developed processes for reproducing texts and illustrations, however, are no longer dependent on the mechanical concept of pressure or even on the material concept of colouring agent. Because these processes represent an important development that may ultimately replace the other processes, printing should probably now be defined as any of several techniques for reproducing texts and illustrations, in black and in colour, on a durable surface and in a desired number of identical copies. There is no reason why this broad definition should not be retained, for the whole history of printing is a progression away from those things that originally characterized it: lead, ink, and the press.

It is also true that, after five centuries during which printing has maintained a quasi-monopoly of the transmission or storage of information, this role is being seriously challenged by new audiovisual and information media. Printing, by the very magnitude of its contribution to the multiplication of knowledge, has helped engender radio, television, film, microfilm, tape recording, and other rival techniques. Nevertheless, its own field remains immense. Printing is used not merely for books and newspapers but also for textiles, plates, wallpaper, packaging, and billboards. It has even been used to manufacture miniature electronic circuits.

The invention of printing at the dawn of the age of the great discoveries was in part a response and in part a stimulus to the movement that, by transforming the economic, social, and ideological relations of civilization, would usher in the modern world. The economic world was marked by the high level of production and exchange attained by the Italian republics, as well as by the commercial upsurge of the Hanseatic League and the Flemish cities; social relations were marked by the decline of the landed aristocracy and the rise of the urban mercantile bourgeoisie; and the world of ideas reflected the aspirations of this bourgeoisie for a political role that would allow it to fulfill its economic ambitions. Ideas were affected by the religious crisis that would lead to the Protestant Reformation.

The first major role of the printed book was to spread literacy and then general knowledge among the new economic powers of society. In the beginning it was scorned by the princes. It is significant that the contents of the first books were often devoted to literary and scientific works as well as to religious texts, though printing was used to ensure the broad dissemination of religious material, first Catholic and, shortly, Protestant.

There is a material explanation for the fact that printing developed in Europe in the 15th century rather than in the Far East, even though the principle on which it is based

had been known in the Orient long before. European writing was based on an alphabet composed of a limited number of abstract symbols. This simplifies the problems involved in developing techniques for the use of movable type manufactured in series. Chinese handwriting, with its vast number of ideograms requiring some 80,000 symbols, lends itself only poorly to the requirements of a typography. Partly for this reason, the unquestionably advanced Oriental civilization, of which the richness of their writing was evidence, underwent a slowing down of its evolution in comparison with the formerly more backward Western civilizations.

Printing participated in and gave impetus to the growth and accumulation of knowledge. In each succeeding era there were more people who were able to assimilate the knowledge handed to them and to augment it with their own contribution. From Diderot's encyclopaedia to the present profusion of publications printed throughout the world, there has been a constant acceleration of change, a process highlighted by the Industrial Revolution at the beginning of the 19th century and the scientific and technical revolution of the 20th.

At the same time, printing has facilitated the spread of ideas that have helped to shape alterations in social relations made possible by industrial development and economic transformations. By means of books, pamphlets, and the press, information of all kinds has reached all levels of society in most countries.

In view of the contemporary competition over some of its traditional functions, it has been suggested by some observers that printing is destined to disappear. On the other hand, this point of view has been condemned as unrealistic by those who argue that information in printed form offers particular advantages different from those of other audio or visual media. Radio scripts and television pictures report facts immediately but only fleetingly, while printed texts and documents, though they require a longer time to be produced, are permanently available and so permit reflection. Though films, microfilms, punch cards, punch tapes, tape recordings, holograms, and other devices preserve a large volume of information in small space, the information on them is available to human senses only through apparatus such as enlargers, readers, and amplifiers. Print, on the other hand, is directly accessible, a fact that may explain why the most common accessory to electronic calculators is a mechanism to print out the results of their operations in plain language. Far from being fated to disappear, printing seems more likely to experience an evolution marked by its increasingly close association with these various other means by which information is placed at the disposal of humankind.

History of printing

ORIGINS IN CHINA

By the end of the 2nd century AD, the Chinese apparently had discovered printing; certainly they then had at their disposal the three elements necessary for printing: (1) paper, the techniques for the manufacture of which they had known for several decades; (2) ink, whose basic formula they had known for 25 centuries; and (3) surfaces bearing texts carved in relief. Some of the texts were classics of Buddhist thought inscribed on marble pillars, to which pilgrims applied sheets of damp paper, daubing the surface with ink so that the parts that stood out in relief showed up; some were religious seals used to transfer pictures and texts of prayers to paper. It was probably this use of seals that led in the 4th or 5th century to the development of ink of a good consistency for printing.

A substitute for these two kinds of surfaces, the marble pillars and the seals, that was more practical with regard both to manageability and to size, appeared perhaps by the 6th century in the wood block. First, the text was written in ink on a sheet of fine paper; then the written side of the sheet was applied to the smooth surface of a block of wood, coated with a rice paste that retained the ink of the text; third, an engraver cut away the uninked areas so that the text stood out in relief and in reverse.

To make a print, the wood block was inked with a paintbrush, a sheet of paper spread on it, and the back of the sheet rubbed with a brush. Only one side of the sheet could be printed.

The oldest known printed works were made by this technique: in Japan about 764–770, Buddhist incantations ordered by Empress Shōtoku; in China in 868, the first known book, the *Diamond Sūtra*; and, beginning in 932, a collection of Chinese classics in 130 volumes, at the initiative of Fong Tao, a Chinese minister.

Invention of movable type (11th century). About 1041–48 a Chinese alchemist named Pi Sheng appears to have conceived of movable type made of an amalgam of clay and glue hardened by baking. He composed texts by placing the types side by side on an iron plate coated with a mixture of resin, wax, and paper ash. Gently heating this plate and then letting the plate cool solidified the type. Once the impression had been made, the type could be detached by reheating the plate. It would thus appear that Pi Sheng had found an overall solution to the many problems of typography: the manufacture, the assembling, and the recovery of indefinitely reusable type.

In about 1313 a magistrate named Wang Chen seems to have had a craftsman carve more than 60,000 characters on movable wooden blocks so that a treatise on the history of technology could be published. To him is also attributed the invention of horizontal compartmented cases that revolved about a vertical axis to permit easier handling of the type. But Wang Chen's innovation, like that of Pi Sheng, was not followed up in China.

In Korea, on the contrary, typography, which had appeared by the first half of the 13th century, was extensively developed under the stimulus of King Htai Tjong, who, in 1403, ordered the first set of 100,000 pieces of type to be cast in bronze. Nine other fonts followed from then to 1516; two of them were made in 1420 and 1434, before Europe in its turn discovered typography.

Transmission of paper to Europe (12th century). Paper, the production of which was known only to the Chinese, followed the caravan routes of Central Asia to the markets at Samarkand, whence it was distributed as a commodity across the entire Arab world.

The transmission of the techniques of papermaking appears to have followed the same route; Chinese taken prisoner at the Battle of Talas, near Samarkand, in 751 gave the secret to the Arabs. Paper mills proliferated from the end of the 8th century to the 13th century, from Baghdad and then on to Spain, then under Arab domination. Paper first penetrated Europe as a commodity from the 12th century onward through Italian ports that had active commercial relations with the Arab world and also, doubtless, by the overland route from Spain to France. Papermaking techniques apparently were rediscovered by Europeans through an examination of the material from which the imported commodity was made; possibly the secret was brought back in the mid-13th century by returning crusaders or merchants in the Eastern trade. Papermaking centres grew up in Italy after 1275 and in France and Germany in the course of the 14th century.

But knowledge of the typographic process does not seem to have succeeded, as papermaking techniques had, in reaching Europe from China. It would seem that typography was assimilated by the Uighurs who lived on the borders of Mongolia and Turkistan, since a set of Uighur typefaces, carved on wooden cubes, has been found that date from the early 14th century. It would be surprising if the Uighurs, a nomadic people usually considered to have been the educators of other Turco-Mongolian peoples, had not spread the knowledge of typography as far as Egypt. There it may have encountered an obstacle to its progress toward Europe, namely, that, even though the Islāmic religion had accepted paper in order to record the word of Allah, it may have refused to permit the word of Allah to be reproduced by artificial means.

THE INVENTION OF PRINTING

Thus, the essential elements of the printing process collected slowly in western Europe, where a favourable cultural and economic climate had formed.

Xylography. Xylography, the art of printing from wood carving, the existence and importance of which in China was never suspected by Marco Polo, appeared in Europe no earlier than the last quarter of the 14th century, spontaneously and presumably as a result of the use of paper. It had been observed that paper was better suited than rough-surfaced parchment for making the impres-

Early
wood-
block
works

Contribu-
tion of the
Uighurs

sions from wood reliefs that manuscript copyists used to reproduce the outline of ornamental initial capital letters.

The process was extended to the making of religious pictures. These at first appeared alone and later were accompanied by a brief text. As engravers became more skillful, the text finally became more important than the illustration, and in the first half of the 15th century small, genuine books of several pages, religious works or compendiums of Latin grammar by Aelius Donatus and called *donats*, were published by a method identical to that of the Chinese. Given the Western alphabet, it would seem reasonable that the next step taken might have been to carve blocks of writing that, instead of texts, would simply contain a large number of letters of the alphabet; such blocks could then be cut up into type, usable and reusable.

It is possible that experiments were in fact made along these lines, perhaps in 1423 or 1437 by a Dutchman from Haarlem, Laurens Janszoon, known as Coster. The encouraging results obtained with large type demonstrated the validity of the idea of typographic composition.

But the results were disappointing with regard to type destined for use for text of the usual size. The letters of the roman alphabet were smaller than Chinese ideograms, and cutting them from wood was a delicate operation. Moreover, type made in this way was fragile, and it wore out at least as quickly as blocks carved with a whole text. Further, since the letters were individually carved, no two copies of the same letter were identical any more than when the text was engraved directly on a wood block. The process, thus, represented no advance in ease of production, durability, or quality.

Metallographic printing (1430?). Metallographic impression is more likely to turn out to be the direct ancestor of typography, although the record is far from clear. Several medieval craft guilds, notably the metal founders, the die-cutters, and goldsmiths and silversmiths, were familiar with the technique of using dies. Masters of this technique apparently realized that it could be applied to a process that would enable texts to be set in relief more quickly than by carving wood blocks, probably in three steps: (1) a set of dies, each bearing a letter of the alphabet, was engraved in brass or bronze; (2) using these dies, the text was struck letter by letter to form a mold on the surface of a matrix of clay or of a soft metal such as lead; (3) lead was then poured over the surface to form a small plate that, once hardened, would bear the text in relief.

The theoretical advantages of this process were that only one engraving per letter, that of the die, was required to make the letter as often as desired, and any two examples of the same letter would be identical, since they came from a single die; sinking the matrix and casting the lead were rapid operations; the lead had better durability than wood; and by casting several plates from the same matrix the number of copies printed could be rapidly increased.

Metallographic printing appears to have been practiced in Holland around 1430 and next in the Rhineland. Gutenberg used it in Strassburg (now Strasbourg, France) between 1434 and 1439.

But the experiments were not followed up because of problems created by the cast plates. It was difficult to strike each letter die with the same force and to keep a regular alignment, and, worse, each strike tended to deform the adjacent letter. It may well be that the major value of metallographic printing was that it associated the idea of the die, the matrix, and cast lead.

The invention of typography—Gutenberg (1450?). This association of die, matrix, and lead in the production of durable typefaces in large numbers and with each letter strictly identical, was one of the two necessary elements in the invention of typographic printing in Europe. The second necessary element was the concept of the printing press itself, an idea that had never been conceived in the Far East.

Johannes Gutenberg is generally credited with the simultaneous discovery of both these elements, though there is some uncertainty about it, and disputes arose early to cloud the honour.

It is true that his signature does not appear on any printed work. If masterpieces such as the Forty-two-Line Bible of

1455 rather than the imperfect products of a nascent typography such as the *donats* of 1445 or the "Astronomic Calendar" of 1447–48 are attributed to him, this is because of deduction and historical and technical cross-checking. The basic assumption is that, since Gutenberg was by profession a silversmith, he would have retained the role of designer in an association set up at Mainz, Germany, with the businessman Johann Fust and Fust's future son-in-law the calligrapher Peter Schöffer. The assumption is based solely on the interpretation of obscure aspects of a lawsuit that Gutenberg lost against his associates in 1455.

Apart from chronicles, all published after his death, that attributed the invention of printing to him, probably the most convincing argument in favour of Gutenberg comes from his chief detractor, Johann Schöffer, the son of Peter Schöffer and grandson of Johann Fust. Though Schöffer claimed from 1509 on that the invention was solely his father's and grandfather's, the fact is that in 1505 he had written in a preface to an edition of Livy that "the admirable art of typography was invented by the ingenious Johan Gutenberg at Mainz in 1450." It is assumed that he had inherited this certainty from his father, and it is hard to see how a new element could have persuaded him to the contrary after 1505, since Johann Fust died in 1466 and Peter Schöffer in 1502.

The first pieces of type appear to have been made in the following steps: a letter die was carved in a soft metal such as brass or bronze; lead was poured around the die to form a matrix and a mold into which an alloy, which was to form the type itself, was poured.

Spectroscopic analyses of early type pieces reveal that the alloy used was a mix of lead, tin, and antimony—the same components used today: tin, because lead alone would have oxidized rapidly and in casting would have deteriorated the lead mold matrices; antimony, because lead and tin alone would have lacked durability.

It was probably Peter Schöffer who, around 1475, thought of replacing the soft-metal dies with steel dies, in order to produce copper letter matrices that would be reliably identical. Until the middle of the 19th century, type generally continued to be made by craftsmen in this way.

The typographer's work was from the beginning characterized by four operations: (1) taking the type pieces letter by letter from a typeset; (2) arranging them side by side in a composing "stick," a strip of wood with corners, held in the hand; (3) justifying the line; that is to say, spacing the letters in each line out to a uniform length by using little blank pieces of lead between words; and (4), after printing, distributing the type, letter by letter, back in the compartments of the typeset.

The Gutenberg press. Documents of the period, including those relating to a 1439 lawsuit in connection with Gutenberg's activities at Strassburg, leave scarcely any doubt that the press has been used since the beginning of printing.

Perhaps the printing press was first just a simple adaptation of the binding press, with a fixed, level lower surface (the bed) and a movable, level upper surface (the platen), moved vertically by means of a small bar on a worm screw. The composed type, after being locked by ligatures or screwed tight into a right metal frame (the form), was inked, covered with a sheet of paper to be printed, and then the whole pressed in the vise formed by the two surfaces.

This process was superior to the brushing technique used in wood-block printing in Europe and China because it was possible to obtain a sharp impression and to print both sides of a sheet. Nevertheless, there were deficiencies: it was difficult to pass the leather pad used for inking between the platen and the form; and, since several turns of the screw were necessary to exert the required pressure, the bar had to be removed and replaced several times to raise the platen sufficiently to insert the sheet of paper.

It is generally thought that the printing press acquired its principal functional characteristics very early, probably before 1470. The first of these may have been the mobile bed, either on runners or on a sliding mechanism, that permitted the form to be withdrawn and inked after each sheet was printed.

Evidence supporting Gutenberg's claim

Steps in metal relief printing

Next, the single thread of the worm screw was replaced with three or four parallel threads with a sharply inclined pitch so that the platen could be raised by a slight movement of the bar. This resulted in a decrease in the pressure exerted by the platen, which was corrected by breaking up the printing operation so that the form was pushed under the press by the movable bed so that first one half and then the other half of the form was utilized. This was the principle of printing "in two turns," which would remain in use for three centuries.

IMPROVEMENTS AFTER GUTENBERG

Several of the many improvements in the screw printing press over the next 350 years were of significance. About 1550 the wooden screw was replaced by iron. Twenty years later, innovators added a double-hinged chase consisting of a frisket, a piece of parchment cut out to expose only the actual text itself and so to prevent ink spotting the nonprinted areas of the paper, and a tympan, a layer of a soft, thick fabric to improve the regularity of the pressure despite irregularities in the height of the type. An engraving of an early printing shop is shown in Figure 1.

Figure 1: An early printing shop with lightly constructed wooden press; 17th-century engraving by Abraham van Weerd.

The Dutch press

About 1620 Willem Janszoon Blaeu in Amsterdam added a counterweight to the pressure bar in order to make the platen rise automatically; this was the so-called Dutch press, a copy of which was to be the first press introduced into North America, by Stephen Daye at Cambridge, Massachusetts in 1639.

About 1790 an English scientist and inventor, William Nicholson, devised a method of inking using a cylinder covered with leather (later with a composition of gelatin, glue, and molasses), the first introduction of rotary movement into the printing process.

The metal press (1795). The first all-metal press was

constructed in England in about 1795. Some years later a mechanic in the United States built a metal press in which the action of the screw was replaced by that of a series of metal joints. This was the "Columbian," which was followed by the "Washington" of Samuel Rust, the apogee of the screw press inherited from Gutenberg; its printing capacity was about 250 copies an hour.

Stereotypy and stereography (late 18th century). An increasing demand for printed matter stimulated the search for greater speed and volume. The concepts of stereotypy and stereography were explored. Stereotypy, used with notable success around 1790 in Paris, consisted in making an impression on text blocks of type in clay or soft metal in order to make lead molds of the whole. The stereotyped plates thus obtained made it economically possible to print the same text on several presses at the same time. The plates left the pieces of type in the form immediately available for further use and thus increased the rate at which they could be recycled.

A variation of stereotypy was the application, after 1848, of galvanoplastic metallization, in which process plates of thin metal lined with a base of lead alloy were made by electrolytic deposition of a coat of copper on a wax mold of the typeform.

Stereography aimed at bypassing the composition of the type in making the mold. Attempts to perfect the old metallographic method of preparing a clay matrix by stamping with dies brought no better results. In 1797 a variation was tried in which sets of copper matrices of each letter were made in large numbers. The matrices were then assembled according to the wording of the text, so that they covered the whole surface of the bottom of a mold in which the lead plate was then cast. Once the cast had been made, the matrices were available for further use.

Koenig's mechanical press (early 19th century). The prospect of using steam power in printing prompted research into means by which the different operations of the printing process could be joined together in a single cycle.

In 1803, in Germany, Friedrich Koenig envisaged a press in which the raising and lowering of the platen, the to-and-fro movement of the bed, and the inking of the form by a series of rollers were controlled by a system of gear wheels (see Figure 2, left). Early trials in London in 1811 were unsuccessful.

Presses with a mechanized platen produced satisfactory results after the perfection, in the United States, of the "Liberty" (1857), in which the action of a pedal caused the platen to be held against the bed by the arms of a clamp.

Though Nicholson very early took out patents for a printing process using a cylinder to which the composed type pieces were attached, he was never able to develop the necessary technology involved.

The cylinder was in fact the most logical geometric form to use in a cyclical process. It was also the one capable of providing the greatest output. Given an equal amount of energy, the pressure exerted by a platen had to be spread over the whole of the surface to be printed, whereas the pressure exerted by a cylinder could be concentrated on

Figure 2: (Left) Friedrich Koenig's mechanical platen press, 1811, and (right) the first stop-cylinder printing machine, 1811, built by Koenig and Andreas Bauer.

the strip of surface actually in contact with the cylinder at any one instant.

A limited demonstration of the efficiency of the cylinder had been made as early as 1784 on a French press for books for the blind.

In 1811 Koenig and an associate, Andreas Bauer, in another approach to the rotary principle, designed a cylinder as a platen bearing the sheet of paper and pressing it against the typeform placed on a flatbed that moved to and fro. The rotation of the cylinder was linked to the forward movement of the bed but was disengaged when the bed moved back to go under the inking rollers (see Figure 2, right).

The
London
Times
press
of 1814

In 1814 the first stop-cylinder press of this kind to be driven by a steam engine was put into service at the *Times* of London. It had two cylinders, which revolved one after the other according to the to-and-fro motion of the bed so as to double the number of copies printed; a speed of 1,100 sheets per hour was achieved.

In 1818 Koenig and Bauer designed a double press in which a sheet of paper printed on one side under one of the cylinders passed to the other cylinder, to be printed on the other side. This was called a perfecting machine. In 1824 William Church added grippers to the cylinder to pick up, hold, and then automatically release the sheet of paper.

The to-and-fro movement of the bed that was retained in these early cylinder presses constituted an element of discontinuity; to make the cycle completely continuous, not only would the platen have to be cylindrical but the typeform also. In 1844 Richard Hoe in the United States patented his type revolving press, the first rotary to be based on this principle. It consisted of a cylinder of large diameter, bearing columns of type bracketed together on its outer surface; pressure was provided by several small cylinders, each of which was fed sheets of paper by hand. This system gave speeds of more than 8,000 copies per hour; its only drawback was its fragility; faulty locking up of the forms caused the type to fall out of the cylinder.

This defect was remedied by applying stereotypy to the production; that is, forming curved plates by making an impression of the typeform on strong pasteboard, the flog, or mat, which was fixed against the inside surface of a rounded mold, which was injected with lead alloy. In France, from 1849 onward, experiments were conducted with this process; it was regularly used in London by the *Times* from 1856 onward and after 1858 was in general use.

But feeding the press with paper still remained outside the mechanized cycle. Mechanization of this step was accomplished by the use of a continuous roll of paper supplied on reels instead of sheets. Techniques for producing paper in a continuous roll had been known since the beginning of the century. The first roll-fed rotary press was made by William Bullock of the United States in 1865. It included a device for cutting the paper after printing and produced 12,000 complete newspapers per hour. Automatic folding devices, the first of which were designed by Bullock and Hoe, were incorporated into rotaries after 1870.

Later, numerous other types of curved stereotype plates were used on rotary presses. These included electrotypes plates that are curved before being backed; rubber or plastic plates made by molding or by a photomechanical process; and metal wraparound plates made by photoengraving or electronic engraving.

Attempts to mechanize composition (mid-19th century). Unlike the mechanization of the printing process, mechanization of the composition process was difficult to achieve in the 19th century. The invention of a compression mold in 1806 opened prospects for the mechanization of the production of type. In 1822 William Church of Boston patented a typesetting machine consisting of a keyboard on which each key released a piece of type of the corresponding letter stored in channels in a magazine. The pieces of type thus obtained had to be assembled by hand and the line justified. Church had avoided the problem of distribution and shown an intuition as to its solution by annexing to the magazine a device for constantly casting new pieces of type.

Numerous machines based on the same principle and with the further addition of a mechanism that placed the type pieces selected the right way round appeared in the course of the next 50 years. On one of these the more than 10,000 pages of the ninth edition of *Encyclopædia Britannica* were composed. These machines produced type at the rate of 5,000 to 12,000 pieces per hour, as opposed to about 1,500 by hand composition. But in all of them the type was simply delivered in a continuous row, which had to be divided into lines and justified.

These machines were completed by the introduction of a mechanical distributor, which was a sort of reverse compositor: pieces of type from lines that had been used passed before the operator, who pressed the corresponding key on his keyboard for the appropriate channel in the magazine to be opened up. The speed of mechanized distribution did not exceed 5,000 pieces of type per hour and was, thus, no faster than hand distribution.

Mechanization of letterpress composition faced two difficulties: first, justification, which required intelligent estimation of the size of spaces to be provided between words; and, second, the time taken during which the pieces of type were used for printing, which delay kept composition and distribution from being integrated into one cycle.

Typesetting compositors (1880s). Finally, in the 1880s in the United States, German-born Ottmar Mergenthaler invented the Linotype, a typesetting compositor that cast a solid one-piece line, or slug, from movable matrices of each letter. Each of the matrices was individually notched so that it could return only to its proper slot in the magazine after use. Justification was carried out by inserting wedged spacebands between groups of matrices immediately after making up the words of a given line. Here the matrices rather than type pieces went through the four basic operations of letterpress composition; cast lead was used for printing. The Linotype can produce the equivalent of 5,000 to 7,000 pieces of type per hour.

Mergen-
thaler's
Linotype
machine

In 1885, also in the United States, Tolbert Lanston invented the Monotype, which casts individual pieces of type for a line and justifies each line by a system of counting in units the width of the spaces taken up by the pieces of type. The matrices are indefinitely reusable, and the pieces of type, which are used only for the impressions, are returned to the caster. The contemporary Monotype typesetter is controlled by a ribbon of paper perforated on a separate keyboard. It can produce 10,000 to 12,000 pieces of type per hour.

In 1911 the American Washington I. Ludlow perfected a typesetting machine for the large display type that bears his name. The matrices are assembled by hand in a composing stick, which is then inserted above the opening of a mold; the matrices are also distributed by hand.

19TH-CENTURY INNOVATIONS

In the course of the 19th century several important innovations laid the foundation for a number of printing techniques that were not directly related to Gutenberg's invention.

Reproduction of illustrations. The first process for reproducing illustrations was xylography, using woodcuts that printed in relief and that therefore could be combined with letterpress, the picture blocks and the pieces of type for texts being locked into the same form. As early as the second half of the 15th century, xylography faced competition from engraving on metal that printed by intaglio; the metal plate (copper, sometimes brass, zinc, and even steel after 1806), engraved with a tool (burin) or etched with acid, was inked and carefully wiped so that ink remained only in the incisions and was transferred to paper under pressure in a cylinder press derived from the rolling mill. Since the intaglio method of printing was not compatible with woodcut printing, sheets of text and of illustrations for the same book had to be printed separately.

Presses for printing curved intaglio-engraved plates were perfected during the 19th century with mechanized inking with the use of rollers and wiping with the use of revolving cloth bands or rotating disks covered with calico. Their printing capacity was limited.

As early as the end of the 18th century, however, intaglio

printing had inspired a method for continuous printing of textiles by passing them under an engraved and inked cylinder from which excess ink had been removed by a scraper. In France in 1860 this technique was applied to printing paper for school-book covers. A solid copper cylinder was engraved not with continuous lines but with a multiplicity of tiny cavities in such a way that they retained the ink uniformly despite gravity, centrifugal force, and the action of the scraper. The process was suitable only for simple graphics.

Lithography: Senefelder (1796). A third printing process that had undergone significant development was lithography, neither relief nor intaglio printing but based on the principle that water and grease will not mix. In 1796 Aloys Senefelder of Prague investigated the properties of a stone with a calcium carbonate base and a fine, homogeneous, porous surface. A design drawn on its surface with greasy ink, wetted with water and then brushed with ordinary ink, retained the ink only on the design. This could consequently be reproduced on a sheet of paper pressed against the stone. Senefelder also established that a design drawn on such a stone and printed on paper could be transferred to another stone in as many identical copies as desired, side by side, which made it possible to obtain several copies at a time by printing a single large sheet. He further established that a metal such as zinc had the same properties.

Senefelder envisaged a press in which the stone, secured to an undercarriage, was inked, covered with the sheet of paper with a sheet of pasteboard above it, and submitted to pressure. By 1850 the first mechanized lithographic press with a cylinder, flannel-covered rollers for wetting, and rollers for inking was perfected.

The fact that it was possible to replace the stone by a zinc plate that could be curved made it possible to build rotary presses (the first in 1868) in which the paper passed between the plate-bearing cylinder and the impression cylinder.

Photosensitivity: Niepce (1820s). While searching for a means of automatically inscribing an image on a lithographic stone, then on a tin plate, in order to engrave it in intaglio, Joseph-Nicéphore Niepce in the 1820s established that certain chemical compounds are sensitive to light. This marked the origins of photogravure (see *Photoengraving* below) and led to both the invention of photography (between 1829 and 1838) and the use of photographic processes for the printed reproduction of photographs.

In 1852 William Henry Fox Talbot, a British scientist and inventor, placed a piece of black cloth (tulle) between the object he wanted to reproduce (the leaf of a tree) and the photosensitive coating spread on a steel plate and obtained a picture that retained the fine mesh of the tulle. Consequently, etching with acid resulted not in an extensive and uniform erosion of an area but in tiny juxtaposed pits all over the photosensitive coating and varying in depth according to the degree of exposure. Talbot simultaneously had invented the screen and also had opened the way for a new development in intaglio printing: rotogravure.

The screen was perfected in the 1880s by substituting for the cloth two sheets of glass with uniform parallel lines that crossed perpendicularly. The screen made possible letterpress and lithographic reproduction of the full range of tones of a photographic document by using the effect of the diffusion of light through the mesh of its grid and converting the different intensity of tones into the different thicknesses of the printing surface.

Gravure and rotogravure (1890s). The circular mechanization of intaglio engraving, meanwhile, came up against two associated difficulties: the need to engrave an infinite number of tiny cells and the need to engrave them directly onto a cylinder. There were problems, because the rubbing of the squeegee to remove excess ink excluded the use of a curved plate that would not have provided a uniform surface in the area in which it was attached, and it was not possible to get photosensitive solutions to adhere to a cylinder.

In 1862–64 J.W. Swan of Britain invented carbon tissue, paper coated with gelatin that can be rendered photosen-

sitive and exposed to light before being applied to a metal surface of any shape.

In 1878 a Czech, Karl Klič (also spelled Klietsch), thought of copying a grid screen directly onto carbon tissue, which could be used to transfer the cells necessary for intaglio printing to a cylinder at the same time as the image to be reproduced. In 1895 Klič, with English colleagues, founded the Rembrandt Intaglio Printing Company, which published reproductions of pictures, on paper, by rotogravure. They kept their process a secret.

In a parallel way, patents for a slightly different process, in which the image to be reproduced was screened before making the impression on the carbon tissue, were taken out in Germany and the United States. But a workman from the Rembrandt Intaglio Printing Company emigrated to the United States in 1903 and there revealed Klič's secret, and rotogravure, using his method, became widespread.

THE 20TH CENTURY

Beginning with the invention of the offset technique, the 20th century saw the steady development of innovations in the direction of mass production, speed, and economy.

Discovery of offset (early 20th century). At the same time, lithography was undergoing a new evolution. After the first mechanical presses had been perfected, this process had developed along two lines: (1) printing on thin sheets of metal (for example, tinplate for packaging canned foods) using a transfer process (1878) in which the impression cylinder carrying the metal sheet to be printed did not come in contact with the stone but did with an intermediary cylinder covered with rubber, the blanket, which transferred the image from the stone to the metal; and (2) printing on paper, which was done only comparatively infrequently in the last years of the 19th century, on cylinder or rotary presses.

In 1904 at Nutley, New Jersey, an American printer, Ira W. Rubel, discovered that an image accidentally transferred from the plate cylinder of his rotary to the rubber blanket of the impression cylinder during a paper-feed stoppage could itself be used for printing and in fact produced a superior impression. Rubel and an associate constructed a three-cylinder press, the first offset press, the term since used to describe this increasingly popular printing device.

Dry offset (1920). A few years later a problem arose in connection with printing the background of checks with a water-soluble ink to prevent forgeries. It was proposed that the lithographic plate of the plate cylinder be replaced with a stereotype plate or with a letterpress wraparound plate. This process, which combines the relief of letterpress, which does not require wetting, with the transfer of offset, is known as dry offset, or letterpress. Its area of application is not limited to check backgrounds but is used in all areas of conventional printing.

Since 1950 another process has been developed, particularly in the United States. It combines rotogravure with the transfer of offset for printing wallpapers, plastic floor coverings, paper plates, and other products.

Colour printing. As early as 1457 a psalter, which Peter Schöffer signed but which some researchers now attribute to Gutenberg, included, in imitation of the contemporary illuminated manuscripts, paragraphs beginning with ornamental capital letters printed in two colours. This was accomplished by the use of two wood blocks that fitted one inside the other and could be separately inked.

Experiments to reproduce pictures in several colours on wood blocks were made in Germany in the 16th century. In the 17th century, different inks were applied to the different parts of the same engraved metal plate in such a way that all the inks were transferred to the paper in a single pressing. In 1719 a painter, Jacques-Christophe Le Blond, took out a patent in England for a process that used the three primary colours, blue, yellow, and red, and black for outlining shapes. Using a dense grid, he engraved four metal plates, bringing out on each plate the relative importance of the colour involved. The same sheet of paper then went through four successive impressions, each in a different colour.

The
Klietsch
process

Early
colour
experi-
ments

In the 19th century the scientific definition of the principles of trichromatism, the enunciation of the fundamental theories of three-colour analysis and synthesis of colours by photography, the perfecting of coatings selectively sensitive to colours, and finally the use of the screen, instead of Le Blond's hand-drawn grid, established the modern trichromatic technique (which becomes quadrichromatic when black is also used).

Automation of composition (after 1929). The search for maximum efficiency had from the very beginning posed the problem of both the mechanization and the automation of composition. The Monotype system, with its separation of keyboard and caster, had constituted one approach to the solution, since the same caster could work at full speed when fed with perforated tapes produced on several keyboards.

The perfection of teletypesetter remote-control composing equipment in the United States by about 1929 permitted widespread application of the principle of separation of human function on the one hand and mechanized function on the other. The operator produces a tape on which each letter, symbol, and space is represented by a combination of perforations. A translator device reads the tape and, according to each combination of holes, orders the release of the necessary matrices for letters, signs, and justifying spaces. Machines casting one-piece fully spaced lines or slugs are able to produce more than 20,000 characters per hour.

Programmed composition (1950s). The production of the perforated tape remained relatively slow, however, because of the time taken by the operator to decide where to make the division in a word at the end of a line. Eventually, in the second half of the 20th century, electronics provided the means of automatically making this decision.

In the 1950s the BBR system, named by the initials of three inventors in France, introduced programmed composition. Starting with a perforated tape continuously produced by the operator, a computer takes over the task of determining the length of lines, the places where words are to be divided according to grammatical rules and typographic usage, the integration of corrections, and even the presentation of the text according to the layout. The speed at which a final tape bearing this information can be produced is limited only by the performance of the perforator, which is the outlet device of the computer. Operating speeds have exceeded 300,000 characters per hour, or 10 times the capacity of the most modern slug-casting machines.

During the 1960s, perforated tape began to be replaced by magnetic tape, which is even more rapidly made, at a rate of about 1,000 characters per second, or 3,600,000 per hour. Although magnetic tape is useless for mechanical compositors casting pieces of type or lines in lead, such speed is practical for other kinds of machines not burdened with the weight of lead and the inertia of their mechanical components.

Photocomposition. In preparing cylinders for rotogravure, offset plates, or letterpress wraparound plates, it is illogical to use the vast weight of lead in letterpress composition to produce a reproduction proof that will then be photographed. Before the end of the 19th century this circumstance led to consideration of machines for composing headings by photographing the images of the letters in succession. In 1915 the Photoline, a photographic equivalent of the Ludlow, assembled matrices of transparent letters in a composing stick in order to film each line of the heading.

First generation of phototypesetters: mechanical. The next idea to be tried involved the adaptation of existing typesetters by replacing the metal matrices with matrices carrying the image of the letters and replacing the caster with a photographic unit. The industrial application of this idea resulted in the Fotosetter (1947), a phototypesetter, and its variant the Fotomatic (1963), controlled by a perforated tape, both derived from the Intertype slugcasting machine; the Linofilm (1950), derived from the Linotype; and the Monophoto (1957), derived from the Monotype. Retaining the mechanical limitations of machines intended to shape lead, they could not achieve apprecia-

bly higher rates of performance. Photocomposition had to be rethought in functional terms. This approach was explored in Germany as early as the 1920s with the Uher typesetter, which had photographic matrices attached to a rotating disk.

Second generation of phototypesetters: functional. The second generation of phototypesetters is characterized by the maximum elimination of factors of inertia, the number of moving parts having generally been reduced to only two: a steadily revolving disk or drum carrying the photographic matrices and an optical device of prisms or mirrors allowing directional action on the beam of light provided by an electronic flashtube.

The first revolutionary application of this notion was the Lumitype, invented as the Lithomat in 1949 by two Frenchmen, René Higonnet and Louis Moyroud. Executed by phototypesetting, *The Marvelous World of Insects* was done on their machine in 1953. The first model had an attached keyboard. Later models with a separate keyboard printed more than 28,000 characters per hour.

A new Linofilm (1954), functional and electronic, was fitted with a device for selecting matrices by the action of the blades on the photographic shutter, producing 12 characters per second, or 43,200 per hour. The model that succeeded it (1965) is equipped with a drum and is capable of double the output. The Photon-Lumitype 713 (1957) also performs at the rate of 70,000 to 80,000 characters per hour. But at this speed the technique of using a rotary matrix case reaches its limit because of the problems posed by centrifugal force. The Lumizip 900 (1959) introduced a further revolutionary change by retaining as moving parts only the lens, which scans in a single movement the fixed series of light matrices so as to photograph at one time the whole line of 20 to 60 letters. Output reaches 200 to 600 characters per second, or more than 2,000,000 per hour; this machine required magnetic tape.

The first book composed with a Lumizip, the *Index Medicus* (1964), was as much of a landmark in the history of phototypesetting as the Forty-two-Line Bible had been in printing. Its more than 600 pages were completed in 12 hours. To produce the same work on a typesetting machine would have taken almost a year.

Third generation of phototypesetters: electronic. Magnetic tape was still faster than the fastest phototypesetters. To narrow this gap, a third generation of phototypesetters appeared in the 1960s, in which all mechanical moving parts were eliminated by omitting the use of light and therefore omitting the moving optical device responsible for operating in its field.

Cathode-ray-tube phototypesetters (RCA, Linotron, etc.) operate on a principle analogous to that of television: a narrow pencil of electrons analyzes an image matrix of each letter and commands the modulation of another pencil of electrons on a luminescent screen, which leaves an impression on photographic film. Performance exceeds 500 characters per second and even approaches 1,000, or more than 3,000,000 per hour.

Digiset, a German development that appeared in 1965, pushed the use of the electron to its logical conclusion by suppressing even the image matrix of the character, simply keeping the binary analysis of its design available in its magnetic memory; this is, in fact, all that is needed to modulate the pencil of electrons on the final screen. Phototypesetters of this kind (called alphanumerical) have theoretical performance rates exceeding 3,000 characters per second, or more than 10,000,000 per hour, and should be able to approach 30,000,000. Speeds such as these exceed the production rate even of magnetic tape. Consequently, to work at its most efficient output, such a typesetter must be directly connected to a computer with a similarly high rate of output.

Toward direct impression. The number of characters thus composed now approaches the number of characters printed on a press in the same time. The narrower this gap becomes, the more a still further revolutionary possibility looms—that of eliminating the press itself, since the typesetter can be made to deliver each page as quickly as the press would have. To accomplish this it would be necessary only to replace the photographic film that the

Introduc-
tion of
magnetic
tape

Speed of
photo-
typesetters

photographer imprints when it is conventionally used with an inexpensive carrier capable of receiving an image in the same way without pressure.

Several pressureless printing processes have already been perfected. In 1923 an electrostatic onset system drew the ink of a cylindrical typeform to the paper by means of an electrical charge. In 1948 two Americans conceived another type of electrostatic printing in which the colouring agent is not ink carried on a typeform but a powder or a solution sensitive to the pull of an electric charge inscribed in a plate. This technique gave birth to xerocopy in office duplicating (see below *Office printing*) and, at the industrial level, to xerography for producing posters and maps.

Printing without pressure can also be accomplished on papers impregnated with photosensitive preparations and passed in front of a cathode-ray screen of a phototypesetter. The first experiment using this facsimile printing process was carried out in Japan in 1964 by the *Mainichi shimbun*, a Tokyo daily newspaper. The image of the newspaper page formed on the cathode-ray screen was transmitted by radio waves, as in television. It was reproduced using the electrostatic system, which does not require chemical treatment of the paper after its exposure.

Serigraphy and collotype: a renaissance. Parallel to the evolution of the three major printing processes, letterpress, offset, and lithography, various other techniques have experienced a similar evolution, which has allowed them to survive or to establish themselves in the course of the 20th century and to preserve or win a place in printing.

The art of reproducing a design by forcing ink through the mesh of a silk screen partly blanked out with a stencil plate (serigraphy) had been practiced by the Chinese and Japanese long before the invention of letterpress. In the 19th century the textile manufacturers of Lyon adopted it for printing textiles. In the 1930s in Great Britain and the United States the most varied materials (glass, wood, plastic) and even the most varied shapes (round objects, for example) were printed by serigraphy, which from a handcraft progressed to an industrial technique, with the screen prepared by photosensitization and printing carried out by semiautomatic or automatic machines.

Another process, patented in France in 1855 under the name Photocollography, was modified in 1865 under the name Phototypy (still used in France) and in Germany in 1868 under the name Albetypy (still used in Germany). This process used photosensitive substances not as agents in making plates for printing but to serve directly as the effective surface of such plates. Known elsewhere as the collotype process, the technique was in great favour between 1880 and 1914, was then neglected, and has recently been revived and mechanized for printing posters and transparencies in black and in colour.

Flexography is a letterpress process using rubber plates on the plate cylinder; it occupies a special place in printing on account of the fluidity of its inks. It was first patented in England in 1890, and it was perfected in Strassburg a few years later. Flexographic printing is particularly suited to relatively coarse surfaces (pasteboard, wrapping paper, plastic or metal film) but has also been adapted to newspaper and magazine printing. It can be carried out by sheet-fed machines but is chiefly used on powerful rotaries.

Three-dimensional printing (1960s). In the 1960s a three-dimensional print was developed, essentially an illustration bearing two views, superimposed, of the same image taken from slightly different angles, on a transparent mount striped with a multitude of imperceptible parallel strips (Xograph process). On account of these strips, each eye, looking at the print from a different angle, sees only one image. The three-dimensional illusion is produced when this binocular vision is interpreted by the brain.

Office printing. The development of industry and commerce, in the 19th and 20th centuries, accompanied by an increase in administrative activity, created a demand for an abundance of printed information at various levels. In the field of office printing the first tool was the typewriter, perfected in 1867. Thereafter, machines appeared that would reproduce large or small numbers of copies of typewritten texts and, later, texts or illustrations of every kind. Some of these machines rely on techniques

very close to those of conventional printing; others turned to original techniques that were in turn extended into modern printing. In 1881 in England appeared the stencil duplicator, basically employing the serigraphic technique. In 1900 a photocopying machine invented in France opened the way to facsimile printing. The offset printing process spread into the area of business printing with small offset duplicating machines; the simplified methods used for preparing plates for these machines eventually were adopted by industrial offset printers.

The application of the electrostatic printing process to xerocopy, perfected in 1938, has since been taken over by industry.

All the various processes of duplication and reproduction of documents make up reprography, a name bestowed during the first congress devoted to these techniques, which was organized at Cologne in 1963. Though its boundaries with conventional printing are poorly delimited, to the extent that reprography can compete with conventional printing when a medium number of copies are concerned, reprography nevertheless represents an original field. In response to the increased need for quality reprography, the typewriter has been improved since the 1950s and given the capability of providing justified composition suitable for conventional printing.

Modern printing techniques

COMPOSITION AND TYPESETTING

Mechanical composition and typesetting. In the first decades of the 20th century all type was set and composed into columns and pages by hand or by mechanical means. These methods are still widely used.

Letterpress composition by hand. The font, which constitutes a complete set of characters of a given typeface, with duplicate numbers of each letter in proportion to the frequency with which each is used, is stored in the compartments of a case; capital letters, proportionately less frequently called for, are in the upper compartments, whence their name, uppercase, and the small letters in the lower compartments, which are more easily accessible and whence their name, lowercase.

The typographer works standing in front of the case. His principal tools are the composing stick, a metal angle iron with one fixed end and a "knee" with a screw or lever for locking; the line gauge, a ruler graduated in units of typographic measurement; and tweezers.

He locks the knee of the composing stick at the justification; that is, at the length of the line to be composed. Against the inside edge of the stick he places a lead, a strip of nonprinting lead alloy that later enables him, using a second lead, to grip the finished line in order to remove it from the composing stick. Holding the composing stick in one hand, he uses the other to select the individual type characters from the case. He can tell by touching which way up they should go, thanks to a nick indicating the top or bottom of the body (the bottom in English-speaking countries and Germany; elsewhere, the top), and he places them side by side in the composing stick. Having completed the proper number of characters to fill the length of the line with a whole word or at the correct division in a word, he adds as necessary to the nonprinting pieces already in place to mark the spaces between the words until the exact justification is obtained.

Having composed and justified the line, the typographer takes it, gripped by its two leads between the thumb and forefinger of both hands, to place it in a galley, a wooden or metal tray with a raised edge on two or three of its sides.

Semimechanized composition. The Ludlow is considered a combination machine; though it automatically casts slugs, it is related to hand composition by the way the matrices are assembled. The matrices are bronze blocks bearing the letter or sign engraved in intaglio on their lower side and with two shoulders on their upper side.

The composer gathers them individually from the case, which is one of the drawers of a desk, and arranges them side by side in a special composing stick. This steel composing stick is hollowed out in the middle to receive the matrices supported on their shoulders with an adjustable

newspaper
experiment

Operations of a
Ludlow
caster

stopscrew for fixing the length of the line. Justification is ensured by blank unengraved matrices in various sizes equally distributed between the words.

The caster resembles a steel workbench with a hollowed-out slot on its surface in which the composing stick is inserted with the matrices face down. A lever starts the casting process by turning on an electric motor. A mold with an opening rises and positions itself under the aligned matrices; a plunger in the melting pot containing the molten alloy forces enough alloy into the mold to cast one line; casting is completed in less than 10 seconds, the mold withdraws and releases the solidified line, and the lever, which releases the composing stick, rises automatically.

Since the body size of the font is a uniform size, the upper part of characters whose body size exceeds its measurement projects beyond each side and has to be supported, when it is being used, with leads.

Since the width of the slugs is also uniform, when shorter lines are being cast the composing stick is furnished with thick, blank matrices; once cast, the line is clipped off to the proper length. For longer lines, composing sticks are used with justifications in multiples of that of the mold. Fractions of the line are cast one after another and fit together exactly. The Ludlow is used especially for casting lines of large type for use as titles and subtitles, using typefaces varying from 12 to 144 points (one point equals $\frac{1}{72}$, or 0.0138, inch).

The Ludlow caster is complemented by an Elrod caster. This automatically casts nonprinting leads and rules, narrow pieces of nonprinting alloy; both items come in various thicknesses.

Another type of mixed typesetter with manual assembly of the matrices is represented by the All-Purpose Linotype, a sort of Linotype from which only the casting part has been retained (see below *Linotype*). It is used primarily in United States printing establishments. An Italian equivalent, the Nebotype, is used, though less widely, in Europe.

Mechanical composition: slugcasting typesetters. The Linotype and Intertype slugcasting typesetters produce lines of letterpress composition in a single operation, starting with the assembling of the movable matrices. The letter matrices are thin, brass 19×32 -millimetre (0.7×1.3 -inch) plates, with two ears and a system of 14 notches arranged in a V on the upper surface and two heels in their lower part. The letter is engraved in intaglio on the face surface; usually two copies of the same letter are superimposed (duplex matrices)—one normal, or roman, the other a variant, either italic (sloping design) or boldface (stronger design). Thus, their thickness varies according to the letter and the body of the character.

The set of matrices is stored in a magazine, a flat, trapezoidal metal box consisting of 90 channels in which the matrices are aligned one behind the other, duplicates of 20 or 24 for each letter or sign, lying face down, resting on an ear and a heel.

Blanks are introduced into the line in two ways: either by using unengraved blank matrices, included in the magazine in three standard sizes, or by using spacebands designed to ensure justification.

The operator sits in front of a keyboard with 90 keys, corresponding to the channels in the magazine, on the left the lowercase letters, on the right the uppercase letters, in the middle the small capitals, numbers, and various symbols. A special bar operates the release of spacebands.

Slugcasting typesetters function as follows: (1) Touching a key releases the matrices, which are brought in proper order on a conveyor belt to a composing stick made of slide-bars and held by their ears. The spacebands, which are stored directly above the composing stick, fall into place between the words. (2) When the matrices and spacebands in the composing stick visibly take up the amount of space planned for the length of the line, the operator completes the line, either with a whole word or by dividing the last word, and pushes a lever to move the line. Since the remaining operations are done automatically he can go on to set the next line. (3) The assembled matrices and spacebands are moved three times in succession: vertically upward on the composing stick; sideways to the left on a transfer slide rest; vertically downward on an elevator that

Figure 3: Lineup of matrices and justifying spacers (spacebands) and a cast line of type in a linocasting operation (see text).

By courtesy of Harris-Intertype

puts them in front of the opening of a mold mounted on a cogwheel called a mold wheel, connected to an electric melting pot containing the molten lead alloy. (4) A justifying hammer forces the long pieces of the spacebands upward, forcing them to separate by equal spaces until all the matrices and spacebands are locked between two steel jaws fixed at the precise justification of the line (see Figure 3). A piston plunges into the melting pot and forces the alloy into the mold to cast the line. (5) While the mold wheel rotates three-quarters of a revolution and the solidified line is finished to its exact letterpress height before it is ejected into a galley, the matrices and spacebands are again moved upward by the elevator. (6) They are pushed to the right toward a triangular bar bearing 14 grooves corresponding to the 14 notches in the matrices. (7) Raised by a catcher arm, this bar removes the matrices, which are caught by their notches; the unnotched spacebands are released and immediately return to the place where they are stored. (8) When the catcher arm is at its highest position, the matrices are pushed to the right toward another triangular bar with 14 grooves along its length and flush with the top part of the magazine; this is the distributor bar. (9) The matrices move along the distributor bar until at a certain point the arrangement of grooves ceases to provide support for the notches, which of course are different for each letter or sign. Each letter's matrix is then released at the opening of its own channel in the magazine.

The automatic cycle of the typesetter is controlled by several large cams mounted on a single shaft driven by an electric motor.

Modern typesetting machines are equipped with several magazines of varying type sizes that can be used alternately. Some so-called double-distribution machines permit two magazines to be used at once by pressing a supplementary key.

The performance of recent models has been improved by accelerating the revolution of the matrices, intensifying the cooling system of the mold, and increasing the number of molds on the mold wheel to six.

The slugcasting typesetter, which furnishes solid, easy to handle, composed type, is particularly suited to printing newspapers. It has the disadvantage that to correct any error, however trivial, the whole line must be recomposed.

The All-Purpose Linotype is a combination manual and automatic machine that retains only the casting part of the Linotype. Special matrices, solidly rectangular or with notches, ears, and heels, are assembled by hand in a composing stick. Justification is done with blank matrices of various sizes. The line of matrices, held by the composing stick, is placed against two set squares fastened to the bedplate of the machine and manually pushed on a slide rest, which takes it to the elevator. The elevator places the matrices in front of the opening to the mold for the casting operation, which delivers the slug. The matrices are then distributed by hand.

Typesetter casting aligned characters. The operation of the Monotype typesetter, which casts individual aligned characters, is based on a system of measuring the width of characters, called the set. In each font, letters and symbols

The nine steps in slugcasting

The
Monotype
keyboard

have sizes determined in units of set, from five units for the narrowest, such as the "i" or the "l," to 18 units for the largest, such as the "W" or the "M."

The Monotype keyboard, separate from the caster, consists, on the standard model, of 274 keys, 30 of which, in two rows numbered from 1 to 15, are called justifying keys. Typing out the text results in the perforation, by an automatic punch, of one or two holes, each letter or symbol having its own pattern, in the width of a paper tape that allows 31 possible arrangements. An automatic calculator adds the widths of the letters and symbols typed out. Moving his forefinger across a scale that he has before him, the operator knows when the end of a line is near. Once he has finished a line, he places his other forefinger on the justifying drum, which indicates which two justifying keys he must now press. This move results in the perforation of one or two holes whose position indicates the quotient of the number of units lacking for the line to be completed by the number of spaces between the words of this line, plus a third hole in a position specifically fixed for the justification process.

The typesetter is composed of an electric melting pot containing molten alloy situated under a mold in the shape of a vertical chimney, the internal dimensions of which can vary according to the measurement in units of set of the characters or spaces to be cast.

The matrices are in the form of small bronze cubic blocks measuring five millimetres (0.2 inch) square, arranged in a steel frame nine centimetres (3.5 inches) square containing 15 rows of 15, enough for five complete alphabets, typically uppercase and lowercase in roman, italic, and boldface, and small capitals, as well as double or triple letters, numbers, and punctuation marks. Each row includes only matrices of letters and symbols of the same unit of set, from the smallest (five units) in the first row to the largest (18 units) in the back row.

The frame can slide horizontally in either direction to place any matrix from any row above the opening to the mold.

The process of setting and casting type on the Monotype is as follows: the roll of perforated paper tape is placed in the pneumatic tower of the typesetter—a row of 31 pipes distributing compressed air. As it unrolls, the tape prevents the compressed air from entering all pipes except those corresponding to the perforations.

The tape unrolls in the direction opposite to that in which it was rolled up—that is, in the opposite order to the way it was typed, the last line appearing first and the justifying perforations being inserted into the pneumatic tower before those for the letters and symbols. The compressed air that the perforations allow to pass into three (or two) of the pipes causes pieces of metal (justifying quoins) to fall into position in such a way as to control the internal measurement of the mold each time that the spaces between the words of the next line are to be cast.

The perforations for each letter or symbol allow the compressed air to pass into two (or only one) of the pipes connected to two blocks, each of which also contains a series of graded pins. Compressed air raises a pin in each block and halts the movement of the matrix frame in either of its sideways movements. In this way the matrix's row and the matrix's place in its row are selected. Selecting the row is the same as selecting a measurement given in units of set. Positioning the row is automatically linked to setting a piece of metal (the set quoin) whose position regulates the dimensions of the mold for casting the letter or symbol.

For the casting, a centring device places the selected matrix precisely against the opening of the mold, and a plunger in the melting pot forces the alloy up to cast the character or the space (that is, the unengraved matrix).

The composed line emerges from the machine completely assembled and justified and is placed in a galley.

The Monotype can cast type ranging in body size from five to 24 points (with a special mold for each). The addition of a speed-reducing device enables it to cast in 48 points. The maximum width of lines assembled is 60 picas.

In the early 1970s Monotype models could be equipped with a frame carrying 15 rows of 17 matrices (255) or 16

rows of 17 (272), with six or seven complete alphabets. The keyboard then has 310 keys.

A special model of the keyboard permits simultaneous perforation of two tapes for composing the same text in identical or different kinds of type and lengths of line.

The advantages of the Monotype system are the quality of its composition and the ease with which corrections can be made without having to reset the whole line. It is not well suited to newspaper printing because of the difficulty of handling lines of movable type and because, since typesetting begins with the end of the tape, composition must wait until all the type has been cast.

Automatic composition (perforated tape). The Teletypesetter (TTS) system extends to slugcasting machines the principle of separation of function originally characteristic of the Monotype: it enables Linotype or Intertype machines to be controlled by a perforated tape produced on a separate keyboard, even situated in a different city, since the combination of the perforations on the tape can be sent telegraphically.

The Teletypesetter tape is six-channelled; that is, it contains six possible positions for perforations across its width. This allows 64 different combinations of from one to six perforations.

This limited capacity, less than the number of keys on the keyboard of the typesetter, is corrected by an arrangement whereby each combination of perforations may have two different uses (for example, the uppercase and the lowercase of the same letter) according to whether it follows one or other of two special signals (themselves represented by combinations of perforations) that control passage of one or other of these uses.

The keyboard for preparing the Teletypesetter tape looks like a typewriter with, in addition to the usual 44 keys and the space bar, 20 special keys. Striking each key establishes contact with the electric circuit or circuits that operate the perforators and at the same time acts on a calculating mechanism: a needle moving across a screen warns the operator of the end of each line.

Usually, as the tape is perforated the text is also typed out on a sheet of paper, which allows the work to be checked, reread, and corrected. For use with a Teletypesetter, the typesetting machine is equipped with a mechanism that translates the tape. In this mechanism the tape passes under six sensors that register electric contacts as the perforations pass. In accordance with the combination of electric contacts thus established, relays control the action of the keys or of the bar that causes the spacebands to drop and, at the end of each line, the starting of the casting cycle.

The most recent typesetters specially designed for use with the Teletypesetter offer such technical refinements as the elimination of the composing stick and immediate dispatch of the line to the elevator, simplifying the path taken by the matrices; and electromagnetic, rather than mechanical coupling, which speeds the starting up of the casting cycle.

Programmed composition (prepared by computer). The use of a computer eliminates manual intervention in preparing the perforated tape, in assessing the length of the lines, and even in deciding how to end them; i.e., whether by completing or dividing a word.

Normally, the operator types out a continuous tape called idiot tape in the United States (kilometre tape in France) without concern for the length or division of lines. This band is inserted into the computer's input device, a tape scanner, which operates by means of either electric sensors or photoelectric cells and converts letters, signs, and orders into combinations of electric impulses. The computer semi-automatically or automatically processes this raw information in accordance with its programmed instructions and immediately communicates the result to an electromagnetic perforator, the output device, that produces a second tape, like the first but that also bears, in the proper places, perforations ordering the ends of lines.

A general program establishes the operation of the computer in its application to the work of composition. Individual programs adapt it to the machinery of the company concerned (models of typesetters, available magazines of matrices) and to the kind of work carried out (usual length

Advantages of
MonotypeThe Teletypesetter
keyboard

of line, method of indenting paragraphs, etc). Finally, special instructions punched on the tape by the operator at the same time as the text can interrupt the execution of the programs registered in the computer with directions valid for this text alone, in its entirety or in certain parts: choice of typeface among those available, transition from one kind of typeface to another available for the same typesetter, length of line and changes in the length, alignment to right or left, squaring of lines, indentations for ornamental capitals, spaces for borders or illustrations, and other details.

Having identified the combinations of the perforations on the tape and separately retained the service signals addressed directly to it, the computer proceeds to estimate the amount of the space occupied in a line by its letters and symbols, referring to instructions registered in its memory regarding each. In the same way, it determines a justification zone in which a division in the line is necessary and possible, the minimum and maximum limits of this zone being fixed by the limits of expansion of the spacebands on the typesetter.

Comput-
erized
division of
words

If the end of a whole word comes within the justification zone, the computer itself signals the end of a line after this word and suppresses the space that would normally follow it. Otherwise, the last word must be divided. The process is said to be semiautomatic if a special operator, seated at a keyboard linked to the computer, must intervene to decide where to place the division in the word submitted to him on, for example, a cathode-ray viewing screen. The process is automatic if the computer is designed and programmed to make the decision itself; the operation then is carried out by starting a subprogram in which all the divisions possible in the word considered are listed (after a prefix, between syllables). This list is tested against prohibited divisions (according to the rules of etymology, phonetics, typography) stored in the rapid-access memory of the computer. From among the positions that are not eliminated during this test, the computer chooses the one situated nearest the end of the word. It automatically inserts the signal for the hyphen and orders the end of the line.

The computer can also carry out the correction of mistakes before composition. Various methods are possible, of which two will be described briefly. In one, the perforation of the justified tape delivered from the computer includes the introduction at the beginning of each line of a numbered signal and is accompanied by a proofing copy of the text with a corresponding reference number for each line. When the mistakes have been corrected on the proofing copy, an operator prepares another, much shorter correction tape, which consists of the corrections preceded by the reference to the line on which they occur. The justified tape and the correction tape are jointly introduced into a double reader, the mixer, which determines anew the length of the line and where the division should occur, as well as for such succeeding lines as need to be modified, before producing a final tape.

In the second method, the proofing copy can be typed out or shown on a cathode-ray viewing screen with the lines numbered but without the tape. At a keyboard connected to the computer, an operator types out the corrections, preceded by their line reference. If a viewing screen is used, the text reappears immediately in its corrected form, and the output perforator immediately delivers a justified and corrected tape.

The computer is usually programmed to sort out and correct even mistakes or anomalies in typing, such as the presence of two consecutive spaces, in which case it cancels one. It can, if its capacity allows, receive a makeup program independent of the tape of the text; following the specifications of the layout (positioning and size of headings, text, and illustrations) coded in binary language, the computer itself introduces onto the perforated tape the special instructions concerning kinds of typeface, length of lines, changes in lines, etc.

Because of the quantity of information needed for composition, the six-channel Teletypesetter tape is being increasingly replaced by seven- and eight-channel tape.

Computer processing using a continuously typed tape

can be applied equally well to the Monotype system. The programmed operation for dividing lines is in this case carried out by the automatic calculation of the width of the spaces between words and by the perforation, before the end-of-line signal, of a signal signifying the appropriate position of the justifying quoins. To enable the text to be read by the pneumatic tower of the typesetter, a converter transcribes the perforations from a narrow six-, seven-, or eight-channel conventionally perforated tape to the wide tape of the Monotype system.

The use of computers is now widespread in preparing photocomposition jobs, with programs adapted to the specifications. The computer's output device can produce magnetic tape instead of perforated paper tape.

One intake device no longer reads perforated tape but is an optical mechanism for scanning a typewritten text. The Retina reader, for example, is a sort of artificial retina made up of a group of photosensitive units able to identify each letter typed by a special typewriter, using only three data: height, width, and gray value; that is, the surface area occupied by the outline of its design.

Optical
scanning
devices

Cold type. Cold type is the expression used, particularly in the United States, to describe a simple and economic method of preparing text by machines resembling ordinary typewriters but capable of producing justified lines in type that varies in width according to the letter involved. Justification is achieved in several ways by different versions of the machine. In the IBM Multipoint, a first typing calculates the total measurement of the type pieces up to the beginning of the justification zone and causes a coded sign to appear. A button is set in position over the coded sign thus assigned to each line before a second, final typing is done. The position of this button determines the automatic adjustment of the spaces between the words to the amount needed to obtain justification.

In the Justowriter, the keyboard on which the uncoded, unjustified proofing copy is typed simultaneously perforates a paper tape with the code for the letters, as well as, for each line, the code for the amount of space between the words as indicated by a calculator. The tape then controls, on a second unit of the machine, the electric typing of the final justified copy.

In the IBM Multipoint with magnetic tapes, a magnetic tape produced at the keyboard is processed by a computer for justification and, if necessary, for corrections. The final tape delivered by the computer controls the action of an output unit, which carries out the final typing.

If the copy thus produced on paper is to be photographed to prepare printing plates by photogravure, cold type cannot be directly incorporated into photocomposition because of the intermediate operation.

Optype is a hybrid process that simultaneously carries out the operation of justifying a text typed directly in cold type and transmits it to photographic film. By means of optical distortion, each line is stretched to the exact length of line projected on the film. The same mechanism also enables the line to be magnified or reduced or set in italics.

Phototypesetting. Using phototypesetting, a direct image of the text is obtained, positive or negative, according to need, on a photosensitive, usually transparent surface by exposing the surface to light through transparent matrices, negative or positive, of the letters and symbols.

Manual phototypesetters. Several small machines permit phototypesetting of short texts and titles in conditions to a greater or lesser degree short of automation. Among them are the following:

Dantype uses separate transparent plastic matrices, which are assembled in a composing stick and placed in direct contact with the photosensitive film inside the machine.

Typro makes use of letters and symbols on a negative film that moves to and fro to place the desired type piece in contact with the photosensitive film.

Headliner incorporates letters and symbols that appear in negative on an interchangeable plastic disk whose position is controlled from outside. The film is exposed by contact.

Hadego uses plastic matrices assembled in a composing stick, exposure taking place through an adjustable photographic lens that permits enlarging or reducing. With just two series of 350 matrices, one with a 20-point body, the

other with a 48-point body, all sizes of type from eight to 110 points can be obtained.

The Starlettograph, comparable to an ordinary photographic enlarger, can be used only in a darkroom. The type, inscribed on a semirigid plastic tape, is set in position one piece at a time, using red light that does not affect the photosensitive film.

Letterphot works on the same principle as the photographic enlarger but on a luminous table. A first projection is made of all the characters of a line without the sensitive surface. Then the sensitive surface is placed on the luminous image of the line, which appears transparently and cannot therefore make an impression. Letters are successively printed in a two-part operation. First the letter is projected in normal light to cause it to coincide with its luminous image; the normal light does not make an impression on the sensitive surface, because the latter has a special composition. After this adjustment has been made, the letter is projected in actinic (photographically active) light, which exposes the sensitive surface.

Diatyp and the Monotype photoheadliner (as well as the Varityper, which is similar in composition) are more elaborate phototypesetters, easier to operate and permitting production speeds of nearly one character per second. The image of each character on the matrix disk is controlled by a symbol that is read by photoelectric cells and which automatically moves the film forward the same amount as the space taken up in the line by the character. A totalizing calculator informs the operator of the rate at which the line is being completed, and justification can be achieved by a first typing without having the source of light in operation; in a second typing, the spaces between the words are adjusted the necessary amount. Adjusting the lens of the Diatyp produces characters ranging in size from four to 36 points and, using the Monotype, from five to 84 points.

Automatic phototypesetting. The first Linofilm was a direct adaptation of the Linotype. Its photographic matrices were the normal Linotype matrices, the only difference being that, instead of bearing an intaglio engraving of the character on their face, they bore its outline in black on a white background. Lines were composed in exactly the same way as on the typesetter, justification being carried out by expanding the spacebands. The justified line is then passed a single time in front of a lens to be photographed.

Fotosetter
operations

The Fotosetter is an adaptation of the Intertype machine but with functional differences. The matrices resemble matrices used for casting; they have the same notching and different thicknesses, depending on the character. But the outline of the character, instead of being inscribed on the face, is a transparency (*i.e.*, a photographic negative), in a capsule set into the level surface of the matrix. These special matrices are called fotomats. In place of spacebands there are space fotomats of different thicknesses.

The Fotosetter is equipped with magazines of 117 channels, 27 more than the typesetters, with an enlarged keyboard of 114 keys.

Once the line has been assembled and justified, using space fotomats of the necessary sizes, the fotomats move inside an optical apparatus that sends a brief flash of light toward the sensitive film. After each exposure, the support of this film is moved slightly sideways by a rack-and-pinion system commanded by the withdrawal of the next fotomat from its alignment; the matrix moves in proportion to the thickness of this fotomat. When all the type pieces in a line have been photographed, the film unwinds the correct amount to present a clean surface ready for the phototypesetting of a new line, while the fotomats are carried off to the distribution bar.

Equipped with a turret of 14 different lenses, the optical apparatus produces 14 sizes of type from three to 72 points, from the same set of fotomats of uniform 12-point size.

The Monophoto is a direct adaptation of the Monotype system with, on the one hand, an independent keyboard that produces a wide perforated tape in the Monotype code and, on the other, a phototypesetter operated by inserting this tape. The type pieces are chosen by positioning a frame, which carries 17 rows of 20 cubelike matrices in

Figure 4: Basic operation of the optical system used in Monotype photocomposition (see text). A film matrix is shown at top.

By courtesy of Monotype

which the letter or symbol appears as a transparency, in negative, in the path of a beam of light (see Figure 4). This beam, after proper processing, is directed toward the sensitive film, on which it makes an impression. It first travels through a combination of magnifying glasses and prisms whose position in relation to each other is adjusted to obtain the desired ratio of enlargement or reduction. The sensitive film remains stationary on the drum carrying it as a composed line, while the element that enables the beam of light to move from letter to letter is a set of two mirrors placed face to face at a 90° angle and mounted on a mobile carriage. Before each exposure, this set of mirrors shifts, parallel to the direction of the sensitive film, the same amount of space as the width of the character about to be composed. This amount of space depends also on the number of units of set of the letter or symbol and on the ratio of photographic enlargement or reduction. The movement of the mirrors is thus subjected to the command mechanisms of two factors: the position of the frame, since the matrices are arranged in rows of the same units of set, and the adjustment of the combination of magnifying glasses and prisms.

Justification is accomplished, as on the typesetter, by predetermining the width of the spaces between the words. Since the justification perforations appear before those for the type pieces, they establish for the line to come the amount of space the set of mirrors has to shift at each space command punched in the perforated tape.

After all of the type in a line has been photographed, the set of mirrors returns to its original position, and the drum bearing the sensitive film turns the amount necessary to

continue on to the composition of the next line according to the degree of line spacing (leading) chosen.

Using matrices of a single eight-point size, the Monophoto makes available the whole range of type size from six to 24 points. For perfect photographic reproduction it is usually found preferable to use two or three sizes of matrices to cover this range. Given the quality of its production, the Monophoto, sometimes linked to a unit programmed to prepare the tape, is popular for work that demands careful composition.

Functional phototypesetters. A second generation of phototypesetters consists of functional machines that are analogous neither in structure nor in operation to typesetters using lead. Outwardly they resemble metal chests comparable to office furniture. Their design aims at reducing mechanical parts, inertia, and friction to the minimum. Their technical characteristics vary according to model, use, and cost.

The keyboard, which is hardly more complex than that of an ordinary typewriter, can be attached or separated; in the latter case, information regarding the text to be composed is inserted by perforated tape. Computer units can be integrated, either merely to direct the machine's operations or to ensure completion of the justification process, division of words, and correction, whether from the adjoining keyboard or from a continuous perforated tape. Selection of the matrix image of each character can be done either by using a mobile support for the matrices (plastic tape, disk, drum) in front of a fixed source for the beam of light or by using a mobile beam of light in front of a fixed support for the matrices (glass or plastic plate); alignment of type pieces is carried out in either case by mobile prisms or mirrors.

Versatile capabilities of the phototypesetter

In addition to enlargement or reduction, the optical apparatus can be designed to carry out special effects, such as converting roman to italic type or stretching a line to make it longer or higher. The photographically composed text can be delivered either on paper or on film, in positive or negative, or in straight reading or reverse reading. The source of light is usually an electronic flash the intensity of which can, if necessary, be made proportionate relative to enlargement or reduction.

Some of the characteristics of phototypesetters are outlined below.

Linofilm (new method): The matrices of the 88 characters in a set are inscribed on a plate of glass that remains stationary during composition. The character is chosen by the shutter of the photographic lens. This shutter consists (as in a commercial camera) of very thin, overlapping metal blades, eight in number. Instead of always opening at the same point at the moment of exposure, it opens facing the desired character, each being set in position by an electromagnet so as to obtain this arrangement. After passing through the matrix of the character thus chosen, the beam of light is taken over by one of the 88 small lenses arranged behind the plate of glass and its trajectory directed towards a mirror mounted on an undercarriage, which carries out the alignment on the sensitive film.

Using this very light electromagnetic mechanism, the Linofilm can produce up to 12 exposures per second, or 43,000 symbols per hour. Eighteen matrix plates arranged in a turret magazine are instantaneously usable, producing 1,584 characters. Three matrix plates are enough to photograph the same type face in 16 sizes, from six to 36 points.

Diatronic, a phototypesetter made in Germany with an adjoining keyboard, uses matrix plates with 126 symbols. Selection is made after the beam of light has passed through all the symbols on the plate, through prisms which take up the position necessary to retain only the light coming from the matrix of the chosen character.

Photon-Lumitype was the first phototypesetter to introduce the selection and photographing of the character in a rapid circular movement without interrupting continuity.

The matrices are inscribed in concentric circles on a disk that revolves continuously at 10 revolutions per second in front of an electronic flashtube whose light lasts a few millionths of a second for each character. Selection is by means of a system of rotary contact makers, controlled by the telegraph system. A nylon drum is integrated with the

Continuous high-speed phototypesetting

matrix disk and turns with it in the same movement; the drum is encircled with as many tracks as there are channels in the binary code used to define the characters. These tracks are the transmitting and isolating elements that pass under a row of electric sensors. A special combination of transmitting and isolating elements corresponds to each character matrix positioned ready to be photographed.

Whether by striking a keyboard or by perforating a tape, selecting a given character consists of the precise formulation of the combination that establishes the electrical contact and initiates the flash of light. This selection can be acted on only at the precise moment when, as the disk revolves, the matrix of the desired character moves into position to be photographed.

Whether textual information is fed into the machine on an adjoining keyboard (as on the early Linotypes) or on a keyboard directly connected to the photographic unit or whether it is done on perforated tape, this information is in every instance preserved, line after line, in a memory, formerly mechanical but magnetic on the later models, which at the same time permits calculation of the size of the spaces between the words and ensures that the character's binary signal is presented during the 1/10-second period of time available.

It is possible to attain a production speed of 10 symbols per second, or, theoretically, about 36,000 per hour; in practice the figure averages less.

Each of the eight concentric circles on the matrix disk contains two complete sets of 90 characters, which can be filmed in 12 sizes, from five to 72 points. In other words, a total of 17,280 characters are immediately available.

Another Photon-Lumitype model operates on the same principle, but the disk is replaced by a drum revolving 30 times per second around an axis that coincides with the source of light. The type matrices are inscribed in negative on two films carried on the surface of the drum, and the source of light consists of two electronic flashtubes, one for the upper, the other for the lower half of the drum (see Figure 5, right). The lens and mirror system for producing images of the matrices on a moving light-sensitive film is shown at the left in Figure 5.

Figure 5: Basic operating principle of the Photon 713-10.

This model's total capacity in characters (four complete sets and eight ratios of enlargement or reduction) is three times smaller, but its speed of composition is three times faster: it can attain 80,000 symbols per hour.

By putting the same films of type matrices in the upper and the lower part of the drum—that is, by cutting in half the number of characters stored—speed of production can be raised to 120,000 symbols per hour.

Europa-Linofilm is similar in design to the Photon-Lumitype just described, with a permanently revolving drum but with an electric type-matrix selection system. These matrices are small individual plates bearing not only the negative image of the letter or symbol but also a series of transparent marks whose arrangement constitutes its binary identification code. In the revolving drum this coded part of the plates passes in front of a scanner made up of a series of photoelectric cells. As soon as the scanner picks up a coincidence between the code of the type matrix and the code of the character selected for composition, it activates the shutter release of the electronic flash.

The Europa-Linofilm drum is composed of four superimposed levels, each containing 120 duplex type matrices—

The
Photon-
Lumizip

for example, with the same letter in both roman and italic—easily interchangeable in order, since their identification is not linked to their place.

Photon-Lumizip is based on a different principle. The performance speed of drum phototypesetters can hardly be increased because of the technical problems posed by the rapid rotation of the drum. To increase speed, the Lumizip abandoned rotary movement. The type matrices are stationary and are aligned in negative on a large-sized plate. There is an individual electronic flash behind each type matrix. The sensitive film is stationary while a line is being composed. The only moving element is the component of the lens placed between the plate and the film, which carries out a rectilinear to-and-fro movement, parallel to them. The flashtube situated behind a given matrix emits its beam of light each time that the component of the lens finds itself, in the course of its to-and-fro movement, in the axis that joins this matrix to the position where the letter to which it corresponds is to appear in the line to be composed on the sensitive film. Thus, the order in which the characters are photographed is neither that in which they appear in the text nor that of the matrices on their plate but that determined by an angular relationship between them both.

A computer is built into the Lumizip. As soon as the coded signals for a line to be composed reach the computer, it determines the order and the exact moment when each flashtube is to operate, synchronized with the movements of the component of the lens.

In practice, the type matrices are aligned on the plate not in a single row but in 11 horizontal rows. The component of the lens always moves in the same horizontal plane, which is the same as that of the line to be composed and also that of the median row, the sixth, of the matrix plate. Alignment of characters from the other rows is achieved by means of two level, horizontal mirrors placed on either side of this horizontal plane, parallel to it and face to face at a small distance from one another. The beams of light coming from the flashtubes of the matrices of the median row pass between these two mirrors without touching them. But the beams of light coming from the flash tubes of the matrices of the other rows strike these mirrors at an angle that is sharper, depending on how far the row is from the median row, and between these mirrors they are repeatedly reflected, the number of reflections depending on the angle: one for rows five and seven, up to five for rows one and 11, the last reflection falling into alignment on the sensitive film.

Mechanical movement in the Lumizip is reduced to the extreme minimum, because the component of the lens is the only moving part. Since it depends on an alternating, rectilinear movement and is therefore handicapped by factors of inertia, its speed, which cannot be as great as that of a continuous rotary movement, is only 10 to-and-fro movements per second. But during a single one of these to-and-fro movements all the several dozen characters for one line are photographed. Thus, the Lumizip attains a performance rate perhaps 20 times superior to that of the Lumitype. Theoretically, it can perform at a rate exceeding 2,000,000 symbols per hour and in practice has produced over 1,000,000.

Electronic phototypesetters. In phototypesetters of the third generation, the beam of light is replaced by a flow of electrons, which offers the advantage that the electrons can be deflected by means of magnetic fields without the intervention of mechanical parts such as mirrors and lenses. Television systems are based on this characteristic, and an early type of electronic phototypesetter is structurally comparable to a closed-circuit television system. A reading device analyzes, by fine scanning, the outline of the matrix of the letter to be composed and converts the luminous information it obtains into electronic signals. The cathode-ray screen of an output device reconstitutes, in accordance with these signals and by a fine scanning device synchronized with the reading device, a luminous image of the letter, which makes an impression, through an optical reducing device, on a photosensitive surface. A computer, depending on the text to be composed, directs the position of the reading device's scanner towards that

part of the matrix plate that bears the matrix of the letter selected, and simultaneously directs the position of the output device's scanner toward that part of the screen that corresponds to the position of this letter in the line being composed.

On some models, the scanning device consists of the equivalent of a television camera whose electron beam is selectively deflected towards the chosen matrix and directly analyzes the luminous information coming from it. On others, a cathode-ray tube takes the place of the emitter of a regular beam of light by scanning behind a plate on which the matrices appear in transparency. On the other side of the plate, photoelectric cells collect this beam at the moment it passes through the matrices and react by emitting electronic signals directed to the output device.

For matrix selection, the face of the emission tube is divided into 16 square sections (four by four), of which only one is illuminated at a time by selective scanning directed towards it. There are 16 photoelectric cells arranged in a square (four by four), only one of which is in operation at a time. Thus, there are 256 (16 by 16) possible arrangements of the chosen section and of the chosen cell. Each combination corresponds to an optical trajectory belonging to one or the other; that is to say, to the precise positioning of one of the matrices over the plate.

On the screen of the output device, the letters have a definition of 650 lines per inch for ordinary work and 1,300 lines per inch for quality work. The line structure is invisible after the letters have been reduced for photographic reproduction.

A more complex model of the Linotron scans, on the screen of the output device, the surface of a whole page, composing as it goes all examples of the same letter in all the places where it occurs on the page. Composition of the page is completed after all the matrices have been exposed once. The average speed of production is on the order of 1,100 symbols per second, or almost 4,000,000 per hour.

Carrying the system of electronic composition to its logical conclusion, designers have replaced the matrices, whose outline had to be repeatedly electronically analyzed, by the results of analyses previously carried out and preserved in binary form in a magnetic rapid-access memory, setting up for each letter the output program for its luminous image on the cathode-ray screen when it is selected for composition. Electronic phototypesetters of this kind are called alphanumeric.

Hell-Digiset carries out a preliminary analysis by inscribing the outline of each letter on a very dense grid of 3,000 to 6,000 small squares, according to the body size of letter envisaged. Those squares covered by the outline are assigned the symbol 1 of the binary code; the others are assigned the symbol 0. The result of the analysis is first inscribed in perforations on an eight-channel tape. Tape containing perforations for an entire set of type in a given style is inserted into a special Digiset reader to instruct the magnetic memory, in a few dozen seconds, concerning type production. All that is necessary to change the style of type is insertion of the tape belonging to another set.

The Digiset 50 T 2 can reach a production speed of 3,000 characters per second, or more than 10,000,000 per hour. One Digiset is designed to permit a whole newspaper page to be composed photographically in a single scanning operation; not only the words but also the illustrations are analyzed in binary code.

Fototronic-CRT and APS (Alphanumeric photocomposition system) reduce the amount of coded information by interpreting each letter as a series of closely packed adjacent vertical lines whose distinguishing parameters are their height and their position. Vertical scanning on the screen of the photographic output device reproduces these lines one after another according to these parameters (see Figure 6).

The number of lines varies from about 50 to 90, depending on the width of the letters, and the number of units calculating the measurement of parameters of height can go up to 80, which amounts to a definition perceptibly as fine as the Digiset grid, or 800 lines per inch in two dimensions on the screen of the output mechanism.

speed of 3,000 to 10,000 characters per second, the latter figure amounting to 36,000,000 per hour.

Makeup of letterpress copy. Preparing a form suitable for use in printing from letterpress copy, whether in individual type pieces or in lines of lead alloy, is an operation called makeup. This is preceded, if the same form is to include several smaller pages to be printed together, such as a book, by an operation called imposition, which consists in laying out the pages in the form so that they are in their numerical order after the printed sheet has been folded into a signature of eight, 16, or 32 pages.

In the case of a daily newspaper, one form is generally used for each page. When the manuscript or typescript copy containing information regarding the type and the justification required arrives at the printing plant, it is divided among several Linotype machines. The titles are composed, depending on their body size, in movable type on a Ludlow or Linotype machine. When corrected from galley proofs, the titles and columns of text arranged in galleys are brought to the compositor, together with, where relevant, plates of illustrations or advertising matter mounted on lead blocks the same height as the type. Standing at a level casting table, the stone, and following the instructions on a layout, the compositor arranges the elements inside a rectangular steel frame, the chase, usually equipped with a locking system using quoins that slide along the inside of two of its adjacent sides.

The compositor inserts leading between paragraphs to bring each column on the page to its proper height. He separates columns and articles using leading or rules cut to the desired dimensions. Once the chase has been locked, proofs are taken to check the page for final corrections before it is pressed on to a metal frame to be brought to the press.

Mounting composition on film. Composition on film consists of a mounting operation carried out on a luminous table. Films of the text and titles and positives or negatives of the screened or unscreened photographs, depending on the printing method to be used, are arranged on a sheet of transparent plastic of the dimensions indicated on the layout, placed under the plastic sheet and lighted from beneath. The film is glued or fixed using pieces of transparent adhesive.

Conversion systems. One composition process can be converted to the other. A page composed on film, in neg-

ative, can be used for photogravure plates or for metal or engraved plates intended for letterpress printing (see below *Printing*). Contrariwise, a page composed in type can be converted to a positive or negative, direct or inverted transparency by any of a number of techniques.

The whole page, including the screened plates or photographic illustrations, can be subjected to conversion, or the text can be taken alone, leaving the positioning of illustrations until the positives or negatives of the illustrations, screened or not, according to the printing process to be used, are included in the makeup at a later stage.

PRINTING (PRESS OPERATION)

Printing in the second sense of the word—that is, press operation—is the technique by which ink or other colouring agent, transferred to paper or any other material, is localized on printing surfaces delimited by the composition of texts or the making of illustration material.

Colour printing. Juxtaposition of colours is achieved by submitting each sheet to successive impressions by typeforms each of which prints only on areas designed to carry a single colour and inked only in that colour.

There are sufficient wavelengths in the three primary colours, blue, red, and green, to reconstitute all the colours of the spectrum. The colour perceived from an inked impression results from the fact that the ink reflects some waves of the range of colours of the spectrum and absorbs the others—that is, prevents them from being seen. Thus, three colours of ink can reconstitute the visual effect of all the range of colours by combining them appropriately. Yellow totally absorbs all waves of colour that are basically blue and reflects waves of colour that are basically red and green; magenta (deep crimson) totally absorbs green and reflects red and blue; cyan (close to turquoise) absorbs red and reflects blue and green.

When two of these inks combine, each annuls in the other the capacity to reflect that one of the two primary colours that it cannot itself reflect; the eye then perceives only the one primary colour that both inks reflect; for example, red, by combining yellow and magenta inks. All three inks combined no longer reflect any of the three primary colours but appear as black.

In trichromatic printing the screened plates necessary for each of the three colours of ink are prepared by selecting the colours through filters. A fourth plate is usually used

Effects of combining coloured inks

for making a print in black ink to accentuate the contours and modelling in the picture, making the process quadrichromatic.

Printing colours by superposition requires the exact positioning on top of one another of the successively printed constituent parts of the picture (usually printed in this order: magenta, yellow, cyan, black). The finer the definition of the screen, the more precise this positioning must be.

Letterpress printing. Letterpress printing consists of transferring a thin film of ink from the printing surface of the typeform to that of the paper by pressing the two together.

Letterpress presses are thus made up of two principal elements, one bearing the type form, the other exerting the pressure. These elements may be either flat or cylindrical. There are three principal types of presses, according to the way these elements are combined: (1) plane to plane; (2) cylinder to plane; and (3) cylinder to cylinder (see Figure 7). In all types of letterpress presses the printing surface must be coated with a uniform layer of ink be-

friction or suction. In a friction-operated feeder, the sheets of a pile of stock on a slightly slanting surface are fanned out so that each sheet projects over the one beneath in such a way that the friction of a cylinder can dispatch them individually one after another toward the feedboard of the press, where three pegs guide each into position. In a suction operation the sheets remain piled up vertically; a wheel brushes a corner of the top sheet and separates it from the others, enabling a compressed-air blower to inject a cushion of air underneath the sheet. A system of vents connected to a suction pipe lifts the paper and carries it towards the press's feedboard. An automatic device lifts the pile of sheets continuously into place. On all letterpress presses, slight irregularities of the surface of the typeform are compensated for by packing the platen with a material soft enough to absorb the irregularities.

As the sheets leave the press, a powder is sprayed onto their surface to form a separative coating that prevents the transfer of ink from one sheet to another. An alternative in modern high-speed presses is the incorporation in the ink of a special quick-drying agent.

Platen presses. Presses that operate plane to plane are called platen presses. A vertical clamping contrivance clamps the bed, which carries the form into which the composed type is locked, and the platen, which carries the sheet of paper while it is being printed. When this clamping contrivance is open, the typeform is inked by a series of rollers that descend and then reascend, and the printed sheet is removed and a new sheet placed in position on the platen.

The pressure exerted during impression is about 40 kilograms per square centimetre (570 pounds per square inch). A platen press can reach a production speed of 5,000 sheets per hour.

Cylinder presses. In presses that operate cylinder to plane, called flatbed presses, a cylinder provides the pressure while the typeform retains its flat surface, generally in a horizontal position. Generally, too, the bed is mobile to allow the typeform, as it moves back and forth, both to pass under the rollers of the inking system and to pass under the impression cylinder around whose outer surface the sheet of paper is wrapped, attached by a set of clamps. Flatbed presses fall into various categories, depending on the cylinder's operation.

In the stop-cylinder press, a toothed rack incorporated in the bed engages a cogwheel incorporated in the cylinder while the bed is moving forward. As it moves back again, the cogs disengage. A shallow cavity in the cylinder makes it possible for the typeform to be slid underneath. Printing speeds can reach 5,000 sheets per hour.

In the two-revolution press, the cylinder never stops revolving but is raised on its bearings as the bed moves back again in order not to touch the form. In its lowered position the cylinder's cogwheel engages a low-toothed rack incorporated in the bed; in its raised position the cogwheel engages a parallel high-toothed rack, which enables the cylinder to continue revolving in the same direction. Printing takes place during the first revolution; during the second revolution the cylinder runs free. Printing speeds are about the same as for the stop-cylinder press. But, by avoiding the mechanical jerkiness due to the stopping of the cylinder, the two-revolution press has a much smoother, more regular, and quieter action.

On a single revolution press, the cylinder does not stop revolving but must be raised while the bed moves back. Its diameter is twice that of the two-revolution cylinder press, but one half of its surface is hollowed out in order not to touch the form. Printing, then, takes place in the first half of the cylinder's revolution.

A perfecting press is a combination of two two-revolution presses bracketed together. It has two cylinders and a single bed bearing two different type forms. Thus, as it moves back and forth the bed prints two impressions, one for each form. The same sheet of paper is passed from one cylinder to the other and is thus printed on both sides. The padding on the second cylinder is constantly cleaned by a kerosene-coated roller to prevent a transfer from the first side of the paper to be printed. In fact, the second impression is better than the first, and the part

Figure 7: Operating principles of the three principal types of letterpress presses (see text).

fore receiving the paper. This inking is carried out by a mechanism composed of up to 20 rollers: take-up rollers carry the paste ink from the ink supply to the distributing and sliding rollers, which operate with a longitudinal to-and-fro movement to crush and spread the ink in an even layer on a level or cylindrical metal surface and finally contact rollers that transfer the ink to the printing surface of the typeform.

The first two kinds of presses are sheet fed. The third can be either sheet fed or roll fed (web fed), depending on the model and type of work. Sheets of paper must be fed into the press in a sequence synchronized with the movement of the press. Most modern presses are equipped with an automatic feeder that functions in conjunction with the movement of the press. The feeders operate by either

The
stop-
cylinder
press

of the job requiring a better quality is reserved for the second cylinder.

The two-colour press also combines two bracketed two-revolution presses, but a small auxiliary drum is interposed between the two cylinders to ensure that a single sheet of paper presents the same side to be printed twice. The typeforms, which are designed to complement one another, are each inked with a different colour.

Contrary to the general design of cylinder presses, the vertical cylinder press is composed of a vertical bed, and both bed and cylinder move vertically with a reciprocating motion, each in an opposite direction. The cylinder revolves only while it is moving up and down, which makes this kind of press similar to the stop-cylinder press.

Printing speeds exceed 5,000 sheets an hour for paper up to about 2,000 square centimetres (300 square inches).

Rotary presses. Presses that operate cylinder to cylinder, usually described as rotary presses, consist of two cylinders turning in opposite directions. The typeform is attached to the surface of one cylinder, and the impression cylinder provides the pressure.

Sheet-fed rotary presses produce the same kind of work as flatbed cylinders, but the size of paper can be slightly larger, and production speed is three times higher using the same size of paper. The inking system is much the same as in flatbed cylinder presses. In both models the sheet of paper is held to the impression cylinder by a set of clamps. On the largest models passage of the paper between the cylinders is controlled only by precise positioning and presentation of the paper.

The two-colour rotary press combines two plate cylinders, each bearing a different typeform and each provided with its own inking system against a single impression system, in a so-called satellite arrangement. Thus, the same side of the same sheet of paper receives two successive impressions of two different colours in a single revolution of the impression cylinder.

The rotary perfecting press uses the same arrangement as the previous machine, but a second impression cylinder of smaller dimensions is interposed between the first impression cylinder and one of the plate cylinders. Thus, the sheet changes sides between one impression and the other and so is printed on both sides.

The two-colour cylinder and flatbed press combines a rotary and a single-revolution press by using the same impression cylinder. Clamped around this cylinder, the sheet of paper first moves against the curved form on a plate cylinder inked by the first inking system; then it moves against a flat form on a mobile bed inked in another colour by a second inking system.

Polychrome rotaries permit three, four, or five colours to be printed on the same sheet without handling the pile of paper. Some of these are designed on the planetary principle, using as many plate cylinders as colours, each being fed by its own inking system and grouped around a single impression cylinder. This type of machine is much more popular in North America than in Europe. Others are designed as a row of identical units each printing one colour, the paper moving from one unit to another by means of a transmission drum or a conveyor contrivance.

Roll-fed rotaries are exceptionally large, with high rates of production, and are used almost exclusively for printing daily newspapers. Their principle is extremely simple; the continuous roll of paper drawn from a reel moves between a plate cylinder and an impression cylinder. In practice, the cylinders of some have a circumference twice the height of a page of newsprint. Thus, each revolution of the cylinder prints two copies of the same page. On others the circumference of the cylinders corresponds to the width of four pages of newsprint side by side; each revolution prints eight copies of the same page.

In another type, the basic unit of the rotary, called the group, is composed of a symmetrical arrangement of two plate cylinders with their impression cylinders. Within the same group the roll of paper moves from one of the plate cylinders, where it is printed on one side, to the other cylinder, where it is printed on the other side. Each revolution of the machine thus produces a group of two times eight pages of newspaper printed on both sides. Inking is

effected by distributing, sliding, and contact rollers that receive ink from dozens of openings distributed across the width of the cylinder, each of which can be precisely adjusted. In each group paper is fed in by a barrel-like device with three axes for supporting the reels, which makes it possible to move over from a finished roll to a new one by a simple gluing operation and a 120° revolution. The reels weigh up to 600 kilograms (about 1,300 pounds). The rotary press is made up of a certain number of identical groups in alignment.

After printing, the roll of paper is automatically folded down the middle so that on both sides only two pages remain face to face. Moving along a triangle with rounded sides and then passing between rollers, each half roll is folded in the middle to form a newspaper. A cutting mechanism, synchronized with the action of the rotary, separates each newspaper from its neighbour.

Depending on the number of pages of the newspaper, various arrangements are possible: rolls coming from different groups can be added to by accumulation to produce two issues in a multiple of four pages. A roll half as wide as the others coming from one of the groups can be added to the middle of one or more of the usual rolls, producing two issues in multiples of four pages, plus two. Two parallel rollers, called turning bars, arranged at an angle of 45° in relation to the flow of the roll, enable the roll, after it has been printed and folded in the middle, to be folded in half again so that each of the two issues produced by the group is formed into a signature of eight pages.

For colour printing, the same roll of paper moves through several groups in succession, in each of which the plate cylinders carry typeforms appropriate for each of the colours necessary.

Modern rotaries can revolve at the rate of 35,000 revolutions per hour (500 metres [1,600 feet] of paper per minute), or at a theoretical production rate of 140,000 newspapers an hour in two issues from the final group. In practice, the average rate of production is about half this figure.

At speeds such as this, inspection and safety precautions are more reliably carried out by electromagnetic devices based primarily on the use of photoelectric cells; for example, a series of cells on the track, over which a roll of paper moves, react to tearing by stopping the machine.

In colour printing, photoelectric cells ensure matching by selectively picking up the guide marks printed in each colour as they go by and by reacting to any irregularities in the distance between these guide marks. Any error is automatically corrected by modifying either the speed of one group or the pressure of the rollers that control the tension of the paper between one group and the next. Matching up across the width of the paper is controlled by cells that react to any lateral digressions as the paper moves along by controlling a lateral-shifting mechanism.

Quality control of colour reproduction is also carried out by photoelectric cells that emit a current whose strength is proportional to the intensity of impression of the guide marks for each colour. By comparing this intensity with a colour scale, a computer determines the continual adjustments needed in the composition of the inks and controls the opening of valves to add pigment if the inks are too light or colourless varnish if they are too dark.

Preparing stereotypes and plates. The curved shapes with which the printing cylinders of the rotaries are fitted are the stereotypes, or plates. These may be produced from ordinary flat typeforms by reproducing the relief surface of the type copy and of the plates for illustrations made from halftone photoengravings and line engravings. Alternatively, screened photographic illustrations are used to make plates from mounted positives of transparencies by means of photoengraving.

In making stereotype plates, a flong, or mat, a thin sheet of pasteboard, pliant enough to register an impression and sufficiently heat-resistant to tolerate the molten type metal, is placed on the type form with paper and cotton packing. It is subjected to heavy pressures in a press at a moderately high temperature to ensure that it dries; it retains an intaglio impression of the relief surface of the type form and is placed against the inside wall of a curved

Folding
and cutting
operations

The
planetary
colour
press

Casting
stereotype
plates

casting box into which a lead alloy is injected. The cooled stereotype plate resembles a rigid shell, solid or ribbed according to its thickness.

The plate is mechanically finished to ensure uniform thickness and to provide properly bevelled edges; metal from nonprinting areas is routed out to avoid ink smudges. Finally, the plate is electroplated with a thin layer of nickel to increase resistance to wear.

Though it is rarely done, stereotype plates can equally well be cast flat, then curved while heated after being finished.

The stereotype process is the fastest and most economical process for obtaining curved plates, but such plates are not suited to the precise matching up necessary in colour printing because of the irregular behaviour of the mat; its performance depends heavily on humidity and temperature conditions.

In making electrotypes, an impression is made of the typeform using a substance that is a conductor of electricity or can be made conductive by treating with black lead or dusting with a powdered metal such as silver. Any of the following may be used: a sheet of wax submitted to heavy pressures in the press; a sheet of lead submitted to extra heavy pressure; a sheet of Tenaplate, a kind of vulcanized plastic covered with a film of black-lead wax, submitted to pressure only slightly less than that for lead; a sheet of celluloid or a sheet of plastic (Vinylite, tenalite composed of a layer of aluminum between two layers of Vinylite, etc.).

After metallizing to ensure conductivity, these molds are electroplated with a thin copper shell, delicately reproducing the relief surface of the type form. This shell is stripped from the mold and reinforced with a backing of lead alloy poured over its underside. Nickel plating can again be employed to increase its wear resistance.

Electrotype plates can be curved while cold after they have been backed or while hot, during leading, when the lead has not yet solidified. There are also impressions that can be curved before electroplating to obtain curved copper shells. The plate is then reinforced by spraying molten metal against the shell while it is fixed against the inside wall of a rapidly spinning drum.

Making electrotypes plates, especially in a curved shape, is a costly process, but they produce the best quality print. An impression made with a sheet of lead is best suited to printing in colour because it is least sensitive to variations in humidity and temperature. Metal-shell plates are attached to the plate cylinder mechanically.

Stereoplastic plates are made in two successive moldings. A hot mold is made in the press from the typeform in a thermosetting material; that is, one that can be melted only once and can thereafter tolerate high temperatures without damage, such as Bakelite. This first molding itself serves as the mold into which is pressed the hot material for the plate—usually cellulose acetate, vinyl resin in sheets or in powder to which a plasticizer has been added to make it more durable, or a sheet of rubber gum that will be vulcanized when pressed. New liquid plastics can also be employed using a method similar to casting.

The plates are trued up by milling or filing to the desired thickness and glued either to the plate cylinder of the rotary or to a metal plate wrapped around it.

Stereoplastic plates are light and easy to use, particularly on small rotaries. Their printing quality is good enough for texts and line illustrations, although they are ill suited for fine-screened halftone illustrations.

Whether wraparound plates (wraparound plates in Great Britain) are made of metal or of plastic, they utilize photosensitive materials in their preparation.

Metal wraparound plates may be of copper, magnesium, or zinc. Only one type of zinc, microzinc, whose molecular structure permits finer prints than ordinary zinc, is used. The plates are covered with a layer of photosensitive material and processed like photoengravings, using negatives of the pages on which the photographic illustrations have already been screened. Because the engraving is only half as deep as letterpress engraving, ink rollers of a larger diameter are used.

The plate can be curved after engraving, but curving

is usually done beforehand, both to avoid breaks in the metal and to obtain an absolutely uniform degree of bend in the various plates for colour printing.

Plastic wraparound plates utilize the property of photosensitive polymers to lose their solubility in certain solvents when exposed to light. Exposure to light through the negative of a page fixes the insolubility of the polymer and limits it to the areas that are to constitute the printing surfaces. A suitable solvent then eliminates all the nonprinting areas and sets off the type in relief.

New polymers with this property and with new qualities are constantly being perfected. Among the better known examples are nylon, Dycril, and KRP. Nylon is sensitized in bulk by immersion in a solution of acetone containing the sensitizing agent. The plate is exposed to ultraviolet light, and the nonprinting areas are dissolved by a bath of methyl and ethyl alcohol. It takes 24 hours for the plate to attain its maximum hardness. Dycril is sensitized by immersing it for 24 hours in a carbon dioxide atmosphere. The nonprinting areas are removed by sprinkling with a solution of sodium hydroxide. Because it is preferable for the plate to be curved before being engraved, exposure takes place on a rotary drum turning in front of an arc lamp and the bath on a rotary drum turning in a trough. The total amount of time required to make a plate is about 45 minutes.

KRP (Kodak Relief Plate) is a sheet of cellulose acetate that is superficially sensitized by the deposit of a thin coat of photographic emulsion. After exposure to light, this emulsion remains only on the printing areas, which it protects from the action of the solvent. Engraving the KRP plate can also take place on a rotary drum.

The polymer of the plastic wraparound plates is usually mounted on a base consisting of a metal sheet. The depth of the engraving can equal the actual thickness of the polymer. The type therefore stands out in sharp relief. Whether metal or plastic, the wraparound plates are easily and rapidly attached by means of register hooks, which ensure perfect tension of the plate on the surface of the rotary's plate cylinder.

Scope of letterpress. Letterpress printing is characterized by the sharpness and strength of bite of the type. It produces good reproduction of illustrations on sheet-fed machines, with these two reservations, that screening prevents the reproduction of pure white, and it is not possible to use more than four colours without risking a speckled moiré pattern. Roll-fed printing still preserves a good sharpness in the text but produces only an acceptable or average photographic illustration, depending on the quality of paper, and then only in black. Colour printing of illustrations on roll-fed rotaries can hardly rise above the mediocre level, even with the use of special rotaries in which the printing groups are drawn as close together as possible.

Rotogravure. Rotogravure is a system of intaglio printing. It consists of transferring to paper fluid ink contained in the cells of the printing cylinder, while the projecting nonprinting areas on the surface of this cylinder are kept free of ink by constant wiping.

The density of the print at each point depends on the depth of the cell at that point and the quantity of ink it contains, rather than on the printing surface, as in the letterpress process. The screen no longer plays an optical role. It is used to establish the partitions that separate all the cells of the honeycomb from each other and that form a surface of uniform height, while the cells are all of different depths, so that the ink is taken up on the engraved surface in an exactly defined quantity. The screen also prevents the wiping mechanism from penetrating the cells of the cylinder and withdrawing the ink. For this reason, line drawings and even the text type must be screened, as well as the photographic illustrations.

Rotogravure rotaries are thus composed of two principal elements: the cylinder bearing the printing form and the impression cylinder; the paper moves between these two cylinders either in sheets or from a roll.

The nature of the ink used in rotogravure and the operation of the wiping mechanism make the use of plates technically more delicate because of the indentation that

Plastic
wrap-
around
plates

would be necessary in the places where they were affixed to the cylinder. Plates are used only on certain sheet-fed machines, because they are easier to prepare and stock. Generally speaking, the image is etched directly onto the printing cylinder, which must therefore be easily handled.

Ink of sufficient fluidity is used to allow direct inking of the engraved cylinder without the use of a roller to spread and distribute it. While the paper tangential to its upper surface is being printed, the lower part of the cylinder is bathing in the pool of ink. In fast-working machines the ink can be poured on through a spout or sprayed onto the surface of the cylinder, to avoid flying ink. On the plate machines, inking must be done by roller to avoid filling the hollows of the clamping system with ink.

The
operation
of the
doctor
blade

Between inking and printing, the wiping mechanism comes into action. It consists of a thin blade of soft steel, the scraper, or doctor blade, which moves slowly to and fro lengthwise. By rubbing against the cylinder with a precisely regulated degree of pressure, it causes the excess ink to drop off before the cylinder moves over the paper.

In sheet-fed machines the impression cylinder is like that of a letterpress press, with a diameter large enough to carry the sheet wrapped around its surface, gripped and released by a system of articulated clamps. Production speed can attain 6,000 sheets per hour.

Roll-fed rotaries generally consist of several printing units in line (up to as many as 18), each composed of a printing cylinder, an inking system, and a hard-rubber impression cylinder of small diameter. Each unit can turn in either direction to allow the paper to move through in any combination.

When printing both sides, the same roll of paper must pass through two successive printing units. In colour printing the same roll must move through as many printing units as there are colours used on each side of the paper. Several rolls coming from different printing units can be added together by accumulation.

Rotogravure rotaries normally include the same folding and cutting systems as letterpress rotaries, along with the electronic devices necessary for controlling the operation. Because of the fluidity of the ink, all rotogravure machines, whether sheet-fed or roll-fed, require a drying process. The paper passes over a heated drum or over sources of infrared rays or through a compartment ventilated with hot or cold air.

Preparing rotogravure cylinders. The printing cylinders or plates are prepared from positives of pages on which neither text nor illustrations are screened. The photosensitive substance necessary for carrying out the photoengraving operation, carbon tissue, is separately packaged to permit it to be treated before being affixed to the metal. Carbon tissue is paper, in sheets or on rolls, coated with a layer of gelatin. This layer is sensitized before use by being plunged into a solution of potassium bichromate. The carbon tissue is first exposed to intense light through a glass plate bearing a transparent screen on an opaque background and then exposed a second time through a positive of the pages. During these two exposures the gelatin is hardened by the light, completely in the white and screened areas, more or less deeply in the halftones of the photographic illustrations, and not at all in the areas covered by text and lines.

The carbon tissue is then applied to the copper surface of the cylinder (or plate). The tissue is then peeled off, leaving the gelatin film fused with the metal. The cylinder (or plate) is plunged into a warm-water bath, which dissolves the gelatin in inverse proportion to the degree to which it was hardened: totally in areas where it received no light like the text and line drawings, more or less deeply in the halftone photographic illustrations, and not at all in the screened areas.

The etching of the copper is begun by sprinkling it with a solution of ferric chloride, which attacks the metal in the areas where the gelatin is totally dissolved and bites into it more or less deeply depending on the thickness of the surviving gelatin that it must penetrate. After being etched, the printing surface can be reinforced by chromium plating.

Improvements on this classic method of preparing the

rotogravure plate are continually being made. The carbon tissue may be replaced with silver emulsions on a plastic base; a direct copy without carbon tissue may be made by dusting the cylinder with a photosensitive substance and projecting the image on the surface of the cylinder by optical means or by electronic engraving.

Plates for rotogravure are made of solid copper. Rotogravure cylinders consist of a steel mandrel on which a layer of copper has been deposited by electroplating. After printing, the etching is removed by grinding and a thin film of copper deposited to restore the cylinder to its original diameter. Restoration is simplified if the film can be prevented from adhering to the cylinder so that it can be ripped off after printing. This can be done by coating the surface of the cylinder with a copper-mercury amalgam before electroplating. After plating, the new copper film is then polished. Some electroplating baths produce a shiny copper finish, dispensing with the polishing operation.

Scope of rotogravure. Even in long runs, rotogravure produces quality illustrations with rich colours. It is less suited to printing small typefaces because they are cut up by the screen.

Offset. The first characteristic of offset printing is that the printing and the nonprinting elements are parts of a single continuous surface. The difference is simply that the printing parts of the surface repel water when moistened but absorb the ink with which they are coated, whereas the nonprinting parts absorb the water and repel the ink. The form used in offset printing is a metal plate the surface of which has been prepared to divide it into the parts with these opposite properties.

The second characteristic of offset printing is that the ink is not transferred directly from the printing form to the paper but is first transferred to a rubber blanket. It is the ink retained by the blanket that is transferred to the paper.

Offset presses utilize three principal elements: the plate cylinder; the blanket cylinder; and the impression cylinder, which applies the paper, in sheets or a roll, against the blanket cylinder.

The plate cylinder is like the cylinder for wraparound plates on a letterpress rotary, with a groove in which the attaching and tension mechanisms are housed. A moistening system and an inking system are connected to this cylinder. The inking system is similar to that on letterpress presses, with a series of alternating hard and soft rollers that grind, spread, and evenly distribute the ink in a uniform thickness.

The wetting system, which dampens the plate before it is inked, consists of a series of rollers that transmit regularly controlled quantities of water taken up by puddling in a tank or sprayed from rotary brushes grazing its surface.

The blanket cylinder also has a groove containing the mechanism for attaching and controlling the tension of the blanket, which consists of several layers of fabric and rubber. During printing the groove of the blanket cylinder and that of the plate cylinder coincide at each revolution.

On sheet-fed machines the impression cylinder has a cavity in which a system of articulated grippers is recessed. The movement of the machine is synchronized so that at each revolution the slightly projecting grippers enter into the groove in the blanket cylinder in such a way as to cause no damage to the latter. This problem does not arise on the impression cylinders of roll-fed rotaries, and their movement does not therefore have to be synchronized with that of the other cylinders.

In sheet-fed presses the three cylinders, usually placed side by side, are of the same diameter and turn at the same speed. The movement of the cylinders is synchronized by meshing sprocket wheels. Paper is fed in by a feeder similar to that of letterpress presses.

Offset machines can be used to print very large sheets. The fastest can produce 10,000 sheets per hour.

In printing two or more colours, during the offset process the dampness of the plate is partly transferred, via the blanket, to the paper. This slightly alters the paper's dimensions, causing difficulties in register. The separate colours are therefore printed as nearly simultaneously as possible.

On some two-colour machines a single impression cylin-

The
three-
cylinder
offset
press

der applies each sheet successively against two blanket cylinders, each of which receives a transfer from its own plate cylinder.

More generally, sheet-fed offset machines printing in two or more colours are designed as a series of printing units each consisting of three cylinders with their wetting and inking systems, the sheet being transferred from one unit to the next on drums of large diameter with a system of articulated grippers. Size of paper and speed are the same as for the one-colour machines.

Blanket-to-blanket machines

In the offset process an unusual arrangement, without impression cylinders, is possible. Simultaneous printing is done of both sides of the sheet as it passes between two juxtaposed blanket cylinders. Each receives a transfer from its own plate cylinder and prints one side of the sheet while at the same time acting as an impression cylinder for printing the other side of the sheet. Thus, the blanket-to-blanket machine consists of a total of only four cylinders.

The various kinds of machines can be used in combination: for example, three one-colour printing units and one blanket-to-blanket machine can print one side of the sheet in four colours, the other side in black.

Roll-fed rotaries work on the same principle as sheet-fed presses, with two differences—the groove for the plate fasteners on the plate cylinder is very narrow, and the impression cylinder, lacking grippers, has an entirely level surface.

In-line rotaries are designed as a succession of one-colour printing units or, more frequently, blanket-to-blanket units. On these, as on the others, printing in several colours is done by sending the paper directly and horizontally through several successive units.

On blanket-to-blanket rotaries, the back is printed simultaneously with the front. On rotaries made up of one-colour units, a turning bar reverses the direction in which the roll of paper presents itself. Feeding the paper into and taking delivery of it from the machine can be combined so that the rolls are superimposed to form a signature.

Satellite rotaries (drum presses) work on the principle of a single impression cylinder of very large diameter that has arranged around its outer surface four, five, or sometimes six blanket cylinders. Each receives a transfer from its own individually moistened and inked plate cylinder. Thus, colour printing one side of a roll of paper is accomplished in a single revolution of the impression cylinder.

Drum cylinders are most often made up of two symmetrical groups printing one side after the other. For quality colour printing with a heavy thickness of ink, rapid drying is necessary to prevent smudging. The roll therefore moves horizontally into a drier heated by a ramp of gas burners or hot-air blowers and is cooled as it passes over metal drums refrigerated by circulating water.

Offset rotaries work at a speed of 15,000 to 20,000 revolutions per hour and have the same cutting and folding systems as letterpress rotaries.

Preparing the plates used in offset involves defining and fixing the joint presence of two mutually repellent materials, one water-receptive for the nonprinting areas, and the other ink-receptive for the printing areas. As in letterpress the screen is necessary to translate the halftones of photographic illustrations into surface densities.

Even though there is no question of creating reliefs, the preparation process is very similar to that of photoengraving. But, because the blanket intervenes between plate and paper, text and illustrations appear on the same offset plate in straight rather than in reverse reading as on letterpress plates.

Offset plate making. Depending on the work they are intended for, various kinds of plates and processes for preparing them exist.

Monometal plates are made of a metal with hydrophilic (water-receptive) properties, such as zinc or aluminum, the surface of which is treated to make it more porous. The plate is coated with a thin layer of a photosensitive substance, covered with a negative of the texts and previously screened photographic illustrations, and exposed to intense light. This hardens the photosensitive substance in the areas of the negative where the light passes through; that is, in those corresponding to the printing areas. The

photosensitive substance is then washed away from the nonprinting areas, where the metal, now stripped, is wetted; the hardened photosensitive substance is inked.

Presensitized plates are monometal plates coated with a photosensitive layer that has a life-span, away from light, of up to six months. Certain presensitized plates for use in short runs can be made of paper or plastic.

Deep-etch plates are monometal plates prepared by inversion. The plate is coated with a photosensitive substance and then exposed to light through a positive of the text and screened photographic illustrations. This exposure hardens the photosensitive substance on the nonprinting areas. Washing eliminates the photosensitive substance on the printing areas, exposing the metal. The plate is then given a mild acid bath, which etches the metal of the printing areas to a shallow depth. An ink-receptive lacquer is spread over the surface of the plate; that is, over the hardened photosensitive substance wherever it still survives, as well as over the etched-metal areas. The hardened photosensitive substance and the lacquer are both removed at the same time by dissolving and brushing, exposing the metal of the nonprinting surfaces to be wetted. Lacquer remains in the cavities of the etched areas, ready to be inked. Plates treated by this process are suitable for longer runs (up to 250,000 copies).

Bimetal or trimetal plates are composed of two superimposed metals, one of which is hydrophilic (aluminum, stainless steel, chromium, nickel) and the other ink-receptive (copper, bronze). Whichever of the two covers the other in a microscopic film is partly eliminated by the photoengraving operation. In the case of a hydrophilic metal, photoengraving is carried out using positives of the text and illustrations. In the opposite case, negatives are used.

Among the combinations used in various commercial plates are chromium on copper or nickel on bronze for use with positives and copper on stainless steel or copper on aluminum for use with negatives. The combination of two metals can, in certain plates, take the form of a double film deposited on a third metal (steel or zinc), which simply serves as a base. Bimetal or trimetal plates are very durable and can be used to produce as many as 500,000 copies.

Alongside these various types of conventional offset plates, special processes are being developed that tend to further simplify the work of preparation. Electrostatic (or xerographic) transfer plates were developed from the principle that certain materials (such as selenium) that are insulators while in the dark become conductors of electricity when exposed to light. A selenium plate is given a positive electric charge in the dark and then exposed to light through the positive of the text and illustrations. In the areas touched by the light, the plate becomes a conductor, and the positive charge disperses. A fine, negatively charged powder is sprinkled over the plate and is attracted by the positive charge in those areas of the plate where it still remains. The image thus revealed is transferred to an aluminum plate, which is positioned on the selenium plate and then given a positive electrical charge. The powder transferred to the aluminum plate is fixed by heating to constitute the ink-receptive printing surface.

This whole operation, which is carried out automatically in a compact apparatus, takes only three minutes. Xerographic plates are used only on small machines.

"Immediate" offset plates consist of a polymer layer that is sensitive not to light but to heat, which makes it become hydrophilic. Those areas not touched by heat retain the opposite property. The plate is then ready for printing without further treatment.

Scope of offset. In offset printing the letters print a little less sharply and strongly than in letterpress, except on special qualities of paper. The reproduction of photographic illustrations, in black and in colour, also depends on the quality of the paper and may rival rotogravure reproduction when printed on offset rotaries with driers.

Other printing processes. *Letterset.* This process, also called indirect letterpress, or dry offset, is a combination of letterpress and offset. Like offset, it has a blanket cylinder as the transfer element between typeform and paper, but, like letterpress, it uses a relief typeform. Thus, letterset

Innovations in offset plates

presses use the same three cylinders as offset, but there is no dampening system.

Because of the use of a blanket, the text and illustrations appear on the typeform straight and not reversed. Consequently, the use of plates is excluded, since these would be made by making a mold of a conventional typeform. On the other hand, all types of metal or plastic wraparound plates, prepared using positive or negative transparencies, can be used. These plates are thinner than those used for letterpress, and the height of their relief is less. Rollers of a quite large diameter must be used for inking, and contact between plate and blanket cylinder must be extremely light.

All the combinations that the blanket allows on offset machines are equally possible on letterpress machines: blanket-to-blanket and drum press. Machines are manufactured that can be used interchangeably, both for offset and for letterpress; in the latter case, the action of the dampening system is suspended. The size of paper and performance rates are the same in letterpress as in offset.

Serigraphy (screen printing). Serigraphic printing consists of forcing an ink, by pressing with a squeegee, through the mesh of a netting screen stretched on a frame, onto the object to be printed. The nonprinting areas of the screen are protected by a cutout stencil or by blocking up the mesh.

Silk
and
other
screens

The screen is usually made of fine but strong silk gauze (available in different mesh sizes) but can also be made of synthetic gauzes (nylon, tergal) or of wire gauze (phosphor bronze, stainless steel, nickel) or of combinations (nylon-copper, nylon-bronze).

Preparation can be carried out by hand. The design to be reproduced is transferred to the screen by drawing with a benzene-soluble ink, spreading glue over the whole surface of the screen, then dissolving the ink so that the glue remains only on the nonprinting areas. The nonprinting areas can also be covered with glued paper or film, cut out in the shape of the desired image and attached either by heat or by a solvent.

Direct or indirect photomechanical processes are being more and more widely used, however. In direct photomechanical processing the screen is covered with a photosensitive layer and then exposed under a positive, the photographic illustrations having been screened previously. In indirect photomechanical processing, the printing and the nonprinting areas are prepared by exposure under a positive (screened, if necessary) of a photosensitive film (carbon tissue, the same as that used in rotogravure, or presensitized film), which is then bonded to the screen.

Screen printing is still done largely by hand, the frame being lifted up after each operation; however, semiautomatic and automatic machines that are driven mechanically or by compressed air can carry out the series of operations: positioning the object to be printed, moving the frame, inking, spreading the ink with the squeegee, delivering the printed sheet or object, and transferring it to a drying apparatus.

Serigraphic printing can be applied to a wide variety of surfaces—paper, cardboard, glass, wood, plastic, posters, bottles, electronic circuits, etc.—and to varied shapes: for printing cylindrical objects, the squeegee is stationary, while the screen revolves under it at the same time as the object to be printed.

Modern machines reach speeds of from 1,000 to 6,000 copies per hour.

Collotype. A photosensitive layer, spread on a plate of glass and exposed under a negative, hardens and loses its hydrophilic properties in the areas where it receives light and in proportion to the intensity of the light received through the halftones of the photographic documents. It is then able to retain both ink and water in all areas, the ink repelling the water in inverse proportion to the intensity of the exposure.

Collotype printing, which is based on this property of mutual repulsion, is thus related to lithography. But it is also related to rotogravure in the fact that the thickness of the film of ink is not uniform but in proportion to the shades of tone in the original image. Collotype, the only printing process that can reproduce photographic docu-

ments without a screen, is characterized by its fidelity of reproduction.

Collotype presses consist essentially of a bed bearing the glass plate prepared for printing, an impression cylinder carrying the sheet to be printed on its outer surface, and a system of ink rollers. The photosensitive preparation retains its own moisture, so no dampening system is necessary. Printing speed is low, rarely more than 200 copies per hour, and the useful life of the printing surface is very limited, from 2,000 to a maximum of 5,000 copies. Increasingly, the glass plate is being replaced by a cellophane film as the surface to which to apply the photosensitive layer. The prints can be cut out and, when glued onto wooden or metal blocks of type height, can be placed alongside a typeform for a limited number of copies to be printed from a flat surface.

Collotype is used for printing limited editions of works that require an excellent quality of photographic reproduction in one or more colours, such as reproductions of documents or pictures, posters, and transparent illustrations for advertising or various artistic uses.

Flexography. Based on letterpress-printing principles, flexographic presses are composed of the same basic elements as letterpress cylinder-to-cylinder presses; that is, the impression cylinder covered with a rubber packing and an inking system, which is simplified, owing to the fluidity of the ink used. Although several sheet-fed models exist, flexographic presses are usually roll-fed rotaries that can reach large dimensions and high printing speeds. They consist of a group of several identical units that print an equal number of colours (up to eight). Flexography provides economical printing, either of solid lines or with quite a coarse screen, on unfinished surfaces, wrapping paper, cardboard, plastic film, and it is also used for printing newspapers and magazines.

Electrostatic printing. Electrostatic printing is a process of printing without contact, without a typeform, and without ink. The paper is coated with a very thin layer of zinc oxide, which makes it an insulator while in the dark and a conductor of electricity when exposed to light. This paper is given a negative electrical charge in the dark. It is then exposed by light projected through a positive film of the document to be reproduced. The zinc oxide layer becomes conductive wherever it is illuminated, and the negative charge is dissipated in those areas that correspond to the blank surfaces of the document. Finally, the paper goes through a bath containing pigmented particles that are attracted by what remains of the negative charge and are fixed by drying.

Electrostatic machines have been designed for printing geographic maps. These are composed of five successive units, each carrying out the same complete cycle of processing the paper to produce an edition in five colours at speeds of about 2,000 copies per hour. Improvements in the bath of pigmented particles are making possible the application of the electrostatic process to printing small books.

Printing inks. Printing inks contain three components: the vehicle, the colouring ingredients, and the additives. The vehicle, responsible for transferring the colouring ingredients from the ink fountain to the typeform, can be either a vegetable base (linseed, rosin, or wood oils), which dries by penetration and oxidation and at the same time ensures fixation, or a solvent base derived from kerosene, in which case drying takes place by evaporation. The colouring ingredients come in several forms: pigments, which are fine, solid particles manufactured from chemicals, generally insoluble in water and only slightly soluble in solvents; agents made from chemicals but soluble both in water and in solvents; and lacquers, obtained by fixing a colouring agent on powdered aluminum. The additives stabilize the mixture and give the ink additional desirable characteristics. The nature and proportions of the ingredients vary according to the printing process to be used and to the material to be printed. The proportions must be checked and sometimes modified during printing.

Letterpress and offset use greasy inks. For printing on sheet-fed presses, thick greasy inks are used in which the vehicle is generally made of vegetable oils with the addition

Speed of
collotype
printing

of hard natural or synthetic resins dispersed in mineral oils. Roll-fed rotaries use fluid greasy inks in which the vehicle is made up of heavy mineral oils.

The colour black is generally obtained from an organic pigment, carbon black, derived from the incomplete combustion of oils or of natural gas. Coloured pigments are inorganic compounds of chromium (yellow, green, and orange), molybdenum (orange), cadmium (red and yellow), and iron (blue).

Inks for offset are more highly coloured than those used in letterpress, because they must be transferred to the blanket before they reach the paper. Furthermore, the pigments must resist being picked up by the water from the dampening system.

Inks with various special qualities exist for both letterpress and offset. In high-gloss inks, the vehicle is not homogeneous, as with ordinary inks, but heterogeneous, based on synthetic resins dissolved in a solvent, with lead and cobalt additives. This ink glazes as it dries. When printing several colours, the whole series of operations must be finished before the ink has time to dry so that the inks can attach themselves to the surface.

Quick-setting inks utilize a vehicle that also has a base of resins dissolved in a quick-drying solvent.

Heat-set inks require the application of heat to facilitate both the oxidation process and the evaporation of the solvent, as well as the penetration of certain elements that had rendered the ink more fluid. Cold-set inks are hardened by chilling after printing, having been kept fluid by heat until they were applied to the typeform.

Moisture-set inks become fixed when they are applied directly to damp paper or upon exposure to a water-spray after they are applied to dry paper. In such inks, which are used more in the United States than they are in Europe, the vehicle is a solvent, soluble in water, that, on contact, penetrates the paper, leaving the pigment on its surface. Odourless moisture-set inks are used for printing food packaging.

Among other special-characteristic inks are metallic inks containing powdered copper, bronze, aluminum, or gold mixed with the pigment; magnetic inks, containing a powdered magnetized iron mixed with the pigment for "recognizing" the shape of printed characters as they pass before electronic reading equipment; and fluorescent inks.

Rotogravure uses fluid inks in which the colouring agent, fixed on a natural or synthetic resin, is integrated in a fluid solvent to which, just before printing, a second, extremely volatile solvent is added.

Flexography also uses fluid inks whose pigments or colouring agents are dissolved in pure alcohol, in alcohol solutions, or in water.

Serigraphy uses inks of extremely varied consistency, depending on the surface to which they are to be applied; some are little different from ordinary paint, except that their composition must not be such that rapid drying would clog the mesh of the screen. (Ro.L.)

Typography

Typography is concerned with the design, or selection, of letter forms to be organized into words and sentences to be disposed in blocks of type as printing upon a page. Typography and the typographer who practices it may also be concerned with other, related matters—the selection of paper, the choice of ink, the method of printing, the design of the binding if the product at hand is a book—but the word without modifier most usually denotes the activities and concerns of those most involved in and concerned with the determination of the appearance of the printed page.

Thus understood, there was by definition almost—but not quite—no typography before the invention of printing from movable type in the mid-15th century; and, thus understood, it is only by analogical extension that the term can be applied, if ever it can be, to "reading" in which the material at hand is something other than words that remain stationary on flat firm surfaces. The electronically created letter that lives out its brief life while moving across the face of a signboard or a cathode-ray tube is not

a typographic item. Typography, then, exists somewhere between the extreme of manuscript writing, on the one hand, and the transient image on the electronic device, on the other hand. Whether the letter be made by metal type or photographic image is no longer important in defining the subject; whether the finished item is a book or a page influences its inclusion as typographic not one bit.

THE NATURE OF TYPOGRAPHY

Typography as a useful art. An overview of typography suggests that a number of generalized observations may be reasonable:

First and most important, typography and printing, the mechanical processes by which the plans of the typographer are realized, are useful arts. Though there is indeed fine typography, typography is not a fine art. Books, the primary source of typographic examples, are written in the main by people with something to say; they are selected for printing in the main by publishers who see merit and hope for profit in disseminating the statements of the writers to an audience; properly they are edited and designed and printed in the main by craftsmen whose boundaries are fixed for them by considerations germane to the needs of the writers to communicate and the needs of the readers to understand and appreciate. The typographer exists not to express his own design preferences, his own aesthetic needs, but to provide a useful (because usable) connection between someone with something to say and someone to say it to.

But to say—as did the late Beatrice Warde, one of England's great typographic authorities—that printing ought to be invisible is not to say that the typographer has no contribution to make; to say that typography is a functional art and as such ought not to get between the writer and the reader is not to say that there is only one solution to every typographical problem, that aesthetics, taste, personal judgments, and imagination cannot find room for expression in the typographic studio.

Nonetheless, there are limitations to what the typographer may and may not do; for, in addition to being a useful art with the generally accepted first use of transmitting information, typography for at least three reasons is a secondary art.

First, it is secondary in that its basic materials, the alphabets or other similar notational systems with which it works, are not of its own invention. The influence of this fact on the art form is obvious. Generally speaking, Western writing, or printing, is accomplished by the use of a relatively small number of individual letters capable of being grouped in almost infinite numbers of meaningful permutations. Even in the face of language differences, there is a wide carry-over of letter shapes and typefaces from one language to another. Because the number of images (letters) to be designed is limited and entirely manageable, the type designer's job is made less difficult. The language carry-over makes possible the establishment of meaningful typologies, the evolution of international styles and conventions, and the development of criteria and traditions of taste by which typographers improve their work. As the result, it is fairly certain that in a little more than 500 years of printing history since Gutenberg, at least 8,000 and very probably 10,000 or 11,000 typefaces have been designed. The practicing typographer has, then, a vast number of types to choose from, and, because the best of those types have evolved within cosmopolitan traditions and have stood the test of judgment by many people in many places over many years, there are, within the several thousands of types available, many that are of unquestioned excellence.

By way of contrast, the Japanese method of writing and printing involves a combination of systems—some 3,000 *kanji* (symbols based on Chinese characters), *seicho* (based on the brush-written Kana), and two groups of phonetic symbols (*hiragana* and *katakana*), each of which consists of 46 separate symbols. The problem of individually designing some 3,000 symbols, some of them of incredible complexity, is not one that many designers are able to surmount in a lifetime. As a result, to all intents and purposes, Japanese typographers have had only two typefaces

Special
quality
inks

Relation-
ship

to choose from—*mincho*, roughly equivalent to the West's roman, and Gothic, functionally a Japanese sans serif. In the 1960s a group of Japanese designers produced a third typeface called Typos (see Figure 8).

Reading conventions and typography

Second, the typographer is limited by reading conventions over which he has little or no effective control. The appearance of a book page, whether well or badly designed, is governed more by the fact that Western readers begin at the top left of a page and read right, a line at a time until they get to the bottom, than it is by the aesthetic desiderata of the designer. Many typographers have long been attracted to the clean and uncluttered look of so-called sans serif type (the two little bases on which the vertical elements of the lowercase "n" rest are serifs, as is the backward pointing slab atop the lowercase "i" or "l," and sans serif types are those in which such embellishments are lacking [7/1]). But the difficulty is that almost every study ever completed has indicated that sans serif type is less easy to read in text than is type with the serif. It may well be that if Western texts were printed vertically, from the bottom of a page to the top and read upward so that each letter occupied a separate line with no horizontal connection to those before and after it, the apparent advantage of serif types in this regard might disappear.

To consider another example of the restrictions put on the typographer by the necessity of working with the reading conventions, it is arguable that the appearance of the

printed page would be changed and one of the petty annoyances of reading—"doubling," in which the eyes finish a line and then return to the left margin and begin the same line all over again—could be eliminated if people could be persuaded to accept the following reading pattern:

Typography as an art is concerned with the design,
into organized be to forms letter of ,selection or
words and sentences to be disposed in blocks of type
.page a upon printing as

or

Typography as an art is concerned with the design,
otni dezinagro eb ot smrof rettlet fo ,noitceles ro
words and sentences to be disposed in blocks of type
.egap a nupu gnitnirp sa

But the fact, of course, is that the problems involved in winning acceptance of any change as fundamental as this one would appear to be so numerous and so substantial as to preclude its further consideration by any but writers of typographical journal articles or textbooks. Basic changes in the format of written text attributable to the typographer or, his earlier form, the printer-typographer, have been few, though occasionally dramatic, as in, for example, the practice of separating succeeding sentences with periods or of separating paragraphs (which in handwritten manuscripts were separated only by the insertion of the scribe's paragraph mark without the initiation of a new line or indentation).

Third, it would appear to be reasonable to call typography a secondary art because, just as the typographer uses letter forms and reading conventions over which he has had little control, so too what he contributes comes into being only through the intervention of a mechanical process that, as often as not, in the 20th century at least, has become the province of the printer, so that the typographer practices his art at least once removed from its final production. The extreme example of the consequence of such a situation may have been seen in the early years of computer-generated typefaces in which, many felt, most faces revealed quite clearly that they had been developed by specialists whose first capabilities were not in the field of typography. And when typographers were later introduced into the process, they found that they had to work through the electronics expert, even as, for many years, those unable to cut their own type had been forced to work through typefoundries.

It will already have become apparent that there is, at the worst, some confusion and, at the least, some lack of uniformity involved in talking about typographers and typography. The words themselves are of relatively recent origin and have been used self-consciously in their contemporary sense only from about the mid-20th century. The difficulty is, of course, the matter of the process involved. Gutenberg was his own typographer. It may well be, in fact, that his major personal contribution to the invention of printing was the development of a way to cut and cast type so that after the shape of the letter had been fixed and the molds prepared each letter form might be replicated over and over again in one relatively simple process. He was also the publisher, who undertook to risk capital in the selection and preparation of material to be printed for sale; he was presumably the man who designed the layout of each page; he may have done whatever editing was required, and he certainly either printed or supervised an assistant in the printing of the finished product. In the course of years many of the functions at first performed by one man came to be divided among several. Quite early, some printers employed men to cut type to their design; others employed men to design and cut the type; some held their services out for hire to others who became publishers; editors were separated from the process, though not always from decision-making roles in the appearance of the final product. After the introduction of bound volumes, trends were initiated that led eventually to the creation of binding designers as separate artists; it became not uncommon to find persons performing services as book designers and, as such, responsible for coordinating and leading the work of type designers, layout artists, binding designers—all who were in any way responsible for the appearance of the book as a whole.

Dependence upon a mechanical process

Function of the book designer

Figure 9: Typeface nomenclature.

The situation became further clouded by the great variety of practice as to the status of each of the persons who perform one or more or, in some cases, all of these functions. They may be professionals retained by printing concerns for a single project; they may be full-time members of a corporate printing staff; in some very few cases they may be a single artist-craftsman-patron carrying out all of the functions in operations (usually necessarily small) devoted self-consciously to the production of "fine books."

Parenthetically, it is significant to note that, in general, the major examples of really fine typography—the significant developments that have raised the possibilities for the improvement of the typographic arts and, in fact, a preponderance of the typographic examples held up as outstanding—have been produced by publisher, printer, and typographer all working within the normal day-to-day requirements of their regular operations. Such a statement must not, however, be taken as dismissing the outstanding services rendered by the best work of the so-called private presses and by the valued demonstration volumes produced in limited numbers by major presses such as the Cambridge University Press in England, in holding up to view the best that the craft is capable of and thus serving as models for the craft itself.

Aesthetic qualities of the typographic page. Confusion notwithstanding, the typographer as he is most generally understood is responsible—whether or not he does all of the work himself—for the appearance of the printed page, and his work is best seen in the several examples of the printed page that are used to illustrate the present article.

The typographic page may be considered in terms of two aesthetic qualities. The first of these has been called "atmosphere," "feel," "impress," "sense," and other similar terms. It is easier felt than defined, and it depends in large measure on such things as the size of the block of type, its placement on the page, the kinds of display letters used for titles, running heads, and subheads, and the size of the margins—all elements that in the hands of a competent typographer create an expectation regarding the contents (possibly even the purpose) of the page and lead to a sense of the time of its production, its seriousness, and its function.

The second aesthetic quality is that of colour, the darkness or lightness of the block of type sensed somehow as a whole rather than as a collection of individual letter forms with substantive meanings. Colour is the result of letter shapes, distances between letters and between words, the amount of space left between lines, the inking of the type, the printing process employed in making the impression on paper, and the paper itself.

Of all elements the design of the letters is, in the dominant view, the most important. It is important that early typography was in fact overtly engaged in the explicit search for typefaces that would mechanically reproduce the written scripts in which, before the invention of printing, books had been prepared. For most of its life since the invention of printing with movable type in the mid-15th century, typography in the West has been dominated by three type families—roman, italic, and black letter (see below). All are easily recognizable as refined and regularized versions of letter styles first developed and standardized by scribes. The debt of sans serif, more a subclass than a family, is apparent but less unequivocal.

To divide the several thousand typefaces that have existed since Gutenberg into three major families is only the grossest type of classification, and historians of typography, like teachers of typography, have found it useful to set up other classifications. Unfortunately, but not unexpectedly, they have not found it possible to agree on a system of classification. The variety of proposals has been so bewildering as to defeat one of the first purposes of classification. Some have concentrated on the influence of seminal workers in the field and talk of "Caslon's," "Bodoni's," etc. Others have concentrated on the major uses or types of literature from which various dominant types have come and talk, for example, of Humanistic faces. Other systems have employed nomenclatures that emphasize the early manuscript models from which a face evolved or a national influence. In attempts to meet

a growing need for standards that can be applied more rigorously in legal and commercial and technical bibliographical uses, some countries and some craft associations have tried to develop classification schemes based on precise, in some cases almost mathematical, descriptions of the various elements of letter shapes. These schemes are not as yet worked out to the satisfaction of all concerned and are matters of some controversy, even among those who applaud the aims.

The system that has enjoyed the longest general favour and seems to be about as useful as any other divides typefaces into four classifications. Unfortunately, though the classifications are based as much on differences in letter styles as on chronology, the names given each suggest a temporal alignment and one that is, at first glance, confusing.

The first of these is called in most places old face—though Americans sometimes call it old style. In general, old faces were largely those types developed from c. 1722 to c. 1763 (dates of William Caslon and John Baskerville). Their letter forms had marked affinities with the penned letter styles of the scribes: they tended to squareness, there was little contrast between the thick and thin strokes, the stresses (the thickest part of the curves in a letter) were heavy and tilted or slanted, and the serifs tended to be full or thick and had brackets—gracefully rounded curves where they joined the letter body proper.

The second classification is usually described as transitional and, as its name suggests, came more or less between—and had letter styling midway between—old face and modern.

So-called modern types were produced between c. 1788 (when Giambattista Bodoni introduced the typeface that retains his name) and approximately 1820, when type design almost everywhere went into a major decline. Modern faces in general share characteristics resulting from the engraver's tool rather than the pen. There is a marked contrast between the thick and thin strokes of the letter, the thins in particular being almost exaggeratedly thin, and the change from thick to thin is sudden and pronounced; serifs tend to be thinner and somewhat longer, and the stresses are less pronounced and are vertical rather than tilted. The effect is that of a letter less square, more up and down, than old-face letters, with lines more sharply defined.

The classification called old style or, in America, modernized old style is reserved for revivals of old faces undertaken by contemporary type designers, a practice typified by the important work of one of England's truly prestigious type designers, Stanley Morison. It is necessary to establish a special classification for such types because in each case the modern reworking, while it owed much to the original, was in fact sufficiently different to be a new creation in its own right.

It is worth pointing out once more that typefaces are assigned to one or the other classification on the basis of the style in which their letters are drawn and not—despite their time-oriented designations—by the year of their creation.

Finally, and although this is not the place for a detailed history of the evolution of the written letter forms on which printing depends, it is significant that models for all

three major type families were in use before the invention of printing by movable type: in England and Germany, a handwriting that was symmetrical, elongated, spiky, magnificently decorative, and difficult to read, not unlike certain parts of letters called today Old English, German script, and Gothic, was to be the origin of black type; in Italy and Spain, a free, open, square, uncluttered writing, not too far from the letter forms regularized by a decree of Charlemagne in the late 8th century, is recognizable today as the seed source of roman type; and a slanted, cursive, more hurried form of the same—from which it evolved by chancery scribes whose work required speed in handwriting—is easily seen to be the origin of italic.

The ready availability of serviceable letter models freed typography from the necessity of creating its own prototypes and left it able to spend its creative impulses in other ways. So well did it succeed that, within the first few decades after Gutenberg, it had brought forth almost every major development that it was to contribute and, in fact, had established itself so well that it may be fair to say that, until the 20th century, the art was a static one for all but the first 50 years of its existence. Further, the fact that the art form could take its basic ingredients from existing sources gave it a stability that it would not otherwise have

had. Since it was unnecessary to wait while various producers in various countries came to agreement on which letter shapes to adopt or what reading conventions to employ, the typographer was enabled to get on with the work of overseeing the printing of books for distribution on a scale never before envisioned. The influence on the Renaissance was of incalculable importance if, indeed, it was not one of cause and effect.

HISTORY OF TYPOGRAPHY

Type, from Gutenberg to the 18th century. Whatever else the typographer works with, he works with type, the letter that is the basic element of his trade. It has already been said that there have been but three major type families in the history of Western printing: (1) black letter, commonly and not quite rightly called Gothic by the English; (2) roman, in Germany still called by its historical name of Antiqua; and (3) italic. All had their origin in the scripts of the calligraphers whose work printing came ultimately to replace.

Calligraphy is dealt with at length in other articles (see further WRITING). It is necessary here only to provide a context for the evolution of the typefaces of the printer's font. The basic letter forms of the Latin alphabet were

By courtesy of the Newberry Library, Chicago

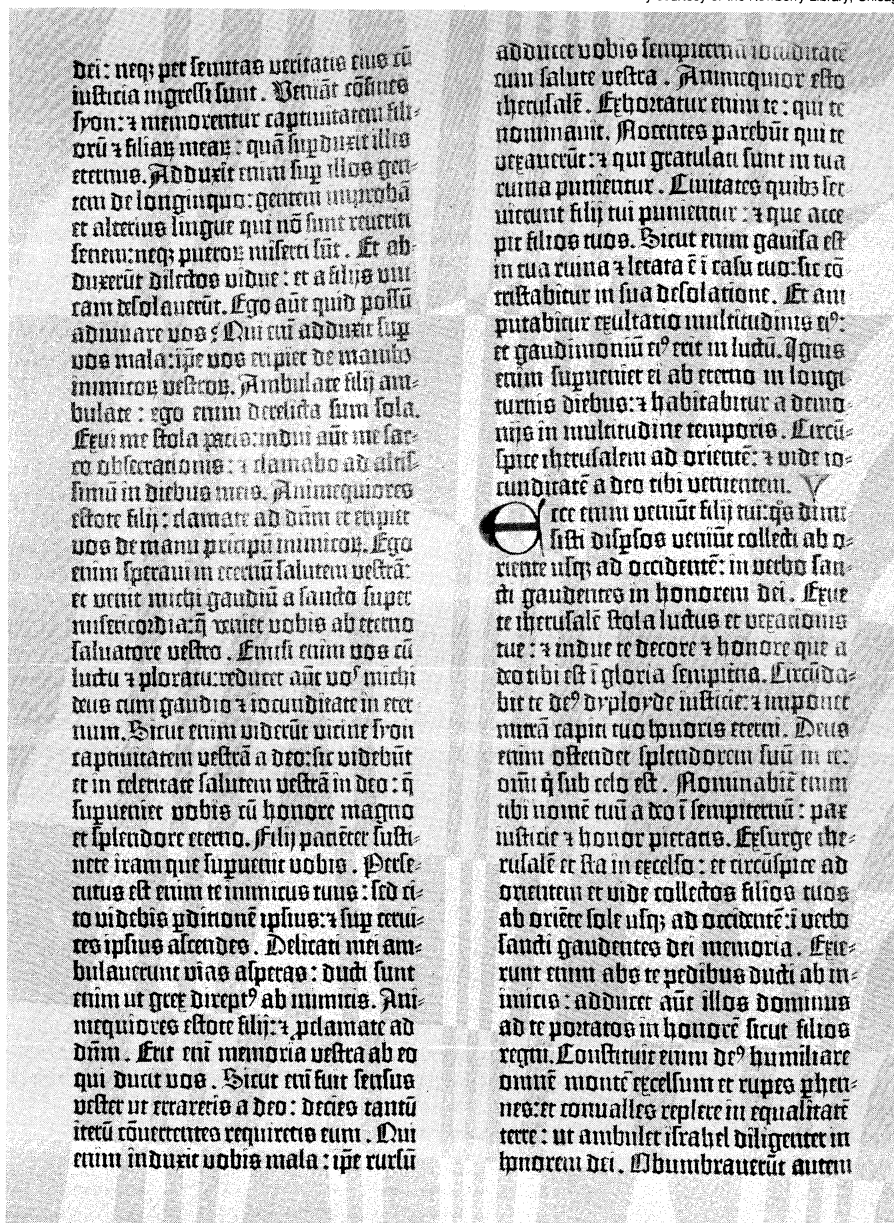

Figure 11: A page from the Gutenberg 42-line Bible, 1456.

established by the classical imperial capital letters of 1st-century Rome. Lowercase letters emerged only slowly, with their most vigorous development coming between the 6th and 8th centuries.

Charlemagne, in order to encourage standardization and discourage further experimentation, ordered his educational program for the Holy Roman Empire to be written in a script consisting of roman capitals and a specific form of minuscules (lowercase letters) known as Caroline. The uniformity thus achieved was short-lived. Under the impact of the national and regional styles of the scribes who worked with the alphabet, the letters—clear, simple, and somewhat broad by today's standards—were gradually compressed laterally, until, by the 11th century, the curves had been converted to points and angles, and the body of the letter had been made thinner while the strokes of which it was composed had been made thicker. This was black letter. By the 15th century it had completed its evolution into the formal, square-text Gothic letter.

It was this formal black letter that provided the first model for printer's type when printing was invented. It served well in Germany, but when printers in Italy, in part under the influence of the Humanist movement, turned to the printing of Latin texts, they found the pointed stateliness of the Gothic letter out of keeping with the spirit of Humanism. For these works, they went back in calligraphic history to a time when the text had been less open than the first Caroline alphabet but more rounded than the narrowed, blackened, and pointed Gothic that it had become. When the printers Konrad Sweynheim and Arnold Pannartz in Subiaco, Italy, brought out an edition of Cicero in 1465, they used a typeface that was explicitly intended to be, but was not, a printed copy of the text of Cicero's own time. To distinguish this type from the Gothic that was more "modern" in the 15th century, the Italians called it Antiqua. Known today as roman, it spread rapidly throughout western Europe except in Germany, where the Humanist movement was blocked by the counter-impulses of the Reformation. There, Gothic type was accepted almost as a national typeface until 1940, when its discontinuance was ordered.

It is notable that the majority of early printers continued for many years to use the Gothic type for non-Humanist texts, ecclesiastical writings, and works on law. In Spain, for example, Jacob Cromberger printed books in which the text was set in roman type and commentary on the text was set in Gothic.

Like the Gothic and roman, the third great family of types had its origins in the writings of the scribes. The italic and the Gothic Schwabacher, which serves as a kind of italic to Fraktur (as black letter is known in Germany), both had their genesis in the fast, informal, cursive, generally ligatured letters developed by chancery clerks to speed their work.

The early years. The 11th edition (1910–11) of *Encyclopædia Britannica*, not uniquely in its day, gave the honour of inventing the printing press to Laurens Coster of Haarlem. Later research in the 20th century, which has more or less become common consent, gives it to Johannes Gutenberg. Actually, the amount of invention involved in the development is open to argument. Certainly, there was in the air at the time much interest in an artificial method of reproducing calligraphic scripts, and books had already been printed from blocks; the techniques necessary to the punching of type and the making of matrices from which to cast it were known to the metalsmiths; paper was replacing vellum; and wine, oil, and cheese presses were readily available as adaptable models. It remained only for someone to combine what was in existence or clearly capable of creation.

Gutenberg began his experiments around 1440 and was ready to put his method to commercial use by 1450. In that year, facing the need (not unknown to later printers) for financing, he borrowed from Johann Fust. About 1452 he borrowed once more from Fust, who at that time became his partner. The only extant printing known for certain to be Gutenberg's is the so-called Forty-two-Line (the number of lines in each column) Bible, completed in 1456, the year after Fust had foreclosed on his partner

and turned the business over to his own future son-in-law, Peter Schöffer. Experts are generally agreed that the Bible displays a technical efficiency that was not substantially bettered before the 19th century. The Gothic type is majestic in appearance, medieval in feeling, and slightly less compressed and less pointed than other examples to appear shortly.

The Forty-two-Line Bible, like the other works of its day, had no title page, no page numbers, no innovations to distinguish it from the work of a manuscript copyist—this was presumably the way both Gutenberg and his customers wanted it.

Some five years later, also in Mainz and quite possibly from the re-established printshop of a refinanced Gutenberg, there appeared the *Catholicon*, notable among other reasons for its early use of a colophon, a tailpiece identifying the printer and place of printing, and for the slight condensation of its type—a move toward more economic use of space on the page and greater type variety in printing.

While not all early results of the printer's art were accepted in all quarters (in 1479 the cardinal who later became Pope Julius II ordered scribes to copy by hand a printed edition of Appian's *Civil Wars* as printed in 1472), they were generally well received by a basically conservative literate public that wanted reading matter in clear, legible, compact forms and in quantities greater than, and at prices less than, would have been possible for the copyists of the day. Within 15 years of the Forty-two-Line Bible, the printing press had been established in all of western Europe except Scandinavia.

When printing moved outward from Germany, it established itself first in Italy, where it was nurtured by German and German-trained craftsmen. Sweynheim and Pannartz (mentioned above) were the first printers in Italy. They opened their press in Subiaco in 1465 and almost immediately produced a Cicero (*De oratore*) printed in an early and interesting Antiqua type that would with time become roman. (This, rather than a type cut by another German, Adolf Rusch, in Strassburg in 1464, is generally credited with being the initial roman simply because to

most modern eyes its connection with the later face seems more clearly demonstrable, less tenuous. Indeed, more conservative theorists are not entirely convinced that even the Subiaco type was close enough to roman to be so called, except in the light of very informed hindsight.)

The brothers Johann and Wendelin von Speyer (sometimes called da Spira and sometimes of Spire) opened the first press in Venice in 1469 and, until Johann died in 1470, had a one-year monopoly on all printing in that city. They used a clear and legible typeface that represented another step toward the contemporary roman. Whether or not these earlier types were really roman, there would seem to be no reason for putting the production of the first clearly recognizable roman any later than the work of a Frenchman, Nicolas Jenson, who had learned printing in Germany and set up business in Venice at about the time the von Speyer monopoly ran out. An excellent idealization of the roman typeform, Jenson's type was cut for an edition of Cicero's *Epistolae ad Brutum*, printed in 1470. It has been described by most modern critics as an elegant cutting, and one—Stanley Morison—called it perhaps the most perfect roman face ever cut. The expertness of the work may be attributed to Jenson's training as a medalist before becoming a printer. It is notable that Jenson never used his roman type for the printing of ecclesiastical or legal works—for which various versions of black letter were to remain standard.

By all measurement the commanding figure in the typography of the late 15th century was Aldus Manutius, who also was in Venice. Manutius established his business around 1490 and, by 1495, was issuing a series of Greek texts which were notable more for their editorial authority than for their typographical excellence. Manutius was his own editor. His type designer and cutter was Francesco Griffo of Bologna, who made two major contributions: he drew on pre-Caroline scripts as the inspiration for a more authentic roman type that soon displaced the Jenson version; and, for what was to become the most important series of books in its time, he cut the first example of the cursive type now known as italic. It was, in the opinion of some critics, not a very good italic face, and it has been described as more a slanted roman than an italic. Nevertheless, it was the first of a new family of typefaces. Interestingly, it was at first a combination of new-face lowercase letters with roman uppercases. Equally interesting, the entire text of the Aldine books for which it was used were set in the new type. Not until 1550 did it become what it is today, a special-function type.

The books for which this new type—based on a cancellery (*cancellaresca*) cursive—was first cut consisted of a spectacularly successful series of Latin texts initiated in 1501, with Virgil's works as the initial release. The se-

ries was planned deliberately to interest a market of new readers—Renaissance men who were hardly interested in liturgical writings or Greek classics but who had instead the Humanist's passion for the Latin writers, with whom, somehow, they associated themselves. To fill that market, Manutius projected a series of books compact enough to be carried easily, set in type that was both economical and highly readable, edited with scrupulous accuracy, and sold as inexpensively as possible. With Griffo's cursive type as the base, the problems of size and readability were both solved; and, by increasing the normal print run to 1,000 copies per edition, the economics were rendered more favourable. They were, indeed, the first pocketbook best-sellers, and they were what would today be called an instant success. The volumes were sought after throughout Europe, as much or more for their scholarly authority as for the excellence of their typography. New volumes were issued every two months for the next five years, and Manutius early had the honour, but dubious pleasure, of being pirated.

The continuity implicit in the work of Manutius and others during this period destroys the value of that older approach to the history of typography that isolated everything printed from 1455 to 1500 as incunabula. The year 1500 did not provide a genuine dividing point, and later historians have generally marked the end of the first valid "period" in typographic history at around 1540, after which the importance of experiments with typefaces tended to be ignored, if not disapproved of.

In Germany and in Italy, the many centres of printing grew up for the most part in the centres of commerce. But in France—where printing was from the first a sponsored activity—there were only two such centres: Lyon, from which significant printing largely disappeared after the Inquisition; and Paris, where it was established in about

Venice

1470 by the rector and librarian of the Sorbonne, who invited three German printers to occupy university-owned property and who later supervised all of their work. The first book printed in France—a manual of instruction in Latin composition—was printed in an Antiqua type; and though there is some history of the use of a mixed Gothic until about 1520, printers in France from the start led the way to establishing the predominance of roman and italic. Important influences in effecting the almost exclusive use of roman type were the printers Simon de Colines, Henri and Robert Estienne, Geoffroy Tory, and the man who was the world's first commercial typesetter, Claude Garamond.

Perhaps because of the quasi-official nature of printing in France, French publishers early established and long maintained a reputation for careful and elegant work. Their volumes, sumptuous more often than not, were characterized by minute attention to almost extravagant detailing. Books of the hours, introduced by one Antoine Vérard, whose tastes ran to illustrated and heavily ornamented pages bound in deluxe editions, were important influences in these directions. It is estimated that Vérard published more than 200 of these editions in a little more than 25 years, beginning in 1485. They are precise, mannered, delicate, and elegant.

France:
the work
of Henri
Estienne

Henri Estienne established himself sometime around the beginning of the 16th century. A scholar, publisher, and printer, he gained his reputation as a publisher of classical literature. His edition of Galen's *De sectis medicorum* is an interesting early scientific work. Estienne, for a time, had as his adviser Geoffroy Tory, a scholar who later became a printer himself. Strongly influenced by Italian typography, Tory experimented with the use of floral ornamentation and ornate initial letters. In 1529 he wrote the first known treatise on the design of type, and in 1530 the title king's printer was created for him.

Tory, Colines, and a few others introduced the Aldine publishing methods into France. Colines designed italic, roman, and Greek type fonts, some of which were cut for him by his punch cutter, Garamond. In 1531 they created, for an edition of St. Augustine's *Sylvius*, the roman typeface to which all later so-called Garamond typefaces are traced.

Garamond quickly became a major force in making well-designed and superbly cut types available to printers, including those who generally could not have afforded the services of capable cutters. Though Garamond's efforts with a Greek font were not notably successful, his French versions of the roman type of Manutius and an italic type of Ludovico degli Arrighi (an official in the apostolic chancellery who soon after 1522 had produced specimen pages of a type based on the cursive letters of the chancellery clerks) were of commanding importance in European typography until the end of the 16th century. In 1540, after years of experimentation, Garamond perfected a roman type that, though it had affinities with the lettering of scribes, was designed unmistakably for mechanical reproduction. It was sharply drawn, graceful and of good contrast, and it soon displaced most other typefaces then in use. This typeface ushered in the new era in which, for the first time, the typographic book was more common than the manuscript one.

From the middle of the 16th until well into the 18th century, if not later, the most notable type designers in Europe were important more for their refinements on Garamond's modifications of earlier faces than for innovations of their own. One of the very few who attempted new departures in type design was Robert Granjon, who, in addition to fashioning some notable versions of Garamond types, also tried—with his type called *Civilité*—to create a fourth major typeface to be different from and stand alongside roman, italic, and Gothic. He envisioned it as a national type for the use of French printers. Reminiscent of a cursive Gothic, it ultimately found its only acceptance as a display face and was not utilized in the printing of books.

Printing was introduced into England near the beginning of the last quarter of the 15th century by an Englishman who had traveled widely throughout Europe to study the

art—William Caxton, who was a gentleman and dilettante. He studied printing, it is said, so that he would be able to print his own translation of a French work—Raoul Le Fèvre's *Recueil des histoires de Troye*—exactly as he wanted it to be printed. Setting up in business in Bruges in 1473, he issued *The Recuyell of the Historyes of Troye*, the first book printed in English, about 1474; in 1476 he returned to England and established a press in Westminster. The first dated book printed in England was the *Dictes and Sayenges of the Philosophers*, issued from his press in 1477. Printed in black-letter type of an almost startling blackness, its pages command attention by means of a contrast too pronounced to be comfortable to the reader. Caxton printed some 90 books—70 of them in English—before turning his business over to Wynkyn de Worde, his former assistant. De Worde used the first italic type in England in 1524.

Stanley Morison is authority for the statement that English typography in the first 100 years after the invention of printing was of a secondary order except for the work of Richard Pynson, a Norman who operated a press in London from 1490 to about 1530. Pynson, who used the first roman type in England in 1518, issued more than 400 works during his approximately 40 years of printing. Of these, a substantial number are legal handbooks and law codes, on the printing of which he enjoyed an effective monopoly.

Well before the end of the first century of typography, the printer had brought to the book the basic forms of nearly every element that he was to contribute. The styles of the three major typefaces had been formalized to the point at which little other than refinement remained to be added to them; most of the business and craft functions that were to mark the production of books down to the present had been identified and differentiated; the printed book had achieved an acceptance comparable to, and an audience far greater than, that of the manuscript volume; and publishing specialties had already emerged. Fully one-third of all of the books printed during the period of the incunabula—that is from the 1450s to 1500—were illustrated. The printing of music had become practical, and the practice of numbering the pages of a volume in sequence had been adopted.

The printer's mark, an identifying device, was used—though only briefly at first—in the typographic book from the very beginning. Almost as early, and probably more important, was the typographer's addition of the colophon, in which the printer-publisher recorded the place and date of publication, asserted his claim to credit for his role in the production of the work, advertised the merits of the enterprise, and, on occasion, attempted to protect his property from the depredations of rival printer-publishers. Indeed, Caxton turned the colophon into a short essay in which he included, in addition to the normal ele-

Maturation
of the
printed
book

ments, an editor's preface and a dedication. Whether or not it is accurate to assert that the title page—the major nonmanuscript feature of the typographic book—emerged from the colophon, it is a fact that the title page took over some of the content of the colophon, which, however, continued to exist.

The first title page was probably used by Gutenberg's successor, Peter Schöffer, in 1463 on a papal bull. It was Schöffer's only known use of the device, and, like the other early versions that followed, it was really—in today's terms—a half title. The full title page did not appear until 1476, when one Erhard Ratdolt in Venice used it on an astronomical and astrological calendar. The device was well established by the end of the incunabula period. Continuing the tradition of relative anonymity of authorship of the manuscript books, the earliest pages never, and later ones only seldom, revealed the author of the work. The title page, apparently, was meant to provide, first, a protective cover for the text within and, second, an opportunity for advertising for the publisher-printer.

The middle years. The first really notable roman type had been cut by Jenson for a text by Cicero in 1470. It had been replaced in popularity and importance by the romans that Francesco Griffo cut for Manutius in the late 15th century. The first italic had been a Griffo design introduced by Manutius in his pocket editions early in the 16th century. These two faces had, in turn, been displaced in European typography by letters designed in the mid-16th century by Garamond in France: a roman based on Griffo's cutting and an italic based on a form put forth by Ludovico degli Arrighi. The Garamond versions of these faces were to be of prime importance in European typographical work until the end of the 16th century, during which time so many adaptations of them were produced that "Garamond type" came to be used as a generic term.

By the end of the 16th century, typography in Europe had, generally speaking, deteriorated in vigour and quality. In France, the first comeback step was taken in 1640 by Louis XIII, who, under the influence of Cardinal de Richelieu, established the Imprimerie Royale at the Louvre. In 1692 Louis XIV ordered the creation of a commission charged with developing the design of a new type to be composed of letters arrived at on "scientific" principles. The commission, whose deliberations were fully recorded, worked mathematically, drawing and redrawing each letter on squares divided into 2,304 equal parts. The approach was far removed from the style of the calligraphers, whose work had provided models for all of the important alphabets until then. It is probably fortunate that Philippe Grandjean, who was called on to do the punch cutting, did not feel himself to be under constraint to carry out his own work with the mathematical precision of the commission members who had drawn the patterns. Using the basic designs merely as suggestive, he cut a type that almost immediately drove the Garamond style from its favoured position. Known as Romain du Roi, it was used first (1702) in one of the *médaille* books that were then popular as commemorative devices. As might be expected, the type is notable for its regularity and precision; there is a good, though not exaggerated, contrast between the thick and thin strokes, and the addition of flat serifs on the lowercase letters was effective.

Though intended for the exclusive use of the Imprimerie Royale, the new roman was immediately copied by other designers, one of the most active of whom was the founder Pierre-Simon Fournier, who is also remembered for his creation of a wide range of printers' devices that could be combined into festoons, borders, and headpieces and tailpieces for the heavily ornamented *éditions de luxe* that were popular in France then and that were to remain so until the Revolution.

It is reasonable to say—as did designer-theorist William Morris—that the Romain du Roi replaced the calligrapher with the engineer as a typographical influence. In general, the calligrapher was not to be reintroduced until Morris himself performed the operation as an ideological matter in the 19th century. Before that could happen, typography was to undergo further modifications under the influence of three great designers, two in England and one in Italy.

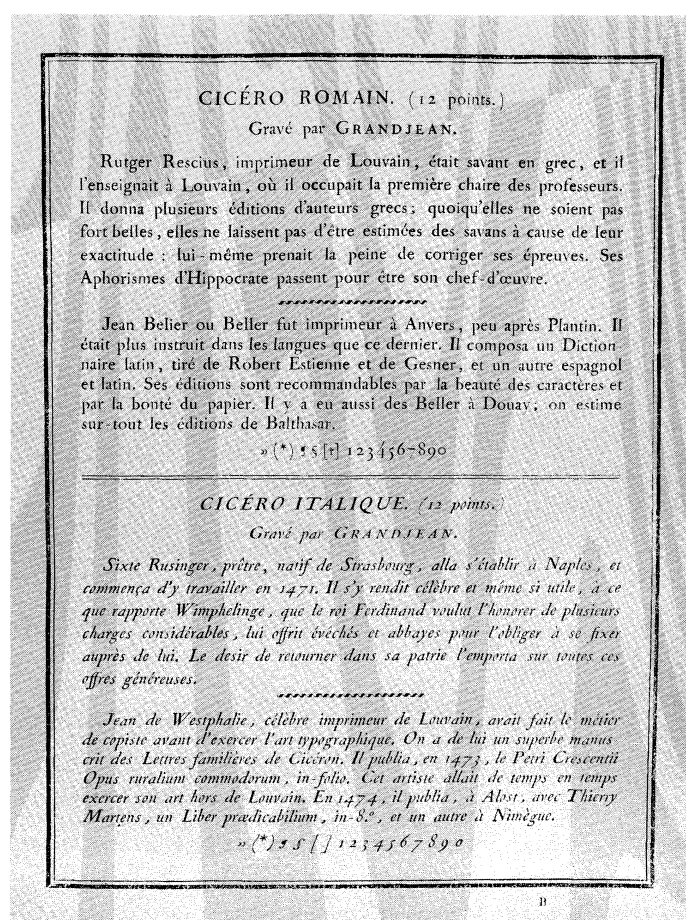

Figure 15: Philippe Grandjean's Romain du Roi type, from the specimen book of the Imprimerie Royale.

William Caslon, who issued his first type-specimen sheet in 1734, made a number of refinements of the Garamond style and created faces that have become traditional and are still much in use. Caslon's refinement of the Garamond version of the Aldine roman was essentially straightforward and unmannered except for a slightly pronounced contrast between the thin strokes and the thick ones. The letters were graceful and well balanced. Serifs were bracketed (see above). They were well cut, and they made up into type blocks that were comfortable to read.

The type won wide acceptance and became well known in the American colonies, where it was introduced by Benjamin Franklin. It was the type in which a Baltimore printer issued the official copies of the United States Declaration of Independence.

Even more significant changes in typographical fashions were achieved about a quarter of a century later by John Baskerville in Birmingham. Baskerville, who taught calligraphy, introduced further variations in the spirit of Caslon. His letters suggest a greater concern for aesthetics. Their feeling of gracefulness is more pronounced. They were more original than Caslon's. His roman letters were open and legible; his italics tended to be spidery and quite pinched. Open and quite rounded, they are, perhaps, more self-consciously pleasing to the eye. As a book designer, Baskerville combined his new faces with exaggerated page margins and relatively wide spacings between letters to suggest new directions in style. By the use of special papers, improved press methods, and special inks, he achieved an effect of almost glaring contrast, an effect heightened by his preference for emphasizing the typographer rather than the illustrator or the engraver. Though his acknowledged masterpiece, a Cambridge Bible, was not printed until 1763, he was an important influence on English and European typography almost from the first printing of his Virgil in 1757.

In Italy, Giambattista Bodoni enthusiastically took up the principle of page design as worked out by Baskerville, though not his typefaces. Further modifying the Aldine roman of Garamond, he mechanically varied the difference between the thick and thin strokes of his letters to achieve the ultimate contrast possible in that direction. His letters are rather narrower than those of either Caslon or Baskerville. He exaggerated his thick lines and reduced the thin ones almost—it seems at times—to the point of disappearance. Like Baskerville, he used opulent papers and inks blended for special brilliance. His pages were not easy to read, but he became, in the words of Stanley Morison, the typographical idol of the man of taste, and his "plain"—though deliberately and artfully contrived—designs were an important factor in the decline in importance of the *édition de luxe* and its replacement by works more austere in feeling, more modern even to today's eyes. He set what was, in general, to be the standard book style of the world until the appearance of William Morris. (W.E.P.)

Type and book design since the 19th century. Two late-19th-century developments—one technological, the other aesthetic—profoundly changed the course of book typography and design. The advent of mechanical type composition in the 1880s (the so-called Linotype machine was patented by Ottmar Mergenthaler, a German inventor, in 1884; the Monotype, by an American, Tolbert Lanston, in 1887) had much to do with the look of the 20th century book. The Arts and Crafts Movement, whose leader in typography as in other aspects was William Morris, had an equally great influence on the quality of modern book printing.

The private-press movement. The Industrial Revolution changed the course of printing not only by mechanizing a handicraft but also by greatly increasing the market for its wares. Inventors in the 19th century, in order to produce enough reading matter for a constantly growing and ever more literate population, had to solve a series of problems in paper production, composition, printing, and binding. The solution that most affected the appearance of the book was mechanical composition; the new composing machines imposed new limitations not only on type design but also on the number and kinds of faces available, since the money required to buy a new typeface was enough to inhibit printers from stocking faces of slight utility. As a result, Victorian exuberance of design, which

might use a dozen or more typefaces within a single book, was effectively curbed.

It is paradoxical that what became known as the Arts and Crafts Movement, with its roots in the romantic Gothicism propounded by the critic John Ruskin and by Morris, should have had a considerable influence on modern industrial design, including that of the book. An Englishman, William Morris was a fervent Socialist who believed that the Industrial Revolution had killed man's joy in his work and that mechanization, by destroying handicraft, had brought ugliness with it. Morris was above all a decorator; his work in the decorative arts had added great lustre to the fame he had already achieved as a writer when, partly as a result of dissatisfaction with the editions

of his own works, he decided to establish a press. In 1888 Morris attended a lecture given by the printer Emery (later Sir Emery) Walker and was entranced by Walker's lantern slides of early types, greatly enlarged. He proposed to Walker that they cut a new font of type that would recapture the strength and beauty of the early letters, based upon medieval calligraphy. The Kelmscott Press, in its brief life (1891–96), printed 52 books that exemplified Morris' standards of perfect workmanship. A firm believer that a return to the past would produce a better society, he commissioned handmade paper like that used in the 15th century, had new, blacker inks made, and used the handpress and hand binding exclusively; a few copies of each title were also printed on vellum. With Walker, he designed three types: a roman, based upon that of Nicolas Jenson, and two Gothics after German models; all were cut and cast by hand. Woodcut initials and borders were engraved to his own design, and wood-block illustrations were cut from drawings by Edward Burne-Jones and other of his friends.

The Kelmscott Press's major book was its *Chaucer*, finished in 1896, a sumptuous folio whose rich decorations and strong black pages are reminiscent of the German incunabula Morris admired. A table book, meant to be looked at rather than read, it is one of the most influential books in the history of printing—a revolutionary book, despite its anachronisms, which caused a whole generation of printers and designers to be dissatisfied with the books they saw about them and to attempt to improve upon the badly made, weakly designed books that were common in the late Victorian age.

Prolifera-
tion of
private
presses

Private presses on the Morris model proliferated in England, on the Continent—especially in Germany and the Scandinavian countries—and in the United States. The best of these, notably the Doves and Ashendene presses in England and the Bremer and Cranach presses in Germany, published books of great style and strength. There were also poorer imitations, as the Roycroft Press in the United States.

The most influential of the private presses was the Doves Press, established in 1900 by T.J. Cobden-Sanderson and Emery Walker. Walker, who was one of the prime movers in fine printing for over half a century, also played an important role in creating type for the Ashendene and Cranach presses. Cobden-Sanderson was one of Morris' circle at Kelmscott House and had become a bookbinder at the suggestion of Mrs. Morris. The bindings executed at his Doves Bindery are notable for their excellent craftsmanship and their clear, simple design, which often used Art Nouveau motifs (see below). The Doves Press books, which were printed in a type based on Nicolas Jenson's 15th-century roman, were austere in their typography, eschewing all decoration and illustration and relying for their effect on the beauty of their type, spacing, and presswork. Occasionally a second colour, a splendid red, was used, and superbly drawn initials adorned many of the 50-odd books. A five-volume Doves Bible, issued between 1903 and 1905, is among the monuments of fine bookmaking, as well as one of the most influential modern books, a

result of its virility, purity of design, and perfection in craftsmanship.

The third great English private press, the Ashendene, was conducted by C.H. St. John Hornby, a partner in the English booksellers W.H. Smith and Son. Hornby in 1900 met Emery Walker and Sydney Cockerell (Morris' secretary at the Kelmscott Press), who encouraged and instructed him and helped in devising two types for his own use: Subiaco, based upon Sweynheim's and Pannartz' semiroman of the 1460s, and Ptolemy, based upon a late 15th-century German model. The Ashendene Press books, like those of Morris, were often illustrated with wood engravings, and many had coloured initials.

In Germany Morris' closest counterpart was Rudolf Koch, who gathered around himself at Offenbach, where he taught at the Arts and Crafts School and designed types for the Klingspor foundry, a community of craftsmen who painted, worked in metal, wood, and stone, printed, and wrote. Above all a consummate penman, Koch made the written word the basis of his designs in any medium, whether tapestry or woodcut. A devout Christian, Koch, like the medieval craftsmen he admired, saw the Gothic style as a supreme manifestation of religious spirit; he was no mere imitator but an artist who freely reinterpreted in his types and books the traditional Fraktur type of Germany. Koch also created a number of modern types, among them sans serifs and romans.

Cobden-Sanderson's influence, however, far exceeded that of Morris in Germany. The most important of the German private presses, the Bremer Presse (1911–39), conducted by Willy Wiegand, like the Doves Press, rejected ornament (except for initials) and relied upon carefully chosen types and painstaking presswork to make its effect. The most cosmopolitan of the German presses was the Cranach, conducted at Weimar by Count Harry Kessler. It produced editions of the classics and of German and English literature illustrated by artists such as Aristide Maillol, Eric Gill, and Gordon Craig and printed with types by Emery Walker and Edward Johnston on paper made by hand in France. Kessler's books did not attempt to imitate medieval or Renaissance models; they sought to create—using the same methods as the early printers—books modern or, rather, timeless, in spirit.

Influence
of Cobden-
Sanderson
in
Germany

The most notable figures of the private-press movement in The Netherlands were S.H. de Roos and Jan van Krimpen. De Roos, like Morris a utopian Socialist, was an industrial designer who hoped to create a better society by improving the appearance of ordinary utilitarian objects. His first book, *Kunst en Maatschappij* (1903), was, significantly, a collection of Morris' essays in translation. De Roos's decorative style became simple and less florid under the influence of Cobden-Sanderson, whose work he greatly admired, although his ideals remained those of the Arts and Crafts Movement. Unlike Morris and Cobden-Sanderson, de Roos was a book designer, designing books for others, rather than a printer—one of the earliest of the new school of typographers, who provided layouts for the publisher or printer, specifying type, format, and overall design. Increasingly, as technology became more complex

and shops more highly specialized and automated, design became more a profession; the typographer, trained in industrial design or graphic arts, succeeded the printer or the publisher in deciding how a book should look. De Roos, who drew a number of typefaces for the Type-foundry Amsterdam, designed books for the Zilverdistel, the Meidoorn, and other private presses, as well as for trade publishers.

Jan van Krimpen used little decoration in his work, which achieved its effect through a classic clarity of style and impeccable printing. His books, for the Enschedé firm for which he worked, for private presses, or for trade publishers, attempted always to interpret the author's meaning as clearly as possible, to reflect it rather than to enhance it. Krimpen also designed a number of typefaces, all of which show his earlier study of calligraphy. Among them are Lutetia, a modern roman and italic of great distinction; Romulus, a family of text types that includes a sloped roman letter instead of the conventional italic; and Cancellaresca Bastarda, an italic notable for its great number of attractive decorative capitals, ligatures, and other swash

(i.e., with strokes ending in flourishes) letters, elegant in appearance.

Another typographer working in the classic mode, Giovanni Mardersteig, spent most of his creative life in Italy, though he was born and trained in Germany. His Officina Bodoni utilized Bodoni's types to print the collected works of D'Annunzio. Mardersteig not only used the handpress for limited editions (usually on handmade Italian papers) that rival 15th-century printing in their beauty of spacing and presswork, but also supervised at the Stamperia Valdònega in Verona long-run editions on high-speed presses, which are likewise remarkable for their craftsmanship. In addition, he designed several typefaces, among them Pacioli, Griffo, Zeno, and Dante.

The Art Nouveau movement was an international style, expressed in the consciously archaic types of Grasset in France; in posters and magazine covers by artist Will Bradley in the United States; and in initials and decorations by Henry van de Velde in Belgium and Germany. Van de Velde, the leading spokesman for the movement as well as one of its most skilled practitioners, in his essay

"Déblaiement d'art" (1892) advocated the development of a new art, one that would be both vital and moral, like the great decorative arts of the past, but that would use contemporary modes. For a reprint of the essay, he designed a series of initials and typographic ornaments that express the characteristics of the style: decoration based upon natural forms; pages whose typography and decoration blend to make overall patterns; and a richness of texture reminiscent of illuminated manuscripts. Van de Velde's most important book was an edition of Nietzsche's *Also sprach Zarathustra*, which he designed for the Insel Verlag and had printed by the Drugulin-Press of Leipzig and for which he created a series of ornaments printed in gold, as well as endpapers, title page, and binding; a small folio, conceived as an architectonic whole rather than a series of unrelated openings, it is a striking, if dated, volume.

Mechanical composition. The private-press movement did much to raise the standards of the ordinary trade book. Small, independent publishers who wished to make a mark not only through the distinction of their titles but also through the distinctiveness of their house styles acted as a bridge between the deluxe bibliophilic editions and ordinary books. Companies such as those of John Lane and Elkin Mathews, who published Oscar Wilde and the periodical *The Yellow Book*; J.M. Dent, who commissioned Aubrey Beardsley to illustrate Malory and who used Kelmscott-inspired endpapers for his Everyman's Library; Stone and Kimball of Chicago and Thomas Mosher of Maine, who issued small, readable editions of avant-garde writers with Art Nouveau bindings and decorated title pages; the Insel Verlag in Germany, with millions of inexpensive yet well-printed and designed pocket books—these and their many colleagues brought within the reach of the ordinary book buyer mass-produced books whose appearance, if not their method of manufacture, had been profoundly altered and improved by the Arts and Crafts Movement.

During the early years of the 20th century, more and more printers installed composing machines (see *Printing* above). The early Linotype and Monotype faces, like the foundry faces they imitated, were weak and poor. The first significant face cut especially for mechanical composition appeared in 1912, when a new face based upon the old-style types of Caslon was produced for *The Imprint*, a short-lived periodical for the printing trade published by Gerard Meynell of the Westminster Press in London. Its contributors included Edward Johnston, who not only wrote for the magazine but designed its calligraphic masthead; and Stanley Morison, who began his career as printing historian and typographer on its staff. Other Monotype faces cut at this time included Plantin, based upon the types of the great Antwerp printer, and Caslon; the latter was made at the instigation of George Bernard Shaw's publishers, since Shaw, who had strong views on typography, would not allow any other face for his books. World War I, however, stopped any further development of types for the composing machines.

In America the generation of designers who had begun as disciples of Morris soon began to develop their own styles. Among the most important were D.B. Updike, Bruce Rogers, F.W. Goudy, and W.A. Dwiggins.

Daniel Berkeley Updike opened the Merrymount Press in Boston in 1893. His books, most of which he designed himself, are noteworthy for the clarity of their organization, their easy readability, and their excellent workmanship, based upon the use of a few carefully selected typefaces and immaculate presswork. Updike stocked only types that met the twin criteria of economy in use and beauty of design. His books, whether a complex folio such as the *Book of Common Prayer* (1930), which is considered by many to be his masterpiece, or the small and amiable *Compleat Angler* (1928), are both functional and pleasing to the eye.

Bruce Rogers was a typographer, trained as an artist, who had the faculty of drawing the best from the printers with whom he worked. His greatest book, a monumental Oxford Lectern Bible of 1935, is the noblest edition of the Bible ever issued in English; his smaller and less ambitious efforts, often decorated with the typographic ornament at which he was a master, possess enormous wit and charm. His one type design, Centaur, which was based upon Jenson, is among the most successful modern adaptations of an early roman, although it is too elegant for frequent use.

Frederic William Goudy, who was the most prolific American type designer, created more than 100 faces during a long career as a printer, editor, and typographer. In 1908 he began a long association with the Lanston Monotype Corporation, for which he did much of his best work. Among his types were Forum and Trajan, which were based upon the roman capital letters inscribed on Trajan's Column; Goudy Modern, his most successful text face; and a number of black-letter and display faces. Goudy edited two journals, *Typographica* and *Ars Typographica*, in which he expounded his theories of design; he also wrote a number of books, among them *Elements of Lettering* and *The Alphabet*.

Education: To prepare us for complete
on which education has to discharge. H
on is properly to draw forth, and imple

Figure 21: Goudy's Old Style typeface.

William Addison Dwiggins, a student of Goudy, was long associated with the publishing firm of Alfred A. Knopf, whose house style he helped to establish. In hundreds of volumes of trade books he designed, typography was taken seriously (each book carried a brief colophon on the history of the type employed); there was an attempt to use contemporary typographic decoration; and the bindings, using designs made up of repeated decorative units like early printers' fleurons, were extremely successful. Dwiggins designed a number of typefaces for the Linotype, two of which, Electra and Caledonia, have had wide use in American bookmaking. In the U.S., unlike England and the Continent, printers have relied far more upon Linotype than Monotype for book composition.

English typography, like that everywhere, marked time during World War I but made remarkable progress soon after. A new generation of typographers, inspired by Morris' ideals of quality but at the same time aware of the need to adapt them to the new mass-production techniques, had begun to make their names. Foremost among these was Stanley Morison, who, after a year's apprenticeship with *The Imprint*, became a typographer on the staff of Burns and Oates, where he worked on a wide variety of books, among them the liturgical texts in which the firm specialized; here he began to develop the rationalistic approach to typographic design that characterizes the English school. Morison demanded that typography be functional: the task of the book and the newspaper designer was to transmit the author's text clearly, and the task of the advertising and display designer was to command attention. In 1922 Morison became typographic adviser to the Monotype Corporation and instituted a program of

Early
Linotype
and
Monotype
faces

ADVERTISEMENT

This pamphlet is the announcement of a new Linotype type face to be called "Electra," cut from designs drawn for The Mergenthaler Linotype Company by W. A. Dwiggins. The face—at this stage completed in twelve point, roman and italic—provides a new type texture for book-page composition. In the larger sizes now in preparation it will furnish the printer with a new note in advertising typography.

The face, as may be seen from this specimen, falls within the "modern" family of type styles, but is

cutting for the composing machine a repertory of types culled from the best faces of the past, to which were added a number of contemporary faces designed for modern needs. He had prepared himself for the task by a strenuous course of self-education in paleography and calligraphy, in order to understand the written hands that the early types imitated, and in the history of printing design itself. In 1923 he joined Oliver Simon in publishing *The Fleuron*, a journal of printing history and design in which he published a number of important articles on calligraphy and typography.

Morison's
work for
Cambridge
University
Press

In 1925 Morison was made typographic adviser to the Cambridge University Press, whose printer, Walter Lewis, had begun a complete reform of its typographic resources. Cambridge stocked most of the types Morison commissioned for Monotype and demonstrated by their intelligent use that mechanical composition could be used to produce books at once handsome and functional. Among these types were Garamond, based upon a 17th-century French letter (see above); Bembo, after an Aldine roman; Centaur, an adaption of Rogers' foundry face; and Baskerville and Bell, based upon English models. Italics included Arrighi, a version of the letter used by the 16th-century papal writing master and printer (see above). Among the modern faces whose design Morison supervised were Eric Gill's Sans Serif, which enjoyed a wide vogue in advertising and avant-garde book typography; Gill's Perpetua, based upon his stonecut letters; and Times New Roman, designed by Morison himself for *The Times* (London), whose staff he joined in 1930. The last has been called the most successful type design of the 20th century, a result of its economy and legibility when used on high-speed presses.

Francis Meynell was another who demonstrated that mechanical composition and printing, if properly used, could produce aesthetically satisfying books. The books of Meynell's Nonesuch Press, which were usually limited editions of the classics reflecting his own catholic and excellent literary taste, are marked by restrained design, fine papers, and careful presswork. More varied and original than those of the earlier private presses, they were printed not by the proprietor but by large, mechanized shops. Meynell's trade books, published under the same imprint, demonstrated that well-designed and manufactured books

Golo Mann, professor and writer of history, was born in 1909 in Munich, Germany, the son of the famous novelist, Thomas Mann. He received his Ph.D. from Heidelberg University in 1932 and, leaving Germany the following year, lectured at French universities until 1937. He then edited the literary review "Mass und Wert" in Zurich, Switzerland, and in the early 1940's moved to the United States. He remained in this country until 1958 and during this time taught at Olivet Col-

need not be costly; the Nonesuch one-volume editions of English classical authors were inexpensive, handsome, and readable.

The most influential modern publisher of English low-priced books, however, was Allen Lane, whose Penguin books, established in 1935 and inspired by such continental publishers as Insel Verlag and Albatross, proved that a well-designed series of inexpensive paperbacks, both worthwhile reprints and new titles, could succeed both commercially and intellectually. They did much to bring about the paperback revolution that swept both the Continent and the United States in the period that followed World War II.

German typography from World War I until the advent of Adolf Hitler was greatly influenced by the Bauhaus, which stressed the graphic arts; its books, which were heavily

Influence
of the
Bauhaus

Figure 23: Catalog cover by El Lissitzky, in the Bauhaus Asymmetric style.

ly illustrated, broke away from traditionally symmetrical layouts, in which pictures were inserted into a rigid framework of text, and strove instead for freer arrangements, usually asymmetrical, in which the type supported the illustrations. The attempt was to create graphic patterns on the page and to enhance the reader's consciousness of the illustrations. Many of the Bauhaus faculty were architects and industrial designers, whose principles demanded that the types they used, like the buildings and machines they designed, be sharp and unornamented, symbolic of a machine-dominated society. Their favourite types were sans serifs, such as Gill's Sans Serif and Paul Renner's Futura. When the Nazis dispersed the Bauhaus group, its style became truly international. It has since lost favour among book designers, except for art and architectural books, partly because sans serif types and asymmetrical layout proved less legible than traditional modes and partly because of its rigid limitations.

Other between-war styles, closely linked to literary or artistic movements that affected book design, were Dadaism and Surrealism. The Dadaists' pamphlets, posters, and books employed free, abstract layout, a great mixture of type sizes and faces, and an attempt to create mood through typography. Surrealist writers such as Guillaume Apollinaire and André Breton often collaborated in the design of their own books, attempting to make the typography of their works reflect its mood.

In France, especially, the production of books intended to be works of art in their own right was dominated by painters and sculptors. Publishers such as Ambroise Vollard commissioned members of the School of Paris, among them Braque, Matisse, Bonnard, and Picasso, to illustrate books in which the illustrator worked closely with highly skilled craftsmen to create colourful, original, limited editions, which, while they sometimes may fail as readable books, achieve admirable success as visual decoration.

During the 20th century, styles in book design, as in all the arts, fine or applied, have become increasingly international. Styles born in one country spread throughout the world and die through overuse at a dizzying rate. As a consequence it has become increasingly difficult to distinguish truly individual or national styles—books, magazines, clothes, paintings, music, regardless of country of origin, all resemble one another far more than they differ. (See also WRITING.) (J.M.Ws.)

Photoengraving

Engraving is the broad term describing the procedure used in making printing plates, in which printing and nonprinting areas are distinguished by their height with respect to the general plane of the surface, the artistic decoration created by mechanically incising a design into a surface, and the creation of original works of art by tooling or etching an image into the surface of a metal (or plastic) plate and transferring the resultant image to paper. For detailed information on these last two subjects, see PRINTMAKING. This section is limited to consideration of the procedures whereby a printing surface useful in the production of multiple ink-on-paper images is produced.

The term photoengraving is correctly applied to the procedures discussed here, since the use of light energy, as involved in photographic processes, is essential. A distinction must be made between a relief (or letterpress) printing plate, in which the ink-carrying (or image-bearing) surface coincides with the general level of the plate surface, with nonimage portions cut below the surface, and intaglio (or gravure) printing surfaces, in which the ink-carrying image elements are incised into the plate surface. In letterpress printing, a uniform film of ink is distributed over the surface of the plate and transferred from the individual image elements to the receiving paper surface. In intaglio printing, the plate is flooded with a low-viscosity (thin) ink, then wiped with a blade (doctor blade) to remove any ink adhering to the surface. The doctoring action leaves the incised intaglio image filled with ink; later, as paper is brought into contact with this image and pressure is applied, surface-tension and capillary-action forces cause the ink to transfer from the plate to the paper.

HISTORY OF PHOTOENGRAVING

The earliest engraved printing units were wood engravings, in which the nonimage areas of an illustration were removed by carving them from the surface of a flat wood block. The oldest known illustration printed from a wooden block was a Buddhist scroll discovered in 1866, in Korea. While the dating of the print is not exact, it is believed to have been prepared about AD 750. The Chinese *Diamond Sutra*, dated 868, incorporates a woodcut title page and text that includes numerous woodcut images.

From these 8th- and 9th-century dates, it is clear that the use of woodcuts (images cut into a surface parallel to the wood grain) and wood-block engravings (images incised into the end grain of an assembled block) antedates the invention of movable type. The earliest extant example of a European print from a wood engraving to which a reliable date may be attributed is a print entitled "St. Christopher," dated 1423, discovered in the library of the Carthusian monastery in Buxheim, Germany. Another authenticated example of 15th-century wood-block printing is the "Apocalypse of St. John," printed in 1450, after a 14th-century manuscript.

Early etched plates. Plates engraved in wood continued to find use in printing application through the late-medieval and early-modern periods. Plates made of copper, pewter, and other metals were also produced, by a process in which an image in wax or bitumen was drawn on, or transferred to, the surface of the plate and nonimage areas removed by action of appropriate acids.

Preparation of intaglio printing plates by coating a metal plate with an etchant-resistant substance (ground) such as wax, bitumen, or shellac, scratching through this substance (ground) to expose the plate surface, then etching in acids is also a late-medieval European development. This process, however, developed as a medium of artistic expression, rather than a technique for the mass production of printed images.

The first experimental application of light-sensitive materials to the production of printing surfaces was made by Joseph Nicéphore Niepce, of France, an early researcher in lithography who began his experiments in about 1813. He is credited with having produced the first permanent photograph. In 1826 Niepce coated a pewter or copper plate with a photosensitive asphaltum and exposed the surface to bright sunlight through an etching of a portrait, which served as a positive image. Sunlight passing through the background of the etching hardened the asphaltum, while the protected areas, under the inked portion of the etching, were developed in oil of lavender and white petroleum to create an image in exposed metal. This image was then etched into the plate, and from the intaglio image, prints were made on a copperplate press.

Though this basic discovery was of historical importance, it did not bring about the immediate use of photoengraved images for printing, and many other attempts to produce engravings by exploitation of the photosensitivity of various natural compounds were made by experimenters in Europe and the United States. The origin of the modern photoengraving process rests, however, on the report (1839) by a Scottish scientist and inventor, Mungo Ponton, of the light-sensitive properties of certain chromium compounds. But Ponton, who demonstrated the chemical change that occurs when glue containing a compound of chromium is acted upon by light, was not concerned with preparation of printing plates, and it remained for William Henry Fox Talbot, an English pioneer in photography, to propose the use of chromium-treated colloids such as albumin as an etchant-resistant for preparation of intaglio printing surfaces.

Early 19th-century work on production of chemically etched letterpress printing plates antedated, in many instances, the invention of photography. A researcher in Paris developed a process for the preparation of engravings on zinc. His work involved transfer of an image to the zinc plate by mechanical means, using ink or wax, and the removal of the nonprinting areas in a series of etching operations, each of which involved applying a coating of ink to the sidewalls of the etched lines by means of resilient rollers. The ink served to protect the lines of the

Early use

sensitive
materials

Letter-
press and
intaglio
printing

engraving from the action of the etching acid, so that the printing area was not reduced.

Wet-collodion photography. The introduction in 1851 of a so-called wet-collodion process for photography provided a means for producing a photographic negative as the basic element in the preparation of engravings. In this process, a glass plate is coated with an alcohol-ether solution of collodion (cellulose nitrate) containing potassium iodide. While still wet, the plate is immersed in a silver nitrate solution, producing light-sensitive silver iodide in the collodion layer. Without drying the film of collodion, the plate is placed in the camera and exposed, followed by development in ferrous sulfate solution and chemical "intensification" to produce an image of greater opacity. The image consists of deposits of metallic silver and other heavy metals imbedded in the collodion layer.

This photographic process also provided a method of stripping the photographic image from the glass plate, permitting assembly of a number of images for plate making, and also making possible the geometric reversal of the image needed in letterpress plate making to produce a right-reading print on paper. The wet-collodion process was used extensively in engraving until the 1930s, when it was gradually replaced by commercially coated stripping films.

The halftone process. Since the letterpress printing process provides a uniform coating of ink on all printing elements, no provision can be made for reproducing tones intermediate between black and white by varying the thickness of the ink film laid down by the press. The production of shades of gray was then the role of the halftone process, in which the image is broken up into dots, and variations of gray tones are obtained by varying the size of the dots, thus controlling the amount of ink laid down in a given area.

The feasibility of the method was demonstrated in about 1850, when a halftone image was produced by photography through a screen of loosely woven fabric. The screen was placed some distance forward of the plane of the receiving photographic surface (film or plate) and had the effect of breaking the gray tones of the subject into dots of varying sizes, through a combination of geometric and diffraction effects involving the spacing of screen from the image surface, the size of the openings in the screen, distance from lens to image plane, and the size of the aperture in the lens. It was obvious that a screen designed for this use could consist of a pattern on a glass or other firm, transparent surface.

A French patent of 1857 described a screen with parallel lines scratched in a single direction in an opaque background. As early as 1869 an image with a crossline halftone was produced in the *Canadian Illustrated News*. Later, in 1882, a crossline halftone was produced using a single-direction screen, by making half the exposure with the screen in one position and half with the screen rotated a quarter turn. Two brothers, Max and Louis Levy, of Philadelphia, in 1890 produced the first commercial halftone screens. The Levy brothers coated selected plates of high-quality optical glass with a lacquer, in which parallel lines were cut. The ruled lines were then etched with hydrofluoric acid and filled with an opaque material. Two such plates were cemented face to face with the lines at 90°, the edges sealed, and the assembly bound in a metal frame.

There has been no significant change in the methods of making halftone screens since those developed by the Levy brothers. Other screen patterns, including triangular dot patterns and the grained (mezzograph) screen, have been proposed, but none has produced consistently satisfactory results. For special effects, screens having straight or wavy line patterns and screens that produce a pattern of circles, concentric about a point that is chosen to be the focal point of the readers' interest, are in use. These screens are generally produced photographically from hand- or machine-drawn patterns and are used in the form of contact screens.

Basis for selection of screen ruling. Halftone screens may be obtained with line frequencies of 50 to 400 lines per inch (one inch equals 25.4 millimetres). The coarser screens are used for reproductions printed on coarse pa-

pers, the fine screens for higher quality reproductions on highly finished and coated papers. Screens in the 50–85-line frequency range are used primarily in newspaper illustration, while 100-, 110-, and 120-line halftones are suitable for highly polished papers and for some magazines, where single-colour and some multicolor work is involved. The 120-, 133-, and 150-lines-per-inch screens are generally used for colour illustrations in magazines and books printed on coated papers, when picture detail is important. Screens of 175 and more lines per inch are seldom used in letterpress printing, since the inks tend to fill the screens, causing difficulties in the press run. Such screens, however, do have some use in printing by offset lithography. In general, where paper quality permits, the finer screens are used when reproduction of fine detail is important. But since the letterpress process requires that the diameter of the finest highlight dot should not be less than 0.0015–0.002 inch, the use of very fine screens will lead to loss of image contrast, since some 3 to 5 percent of the picture area, in highlights, will be ink covered.

An interesting development in glass screens was the "Altone Gradar Screen," manufactured in Germany. These are glass screens, ruled and etched in the usual manner, but with the rulings of the two glass elements filled with a transparent magenta lacquer of two different optical densities. When the screens are assembled, lines in one direction exhibit a density different from that of lines in the perpendicular direction, and the intersections have a density equal to the sum of the densities of the two lacquers. The effect is to provide elongated halftone dots, with improved tonal reproduction in intermediate gray tones on coarse paper such as newspaper stock.

Contact screens. Perhaps the most significant recent advance in the halftone process has been the use of contact screens—films bearing a gray or magenta-dyed image of the light-distribution pattern behind a conventional halftone screen. The screen is placed in contact with the surface of a high-contrast film, in the image plane. The image, as recorded on the film surface, has the characteristic of a halftone exposed through a glass screen, with significant improvements in rendition of detail of the subject. Though first proposed in 1855 and developed by a number of later investigators, this technique was not fully exploited commercially until the 1940s. The contact screen eliminates certain diffraction effects inherent in glass screens, frees the operator from some of the lens-diaphragm restrictions imposed by the glass screen, and eliminates the necessity that lens opening, bellows extension, screen distance from the focal plane, and screen ruling all be in a particular relationship.

Contact screens are made with a silver (gray) screen pattern image and with a magenta dye image. The dyed screen gives some additional control over halftone negative quality through use of colour filters on the camera.

The benday process. An entirely mechanical procedure for production of a halftone image on a metal printing plate is the benday process (1879), named after its inventor, Benjamin Day, a New York newspaper engraver. This process utilizes a series of celluloid screens bearing raised images of dot and line patterns. The screen surface is covered with a waxy ink and the ink transferred, by pressure and rolling, to prepared portions of a metal plate. By selecting different screen patterns for transfer to different parts of the image, a mechanically produced halftone image is rendered. The ink image is reinforced with powdered resins and the plate etched. This process has been supplanted by completely photomechanical techniques.

Special effects. Such techniques as dropping out the highlights from the halftone negative (*i.e.*, eliminating the dots in these areas) in order to achieve increased contrast in illustrations were studied and introduced by several individuals. Such a method was patented in 1893, and in 1925 a camera attachment was introduced, making it possible to impart a slight motion to the image on the film and thus reduce exposure to the point at which small highlight halftone dots were not printed or developed.

The most successful of the highlighting methods were those employing fluorescence phenomena, in which an object produces visible light when exposed to ultraviolet

"Altone
Gradar
Screen"

Halftone
feasibility
proved

radiation. In 1938, for example, the fluorographic process, in which fluorescing materials were incorporated in the artist's pigments, was patented. Similar pigments, designed for colour correction in watercolour illustrations, were patented in 1935 and 1938. Another process introduced shortly thereafter utilized a fluorescing paperboard. All of these processes were based on the same procedure: making an exposure under normal lighting for overall reproduction and then making an additional correcting exposure under ultraviolet. The fluorescence produced by the ultraviolet illumination provided additional exposure in the affected areas that gave the necessary correction for highlighting or colour correction, by eliminating the screen pattern from "white" areas, in the case of monochrome, or reducing printing dot sizes, in critical areas of colour work.

Process developments. The discovery of the halftone screen was primarily responsible for the development and growth of photoengraving; further growth was related to other developments in the printing and allied industries. The introduction in 1935 of the first practical colour film for amateur and professional use probably did more to accelerate printing developments than any single invention. By making bulky studio-type colour cameras obsolete and permitting the use of readily portable camera equipment for the production of colour images, on-the-spot colour photography became possible, greatly increasing the use of coloured illustrations.

At approximately the same time, the commercial production of coated paper and heat-drying printing inks for letterpress printing began. Many colour developments for films, printing processes, and materials followed.

Chemical etching—traditional and powderless processes. Early methods of etching zinc and copper, methods that have persisted in some areas to the present day, were tedious and inexact and could be learned only through trial-and-error training. The principal difficulty stemmed from the fact that the chemical removal of metal from nonimage areas proceeds in all directions. Thus, etching of the plate surface proceeds not only in the desired direction, to achieve the depth required for satisfactory printing, but also sideways, causing reduction in width of lines and dots of the printing image and also undercutting halftone dots—producing a below-surface dimension smaller than the printing surface. The mechanical weakening of the dot may lead to its collapse under printing pressure.

Some success in overcoming this problem has been achieved by depositing an etchant-resistant material about the sidewalls of etched lines and dots, thus preventing lateral etching. The method of rolling a waxy ink onto sidewalls of lines and dots, called gillotage, has found wide use among European engravers. The "powdering" process, most widely used in the United States, involves brushing a resinous powder (dragons' blood) against the sides of partially etched lines and dots and fusing, with heat, to provide an etchant-resistant coating. Several repetitions of the operation—etching, application of the protective material, and etching again—are needed before sufficient depth is attained. Results of this process are dependent upon the skill of the operator and on such ambient conditions as temperature and relative humidity, since these affect the performance of the powder. A major step toward solving the problem—in fact, the most important development in the field of etching since photoengraving was invented—came with introduction of a process of etching a magnesium plate without the use of powder. Experimenters found that by adding an oily material and a surface-active (wetting) agent to the nitric acid bath and controlling the conditions under which the plate was etched, they could produce characters in relief with adequate etching depth and virtually no printing-area loss during the etching. Later adapted to the etching of zinc, the process was quickly adopted by engravers in all parts of the world.

With this major hurdle in the etching of zinc and magnesium overcome, attention turned to copper, and in 1954 it was found that a powderless etching process for copper resulted from the addition of an organic compound (thiourea) to the iron chloride etching bath. Further refinements in the process and the introduction of new compounds to add to the etching bath followed.

Electromechanical plate making. While these developments in chemical etching were taking place, other experiments were being conducted to assess the feasibility of replacing traditional methods with the techniques of electronics, optics, and mechanics. The first successful result of these efforts was a device, introduced in 1947, that optically scanned a picture and simultaneously reproduced it as a relief printing plate on a plastic sheet. This device found wide application, particularly in newspaper plants, where the slowness of photoengraving procedures was particularly objectionable. Within a short time, machines were developed that were capable of making etched plates in metals.

Meanwhile, investigators in the United States discovered about 1950 that some methacrylate compounds could be quickly polymerized (converted to products of high molecular weight and low solubility) by exposure to light. Nylon was also found to be photosensitive, and by 1958 both materials were being offered for use in printing plates. Another plate-making system, reportedly based on light-sensitive polyurethane resins, was introduced in 1968.

Colour scanners. Paralleling the development of the electromechanical engraving machine, experimenters in the United States and Europe independently devised a number of electromechanical devices that automatically produce, from a colour-transparency image, corrected film negatives from which the four printing plates used in full-colour reproduction can be prepared.

In one of these, a photographic transparency, wrapped around a glass cylinder, is scanned by a narrow beam of light. After passing through the transparency, the light continues through a colour splitter, and the blue, green, and red components are directed onto the sensitive surfaces of photocells. The electronic signals thus generated are modified and amplified in a computer that functions as an electronic analogue of photographic colour-separation processes. The computer activates a series of lamps, which expose the colour-corrected images onto photographic films mounted on another drum, attached to the same shaft as the transparency holder. This development was based on initial experimentation in commercial laboratories in the late 1930s and early 1940s. Other units, based on similar principles but differing in some details of structure and operating procedures, have been manufactured in the United States, West Germany, and Great Britain.

MODERN PHOTOENGRAVING TECHNIQUES

In terms of cost, engraving methods range in ascending order as follows: line engravings; halftone engravings; combination line-and-halftone engravings; single-colour, two-colour, and duotone engravings; and process colourplates. Each of the types may be produced in any of the customary metals or plastics. Process colourplates are usually made of copper in the United States and United Kingdom and of zinc elsewhere.

Basic production processes. The essential operations for the production of all types of photoengravings are similar. They include photography, photomechanical operations, etching, finishing, routing, blocking, and proofing.

Camera and darkroom equipment. The engravers' camera, called a process camera, is a rigidly built machine designed to allow precise positioning of the lens and copyboard so as to provide control over the enlargement or reduction in size of the copy. It has a colour-corrected lens designed to give the sharpest possible overall image when focussed on a plane surface, without the distortions common (though usually unnoticed) in the average portrait or amateur camera lens. Process cameras are designated as gallery or darkroom types. The gallery camera is free-standing and may be installed in any convenient location, but film must be removed in a light-tight cassette and processed in a separate darkroom. The darkroom camera is installed with its film holder as an integral part of the darkroom wall, giving easy access to the darkroom facilities.

The material to be reproduced, called copy, is mounted on a board or glass-covered copyholder, carried on the bed of the camera. Illumination for exposure is provided by arc lamps or high-intensity gas-discharge lamps. The most common camera lamp systems in late years have involved

pulsed xenon lamps, in which a high-voltage alternating current, passing through a glass tube containing the rare gas xenon, causes the emission of a light rich in the ultraviolet wavelengths.

Virtually all photographic work is done on film coated with high-contrast emulsions especially developed for graphic arts work. The introduction of dimensionally stable film bases has nearly eliminated the use of glass plates. Film emulsions used for halftones yield the extremely high contrast needed for halftone or line reproduction. Stripping film, a laminated film with a soft adhesive layer between the base and the emulsion layer, is widely used to permit images to be removed from the base and properly oriented on the glass or film flat through which the metal plate will be exposed.

In the early days of photoengraving, with wet-plate images on a glass support, it was impossible to process photographic images by any means other than immersion in solutions contained in a shallow pan or tray or by dipping into a tank of solution. Such tank and tray processing remains important but is now being supplanted by the use of automatic film-processing machines. Derived from equipment originally designed for processing of motion-picture film or photostat prints, these consist of belt- or roller-driven apparatus that carries the film through developer, fixing, and washing solutions, and, in most cases, through a drier, permitting delivery of a processed, dried film within three to five minutes after insertion into the machine. Such machines, with different processing solutions, may be used for continuous-tone or lith-type films.

Plate coating and printing. Photomechanical operations include cleaning the metal plate surfaces, coating with a light-sensitive solution, drying the coating (known as the top or enamel), and making the exposure on this coating through the negative prepared in the photographic step. Throughout these operations care is required to prevent imperfections such as bubbles, dirt, or scratches in the light-sensitive coating. The zinc, magnesium, or copper is prepared by careful cleaning with pumice and water. The light-sensitive coatings are usually poured over the surface, and the plate, held flat, is whirled to ensure uniform coverage by the solution.

Light-sensitive coatings are usually a dichromated colloid material, but light-sensitive resins are also used. "Cold top" enamels are used on zinc and magnesium, which cannot be heated; these are usually slightly alkaline solutions of shellac or polyvinyl alcohol to which a dichromate is added. "Hot top" enamels nearly always contain fish glue as well as some egg albumin, to which is added a dichromate sensitizer. Mixtures of glue and albumin are used when it is necessary to control the etch resistance and the ease with which the edges of the enamel break away during the etching process. Hot top enamels must be set at temperatures of 550°–650° F (285°–345° C) and are used mainly on copper, the crystal structure of which is not altered at these temperatures. Polyvinyl alcohol and shellac resins are set at temperatures of 350° and 220° F (175° and 105° C) respectively; therefore they are used on zinc and magnesium.

The tops are high-contrast materials that, when exposed to strong ultraviolet light, harden where the light has struck them and lose their solubility in water. Development in water then removes the coating from the unwanted areas of metal, exposing the metal for the etching process. Photosensitive resinous materials find wide application in electronic circuit printing, an operation analogous to photoengraving. They have more limited applications in the making of photoengraved letterpress plates, where they are used especially on zinc and magnesium and where their excellent storage properties permit their application in the metal-finishing plant, obviating the necessity for coating of the resist onto the metal in the photoengraving shop. These resinous materials are developed in organic solvents.

Etching and finishing. Nitric acid is commonly used in etching zinc and magnesium, the strength varying from 6 to 15 percent, depending on the metal. Copper is more readily attacked by ferric chloride (iron chloride), which is commonly used in concentrations of 28–45 percent. The etching may be done in an open tub or tray, though this

method does not give the control needed for economical operation and is employed only where control is not critical. Most quality work is carried out in etching machines provided with impellers that break up the etchant into a spray and force it against the plate.

In the conventional etching processes, the acid or iron chloride is used without modification, although great care is needed to prevent overetching. In many cases, especially when making line plates, etchers powder to protect the upper printing areas from attack while continuing to etch in depth. The powderless etching processes, described earlier, have made the powdering technique obsolete and are now almost universally in use. Line plates are usually etched to depths of 0.010 to 0.045 inch. Halftones may be etched to depths of 0.0023 to 0.009 inch, depending on the fineness of the screen. Coarser screens are etched deeper.

Photosensitive plastic plates are not etched in the ordinary sense. Unexposed resins, from nonprinting areas, are washed out with either dilute alkali or alcohol. Overetching is not a problem with this type of plate.

Finishing includes hand operations with engravers' tools, to remove imperfections in the image area of the plate and to improve its appearance. In colourplates, finishing also includes colour correction, a process of further etching or burnishing selected areas to improve the fidelity of reproduction. Finally, unwanted metal in the nonprinting areas of the plate is removed by a mechanical routing machine.

Blocking and proofing. Blocking consists of attaching the plates to cherry wood, plywood, or metal blocks to bring the printing surface to type height, which is 0.918 inch. Until the development of thermoplastic adhesives in the 1940s, blocking was always done by nailing the plates to wooden blocks. This tedious and costly operation has been largely replaced by hot mounting, in which process the plate is placed on a block of wood precoated with adhesive and this sandwich is subjected to heat and pressure. Upon cooling, the plate adheres firmly to the block.

Proofing consists in placing the plates on a precision press and taking sample impressions, or proofs, that show how the plates will print during a regular press run.

Colourplate production. The first printed colour work was produced manually; artists painted in the necessary colours on black-and-white printed sheets. Later, stencils were used to speed this work, and in a further development, colours were printed, either as solids or tints, from hand-engraved plates. All of the work was crude by modern standards, however, and nothing approaching four-colour process printing was possible.

Modern colour printing, done with either three or four plates, each using a different colour of ink and overprinting the others, is based on a subtractive system of colours in which intermediate hues are obtained by some combination of two or more of the subtractive, or secondary, colours. The best colour printing is usually done with four process colours: yellow, magenta (blue-red), cyan (blue-green), and black.

The black plate is used to provide added uniformity of colour reproduction, since it will overcome changes in hue of critical neutral tones that could occur with random or cyclic variations in the amount of ink being transferred to the plate from the press inking system. Further, the use of a black plate aids in maintaining sharpness of picture detail.

In theory, black should result whenever the three subtractive colours are superimposed. Thus, it should be possible to produce black wherever all three of the secondary colours are present without affecting reproduction. Further, any colour that is within the range of colours reproducible with inks on paper can theoretically be obtained by using only black plus the proper pair of the secondary colours. But this has not been found practical because of the nature of printing ink pigments and the lack of total precision in the printing operation. Consequently, it is common practice to use the black plate to supplement the colourplates, portions of which are allowed to print in all except pure white areas of an illustration. The colourplates and the black plate must all be printed in register; *i.e.*, they must be superimposed so that identical portions of the image in each plate colour overprint each other.

processors

Modern
colour
printing

Colour separation. In manufacture, the production of an individual colourplate involves the same steps used in producing an ordinary black-and-white engraving, once the etchant-resisting image has been printed on the metal. Prior to this, the only differences lie in the use of colour filters on the engraver's camera and in steps to reduce the range of colour contrast of the copy. Negatives representing the images to be printed with each of the coloured inks are obtained by photographing the colour copy through colour filters. These filters, usually used in the form of thin sheets of dyed gelatin inserted into the lens, are complementary in colour to the coloured printing inks used.

Masking is the use of positive or negative images, taken from one or more of the set of colour-separation negatives and used in register with a given negative, to correct for the deficiencies in printing inks and colour of the copy. Common colour errors corrected by masking include the removal of excessive yellow values and magenta values from the blue (yellow printer) and green (magenta printer) negatives.

Colourplates may be made by the use of two general photographic methods—one indirect and one direct. The indirect method produces either continuous-tone negative images, from which halftone negatives are made, or continuous-tone negatives, from which continuous-tone positives are prepared. In the direct method, screen negatives are prepared directly from the copy through the colour-separation filters and a halftone screen onto a high-contrast panchromatic film or plate to produce a negative ready for transfer to the metal plate.

Proofing
of
colour-
plates

The proofing of halftone colourplates for wet printing on high-speed presses (when one colour does not have time to dry before the next is laid down) is a critical operation, for the proofing must be carried out under conditions simulating as closely as possible those that will be encountered on the production press. Specially built proof presses make this possible. In appearance they resemble four conventional press units placed end-to-end, and the sheet of paper is passed in turn over the four plates. However, because the production press employs not the original flat plates but curved duplicates made from them, and because ink and paper specifications are highly variable, exact duplication of production results in a proofing operation is difficult.

Elimination of moiré. A serious problem in colour reproduction is the occurrence of an interference pattern, or moiré, caused by the overprinting of the screens in the colourplates (a similar effect can be obtained by superimposing two pieces of window screening or fine net cloth). Because it is impossible to maintain printing register within the degree necessary to avoid such an effect, it is common practice to rotate the halftone screen when making the negatives so that each of the four plates has its screen pattern in a different position.

Electromechanical engraving machines—colour scanners. Reference has been made to devices for the electromechanical production of relief printing plates. The first of these utilized a heated pyramidal stylus, the motion of which was controlled by an electrical signal from a scanning photocell, to penetrate a plastic plate to a distance inversely proportional to the optical density of copy, thus burning out varying areas from the plate surface. In another machine of the same general type, an oscillating gouge cuts a halftone pattern in a flat plastic or metal plate, under control of a signal from a scanning photocell; in yet another a spiral groove, of varying width, is cut into the surface of a plastic plate wrapped on a rotating cylinder.

The colour scanner has been described elsewhere in this article. The first such devices were capable only of producing colour-separation negatives of the same size as the copy that was scanned. In later developments, circuits were provided to produce positive images, and mechanical or electronic devices were developed to allow enlargement or reduction of the size of the final image as compared with size of the original copy. When scanners were first made available, it was believed that their cost would limit their use to a few large plate-making establishments, but their acceptance exceeded expectations.

Production specifications. These include specifications

for line plates, halftone specifications, and combination plates.

Line plates. In line illustrations all of the image areas are either black or white, and hence no halftone screen is required to copy them for use in making a printing plate. Suitable copy consists of line drawings, etchings, etc. The negative as it comes from the process camera is suitable to transfer the line image onto the metal.

Plate preparation, coating, burning in, etching, and finishing are essentially the same as for halftone plates. Certain specifications must be met, however. The nonprinting areas must be etched sufficiently deep to prevent the ink rollers from touching them on the press, and to prevent them from rubbing on the surface of the paper during wet colour printing. For presses with accurately adjustable ink rollers, the etch depth may be as little as 0.01 inch. The same depth is permissible in thin, wraparound press plates. For conventional printing presses, the minimum etch depth is about twice this. Plates that are to be duplicated by electrotpe or stereotype processes may require slightly greater depths, although normal etching ordinarily is sufficient to produce good duplicates. Plates from which rubber duplicates are to be made will require etch depths as great as 0.045 inch.

Halftone specifications. Etch depths in halftone plates need not be as great as those in line plates, but the contour of the halftone dot and the depth of the etched areas are very important. Etch depth in highlight areas, the most critical portions of halftones, varies from 0.006 inch in a 65-line halftone to 0.002 inch in a 133-line.

Combination line-and-halftone plates. These plates must be prepared by assembling, in the negative form, the halftone and the line portions of the illustration and then, after transferring them onto the metal, etching them in two operations, so as to attain the best results for both portions. The powderless etching processes, however, permit easier etching of coarse-screen combination plates for use in newspapers. Combination line-and-halftone plates may also be produced by making two plates in separate operations and mounting them on a single block in proper position with respect to each other.

Engraving techniques applied to intaglio processes. Procedures similar to those described for production of letterpress printing surfaces are applicable to the production of intaglio printing surfaces. In intaglio, or gravure, printing, the image to be transferred to paper is etched or incised into the surface of the printing plate or cylinder. The entire surface is covered with ink, and by means of a doctoring, or wiping, operation, excess ink is removed from the surface, leaving only that which is retained in the image areas. Paper is brought into contact with the surface, and, under high mechanical pressures, the ink transfers from plate to paper.

Intaglio printing surfaces are of two general types: line intaglio (sometimes referred to as copperplate gravure), in which the ink-retaining image consists of discrete lines that may vary in width and depth; and gravure (also known as rotogravure), in which both continuous-tone and line copy are reproduced as a series of tiny cells etched into the printing surface. These cells commonly vary in depth, and hence in the volume of ink they will retain. Variations in density are produced on paper by the different amounts of ink that the cells transfer to paper.

In the rotogravure printing process, the walls surrounding each cell act as a support for the doctor blade that removes ink from the printing cylinder or plate surface.

Line intaglio. This process is widely used in the production of bank notes, securities, stamps, and engraved documents. The distinctive sharpness of fine lines and readily discernible differences in ink thickness that the process produces make it a preferred technique for production of bank notes and securities. These appearance characteristics cannot be readily counterfeited by photomechanical processes.

The printing surface is created either by mechanically scratching an acid-resistant ground from the plate surface, as described above, or by use of a photographic positive of the desired line pattern to prepare a photoresist image on the metal. The image is etched into the plate, using

Intaglio
printing
surfaces

the techniques of letterpress line etching, with maximum depth of etch usually less than 0.007 inch. Metals commonly used include steel, brass, and copper.

When a mechanical engraver is used to expose the metal for etching, a pointer or stylus is used to follow a usually enlarged pattern in a metal or plastic master stencil, causing a diamond stylus, which is in contact with the lacquer-covered plate surface, to remove the lacquer in a sharply defined pattern. The intaglio image is then prepared by etching the exposed metal with the appropriate chemicals.

In printing from intaglio forms, the plate is flooded with an ink of medium viscosity and the surface of the plate wiped clean with either a metal doctor blade or a piece of hard-surfaced paper. To minimize wear of the plate from the abrasion of the wiping mechanism, the surface is ordinarily protected by an electroplated chromium layer.

Wiped free of excess ink, the plate is brought into contact with the paper surface. A roughly outlined relief image (counter) of the printing pattern is often used to provide high local pressures, forcing the paper into the ink-filled intaglio image. As the paper is pulled from the plate, capillary-attraction and surface-tension forces act to pull the ink from the plate. After drying, the image has a distinctive appearance in which the ink has appreciable thickness, and thin lines have less thickness than wider lines.

Gravure and rotogravure. The gravure printing process is one of the three major processes that are used for catalogs, magazines, newspaper supplements, cartons, floor and wall coverings, textiles, and plastics. The gravure printing process is done with flat plates or, more commonly, with cylindrical surfaces. A screen pattern is superimposed over all image areas; thus the edges of type or lines printed by gravure will have a rough, or sawtoothed, appearance. This does not detract from readability.

Early
gravure
work

The early work as described above formed the foundation for modern gravure engraving and printing. Karl Klič (also spelled Klietsch) of Bohemia, who was instrumental in making photogravure a practical commercial process, in 1878 exposed a positive transparency over carbon tissue, a film that was made of coloured gelatin sensitized with potassium dichromate and backed by a sheet of paper. The exposed film was pressed down on a copper plate that was coated with an even layer of resin or asphalt powder. The carbon tissue was developed in water, making the gelatin swell in inverse proportion to the exposure it had received. The plate was etched with ferric chloride in successive baths of varying strengths. Penetration of the tissue by the etchant, and hence the resulting depth of etch in the metal surface, was controlled by the degree of swelling of the gelatin. Klič's process produced sure and predictable results and became the preferred method for later workers.

In later developments, the irregular grain pattern, which is produced by use of resinous powders, was replaced by a regular overall pattern of intersecting lines, which is produced by exposing the carbon tissue to a glass screen bearing an overall pattern of clear lines, intersecting at right angles.

In rotogravure, separate negatives of type matter, other line copy, and continuous-tone copy are assembled and positioned according to a prepared layout. After the negatives are retouched, a continuous-tone positive is made and retouched to ensure desired density values.

A sheet of carbon tissue is next exposed under a gravure screen. This screen is a film or sheet of glass on which fine transparent lines, usually 150–175 per inch, cross at right angles to form opaque squares. The lines of the screen are positioned at an angle of 45° to the axis of the printing cylinder. Their purpose is to provide a support for the doctor blade, which wipes ink from nonprinting areas. The lines of the screen allow the light to penetrate to the film and harden the gelatin. The square "islands" remain soft.

Next, the continuous-tone positive is placed in contact with the carbon tissue and is exposed under an arc light. The soft squares are hardened in proportion to the amount of light that penetrates the varying grays of the positive. The carbon tissue is pressed with a rubber roller to a cylinder that has a polished electroplated copper surface. After

adhering the exposed carbon tissue to the cylinder surface, it is "developed" with warm water, which has the effect of swelling and removing unhardened gelatin. The result is an image in hardened gelatin, which varies inversely in thickness according to the density of the photographic positive. The cylinder is rotated in a tray of ferric chloride, which produces an etched image in the copper surface. The squares are etched to varying depths, depending on the degree to which they were hardened. The crosslines of the screen, which were entirely light-hardened, are not etched at all. In this way, pits or wells of different depths are etched into the copper. For very long press runs, the cylinder can be strengthened by plating with nickel or chromium.

In rotogravure printing, the cylinder usually is arranged so that during its rotary movement it passes through a trough filled with a thin solution of fast-drying ink. A thin steel doctor blade moves across the cylinder with a slight oscillating action and removes the ink from the surface, but not from the wells beneath. The cylinder then comes in contact with the paper, and the paper draws the ink out of the wells in the plate. After being printed, the paper shows through thin deposits of translucent ink, thus creating pale grays; heavier ink deposits from the more deeply etched wells appear correspondingly opaque. Thus a full range of tonal values can be printed. Since the ink used in rotogravure printing is quite fluid, it penetrates through the pores of the paper surface, obliterating the screen pattern. In reproducing illustrations, gravure comes closest to simulating continuous-tone copy. In colour printing, a separate cylinder is prepared for each colour.

Roto-
gravure
printing

Other methods. In the so-called Dultgen halftone intaglio process, which is widely used in colour work, two positives are made from the continuous-tone copy, one through a halftone screen or a special contact screen and the other without a screen. The carbon tissue is first exposed to the screened positive, which produces an image of dots of varying sizes, then to the continuous-tone positive, which produces differing degrees of hardening of the dot image. When etched, the dots are of differing sizes and of differing depths. This method thus uses two methods for controlling tonal values.

The Henderson process, sometimes referred to as "direct transfer," or "inverse halftone," gravure, has won some acceptance in the printing of packaging materials. Retouched continuous-tone positives are used in preparation of halftone negatives and, by a contact-printing operation, halftone positives. These positives show dot size variations proportional to the desired print density. The cylinder is coated with a cold-top photoresist, as in letterpress engraving. This resist is then exposed to ultraviolet light, through the positives, and the image developed. The cylinder may then be etched either in ferric chloride solution or in a powderless etching bath, similar to that used for letterpress photoengraving. Tonal variation in the resulting print on paper is caused almost entirely by variation in the area of dots. (P.F.B.)

BIBLIOGRAPHY

Printing: The history of printing has been the subject of many volumes. See D.C. MCMURTRIE (ed.), *The Invention of Printing: A Bibliography* (1962). Books retracing the origins of typography include: L.P.V. FEBVRE and H.J. MARTIN (eds.), *L'Apparition du livre* (1958); P. BUTLER, *The Origin of Printing in Europe* (1966); E.G. DUFF, *Early Printed Books* (1893, reprinted 1968); and T.L. DE VINNE, *The Invention of Printing* (1876, reprinted 1969). Biographical works on contributors to the invention of printing are: S. JENNETT, *Pioneers in Printing* (1958); J. GUIGNARD, *Gutenberg et son oeuvre* (1963); G.P. WINSHIP, *Gutenberg to Plantin* (1968); and A. VAN DER LINDE, *De Haarlemsche Costerlegende* (Eng. trans., *The Haarlem Legend of the Invention of Printing*, by Lourens Janszoon Coster, 1871, reprinted 1968). The subject of an entire family devoted to the typographic art is treated by A.J. GEORGE in *The Didot Family and the Progress of Printing* (1961). The various stages of evolution of the techniques of printing are developed in: S.H. STEINBERG, *Five Hundred Years of Printing*, 2nd ed. rev. (1962); M. AUDIN in M. DAUMAS (ed.), *Histoire générale des techniques*, 3 vol. (1962–68; Eng. trans. of vol. 1–2, *A History of Technology and Invention*, 1965–69); I.B. SIMON, *The Story of Printing from Wood Blocks to Electronics* (1965); J. WATSON, *The History of the Art of Printing* (1713, reprinted 1965); C.A.

CLAIR, *Chronology of Printing* (1969); and I. THOMAS, *The History of Printing in America, with a Biography of Printers* (1874; 2nd ed., 2 vol., reprinted 1967). One particular aspect of the history of printing is treated in C.H. BLOY, *A History of Printing Ink: Balls, and Rollers, 1440-1850* (1967). Both history and technology are covered in P. LUCKOMBE, *The History and Art of Printing* (1771, reprinted 1965); G. BAUDRY and R. MARANGE, *Comment on imprime*, 3rd ed. (1966), and also in G.A. STEVENSON, *Graphic Arts Encyclopedia* (1968). Later sources include BENJAMIN FRANKLIN V (ed.), *Boston Printers, Publishers, and Booksellers, 1640-1800* (1980); STANLEY MORISON, *Selected Essays on the History of Letter-Forms in Manuscript and Print*, 2 vol., ed. by DAVID MCKITTERICK (1981); and MIRIAM USHER CHRISMAN, *Lay Culture, Learned Culture* (1982), all three covering different aspects of printing history.

The specialized language of the profession and the technical terms that are appropriate to it are collected in the following dictionaries: *Pocket Encyclopedia of Paper and Graphic Arts Terms* (1960); W.M. PEPPER, *Dictionary of Newspaper and Printing Terms: English-Spanish, Spanish-English* (1959); E.M. ALLEN, *Harper's Dictionary of the Graphic Arts* (1963); W.A. SAVAGE, *Dictionary of the Art of Printing* (1841, reprinted 1966); W.W. PASKO (ed.), *American Dictionary of Printing and Book-making* (1894; reprinted with new introduction, 1967); C.T. JACOBI, *The Printer's Vocabulary* (1888, reprinted 1969); and R. HOSTETTLER, *Technical Terms of the Printing Industry*, 5th rev. ed. (1969), which gives the equivalents of the words in five languages. In addition to general technical works on printing, such as F. PATEMAN and L.C. YOUNG, *Printing Science* (1963); and R.R. COUPE, *Science of Printing Technology* (1966); there are numerous treatises for professionals, such as: C.A. HURST and F.R. LAWRENCE, *Letterpress, Composition and Machine Work* (1963); E.A.D. HUTCHINGS, *Printing by Letterpress* (1964); V.S. GANDERTON and H. COPELAND, *Cylinder Presses*, 2nd ed. (1965); L. HEITNER, *Introduction to Offset* (1964); R.R. KARCH and E.J. BUBER, *Graphic Arts Procedures: The Offset Processes* (1967); J.E. COGOLI, *Photo-Offset Fundamentals*, 2nd ed. (1967); A. KINSEY, *Introducing Screen Printing* (1967); A. KOSLOFF, *Photographic Screen Process Printing*, 3rd ed. (1968); A.H. PHILLIPS, *Computer Peripherals and Typesetting* (1968); E.A. APPS, *Printing Ink Technology* (1958) and *Ink Technology for Printers and Students* (1963). On the economics of the printing industry, see *Printing Industry in Britain, U.S.A. and Japan* (1964), ed. by the NATIONAL PRODUCTIVITY COUNCIL, NEW DELHI. Some philosophical and social elements are discussed in MARSHALL MCLUHAN, *The Gutenberg Galaxy: The Making of Typographic Man* (1962); J. CARTER, *Printing and the Mind of Man* (1967); and W.M. IVINS, *Prints and Visual Communication* (1969). See also GEOFFREY A. GLAISTER, *Glaister's Glossary of the Book*, 2nd ed. (1979); JANET N. FIELD (ed.), *Graphic Arts Manual* (1980); PATRICIA B. MINTZ, *Dictionary of Graphic Arts Terms* (1981); and EDWARD BOOTH-CLIBBORN and DANIELE BARONI, *The Language of Graphics*, trans. from Italian (1980).

Typography: There is a vast literature on typography and printing history. *A Bibliography of Printing*, comp. by EDWARD C. BIGMORE and C.W.H. WYMAN, 2nd ed., 2 vol. (1880-86), was still useful enough to merit reprinting in 1945. Several learned and technical journals print annual bibliographies. See especially *Studies in Bibliography* and *Publications of the Modern Language Association*, which emphasize articles dealing with analytic bibliography and printing history. The best brief history in English is SIGFRID H. STEINBERG, *Five Hundred Years of Printing*, rev. ed. (1962). CURT BUHLER, *The Fifteenth-Century Book* (1960), is an excellent survey of early printing and publishing practice. JOSEPH MOXON, *Mechanick Exercises on the Whole Art of Printing* (1683-84), is the earliest comprehensive manual on printing, typography, and type making. The 1962 edition of HERBERT DAVIS and HARRY CARTER, with an excellent introduction and full annotation, gives considerable insight into the typography and printing of the day; there were no significant changes from the invention, c. 1450, until the early 19th century. DANIEL B. UPDIKE, *Printing Types*, 3rd

ed., 2 vol. (1962), is a thorough and interesting history of the development of type design from the beginnings to about 1930—highly personal, highly dogmatic, but the classic work on the subject. Of the many books and articles by STANLEY MORISON, three are especially noteworthy to the nonprofessional reader: *First Principles of Typography*, 2nd ed., with postscript (1967), is an expanded version of his Britannica article on "Typography," which became the definitive statement of his views on the subject, and has been translated into several languages. *The Typographic Arts* (1950), contains two essays on, *inter alia*, the interrelationship between calligraphy, engraving, and type design. *The Typographic Book*, ed. by KENNETH DAY (1962), is an expanded version of Morison's *Four Centuries of Fine Printing* (1924). It contains good reproductions of specimen titles and text pages spanning 1450-1935. HELLMUT LEHMANN-HAUPT (ed.), *The Book in America*, 2nd ed. (1951), is a historical survey of American printing and publishing from the beginning to the present. KENNETH DAY (ed.), *Book Typography, 1815-1965, in Europe and the United States of America* (1966), contains uneven but generally good articles on its subject. JOHN CARTER and PERCY MUIR (eds.), *Printing and the Mind of Man* (1967), the catalog of two major exhibitions held in London for an International Printing Exhibition, contains much technical information on the technological development of printing and type founding from the invention to today, as well as notes on books important for their intellectual or aesthetic impact. HENRI J. MARTIN and LUCIEN FEBVRE, *L'Apparition du livre* (1958), while heavily French in its emphasis, is a stimulating and original history of the social, economic, cultural, and technical evolution of the book trades from the manuscript period to the 19th century. Of the many modern manuals on typography, mainly reflecting the Bauhaus school, two that are representative and better than average are JAN TSCHICHOLD, *Typographische Gestaltung* (1935; Eng. trans., *Asymmetric Typography*, 1967); and EMIL RUDER, *Typographie* (1967). The latter has text in German, French, and English, and also shows Dadaist and other modern schools. Tschichold became converted to traditional typography, and in *Designing Books* (1951), gives an excellent exposition of his later views. HUGH WILLIAMSON, *Methods of Book Design*, 2nd ed. (1966), is a full and good survey of modern book design and production methods. *The Penrose Annual*, published in London, has technical articles on new developments in design and processes as well as good essays on the history and aesthetics of printing. *The Gutenberg Jahrbuch*, emanating from Mainz, the cradle of printing, emphasizes incunabula but includes articles on later printing, publishing, and binding. Valuable information is found in HERBERT LECHNER, *Geschichte der modernen Typographie: von der Steglitzer Werkstatt zum Kathodenstrahl* (1981); ERIK LINDEGREN, *ABC of Lettering and Printing* (1982); BILL GRAY, *Tips on Type* (1983); and *Words of the World: A Typographic Demonstration of World Alphabets and Languages* (1983).

Photoengraving: J.S. MERTLE and G.L. MONSEN, *Photomechanics and Printing* (1957), a good basic text, emphasizing equipment and techniques of use, now obsolete in many technical details; W.J. SMITH, E.L. TURNER, and C.D. HALLAM, *Photoengraving in Relief*, 3rd ed. (1951), basic information, should be supplemented with more recent texts; R.W.G. HUNT, *Reproduction of Colour*, 2nd ed. (1967), an authoritative presentation of fundamentals of colour printing and platemaking; F.G. WALLIS and R.V. CANNON, *Letterpress Platemaking* (1969), a recent general work on the platemaking process, recommended as both comprehensive and current; H.M. CARTWRIGHT, *Iford Graphic Arts Manual*, vol. 1, *Photo-engraving* (1962), an excellent basic text, combining historical data and practical information, with bibliographies for further study; *Photogravure*, 2nd ed. (1939), a good presentation of principles and basic technology; and with R. MACKAY, *Rotogravure* (1956), a recent work on the technology of gravure; H. DENISON, *A Treatise on Photogravure* (1894), a classic volume dealing with this process. See also ROBERT M. SWERDLOW, *The Step-by-Step Guide to Photo-Offset Lithography* (1982).

Printmaking

To the modern reader, the word print might suggest mechanically mass-produced commercial products, such as books, newspapers, and textiles. In this article the print refers to the original creation of an artist who, instead of the paintbrush or the chisel, has chosen printmaking tools to express himself.

The fine print is a multiple original. Originality is generally associated with uniqueness, but a print is considered original because the artist from the outset intended to create an etching, woodcut, or other graphic work and thus conceived his image within the possibilities and limitations of that technique. Without doubt, early printmaking was strongly influenced by a desire for multiple prints. Artists quickly discovered, however, that when a drawing is translated into a woodcut or engraving it takes on totally new characteristics. Each technique has its own distinctive style, imposed by the tools, materials, and printing methods. The metamorphosis that takes place between drawing and print became the strongest attraction for the creative artist. It is important to understand that the artist does not select his printing method arbitrarily but chooses the one in which he can best express himself. Thus, any of the proofs printed from an original plate is considered an original work of art, and, although most fine prints are pulled in limited quantities, the number has no bearing on originality, only on commercial value.

What is the difference between a reproduction and an original print? In the very early days of printmaking this was not a serious problem because the print was not looked upon as a precious art object, and prices were low. The question of originality became an issue only in the 18th century, and, in the 19th century, artists started to hand sign their prints. Since then, the signed print has been accepted by most people as the proof of its originality.

With regard to the name with which he signed his works, the Japanese artist followed a bewildering custom: he adopted and discarded names at will. If he admired another artist, he simply adopted his name. Thus, in the art history of Japan, it is common to find several unrelated artists bearing the same name and one artist bearing many names; during his long life, Hokusai, for example, used about 50 different names. In fact, a signature by itself means little or nothing. For instance, Pablo Picasso issued many signed reproductions of his paintings; on the other hand, many of his original etchings have been published in split editions, some signed, some not. These unsigned etchings are original, while the signed reproductions are not. The crucial difference is that Picasso made the plate for the original print, while the signed reproduction was photomechanically produced.

In 1960 the International Congress of Plastic Arts drafted a resolution intended to regulate contemporary prints. The crucial paragraph reads:

The above principles apply to graphic works which can be considered originals, that is to say to prints for which the artist made the original plate, cut the woodblock, worked on the stone or any other material. Works that do not fulfill these conditions must be considered "reproductions."

Although this is a straightforward statement, later devel-

opments have proved it to be highly controversial. Since the rise of the Pop and Op movements, a great number of photographically produced prints have been published and sold as signed originals. Because museum curators, art critics, and artists have not taken a firm stand on the question, any print that the artist declares to be original is now accepted as such, regardless of how it was made. Although the art world is divided on the solution, nearly everybody agrees that something should be done to clarify the situation. The state of New York, for example, has passed a law requiring complete disclosure by the dealer of how, and by whom, the print was made.

Many artists believe that the answer lies in the giving of honest information. In the 17th and 18th centuries in the West, most prints carried all the relevant information on their margins. The name of the individual was followed by a Latin abbreviation indicating his role in the work. Common examples are *del.* (*delineavit*): "he drew it"; *imp.* (*impressit*): "he printed it"; and *sculp.* (*sculpsit*): "he engraved it." This type of information, together with the total edition number, should be furnished by the artist or the dealer to the buyer. Clearly, it is impossible to make completely rigid rules to define originality. Probably the most realistic solution is to establish degrees of originality, based on the degree of the artist's participation in the various steps in the creation of the finished print.

There may also be confusion about edition numbering. In contemporary printmaking, an original print in limited edition should carry information about the size of the total edition and the number of the print. A problem can arise because, in addition to the regular edition, there are "artist's proofs" or the French "H.C." (*hors de commerce*) proofs. These are intended for the artist's personal use and should be no more than 10 percent of the edition; but, unfortunately, this practice is often abused. All of the prints pulled between working stages are called "trial proofs." These can be of great interest because they reveal the artist's working process and of great value because the number of proofs is small.

With prints of old masters in the West, originality is a very complex and difficult issue. These artists did not publish their prints in limited editions but printed as many as they could sell and without signing or numbering their works. There are arguments even between experts about the authenticity of many old prints. Important works of the masters are documented in catalogs and, although these must be revised from time to time, they furnish the only firm information available. After the edition is printed, the modern artist usually either destroys the plate or marks ("strikes") it in a distinctive manner to guarantee that any reprint from the plate is identifiable.

The 19th-century U.S. painter and etcher James McNeill Whistler was one of the first Western artists to hand sign his prints. Signing is now regulated by a convention. Upon completing the edition, the artist signs and numbers each print. Usually the signature is in the lower right corner; the edition number is on the left. Some artists put the title in the centre.

Major techniques of printmaking

The techniques of printmaking are divided into three major processes: relief, intaglio, surface. The surface processes are subdivided into two categories: planographic (lithography) and stencil methods. The methods are often combined.

RELIEF PROCESSES

In relief processes, the negative, or nonprinting part of the block or plate, is either cut or etched away, leaving the design standing in relief. Or, instead of cutting away the background, the relief print can be created by building up the printing surface. The relief is the positive image and represents the printing surface. The most familiar relief-printing materials are wood and linoleum, but many other materials can be used, such as aluminum, magnesium, and plastics. Any metal or plastic plate incised or worked in relief can be first inked in the depressions (intaglio inked) and then surface rolled, thus combining relief and intaglio processes.

Relief printing lends itself particularly to a bold conception of design, expressed more in areas than lines. This varies, however, depending on the material used: metal allows more intricate detail than wood, for example.

Woodcut. Woodcut, which appeared in the 8th century in the East and in the early 15th century in the West, is the earliest known relief-printing method. In this method, the design is first either painted directly onto the wood block or pasted on it. Then the surface of the wood is cut away around the design. For fine details and outlines the knife is used; larger areas are removed with gouges. The depth of the relief depends on the design: open areas must be cut deeper than the fine details so that the roller will not deposit ink in these areas. Although woodcuts are generally conceived in bold lines, or large areas, tonal variations can be achieved with textures, a variety of marks made with gouges, chisels, or knives. In contemporary woodcuts many other methods, such as scraping, scratching, and hammering, are also used to create interesting textures.

Originally, woodcut was a facsimile process; *i.e.*, the cutting was a reproduction of a finished design. With most contemporary woodcuts, however, the artist creates his design in the process of cutting.

As wood is a natural material, its structure varies enormously and this exercises a strong influence on the cutting. Wood blocks are cut plankwise. The woods most often used are pear, rose, pine, apple, and beech. The old masters preferred fine-grained hardwoods because they allow finer detail work than softwoods, but modern printmakers value the coarse grain of softwoods and often incorporate it into the design.

The printing of woodcuts is a relatively simple process because it does not require great pressure. Although presses are used, even hand rubbing with a wooden spoon can produce a good print. The ink used to print woodcuts must be fairly solid and sticky, so that it lies on the surface without flowing into the hollows. The printing ink can be deposited on the relief either with dabbers or with rollers. Japanese rice or mulberry papers are particularly suitable for woodcuts because they make rich prints without heavy pressure.

Colour woodcut. The standard procedure for making a woodcut with two or more colours is to cut a separate block for each colour. If the colour areas are distinctly separated and the block is large, one block can be used for more than one colour. All blocks must be the same size to assure that in the finished print the colours will appear in their proper relation to one another, that is, properly registered.

The first, the key block, is generally the one that contains most of the structural or descriptive elements of the design, thus serving as a guide for the disposition of the other colours. After the key block is finished and printed, the print is transferred to the second block. This procedure is repeated until all of the blocks are finished.

The registering system depends on the method of printing used. On a press the registering presents no problem:

the wood block is locked into position and the uniformly cut paper is automatically fed into the proper position by the press. For hand rubbing, several registering methods can be used. One method uses a mitred corner nailed to a table or special board. A sheet of paper is attached to one side of this corner, after which the wood block is placed securely in position and the print is made. Once the first colour has been printed, the paper is folded back and the first block is replaced with the second, and so on.

In woodcut colour printing, the artist must consider whether he can print wet on wet or whether the print should dry before it is overprinted. Usually a second colour can be printed immediately but, if the ink deposit is heavy, the print will have to dry before additional colours can be printed. This problem arises mainly with oil colours, which dry more slowly than water-base colours. When using oil paints, the artist has to understand how variations in viscosity affect the overprinting of colours.

Use of
small
movable
blocks

Movable small blocks have also come to be used by a number of printmakers. These involve some planning in order to print them in register with the large blocks. The easiest way is to put a light cardboard that is exactly the size of the main block (the key block) in position. Once the small blocks are registered, their location can be marked on the cardboard. Then the small blocks can be glued down to the cardboard in order to avoid the danger of shifting.

The conception and technique of the Japanese colour woodcut was totally different from that of the European woodcut. Except for chiaroscuro prints, no real colour woodcut existed in Europe before the 19th century. In the West, the woodcut was primarily a reproductive facsimile process: usually, the artist made a completed drawing that was copied by the cutter. The Japanese print, on the other hand, was the result of intricate, perfectly coordinated effort by the designing artist, the cutter, and the printer. Instead of painting a complete picture to be copied, the artist furnished a separate drawing for each colour. The engraver or cutter pasted each drawing on a wood block and cut away the white (negative) part. In this process the drawing was destroyed. Printing started only after all of the blocks had been cut. As the Japanese used water-base colours, often blending tones, printing itself was a very delicate and crucial operation, requiring perfect coordination and speed. Only after the completion of this process could the artist see the total image.

Wood engraving. Wood engraving is a variation of woodcut. The main difference is that, for wood engraving, the block—usually pear, apple, cherry, sycamore, or beech—is cut cross-grained rather than plankwise; on the end-grain block the artist can thus cut freely in any direction, allowing him to do much more intricate work with much finer tools. The image is created by fine white lines and textures. On most wood engravings, the whites appear as the positive image against a dominant black. The blocks are usually cut at the same height as printing type so that they can be printed on a press. Invented in the 18th century, wood engraving was primarily used by illustrators.

Linoleum cut. Since linoleum is easy to cut and does

not have a grain, the linoleum cut often is used to introduce children to printmaking. The process was held in low esteem until, in the 1950s, Pablo Picasso made a series of brilliant colour linoleum cuts.

The printing of linoleum cuts is similar to the printing of woodcuts or wood engravings. They can be printed by hand rubbing or, properly mounted, can be printed on a press. The colour printing process follows the woodcut principles.

Metal cut. At times artists have used soft metals, such as lead or zinc, to make prints that are similar to woodcuts or wood engravings. In the 19th century, lead cuts were often used for newspaper illustrations. The distinguished Mexican artist José Guadalupe Posada, for example, used lead frequently for his prints. Lead was used primarily because it was inexpensive and easy to work. Because metal cuts were printed like woodcuts or wood engravings, it is often difficult to tell from the print which material was used.

Cardboard (paper) cut. Elementary school children are often introduced to printmaking by making cardboard cuts, and sophisticated artists use the same material to print complex abstract images. Cardboard and paper are not only inexpensive, readily available, and workable with simple tools but, when properly prepared, have also proved to be remarkably durable. Cardboard cuts can be made either by building up or cutting out. In the first process, cutout pieces are glued to a support. When the plate is finished, it is coated with a plastic varnish to make sure the surface is tough and nonabsorbent. In the cutting-out method a heavy laminated cardboard is used, and the cutout sections are simply peeled off to the desired depth. When finished, the cut is varnished. The printing of cardboard plates follows the same principle as woodcuts or linoleum cuts.

Advantages
of
cardboard
and paper

Relief etching. When large areas of a metal plate are etched out (see below *Etching*), leaving the design in relief to be surface printed, the process is generally called relief etching. Usually the method is used for areas, but it can be also used for lines. The English artist and poet William Blake was the first printmaker to experiment extensively with relief etching. He devised a method of transferring his handwritten poems, together with the illustrations, onto the metal plate to be etched.

In contemporary printmaking, relief etching is used extensively for colour printing. The different levels of the plate can be inked with different colours. Relief etching is also a popular method of making inkless intaglio prints (shallow bas-reliefs on paper).

Rubbing. Simply by placing a fine paper over an incised or carved surface and rubbing the paper with heelball (wax and carbon black) or daubing it with special ink, an artist can use practically any surface for printing—including, as in Japan, the body of a fish. Rubbings were probably the earliest prints made by man. In India rubbings were made of tombstones and temple bas-reliefs, and in China rubbings were used to reproduce calligraphy as early as the 2nd century AD. In addition to fish rubbings, the Japanese made rubbings of metal ornaments.

"Duo H," inkless intaglio print (relief of design etched on plastic and mounted on Plexiglas) by Josef Albers, 1966. Image 12.7 cm × 34.3 cm.

Scenes from the tomb of the Wu family in Shantung, China, stone rubbing, AD 147 (Han dynasty), 7.5 m × 6.3 m. By courtesy of the Philadelphia Museum of Art, gift of Horace H.F. Jayne

Today many museums sell rubbings of bas-reliefs in their collections. In the United States rubbings often are made of colonial and early 19th-century gravestones, and in Europe they are applied to brass plaques mounted in stone slabs.

Dotted print (criblé). A traditional technique of the goldsmith long before engraving for printing purposes was developed, *criblé* was also used to make the earliest metal prints on paper. *Criblé* was a method of dotting the plate with a hand punch; with punch and hammer; with a serrated, flatheaded tool called a matting punch; with various gouges; or, sometimes, with a hollow, circular-headed ring-punch. *Criblé* plates were relief printed like woodcuts. On most dotted prints, a black background dominates a fine lacelike design.

INTAGLIO PROCESSES

Intaglio printing is the opposite of relief printing, in that the printing is done from ink that is below the surface of the plate. The design is cut, scratched, or etched into the printing surface or plate, which can be copper, zinc, aluminum, magnesium, plastic, or even coated paper. The printing ink is rubbed into the incisions or grooves, and the surface is wiped clean. Unlike surface printing, intaglio printing—which is actually a process of embossing the paper into the incised lines—requires enormous pressure. The major working methods for intaglio printing are engraving, etching, drypoint, and mezzotint. Intaglio processes are probably the most versatile of the printmaking methods, as various techniques can produce a wide range of effects, from the most delicate to the boldest. The intaglio print also produces the richest printed surface, as it is three-dimensional.

Engraving. In engraving, the design is cut into metal with a graver or burin. The burin is a steel rod with a square or lozenge-shaped section and a slightly bent shank. The cutting is accomplished by pushing the burin into the metal plate. The deeper it penetrates into the metal, the wider the line; variations in depth create the swelling-tapering character of the engraved line. After the engraving is finished, the slight burr raised by the graver is cleaned off with a scraper. The engraved line is so sharp and clean that it asserts itself even if cut over a densely etched area. In the print, the engraved line is notable for its precision and intensity. In engraving, the hand does not move freely in any direction but pushes the graver forward in a line; a change of direction is achieved by the manipulation of

the plate with the other hand. Although copper, zinc, aluminum, and magnesium plates are used—and in the past soft iron and even steel were used—the best all-around metal is copper. It has the most consistent structure and is neither too soft nor too hard.

Drypoint. Next to engraving, the drypoint is the most direct of the intaglio techniques. In printing, however, it represents the opposite end of the spectrum. Engraving is precise; drypoint is rugged, warm, and irregular.

Drypoint is made by scratching lines into metal plates with steel- or diamond-point needles. In this method the penetration into the plate is negligible; it is the metal burr raised by the point that holds the ink. Because the burr is irregular, it prints as a soft, velvety line. The angle of the needle has much more effect on the width of the line than the pressure does. If the needle is perpendicular to the plate, it throws burr on both sides, which then produces a thin double line; for wide lines the optimum angle is 60 degrees. Many artists use an electric graver to make drypoints. The oscillating point of the tool punches little craters into the plate. Because the line consists of thousands of these small craters, it is richer than the conventional scratched line made by the needle and stands up better to printing.

Copper plate is the best for drypoint. The plates are fragile because the burrs are easily flattened down by the printing pressure. Even a too vigorous wiping can damage a plate. Thus, unless the artist is satisfied with a very limited number of proofs (three or four), the plate must be faced with steel, a process in which steel is deposited by electrolytic means on the copper plate. This coating is very thin and, if it is properly done, the burrs are hardened without affecting printing quality. Zinc and aluminum, however, cannot be steel-faced.

Mezzotint. In mezzotint the metal plate is roughened with fine burrs until it prints a rich, velvety black. The

Importance of needle angle

plate is then worked back toward the lighter values with scrapers and burnishers. For this reason, mezzotint is also called *manière noire*, or the "black manner."

Mezzotint flourished throughout the 18th and 19th centuries and was primarily used for portraits or to reproduce paintings. None of the important printmakers of the past used the technique. After the invention of photoengraving, the technique of mezzotint was nearly forgotten, but a few printmakers have started to work again with this exotic medium.

The first step in preparing a mezzotint plate is to rough up the whole plate surface as evenly as possible. The tool used is the rocker, a blade with a curved serrated edge. The rougher the rocker, the heavier is the burr. The rocker is held with its cutting edge at a right angle to the plate, and the curved edge is rocked systematically over the entire surface. If this is properly done, the entire plate is covered with uniform burrs. Then the work with scrapers and burnishers begins. Where lighter tones are desired, the burr is gradually removed, and in the white areas the plate is burnished back to its original finish.

As with drypoint, mezzotint plates must be steel faced if a large edition is desired. The printing of mezzotints differs slightly from the printing of etchings or engravings. Since the layer of burr on the mezzotint acts as a blotting paper, the ink must be selected with this fact in mind. The inking and wiping must be done gently with soft rags. Printing pressure should be considerably less than that used for engravings or deeply etched plates.

Crayon manner and stipple engraving. Invented in the 18th century, crayon manner was purely a reproduction technique; its aim was the imitation of chalk drawings. The process started with a plate covered with hard ground (see below *Etching*). The design was created using a great variety of etching needles (some of them multiple). After the design was etched in, the ground was removed and the design further developed with various tools. Fine corrections and tonal modifications were made with scrapers and burnishers. Finally, engraving was used for additional strengthening of the design. Pastel manner is essentially the same as the crayon manner except that it is usually used to imitate pastel drawings.

Stipple engraving, also a reproduction method, is closely related to the crayon manner. The exact date of its invention is not known, but it is reasonably certain that it

came after the crayon manner. The first step in stipple engraving was to etch in the outlines of the design with fine dots made either with needles or with a roulette, a small wheel with points. The tonal areas were then gradually developed with tiny flick dots made with the curved stipple graver. For very fine tonal gradations, roulettes were also used. The only artist of any importance to use pure stipple engraving was Giulio Campagnola in the 16th century.

Etching. Etching is a process in which lines or textures are bitten (etched) into a metal plate with a variety of mordants (acids). The metal plate is first covered with an acid-resistant coating (ground). The design is then scratched or pressed into the ground, exposing the metal in these areas. Finally, the plate is submerged in an acid solution until the desired depth and width in the exposed areas is reached.

Although the basic principle of etching is very simple, there are many possible variations that have a strong influence on the final result. The materials themselves offer a wide range of possible variations: for example, copper, zinc, aluminum, or magnesium plates can be used; and nitric acid, hydrochloric acid, or ferric chloride can be used for the etching process. Other variations include the strength of the mordants, the biting time, the kinds of grounds and the ways in which they can be worked, and, finally, all the possible methods of printing.

Although all of these matters seem purely technical, every tool or material that is used, every step that is followed, is an integral part of the creative process. The biting action of the acid is just as much part of the drawing as is the incising into the ground. The selection of the paper or the method of wiping the plate can completely change the nature of a print.

Hard-ground etching. Any acid-resistant coating used to make an etching is called a ground. In the past a great variety of different grounds were used, and each master had his own formula. Most of them had wax as a basis, combined with various oils and varnishes. Today, the most commonly used ground consists of two parts Egyptian asphaltum, two parts beeswax, and one part resin.

Use of the
rocker

These ingredients are either dissolved and mixed or fused by heat. Ground comes in either lump or liquid form.

The plate is cleaned before the ground is applied because grease or dirt can affect the ground's adhesion, making it peel or crack. If ground in solid form is used, it is melted on low heat and rolled out evenly. Liquid ground is brushed on the plate, and then the ground is heated to make it more even and to evaporate the solvents. In both cases, after the plate cools, the ground should be solid rather than sticky.

Normally, a good ground is dark enough to offer sufficient contrast with the plate to see the work. If, however, a black ground is desired, it can be achieved by darkening the ground with the smoke of a candle.

In etching the ground, any number of tools and instruments may be employed. The old masters were restricted, but the contemporary printmaker uses a whole arsenal, including electrical drills and gravers. The line produced by the etching needle is threadlike and uniform in thickness. The exception is a line made by the tool called *échoppe*, developed by Jacques Callot, which may be used to imitate the engraved line. Other instruments are used to introduce a great variety of marks. The character of the etching is further influenced by the choice of the metal and the type of acid used. For controlled, regular bite, it is common to use Dutch mordant (nine parts of water saturated with potassium chlorate to one part of hydrochloric acid) on copper. For a rugged, irregular bite, nitric acid (one part to nine parts of water) is used on zinc. A plate can be etched in stages by covering some of the already etched areas with stop-out varnish (rosin dissolved in alcohol), which resists the acid, and then etching the rest for a longer period. This procedure can be repeated many times. Most artists develop their plates by repeated bites. After the etching is finished, the ground is removed with solvent (such as kerosene or benzene), and the plate is printed.

The first print is a state, or trial, proof. If further work is desired, the plate is cleaned and covered again with ground, the previous work remaining visible through the new ground. The whole process is repeated as many times as is necessary.

Soft-ground etching. Soft-ground etching is basically the same as hard-ground etching except that the ground contains about one-third grease, which keeps it in a semihard, or tacky, condition.

Initially, in the 19th century, soft ground was used primarily for offset drawings. The artist placed a paper on the grounded plate and made his drawing on the paper with a sharp pencil or other drawing instrument. Under the pressure, the paper picked up the ground and produced a soft granular line. Then the plate was etched normally with a fairly weak acid.

Soft ground has come to be used more often to etch various textures into the plate. Textured materials are placed on the soft ground and the plate run through the press. A thin, even ground picks up the finest textures. The design is controlled by applying a stop-out varnish to areas that should not be etched. The remaining textures are etched into the metal in the same way as in conventional hard-ground etching. This technique lends itself well to collage-type effects on the plate.

Relief etching. To make a relief etching, the areas not to be removed by acid are protected with liquid ground or varnish. The varnish used has to be tough (asphaltum, or ground) because the relief bite takes a long time, and when large areas are bitten, the plate has a tendency to heat up. If various levels are desired, relief etching can be done in stages, as in regular etching.

Aquatint. Aquatint is a process used to etch tonal areas on the plate. The first step is to give the plate a porous ground by dusting it with rosin powder and fusing the powder to the plate by means of heat. When the plate is etched, the acid goes through the pores in the ground and bites tiny cavities in the metal. These cavities hold the ink. A variety of tones and textures can be created, depending on the density, width, and depth of the cavities.

The aquatint method was invented in the 18th century, and, although a great number of pure aquatint plates were done, the technique was mainly used with line etching.

"Minotauremachy," etching by Pablo Picasso, 1935.
49.5 cm × 69.7 cm.

Theoretically, there is no limit to the range of tones that can be etched with aquatint.

For the aquatint process, the plate is cleaned, as in hard-ground etching, and then dusted with rosin. Care in this step is crucial, as an incorrectly distributed rosin ground will produce uneven, spotty tones. To achieve even tones, a fine-grain rosin is used. The quantity should cover about 50 percent of the surface, neither too thin nor too thick. The dusting can be done either with a dust box or with dust bags.

The dust box is a completely enclosed container with a sliding tray (usually made of steel mesh) that holds the plate in position above the dust tray, which is filled with fine rosin dust. After the plate is placed in the box, the rosin dust is agitated either by a bellows, by an electric fan, or by shaking.

Dusting bags are made of various materials; the finer the material, the finer the dust coming through. The dusting bags have the advantage of allowing the artist to visually control the amount of dust deposited and also to use different textures in different areas.

After dusting, the plate is placed on the heating plate, and the rosin is fused to the metal. When the plate has cooled, the design is applied with a stop-out varnish. To achieve various tones the plate is bitten in stages, much as in hard-ground etching but with one important difference: aquatint is much more delicate, and the time element is more critical. A biting time of a few seconds can produce a fine gray, but a proportionately longer time is needed as the artist proceeds toward the darker tones.

Plastic sprays are also used to make aquatints. These lacquers and enamels are sold in pressurized spray cans and are sufficiently acid resistant to use for moderately long bites. They are easy to control and simpler to use, but they must be used in spray booths or other well-ventilated places.

Lift-ground etching (sugar-lift aquatint). In lift-ground etching, a positive image is etched on an aquatint plate by drawing with a water-soluble ground. In the conventional aquatint technique, the artist controls the image by stopping out negative areas with varnish, thus working around the positive image. But for lift-ground etching, he uses a viscous liquid (such as India ink, gamboge, or ordinary poster paint mixed with sugar syrup) to paint directly on the plate. After the painting is finished and dried, the whole surface is covered with thin, liquid hard ground. When dry, the plate is placed in lukewarm water that dissolves the painted design, lifting the ground and dislodging it from the places that had been painted, thus exposing the metal surface to be etched. Aquatinting can be handled two ways: either the whole plate can be aquatinted before painting with lift ground or it can be aquatinted after the design is lifted. Lift-ground etching is particularly well-suited to free, spontaneous, calligraphic designs.

Acid bite

Acids and the etching process. The acid bite of the plate is a critical stage in the making of an etching. The printmaker must be familiar with the characteristics of the materials that are being used. On a zinc plate nitric acid is used. In the process of biting, this acid develops air bubbles over the bitten area. Under the bubbles the acid action is slower, and, therefore, if the bubbles are not constantly moved around by brushing, the etched line will be uneven. Nitric acid also has a tendency to underbite, that is, to bite not only straight down but also sideways. For this reason, areas of dense texture must be watched very closely.

Nitric acid also can be used on copper, but, except to bite out large areas, Dutch mordant is much better suited for this metal. The action of hydrochloric acid on copper is much more even and controlled than that of nitric acid. Thus, for a bold, rough bite, nitric acid on zinc is fine; but for delicate, controlled etching, Dutch mordant on copper is preferred.

Metal graphic. This method was originated by Rolf Nesch, the German-Norwegian printmaker. In all the intaglio methods previously discussed, the artist's design was created by making incisions in the plate. Nesch's method is the reverse of this process: the design is built up like a montage, by cutting out metal shapes and soldering them on the plate surface. Instead of the etching needle and the graver, the tools are shears, wire cutters, and a soldering iron. These plates are in deep relief and thus produce a heavily embossed print. Often such plates are combined with conventionally etched or engraved sections. In addition to metal shapes, wood and plastics may be used. Because of the extremely high relief, the printing of the plates requires specially prepared presses. A few contemporary artists work in such a high relief that the ordinary etching press cannot print their work and standard printing papers cannot be used. In some cases the high relief is created by compressing paper pulp into molds with hydraulic presses.

The use of embossing is not new. Some Japanese woodcuts have sections that have been decorated with "goufrage" (blind pressing). In contemporary printmaking, embossing has become a major interest, and many artists are exploring the possibilities of the intaglio print

by using shallow paper bas-reliefs to exploit the interplay of shadow and light.

Printing by intaglio processes. The most important piece of equipment in intaglio printing is the etching press, a simple machine whose basic principle has not changed for centuries. Motorization and the use of pressure gauges are the only major improvements. The press consists of a solid steel plate, called the bed, that is driven between two rollers; a screw mechanism on both sides of the top roller adjusts the pressure. Large modern presses are motor driven.

The
etching
press

The print is made by placing the inked plate face up on the bed. Dampened paper is placed carefully on the plate and covered with several layers of pure wool printing felts. The bed is then driven through the rollers. The felts, which are squeezed between the metal rollers and the plate, push the paper into the crevices of the plate, forcing the paper into contact with the ink and thus transferring the image.

A fairly heavy pure rag paper is normally used. It is soaked until its fibres are softened and then, before printing, it is blotted until no surface water is visible. For inking, the plate is placed on a heater and kept warm throughout the inking and wiping steps. Heat makes the ink looser and thus facilitates both of these processes. Wiping is the operation in which the ink is removed from the surface of the plate, while leaving it in the recesses. Usually a carefully folded starched cheesecloth (tarlatan) is used. When a clean, crisp print is desired, the plate is given a final wiping with the palm of the hand.

Inks for intaglio printing are especially made for this purpose. The consistency of the ink must be such that it comes off the surface of the plate cleanly during the wiping operation, but at the same time it must have enough body to retain its relief on the paper. The printing ink must also have sufficient viscosity to stick to the damp printing paper to produce a clear and rich image.

After the print is pulled, it is dried, either between blotters or taped to a large, stiff board. This choice depends on the size of the print and the type of paper used.

Intaglio colour printing. The intaglio colour print is made with two or more intaglio plates successively overprinted on the same paper. Each plate represents one colour and its possible gradations. In principle, it is possible to take four plates—the three basic colours, yellow, red, and blue, plus black—and make a print that will have the full range of colours. If the colour areas are distinctly separated, more than one colour can be printed from one

Problems
of colour
registration

plate. This method involves an extremely meticulous inking and wiping process.

One of the greatest problems with intaglio colour printing is registering the successive colours in their precise location. If the colours can be printed immediately, wet on wet, then it is relatively simple, but often this is not possible. If the first plate has high relief and is overprinted while wet, the second plate will crush it completely. In this case the first print must be thoroughly dried and then rewetted for the second printing. Because the paper shrinks in the drying process, it is difficult to get it back to the original size when rewetted.

Several methods of registering can be used, depending on the particular problem. For wet-on-wet printing the process is simple. After both plates are inked, the first plate is placed on the press bed and its position is marked. Paper is placed over the plate and secured at one end with masking tape, or, if there is enough margin, the paper is run through so that one end remains caught under the printing roller. The print is then folded back and the first plate is replaced with the second.

Another method uses mats. The paper to be used in the edition is cut to the same size. A cardboard or metal mat is cut, corresponding to the size of the wet paper. The plate position is either cut out or marked on the mat. Registration consists of lining the paper up with the mat.

The most precise registering is with pinholes. Two pinholes are punched in opposite corners of the mat. Corresponding pinholes are punched through all the printing papers. In printing, the paper is picked up with two heavy needles through the punched holes. The needles are then inserted in the corresponding holes on the mat and the paper is released. The holes should be placed close to an edge that will be trimmed after the print is dry.

Stencilled colours with an intaglio plate. Stencilling is one of the simplest ways to use a number of colours combined with an intaglio plate. This method has advantages and also limitations. The main advantage is that it eliminates the registering problems of intaglio colour printing. On the other hand, it is limited to flat, sharply defined colour areas. One method does not replace the other, but each may be used to solve a particular problem.

The procedure itself is very simple. The intaglio plate is inked and wiped normally. The desired colour shape is cut out on a stencil paper. The stencil is placed on the already inked plate and the colour is rolled onto the surface of the plate using a gelatin or soft rubber roller. For surface rolling, regular artist oil colours can be used. The use of stencils allows a great number of colours to be printed with a single run on the press. This is done by surface rolling colours through stencils onto the intaglio inked and wiped plate surface.

For more complex colour combinations, it is possible to combine colours stencilled directly on the paper with colours offset from the intaglio plate. For more sophisticated stencilling, silk screen can be used also in combination with the intaglio plate. When intaglio and stencilling are combined, the process is often designated as mixed or combined technique. This is essentially the same procedure as conventional stencilling except that with silk screen more complex designs and textures can also be stencilled on the plate (see below *Stencil processes*).

Intaglio and surface colour with relief etching. In this technique the main colour structure is defined by the plate surface, which is etched to different levels. The linear or textural elements moving from one level to another bind the whole together.

Inking to
different
levels

The sequence of printing begins with the intaglio inking and wiping of the plate. Next, the first surface colour is rolled on with a soft gelatin roller that penetrates the lower levels of the relief. The high areas are inked with a hard rubber or composition roller. The sequence of rolling can change, according to the demands of the particular colour problem.

In addition to plate levels and roller variety, control of colour viscosity is an important factor. The thorough description of this method is so complex that the reader is referred to some of the technical books listed in the *Bibliography*.

SURFACE-PRINTING PROCESSES

Surface printing comprises those techniques in which the image is printed from the flat surface of the metal, stone, or other material. The major surface method is lithography, a planographic process. Although many experts place silk screen and stencilling in a separate category, they can be considered surface-printing processes. In lithography, the control of the design is achieved by the chemical treatments of the drawing surface. In stencilling, the design is created by holes in the stencil and the printing ink is either rolled or squeezed through the stencil onto the paper. Silk screen is a special form of stencilling.

Lithography. Lithography is based on the fact that water and grease do not mix. The image is drawn or painted on the stone or metal plate with greasy litho crayon or a greasy black ink (tusche). Once the drawing is finished, it is fixed with an etch to prevent the spreading of the grease. A heavy, syrupy mixture of gum arabic and a small quantity of nitric acid, the etch is used to protect the drawing from water and to further desensitize the undrawn areas to printing ink. The nitric acid opens the pores of the stone, enabling the gum and the grease to enter easily. The gum arabic surrounds the greasy sections, forming an insoluble surface film that sticks to the negative areas and crevices of the grain. This coating around the image repels the water applied during printing and establishes a grease reservoir. It does not smear, and it prevents seepage that would blur the image.

Because of the antipathy of grease and water, the image attracts oily ink but repels water. Thus, when the stone is dampened with a sponge and an ink-charged roller is passed over it, the ink is deposited on the greasy drawing but not on the wet stone.

In lithography, the assumption is that the drawing made on the stone or plate will be closely duplicated on the print. While intaglio processes yield prints unlike any drawing technique, lithography is quite reproductive. Although it is a complex method, if lithography is well done, the effect of the print is deceptively simple and direct, making the technique attractive to artists who wish to avoid the more idiosyncratic printmaking methods.

A highly skilled technician is needed to produce a good lithograph, and most lithography is done in workshops

where well-trained workers are available. The artist usually works on the stone or plate under the guidance of master printers. When the artist finishes a drawing, the master printers etch the stone and do the printing. In the basic technique, the first step is the preparation of the stone or plate. If a stone has been used before, its surface must be reground. The stone is placed in a sink and thoroughly wetted, and carborundum powder is sprinkled over it. Then, either with a levigator (a heavy steel disk with a handle) or by rubbing two stones together, the surface is thoroughly reground. From time to time the surface should be tested with a steel straightedge to make sure it is level; otherwise it will print unevenly. After the stone has dried, it is ready for work. It is very important to keep the stone clean because any dirt, particularly grease, will show up on the print. Smudges and dirt can be cleaned off with erasers and abrasives.

Metal plates (zinc or aluminum) can also be used, and these, too, may be reground. Although metal plates are satisfactory, stone is far superior, particularly for producing subtle tones and details.

Use of
crayons
and
tusches on
stone

With litho crayons and tusches the artist can work on the stone as he would on paper. A whole arsenal of effects is available, including pen, pencil, splashing, sprinkling, spraying, texture transfers, and scraping. After the drawing is finished and before etching, the image must be protected from the etching solution by rubbing rosin and then talcum powder on the stone. The acid-resistant rosin protects the drawing; the talcum absorbs the excess grease, allowing the adhesion of the gum etch to the edges of the drawing.

Next, the whole surface of the stone is coated with undiluted gum arabic, applied with a wide, soft brush. The subsequent etching process is done in stages. The weakest acid solution is usually brushed first on the lightest areas of the drawing. After an appropriate interval, the next strength solution is brushed on, and this continues until the strongest etch has coated the darkest areas.

After the allotted time has elapsed, the excess etch solution is blotted with newsprint paper. The surface is then wiped down and buffed with cheesecloth to a smooth, even layer. When properly handled, the stone should appear dry. It should be allowed to stand for two hours before washing out, the next step.

The washout is done by pouring a small amount of turpentine or Lithotine over the drawn areas. Gently rubbing the drawn areas with a clean dry rag removes the drawing through the gum-etch coating. The image is preserved by the absorbed grease in the porous limestone.

Next, the stone is rubbed with liquid asphaltum or printing ink dissolved in turpentine. This procedure saturates the image and protects it at the same time.

After the stone is dry, it is ready to be inked (rolled up). First, it is dampened with a wet sponge. (In between the rollings, the stone should be redampened.) Ink rolling should be carried out according to a set pattern, gradually building up the image. To facilitate the even distribution of ink it is important to use a roller wider than the image.

The lithographic press prints with scraping pressure. The press itself consists of a metal frame that accommodates a travelling steel plate (the bed), which passes with the stone under a scraping bar (or yoke). The bed can be lowered (to position the stone) and raised (to print). The pressure on the scraping bar can be adjusted.

Lithographs can be printed on either dry or damp paper. The advantage of dampening is that it is possible to use less ink and less pressure, thus minimizing the risk of clogging the image.

To print, the printing paper is first placed on the stone, followed by a newsprint paper, and then a blotter. Last comes the tympan, a sheet of smooth, tough material that can withstand great pressure without stretching. After the bed is raised to printing position, grease is spread evenly in front of the scraping bar on the tympan to allow it to slide easily. Then the print is made.

The prints of the French artist Henri de Toulouse-Lautrec demonstrate that lithography offers endless possibilities in colour printing. Because the effect of lithography is much more painterly than either woodcut or intaglio printing, it

"Pleiades," silk-screen print by Ben Shahn, 1960.
52 cm × 67.3 cm.

is natural that the strong preoccupation with pure colour in contemporary art has created a revival of interest in this medium. The planning and the principle of colour separation are similar to those for the colour woodcut or intaglio colour.

Stencil processes. In stencilling, one of the simplest methods of duplication, the design is cut out of paper (or any other suitable thin, strong material) and is then printed by rubbing, rolling, or spraying paint through the cutout areas.

Silk screen is a sophisticated stencil process, developed about 1900 and first used mainly for advertising and display work. About 1950, fine artists started to use the process extensively, giving it the name serigraphy.

The silk-screen process got its name from the fine mesh silk that, when tacked to a wooden frame, serves as a support for a cut paper stencil. The stencil is glued to the silk. In the basic process, the open mesh of the silk lets the paint through, while the paper stencil blocks it out. A design can also be blocked out on the screen with glue or other suitable substance.

A common method of stencil preparation is to cut the stencil with a knife. In this method the artist can use commercially produced screen process printing plates or conventional stencil papers. For fine, accurate work, process plates, which consist of a film on a backing, are preferred. Areas to be printed are cut out of the film and peeled off, leaving the rest of the film on the backing paper. After the plate is attached to the screen, the backing paper is removed; thus, the screen is covered with film except in the printing areas. Process plates are available in different colours to make registering easier, and they are attached to the screen either by heat or by the use of a special solvent.

Another method that is quite common is the so-called tusche-and-glue method, which is similar to lift-ground aquatint etching. The design is painted on the screen with tusche and, when dry, the whole screen is covered with glue. When the glue dries, the design is washed out with either kerosene or turpentine. The tusche comes in liquid form for brushing or in solid crayon form. The use of the crayon results in screen prints that deceptively resemble lithographic prints.

Stencil plates can also be made photographically. These plates are made by placing a photographic positive on a photosensitized gelatin stencil plate in a vacuum printing frame. Exposure to light hardens the gelatin under the transparent areas but leaves the gelatin soft under the dark areas. In warm water the soft areas wash out. The stencil is attached to the screen in the same manner as other stencils.

To make a silk-screen print, the wooden frame holding the screen is hinged to a slightly larger wood board. The

The
silk-screen
process

Silk-screen
prints

printing paper is placed on the board, under the screen. The consistency of the ink is important: it must be liquid enough to pass through the screen but not so liquid that it runs. The ink is pressed through the screen with the squeegee (a rubber blade, usually the same width as the screen, set in a wooden handle). Any number of colours can be used, a separate screen for each colour.

SPECIAL TECHNIQUES

Monoprint (monotype). A monoprint is a unique print. The artist paints on a surface such as metal, plastic, or glass and then transfers the wet design to paper, either by rubbing or with an etching press. The primary reason for making a monoprint is that, when the image is offset from the plate to the paper, the print achieves a separate quality and luminosity totally unlike a painting made directly on paper. In the 19th century, Edgar Degas did considerable experimentation with monoprints and produced a great number of superb ones. He often worked over the proofs with paint or pastel. There has been a strong revival of interest in this method.

Cliché-verre. The method of printing known as *cliché-verre* was used by a few artists in the 19th century during the period when photography was a new and exciting invention. The *cliché-verre* method follows the principle of photography but does not have its tonal variations. The print was made by covering a piece of clear glass with an opaque pigment or emulsion; the design was then scratched through with a sharp etching needle or stylus. When the drawing was finished, the glass plate (negative) was placed on a photosensitized paper, exposed to light, and then developed. The result was a (positive) print with strong black-and-white contrasts. Some of the best *cliché-verre* prints were made by the French landscape painter Camille Corot.

The cellocut. The cellocut method was named by its originator, U.S. printmaker Boris Margo, one of the first to experiment extensively with plastics.

In this method, liquid plastic that has been dissolved in acetone is poured onto a rigid support backing, such

"The Alchemist, No. 2," cellocut by Boris Margo, c. 1947.
85.3 cm × 58.3 cm.

as fibreboard or cardboard. The solidified plastic can be textured, raised into relief, and worked with various tools. It can be engraved, scratched, sanded, and filed. The resulting plastic plate can be printed either as a relief or as an intaglio plate, or even both. It can be printed alone or in combination with other techniques. Thin layers of plastics can easily be placed on top of intaglio plates and printed together.

Collagraphy. Like the metal graphic process, collagraphy is an additive method; the printing surface is built up. It is essentially an intaglio method, but it can be combined with relief printing. The printing surface is created by gluing various materials and textures to a support. Today, with the variety of new material available, the possibilities are limitless.

The support (plate) for collagraphy must be thin and strong. A porous material, such as cardboard, must be treated with a sealer. To build up a tough, durable printing surface, a strong adhesive such as polyvinyl acetate must be used.

Among the materials that can be used for tonal areas are sawdust, sand, carborundum, sandpaper, and ground walnut shells. For specific textures, materials such as tarlatan, laces, and crushed paper can be glued into the adhesive.

After the plate has been constructed, the surface is sealed. The sealer can be either brushed or sprayed on. Plastics are preferred because they are tough and are not dissolved by the solvents generally used to clean the plate.

The printing of collagraphs is essentially the same as for intaglio printing.

Plaster print. Good proofs of an intaglio plate can be made by plaster casting, for fine plaster of paris will pick up the most delicate details. This method will produce a particularly attractive proof if the plate has deeply etched or engraved sections.

To make a plaster print, the plate is inked in the same manner as it would be for normal printing. The inked and wiped plate is placed face up on a glass plate, and a precut wood frame is placed around the plate to contain the plaster. After the plaster is poured, it is allowed to cool and set, after which the plate is gently removed.

PROCESS PRINTS

Process-printing methods are primarily used for commercial reproduction. Today, however, many artists use commercial methods to produce fine art. Silk-screen printing itself began as a commercial process, and today it is one of the most popular techniques in printmaking because its character is well suited for hard-edge geometric images. Photomechanical processes are incorporated in the work of many contemporary printmakers.

Linecut. The linecut technique is the simplest and least expensive of all the photoreproductive processes. As it cannot register tone, it is used mostly to reproduce black-and-white line drawings. If tones are needed in a linecut, they are achieved with the use of screens consisting of dots (Ben Day screens). The linecut is similar to the woodcut in that both are used in relief printing.

Linecuts are usually made on zinc plates coated with an emulsion of albumin or gelatin mixed with potassium bichromate. This emulsion hardens on exposure to light. The light passing through the transparent part of the negative hardens the emulsion. The areas of the emulsion that are protected by the black on the negative remain in their soluble state. The plate is then rolled with greasy ink and soaked in water. The unexposed soft emulsion is washed out by the water. The plate is then dried and dusted with powdered rosin, which adheres to the remaining inked emulsion areas. Heating causes the rosin to melt, forming an acid-resistant coating. The plate can then be etched so that the design stands up in high relief.

Halftone cut or plate. Halftone is more sophisticated than linecut, since it is capable of reproducing fine tonal variations. The subject is photographed first through a glass plate that has fine lines printed on it at right angles. The result is an image broken up into tiny dots corresponding to the openings in the screen. When printed, these dots create the optical illusion of continuous tones. There are great variations in screens from coarse (50 lines per inch) to very fine (175 lines per inch). The selection of the screen is dictated by the paper to be used for printing.

After the photonegative of the image is finished, it is printed on a sensitized copper plate. For halftone work, copper is used because of its ability to record fine details. The procedure of washout and etch is similar to that used with linecuts.

Rotogravure. To make a gravure plate, a screen is used that is the reverse of the halftone screen, in that the lines are transparent and the areas between the lines are opaque squares. When the sensitized plate is exposed to light through the screen, the emulsion on the plate hardens under the lines but leaves the squares soft. Then the plate is exposed again through a diapositive (a positive transparency) of the subject. This time the soft emulsion squares harden in proportion to the range of grays. In etching, the softest squares are affected by the acid first and the hardest ones last. The result, after the etch, is a plate covered with squares of equal size but varying depth. As the deep squares hold more ink than the shallow ones, the tones in the reproduction are controlled in the same manner as in all intaglio printing methods. The rotogravure plate is inked by an ink-carrying cylinder and wiped by a steel blade that removes all the excess ink from its surface.

Although rotogravure is an intaglio printing process, it is printed on dry paper with light pressure and thin ink. Hence, there is hardly any embossing.

Offset lithography. Offset lithography is the application of lithography to commercial mass production. The plate, instead of being a stone, is of specially treated zinc or aluminum, suitable for mounting on a cylinder. The image is photographed on the sensitized litho-plate through a screen. The offset method involves double printing. The image from the plate is printed on another roller covered with a rubber blanket, and from this roller it is transferred to the paper. Because the image is reversed twice, the final print corresponds to the original plate. Since the litho offset ink is thin, to speed up inking and facilitate transfer, the tonal areas lose some of their richness and tend to print gray. Litho offset is often used for colour printing. The colour separation is made photographically.

CONTEMPORARY EXPERIMENTATION

One of the most crucial changes in the 20th century involved the size of the print. All through its history, with few exceptions, the print was considered an intimate art form, enjoyed by the few. The change started with the Lautrec posters: the print started to grow until it became mural size. As the dimensions of the print changed, so did its character. It became increasingly bolder and more colourful. Today, the print often competes with painting, a situation deplored by many people who feel that in the process the print is losing its particular character and beauty. For a time, major print shows tended to exhibit only a limited number of small, delicate prints, but two more recent developments seem to be balancing that trend. One is the reappearance of the intimate, introspective, black-and-white print. The other is the revival of the long-neglected woodcut, due particularly to the interest of the Postmodernist artists in German Expressionism.

Next to the size of the print, the greatest change has been in the technology of colour printing. In this area, techniques have become so varied that practically any effect is possible. This development has contributed to the vitality of printmaking, because it has encouraged the participation of colour-oriented artists. The combining of various media is closely related to the experimentation in colour printing. Each medium has its own capabilities and limitations; combined, the media often complement each other. It is now common to see three or four different techniques combined.

Another area of experimentation is in three-dimensional surfaces. The trend started with embossing, and today artists are creating completely three-dimensional printed objects.

The shaped print is a printed paper sculpture, made by cutting and folding the printed paper or by assembling pre-cut printed surfaces. Many of these surfaces are metal or plastic objects with printing, usually done by the silk-screen process.

Instead of using rectangular painting surfaces, many painters now work on shaped canvases. In the same way, printmakers, instead of using rectangular plates, are using many different shapes. Printing with movable plates, which became particularly popular in intaglio colour printing and with colour woodcuts, is the logical extension of this freedom. In this method small cutout plates are placed on top of larger plates and printed together, or they are assembled on a cardboard support and printed. This procedure facilitates the use of many colours and also offers great freedom in composing.

Photography is profoundly affecting printmaking. Photographic methods can be combined with intaglio, lithography, or silk screen to enrich their vocabulary. The possibilities are nearly limitless. Yet photography can be corrupting when it reintroduces reproductive ideas, and, unfortunately, it is often used for this effect.

Kinetic (moving) art, such as the mobile, is a major contemporary preoccupation in painting and sculpture. At present there are few attempts in this direction in printmaking, but there will probably be more. The problem in such works is how to combine the print with motion without destroying its very nature.

MOUNTING AND CARE OF PRINTS

Very few people know how to display prints and how to take care of them properly. It is heartbreaking to see a great master's print glued to a cheap cardboard or the border of a fine print ruined with tape.

Because paper, particularly old paper, is fragile, it should be handled as little as possible and never picked up with one hand since this might put too much stress on the paper and tear it. To protect it, a print should be mounted as soon as possible.

The surface of the print, especially an intaglio print, is delicate, and rubbing might permanently injure it. Prints should not be stacked without protective layers of tissue paper between them. Wood-pulp papers should not be used, as the acid content in these can burn the print. A print should not be exposed to intense sunlight; this is true particularly of colour prints, for very few colours are

stable enough to withstand long exposure to direct sun. Light can also affect the paper. Because wood-pulp board contains chemicals that in time can burn or discolour the paper, a permanent mat should be constructed out of pure rag board. A properly constructed mat consists of two parts: the backing board to support the print and the covering frame to display it. The width of the mat frame should be related to the print's dimensions so that the mat does not overpower the image. The window size of the mat should never obscure the printed image itself, or the signature and edition number.

Because temperature changes in a damp climate can cause condensation and the print can develop fungi, prints should be kept from direct contact with the glass. The simplest protection is a deep enough pure rag mat. If this is not sufficient, a filler should be inserted into the frame to increase the space between the mat and the glass.

The backboard of the frame should be also rag board, or at least faced with rag paper, although the latter is not the perfect solution. The back of the frame should be sealed with tape to prevent the penetrating of dust. In damp climates it is advisable to keep the frame away from the wall by placing corks on its four corners. This facilitates the free circulation of air. Air-conditioning and humidity controls are the best protection.

History of printmaking

Engraving is one of the oldest art forms. Engraved designs have been found on prehistoric bones, stones, and cave walls. The technique of duplicating images goes back several thousand years to the Sumerians (c. 3000 BC), who engraved designs and cuneiform inscriptions on cylinder

seals (usually made of stone), which, when rolled over soft clay tablets, left relief impressions. They conceived not only the idea of multiplication but also the mechanical principle, the roller, which in more sophisticated form became the printing press.

On the basis of stone designs and seals found in China, there is speculation that the Chinese may have produced a primitive form of print—the rubbing—about the 2nd century AD. The first authenticated prints rubbed from wood blocks were Buddhist charms printed in Japan and distributed between AD 764 and 770. It is believed that the first wood-block prints on textiles were made by the Egyptians in the 6th or 7th century; but the earliest printed image with an authenticated date is a scroll of the *Diamond Sūtra* (one of the discourses of the Buddha) printed by Wang Chieh in AD 868, which was found in a cave in eastern Turkestan.

In Europe, stamping (to imprint royal seals and signatures) preceded printing by rubbing or with a press. The earliest documented impressed royal signature is that of Henry VI of England, dated 1436.

Textile printing, however, was known in Europe in the 6th century, the designs consisting largely of repeated decorative patterns. Printing on paper developed from textile printing, following the introduction of paper from the Orient. The first European paper was made in 1151, at Xativa (modern Játiva), Spain. Soon afterward paper manufacturing began in France and then in Germany and Italy, notably by Fabriano, whose enterprise was established in 1276.

The first woodcuts on paper, printed in quantity, were playing cards. The term *Kartenmahler* or *Kartenmacher* ("painter or maker of playing cards," respectively) appears on a German document dated 1402; and documents from both Italy and France from the middle of the 15th century mention wood blocks for the printing of playing cards. The earliest dated woodcut is a "Madonna with Four Virgin Saints in a Garden" from the year 1418.

Many documents from the 15th century indicate that a clear distinction was made between the designer and the cutter of the wood blocks. From the outset, woodcut was primarily a facsimile process: the cutter copied a drawing provided by the designer.

Printing from a metal engraving, introduced a few decades after the woodcut, had an independent development. The art of engraving and etching originated with goldsmiths and armour makers—men who were thoroughly professional craftsmen, practicing an art that had a long, respected tradition. Since the armour makers and goldsmiths were designers themselves, the whole process was controlled by the creative artist.

PRINTMAKING IN THE 15TH CENTURY

Germany. Single prints (in contrast to those printed in a series or as part of an illustrated book) of the early 15th century were not signed or dated, and, because they were religious images carried by pilgrims from one place to another, it is nearly impossible to establish with certainty their place of origin. Their style alone must be relied upon for some indication of origin.

The first phase of woodcut, from about 1402 until about 1425, was dominated by boldly designed single figures against a blank background. Most of the cuts were made to be hand coloured. In the second half of the 15th century the cuts became more complex: architectural and landscape elements came into use, and often the image was framed in an elaborate border.

The first metal prints (criblé, or dotted, print) were made in the second half of the 15th century. The design was created by tiny dots punched into the metal and intermingled with short cuts. Surface printed, the whites are the positive part of the design, which is dominated by the dark background. Tiny holes in the borders indicate that most of these plates were intended as decorations to be mounted rather than as printing plates.

The earliest dated intaglio-printed engraving is from 1446: "The Flagellation," of a Passion series. Around this time, the first distinct personality to have great influence on German engraving appeared. He is known as the Mas-

Woodcuts
of playing
cards

Deutsche Fotothek, Dresden

ter of the Playing Cards. His style was simple, nearly monumental; unlike the printwork of goldsmiths, his engravings lack ornamentation. For shading he used slightly diagonal parallel cuts. The Master of the Playing Cards heralds the beginning of a century of great printmakers in Germany. Another significant engraver, the Master of the Banderoles, was named after the ribbon scrolls characteristic of his prints, which are more decorative than those of the Master of the Playing Cards.

In the second half of the 15th century, the outstanding printmaker was Master E.S., who flourished about 1440–67 and was one of the first to use initials as a signature on his plates. Little is known about him, but the personality that emerges from approximately 317 plates is forceful and distinct. Although it is evident from his prints that, like most early engravers, he was first trained as a goldsmith, his work has strong pictorial quality.

Martin Schongauer was the first great engraver who is known to have been a painter rather than a goldsmith. Although Schongauer's style was still Gothic in character, he composed with much greater freedom than his contemporaries, thus representing a transition into the Renaissance. He made about 115 plates, mostly of religious subjects, and was a powerful influence on the young Albrecht Dürer (see below *Printmaking in the 16th century*). During the second half of the 15th century, a group of brilliant engravers known only by their initials emerged in Germany. They are the Masters B.G., B.M., L.G.S., A.G., B.R., and W.H. The controversial figure of Israhel van Meckenem appeared at the end of the 15th century. A superb and extremely prolific engraver, he was a rather eclectic artist, borrowing from other masters and often copying them.

Italy. In the 15th century, Italian printmaking was dominated by the northern cities: Florence, Venice, and Milan. Throughout the century, printmaking was mainly concerned with playing cards and book illustrations, with a few single prints appearing in the second half of the century. While in Germany and the Netherlands the art was completely dominated by devotional, religious sub-

ject matter, Italian printmaking covered a relatively broad range. The awakening Renaissance attitude made the artists much more receptive to purely aesthetic, decorative, sensuous experience. In addition to religious subject matter, Italian prints included mythology, pure ornamentation, and some of the finest early portrait engravings.

Giorgio Vasari, the chronicler of the Renaissance, credited the Florentine goldsmith Maso Finiguerra with the invention of printed engraving, but present knowledge indicates that, at the same period in Germany and the Netherlands, printmaking was in a more advanced stage. In spite of the fact that book printing was originally introduced from the northern countries into Italy, engraving remained a national, regional development, free of strong foreign influence until the beginning of the 16th century.

Two methods of engraving were practiced in Italy, the broad manner and the fine manner. The fine manner, associated with the Finiguerra school, is characterized by closely cut and extremely fine lines combined with cross-hatching intermingled at times with dots. The broad manner is less dense, and forms are modelled using diagonally cut parallel lines, interlaid at times with short cuts or dots. In shading, the spacing between the lines is wider than in the fine manner and there is no cross-hatching.

Finiguerra himself was not an important artist. His significance lies in his influence on Antonio Pollaiuolo, a Florentine painter, sculptor, and architect whose reputation as one of the most distinguished engravers of the 15th century is based on his one authenticated print, "The Battle of the Nudes" (c. 1465)—a powerful image, beautifully engraved in the broad manner.

While Pollaiuolo worked in Florence, Andrea Mantegna, a great painter and certainly the most eminent Italian printmaker, lived and worked in Mantua. Mantegna produced approximately 20 plates (only seven of which are completely authenticated), all line engravings in the broad manner. A superb draftsman and a virtuoso engraver, Mantegna could achieve, in spite of the limitations of his method, an incredible range of colour in his prints, a quality lacking in the work of most of his followers.

Broad manner and fine manner engraving

By courtesy of the Art Institute of Chicago

"The Battle of the Nudes," engraving by Antonio Pollaiuolo (c. 1431/32–98). About 40 cm × 61 cm.

In addition to the masters, talented engravers included Cristofano Robetta, a Florentine who made some rich, intricate engravings in the fine manner; and the Venetian Jacopo de' Barbari, who travelled in Germany and whose refined engravings show the influence of Albrecht Dürer.

Other countries. *The Netherlands and Burgundy.* The first half of the 15th century in the Netherlands and Burgundy was dominated by woodcut book illustrations. Although no single prints of great importance were produced, beautiful books were published. Antwerp and Delft were the main printing centres.

Parallel with, if not even a little earlier than, the emergence of distinguished printmakers in mid-15th-century Germany, a group of great engravers emerged in the Netherlands and neighbouring Burgundy. Superb artists,

Engravings of Master E.S.

cuts and textures to imitate the surface qualities of materials. Other printmakers of the period include Allaert Claesz and Cornelis Matsys.

Italy. After the death of Mantegna in 1506, Italian printmaking of the 16th century was dominated by lesser figures. During the 16th century the few etchings produced in Italy have only historical interest.

The most influential engraver of the century was Marcantonio Raimondi. Under the influence of Dürer, Raimondi became a virtuoso engraver; technically Dürer's equal, he lacked his master's originality. Raimondi eventually became the engraver of Raphael, organizing a workshop that was dedicated primarily to making reproductions of the master's work. Thus, Raimondi won the dubious honour of being the first of the many printmakers who ultimately were influential in turning the art of engraving into mere reproduction. He was followed by a whole generation of competent engravers who were devoted solely to reproduction.

One of the exceptions was Giorgio Ghisi of Mantua, who in his isolated regional development escaped the corrupting influence of Rome. His 1550 visit to Antwerp made Ghisi an important link between Italian and northern engraving.

France. The only major figure in 16th-century French engraving is Jean Duvet, whose predilection for excessive ornamentation indicates that he was trained as a goldsmith. Although Duvet's style was influenced by Mantegna, his imagery was completely original. His greatest work, "The Apocalypse," reveals a feverish, mystical imagination.

Apart from the work of Duvet, ornamental engraving was the most significant achievement of 16th-century French printmaking. Although these elegant engravings cannot be ranked with the work of the great masters, they represent a genuine expression of the French spirit. The outstanding figure of this school was Étienne Delaune. Although his motifs were influenced by those employed by Raphael for his fresco wall paintings in the Vatican, Delaune nonetheless achieved a personal style.

Trends in the late 16th century. By the second half of the 16th century, the quality of printmaking, particularly engraving, had gone into a severe decline. Masters like Dürer and Mantegna were replaced by skilled craftsmen. The trend toward reproduction that had begun with Rai-

mondi gained ground, sapping the vitality of engraving. Yet at the same time, the quantity of production increased. Except for the modern era, this was probably the most prolific period of printmaking. Since it was the beginning of the age of travel, discovery, and religious upheaval, the demand for maps, religious pictures, illustrations, and portraits was enormous.

One after the other, print publishing houses opened all over Europe. Dutch and Flemish families dominated the new profession: in the Netherlands, the firms Cock, Galle, and Passe; in Augsburg, Dominicus Custos; in Antwerp, Brussels, Prague, and Venice, the Sadeler family. In Italy, Antonio Salamanca cornered the market and flooded it with bad reprints of Raimondi engravings.

The publishers of this period usually bought the original plates outright from the artist and issued prints on demand in unlimited quantities. If the plates wore out, they were reworked in the publishers' own workshops, a practice that was responsible for the destruction of many fine artworks. In many cases, it is no longer possible to identify the creator of the original plate.

In this period, map engravers were particularly important: the maps of Abraham Ortelius were engraved by Franz Hogenberg; Gerardus Mercator engraved his own map designs; and Jodocus Hondius bought the Mercator plates after their use in the edition of 1596 and introduced them in England, along with some of his own work.

engravers

PRINTMAKING IN THE 17TH CENTURY

Portrait engraving. *France.* The end of the 16th century and the beginning of the 17th were dominated by ornamental engravers and illustrators, who were working under Flemish influence; by the middle of the 17th century, however, a distinctly French school of portrait engraving had emerged. Although this school did not produce a major master, it represents a significant phase of European printmaking.

Michael Lesne, a French portraitist whose influence was considerable, worked for a time in the Rubens workshop, later returning to France. Claude Mellan, another major influence, was trained in Rome. Technical virtuosity dominated his prints; for example, the modelling of a face with one continuous spiral.

A superb engraver and a fine draftsman, Robert Nanteuil is considered the undisputed master of French portrait engraving. His style is simple, elegant, and free of the mannerism characteristic of his contemporaries. He and his two rivals—Gerard Edelinck, who was born in Antwerp but studied and developed his style in France, and Antoine Masson, who engraved portraits in the grand style—represented the dominant forces in 17th-century French portrait engraving.

Germany. After the glories of the 15th and 16th centuries, German graphic genius was dormant for nearly three centuries. Historically, Ludwig von Siegen, a minor painter and medalist, is important for his invention of the mezzotint printing method. But the perfecting of this tonal technique increased the reproductive facility of printmaking, thus contributing to the decline of artistic creativity.

Like France, Germany produced a school of portrait engravers; but, although competent technicians, they failed to develop a distinctly national school comparable to the French. Of this group, two are significant: Jeremias Falck, a student of Hondius, and Bartholomäus Kilian, who studied in Paris and later introduced French influence into German printmaking.

The Netherlands. Portrait engraving in Holland was on a higher level than in Germany. Cornelis van Dalen was a fine engraver who emigrated to England and died there. More gifted than his father, Cornelis van Dalen II was an artist of considerable stature, who engraved some of the most powerful portraits of his time.

Abraham Blooteling, a pupil of van Dalen II, was also a fine portrait engraver. His major contribution, however, was in the development of the new technique of mezzotint—specifically, the invention of the rocker, the tool used in the technique. He also introduced the mezzotint into England, where it was adopted with such success that it later became known as the "English Manner."

England. In the 17th century, English printmaking produced a portrait engraver of considerable stature, William Faithorne. He studied in France and initially was under the influence of Mellan and Nanteuil; in his late work, however, he developed a style independent of theirs. Faithorne was England's only major native printmaker during this period, when most prints were reproductive engravings. By the end of the century, engraving was in total decline, replaced by the fashionable mezzotint.

Flemish printmaking. One of the dominant figures of European art was Peter Paul Rubens, who was a painter, diplomat, and businessman. Quickly recognizing the commercial potential of printmaking, Rubens organized a graphic workshop where, under his supervision, reproductions of his work were produced. Only one etching, "St. Catherine," is considered as his own. The quality of this one print indicates how great was the loss to the art of printmaking that this great draftsman did not make more original etchings.

Rubens' pupil Anthony Van Dyck was one of the most distinguished portrait painters of his time. At age 27 he undertook a very ambitious project: the etched portraits

of the 100 most famous men of his day. For this set of prints, known as the "Iconography," he completed 18 portraits. But only five of these ("Peter Brueghel the Younger," "Snellinx," "Erasmus," "Suttermans," and "Josse de Momper") remained unchanged; another five were retouched by professional engravers, and the rest were completely reworked by them.

European etching. Like the Van Dyck portraits, nearly all of the outstanding prints produced in the 17th century were etchings. Etching emerged as the dominant technique for many reasons. The fact that engraving had become a completely commercialized, reproductive method and that mezzotint had never been anything else alienated many artists. As an unexploited and relatively unexplored medium, etching intrigued the experimentally oriented. Furthermore, the fluid, flexible technique of etching was a lure for the creative painter, whose own medium had become freer and more spontaneous.

Italy. At the beginning of the 17th century, there was more etching in Italy than in any other European country. Strangely enough, probably the three most important etchers—Jacques Callot, Claude Lorrain, and José de Ribera—were foreign-born.

The Bolognese school was formed around Guido Reni, whose delicate etching style of light lines and dots became a standard technique for most Italian etchers of his time. His school, however, did not produce any superior printmakers.

The Spanish painter José de Ribera was the dominant figure of the Neapolitan school. Though he was the first major realist painter in Italy and a strong influence against the idealizing trend, both his paintings and his etchings were outside the mainstream of Italian art.

Next to Ribera, Salvator Rosa, an Italian, was the most notable artist of the Neapolitan school, producing a large number of etchings that are full of charm but of no great importance.

Born in Nancy, France, Jacques Callot ran away from home as a boy to study art in Italy. Of all the artists engaged in 17th-century Italian printmaking, he was historically the most significant; for he was one of the first to use repeated bitings on his plates to achieve tonal variations. His drawing style represented a transition between engraving and etching: using a specially shaped etching needle of his own invention, he imitated the swelling and tapering characteristics of the engraved line. His illustrations record and ironically comment upon the customs, historical events, and morals of his time. Callot's work was often decorative and manneristic; but, at his best, as in the series "The Miseries and Disasters of War" (1633), he transcended mere illustration and achieved powerful images of universal significance.

Claude Lorrain, also French-born, was one of the finest landscape painters in Italy, and he had an intuitive understanding of the etching medium. His spontaneous interpretation of the atmospheric quality of his subject

Callot's
etching

foreshadows the Barbizon school and Impressionism in the 19th century.

The Netherlands. In the beginning of the 17th century, Holland suddenly exploded into a frenzy of creativity in etching. The sensitive, atmospheric etchings of the brothers Esaias and Jan van de Velde can be considered the beginning of the Dutch landscape school. Others were Adriaen van Stalbert, Pieter de Molijn, and Willem Buytewech—all fine printmakers, but all eventually overshadowed by the dramatic personality of Rembrandt. Before him, however, another artist appeared who was so original that no historical precedent could anticipate him. Hercules Seghers is one of the most interesting and mysterious figures in the history of printmaking. He was a lonely, tragic man, an experimenter who was so far ahead of his time that it took centuries for the real significance of his work to become apparent. It is known that Rembrandt appreciated his work. He owned some of Seghers' prints and even reworked one of his plates, "Tobias and the Angel" (c. 1633); keeping the landscape, he changed the figures, making it "The Flight into Egypt" (1653).

Seghers was the first real experimenter in intaglio colour printing. His methods were completely unorthodox: he printed on tinted canvas, tried light lines on a dark background, and also mixed printing with hand colouring. Seghers' etching technique was itself very unorthodox. His eroded lines, so well suited to his subject matter, are unlike any etched line made before him, which has led some experts to the conclusion that Seghers invented the lift ground, an aquatint technique.

"The Rocky River Landscape," 17th-century etching by Hercules Seghers. 17.6 cm × 21.7 cm.

Most of Seghers' etchings represent craggy, arid landscapes. Everything he drew—landscapes, still lifes, even figures—seem to be made of stone. It is a world suspended in the timelessness of death.

The graphic distinction of Rembrandt

Even among the supreme artists of the world, Rembrandt van Rijn occupies a very special place. One of the most eminent painters of all time, he also left a graphic oeuvre of heroic proportions both in quantity and quality. A great innovator, he was the first artist to fully explore the possibilities of the etched line.

Rembrandt made approximately 300 plates. His subject matter represents practically every aspect of human existence: he rendered religious and historical subjects; he explored themes of love and death; and he created profound portraits and sensitive landscapes. Everything that was part of life concerned him, from the highest ideals to the most mundane bodily functions.

While Rembrandt's early prints are pure etchings, his later works frequently combine the techniques of etching and drypoint. Since he often reworked his plates between printings, there are sometimes enormous variations between proofs. Rembrandt's immediate influence on his

students and followers was not very productive, for his personality was so overpowering that those close to him fell under his spell and simply imitated his style. Associated artists such as J.G. van Vliet, who copied and reworked many of the master's plates, and Jan Lievens were mere shadows of Rembrandt. Among those closely associated with Rembrandt, probably Ferdinand Bol was the strongest, but even he is dwarfed by comparison.

Also active during Rembrandt's time and somewhat overshadowed by him was Adriaen van Ostade, one of the most gifted of Dutch genre painters. The subjects of both his paintings and prints were taken mainly from the daily lives of simple people, usually peasants. In spirit, his work represented an important departure from the heroic orientation of historic and religious painting, reflecting a crucial social change—the emergence of a middle class in Europe. For the first time, common people replaced the clergy and the nobility as a source of inspiration for an artist. Van Ostade's etching technique was influenced by the early Rembrandt, but his drawing style was personal. It was simple, undramatic, and direct—well suited to his intimate subject matter.

Throughout the 17th century, landscape painting and etching thrived in Holland. Jan van Goyen and Roelant Roghman both made fine landscape paintings and etchings. In this group the most interesting figure is Jacob van Ruisdael, whose sensitive, luminous landscape etchings foreshadowed the Barbizon school.

Toward the end of the century, a strong Italian influence invaded Holland. Since the earthiness of the Dutch temperament did not mix well with the Italian tendency toward idealization, the result was an eclecticism that drained Dutch art of much of its vitality.

Japanese Ukiyo-e prints. Until the 17th century, Japanese painting was completely dominated by Chinese influence. The Japanese silk paintings and screens of idealized landscapes were hardly distinguishable from their Chinese counterparts. Then, in the early 17th century, an artist of aristocratic origin, Iwasa Matabei, started to paint images related to his environment and personal experience. Although this era of Japanese art history is rather obscure, he is credited with being one of the founders (along with Iwasa Matabei II and Iwasa Matabei of Otsu) of Ukiyo-e, whose woodcuts of the transient world or the world of everyday life represented a drastic break with the classical tradition. Of the three artists Matabei of Otsu was the most original and had the strongest influence on the development of Japanese printmaking. By standards of Western taste, the images the Ukiyo-e school produced are highly stylized and thoroughly refined. Cultured Japanese, however, found them shockingly vulgar. The very fact that ordinary landscapes and the daily life of common people, actors, and courtesans were the inspiration for the Ukiyo-e artist represented a startling departure from tradition. Just as the emerging middle class revolutionized taste in Europe, the prosperous city dwellers of Edo, Kyōto, and Ōsaka de-

"Tamatori" ("Getting the Pebble"), colour woodcut by Hishikawa Moronobu, 17th century. 30.5 cm × 40 cm.

veloped their own aesthetic subculture. The development of the popular Kabuki theatre, as distinct from the aristocratic Nō drama, parallels the blossoming of Japanese printmaking.

The first great master of Japanese printmaking was Hishikawa Moronobu. A creative innovator, he was the first to use street scenes, peddlers, and crowds as his subject matter and to make his prints available to the common people. As a result, he was looked upon by many as the inventor of printmaking. He illustrated more than 100 books, mirroring the culture and customs of his time. Moronobu's style was a perfect harmony of rhythm, delicacy, and monumental simplicity, leading the way toward the great flowering of Japanese printmaking in the 18th century.

PRINTMAKING IN THE 18TH CENTURY

Italy. In the 18th century, Italy was the most fertile soil in Europe for printmaking. The first outstanding printmaker of the century was the Rococo master Giovanni Battista Tiepolo. His lightly bitten, spontaneous plates reveal superb draftsmanship. With rhythmic, delicate textures, he created a living, luminous space. His 50 plates represent a major contribution to the development of etching—a contribution that was further enhanced by his influence on Goya (see below *Spain*). Giovanni Domenico Tiepolo, the son of Battista, produced a greater quantity of prints than did his father but remained under his influence all his life.

One of the most original printmakers of the period, Canaletto (Giovanni Antonio Canal) created lyrical etchings that were charged with the misty atmosphere of Venice. Inexhaustible in linear and textural invention,

By courtesy of the Yale University Art Gallery, New Haven, Conn., gift of Edward B. Greene

"La Torre di Malghera," etching by Canaletto (1697–1768). 29.8 cm × 43 cm.

they are perfect examples of the simulation of colour and light by purely graphic means. His nephew and pupil, Bernardo Bellotto (Canaletto), who assumed his name, was a prolific printmaker, but, again, he remained under his uncle's influence.

Giambattista Piranesi was the greatest architectural printmaker of his time and probably of all time. Trained as an architect, he was passionately interested in Roman antiquities. Of the approximately 3,000 large etchings completed by Piranesi, all are brilliant, and many rise above documentation. His most important work is the *Carceri d'invenzione* (imaginary prison scenes). The plates, which were made in his youth (published c. 1750), are personal, rich, and evocative, far surpassing anything he created after them.

England. Until the 18th century, English printmaking was dominated by foreign influences. William Hogarth, the first major English printmaker, created not only a personal style but a national school. He was a gifted pictorial satirist, belonging in some respects to the tradition of Callot and Goya. He is, however, more earthy than Callot and lacks the savagery of Goya. Hogarth was a printmaker

Carceri d'invenzione ("Prisons"), plate 4, etching by Giambattista Piranesi, 1750(?). 55 cm × 41 cm.

of the people, whose work was so popular that to protect it from imitators he instigated the first engraving copyright act of 1735. Although his drawing was rather pedestrian, Hogarth's prints reveal a sharp observation, projected with robust vitality.

Next to Hogarth, Thomas Rowlandson is the most significant representative of English satire. A brilliant draftsman and a deft caricaturist, he spoofed the moral and social life of England with great humour.

William Blake is by far the most interesting figure in English printmaking. Poet and experimental printmaker, he was a visionary, creating his works totally outside the mainstream of art history. His printed work consisted primarily of book illustrations. Original and inventive in technique, he used a great range of media, from wood and metal engraving to relief etching. In the latter he devised

"The Cockpit," engraving by William Hogarth, 1759. 31.7 cm × 38.4 cm.

Pictorial
satire of
Hogarth

a transfer method that enabled him to etch the text and the illustration on the same plate. Many of his prints were hand coloured, but he also printed colour by an offset method of his own invention.

Thomas Bewick was a provincial illustrator who made a great number of charming wood engravings, primarily of animals and rural genre scenes. He was a pioneer in the technique of wood engraving, introducing tonal variations by slightly varying the level of his blocks.

To reproduce the fashionable paintings of the day, commercial engravers perfected a whole arsenal of reproduction techniques, such as mezzotint, stipple engraving and etching, and crayon manner.

Spain. Spanish printmaking in the 17th century had been dominated by Flemish and French influences, and no printmaker of importance emerged during the period.

In the 18th-century artist Francisco de Goya, Spain had not only its first truly great printmaker but also the only printmaker whose etchings rival Rembrandt's. Moreover, he is the most eminent satirist printmaker has produced. His visual comments on human folly, war, and religious persecution are devastating.

Goya created four major cycles of prints. The first, "Los caprichos" (1797–98), consists of 80 enigmatic prints commenting on all phases of life. In 1810 he began the 83 plates of "Los desastres de la guerra," a strong visual protest against the brutality of war. After this came "La tauromaquia" (1815–16), a brilliant series on bull fighting. The last important series was "Los disparates," or "Proverbs" (c. 1820–24), a biting, though often humorous, interpretation of human folly.

Technically, the Goya etchings are simple and direct. He usually combined line etching with aquatint; his masterful control of the latter, a relatively new technique, has never been surpassed. Toward the end of his life, he also made a few rich, powerful lithographs.

France. Most 18th-century French etchings were drawings transferred to copper, in which the effects of pencil, pen, or chalk were imitated. Although some distinguished painters, such as Antoine Watteau, made etchings, no prints of importance were produced. Jean-Honoré Fragonard made a few lovely etchings reminiscent of Tiepolo. They have a luminous, transparent quality and express the Rococo spirit but are nevertheless minor works of a major painter. Two artists are notable for technical achievements: Jean-Charles François developed the crayon manner, and Jean-Baptiste Le Prince is credited with the invention of aquatint.

Japan. The first Japanese artist to produce single prints in quantity was Torii Kiyonobu, who specialized in portraits of actors and theatre posters. His school, the Torii, dominated printing for the theatre for two centuries. Another imaginative innovator of the early 18th century was Okumura Masanobu, who experimented with inks, embossing, and gold and silver overlays. He also invented the two-colour print and generally standardized colour printing. His studio greatly influenced the evolution of colour woodcut. Suzuki Harunobu, one of the most charming masters of Japanese woodcut, created prints of infinite delicacy and grace. In this respect he is a forerunner and rival of Utamaro. A highly gifted colourist, he was one of the first to exploit the *nishiki-e*, or full-colour print. He was also the first to colour print backgrounds and to use blind embossing extensively to give his prints three-dimensional textures. Katsukawa Shunshō is notable for his austere portraits of actors, which he designed with much strength and intensity. Some of his portraits are among the finest in Japanese printmaking.

The period from 1780 to 1790 was dominated by Torii Kiyonaga, whose work represents the Ukiyo-e at its height. He was a great draftsman and designer and could harmonize in his prints the two seemingly contradictory qualities of elegance and power. Kiyonaga was one of the first to experiment with the compositional possibilities of the diptych, triptych, and pentaptych formats. Although he conceived each block as a self-contained unit, they functioned together in harmony. Kitagawa Utamaro can justly be called the supreme poet of Japanese art. Utamaro's prints are the most perfect expression

"Two Lovers Under an Umbrella in Snow," woodcut by Suzuki Harunobu (1724–70). 26.7 cm × 19.7 cm.

of a tender, loving contemplation of nature, which included not only birds and flowers but women as well. At the age of 50, he was put in jail for an offending print; broken in spirit, he died shortly after his release. During his lifetime he produced over 600 series of books and albums. Toshusai Sharaku is not only one of the most distinguished but also one of the most mysterious figures of Japanese art. Seemingly out of nowhere, his magnificent, powerful portraits of actors suddenly appeared on posters. The boldness of the portraits, verging on caricature; their psychological insight; their richness in colour all represented a daring new attitude. The originality of these prints disturbed the authorities to such an extent that the police prohibited them. In less than two years of working life, Sharaku had produced approximately 145 portraits; then the prodigious flow of work stopped, and he disappeared again.

PRINTMAKING IN THE 19TH CENTURY

The 19th century was a turbulent period of art, one aesthetic revolution following the other.

France. French domination of 19th-century art is comparable to northern domination of 15th-century printmaking. Few graphic artists of importance worked outside France. The great French painter Jean-Auguste-Dominique Ingres made only a few etchings, mainly portraits; but, as demonstrated by the lithograph "L'Odalisque" (1825), his draftsmanship was incomparable. Eugène Delacroix left a much more extensive graphic oeuvre: 24 etchings and 131 lithographs. Both in subject matter and style, Delacroix's prints are eloquent expressions of the Romantic spirit. In his tragically short life, Théodore Géricault made a series of powerful lithographs; his horses are considered classics in their genre.

At midcentury, a rebellion against studio painting took place. A group of young landscape painters, most of whom were also printmakers, formed a group that became known as the Barbizon school. The etchings of Charles-François Daubigny, Théodore Rousseau, and Jean-Baptiste-Camille Corot were close to the spirit of the 17th-century Dutch landscapes. Corot made prints whose spontaneity foreshadowed Impressionism; he also experimented with the newly discovered photographic method of *cliché-verre*.

Political
satire of
Daumier

Another member of this group, Jean-François Millet, was concerned particularly with depicting peasant life. His small but simple etchings are reminiscent of the 17th-century Dutch genre painter van Ostade at his best.

Honoré Daumier, one of the foremost political satirists of printmaking, was associated with the Barbizon school only through friendships. He produced over 4,000 lithographs (many of them newspaper illustrations), which are visually powerful expressions of his passionate convictions. His best work ranks with that of the greatest masters of printmaking.

A number of French artists were solitary figures working outside of any school; Charles Méryon, Rodolphe Bresdin, and Odilon Redon, for example. Méryon led a short, tragic life, living in poverty and dying insane. His major work is a series of landscapes of Paris—powerfully drawn, moody prints combining an air of mystery with morbid poetry. Bresdin was also a solitary figure, unappreciated and misunderstood most of his life. His etchings and lithographs are characterized by completely personal and fantastically rich imagery. The great symbolist painter Redon initially made prints under the influence of Bresdin. His graphic work—a few etchings but mostly lithographs—consists of about 206 prints, whose strange, often bizarre imagery powerfully influenced the Surrealists of the 20th century.

Although, basically, the Impressionists were concerned with the creation of light through colour, several artists identified with them made major contributions to printmaking. Of these, Édouard Manet and Edgar Degas are the most important. Both were superb draftsmen, and, in

"Rue Transnonain, April 15, 1834," lithograph by Honoré Daumier. 44.5 cm × 29 cm.

spite of their association with an avant-garde movement, their roots were firmly planted in traditional art. Manet made a few fine etchings, but his best and most personal works are lithographs, in which his swift but astonishingly precise drawing found its proper medium. Degas's drawings of horses and ballet dancers are miracles of observation and precision—as are his etchings and lithographs. Degas also made a series of monoprints, including a group of remarkably abstract landscapes. The grand old man of the Impressionists, Camille Pissarro, made 194 prints, both etchings and lithographs. His fine graphic work is representative of forceful Impressionist drawing.

Influence
of Japanese
woodcuts
on
European
art

The discovery of Japanese colour woodcuts was a revelation that profoundly influenced European art. Until the middle of the 19th century, Japanese printmaking was unknown to the West. As trade relations opened up with Japan, some colour prints came into the hands of young Parisian artists, who responded to the exotic images with great enthusiasm. The simple, abstract handling of colour and design represented a totally new visual experience. Paul Gauguin was one who profited greatly from their influence, which is perhaps more evident in his paintings than in his prints. Following centuries in which the woodcut was used for reproduction, Gauguin's powerful, boldly cut wood blocks were like a breath of fresh air. In the prints of Henri de Toulouse-Lautrec, Japanese in-

"Le Bon Samaritain" ("The Good Samaritan"), etching by Rodolphe Bresdin (1822–85). 56.3 cm × 44.3 cm.

fluence is more immediate. Although most of his prints were lithographs, the simple bold design, the flat, decorative colour, and the startling disposition of blacks clearly show this influence, which he assimilated and turned into a thoroughly personal expression. A very strong Japanese influence can be seen also in the brilliant color aquatints of the American-born Impressionist Mary Cassatt.

The giant of Postimpressionism, Paul Cézanne, made three etchings and three lithographs. His immense influence on modern art makes his colour lithograph "The Bathers" (c. 1900) an important graphic document. The Dutch artist Johan Barthold Jongkind, who lived in France, created sensitive landscapes and marine etchings that were a transition between the Barbizon school and Impressionism.

Hokusai's
woodcuts

Japan. The most famous Japanese master of woodcut, Hokusai, was born near Edo (Tokyo). From the age of 15, when he became an apprentice, until his death in 1849 at the age of 89, he produced an unending stream of masterpieces—about 35,000 drawings and prints, a staggering figure even considering his long life. He also wrote books and poems. There are few masters in the history of art whose work is comparable to Hokusai's in variety and depth. His interests encompassed history and mythology, popular customs, animal life, and landscape. His output was so enormous and the quality of his work so high that it is difficult to single out individual pieces. The "Thirty-six Views of Mt. Fuji" (c. 1826–33) is probably his most popular set of prints. The 15 volumes of the *Hokusai manga* ("Hokusai's Sketches"), published between 1814 and 1878, are fascinating work, for in these rather informal woodcuts the artist gives a comprehensive record of Japanese life and culture. Of all the Japanese masters, the universal genius of Hokusai had the greatest impact on European art.

The last master printmaker of Japan was Andō Hiroshige, whose death in 1858 ends the remarkable dynasty of artists that had begun two centuries earlier. Hiroshige was a great landscape painter and, with Hokusai, the first to capture the European imagination. He was also a versatile artist, famous in Europe as a painter at a time when in Japan he was known mainly as a poet. His greatest period of landscape-painting activity was from 1830 to about 1844. During that time he embarked on a sketching journey (1832), and these sketches formed the basis of "Fifty-three Stages on the Tōkaidō," his most important series of landscapes.

Like the work of the Impressionists in Western art history, Hiroshige's prints are spontaneous both in style and in atmosphere, capturing the essence of the fleeting moments of nature.

Other countries. In Germany, Max Liebermann made a few etchings of real individuality, but the most important German achievement of the period was the invention of lithography (c. 1796) by Aloys Senefelder, who was not an artist. Although the Belgian artist Félicien Rops lived outside France, he was strongly influenced by the school of Paris. His witty, erotic etchings represent a minor but personal expression of the period. In Sweden, the enormously successful Anders Zorn made etchings and drypoints with great virtuosity.

English printmaking of the 19th century centred around two great personalities, Sir Francis Seymour Haden and his brother-in-law, James McNeill Whistler. Haden was a Victorian country gentleman, a surgeon who loved and collected etchings. He started to make prints in his leisure time—and ultimately produced over 200 plates. His etchings, sensitively observed documentations of his environment, represent a significant contribution to the English landscape tradition. Whistler was born in America and attended West Point for a period; but he left to study art in Paris, where he met many of the leading artists, including Degas. In 1859 he went to London, where he resided until his death. Whistler was an immensely gifted, complex personality. Simultaneously with his fashionable portraiture, he did a great deal of experimentation; in the nearly abstract paintings and prints that he called "Nocturnes" (begun in 1866), for example, he was far ahead of his time. His graphic oeuvre, 442 etchings and drypoints and 150 lithographs, had great impact on modern printmaking. The freedom and painterliness of Whistler's etchings were particularly significant because they came to act as a strong liberating influence.

Printmaking in 19th-century America was still provincial and did not produce any artist comparable to the European masters. The colour engravings of flora and fauna executed by the naturalist John James Audubon constitute a significant body of work, however.

In Mexico, the popular illustrator José Guadalupe Posada produced thousands of woodcuts and lead cuts for newspapers in a completely original style—a mixture of sophistication and the naïveté of popular art. His work had a substantial influence on the young Mexican revolutionary art movement.

PRINTMAKING IN THE 20TH CENTURY

The invention of photography in the early 1800s had a great influence on the development of the visual arts. Its effect was the most immediate on printmaking: photographic reproduction processes made reproductive printmaking obsolete, and printmaking was returned to the creative artist.

The experimental attitude that originated with the Impressionists accelerated in the 20th century. The new styles and new directions that arose with bewildering rapidity made the first half of the century one of the most exciting periods in the history of art.

Continuing the pattern set in the 19th century, France dominated the art world. Attracted by its creative climate, young artists like the Spaniard Pablo Picasso flocked to Paris from other countries and, together with the French, formed the school of Paris, which produced many first-rate artists.

At the same time, Germany became again a vital art centre. German Expressionism and later the Bauhaus school

tions of
Haden and
Whistler

not only produced a number of distinguished artists but eventually exerted international influence.

The following discussion deals only with the "old masters" of contemporary art, those considered to be in historically secure positions. Four transitional figures are singled out as being of particular importance because they represent a bridge between the 19th and 20th centuries. Edvard Munch was an extraordinarily gifted Norwegian painter and printmaker who worked in Paris and in Berlin. His intense imagery, with psychological undertones, relates him to German Expressionism. A versatile artist, he made outstanding etchings, drypoints, colour lithographs, and experimental woodcuts. The Belgian artist James Ensor made superb etchings in a style related to Impressionism, but with fantastic imagery that was close to Surrealism. Close friends, the Frenchmen Pierre Bonnard and Édouard Vuillard produced similar graphic works. Inspired by the Japanese woodcut prints, both made sensitive, beautiful colour lithographs.

France. Pablo Picasso was without doubt the most dramatic and monumental figure of contemporary graphic art. Besides being a superb painter and sculptor, he created a graphic oeuvre so rich and all-encompassing that he stands alone. He made well over 1,000 prints, including etchings, engravings, drypoints, woodcuts, lithographs, and linoleum cuts. Georges Braque, the cofounder with Picasso of Cubism, produced 10 major Cubist etchings. The distinguished French painter Henri Matisse was a remarkable colorist and a highly accomplished draftsman. Although the majority of his more than 500 prints are lithographs, he also made some outstanding line etchings and, late in his career, some cutout prints that are masterpieces of design and colour orchestration. Georges Rouault, the French Expressionist, was a solitary figure in contemporary art. The most important graphic work of this religious painter was the "Miserere," a set of etchings published in 1948. Jacques Villon, a major French printmaker, was recognized late in his life as a great painter. Early in his career he made colour aquatints, after the paintings of his more celebrated contemporaries, that raised the level of intaglio colour printing to new heights. Later he developed a completely personal style within the Cubist tradition. He made more than 600 prints including engravings, etchings, drypoints, and colour lithographs. The poetic, naïve, and, at the same time, sophisticated style of Marc Chagall, a Russian Jewish member of the school of Paris, sets him apart from any art movement. In his significant body of graphic work, the most accomplished prints are illustrations of the Bible, the works of the Russian writer Nikolay Gogol, and the fables of the Frenchman Jean de La Fontaine. Like his compatriot Picasso, the Spanish painter and sculptor Joan Miró was a prolific printmaker. His witty colour etchings and lithographs represent an achievement equal to his paintings. Max Ernst was a founder of Surrealism and one of the most inventive and influential members of the group. In his extensive graphic work, he introduced a number of new techniques; most notable was his imaginative use of the "collage" in printmaking. Stanley William Hayter, an English painter-printmaker who lived in Paris, has an important position in the development of contemporary experimental printmaking. His significance lies not only in his work as an artist but also in his influence as a teacher. In the 1930s his "Atelier 17" printmaking group was the centre of experimental intaglio work in Paris. In the 1940s he came to the United States and, through his teaching in New York, exercised a powerful influence on contemporary American printmaking. Other artists who did noteworthy graphic work in France include Jean (Hans) Arp, Salvador Dalí, André Derain, Jan Dubuffet, André Dunoyer de Segonzac, Alberto Giacometti, Fernand Léger, André Masson, Louis Marcoussis, and Jules Pascin.

Germany. Unlike the extremely varied school of Paris, German Expressionism was quite homogeneous and also much less international. The Expressionists were not united by an aesthetic theory but by their human attitudes and spiritual aspirations. Nearly all of them were active in printmaking, and, although they worked in every con-

Jazz, Plate XV, serigraph by Henri Matisse, 1947.
41.9 cm × 64.7 cm.

porary graphic medium, the directness of drypoint and woodcut most appealed to their temperaments.

Louis Corinth represents a transition from 19th-century naturalism to the Expressionist movement. Although Corinth made etchings, woodcuts, and lithographs, his rich, virile drypoints are his best work. Although not innovative, Käthe Kollwitz's moving, powerful protest prints against war and poverty are significant graphic statements. Ernst Ludwig Kirchner, one of the major figures of German Expressionism, produced a rich graphic oeuvre consisting of etchings, lithographs, and woodcuts. His experimental colour woodcuts represent one of the most distinguished achievements in contemporary graphic art. Emil Nolde produced prints characterized by violent imagery. He worked spontaneously, often making woodcuts without preliminary drawings. Although Nolde came late to graphic work, he left an impressive number of woodcuts, etchings, and lithographs. Max Beckmann was an outstanding draftsman who made many woodcuts and drypoints. In the latter technique he created some of the finest portrait prints of the 20th century. During World War II Beckmann came to the United States, where he exerted considerable influence through his teaching. George Grosz used etchings and lithographs to give savage expression to his social criticism of Germany between the wars. The following Expressionists also left significant graphic work: Ernst Barlach, Erich Heckel, Oskar Kokoschka, and Karl Schmidt-Rottluff.

Other artists moved in a more formal, abstract direction. Based on their philosophy of "new objectivity," they founded the Bauhaus school in Germany in 1919. The two major artists in this group were the Russian Wassily Kandinsky and the Swiss Paul Klee. Kandinsky was one of the great innovators of contemporary art. In his early, lyrical paintings he was a forerunner of Abstract Expressionism, and in his late mature work he introduced Geometric Abstraction. His graphic work consists of an impressive number of woodcuts and lithographs. The whimsical, lyrical abstractions of Klee also had great influence on the course of modern art. His work—about 120 etchings and lithographs—is full of graphic invention and a rare sense of humour. Lyonel Feininger, born in the United States of German parents, studied in Europe and worked most of his life in Germany. He was associated with the Blaue Reiter group (artists who wished to express through their work the spiritual realities they felt had been ignored by the Impressionists) and then in 1919–33 with the Bauhaus. Feininger concentrated mostly on landscapes, executed in a very personal Cubist style, and was one of the most productive graphic artists at the Bauhaus. In the beginning, he made some etchings and lithographs but from 1918 worked mainly in woodcuts. Josef Albers, also associated with the Bauhaus, was born in Germany and moved to the United States in 1933. He made a considerable number of prints, including colour silk screens. Rolf Nesch was born in Germany, where he started printmaking with the en-

Artists

Influence
of Hayter
on print-
making

couragement of Kirchner. He fled to Oslo from Germany in 1933. One of the most gifted experimental printmakers of the 20th century, Nesch developed the method called metal graphic, which he used to make extremely intricate, heavily embossed colour prints.

Other countries. Printmaking in Italy was far behind France and Germany. The Futurist artist Umberto Boccioni made a few interesting etchings and the Cubist Gino Severini published a number of rather manneristic etchings and colour lithographs, but neither could be considered important printmakers. Giorgio Morandi is the only major Italian printmaker of this period. His intimate, delicate still-life and landscape etchings occupy a very special position in contemporary graphic art.

In Great Britain, Henry Moore, one of the great sculptors of the 20th century, published a number of strong lithographs. Graham Sutherland, a painter, made more than 100 etchings and lithographs in a distinctly personal style. Anthony Gross, one of the most talented and prolific English printmakers, has published an impressive body of excellent landscape etchings and engravings. Among later artists, the imaginative and personal graphic work of David Hockney should be singled out.

In the United States, after the turn of the century, most of the prominent painters became fairly active printmakers: George Wesley Bellows, in lithography; John Sloan and Reginald Marsh, in etching; Milton Avery, in drypoint and a large number of monoprints; and Stuart Davis, in colour lithography. Among these painter-printmakers, two artists are particularly notable: Edward Hopper, whose few etchings are very personal and of unusually high quality; and Ben Shahn, an extremely prolific printmaker, who left an impressive graphic oeuvre in practically every medium. Of the present generation of established painter-printmakers, only a few are creatively involved in the process, while the rest let the commercial printer take over.

A revival of the art of the woodcut began in Japan in the late 1920s as part of the modern art movement. Onchi Kōshirō and Hiratsuka Un-ichi were early exponents who, though working in different styles, did most for the renaissance of this national art, which thrived once again after World War II. Among the notable woodcut artists of the postwar period are Munakata Shikō and Saitō Kiyoshi.

Since the mid-20th century, there has been a spectacular increase in printmaking activity. Artists all over the world are enthusiastically working and experimenting in every conceivable medium. In this period probably more prints were made and more technical innovations introduced than in the previous history of printmaking.

Probability Theory

The word probability has several meanings in ordinary conversation. Two of these are particularly important for the development and applications of the mathematical theory of probability. One is the interpretation of probabilities as relative frequencies, for which simple games involving coins, cards, dice, and roulette wheels provide examples. The distinctive feature of games of chance is that the outcome of a given trial cannot be predicted with certainty, although the collective results of a large number of trials display some regularity. For example, the statement that the probability of “heads” in tossing a coin equals one-half, according to the relative frequency interpretation, implies that in a large number of tosses the relative frequency with which “heads” actually occurs will be approximately one-half, although it contains no implication concerning the outcome of any given toss. There are many similar examples involving

collections of people, molecules of a gas, genes, and so on. Actuarial statements about the life expectancy for persons of a certain age describe the collective experience of a large number of individuals but do not purport to say what will happen to any particular person. Similarly, predictions about the chance of a genetic disease occurring in a child of parents having a known genetic makeup are statements about relative frequencies of occurrence in a large number of cases but are not predictions about a given individual.

A second interpretation of probability, as a personal measure of uncertainty, is discussed below. For further discussion of the applications of probability theory, see STATISTICS.

DEVELOPMENT OF PROBABILITY THEORY

Although some ideas about probability appear in works from antiquity, the systematic development of probability theory began only in the 16th and 17th centuries when the European mathematicians Gerolamo Cardano, Pierre de Fermat, Blaise Pascal, and Christiaan Huygens began to analyze simple games of chance involving cards and dice. One of the first attempts to use ideas of relative frequency to study human populations arose in the mortality statistics assembled by John Graunt in 17th-century London at the time of the plague.

The most important early contributions to probability theory were Jakob Bernoulli's *Ars Conjectandi* (1713; “The Art of Conjecturing”) and Abraham de Moivre's *Doctrine of Chances* (1718, 1738, 1756). Bernoulli was the most distinguished of a distinguished family of Swiss mathematicians. He contributed to many branches of mathematics, and to probability theory he gave the law of large numbers, the first precise mathematical theorem to interpret probabilities in terms of observable relative frequencies. De Moivre was a French Protestant who fled to England to escape persecution. He is known today primarily because of his work in probability theory, notably his contribution to the central limit theorem, which along with the law of large numbers is discussed below.

After a century of comparatively slow progress, the development of probability theory accelerated in the mid-19th century. The Russian Pafnuty Lvovich Chebyshev began a tradition of elegant mathematical contributions that has continued in the Soviet Union to the present day. British interest in heredity, spearheaded in its quantitative development by Sir Francis Galton, and the rapid development at the turn of the century of the physical theories of Brownian motion and statistical mechanics provided scientific sources of new problems.

In the 20th century the mathematical theory of probability has been given an axiomatic foundation, and like other branches of mathematics its development from these axioms depends only on its logical correctness, whether or not its theorems refer to phenomena of the physical world. Nevertheless, its usefulness in describing variable or uncertain phenomena explains the ubiquity of probability theory in modern science and technology.

This article contains a description of the important mathematical concepts of probability theory, illustrated by some of the applications that have stimulated their development. Since applications inevitably involve simplifying assumptions that focus on some features of a problem at the expense of others, it is advantageous to begin, like the 17th-century mathematicians mentioned above, by thinking about simple experiments, such as tossing a coin or rolling dice, and later to see how these apparently frivolous investigations relate to important scientific questions.

EXPERIMENTS, SAMPLE SPACE, EVENTS, AND EQUALLY LIKELY PROBABILITIES

The fundamental ingredient of probability theory is an experiment that can be repeated, at least hypothetically, under essentially identical conditions and that may lead to different outcomes on different trials. The set of all possible outcomes of an experiment is called a “sample space.” The experiment of tossing a coin once results in a sample space with two possible outcomes, “heads” and “tails.” Tossing two dice has a sample space with 36 possible outcomes, each of which can be identified with an ordered pair (i, j) , where i and j assume one of the values 1, 2, 3, 4, 5, 6 and denote the faces showing on the individual dice. It is important to think of the dice as identifiable (say by a difference in colour), so that the outcome $(1, 2)$ is different from $(2, 1)$. An “event” is a well-defined subset of the sample space. For example, the event “the sum of the faces showing on the two dice equals six” consists of the five outcomes $(1, 5)$, $(2, 4)$, $(3, 3)$, $(4, 2)$, and $(5, 1)$.

A third example is to draw n balls from an urn containing balls of various colours. A generic outcome to this experiment is an n -tuple, where the i th entry specifies the colour of the ball obtained on the i th draw ($i = 1, 2, \dots, n$). In spite of the simplicity of this experiment, a thorough understanding gives the theoretical basis for opinion polls and sample surveys. For example, individuals in a population favouring a particular candidate in an election may be identified with balls of a particular colour, those favouring a different candidate may be identified with a different colour, and so on. Probability theory provides the basis for learning about the contents of the urn from the sample of balls drawn from the urn; an application is

The sample space

to learn about the electoral preferences of a population on the basis of a sample drawn from that population.

Another application of simple urn models is to clinical trials designed to determine whether a new treatment for a disease, a new drug, or a new surgical procedure is better than a standard treatment. In the simple case in which treatment can be regarded as either success or failure, the goal of the clinical trial is to discover whether the new treatment more frequently leads to success than does the standard treatment. Patients with the disease can be identified with balls in an urn. The red balls are those patients who are cured by the new treatment, and the black balls are those not cured. Usually there is a control group, who receive the standard treatment. They are represented by a second urn with a possibly different fraction of red balls. The goal of the experiment of drawing some number of balls from each urn is to discover on the basis of the sample which urn has the larger fraction of red balls. A variation of this idea can be used to test the efficacy of a new vaccine. Perhaps the largest and most famous example was the test of the Salk vaccine for poliomyelitis conducted in 1954. It was organized by the United States Public Health Service and involved almost two million children. Its success has led to the almost complete elimination of polio as a health problem in the industrialized parts of the world. Strictly speaking, these applications are problems of statistics, for which the foundations are provided by probability theory.

In contrast to the experiments described above, many experiments have infinitely many possible outcomes. For example, one can toss a coin until "heads" appears for the first time. The number of possible tosses is $n = 1, 2, \dots$. Another example is to twirl a spinner. For an idealized spinner made from a straight line segment having no width and pivoted at its centre, the set of possible outcomes is the set of all angles that the final position of the spinner makes with some fixed direction, equivalently all real numbers in $[0, 2\pi)$. Many measurements in the natural and social sciences, such as volume, voltage, temperature, reaction time, marginal income, and so on, are made on continuous scales and at least in theory involve infinitely many possible values. If the repeated measurements on different subjects or at different times on the same subject can lead to different outcomes, probability theory is a possible tool to study this variability.

Because of their comparative simplicity, experiments with finite sample spaces are discussed first. In the early development of probability theory, mathematicians considered only those experiments for which it seemed reasonable, based on considerations of symmetry, to suppose that all outcomes of the experiment were "equally likely." Then in a large number of trials all outcomes should occur with approximately the same frequency. The probability of an event is defined to be the ratio of the number of cases favourable to the event—i.e., the number of outcomes in the subset of the sample space defining the event—to the total number of cases. Thus, the 36 possible outcomes in the throw of two dice are assumed equally likely, and the probability of obtaining "six" is the number of favourable cases, 5, divided by 36, or $5/36$.

Now suppose that a coin is tossed n times, and consider the probability of the event "heads does not occur" in the n tosses. An outcome of the experiment is an n -tuple, the k th entry of which identifies the result of the k th toss. Since there are two possible outcomes for each toss, the number of elements in the sample space is 2^n . Of these, only one outcome corresponds to having no heads, so the required probability is $1/2^n$.

It is only slightly more difficult to determine the probability of "at most one head." In addition to the single case in which no head occurs, there are n cases in which exactly one head occurs, because it can occur on the first, second, \dots , or n th toss. Hence, there are $n+1$ cases favourable to obtaining at most one head, and the desired probability is $(n+1)/2^n$.

This last example illustrates the fundamental principle that, if the event whose probability is sought can be represented as the union of several other events that have no outcomes in common ("at most one head" is the union

of "no heads" and "exactly one head"), then the probability of the union is the sum of the probabilities of the individual events making up the union. To describe this situation symbolically, let S denote the sample space. For two events A and B , the intersection of A and B is the set of all experimental outcomes belonging to both A and B and is denoted $A \cap B$; the union of A and B is the set of all experimental outcomes belonging to A or B (or both) and is denoted $A \cup B$. The impossible event—i.e., the event containing no outcomes—is denoted by \emptyset . The probability of an event A is written $P(A)$. The principle of addition of probabilities is that, if A_1, A_2, \dots, A_n are events with $A_i \cap A_j = \emptyset$ for all pairs $i \neq j$, then

$$P(A_1 \cup A_2 \cup \dots \cup A_n) = P(A_1) + P(A_2) + \dots + P(A_n). \quad (1)$$

Equation (1) is consistent with the relative frequency interpretation of probabilities; for, if $A_i \cap A_j = \emptyset$ for all $i \neq j$, the relative frequency with which at least one of the A_i occurs equals the sum of the relative frequencies with which the individual A_i occur.

Equation (1) is fundamental for everything that follows. Indeed, in the modern axiomatic theory of probability, which eschews a definition of probability in terms of "equally likely outcomes" as being hopelessly circular, an extended form of equation (1) plays a basic role (see the discussion of axiomatic probability below).

An elementary, useful consequence of (1) is the following. With each event A is associated the complementary event A^c consisting of those experimental outcomes that do not belong to A . Since $A \cap A^c = \emptyset$, $A \cup A^c = S$, and $P(S) = 1$ (where S denotes the sample space), it follows from (1) that $P(A^c) = 1 - P(A)$. For example, the probability of "at least one head" in n tosses of a coin is one minus the probability of "no head," or $1 - 1/2^n$.

A basic problem first solved by Jakob Bernoulli is to find the probability of obtaining exactly i red balls in the experiment of drawing n times at random with replacement from an urn containing b black and r red balls. To draw at random means that, on a single draw, each of the $r+b$ balls is equally likely to be drawn and, since each ball is replaced before the next draw, there are $(r+b) \times \dots \times (r+b) = (r+b)^n$ possible outcomes to the experiment. Of these possible outcomes, the number that is favourable to obtaining i red balls and $n-i$ black balls in any one particular order is

$$\overbrace{r \times r \times \dots \times r}^i \times \overbrace{b \times b \times \dots \times b}^{n-i} = r^i \times b^{n-i}.$$

The number of possible orders in which i red balls and $n-i$ black balls can be drawn from the urn is the binomial coefficient

$$\binom{n}{i} = \frac{n!}{i!(n-i)!}, \quad (2)$$

where $k! = k \times (k-1) \times \dots \times 2 \times 1$ for positive integers k , and $0! = 1$. Hence, the probability in question, which equals the number of favourable outcomes divided by the number of possible outcomes, is

$$\binom{n}{i} \frac{r^i b^{n-i}}{(r+b)^n} = \binom{n}{i} p^i q^{n-i} \quad (i = 0, 1, 2, \dots, n), \quad (3)$$

where $p = r/(r+b)$ and $q = b/(r+b) = 1-p$.

For example, suppose $r=2b$ and $n=4$. According to (3), the probability of "exactly two red balls" is $\binom{4}{2} (2/3)^2 (1/3)^2 = 6 \times 4/81 = 8/27$. In this case the $\binom{4}{2} = 6$ possible outcomes are easily enumerated: $(rrbb)$, $(rbrb)$, $(brrb)$, $(rbbr)$, $(brbr)$, $(bbrr)$.

(For a derivation of (2), observe that in order to draw exactly i red balls in n draws one must either (a) draw i red balls in the first $n-1$ draws and a black ball on the n th draw or (b) draw $i-1$ red balls in the first $n-1$ draws followed by the i th red ball on the n th draw. Hence, $\binom{n}{i} = \binom{n-1}{i} + \binom{n-1}{i-1}$, from which (2) can be verified by induction on n .)

Two related examples are (i) drawing without replacement from an urn containing r red and b black balls and (ii) drawing with or without replacement from an urn

The principle of additivity

Probability theory and statistics

containing balls of s different colors. If n balls are drawn without replacement from an urn containing r red and b black balls, the number of possible outcomes is $\binom{r+b}{n}$, of which the number favourable to drawing i red and $n-i$ black balls is $\binom{r}{i}\binom{b}{n-i}$. Hence, the probability of drawing exactly i red balls in n draws is the ratio

$$\frac{\binom{r}{i}\binom{b}{n-i}}{\binom{r+b}{n}}.$$

If an urn contains balls of s different colors in the ratios $p_1:p_2:\dots:p_s$, where $p_1+\dots+p_s=1$, and if n balls are drawn with replacement, the probability of obtaining i_1 balls of the first colour, i_2 balls of the second colour, and so on is the multinomial probability

$$\frac{n!}{i_1!i_2!\dots i_s!}p_1^{i_1}p_2^{i_2}\dots p_s^{i_s}.$$

The evaluation of (3) with pencil and paper grows increasingly difficult with increasing n . It is even more difficult to evaluate related cumulative probabilities—for example the probability of obtaining “at most j red balls” in the n draws, which can be expressed as the sum of (3) for $i=0, 1, \dots, j$. The problem of approximate computation of probabilities that are known in principle is a recurrent theme throughout the history of probability theory and will be discussed in more detail below.

The
birthday
problem

An entertaining example is to determine the probability that in a randomly selected group of n people at least two have the same birthday. If one assumes for simplicity that a year contains 365 days and that each day is equally likely to be the birthday of a randomly selected person, then in a group of n people there are 365^n possible combinations of birthdays. Of these possibilities, the number that is unfavourable to the event that at least two have the same birthday is that the first person has any of the 365 days for his birthday, the second any of the other 364 days for his birthday, the third any of the remaining 363 days, \dots , and the n th any of the remaining $365-n+1$. Hence, the number of ways that all n people can have different birthdays is $365 \times 364 \times \dots \times (365-n+1)$, so that the probability that at least two have the same birthday is

$$P = 1 - \frac{365 \times 364 \times \dots \times (365-n+1)}{365^n}.$$

Numerical evaluation shows, rather surprisingly, that for $n=23$ the probability that at least two people have the same birthday is about 0.5. For $n=42$ the probability is about 0.9.

This example illustrates that applications of probability theory to the physical world are facilitated by assumptions that are not strictly true, although they should be approximately true. Thus, the assumptions that a year has 365 days and that all days are equally likely to be the birthday of a random individual are false, because one year in four has 366 days and because birth dates are not distributed uniformly throughout the year. Moreover, if one attempts to apply this result to an actual group of individuals, it is necessary to ask what it means for these to be “randomly selected.” It would naturally be unreasonable to apply it to a group known to contain twins. In spite of the obvious failure of the assumptions to be literally true, as a classroom example it rarely disappoints instructors of classes having more than forty students.

CONDITIONAL PROBABILITY

Suppose two balls are drawn sequentially without replacement from an urn containing r red and b black balls. The probability of getting a red ball on the first draw is $r/(r+b)$. If, however, one is told that a red ball was obtained on the first draw, the conditional probability of getting a red ball on the second draw is $(r-1)/(r+b-1)$, because for the second draw there are $r+b-1$ balls in the urn, of which $r-1$ are red. Similarly, if one is told that the first ball drawn is black, the conditional probability of getting red on the second draw is $r/(r+b-1)$.

In a number of trials the relative frequency with which B occurs among those trials in which A occurs is just the fre-

quency of occurrence of $A \cap B$ divided by the frequency of occurrence of A . This suggests that the conditional probability of B given A (denoted $P(B|A)$) should be defined by

$$P(B|A) = \frac{P(A \cap B)}{P(A)}. \quad (4)$$

If A denotes a red ball on the first draw and B a red ball on the second draw in the experiment of the preceding paragraph, then $P(A) = r/(r+b)$ and

$$P(A \cap B) = \frac{r(r-1)}{[(r+b)(r+b-1)]},$$

so (4) is consistent with the “obvious” answer derived above.

Rewriting (4) as $P(A \cap B) = P(A)P(B|A)$ and adding to this expression the same expression with A replaced by A^c (“not A ”) leads via (1) to the equality

$$\begin{aligned} P(B) &= P(A \cap B) + P(A^c \cap B) \\ &= P(A)P(B|A) + P(A^c)P(B|A^c). \end{aligned}$$

More generally, if A_1, A_2, \dots, A_n are mutually exclusive events and their union is the entire sample space, so that exactly one of the A_k must occur, essentially the same argument gives a fundamental relation, which is frequently called the law of total probability:

The law
of total
probability

$$\begin{aligned} P(B) &= P(A_1)P(B|A_1) + P(A_2)P(B|A_2) \\ &\quad + \dots + P(A_n)P(B|A_n). \end{aligned}$$

An application of the law of total probability to a problem originally posed by Huygens is to find the probability of “gambler’s ruin.” Suppose two players, often called Peter and Paul, initially have x and $m-x$ dollars, respectively. A ball, which is red with probability p and black with probability $q=1-p$, is drawn from an urn. If a red ball is drawn, Paul must pay Peter one dollar, while Peter must pay Paul one dollar if the ball drawn is black. The ball is replaced, and the game continues until one of the players is ruined. It is quite difficult to determine the probability of Peter’s ruin by a direct analysis of all possible cases. But let $Q(x)$ denote that probability as a function of Peter’s initial fortune x and observe that after one draw the structure of the rest of the game is exactly as it was before the first draw, except that Peter’s fortune is now either $x+1$ or $x-1$ according to the results of the first draw. The law of total probability with $A = \{\text{red ball on first draw}\}$ and $A^c = \{\text{black ball on first draw}\}$ shows that

$$Q(x) = pQ(x+1) + qQ(x-1). \quad (5)$$

This equation holds for $x=2, 3, \dots, m-2$. It also holds for $x=1$ and $m-1$ if one adds the boundary conditions $Q(0)=1$ and $Q(m)=0$, which say that, if Peter has 0 dollars initially, his probability of ruin is 1, while, if he has all m dollars, he is certain to win.

It can be verified by direct substitution that equation (5) together with the indicated boundary conditions are satisfied by

$$\begin{aligned} Q(x) &= \frac{\left(\frac{q}{p}\right)^x - \left(\frac{q}{p}\right)^m}{1 - \left(\frac{q}{p}\right)^m} \quad \left(p \neq \frac{1}{2}\right) \\ &= 1 - \frac{x}{m} \quad \left(p = \frac{1}{2}\right). \end{aligned} \quad (6)$$

With some additional analysis it is possible to show that these give the only solutions of (5) and hence must be the desired probabilities.

Suppose $m=10x$, so that Paul initially has nine times as much money as Peter. If $p=1/2$, the probability of Peter’s ruin is 0.9 regardless of the values of x and m . If $p=0.51$, so that each trial slightly favours Peter, the situation is quite different. For $x=1$ and $m=10$, the probability of Peter’s ruin is 0.88, only slightly less than before. However, for $x=100$ and $m=1,000$, Peter’s slight advantage on each trial becomes so important that the probability of his ultimate ruin is now less than 0.02.

Generalizations of the problem of gambler’s ruin play

an important role in statistical sequential analysis, developed by the Hungarian-born American statistician Abraham Wald in response to the demand for more efficient methods of industrial quality control during World War II. They also enter into insurance risk theory, which is discussed below.

The following example shows that, even when it is given that A occurs, it is important in evaluating $P(B|A)$ to recognize that A^c might have occurred, and hence in principle it must be possible also to evaluate $P(B|A^c)$. By lot, two out of three prisoners—Sam, Jean, and Chris—are chosen to be executed. There are $\binom{3}{2} = 3$ possible pairs of prisoners to be selected for execution, of which two contain Sam, so the probability that Sam is slated for execution is $2/3$. Sam asks the guard which of the others is to be executed. Since at least one must be, it appears that the guard would give Sam no information by answering. After hearing that Jean is to be executed, Sam reasons that, since either he or Chris must be the other one, the conditional probability that he will be executed is $1/2$. Thus, it appears that the guard has given Sam some information about his own fate. However, the experiment is incompletely defined, because it is not specified how the guard chooses whether to answer “Jean” or “Chris” in case both of them are to be executed. If the guard answers “Jean” with probability p , the conditional probability of the event “Sam will be executed” given “the guard says Jean will be executed” is

$$\frac{\frac{1}{3}}{\frac{1}{3} + p} = \frac{1}{1 + p}.$$

Only in the case $p = 1$ is Sam’s reasoning correct. If $p = 1/2$, the guard in fact gives no information about Sam’s fate.

The concept of independence

One of the most important concepts in probability theory is that of “independence.” The events A and B are said to be (stochastically) independent if $P(B|A) = P(B)$, or equivalently by (4) if

$$P(A \cap B) = P(A)P(B). \quad (7)$$

The intuitive meaning of the definition in terms of conditional probabilities is that the probability of B is not changed by knowing that A has occurred. Equation (7) shows that the definition is symmetric in A and B .

It is intuitively clear that, in drawing two balls with replacement from an urn containing r red and b black balls, the event “red ball on the first draw” and the event “red ball on the second draw” are independent. (This statement presupposes that the balls are thoroughly mixed before each draw.) An analysis of the $(r + b)^2$ equally likely outcomes of the experiment shows that the formal definition (7) is indeed satisfied.

In terms of the concept of independence, the experiment leading to the binomial distribution (3) can be described as follows. On a single trial a particular event has probability p . An experiment consists of n independent repetitions of this trial. The probability that the particular event occurs exactly i times is given by (3).

Independence plays a central role in the law of large numbers, the central limit theorem, the Poisson process, and the Brownian motion process (see below).

Consider now the defining relation (4) for the conditional probability $P(A_n|B)$, where the A_i are mutually exclusive and their union is the entire sample space. Substitution of $P(A_n)P(B|A_n)$ in the numerator of (4) and substitution of the right-hand side of the law of total probability in the denominator yields a result known as Bayes’s theorem (after the 18th-century English clergyman Thomas Bayes) or the law of inverse probability:

$$P(A_n|B) = \frac{P(A_n)P(B|A_n)}{\sum_i P(A_i)P(B|A_i)}.$$

As an example, suppose that two balls are drawn without replacement from an urn containing r red and b black balls. Let A be the event “red on the first draw” and B the event “red on the second draw.” From the obvious relations $P(A) = r/(r + b) = 1 - P(A^c)$, $P(B|A) =$

$(r - 1)/(r + b - 1)$, $P(B|A^c) = r/(r + b - 1)$, and Bayes’s theorem, it follows that the probability of a red ball on the first draw given that the second one is known to be red equals $(r - 1)/(r + b - 1)$. A more interesting and important use of Bayes’s theorem appears below in the discussion of subjective probabilities.

RANDOM VARIABLES, DISTRIBUTIONS, EXPECTATION, AND VARIANCE

Usually it is more convenient to associate numerical values with the outcomes of an experiment than to work directly with a nonnumerical description such as “red ball on the first draw.” For example, an outcome of the experiment of drawing n balls with replacement from an urn containing black and red balls is an n -tuple that tells us whether a red or a black ball was drawn on each of the draws. This n -tuple is conveniently represented by an n -tuple of ones and zeros, where the appearance of a one in the k th position indicates that a red ball was drawn on the k th draw. A quantity of particular interest is the number of red balls drawn, which is just the sum of the entries in this numerical description of the experimental outcome. Mathematically a rule that associates with every element of a given set a unique real number is called a “(real-valued) function.” In the history of statistics and probability, real-valued functions defined on a sample space have traditionally been called “random variables.” Thus, if a sample space S has the generic element e , the outcome of an experiment, then a random variable is a real-valued function $X = X(e)$. Customarily one omits the argument e in the notation for a random variable. For the experiment of drawing balls from an urn containing black and red balls, R , the number of red balls drawn, is a random variable. A particularly useful random variable is $1[A]$, the indicator variable of the event A , which equals 1 if A occurs and 0 otherwise. If A_k denotes the event “a red ball is drawn on the k th draw,” then R has the useful representation: $R = 1[A_1] + \cdots + 1[A_n]$. A “constant” is a trivial random variable that always takes the same value regardless of the outcome of the experiment.

Random variables

Suppose X is a random variable that can assume one of the values x_1, x_2, \dots, x_m , according to the outcome of a random experiment, and consider the event $\{X = x_i\}$, which is a shorthand notation for the set of all experimental outcomes e such that $X(e) = x_i$. The probability of this event, $P\{X = x_i\}$, is itself a function of x_i , called the “(probability) distribution” of X . Thus, the distribution of the random variable R defined in the preceding paragraph is the function of $i = 0, 1, \dots, n$ given in (3). Introducing the notation $f(x_i) = P\{X = x_i\}$, one sees from the basic properties of probabilities that

$$f(x_i) \geq 0 \text{ for all } i, \quad \sum_i f(x_i) = 1,$$

and

$$P\{a < X \leq b\} = \sum_{a < x_i \leq b} f(x_i),$$

for any real numbers a and b . If Y is a second random variable defined on the same sample space as X and taking the values y_1, y_2, \dots, y_n , the function of two variables $h(x_i, y_j) = P\{X = x_i, Y = y_j\}$ is called the “joint distribution” of X and Y . Since $\{X = x_i\} = \cup_j \{X = x_i, Y = y_j\}$, and this union consists of disjoint events in the sample space,

$$f(x_i) = \sum_j h(x_i, y_j), \quad \text{for all } i. \quad (8)$$

Often f is called the “marginal distribution” of X to emphasize its relation to the joint distribution of X and Y . Similarly, $g(y_j) = \sum_i h(x_i, y_j)$ is the (marginal) distribution of Y . The random variables X and Y are defined to be independent if the events $\{X = x_i\}$ and $\{Y = y_j\}$ are independent for all i and j —i.e., if $h(x_i, y_j) = f(x_i)g(y_j)$ for all i and j . The joint distribution of an arbitrary number of random variables is defined similarly.

Suppose two dice are thrown. Let X denote the sum of the numbers appearing on the two dice, and let Y denote the number of even numbers appearing. The possible values of X are 2, 3, \dots , 12, while the possible values

Joint Distribution of X and Y												
j	i											row sum = $g(j)$
	2	3	4	5	6	7	8	9	10	11	12	
0	$1/36$	0	$1/18$	0	$1/12$	0	$1/18$	0	$1/36$	0	0	$1/4$
1	0	$1/18$	0	$1/9$	0	$1/6$	0	$1/9$	0	$1/18$	0	$1/2$
2	0	0	$1/36$	0	$1/18$	0	$1/12$	0	$1/18$	0	$1/36$	$1/4$
column sum = $f(i)$	$1/36$	$1/18$	$1/12$	$1/9$	$5/36$	$1/6$	$5/36$	$1/9$	$1/12$	$1/18$	$1/36$	

of Y are 0, 1, 2. Since there are 36 possible outcomes for the two dice, the accompanying table giving the joint distribution $h(i, j)$ ($i = 2, 3, \dots, 12; j = 0, 1, 2$) and the marginal distributions $f(i)$ and $g(j)$ is easily computed by direct enumeration.

For more complex experiments, determination of a complete probability distribution usually requires a combination of theoretical analysis and empirical experimentation and is often very difficult. Consequently, it is desirable to describe a distribution insofar as possible by a small number of parameters that are comparatively easy to evaluate and interpret. The most important are the mean and the variance. These are both defined in terms of the "expected value" of a random variable.

Given a random variable X with distribution f , the expected value of X , denoted $E(X)$, is defined by $E(X) = \sum_i x_i f(x_i)$. In words, the expected value of X is the sum of each of the possible values of X multiplied by the probability of obtaining that value. The expected value of X is also called the "mean" of the distribution f . The basic property of E is that of linearity: if X and Y are random variables and if a and b are constants, then $E(aX + bY) = aE(X) + bE(Y)$. To see why this is true, note that $aX + bY$ is itself a random variable, which assumes the values $ax_i + by_j$ with the probabilities $h(x_i, y_j)$. Hence,

$$\begin{aligned} E(aX + bY) &= \sum_{i,j} (ax_i + by_j)h(x_i, y_j) \\ &= a \sum_{i,j} x_i h(x_i, y_j) + b \sum_{i,j} y_j h(x_i, y_j). \end{aligned}$$

If the first sum on the right-hand side is summed over j while holding i fixed, by (8) the result is $\sum_j x_i f(x_i)$, which by definition is $E(X)$. Similarly, the second sum equals $E(Y)$.

If $1[A]$ denotes the "indicator variable" of A —i.e., a random variable equal to 1 if A occurs and equal to 0 otherwise—then $E(1[A]) = 1 \times P(A) + 0 \times P(A^c) = P(A)$. This shows that the concept of expectation includes that of probability as a special case.

As an illustration, consider the number R of red balls in n draws with replacement from an urn containing a proportion p of red balls. From the definition and the distribution of R given in (3), $E(R) = \sum_i i \binom{n}{i} p^i q^{n-i}$, which can be evaluated by algebraic manipulation and found to equal np . It is easier to use the representation $R = 1[A_1] + \dots + 1[A_n]$, where A_k denotes the event "the k th draw results in a red ball." Since $E(1[A_k]) = p$ for all k , by linearity $E(R) = E(1[A_1]) + \dots + E(1[A_n]) = np$. This argument illustrates the principle that one can often compute the expected value of a random variable without first computing its distribution. For another example, suppose n balls are dropped at random into n boxes. The number of empty boxes, Y , has the representation $Y = 1[B_1] + \dots + 1[B_n]$, where B_k is the event that "the k th box is empty." Since the k th box is empty if and only if each of the n balls went into one of the other $n-1$ boxes, $P(B_k) = [(n-1)/n]^n$ for all k , and consequently $E(Y) = n(1 - 1/n)^n$. The exact distribution of Y is very complicated, especially if n is large.

Many probability distributions have small values of $f(x_i)$ associated with extreme (large or small) values of x_i and larger values of $f(x_i)$ for intermediate x_i . For example, both marginal distributions in the table are symmetrical about a midpoint that has relatively high probability, and the probability of other values decreases as one moves away from the midpoint. Insofar as a distribution $f(x_i)$

follows this kind of pattern, one can interpret the mean of f as a rough measure of location of the bulk of the probability distribution, because in the defining sum the values x_i associated with large values of $f(x_i)$ more or less define the center of the distribution. In the extreme case, the expected value of a constant random variable is just that constant.

It is also of interest to know how closely packed about its mean value a distribution is. The most important measure of concentration is the "variance," denoted by $\text{Var}(X)$ and defined by $\text{Var}(X) = E[(X - E(X))^2]$. By linearity of expectations, one has equivalently $\text{Var}(X) = E(X^2) - (E(X))^2$. The "standard deviation" of X is the square root of its variance. It has a more direct interpretation than the variance because it is in the same units as X . The variance of a constant random variable is 0. Also, if c is a constant, $\text{Var}(cX) = c^2 \text{Var}(X)$.

There is no general formula for the expectation of a product of random variables. If the random variables X and Y are independent, $E(XY) = E(X)E(Y)$. This can be used to show that, if X_1, \dots, X_n are independent random variables, the variance of the sum $X_1 + \dots + X_n$ is just the sum of the individual variances, $\text{Var}(X_1) + \dots + \text{Var}(X_n)$. If the X s have the same distribution and are independent, the variance of the average $(X_1 + \dots + X_n)/n$ is $\text{Var}(X_1)/n$. Equivalently, the standard deviation of $(X_1 + \dots + X_n)/n$ is the standard deviation of X_1 divided by $n^{1/2}$. This quantifies the intuitive notion that the average of repeated observations is less variable than the individual observations. More precisely, it says that the variability of the average is inversely proportional to the square root of the number of observations. This result is tremendously important in problems of statistical inference. (See the discussion of the law of large numbers and the central limit theorem below.)

Consider again the binomial distribution (3). As in the calculation of the mean value, one can use the definition combined with some algebraic manipulation to show that, if R has the distribution defined by (3), then $\text{Var}(R) = npq$. From the representation $R = 1[A_1] + \dots + 1[A_n]$ defined above, and the observation that the events A_k are independent and have the same probability, it follows that

$$\text{Var}(R) = \text{Var}(1[A_1]) + \dots + \text{Var}(1[A_n]) = n \text{Var}(1[A_1]).$$

Moreover,

$$\text{Var}(1[A_1]) = E(1[A_1]^2) - [E(1[A_1])]^2 = p - p^2 = pq,$$

so $\text{Var}(R) = npq$. Also, $\text{Var}(R/n) = \text{Var}(R)/n^2 = pq/n$.

The conditional distribution of Y given $X = x_i$ is defined by:

$$P(Y = y_j | X = x_i) = \frac{h(x_i, y_j)}{f(x_i)}$$

(compare (4)), and the conditional expectation of Y given $X = x_i$ is

$$E(Y | X = x_i) = \sum_j \frac{y_j h(x_i, y_j)}{f(x_i)}. \quad (9)$$

One can regard $E(Y | X)$ as a function of X ; since X is a random variable, this function of X must itself be a random variable. The conditional expectation $E(Y | X)$ considered as a random variable has its own (unconditional) expectation $E(E(Y | X))$, which is calculated by multiplying (9) by $f(x_i)$ and summing over i to obtain the important formula

$$E(E(Y | X)) = E(Y). \quad (10)$$

Properly interpreted, equation (10) is a generalization of the law of total probability.

Variance

The expected value of a random variable

For a simple example of the use of (10), recall the problem of gambler's ruin and let $e(x)$ denote the expected duration of the game if Peter's fortune is initially equal to x . The reasoning leading to (5) in conjunction with (10) shows that $e(x)$ satisfies the equations $e(x) = 1 + pe(x+1) + qe(x-1)$ for $x = 1, 2, \dots, m-1$ with the boundary conditions $e(0) = e(m) = 0$. The solution for $p \neq 1/2$ is rather complicated; for $p = 1/2$, $e(x) = x(m-x)$.

AN ALTERNATIVE INTERPRETATION OF PROBABILITY

Probability
as a
measure of
uncertainty

In ordinary conversation the word probability is applied not only to variable phenomena but also to propositions of uncertain veracity. The truth of any proposition concerning the outcome of an experiment is uncertain before the experiment is performed. Many other uncertain propositions cannot be defined in terms of repeatable experiments. An individual can be uncertain about the truth of a scientific theory, a religious doctrine, or even about the occurrence of a specific historical event when inadequate or conflicting eyewitness accounts are involved. Using probability as a measure of uncertainty enlarges its domain of application to phenomena that do not meet the requirement of repeatability. The concomitant disadvantage is that probability as a measure of uncertainty is subjective and varies from one person to another.

According to one interpretation, to say that someone has subjective probability p that a proposition is true means that for any integers r and b with $r/(r+b) < p$, if that individual is offered an opportunity to bet the same amount on the truth of the proposition or on "red in a single draw" from an urn containing r red and b black balls, he prefers the first bet, while, if $r/(r+b) > p$, he prefers the second bet.

An important stimulus to modern thought about subjective probability has been an attempt to understand decision making in the face of incomplete knowledge. It is assumed that an individual, when faced with the necessity of making a decision that may have different consequences depending on situations about which he has incomplete knowledge, can express his personal preferences and uncertainties in a way consistent with certain axioms of rational behaviour. It can then be deduced that the individual has a "utility function," which measures the value to him of each course of action when each of the uncertain possibilities is the true one, and a "subjective probability distribution," which expresses quantitatively his beliefs about the uncertain situations. The individual's optimal decision is the one that maximizes his expected utility with respect to his subjective probability. The concept of utility goes back at least to Daniel Bernoulli (Jakob Bernoulli's nephew) and has been developed in the twentieth century by John von Neumann and Oskar Morgenstern, Frank P. Ramsey, and Leonard J. Savage, among others. Ramsey and Savage have stressed the importance of subjective probability as a concomitant ingredient of decision making in the face of uncertainty. An alternative approach to subjective probability without the use of utility theory has been developed by Bruno de Finetti.

The mathematical theory of probability is the same regardless of one's interpretation of the concept, although the importance attached to various results can depend very much on the interpretation. In particular, in the theory and applications of subjective probability, Bayes's theorem plays an important role.

A priori
and
a posteriori
distribution

For example, suppose that an urn contains N balls, r of which are red and $b = N-r$ of which are black, but r (hence b) is unknown. One is permitted to learn about the value of r by performing the experiment of drawing with replacement n balls from the urn. Suppose also that one has a subjective probability distribution giving the probability $f(r)$ that the number of red balls is in fact r where $f(0) + \dots + f(N) = 1$. This distribution is called an a priori distribution because it is specified prior to the experiment of drawing balls from the urn. The binomial probability (3) is now a conditional probability, given the value of r . Finally, one can use Bayes's theorem to find the conditional probability that the unknown number of red balls in the urn is r , given that the number of red balls drawn from the urn is i . The result is

$$\frac{f(r)r^i b^{n-i}}{\sum_{r=0}^n f(r)r^i b^{n-i}}, \quad \text{where } b_0 = N - r_0.$$

This distribution, derived by using Bayes's theorem to combine the a priori distribution with the conditional distribution for the outcome of the experiment, is called the a posteriori distribution.

The virtue of this calculation is that it makes possible a probability statement about the composition of the urn, which is not directly observable, in terms of observable data, from the composition of the sample taken from the urn. The weakness, as indicated above, is that different people may choose different subjective probabilities for the composition of the urn a priori and hence reach different conclusions about its composition a posteriori.

To see how this idea might apply in practice, consider a simple urn model of opinion polling to predict which of two candidates will win an election. The red balls in the urn are identified with voters who will vote for candidate A and the black balls with those voting for candidate B . Choosing a sample from the electorate and asking their preferences is a well-defined random experiment, which in theory and in practice is repeatable. The composition of the urn is uncertain and is not the result of a well-defined random experiment. Nevertheless, to the extent that a vote for a candidate is a vote for a political party, other elections provide information about the content of the urn, which if used judiciously should be helpful in supplementing the results of the actual sample to make a prediction. Exactly how to use this information is a difficult problem in which individual judgment plays an important part. One possibility is to incorporate the prior information into an a priori distribution about the electorate, which is then combined via Bayes's theorem with the outcome of the sample and summarized by an a posteriori distribution.

THE LAW OF LARGE NUMBERS, THE CENTRAL LIMIT THEOREM, AND THE POISSON APPROXIMATION

The relative-frequency interpretation of probability is that, if an experiment is repeated a large number of times under identical conditions and independently, then the relative frequency with which an event A actually occurs and the probability of A should be approximately the same. A mathematical expression of this interpretation is the law of large numbers. This theorem says that, if X_1, X_2, \dots, X_n are independent random variables having a common distribution with mean μ , then for any number $\varepsilon > 0$, no matter how small, as $n \rightarrow \infty$,

$$P\{|n^{-1}(X_1 + \dots + X_n) - \mu| < \varepsilon\} \rightarrow 1. \quad (11)$$

The law of large numbers was first proved by Jakob Bernoulli in the special case where X_k is 1 or 0 according as the k th draw (with replacement) from an urn containing r red and b black balls is red or black. Then $E(X_k) = r/(r+b)$, and (11) says that the probability that "the difference between the empirical proportion of red balls in n draws and the probability of red on a single draw is less than ε " converges to 1 as n becomes infinitely large.

Insofar as an event which has probability very close to 1 is practically certain to happen, this result justifies the relative-frequency interpretation of probability. Strictly speaking, however, the justification is circular because the probability in (11), which is very close to but not equal to 1, requires its own relative-frequency interpretation. Perhaps it is better to say that the weak law of large numbers is consistent with the relative-frequency interpretation of probability.

The following simple proof of the law of large numbers is based on Chebyshev's inequality, which illustrates the sense in which the variance of a distribution measures how the distribution is dispersed about its mean. If X is a random variable with distribution f and mean μ , then by definition $\text{Var}(X) = \sum_i (x_i - \mu)^2 f(x_i)$. Since all terms in this sum are positive, the sum can only decrease if some of the terms are omitted. Suppose one omits all terms with $|x_i - \mu| < b$, where b is an arbitrary, given number. Each term remaining in the sum has a factor of the form $(x_i - \mu)^2$,

Chebyshev's
inequality

which is greater than or equal to b^2 . Hence, $\text{Var}(X) \geq b^2 \sum' f(x_i)$, where the prime on the summation sign indicates that only terms with $|x_i - \mu| \geq b$ are included in the sum. Chebyshev's inequality is this expression rewritten as

$$P\{|X - \mu| \geq b\} \leq \frac{\text{Var}(X)}{b^2}.$$

This inequality can be applied to the complementary event of that appearing in (11), with $b = \varepsilon$. The X s are independent and have the same distribution, $E[n^{-1}(X_1 + \cdots + X_n)] = \mu$ and $\text{Var}[(X_1 + \cdots + X_n)/n] = \text{Var}(X_1)/n$, so that

$$P\left\{\left|\frac{(X_1 + \cdots + X_n)}{n} - \mu\right| < \varepsilon\right\} \geq 1 - \frac{\text{Var}(X_1)}{n\varepsilon^2}.$$

This not only proves (11), but it also says quantitatively how large n should be in order that the empirical average, $n^{-1}(X_1 + \cdots + X_n)$, approximate its expectation to any required degree of precision.

Suppose, for example, that the proportion p of red balls in an urn is unknown and is to be estimated by the empirical proportion of red balls in a sample of size n drawn from the urn with replacement. Chebyshev's inequality with $X_k = 1$ {red ball on the k th draw} implies that, in order that the observed proportion be within ε of the true proportion p with probability at least 0.95, it suffices that n be at least $20 \times \text{Var}(X_1)/\varepsilon^2$. Since $\text{Var}(X_1) = p(1-p) \leq 1/4$ for all p , for $\varepsilon = 0.03$ it suffices that n be at least 5,555. It is shown below that this value of n is much larger than necessary, because Chebyshev's inequality is not sufficiently precise to be useful in numerical calculations.

Although Jakob Bernoulli did not know Chebyshev's inequality, the inequality he derived was also imprecise, and, perhaps because of his disappointment in not having a quantitatively useful approximation, he did not publish the result during his lifetime. It appeared in 1713, eight years after his death.

The desired useful approximation is given by the central limit theorem, which in the special case of the binomial distribution was first discovered by de Moivre about 1730. Let X_1, \dots, X_n be independent random variables having a common distribution with expectation μ and variance σ^2 . The law of large numbers implies that the distribution of the random variable $\bar{X}_n = n^{-1}(X_1 + \cdots + X_n)$ is essentially just the degenerate distribution of the constant μ , because $E(\bar{X}_n) = \mu$ and $\text{Var}(\bar{X}_n) = \sigma^2/n \rightarrow 0$ as $n \rightarrow \infty$. The standardized random variable $(\bar{X}_n - \mu)/(\sigma/n^{1/2})$ has mean 0 and variance 1. The central limit theorem gives the remarkable result that, for any real numbers a and b , as $n \rightarrow \infty$,

$$P\{a < \frac{(\bar{X}_n - \mu)}{(\sigma/n^{1/2})} \leq b\} \rightarrow G(b) - G(a), \quad (12)$$

where $G(z) = (2\pi)^{-1/2} \int_{-\infty}^z \exp(-t^2/2) dt$. Thus, if n is large, the standardized average has a distribution that is approximately the same, regardless of the original distribution of the X s. Equation (12) also illustrates clearly the "square root law": the accuracy of \bar{X}_n as an estimator of μ is inversely proportional to the square root of the sample size n .

Use of (12) to evaluate approximately the probability on the left-hand side of (11), by setting $b = -a = \varepsilon n^{1/2}/\sigma$, yields the approximation $G(\varepsilon n^{1/2}/\sigma) - G(-\varepsilon n^{1/2}/\sigma)$. Since $G(2) - G(-2)$ is approximately 0.95, n must be about $4\sigma^2/\varepsilon^2$ in order that the difference $|\bar{X}_n - \mu|$ will be less than ε with probability 0.95. For the special case of the binomial distribution, one can again use the inequality $\sigma^2 = p(1-p) \leq 1/4$ and now conclude that about 1,100 balls must be drawn from the urn in order that the empirical proportion of red balls drawn will be within 0.03 of the true proportion of red balls with probability about 0.95. The frequently appearing statement in newspapers in the United States that a given opinion poll involving a sample of about 1,100 persons has a sampling error of no more than 3 percent is based on this kind of calculation. The qualification that this 3 percent sampling error may be exceeded in about 5 percent of the cases is often omitted. (The actual situation in opinion polls or sample surveys generally is more complicated. The sample is drawn without replacement, so strictly speaking the binomial dis-

tribution is not applicable. However, the "urn"—i.e., the population from which the sample is drawn—is extremely large, in many cases infinitely large for practical purposes. Hence, the composition of the urn is effectively the same throughout the sampling process, and the binomial distribution applies as an approximation. Also, the population is usually stratified into relatively homogeneous groups, and the survey is designed to take advantage of this stratification. To pursue the analogy with urn models, one can imagine the balls to be in several urns in varying proportions, and one must decide how to allocate the n draws from the various urns so as to estimate efficiently the overall proportion of red balls.)

Considerable effort has been put into generalizing both the law of large numbers and the central limit theorem, so that it is unnecessary for the variables to be either independent or identically distributed.

The law of large numbers discussed above is often called the "weak law of large numbers," to distinguish it from the "strong law," a conceptually different result discussed below in the section on infinite probability spaces.

The weak law of large numbers and the central limit theorem give information about the distribution of the proportion of successes in a large number of independent trials when the probability of success on each trial is p . In the mathematical formulation of these results, it is assumed that p is an arbitrary, but fixed, number in the interval $(0, 1)$ and $n \rightarrow \infty$, so that the expected number of successes in the n trials, np , also increases toward $+\infty$ with n . A rather different kind of approximation is of interest when n is large and the probability p of success on a single trial is inversely proportional to n , so that $np = \mu$ is a fixed number even though $n \rightarrow \infty$. An example is the following simple model of radioactive decay of a source consisting of a large number of atoms, which independently of one another decay by spontaneously emitting a particle. The time scale is divided into a large number of very small intervals of equal lengths, and in each interval, independently of what happens in the other intervals, the source emits one or no particle with probability p or $q = 1 - p$ respectively. It is assumed that the intervals are so small that the probability of two or more particles being emitted in a single interval is negligible. One now imagines that the size of the intervals shrinks to 0, so that the number of trials up to any fixed time t becomes infinite. It is reasonable to assume that the probability of emission during a short time interval is proportional to the length of the interval. The result is a different kind of approximation to the binomial distribution, called the Poisson approximation (after the French mathematician Siméon-Denis Poisson), or the law of small numbers.

Assume, then, that a biased coin having probability $p = \mu\delta$ of heads is tossed once in each time interval of length δ , so that by time t the total number of tosses is an integer n approximately equal to t/δ . Introducing these values into (3) and passing to the limit as $\delta \rightarrow 0$ gives as the distribution for $N(t)$ the number of radioactive particles emitted in time t :

$$P(N(t) = i) = \frac{(\mu t)^i \exp(-\mu t)}{i!} \quad (i = 0, 1, \dots). \quad (13)$$

The right-hand side of (13) is called the Poisson distribution. Its mean and variance are both equal to μt . Although the Poisson approximation is not comparable to the central limit theorem in importance, it nevertheless provides one of the basic building blocks in the theory of stochastic processes (see below).

INFINITE SAMPLE SPACES AND AXIOMATIC PROBABILITY

The experiments described in the preceding discussion involve finite sample spaces for the most part, although the central limit theorem and the Poisson approximation involve limiting operations and hence lead to integrals and infinite series. In a finite sample space, calculation of the probability of an event A is conceptually straightforward because the principle of additivity tells one to calculate the probability of a complicated event as the sum of the probabilities of the individual experimental outcomes whose union defines the event.

The
central
limit
theorem

The
Poisson
approxima-
tion

Experiments having a continuum of possible outcomes—for example, that of selecting a number at random from the interval $[r, s]$ —involve subtle mathematical difficulties that were not satisfactorily resolved until the 20th century. If one chooses a number at random from $[r, s]$, the probability that the number falls in any interval $[x, y]$ must be proportional to the length of that interval; and, since the probability of the entire sample space $[r, s]$ equals 1, the constant of proportionality equals $1/(s-r)$. Hence, the probability of obtaining a number in the interval $[x, y]$ equals $(y-x)/(s-r)$. From this and the principle of additivity one can determine the probability of any event that can be expressed as a finite union of intervals. There are, however, very complicated sets having no simple relation to the intervals—e.g., the rational numbers—and it is not immediately clear what the probabilities of these sets should be. Also, the probability of selecting exactly the number x must be 0, because the set consisting of x alone is contained in the interval $[x, x+1/n]$ for all n and hence must have no larger probability than $1/[n(s-r)]$, no matter how large n is. Consequently, it makes no sense to try to compute the probability of an event by “adding” the probabilities of the individual outcomes making up the event, because each individual outcome has probability 0.

A closely related experiment, although at first there appears to be no connection, arises as follows. Suppose that a coin is tossed n times, and let $X_k = 1$ or 0 according as the outcome of the k th toss is heads or tails. The weak law of large numbers given above says that a certain sequence of numbers—namely the sequence of probabilities given in (11) and defined in terms of these n X s—converges to 1 as $n \rightarrow \infty$. In order to formulate this result, it is only necessary to imagine that one can toss the coin n times and that this finite number of tosses can be arbitrarily large. In other words, there is a sequence of experiments, but each one involves a finite sample space. It is also natural to ask whether the sequence of random variables $(X_1 + \cdots + X_n)/n$ converges as $n \rightarrow \infty$. However, this question cannot even be formulated mathematically unless infinitely many X s can be defined on the same sample space, which in turn requires that the underlying experiment involve an actual infinity of coin tosses.

For the conceptual experiment of tossing a fair coin infinitely many times, the sequence of zeros and ones, (X_1, X_2, \dots) , can be identified with that real number that has the X s as the coefficients of its expansion in the base 2, namely $X_1/2^1 + X_2/2^2 + X_3/2^3 + \cdots$. For example, the outcome of getting heads on the first two tosses and tails thereafter corresponds to the real number $1/2 + 1/4 + 0/8 + \cdots = 3/4$. (There are some technical mathematical difficulties that arise from the fact that some numbers have two representations. Obviously $1/2 = 1/2 + 0/4 + \cdots$, and the formula for the sum of an infinite geometric series shows that it also equals $0/2 + 1/4 + 1/8 + \cdots$. It can be shown that these difficulties do not pose a serious problem, and they are ignored in the subsequent discussion.) For any particular specification i_1, i_2, \dots, i_n of zeros and ones, the event $\{X_1 = i_1, X_2 = i_2, \dots, X_n = i_n\}$ must have probability $1/2^n$ in order to be consistent with the experiment of tossing the coin only n times. Moreover, this event corresponds to the interval of real numbers $[i_1/2^1 + i_2/2^2 + \cdots + i_n/2^n, i_1/2^1 + i_2/2^2 + \cdots + i_n/2^n + 1/2^n]$ of length $1/2^n$, since any continuation X_{n+1}, X_{n+2}, \dots corresponds to a number that is at least 0 and at most $1/2^{n+1} + 1/2^{n+2} + \cdots = 1/2^n$ by the formula for an infinite geometric series. It follows that the mathematical model for choosing a number at random from $[0, 1]$ and that of tossing a fair coin infinitely many times assign the same probabilities to all intervals of the form $[k/2^n, l/2^n]$.

The mathematical relation between these two experiments was recognized in 1909 by the French mathematician Émile Borel, who used the then new ideas of measure theory to give a precise mathematical model and to formulate what is now called the “strong law of large numbers” for fair coin tossing. His results can be described as follows. Let e denote a number chosen at random from $[0, 1]$, and let $X_k(e)$ be the k th coordinate in the expansion of e to the base 2. Then X_1, X_2, \dots are an infinite sequence of independent random variables taking

the values 0 or 1 with probability $1/2$ each. Moreover, the subset of $[0, 1]$ consisting of those e for which the sequence $n^{-1}[X_1(e) + \cdots + X_n(e)]$ tends to $1/2$ as $n \rightarrow \infty$ has probability 1. Symbolically:

$$P\left\{\lim_{n \rightarrow \infty} [n^{-1}(X_1 + \cdots + X_n)] = \frac{1}{2}\right\} = 1. \quad (14)$$

The weak law of large numbers given in (11) says that for any $\varepsilon > 0$, for each sufficiently large value of n , there is only a small probability of observing a deviation of $\bar{X}_n = n^{-1}(X_1 + \cdots + X_n)$ from $1/2$ which is larger than ε ; nevertheless, it leaves open the possibility that sooner or later this rare event will occur if one continues to toss the coin and observe the sequence for a sufficiently long time. The strong law, however, asserts that the occurrence of even one value of \bar{X}_k for $k \geq n$ that differs from $1/2$ by more than ε is an event of arbitrarily small probability provided n is large enough. The proof of (14) and various subsequent generalizations is much more difficult than that of the weak law of large numbers. The adjectives “strong” and “weak” refer to the fact that the truth of a result such as (14) implies the truth of the corresponding version of (11), but not conversely.

During the two decades following 1909, measure theory was used in many concrete problems of probability theory, notably in the American mathematician Norbert Wiener’s treatment (1923) of the mathematical theory of Brownian motion (see below), but the notion that all problems of probability theory could be formulated in terms of measure is customarily attributed to the Soviet mathematician Andrey Nikolayevich Kolmogorov in 1933.

The fundamental quantities of the measure-theoretic foundation of probability theory are the sample space S , which as before is just the set of all possible outcomes of an experiment, and a distinguished class M of subsets of S , called events. Unlike the case of finite S , in general not every subset of S is an event. The class M must have certain properties described below. Each event is assigned a probability, which means mathematically that a probability is a function P mapping M into the real numbers that satisfies certain conditions derived from one’s physical ideas about probability.

The properties of M are as follows: (i) $S \in M$; (ii) if $A \in M$, then $A^c \in M$; (iii) if $A_1, A_2, \dots \in M$, then $A_1 \cup A_2 \cup \cdots \in M$. Recalling that M is the domain of definition of the probability P , one can interpret (i) as saying that $P(S)$ is defined, (ii) as saying that, if the probability of A is defined, then the probability of “not A ” is also defined, and (iii) as saying that, if one can speak of the probability of each of a sequence of events A_n individually, then one can speak of the probability that at least one of the A_n occurs. A class of subsets of any set that has properties (i)–(iii) is called a “ σ -field.” From these properties one can prove others. For example, it follows at once from (i) and (ii) that \emptyset (the empty set) belongs to the class M . Since the intersection of any class of sets can be expressed as the complement of the union of the complements of those sets (DeMorgan’s law), it follows from (ii) and (iii) that, if $A_1, A_2, \dots \in M$, then $A_1 \cap A_2 \cap \cdots \in M$.

Given a set S and a σ -field M of subsets of S , a probability measure is a function P that assigns to each set $A \in M$ a nonnegative real number and that has the following two properties: (a) $P(S) = 1$ and (b) if $A_1, A_2, \dots \in M$ and $A_i \cap A_j = \emptyset$ for all $i \neq j$, then $P(A_1 \cup A_2 \cup \cdots) = P(A_1) + P(A_2) + \cdots$. Property (b) is called the “axiom of countable additivity.” It is clearly motivated by equation (1), which suffices for finite sample spaces because there are only finitely many events. In infinite sample spaces it implies, but is not implied by, equation (1). There is, however, nothing in one’s intuitive notion of probability that requires the acceptance of this property. Indeed, a few mathematicians have developed probability theory with only the weaker axiom of finite additivity, but the absence of interesting models that fail to satisfy the axiom of countable additivity has led to its virtually universal acceptance.

To get a better feeling for this distinction, consider the experiment of tossing a biased coin having probability p of heads and $q = 1 - p$ of tails until heads first appears.

The axiom of countable additivity

The strong law of large numbers

To be consistent with the idea that the tosses are independent, the probability that exactly n tosses are required equals $q^{n-1}p$, since the first $n-1$ tosses must be tails, and they must be followed by a head. One can imagine that this experiment never terminates—i.e., that the coin continues to turn up tails forever. By the axiom of countable additivity, however, the probability that heads occurs at some finite value of n equals $p + qp + q^2p + \cdots = p/(1-q) = 1$, by the formula for the sum of an infinite geometric series. Hence, the probability that the experiment goes on forever equals 0. Similarly, one can compute the probability that the number of tosses is odd, as $p + q^2p + q^4p + \cdots = p/(1-q^2) = 1/(1+q)$. On the other hand, if only finite additivity were required, it would be possible to define the following admittedly bizarre probability. The sample space S is the set of all natural numbers, and the σ -field M is the class of all subsets of S . If an event A contains finitely many elements, $P(A) = 0$, and, if the complement of A contains finitely many elements, $P(A) = 1$. As a consequence of the deceptively innocuous axiom of choice (which says that, given any collection C of nonempty sets, there exists a rule for selecting a unique point from each set in C), one can show that many finitely additive probabilities consistent with these requirements exist. However, one cannot be certain what the probability of getting an odd number is, because that set is neither finite nor its complement finite, nor can it be expressed as a finite disjoint union of sets whose probability is already defined.

It is a basic problem, and by no means a simple one, to show that the intuitive notion of choosing a number at random from $[0, 1]$, as described above, is consistent with the preceding definitions. Since the probability of an interval is to be its length, the class of events M must contain all intervals; but in order to be a σ -field it must contain other sets, many of which are difficult to describe in an elementary way. One example is the event in (14), which must belong to M in order that one can talk about its probability. Also, although it seems clear that the length of a finite disjoint union of intervals is just the sum of their lengths, a rather subtle argument is required to show that length has the property of countable additivity. A basic theorem says that there is a suitable σ -field containing all the intervals and a unique probability defined on this σ -field for which the probability of an interval is its length. The σ -field is called the class of Lebesgue-measurable sets, and the probability is called the Lebesgue measure, after the French mathematician and principal architect of measure theory, Henri-Léon Lebesgue.

Lebesgue-measurable sets

In general, a σ -field need not be all subsets of the sample space S . The question of whether all subsets of $[0, 1]$ are Lebesgue-measurable turns out to be a difficult problem that is intimately connected with the foundations of mathematics and in particular with the axiom of choice.

For random variables having a continuum of possible values, the function that plays the same role as the probability distribution of a discrete random variable is called a “probability density function.” If the random variable is denoted by X , its probability density function f has the property that

$$P(a < X \leq b) = \int_a^b f(x) dx$$

for every interval $(a, b]$; i.e., the probability that X falls in $(a, b]$ is the area under the graph of f between a and b (see Figure 1). For example, if X denotes the outcome of selecting a number at random from the interval $[r, s]$, the probability density function of X is given by $f(x) = 1/(s-r)$ for $r < x < s$ and $f(x) = 0$ for $x < r$ or $x > s$. The function $F(x)$ defined by $F(x) = P\{X \leq x\}$ is called the “distribution function” or “cumulative distribution function” of X . If X has a probability density function $f(x)$, the relation between f and F is $F'(x) = f(x)$ or equivalently $F(x) = \int_{-\infty}^x f(t) dt$. The distribution function F of a discrete random variable should not be confused with its probability distribution f . In this case the relation between F and f is $F(x) = \sum_{x_i \leq x} f(x_i)$.

If a random variable X has a probability density function $f(x)$, its “expectation” can be defined by

$$E(X) = \int_{-\infty}^{\infty} xf(x) dx, \quad (15)$$

provided that this integral is convergent. It turns out to be simpler, however, not only to use Lebesgue’s theory of measure to define probabilities but also to use his theory of integration to define expectation. Accordingly, for any random variable X , $E(X)$ is defined to be the Lebesgue integral of X with respect to the probability measure P , provided that the integral exists. In this way it is possible to provide a unified theory in which all random variables, both discrete and continuous, can be treated simultaneously. In order to follow this path, it is necessary to restrict the class of those functions X defined on S that are to be called random variables, just as it was necessary to restrict the class of subsets of S that are called events. The appropriate restriction is that a random variable must be a measurable function. The definition is taken over directly from the Lebesgue theory of integration and will not be discussed here. It can be shown that, whenever X has a probability density function, its expectation (provided it exists) is given by (15), which remains a useful formula for calculating $E(X)$.

A unified theory

Some important probability density functions are the following:

(i) Normal: $f(x) = (2\pi\sigma^2)^{-1/2} \exp \left[\frac{-(x-\mu)^2}{2\sigma^2} \right]$

$(-\infty < x < +\infty); \quad E(X) = \mu, \text{Var}(X) = \sigma^2.$

(ii) Exponential: $f(x) = \mu \exp(-\mu x) \quad (0 \leq x < +\infty),$

$f(x) = 0 \quad (x < 0); \quad E(X) = \frac{1}{\mu}.$

(iii) Cauchy: $f(x) = \frac{1}{[\pi(1+x^2)]} \quad (-\infty < x < +\infty);$

$E(X)$ does not exist.

The cumulative distribution function of the normal distribution with mean 0 and variance 1 has already appeared as the function G defined following equation (12). The law of large numbers and the central limit theorem continue to hold for random variables on infinite sample spaces. A useful interpretation of the central limit theorem stated formally in (12) is as follows: The probability that the average (or sum) of a large number of independent, identically distributed random variables with finite variance falls in an interval $(c_1, c_2]$ equals approximately the area between c_1 and c_2 underneath the graph of a normal density function chosen to have the same expectation and variance as the given average (or sum). Figure 2 illustrates the normal approximation to the binomial distribution with $n = 10$ and $p = 1/2$.

The exponential distribution arises naturally in the study of the Poisson distribution introduced in (13). If T_k denotes the time interval between the emission of the k -1st and k th particle, then T_1, T_2, \dots are independent random variables having an exponential dis-

Figure 1: Probability density function.

Figure 2: Normal approximation to the binomial distribution.

tribution with parameter μ . This is obvious for T_1 from the observation that $\{T_1 > t\} = \{N(t) = 0\}$. Hence, $P(T_1 \leq t) = 1 - P(N(t) = 0) = 1 - \exp(-\mu t)$, and by differentiation one obtains the exponential density function.

Properties
of the
Cauchy
distribution

The Cauchy distribution does not have a mean value or a variance, because the integral (15) does not converge. As a result it has a number of unusual properties. For example, if X_1, X_2, \dots, X_n are independent random variables having a Cauchy distribution, the average $(X_1 + \dots + X_n)/n$ also has a Cauchy distribution. The variability of the average is exactly the same as that of a single observation. Another random variable that does not have an expectation is the waiting time until the number of heads first equals the number of tails in tossing a fair coin.

CONDITIONAL EXPECTATION AND LEAST SQUARES PREDICTION

An important problem of probability theory is to predict the value of a future observation Y given knowledge of a related observation X (or, more generally, given several related observations X_1, X_2, \dots). Examples are to predict the future course of the national economy or the path of a rocket, given its present state.

Prediction is often just one aspect of a "control" problem. For example, in guiding a rocket, measurements of the rocket's location, velocity, and so on are made almost continuously; at each reading, the rocket's future course is predicted, and a control is then used to correct its future course. The same ideas are used to steer automatically large tankers transporting crude oil, for which even slight gains in efficiency result in large financial savings.

Given X , a predictor of Y is just a function $H(X)$. The problem of "least squares prediction" of Y given the observation X is to find that function $H(X)$ that is closest to Y in the sense that the mean square error of prediction, $E\{[Y - H(X)]^2\}$, is minimized. The solution is the conditional expectation $H(X) = E(Y|X)$.

In applications a probability model is rarely known exactly and must be constructed from a combination of theoretical analysis and experimental data. It may be quite difficult to determine the optimal predictor, $E(Y|X)$, particularly if instead of a single X a large number of predictor variables X_1, X_2, \dots are involved. An alternative is to restrict the class of functions H over which one searches to minimize the mean square error of prediction, in the hope of finding an approximately optimal predictor that is much easier to evaluate. The simplest possibility is to restrict consideration to linear functions $H(X) = a + bX$. The coefficients a and b that minimize the restricted mean square prediction error $E\{(Y - a - bX)^2\}$ give the "best linear least squares predictor." Treating this restricted mean square prediction error as a function of the two coefficients (a, b) and minimizing it by methods of the calculus yield the optimal coefficients: $\hat{b} = E[(X - E(X))[Y - E(Y)]]/\text{Var}(X)$ and $\hat{a} = E(Y) - \hat{b}E(X)$. The numerator of the expression for \hat{b} is called the "covariance" of X and Y and is denoted $\text{Cov}(X, Y)$. Let $\hat{Y} = \hat{a} + \hat{b}X$ denote the optimal

linear predictor. The mean square error of prediction is $E\{(Y - \hat{Y})^2\} = \text{Var}(Y) - [\text{Cov}(X, Y)]^2/\text{Var}(X)$.

If X and Y are independent, then $\text{Cov}(X, Y) = 0$, the optimal predictor is just $E(Y)$, and the mean square error of prediction is $\text{Var}(Y)$. Hence, $|\text{Cov}(X, Y)|$ is a measure of the value X has in predicting Y . In the extreme case that $[\text{Cov}(X, Y)]^2 = \text{Var}(X)\text{Var}(Y)$, Y is a linear function of X and the optimal linear predictor gives error-free prediction.

There is one important case in which the optimal mean square predictor actually is the same as the optimal linear predictor. If X and Y are jointly normally distributed, the conditional expectation of Y given X is just a linear function of X , and hence the optimal predictor and the optimal linear predictor are the same. The form of the bivariate normal distribution as well as expressions for the coefficients \hat{a} and \hat{b} and for the minimum mean square error of prediction were discovered by the English eugenicist Sir Francis Galton in his studies of the transmission of inheritable characteristics from one generation to the next. They form the foundation of the statistical technique of linear regression.

THE POISSON PROCESS AND THE BROWNIAN MOTION PROCESS

The theory of stochastic processes attempts to build probability models for phenomena that evolve over time. A primitive example appearing earlier in this article is the problem of gambler's ruin.

Stochastic
processes

An important stochastic process described implicitly in the discussion of the Poisson approximation to the binomial distribution is the Poisson process. Modeling the emission of radioactive particles by an infinitely large number of tosses of a coin having infinitesimally small probability for heads on each toss led to the conclusion that the number of particles $N(t)$ emitted in the time interval $[0, t]$ has the Poisson distribution given in (13) with expectation μt . The primary concern of the theory of stochastic processes is not this marginal distribution of $N(t)$ at a particular time but rather the evolution of $N(t)$ over time. Two properties of the Poisson process that make it attractive to deal with theoretically are: (i) The times between emission of particles are independent and exponentially distributed with expected value $1/\mu$. (ii) Given that $N(t) = n$, the times at which the n particles are emitted have the same joint distribution as n points distributed independently and uniformly on the interval $[0, t]$.

As a consequence of property (i) a picture of the function $N(t)$ is very easily constructed. Originally $N(0) = 0$. At an exponentially distributed time T_1 , the function $N(t)$ jumps from 0 to 1. It remains at 1 another exponentially distributed random time, T_2 , which is independent of T_1 , and at time $T_1 + T_2$ it jumps from 1 to 2, and so on.

Examples of other phenomena for which the Poisson process often serves as a mathematical model are the number of customers arriving at a counter and requesting service, the number of claims against an insurance company, or the number of malfunctions in a computer system. The importance of the Poisson process consists in (a) its simplicity as a test case for which the mathematical theory, and hence the implications, are more easily understood than for more realistic models and (b) its use as a building block in models of complex systems.

The most important stochastic process is the Brownian motion or Wiener process. It was first discussed by Louis Bachelier (1900), who was interested in modeling fluctuations in prices in financial markets, and by Albert Einstein (1905), who gave a mathematical model for the irregular motion of colloidal particles first observed by the Scottish botanist Robert Brown in 1827. The first mathematically rigorous treatment of this model was given by Wiener (1923). Einstein's results led to an early, dramatic confirmation of the molecular theory of matter in the French physicist Jean Perrin's experiments to determine Avogadro's number, for which Perrin was awarded a Nobel Prize in 1926. Today somewhat different models for physical Brownian motion are deemed more appropriate than Einstein's, but the original mathematical model continues to play a central role in the theory and application of stochastic processes.

Random
walk

Let $B(t)$ denote the displacement (in one dimension for simplicity) of a colloidal suspended particle, which is buffeted by the numerous much smaller molecules of the medium in which it is suspended. This displacement will be obtained as a limit of a "random walk" occurring in discrete time as the number of steps becomes infinitely large and the size of each individual step infinitesimally small. Assume that at times $k\delta$, $k = 1, 2, \dots$, the colloidal particle is displaced a distance hX_k , where X_1, X_2, \dots are $+1$ or -1 according as the outcomes of tossing a fair coin are heads or tails. By time t the particle has taken m steps, where m is the largest integer $\leq t/\delta$, and its displacement from its original position is $B_m(t) = h(X_1 + \dots + X_m)$. The expected value of $B_m(t)$ is 0 and its variance is h^2m , or approximately h^2t/δ . Now suppose that $\delta \rightarrow 0$, and at the same time $h \rightarrow 0$ in such a way that the variance of $B_m(t)$ converges to some positive constant, σ^2 . This means that m becomes infinitely large, and h is approximately $\sigma(t/m)^{1/2}$. It follows from the central limit theorem (12) that $\lim P(B_m(t) \leq x) = G(x/\sigma t^{1/2})$, where $G(x)$ is the standard normal cumulative distribution function defined just below equation (12). The Brownian motion process $B(t)$ can be defined to be the limit in a certain technical sense of the $B_m(t)$ as $\delta \rightarrow 0$ and $h \rightarrow 0$ with $h^2/\delta \rightarrow \sigma^2$.

The process $B(t)$ has many other properties, which in principle are all inherited from the approximating random walk $B_m(t)$. For example, if (s_1, t_1) and (s_2, t_2) are disjoint intervals, the increments $B(t_1) - B(s_1)$ and $B(t_2) - B(s_2)$ are independent random variables that are normally distributed with expectation 0 and variances equal to $\sigma^2(t_1 - s_1)$ and $\sigma^2(t_2 - s_2)$, respectively.

Einstein took a different approach and derived various properties of the process $B(t)$ by showing that its probability density function, $g(x, t)$, satisfies the diffusion equation $\partial g/\partial t = D\partial^2 g/\partial x^2$, where $D = \sigma^2/2$. The important implication of Einstein's theory for subsequent experimental research was that he identified the diffusion constant D in terms of certain measurable properties of the particle (its radius) and of the medium (its viscosity and temperature), which allowed one to make predictions and hence to confirm or reject the hypothesized existence of the unseen molecules that were assumed to be the cause of the irregular Brownian motion. Because of the beautiful blend of mathematical and physical reasoning involved, a brief summary of the successor to Einstein's model is given below.

Unlike the Poisson process, it is impossible to "draw" a picture of the path of a particle undergoing mathematical Brownian motion. Wiener (1923) showed that the functions $B(t)$ are continuous, as one expects, but nowhere differentiable. Thus, a particle undergoing mathematical Brownian motion does not have a well-defined velocity, and the curve $y = B(t)$ does not have a well-defined tangent at any value of t . To see why this might be so, recall that the derivative of $B(t)$, if it exists, is the limit as $h \rightarrow 0$ of the ratio $[B(t+h) - B(t)]/h$. Since $B(t+h) - B(t)$ is normally distributed with mean 0 and standard deviation $h^{1/2}\sigma$, in very rough terms $B(t+h) - B(t)$ can be expected to equal some multiple (positive or negative) of $h^{1/2}$. But the limit as $h \rightarrow 0$ of $h^{1/2}/h = 1/h^{1/2}$ is infinite. A related fact that illustrates the extreme irregularity of $B(t)$ is that in every interval of time, no matter how small, a particle undergoing mathematical Brownian motion travels an infinite distance. Although these properties contradict the commonsense idea of a function—and indeed it is quite difficult to write down explicitly a single example of a continuous, nowhere-differentiable function—they turn out to be typical of a large class of stochastic processes, called "diffusion processes," of which Brownian motion is the most prominent member. Especially notable contributions to the mathematical theory of Brownian motion and diffusion processes were made by Paul Lévy and William Feller during the years 1930–1960.

A more sophisticated description of physical Brownian motion can be built on a simple application of Newton's second law: $F = ma$. Let $V(t)$ denote the velocity of a colloidal particle of mass m . It is assumed that

$$mdV(t) = -fV(t)dt + dA(t). \quad (18)$$

The quantity f retarding the movement of the particle is due to friction caused by the surrounding medium. The term $dA(t)$ is the contribution of the very frequent collisions of the particle with unseen molecules of the medium. It is assumed that f can be determined by classical fluid mechanics, in which the molecules making up the surrounding medium are so many and so small that the medium can be considered smooth and homogeneous. Then by Stokes's law, for a spherical particle in a gas, $f = 6\pi a\eta$, where a is the radius of the particle and η the coefficient of viscosity of the medium. Hypotheses concerning $A(t)$ are less specific, because the molecules making up the surrounding medium cannot be observed directly. For example, it is assumed that, for $t \neq s$, the infinitesimal random increments $dA(t) = A(t+dt) - A(t)$ and $A(s+ds) - A(s)$ caused by collisions of the particle with molecules of the surrounding medium are independent random variables having distributions with mean 0 and unknown variances $\sigma^2 dt$ and $\sigma^2 ds$ and that $dA(t)$ is independent of $dV(s)$ for $s < t$.

The differential equation (18) has the solution

$$V(t) = V(0)\exp(-\beta t) + m^{-1} \int_0^t \exp[-\beta(t-s)] dA(s), \quad (19)$$

where $\beta = f/m$. From (19) and the assumed properties of $A(t)$, it follows that $E[V^2(t)] \rightarrow \sigma^2/(2mf)$ as $t \rightarrow \infty$. Now assume that, in accordance with the principle of equipartition of energy, the steady-state average kinetic energy of the particle, $m \lim_{t \rightarrow \infty} E[V^2(t)]/2$, equals the average kinetic energy of the molecules of the medium. According to the kinetic theory of an ideal gas, this is $RT/2N$, where R is the ideal gas constant, T is the temperature of the gas in kelvins, and N is Avogadro's number, the number of molecules in one gram molecular weight of the gas. It follows that the unknown value of σ^2 can be determined: $\sigma^2 = 2RT/fN$.

If one also assumes that the functions $V(t)$ are continuous, which is certainly reasonable from physical considerations, it follows by mathematical analysis that $A(t)$ is a Brownian motion process as defined above. This conclusion poses questions about the meaning of the initial equation (18), because for mathematical Brownian motion the term $dA(t)$ does not exist in the usual sense of a derivative. Some additional mathematical analysis shows that the stochastic differential equation (18) and its solution (19) have a precise mathematical interpretation. The process $V(t)$ is called the Ornstein-Uhlenbeck process, after the physicists Leonard Salomon Ornstein and George Eugene Uhlenbeck. The logical outgrowth of these attempts to differentiate and integrate with respect to a Brownian motion process is the Ito (named for the Japanese mathematician Itô Kiyosi) stochastic calculus, which plays an important role in the modern theory of stochastic processes.

The displacement at time t of the particle whose velocity is given by (19) is

$$\begin{aligned} X(t) - X(0) &= \int_0^t V(u)du = \beta^{-1}V(0)[1 - \exp(-\beta t)] \\ &\quad + \beta^{-1}A(t) - \beta^{-1} \int_0^t \exp[-\beta(t-u)] dA(u). \end{aligned}$$

For t large compared to β the first and third terms in this expression are small compared to the second. Hence, $X(t) - X(0)$ is approximately equal to $A(t)/\beta$, and the mean square displacement, $E[(X(t) - X(0))^2]$, is approximately $\sigma^2 t/\beta^2 = RT/(3\pi a\eta N)$. These final conclusions are consistent with Einstein's model, although here they arise as an approximation to the model obtained from (19). Since it is primarily the conclusions that have observational consequences, there are essentially no new experimental implications. However, the analysis arising directly out of Newton's second law, which yields a process having a well-defined velocity at each point, seems more satisfactory theoretically than Einstein's original model.

STOCHASTIC PROCESSES

A stochastic process is a family of random variables $X(t)$ indexed by a parameter t , which usually takes values in

The Ito
stochastic
calculusDiffusion
processes

the discrete set $T = \{0, 1, 2, \dots\}$ or the continuous set $T = [0, +\infty)$. In many cases t represents time, and $X(t)$ is a random variable observed at time t . Examples are the Poisson process, the Brownian motion process, and the Ornstein-Uhlenbeck process described in the preceding section. Considered as a totality, the family of random variables $\{X(t), t \in T\}$ constitutes a "random function."

The mathematical theory of stochastic processes attempts to define classes of processes for which a unified theory can be developed. The most important classes are stationary processes and Markov processes. A stochastic process is called stationary if, for all n , $t_1 < t_2 < \dots < t_n$, and $h > 0$, the joint distribution of $X(t_1 + h), \dots, X(t_n + h)$ does not depend on h . This means that in effect there is no origin on the time axis; the stochastic behaviour of a stationary process is the same no matter when the process is observed. A sequence of independent identically distributed random variables is an example of a stationary process. A rather different example is defined as follows: $U(0)$ is uniformly distributed on $[0, 1]$; for each $t = 1, 2, \dots$, $U(t) = 2U(t-1)$ if $U(t-1) \leq 1/2$, and $U(t) = 2U(t-1) - 1$ if $U(t-1) > 1/2$. The marginal distributions of $U(t)$, $t = 0, 1, \dots$ are uniformly distributed on $[0, 1]$, but, in contrast to the case of independent identically distributed random variables, the entire sequence can be predicted from knowledge of $U(0)$. A third example of a stationary process is

$$X(t) = \sum_k c_k [Y_k \cos(\theta_k t) + Z_k \sin(\theta_k t)],$$

where the Y s and Z s are independent normally distributed random variables with mean 0 and unit variance, and the c s and θ s are constants. Processes of this kind can be useful in modeling seasonal or approximately periodic phenomena.

A remarkable generalization of the strong law of large numbers is the "ergodic theorem": if $X(t)$, $t = 0, 1, \dots$ or $0 \leq t < \infty$ is a stationary process such that $E[X(0)]$ is finite, then with probability 1 the average

$$s^{-1} \sum_{t=0}^{s-1} X(t), \text{ if } t \text{ is discrete, or } s^{-1} \int_0^s X(t) dt,$$

if t is continuous, converges to a limit as $s \rightarrow \infty$. In the special case that t is discrete and the X s are independent and identically distributed, the strong law of large numbers is also applicable and shows that the limit must equal $E[X(0)]$. However, the example that $X(0)$ is an arbitrary random variable and $X(t) \equiv X(0)$ for all $t > 0$ shows that this cannot be true in general. The limit does equal $E[X(0)]$ under an additional rather technical assumption to the effect that there is no subset of the state space, having probability strictly between 0 and 1, in which the process can get stuck and never escape. This assumption is not fulfilled by the example $X(t) \equiv X(0)$ for all t , which gets stuck immediately at its initial value. It is satisfied by the sequence $U(t)$ defined above, so by the ergodic theorem the average of these variables converges to $1/2$ with probability 1. The ergodic theorem was first conjectured by the American chemist J. Willard Gibbs in the early 1900s in the context of statistical mechanics and was proved in a corrected, abstract formulation by the American mathematician George David Birkhoff in 1931.

A stochastic process is called Markovian (after the Russian mathematician Andrey Andreyevich Markov) if at any time t the conditional probability of an arbitrary future event given the entire past of the process—i.e., given $X(s)$ for all $s \leq t$ —equals the conditional probability of that future event given only $X(t)$. Thus, in order to make a probabilistic statement about the future behaviour of a Markov process, it is no more helpful to know the entire history of the process than it is to know only its current state. The conditional distribution of $X(t+h)$ given $X(t)$ is called the "transition probability" of the process. If this conditional distribution does not depend on t , the process is said to have "stationary" transition probabilities. A Markov process with stationary transition probabilities may or may not be a stationary process in the sense of the preceding paragraph. If Y_1, Y_2, \dots are independent

random variables and $X(t) = Y_1 + \dots + Y_n$, the stochastic process $X(t)$ is a Markov process. Given $X(t) = x$, the conditional probability that $X(t+h)$ belongs to an interval (a, b) is just the probability that $Y_{t+1} + \dots + Y_{t+h}$ belongs to the translated interval $(a-x, b-x)$; and because of independence this conditional probability would be the same if the values of $X(1), \dots, X(t-1)$ were also given. If the Y s are identically distributed as well as independent, this transition probability does not depend on t , and then $X(t)$ is a Markov process with stationary transition probabilities. Sometimes $X(t)$ is called a "random walk," but this terminology is not completely standard. Since both the Poisson process and Brownian motion are created from random walks by simple limiting processes, they too are Markov processes with stationary transition probabilities. The Ornstein-Uhlenbeck process defined as the solution (19) to the stochastic differential equation (18) is also a Markov process with stationary transition probabilities.

The Ornstein-Uhlenbeck process and many other Markov processes with stationary transition probabilities behave like stationary processes as $t \rightarrow \infty$. Roughly speaking, the conditional distribution of $X(t)$ given $X(0) = x$ converges as $t \rightarrow \infty$ to a distribution, called the "stationary distribution," that does not depend on the starting value $X(0) = x$. Moreover, with probability 1, the proportion of time the process spends in any subset of its state space converges to the stationary probability of that set; and, if $X(0)$ is given the stationary distribution to begin with, the process becomes a stationary process. The Ornstein-Uhlenbeck process defined in (19) is stationary if $V(0)$ has a normal distribution with mean 0 and variance $\sigma^2/(2mf)$.

At another extreme are "absorbing" processes. An example is the Markov process describing Peter's fortune during the game of gambler's ruin. The process is absorbed whenever either Peter or Paul is ruined. Questions of interest involve the probability of being absorbed in one state rather than another and the distribution of the time until absorption occurs. Some additional examples of stochastic processes follow.

The Ehrenfest model of diffusion (named after the Austrian-Dutch physicist Paul Ehrenfest) was proposed in the early 1900s in order to illuminate the statistical interpretation of the second law of thermodynamics, that the entropy of a closed system can only increase. Suppose N molecules of a gas are in a rectangular container divided into two equal parts by a permeable membrane. The state of the system at time t is $X(t)$, the number of molecules on the left-hand side of the membrane. At each time $t = 1, 2, \dots$ a molecule is chosen at random (i.e., each molecule has probability $1/N$ to be chosen) and is moved from its present location to the other side of the membrane. Hence, the system evolves according to the transition probability $p(i, j) = P\{X(t+1) = j | X(t) = i\}$, where

$$\begin{aligned} p(i, i+1) &= 1 - \frac{i}{N}, & p(i, i-1) &= \frac{i}{N}, \\ p(i, j) &= 0 & \text{for } j \neq i+1, i-1. \end{aligned}$$

The long run behaviour of the Ehrenfest process can be inferred from general theorems about Markov processes in discrete time with discrete state space and stationary transition probabilities. Let $T(j)$ denote the first time $t \geq 1$ such that $X(t) = j$ and set $T(j) = \infty$ if $X(t) \neq j$ for all t . Assume that for all states i and j it is possible for the process to go from i to j in some number of steps—i.e., $P\{T(j) < \infty | X(0) = i\} > 0$. If the equations

$$Q(j) = \sum_i Q(i)p(i, j) \quad (20)$$

have a solution $Q(j)$ that is a probability distribution—i.e., $Q(j) \geq 0$, and $\sum Q(j) = 1$ —then that solution is unique and is the stationary distribution of the process. Moreover, $Q(j) = 1/E\{T(j) | X(0) = j\}$; and, for any initial state j , the proportion of time t that $X(t) = i$ converges with probability 1 to $Q(i)$.

For the special case of the Ehrenfest process, assume that N is large and $X(0) = 0$. According to the deterministic prediction of the second law of thermodynamics, the entropy of this system can only increase, which means that $X(t)$

The
ergodic
theorem

The
Ehrenfest
model of
diffusion

will steadily increase until half the molecules are on each side of the membrane. Indeed, according to the stochastic model described above, there is overwhelming probability that $X(t)$ does increase initially. However, because of random fluctuations, the system occasionally moves from configurations having large entropy to those of smaller entropy and eventually even returns to its starting state, in defiance of the second law of thermodynamics.

The accepted resolution of this contradiction is that the length of time such a system must operate in order that an observable decrease of entropy may occur is so enormously long that a decrease could never be verified experimentally. To consider only the most extreme case, let T denote the first time $t \geq 1$ at which $X(t) = 0$ —i.e., the time of first return to the starting configuration having all molecules on the right-hand side of the membrane. It can be verified by substitution in (20) that the stationary distribution of the Ehrenfest model is the binomial distribution $Q(j) = \binom{N}{j} 2^{-N}$, and hence $E(T) = 2^N$. For example, if N is only 100 and transitions occur at the rate of 10^6 per second, $E(T)$ is of the order of 10^{15} years. Hence, on the macroscopic scale, on which experimental measurements can be made, the second law of thermodynamics holds.

A Markov process that behaves in quite different and surprising ways is the symmetric random walk. A particle occupies a point with integer coordinates in d -dimensional Euclidean space. At each time $t = 1, 2, \dots$, it moves from its present location to one of its $2d$ nearest neighbours with equal probabilities $1/(2d)$, independently of its past moves. For $d = 1$ this corresponds to moving a step to the right or left according to the outcome of tossing a fair coin. It may be shown that for $d = 1$ or 2 the particle returns with probability 1 to its initial position and hence to every possible position infinitely many times, if the random walk continues indefinitely. In three or more dimensions, at any time t the number of possible steps that increase the distance of the particle from the origin is much larger than the number decreasing the distance, with the result that the particle eventually moves away from the origin and never returns. Even in one or two dimensions, although the particle eventually returns to its initial position, the expected waiting time until it returns is infinite, there is no stationary distribution, and the proportion of time the particle spends in any state converges to 0!

The simplest service system is a single-server queue, where customers arrive, wait their turn, are served by a single server, and depart. Related stochastic processes are the waiting time of the n th customer and the number of customers in the queue at time t . For example, suppose that customers arrive at times $0 = T_0 < T_1 < T_2 < \dots$ and wait in a queue until their turn. Let V_n denote the service time required by the n th customer, $n = 0, 1, 2, \dots$, and set $U_n = T_n - T_{n-1}$. The waiting time, W_n , of the n th customer satisfies the relation $W_0 = 0$, and, for $n \geq 1$, $W_n = \max(0, W_{n-1} + V_{n-1} - U_n)$. To see this, observe that the n th customer must wait for the same length of time as the $n-1$ st customer plus the service time of the $n-1$ st customer minus the time between the arrival of the $n-1$ st and n th customer, during which the $n-1$ st customer is already waiting but the n th customer is not. An exception occurs if this quantity is negative, and then the waiting time of the n th customer is 0. Various assumptions can be made about the input and service mechanisms. One possibility is that customers arrive according to a Poisson process and their service times are independent, identically distributed random variables that are also independent of the arrival process. Then, in terms of $Y_n = V_{n-1} - U_n$, which are independent, identically distributed random variables, the recursive relation defining W_n becomes $W_n = \max(0, W_{n-1} + Y_n)$. This process is a Markov process. It is often called a random walk with reflecting barrier at 0, because it behaves like a random walk whenever it is positive and is pushed up to be equal to 0 whenever it tries to become negative. Quantities of interest are the mean and variance of the waiting time of the n th customer and, since these are very difficult to determine exactly, the mean and variance of the stationary distribution. More realistic queueing models try to accommodate systems with several servers and different classes of customers, who are

served according to certain priorities. In most cases it is impossible to give a mathematical analysis of the system, which must be simulated on a computer in order to obtain numerical results. The insights gained from theoretical analysis of simple cases can be helpful in performing these simulations. Queueing theory had its origins in attempts to understand traffic in telephone systems. Present-day research is stimulated, among other things, by problems associated with multiple-user computer systems.

Reflecting barriers arise in other problems as well. For example, if $B(t)$ denotes Brownian motion, then $X(t) = B(t) + ct$ is called Brownian motion with drift c . This model is appropriate for Brownian motion of a particle under the influence of a constant force field such as gravity. One can add a reflecting barrier at 0 to account for reflections of the Brownian particle off the bottom of its container. The result is a model for sedimentation, which for $c < 0$ in the steady state as $t \rightarrow \infty$ gives a statistical derivation of the law of pressure as a function of depth in an isothermal atmosphere. Just as ordinary Brownian motion can be obtained as the limit of a rescaled random walk as the number of steps becomes very large and the size of individual steps small, Brownian motion with a reflecting barrier at 0 can be obtained as the limit of a rescaled random walk with reflection at 0. In this way, Brownian motion with a reflecting barrier plays a role in the analysis of queueing systems. In fact, in modern probability theory one of the most important uses of Brownian motion and other diffusion processes is as approximations to more complicated stochastic processes. The exact mathematical description of these approximations gives remarkable generalizations of the central limit theorem from sequences of random variables to sequences of random functions.

The ruin problem of insurance risk theory is closely related to the problem of gambler's ruin described earlier and, rather surprisingly, to the single-server queue as well. Suppose the amount of capital at time t in one portfolio of an insurance company is denoted by $X(t)$. Initially $X(0) = x > 0$. During each unit of time, the portfolio receives an amount $c > 0$ in premiums. At random times claims are made against the insurance company, which must pay the amount $V_n > 0$ to settle the n th claim. If $N(t)$ denotes the number of claims made in time t , then $X(t) = x + ct - \sum_{i=1}^{N(t)} V_i$ provided that this quantity has been positive at all earlier times $s < t$. At the first time $X(t)$ becomes negative, however, the portfolio is ruined. A principal problem of insurance risk theory is to find the probability of ultimate ruin. If one imagines that the problem of gambler's ruin is modified so that Peter's opponent has an infinite amount of capital and can never be ruined, then the probability that Peter is ultimately ruined is similar to the ruin probability of insurance risk theory. In fact, with the artificial assumptions that (i) $c = 1$, (ii) time proceeds by discrete units, say $t = 1, 2, \dots$, (iii) V_n is identically equal to 2 for all n , and (iv) at each time t a claim occurs with probability p or does not occur with probability q independently of what occurs at other times, then the process $X(t)$ is the same stochastic process as Peter's fortune, which is absorbed if it ever reaches the state 0. The probability of Peter's ultimate ruin against an infinitely rich adversary is easily obtained by taking the limit of equation (6) as $m \rightarrow \infty$. The answer is $(q/p)^x$ if $p > q$ —i.e., the game is favourable to Peter—and 1 if $p \leq q$. More interesting assumptions for the insurance risk problem are that the number of claims $N(t)$ is a Poisson process and the sizes of the claims V_1, V_2, \dots are independent, identically distributed positive random variables. Rather surprisingly, under these assumptions the probability of ultimate ruin as a function of the initial fortune x is exactly the same as the stationary probability that the waiting time in the single-server queue with Poisson input exceeds x . Unfortunately, neither problem is easy to solve exactly, although there is a very good approximate solution originally derived by the Swedish mathematician Harald Cramér.

As a final example, it seems appropriate to mention one of the dominant ideas of modern probability theory, which at the same time springs directly from the relation of probability to games of chance. Suppose that

The

random
walk

Other
queueing
models

Martin-
gales

X_1, X_2, \dots is any stochastic process and, for each $n=0, 1, \dots, f_n = f_n(X_1, \dots, X_n)$ is a (Borel-measurable) function of the indicated observations. The new stochastic process f_n is called a "martingale" if $E(f_n | X_1, \dots, X_{n-1}) = f_{n-1}$ for every value of $n > 0$ and all values of X_1, \dots, X_{n-1} . If the sequence of X s are outcomes in successive trials of a game of chance and f_n is the fortune of a gambler after the n th trial, then the martingale condition says that the game is absolutely fair in the sense that, no matter what the past history of the game, the gambler's conditional expected fortune after one more trial is exactly equal to his present fortune. For example, let $X_0 = x$, and for $n \geq 1$ let X_n equal 1 or -1 according as a coin having probability p of heads and $q = 1 - p$ of tails turns up heads or tails on the n th toss. Let $S_n = X_0 + \dots + X_n$. Then $f_n = S_n - n(p - q)$ and $f_n = (q/p)^{S_n}$ are martingales. One of the basic results of martingale theory is that, if the gambler is free to quit the game at any time using any strategy whatever, provided only that this strategy does not foresee the future, then the game remains fair. This means that, if N denotes the stopping time at which the gambler's strategy tells him to quit the game, so that his final fortune is f_N , then

$$E(f_N | f_0) = f_0. \quad (21)$$

Strictly speaking, this result is not true without some additional conditions that must be verified for any particular application. To see how efficiently it works, consider once again the problem of gambler's ruin and let N be the first value of n such that $S_n = 0$ or m ; i.e., N denotes the random time at which ruin first occurs and the game ends. In the case $p = 1/2$, application of (21) to the martingale $f_n = S_n$ together with the observation that $f_N =$ either 0 or m , yields the equalities $x = f_0 = E(f_N | f_0 = x) = m[1 - Q(x)]$, which can be immediately solved to give the answer in (6). For $p \neq 1/2$, one uses the martingale $f_n = (q/p)^{S_n}$ and similar reasoning to obtain

$$\left(\frac{q}{p}\right)^x = E(f_N | f_0 = x) = 1Q(x) + \left(\frac{q}{p}\right)^m [1 - Q(x)],$$

from which the first equation in (6) easily follows. The

expected duration of the game is obtained by a similar argument.

A particularly beautiful and important result is the martingale convergence theorem, which implies that a non-negative martingale converges with probability 1 as $n \rightarrow \infty$. This means that, if a gambler's successive fortunes form a (nonnegative) martingale, they cannot continue to fluctuate indefinitely but must approach some limiting value.

Basic martingale theory and many of its applications were developed by the American mathematician Joseph Leo Doob during the 1940s and '50s following some earlier results due to Paul Lévy. Subsequently it has become one of the most powerful tools available to study stochastic processes.

(D.O.S.)

Procedural Law

Law, to be effective, must go beyond the determination of the rights and obligations of individuals and collective bodies to an indication of how these rights and obligations can be enforced. It must do this, moreover, in a systematic and formal way. Otherwise, the numerous disputes that arise in a complex society cannot be handled efficiently, fairly, without favouritism, and, equally important for the maintenance of social peace, without the appearance of favouritism. This systematic and formal way is procedural law. Procedural law, then, constitutes the sum total of legal rules designed to ensure the enforcement of rights by means of the courts. It thus contrasts with substantive law, the sum total of the rules determining the essence of the rights and obligations.

Because procedural law is only a means for enforcing substantive rules, there are different kinds of procedural law, corresponding to the various kinds of substantive law. Criminal law, for example, is the branch of substantive law dealing with punishment for offenses against the public and has as its corollary criminal procedure, which indicates how the sanctions of criminal law must be applied. Substantive private law, which deals with the relations be-

tween private (that is, nongovernmental) persons, whether individuals or corporate bodies, has as its corollary the rules of civil procedure. Because the object of judicial proceedings is to arrive at the truth using the best available evidence, there must be procedural laws of evidence to govern the presentation of witnesses, documentation, and physical proof. The law of conflict of laws, in both its civil and criminal applications, provides methods for resolving problems that arise from the diversity of legal systems in the world.

This article deals with procedural laws as they apply to the Anglo-American common law and the continental European civil law. For discussion of other legal systems, such as the laws of Communist countries, see the *Macropædia* article LEGAL SYSTEMS, THE EVOLUTION OF MODERN WESTERN. Substantive laws are covered in such articles as CRIMINAL LAW; BUSINESS LAW; and CONSTITUTIONAL LAW. For treatment of administrative procedural law, see PUBLIC ADMINISTRATION. (P.E.H./Ma.E.O.)

Civil procedure

HISTORICAL DEVELOPMENT

Roman law. Civil procedure in ancient Rome had a marked influence on later development on the European continent and, to some extent, in England. The procedure of very early Roman law left little permanent impact on the law. Highly formalized, it was based on strict compliance with rules of pleadings and was replaced during the 1st century BC by the more flexible formulary procedure that in some respects bears marked similarity to Anglo-American civil procedure. Law suits were divided into two phases. In the first phase, devoted to defining the issues, the parties presented their claims and defenses orally to a

judicial official called a praetor, whose main function was to hear the allegations of the parties and then to frame a formula or instruction applicable to the issue presented by the parties. The praetor did not decide the merits of the case. Instead, with the consent of the parties, he selected from a list of approved individuals a private individual (*judex*), whose duty it was to hear witnesses, examine the proof, and render a decision in accordance with the applicable law contained in the formula. There was no appeal. The procedure facilitated growth and change in the law: by adapting existing formulas, or modifying them, the praetors were, in effect, able to change substantive rules of law.

The formulary system with its separation of fact-finding

The formulary system

and determination of the law was not followed in the provinces conquered by the Romans. There, administrative officials rendered justice under general administrative powers. In the late imperial period, the procedure used in the provinces was also introduced in Rome itself. The creative role of the praetor came to an end, the formulas were abolished, and the division of a lawsuit into two phases was also terminated. Lawsuits were now initiated by a written pleading. Appeals from lower to higher judges became possible, and the procedure lent itself to delay. As a result, parties often submitted their disputes to arbitration or to religious leaders for settlement. Consequently, the leaders of various religious communities, including in particular those of the Christian Church, came to exercise judicial functions that in the very late Roman Empire received a degree of state recognition.

Medieval European law. The Germanic tribes that conquered the Roman Empire in the 5th century carried their own procedure with them into the conquered territories. That procedure was quite formalistic: in court, which often was the assembly of all the freeborn men of the district, the parties had to formulate their allegations in precise, traditional language; the use of improper words could mean the loss of the case. At this point the court determined what method of proof should be used: ordeal, judicial combat between the parties or their champions, or wager of law (whereby each side had to attempt to obtain more persons who were willing to swear on their oaths as to the uprightness of the party they were supporting). Roman law procedure, however, never entirely disappeared from the territories conquered by the Germanic tribes. In addition, a modified form of late Roman procedure was in use in the ecclesiastical courts that applied the still-developing canon law. This late Roman and canonical procedure appears to have been preferable to the Germanic procedure and gradually supplanted it in Italy and France, and somewhat later in Germany, though all elements of the Germanic procedure did not disappear. In Scandinavia, on the other hand, indigenous procedure was able to resist displacement by foreign law.

The Roman-canonical procedure, with its heavy reliance on written, rather than oral, presentations, necessitated representation by learned counsel. The whole procedure was divided into rigidly formalized stages. Precise rules governed the presentation of evidence; thus the concordant testimony of two male witnesses usually amounted to "full proof," and one witness was ordinarily insufficient to prove any matter, unless he was a high ecclesiastic. A court order was needed before testimonial evidence could be used; witnesses were ordinarily examined not before the full court but by a judge, with a court clerk or notary committing the witnesses' testimony to writing for later submission to the court. This complex procedure was ill-suited to the day-to-day needs of commerce; as a result, special courts operated by and for businessmen sprang up in important mercantile centres (maritime courts, commercial courts) to deal with matters of maritime and inland commerce.

As the Middle Ages ended, there was an increasing tendency to favour written over oral evidence. At the same time, there was a tendency to "nationalize" the general Roman-canonical procedure prevalent in much of Europe and to create national procedural laws. In 1667 in France this led to the enactment by Louis XIV of the *Ordonnance Civile*, also known as *Code Louis*, a comprehensive code regulating civil procedure in all of France in a uniform manner. The *Code Louis* continued, with some improvements, many of the basic principles of procedure that had prevailed since the late Middle Ages.

Common law. Originally, procedure in English local and feudal courts resembled quite closely that of other countries with a Germanic legal tradition. But unlike the countries on the continent of Europe, England never romanized its indigenous procedure once the latter had become inadequate but instead developed a procedure of its own capable of substantial growth and adjustment. That England was able to do this seems to have been due to two related factors, both the result of the strong monarchy that followed the Norman invasion: the growth

of the jury system and the establishment of a centralized royal court system. The former offered a substitute for the antiquated methods of proof of the traditional Germanic law—ordeals, trial by battle, and wager of law—and the latter led to the creation of a definite legal tradition, the common law, and to the administration of justice through permanent professional judges, and their attendant clerks, instead of the popular assemblies or groups of wise men who rendered justice elsewhere.

Royal courts could be used only if permitted by a special royal writ, or writ, issued in the name of the king. Such writs were at first issued when there was a complaint that local or feudal courts were not rendering justice. Later, they were issued in cases involving land; such a writ might direct the defendant to return the land or explain why he refused to do so or, later on, direct the sheriff to bring the defendant before the court so that he might answer for his conduct. Eventually the writs became standardized. Through ingenious fictions (assumptions, for judicial purposes, of facts that do not exist), substantially all litigation not reserved to the ecclesiastical or other specialized courts could be brought before the royal courts, a situation preferred by suitors, since the royal courts abandoned much of the awkward Germanic law of proof in favour of trial by jury sooner than did local courts.

As the system of royal courts developed, the parties, or rather their counsel, formulated the issues to be settled through their "pleadings" before the court in London; after that the issues would be tried before a jury in the county where the facts arose. The mechanics of pleading gradually became quite complex. Originally, Germanic pleading practices, which involved oral formulation of issues in rather precise words, prevailed. Eventually, the clerks of the court wrote a summary of these oral pleadings and later recorded the entire substance. The plaintiff had to plead facts that came within the writ used to start the action; the defendant could either generally deny the facts asserted by plaintiff or assert specific defenses. (For modern pleadings procedure, see below *Preliminaries to proceedings: Pleadings*.)

The complexities of the common-law procedure led some parties to request relief directly from the king, who in medieval theory was considered as the ultimate fountainhead of justice. These requests were transferred to the royal chancery—that is, the office of the lord chancellor—which, in this way, developed into another court; it was supposed to deal "equitably" with cases in which the strict rules of the common law failed. In the course of time this function of the chancery developed into a body of well-defined rules known as "equity." Until the 16th century the chancellors were generally ecclesiastics; hence procedure in chancery to obtain equity was to some extent influenced by canonical procedures. In particular, there was no jury trial, no writ circumscribing a precise cause of action, and so forth.

The procedure of the common-law courts and the existence of a separate procedure for equity matters were both taken over in the United States. In the 19th century there developed in both England and the United States movements to simplify procedural complexities. These involved several related approaches: (1) a reform in court organization, doing away with separate courts of equity and, to the extent they existed, with coordinated common-law courts of general jurisdiction and establishing a more rational system of appeals courts; (2) a reform of pleading, abandoning largely the need to plead a specific cause of action based on writs, and giving judges power to promulgate rules of procedure. In the United States these principles were first embodied in the widely followed New York Code of Civil Procedure of 1848. In the 20th century, however, the notion gained ground that legislation was too slow a means for the adoption of new procedural rules. This led to the Rules Enabling Act of 1934, which authorized the U.S. Supreme Court to adopt (subject to congressional veto) Rules of Civil Procedure for the federal district courts, though some matters, such as subject-matter jurisdiction, remained governed by acts of Congress. The federal Rules of Civil Procedure were later followed by Rules of Appellate Procedure and Rules

of Evidence. There were similar developments in many of the states and also in England and Wales.

The reforms were not entirely successful; early court decisions interpreted the revised pleading rules in a restrictive fashion, and the merger of common-law and equity courts did not result in a complete merger of procedures. U.S. federal and state constitutions, for example, guaranteed a jury trial in all cases at common law but not in equity.

Civil-law codifications. Dissatisfaction with the system of judicial administration was a major cause of the French Revolution of 1789. One of the earliest actions taken by the newly constituted National Assembly was the creation of a new court system (1790). But no reform of a lasting nature was undertaken in the field of civil procedure. The introduction of a jury system was debated, but it was adopted for criminal cases only.

Napoleon attempted to restore normality and unity to France after the Revolution through the creation of codes encompassing an entire field of law and containing the best of both the old pre-Revolutionary and the Revolutionary law. His Code of Civil Procedure of 1806, however, relied heavily on the 1667 code but continued certain procedures created during the Revolution.

During the 19th century, codifications of procedural law were enacted in other countries (Italy in 1865 and Germany in 1877). They usually retained large elements of the Roman-canonical or French procedure and were often cumbersome and slow. Austria departed from the Roman-canonical model in 1895 with the adoption of a new Code of Civil Procedure. The new code adopted comprehensively the principle of oral presentation: only matters presented orally in open court were important for a decision of the case; writings could have only a preparatory role; witnesses were no longer heard before a delegated judge who prepared a written record but by the court or judge that actually decided the case; finally, the parties were obligated to present their cases fully and truthfully, and the judge was directed to make certain that all relevant facts were stated. These notions were widely followed by other countries when they amended their codes of civil procedure.

Revisions
in the 20th
century

Changes made in French civil procedure beginning in 1958 were to some extent inspired by the Austrian model. Originally adopted in a series of individual decrees, they were consolidated in the new Code of Civil Procedure of 1975. Following earlier amendments to the 1877 German code that had strengthened the role of the judge, a statute adopted in 1976 in West Germany, called the simplification amendment, was designed to expedite proceedings further. A somewhat contrary trend occurred in Italy, where later amendments to the more progressive 1942 Code of Civil Procedure to some extent reemphasized written presentations. A step contrary to some modern European thinking was also taken by the Belgian Judicial Code of 1967 (effective 1969). It reduced the role of the judge and correspondingly increased that of the parties and their counsel. Even more atypical were developments in Japan. In 1890 that country adopted a Code of Civil Procedure, very largely modeled on the German Code of 1877. In 1926 the code was amended in order to expedite procedures. Austrian ideas about the role of the judge were heavily relied on. But after the defeat of Japan at the end of World War II, an attempt was made to introduce some of the features of the American civil trial, with its heavy reliance on the presentation of facts by the parties' attorneys and the correspondingly less significant role of the judge. For a variety of reasons, the attempt was not entirely successful. Present Japanese law blends a procedure largely based on the German model with some features of Anglo-American origin.

Constitutional bases of civil procedure. The U.S. Supreme Court holds that all procedural rules, whether found in statutes, rules of court, or case law, must be consistent with the mandates of the Constitution—in particular with the due process clauses of the Fifth and Fourteenth amendments. Thus, a defendant from one state or a foreign country cannot be required to defend a suit in another state unless the defendant has had enough contacts with that state not to offend "traditional notions of

fairness and substantial justice." Likewise, "due process" implies that a party may not be deprived of substantial rights without having had an opportunity to present his side of the case. As a result of the adoption in many other countries of written constitutions with legally binding fundamental rights—and of the creation, after World War II, of special constitutional courts—constitutional rules granting a right to be heard, and, more generally, access to justice (often including access to legal aid) were created. These developments were reinforced by certain international agreements, in particular Article 6 of the 1950 European Convention for the Protection of Human Rights and Fundamental Freedoms.

CIVIL-LAW PROCEDURE AND COMMON-LAW PROCEDURE

It is sometimes said that the Anglo-American common-law procedure is adversarial, while the continental European civil-law procedure is inquisitorial. This means that, in the common law, a lawsuit is essentially the concern of the adversaries, that is, the parties and their lawyers. It is the lawyers who present the evidence, and, unless a procedural problem arises, the judge simply listens to the presentation. By contrast, in the civil law there is a greater emphasis on the judge as a guarantor of a just outcome of the case, regardless of the lawyers' abilities. To this end he often functions as an inquisitor, questioning the parties as to the factual matters of the case. In some countries, such as West Germany, the judge is required to guide the proceedings—for instance, by suggesting to the parties that they direct their attention to a particular point of fact or law. These differences in procedure create problems when, for a lawsuit pending in a country of one system, it is necessary to obtain evidence located in a country of the other system. In such cases, "judicial assistance" must be given to the courts in one country by those in the other (see below *Conflict of laws*).

The impact of the jury. The differences between various aspects of civil- and common-law procedure have their origin in several factors, but the most important is the institution of the jury trial. A lay jury will be able to determine factual issues only if they are presented in a focused manner; hence the need, in common-law countries, for initial pleadings that serve to establish beforehand the factual matters in dispute. This is less necessary in civil-law procedure, where the case is handled over a series of hearings by professional judges. Furthermore, because a jury of 12 laypersons cannot be kept together for an indefinite period of time, proceedings must be conducted in a concentrated fashion. This gives the Anglo-American trial its peculiar dramatic character. Where the determination of factual issues is entrusted to a professional judge (who, presumably, will be available for a considerable time), the process can be extended over several shorter hearings. Because a disbanded jury cannot easily be reassembled, the evidence presented by parties must be available at the beginning of the trial. Consequently, there must be procedures (called "discovery") that enable the parties to obtain information they will need at the trial (see below *Discovery procedures*). Such procedures are much less important in civil-law procedure, where evidence that has come to light during the proceedings can be submitted at a subsequent hearing. Also, when factual matters are to be decided by a body of laypersons, the law must ensure that the jury will not be misled by evidence that is plausible on the surface but may be misleading. There is less need to guard against that danger whenever factual determinations are made by professional judges.

Finally, because the jury decides questions of fact while the judge decides only questions of law, in common-law procedure a clear distinction must be drawn from the beginning between factual and legal issues. In civil-law procedure, on the other hand, where the judges decide both questions of fact and questions of law, there is normally no need to make a sharp distinction between these two issues until a case reaches the highest level of civil courts, where only questions of law are open for review.

Convergence of civil- and common-law procedure. In spite of the distinctions between civil and common law, some trends toward a convergence of procedure exist. In

The roles
of lawyers
and judges

private-law matters, courts in civil-law countries do not initiate proceedings on their own motion; rather, they decide only claims brought forward by the parties and normally only on the basis of evidence proposed by them. Nor do judges in common-law countries always play merely the role of an impartial arbiter. In some cases, such as those involving the welfare of children, they often take a more active role in seeking out the facts.

Because a series of separate hearings makes a proceeding unduly long, there are procedural reforms in some civil-law countries that favour (but do not mandate) a single, well-prepared, main hearing at which the decision is reached. On the other hand, in England, where the civil jury trial originated, the jury has fallen into almost complete disuse in civil cases, except in suits of defamation. In the United States, trial by jury is a constitutional right, but steps have been taken toward more judicial control over proceedings. Thus, Rule 11 of the Federal Rules of Civil Procedure authorizes judges to penalize frivolous or harassing procedural tactics by lawyers; there is also a trend toward greater judicial supervision of discovery proceedings.

trial pro-
ceedings

PRELIMINARIES TO PROCEEDINGS

Jurisdiction, competence, and venue. The words jurisdiction and competence refer generally to the power of an official body (legislative, judicial, or administrative) to deal with a specific matter. This section is concerned with judicial jurisdiction, the power of a court to act. That power may depend on the relationship of the court to the subject matter of the action; in such an instance one speaks generally of subject matter jurisdiction. The jurisdiction of a court may also depend on the relationship between the court and the defendant in the action. As to that relationship, important conceptual differences exist between the countries of the common-law orbit, which usually refer to this problem as the question of "jurisdiction over the defendant" and countries within the civil-law tradition, which are likely to subdivide the problem into questions of "international jurisdiction" (*i.e.*, which country may take the case) and questions of "territorial jurisdiction" (*i.e.*, courts in which part of the country may take the case). As noted above, in the United States, the due process clause of the Constitution imposes limits on the states' power to confer jurisdiction on their courts. It has been suggested that the word jurisdiction should be used only when discussing the power of the courts in a state generally to act in a given situation without violating the due process clause, whereas the word competence should be used to refer to the power of a particular court in a state to act pursuant to the laws of that state, but frequently the terms jurisdiction and competence are used interchangeably. (For a more detailed discussion, especially in relation to matters containing foreign elements, see below *Conflict of laws*.)

For reasons having to do with the historical tradition of the common-law courts—especially with the practice of the royal courts in London to send out judges to conduct trials throughout the country with the help of locally selected juries—in common-law countries the various higher courts existing in a given state are not ordinarily viewed as completely separate tribunals but essentially as parts of one overall court. Hence the question of "venue," which is usually not so problematical as lack of jurisdiction. The most common venue rule is that the action may be initiated where either the plaintiff or defendant resides, where the cause of action arose, or, if real property is involved, where the real property is situated. Even when all formal legal requirements of jurisdiction and venue are fulfilled, American courts are sometimes authorized to dismiss an action on the ground that the choice of court will create serious inconvenience for the parties or the court itself.

Parties. In spite of differences in terminology, rules prevailing in various legal systems concerning the parties to a case show some basic similarities. It is quite generally recognized that in order to participate in a lawsuit as a plaintiff or as a defendant, a party must have the capacity to sue and must, in addition, be a "proper" party (that is, have standing before the court).

Venue

All persons recognized as such by law, including corporations and even groups of individuals without formal corporate status, may, at least in the abstract, assert their rights in court and are liable to suit by others. In practice, however, the law obliges certain persons to act through another person. These persons, such as minors and mental incompetents, are usually said to lack procedural capacity, or to have it only to a limited extent, and must act through parents or guardians. Corporations can frequently sue in their own name, though some countries (such as Sweden) require that actions be brought by or against the board of directors or similar body.

All legal systems limit in some respects the number of individuals who may engage in lawsuits; generally, only persons who have an actual interest in the outcome of the lawsuit may sue or be sued. Furthermore, only a person who owns (or claims to own) the right or obligation under suit can be a party to a suit involving that right. In the United States this rule is frequently called the real party in interest rule, and similar rules are found elsewhere—for example, in Italy and France. Frequently the real party in interest will be the person who will ultimately benefit from any recovery obtained, but this is not true in all cases. In the United States, for instance, the trustee of a trust is deemed the real party in interest in connection with suits involving the trust, though any recovery obtained by him will ultimately benefit the beneficiaries of the trust. Because of the problems inherent in the real parties in interest rule, some modern codifications have omitted any reference to it.

In connection with matters of public law, the ability to sue is sometimes restricted less narrowly than in pure private-law actions. In France, for instance, citizens are able to bring actions in court to attack municipal expenditures (though not expenditures of the national government).

Ordinarily, only parties to an action are bound by its outcome. But when a very large group may be affected by a particular controversy, it is frequently impractical for all members of the group to join in the litigation. For this reason, the law in the United States sometimes authorizes so-called class actions, in which a limited number of persons sue to vindicate the rights of a much larger class; in the end all members are bound by the outcome of the suit. Class actions are frequently, but by no means exclusively, used in actions involving shareholders of a corporation. Countries with a civil-law tradition generally do not authorize class actions, though in some limited situations proceedings brought by one person may affect the rights of other persons not party to the suit. Sometimes associations (for example, organized consumers' groups) are authorized to sue.

Class suits

Although a person is ordinarily free to decide for himself whether or not he wants to attempt to enforce his rights by legal proceedings, his refusal to do so may cause harm to others. For this reason, the laws of many countries authorize creditors, for instance, to prosecute actions of their debtors if the debtors fail to do so.

Legal controversies are not necessarily limited to two persons, one plaintiff and one defendant. Sometimes, for instance, in actions involving co-ownership or joint obligations, the rights of several parties may be so inextricably intertwined that, for all practical purposes, it is impossible to adjudicate the rights of one person standing alone. In such cases, the procedural rules of many countries require that all such persons be made parties to the lawsuit. In other cases, however, the presence of several individuals may be merely useful, but not absolutely essential, to a resolution of a dispute. In such cases the law simply "permits" the individuals to join in, or be brought into, the lawsuit. It is also possible that persons not originally participating in a lawsuit may find that their rights are affected in some manner, directly or indirectly, by such a suit. To avoid a multiplicity of actions, such persons will often be authorized to intervene in the pending lawsuit, if their own claim has a sufficiently close connection in law or fact with it. In civil-law countries a person wishing to support the claim of some other party must proceed by way of direct intervention. In the United States an individual who wants to promote the claim of some other party may

Amicus
curiae

ask the court for leave to appear as *amicus curiae* (friend of the court) so that he may present arguments in favour of the person he supports. In certain cases, furthermore, defendants are authorized to bring third parties into an action when, for instance, these third parties are or may be liable to the defendants on account of the claim asserted against the defendants. This is known as impleader.

In general, a person's capacity to sue or be sued is not affected by the fact that he is an alien or nonresident, unless a state of war exists between his home country and the country he wishes to sue. Even a state of war generally will not destroy capacity to be sued. But an alien may experience some disadvantages. Many countries, for example, withhold legal aid from aliens, particularly if the alien's home country does not grant reciprocity. More important, many European and Latin-American countries require alien plaintiffs to post security to guarantee that they will be able to reimburse the defendant for the expenses of the lawsuit, and sometimes even for additional damage, should they lose the case. As a result of the 1954 Hague Convention on Civil Procedure and numerous other treaties, this security for costs has been eliminated between many countries. In the United States the nationality of a party is not material to the issue of whether security for costs is due; any nonresident of the state where the action is brought is required to post security. The rule is similar in most other countries with an English legal tradition.

Provisional remedies. Lawsuits frequently take a long time. A judgment in an action concerning whether or not the defendant has the right to cut down certain trees, for instance, will be of little value if, while the suit is pending, the trees have already been cut down. For this reason, legal systems quite generally provide so-called provisional remedies that enable the plaintiff to obtain some guarantees that any judgment obtained against the defendant will not be in vain. There appears to be a rather remarkable similarity between remedies in common-law and civil-law countries, although the legal technicalities are often different. The provisional remedies are frequently available even before an action has been initiated; but in such a case, an action must ordinarily be started within a short period of time after the grant of the remedy.

Attach-
ment

Some remedies serve to prevent the disappearance either of funds required for the payment of the eventual judgment or of specific property involved in litigation. This purpose is served by attachment (bringing the property under the custody of the law), replevin (an action to recover property taken unlawfully), or other similar remedies. Usually, the remedy is granted by a judge at the request of the plaintiff, upon showing that certain facts exist that make it probable that the plaintiff has a good claim and that the payment of the judgment by the defendant may be threatened. Attachment ordinarily involves the seizure of the property by an officer of the court, who will hold it pending final disposition of the case, or, occasionally, involves merely an order to the person holding the property not to dispose of it. Attachment can also be used in connection with intangible property (such as money due or bank accounts). These remedies are frequently granted in a proceeding in which the defendant is not initially heard (*i.e.*, *ex parte*).

Temporary
injunctions
and
restraining
orders

Other remedies are intended to stabilize a situation pending the outcome of litigation. In such instances, courts are frequently authorized to issue orders (known in Anglo-American law as temporary injunctions) commanding the parties to do or not to do certain acts that may cause irreparable harm to the other side while the suit is pending. In both civil-law and common-law countries, orders of this nature ordinarily are granted only after a hearing in which both sides appear. Sometimes a court order of an even more temporary and short-lived nature (temporary restraining order) may be obtained without hearing the other side.

In countries with a common-law tradition a person disobeying an injunction issued by a court is guilty of "contempt of court" and can be punished quite severely. In civil-law countries, punishment for contempt is largely unknown, and since broad orders to defendants may therefore be difficult to enforce, such orders are sometimes limited

to specific narrow situations. For constitutional reasons, the U.S. Supreme Court has limited *ex parte* remedies.

Commencement of action. In Anglo-American procedure, a lawsuit is generally divided into two stages, the first, or pleading, stage and the trial stage. At the pleading stage the parties notify each other of their claims and defenses; at the trial stage, they or their counsel prove their factual contentions before the jury primarily through the oral examination of witnesses produced by them. The verdict of the jury and the judgment based on it follow immediately thereafter.

In civil-law countries, the procedure consists essentially of a series of hearings at which counsel argue their clients' position and submit documentary evidence; any other form of evidence can be utilized only with a special court order definitely describing the type of evidence and the matter to be proved by it.

The summons and the requirements of service. In most countries when a civil action is initiated, some form of notice to that effect must be served immediately upon the defendant. This notice may consist merely of a statement to the effect that the plaintiff is suing the defendant and that the defendant must appear in court on a specified day or be in default. Such a notice is commonly referred to as a summons, the successor to the old English "writ" initiating the action. When the notice of the lawsuit consists only of the summons, it is necessary, either at the same or a subsequent time, to supply the defendant with more specific information about the nature of the claim against him. This information is contained in the plaintiff's first pleading, the complaint.

In common-law countries it was originally necessary to deliver the summons to the defendant in person (personal service). Now, other forms of service to notify the defendant, such as leaving the summons with an agent, employee, or a person of suitable age at his home, are also permissible provided their intent is to apprise the defendant that the suit is pending. Service by publication in a newspaper is generally authorized only when no other form of service is reasonably possible.

Delivering
the
summons

In civil-law countries the summons proper is often combined with the statement of plaintiff's claim in a single document (*assignation* in France, *citazione* in Italy). Other detailed formal rules must often be observed, and the documents sometimes must be written on paper bearing tax stamps. The document need not be served to the individual himself; a member of the household, or even a neighbour or janitor, usually will be an adequate recipient. In Austria and several other countries, service can be effected through the use of the mail.

Pleadings. Pleadings are the formal written documents by which the parties set forth their contentions. They serve several functions including giving notice of the nature of the claim or defense, stating the facts that each party believes to exist, narrowing the number of issues that ultimately must be decided, providing a means to determine whether the party has a valid claim or defense, and serving as a record of what has been actually decided once the suit is ended.

In the English common law the pleadings were primarily designed to state the legal theory relied upon and to narrow the issues to be tried. Accordingly, in common-law proceedings, the plaintiff and defendant alternately submitted documents, each responding to the one that preceded it, and narrowed the field of conflict until there remained only one issue, upon which the trial would be based. Because narrowing the issues was deemed of great importance, the parties were not allowed to plead alternative or contradictory states of fact and the defendant was permitted to rely on only one defense at one time.

In the United States during the 19th century, numerous procedural reforms were instituted. The parties were no longer required to plead on the basis of legal theories but instead were to allege a statement of facts constituting the cause of action or defense; the court could then apply any legal theory that was applicable under the facts alleged and later proved. The insistence upon fact pleading had substantial drawbacks, however, especially since the courts demanded a high degree of specificity, made technical

distinctions between fact and evidence (forbidding the insertion of the latter in the pleading), and bound the parties to prove the facts alleged or lose the lawsuit. This last rule was particularly harsh since it forced the party to allege detailed facts early in the proceedings when he frequently was not yet certain precisely what facts had occurred.

Modern reforms have gone a long way toward elimination of the injustices of the former system. U.S. federal rules require only "a short and plain statement of the claim showing that the pleader is entitled to relief"; the defendant "shall state in short and plain terms his defenses." There is no requirement that legal theory be stated in the pleading or that only facts be alleged. Other rules specifically permit the parties to plead alternative or contradictory claims or defenses and provide that in the usual case, only two pleadings, the complaint and the answer, shall be permitted. The effect of these changes has been to substantially downgrade the importance of the pleading stage of the lawsuit. The primary function of the pleadings is now only to give a general notice of the subject matter of the suit to the opposing party.

Civil-law
pleadings

Under modern European codes, pleading problems have not been as pronounced as in Anglo-American law. European pleadings tend to be more general, with fewer distinctions between ultimate facts, evidentiary facts, and matters of law. The narrowing of issues is generally a judicial function, to be achieved either at a special preliminary hearing or even at a plenary hearing before the full court; the creation of a permanent record is a function of the final judgment, which, unlike the general—and therefore uninformative—verdict in an American jury trial, must ordinarily contain a description of the facts and legal reasons on which it is based. Pleadings therefore serve primarily to inform the court and parties concerning their respective claims, a function of limited importance, since under some codes (such as the Austrian Code of Civil Procedure of 1895) only statements by the parties or their counsel in open court are fully effective for this purpose. In addition, amendments or changes can ordinarily be made without difficulty, though, in order to avoid dilatory tactics and surprise, some limitations exist.

Appearance of defendant and plaintiff. The summons or analogous document by which action is initiated by the plaintiff quite generally commands the defendant to appear in court a specified number of days after its service. In case of failure to appear, he is threatened with a "default" judgment. In both the Anglo-American and the continental European systems the appearance in court is normally a legal fiction. The defendant "appears" by serving the plaintiff with a notice indicating that he will defend the lawsuit and giving the name of the attorney or similar representative who will act for him in this connection. Certain other procedural steps indicating a willingness to defend the lawsuit are sometimes considered the equivalent of such a notice.

The time limits for the appearance vary greatly. European countries frequently provide a great many different time periods varying with the distance between defendant and the court where the action is pending. In some countries the time to appear is fixed by the court. Less attention is usually paid to geography in the United States. In New York, for instance, the defendant must appear in 20 days if the summons was served personally, and 30 days if some other form of service was employed.

In some countries, where appearance involves either actual presence in courts, or at least the delivery of documents to the court (Italy, Sweden), plaintiff and defendant may both be required to appear.

The preparatory stage. As noted above, in countries whose procedure is based on English common law, the concentrated trial, traditionally before a jury, serves as a climax to earlier procedures. At this time, the parties attempt to prove the facts at issue, primarily through the presentation of oral evidence. The climax of a European proceeding, however, is the hearing before the full bench of judges—a hearing that is essentially devoted to argument of counsel and the presentation of documentary evidence. In both legal systems there are procedures to prepare for the trial or hearing.

In Anglo-American procedure a preparatory phase can be devoted to numerous purposes. First, since a jury trial is required only when there are disputes as to matters of fact, the court may be asked to make a decision on those cases that can be decided purely on legal matters, without any regard to the facts in dispute. This will be true, for example, when the court lacks jurisdiction or when it is obvious that a dispute between the parties as to the facts is more apparent than real. In these cases the party concerned will address a motion to the court (either a motion to dismiss for lack of jurisdiction or a motion for summary judgment) that can be decided immediately by a judge sitting alone, without waiting for a trial date.

It should also be noted that there may be a pretrial hearing before a judge, at which the judge will attempt to narrow the issues in controversy and, if possible, try to settle the case, thus making the trial unnecessary.

If the suit has not come to an end as a result of such preliminaries, the parties must prepare for trial. At the trial, evidence is presented in an uninterrupted fashion, without any possibility for additional proof after its close; each side in the end must stand or fall on the testimony presented by it.

The European system is in some ways similar to the Anglo-American. Frequently, such questions as jurisdiction can be decided in the preliminary phase, without waiting for the full hearing. The preliminary phase may also serve to narrow issues and produce a settlement. Furthermore, proof proceedings sometimes occur during the preliminary phases rather than at the main hearing; though in Austria the full court holds hearings devoted to all aspects of the case, without distinguishing between matters considered preliminary and those more pertinent to the main hearing.

Pretrial motions. Because court calendars for jury trials are often extremely crowded, especially in the larger cities, the parties involved in a case often will resort to pretrial motions if there is any remote possibility that such an action would lead to a resolution of the dispute without trial. The party making the motion summons his opponent to appear before a judge designated for that purpose and transmits at that time copies of the papers pertaining to the motion, such as sworn statements (affidavits) of persons having knowledge of the facts or memorandums concerning the applicable law; the other side may submit opposing papers. At the time the judge hears the motion, attorneys for both sides argue briefly concerning the matter in question; no witnesses are heard. In addition to cases in which there may be a lack of jurisdiction, it may also occur that the right asserted by the plaintiff does not exist and that he is not entitled by law to relief; in either case a motion for dismissal would be made.

On a somewhat different plane stands the motion for summary judgment. Frequently it appears that the issues of fact raised in the pleadings do not really exist. In such a case, since the outcome would not be in any reasonable doubt, a trial would be a mere formality. To avoid the needless expense and delay of a trial, a motion for summary judgment can be made. (The rules relating to this motion are strict so as to abridge neither the right to a day in court nor the constitutionally guaranteed right to a jury trial.) The sole function of the judge is to determine if, from all the available evidence, there exists a material issue of fact that is honestly disputed. If he finds a material issue of fact to be in dispute, he must deny the motion and set the case down for a future trial. If he finds no such issue, he may grant a final and binding judgment.

In those civil-law countries that have a preparatory phase before a single judge and a final hearing before a three-judge bench, procedural defenses similar to pretrial motions are ordinarily raised before the single judge. Sometimes, however, in cases of lack of jurisdiction or lack of competence a hearing is held before the full court. Where the issue is one of territorial competence the result may be the transfer of the case to the proper court. General summary proceedings have lost considerable importance in France and have been abandoned completely in Italy, but in actions involving claims based on negotiable or other written instruments, for instance, special procedures have

Attempts
to end a
suit before
trial

Summary
judgment

been developed that permit a judgment to be obtained with great dispatch, particularly if the defendant has no effective defense on the merits.

Discovery procedures. In general, English common law lacked procedural devices aimed at giving the parties and the court advance notice of the factual contentions of both sides prior to the trial of the action. Whatever information was obtained by a party about the opposing party's case was received from the pleadings. This absence of discovery devices was a reflection of a judicial philosophy that held that surprise was a proper tactical device and that withholding information from one's opponent until trial would prevent an unscrupulous adversary from fabricating evidence. Limited discovery devices were, however, available in the equity courts.

Reforms were instituted in the 19th and 20th centuries. A mid-19th-century New York code, for example, provided that each party could serve written questionnaires on its adversary, could compel the adversary to produce documents prior to the trial, and could, under some circumstances, take the oral deposition of any witness, whether or not a party to the action. Even with these changes, discovery proceedings were limited. In 1938 new U.S. federal rules expanded the discovery process further. It was hoped that more complete disclosure would result in a more thorough preparation and presentation of cases, encourage pretrial settlement by making each party cognizant of the true value of his claim, and expose, at an early stage in the proceedings, insubstantial claims that should not go to trial.

Thus, a party may seek discovery not only of information that would be admissible at trial but also any information that, though not admissible, might lead to the discovery of admissible testimony. Some limitations remain, however; materials prepared in anticipation of the pending litigation by or for a party, for instance, are not discoverable unless the party seeking discovery shows a substantial need for the information and an inability to obtain substantially equivalent information by alternative means. Most discovery devices may be utilized without prior court approval and the procedures take place in lawyers' offices; judicial intervention must ordinarily be sought only when there is a dispute concerning the permissible scope of discovery or when there is a need to impose sanctions for failure to obey a court order compelling discovery.

European
procedures
to secure
informa-
tion

With the exception of procedures to secure, in advance of lawsuit, evidence that is in danger of being lost (for instance, because a witness may die), there are few procedures in civil-law countries to enable a party to secure information to use later. There are several reasons for this. The absence of a concentrated trial makes it less important to have all information available at once, and the greater role given the judge in bringing out factual matters further reduces the need to obtain information in anticipation of the hearing.

Consequently, discovery of documents is usually possible only in very limited cases, although a party that actually intends to use a document has to make it available to the other side. In France, for instance, production of documents to the other side is possible in bankruptcy and related commercial matters, and it is required in commercial cases generally that books be produced for inspection by the court. Traditionally, discovery of documents has been unavailable in noncommercial cases; legislation in 1965 did authorize the judge to request the parties to produce any documents, but this is production before the court, not for a party's use as such.

Pretrial conference. The discovery process frequently makes the parties aware of significant issues not previously considered or may make it clear that an issue considered important before discovery is no longer so. In order to provide a means for reflecting these changes and also to assist in simplifying the issues to be tried, shortening the time for trial, and possibly eliminating the need for trial completely, the court may direct the parties to appear before it for a pretrial conference.

At the conference, no testimony of witnesses is heard, and no formal adversary proceeding takes place. The attorneys representing the litigants, with the assistance of

the judge, try to reach agreement on amendments to the pleadings, the elimination of issues raised at an earlier stage that are no longer deemed pertinent, and the crystallization of the real, controversial issues that must be determined at the trial.

An indirect benefit of the pretrial conference is the possibility that a settlement of the case will be reached by the parties without the necessity of trial. Although some authorities feel that this should be a primary goal of the pretrial conference, the prevailing view is that "settlements must be a by-product rather than the object of pretrial, the primary aim being to improve the quality of the expected trial rather than to avoid it." It should be noted, however, that a considerable number of lawsuits, and the vast majority of personal injury cases, are settled before a final verdict.

Settling out
of court

In civil-law countries, procedures somewhat analogous in purpose to pretrial conferences are fairly prevalent. Since such preliminary hearings are ordinarily held before a single judge, rather than a formal three-judge court, a considerable saving of judicial time may result. Under the French code of civil procedure, each case is assigned to a special "prehearing" judge, who sets time limits for the exchange of pleadings, decides how many pleadings after the original summons and complaint shall be used and when they shall be submitted, and may penalize dilatory parties by delivering a default judgment or, if both sides are dilatory, by striking the case off the calendar. In addition, he may call in the parties' counsel for a conference and must make sure that all documents that the parties intend to use at the main hearing have been filed. He may also call in the parties themselves for a conference concerning a possible settlement. He must, in short, either settle the case or put it in shape for the formal hearing. Under the 1976 reforms to the West German Code of Civil Procedure, the parties may be directed, through a preliminary written or oral procedure, to prepare the main hearing in such a manner that it can lead to an immediate decision of the case.

THE TRIAL OR MAIN HEARING

The climactic and decisive part of an Anglo-American civil action is the trial, in which the parties present their proof in a concentrated fashion. The climactic event in a lawsuit based on European codes is the hearing before the full court. The differences between these two procedures are so fundamental that discussion of the two will be essentially separate.

The Anglo-American jury trial. Many of the procedural rules governing trials in civil actions have been designed to reflect the basic premise that the function of the jury is to determine the facts of the case, whereas the function of the judge is to determine the applicable law and to oversee the parties' presentation of the facts to the court. The consequences of the presence of the jury have been so pervasive that even in cases tried by a judge without a jury, the procedural rules designed to accommodate jury trials remain largely intact, with the important exception, of course, that the judge will determine both the facts and the law.

The order of trial. Although some variations may exist, a trial is conducted most frequently in the following manner. The attorneys for plaintiff and the defendant make opening statements to the jury, outlining what each conceives to be the nature of the case and what each hopes to prove as the trial proceeds. Next, the attorney for the plaintiff presents his case by calling witnesses, questioning them, and permitting them to be cross-examined by the attorney for the defense; when the former has concluded his presentation, the latter frequently will ask for a dismissal of the suit for failure of plaintiff to establish a *prima facie* case (that is, a case sufficient until contradicted by evidence); if this is unsuccessful, he will call and examine witnesses in order to establish his defenses, and these witnesses are subject to cross-examination by the plaintiff's attorney. The attorneys for each side then make a closing argument to the jury, marshaling the evidence presented in a light most favourable to their respective clients; the judge will instruct the jury on the applicable law; and the

Question-
ing and
cross-
examina-
tion

jury will retire to deliberate in private until it reaches a verdict, which will then be announced in open court.

Rules of evidence. Although the parties, and not the judge, are charged with the primary obligation to call and question the witnesses, the judge must act as arbiter in all disputes between the parties concerning the admissibility of evidence. When one party objects to the introduction of testimony, the judge will decide whether or not, in accordance with established rules of admissibility, the evidence sought to be introduced is to be heard by the jury. In keeping with the adversary system, the judge is not entitled to rule that evidence is inadmissible unless a party objects to its introduction. The party objecting to the evidence must state the grounds for his objection and the judge must permit the jury to hear the evidence unless the specified grounds given by the attorney are applicable. Even within this narrow framework, the judge's role is limited, for the rules of evidence leave little room for discretion on the part of the judge. (See below *The law of evidence*.)

Directed verdicts. When the party having the burden of proof of an issue has completed its presentation to the jury, the opposing side may ask the court to rule as a matter of law that the evidence presented does not provide sufficient proof for a reasonable jury to find for the party who presented the evidence. When a judge so finds, he may "direct a verdict," thus in effect withholding from the jury the right to rule independently on the issues at all. It has been held that this device, if properly applied, is not a violation of the constitutional right to jury trial because similar devices have historically been available to judges and because a verdict is directed only when there has not been sufficient evidence introduced to create a material issue of disputed fact for the jury to decide. The granting of a directed verdict results in a final judgment and the termination of the trial.

Instructions to the jury. It is the obligation of the judge, at the conclusion of the trial, to instruct the jury as to the applicable law governing the case in order to guide it in arriving at a just verdict. Although this is solely the judge's obligation, in practice the parties will propose instructions for his consideration. The judge then selects among the proposals that have been submitted and offers the parties the opportunity, out of the hearing of the jury, to object to any proposed instruction that they deem to be incorrect. Failure at this time to object generally precludes a party from arguing later that the instructions given were incorrect.

There has been much debate as to the relevance of jury instructions generally, some commentators urging that the jury seldom understands the instructions given or often ignores them. The charge, however, that the judge gave improper instructions to the jury is one of the most frequent grounds of error offered by parties when appealing an adverse decision.

In addition to the judge's obligation to charge the jury on the law, U.S. federal rules and some other procedural codes permit the judge to comment on the evidence. When it is permitted, the judge may give his opinion with regard to the merits of the case so long as he makes clear to the jury that this opinion is not binding and that the jury, not he, is solely responsible for finding the truth as to the facts in dispute.

Types of verdict. Most frequently the jury will be requested to return a general verdict—that is, a decision merely stating in general terms the ultimate conclusion that it has reached (for example, the award of X dollars to the plaintiff). This form of verdict gives considerable leeway to the jury and permits, if it does not encourage, some deviation from a strictly logical and technical application of the law to the facts. An alternative that offers greater control over the decision-making process is the special verdict whereby the jury is instructed merely to answer a series of specific factual questions proposed by the judge, who will then himself determine the verdict, based upon the jury's responses to the questions asked. Because of the difficulty in drawing up questions that would cover completely the issues of the case, the special verdict is cumbersome and not frequently used.

New trial and other relief. After the trial is completed,

either party may request the trial judge to vacate the verdict and grant a new trial. Innumerable grounds are available for requesting a new trial, including, for example, judicial error, excessiveness of the verdict, and jury misconduct. Considerable discretion is given the judge, and a decision to grant a new trial will seldom be overturned on appeal. The grant of a new trial, unlike the directed verdict, does not result in the judge substituting his opinion for that of the jury but only mandates another jury to hear the case at another trial. But in the very limited cases in which a judge may grant a directed verdict, he can also substitute his decision for that of the jury by a judgment not on the verdict.

The civil-law main hearing. In civil-law countries the hearing before the full court is the essential part of a civil action. At that hearing, counsel for both sides present argument as to the law and the facts of the case and submit documentary evidence. The hearing serves several purposes: it informs the court of the contentions of the parties, both legal and factual; it narrows the issues that may have been raised by the original pleadings; and it leads to the submission of at least one type of evidence, namely, documentary evidence. The extent of proof presentation and the narrowing of issues vary from country to country.

In such countries as Italy and France, which divide the lawsuit into a preparatory and a final stage, the judge in charge of the preparatory proceedings attempts to narrow the issues and may, for this purpose, examine the parties. In countries where there is only one stage, this process takes place during the full hearing. In general, in civil-law countries, evidence other than documentary evidence may be introduced only pursuant to a specific court order specifying the matter on which such evidence is to be received and the form that such evidence is to take (witness, experts, etc.). But again two forms are possible. Under the Austrian Code of Civil Procedure, the court that decides the case must hear the witness, expert, or whatever. In such a case, an order will be made at the hearing and will be implemented by the calling of the witness or expert. Subsequently the arguments of counsel may continue, interrupted perhaps by a new proof order, should the court feel this to be necessary. In France and Italy the court or the judge of the prehearing phase will make an order for the hearing of a witness or expert, but the witness or expert will be heard by a single judge not ordinarily part of the court, who will prepare a summary of the testimony. Later on, that summary will be submitted to the court; there will be additional argument and finally a decision will be made based on the record so made. Because witnesses or experts are always acting pursuant to court order, they are never considered a party's witness.

Types of proof proceedings. Various types of proof proceedings are generally available, including (1) hearing of witnesses who are not themselves parties; (2) the expert's report; (3) the examination of parties, either informally or pursuant to formal interrogatories.

A party wishing a witness to be heard must make an appropriate request, informing the other side of the name of the witness and the subject on which the witness is to be heard; this is to enable the party to prepare its own side of the case. At the examination the judge will ask the witness to state in narrative form what he knows about the precise issue mentioned in the proof order; subsequently, the judge may ask additional, clarifying questions. If counsel for both sides wish to propose questions, they must ordinarily put them to the judge, who presents them to the witness. A more or less extensive summary of the testimony is prepared immediately by a clerk under the direction of the judge and signed by the witness, the judge, and the clerk. In the case of witnesses who live too far away from the court where the action is pending, interrogation sometimes takes place in a local court.

The examination of an expert is obtained in the same manner as that of a witness. Although the parties may suggest an expert to the court, those chosen are ordinarily taken from a list of experts approved by the court. The expert is considered an impartial auxiliary of the court; his use is ordinarily limited to cases involving some technical or scientific problem. The court or judge issuing the proof

on
evidence

Parties not
considered
witnesses

order may authorize him to make certain scientific investigations (e.g., in an automobile accident case, to examine the car involved) and to report thereon.

Parties are not considered witnesses, and different procedures for parties ordinarily exist. A court is usually authorized informally to question parties, ordinarily not under oath, either on the court's own motion or on the request of a party. Though this questioning is designed mainly to narrow issues, it does also have a function in the gathering of evidence. In Austria and some other countries the judge questioning a party may put the party under oath if he feels this to be necessary for an elucidation of the truth. In other countries, a party may be challenged by his adversary to make a statement under oath.

Rules of evidence. In European courts, rules as to the admission of evidence are ordinarily quite liberal since there has been no need to develop complex rules to keep certain evidence from a jury. It is generally required that evidence relate directly to the facts in issue and be neither superfluous nor unduly repetitious. But since judicial review of lower court decisions on the admission of evidence is frequently quite limited, these requirements have never been developed into the detailed rules existing in Anglo-American law. (See below *The law of evidence*.)

Judgment and execution. *Drafting and form of judgment.* When proceedings are terminated, the court that has considered the case will render a judgment. In such a case one speaks of a final judgment. Judgments deciding some procedural matter but not terminating the proceedings are known as interlocutory judgments.

In American practice, the judgment of a court after a jury trial is presented in a stylized document that merely recites certain relevant data, such as the names of the parties, the fact that a jury verdict has been rendered, and the disposition to be made. No detailed grounds are given for the decision. If a judge decides a case without a jury, he is often required to indicate the factual and legal bases for his decision in order to facilitate appellate review; in practice, such findings, too, are often rather stylized. Courts sitting without juries sometimes prepare, in addition, an opinion in which their reasoning is explained in narrative form.

Dissenting
opinion

Judgments in civil-law countries quite generally consist of not only statements indicating the names of the parties and the like and the decision of the court but also an opinion in which the court explains its decision. The opinion may vary in style. In West Germany and Austria it is narrative in nature, as in the United States; in France it is traditionally cast in the form of one long sentence consisting of a syllogism using the facts and the applicable law as premises. When the court consists of several judges, it is frequent practice in Anglo-American countries for judges who disagree with the decision of the majority to prepare and file dissenting opinions, in which they explain the reasons for their disagreements. In civil-law countries, such dissenting opinions are rarely allowed; indeed, the courts are generally forbidden from disclosing the position taken by an individual member.

Quite generally, originals of judgments are filed in court clerks' offices; the parties may then procure copies to use as they see fit. In some countries, the rules for the formal preparation, signing, and filing of judgments tend to be quite technical and complex; this is much less so in the United States. Furthermore, judgments must frequently be written on stamped paper or presented to some tax office for the payment of a tax.

Effects of judgment: *res judicata*; collateral estoppel. Judgments generally have a continuing effect on parties and others long after they are rendered. In some situations the doctrine of *res judicata* will grant a binding effect on issues determined in the lawsuit. The doctrine is intended to avoid excessive litigation and is known in some form in most countries. Thus, it is uniformly held in the United States that when a valid and final personal judgment in an action for the recovery of money is rendered in favour of the plaintiff, the plaintiff or his legal successors are prevented from instituting an action against the defendant on the same cause. In effect, what was considered in the first action, or even that which should have been considered

but was not, cannot form the basis of a second action. This does not preclude a second lawsuit based on a different cause of action or claim, but the related doctrine of "collateral estoppel" will preclude the parties from relitigating in the second suit based on a different cause of action any issue of fact common to both suits that was actually litigated and necessarily determined in the first suit.

The doctrine of collateral estoppel traditionally had been limited to the parties to the past action. For instance, A, as the driver of B's truck, is involved in an accident with a car driven by C. If A sues C and recovers a judgment because of the negligence of C, the traditional rule has been that in a subsequent suit filed by B against C for damage to the truck, C is not precluded from claiming that he was not negligent since B was not a party to the first suit and would not be bound by the decision in it. Many courts now, however, are holding that even though the same parties are not involved, when the issues are the same and when the defendant has presented a complete and full defense in the first trial, collateral estoppel will now bind him to the finding in the first suit that he was negligent in the occurrence.

The principle of *res judicata* is followed in civil-law countries as well, but there are differences. Substantively, *res judicata* applies generally only in new proceedings between the same parties (or their heirs or successors in interest), and the new proceedings must involve the same type of action (the same bases for the action and the same demand for relief). There is, however, no collateral estoppel, though a judgment that is no longer subject to any form of review (appeal, etc.) is binding as to all procedural rulings. In effect, *res judicata* becomes procedurally operative only after all normal means of review have been exhausted or the time limit to use them has lapsed.

Enforcement of judgment. All countries have procedures intended to overcome the resistance of a party who fails to comply with the judgment of a court. This is usually known as the enforcement or execution of a judgment. Rules vary greatly, and they are usually highly technical and thus can only be dealt with generally. In the United States a party who obtains a judgment for a sum of money is entitled normally to avail himself at once of the procedural devices designed to enforce the judgment. The fact that the period for appeal has not yet passed or that an appeal is filed does not, of itself, affect the right to enforce the judgment; the losing party, seeking to postpone enforcement of the judgment pending appeal, must request such relief either from the trial court or the court to which the appeal is taken. Frequently, such a request will be granted if the losing party posts a bond or other security to ensure that the delay in enforcement will not adversely affect the rights of the winning party should the appellate court affirm the judgment of the trial court.

When the judgment results in an order to the losing party to do or refrain from doing some act, the court has the power to enforce the judgment by punishing a party who fails to comply, by a fine or a jail sentence, on the grounds that his disobedience constitutes "contempt of court."

When the judgment results in an award of money damages, the usual procedures for enforcement are the "levy of execution" on property belonging to the defendant or an execution against his income. All property that is not exempt by a specific statute, as well as income earned and debts owed by third persons, are subject to this enforcement process. Exemptions generally are given for such necessities as wearing apparel, tools and implements used in earning a living, household furniture, and such personal items as wedding rings, family Bibles, and family photographs. The attorney for the party in whose favour the judgment has been rendered or the clerk of the court in which the judgment was obtained issues a command to the sheriff to seize the property. Once the sheriff has taken possession of the property he sells it at public auction and, after deducting his fees, turns over to the judgment creditor only those proceeds of the sale necessary to satisfy the judgment; any excess is returned to the defendant.

The remedy of garnishing the earnings of the defendant, although generally permitted, is accompanied by certain safeguards to prevent oppression. Thus, only if the debtor

Res
judicata in
civil-law
countries

Garnish-
ment of
wages

fails to make payments voluntarily, can his wages be seized, and even then only a limited percentage of the wages.

Rules for the enforcement of judgments in civil-law countries are in some respects similar to those in the United States or other common-law countries, although some differences do exist. Frequently, judgments cannot be enforced by execution or in some other way until all appeals have been heard or until the time for such appeals has run out, but the precise rules differ greatly from country to country and often depend on the subject matter of the action or the court to which an appeal is taken. In West Germany, for instance, it is sometimes possible to receive an execution on a judgment still subject to appeal, but the money recovered on execution must be paid into the court clerk's office pending determination of the appeal.

In all countries there are detailed rules exempting certain types of property from seizure, but continental European rules are much less generous toward the debtor than corresponding rules in the United States. In France, for instance, all wages exceeding a stated amount may be seized, whereas in New York no more than 10 percent of wages may ever be taken. If several judgments exist against a debtor, threatening to exceed his available assets, other procedures are available to ensure that these assets will be distributed fairly. To some extent, such procedures replace bankruptcy, which in some European countries is available only to businessmen and not to private debtors.

Problems arise in connection with judgments ordering a party to do or not to do a certain act, since contempt procedures, outside of mild fines or jail sentences available to secure the maintenance of order in the courtroom, are generally unknown in Europe. For this reason, Italian judgments will order the performance of a specified act only when, in the case of disobedience by the party, the act can be performed by a substitute appointed by the court. For instance, if the defendant is ordered to tear down a wall and refuses to do so, the court may appoint a contractor to perform this operation. French courts have not limited themselves so narrowly and have developed a kind of civil penalty in order to compel compliance with their judgments.

Costs and disbursements. Generally, the prevailing party recovers not only the amount of the judgment but also the costs and expenses of the suit. These include filing fees, government taxes, witness fees, and the like, but not funds spent in the preparation of the case. In countries like Austria and West Germany that regulate the fees of attorneys by an official schedule, such fees are ordinarily recoverable. In the United States, where such fees normally are not regulated by schedule, they usually must be borne by the party that has incurred them.

APPEALS AND OTHER METHODS OF REVIEW

A judgment of a court of first instance may be attacked either by appeal to a higher court or by a request for some form of review of the judgment by the court that rendered it. Thus, it is quite generally possible for a defendant who has defaulted to ask a court to reopen the case and hear it on its merits. As noted above, in Anglo-American courts, it is frequently possible to ask for a new trial. In some cases (if, for example, there is newly discovered evidence) procedures analogous to motions for a new trial exist in European countries. In certain countries and in some states of the United States, an appeal of a judgment that is not a final decision can be made in addition to appeals of final decisions.

The appeal process is somewhat different in civil-law and common-law countries. In Europe the appeal from the court of first instance to the intermediate appellate court ordinarily involves a reexamination of the entire case, both the law and the facts, and new evidence frequently can be introduced. An appeal to the supreme or highest court is restricted to matters of law. In the Anglo-American system, on the other hand, both the intermediate appellate court and the supreme court examine only the written record created in the court below and do not receive new evidence. Furthermore, review is generally restricted to matters of law, though the scope of review is broader in

the intermediate appellate court than the supreme court. Rules of appeal in all systems tend to combine the desire that justice be done and error be corrected with the desire to find some point at which the proceedings will end and judgment will be deemed final.

Common-law appellate procedure. A fundamental principle underlying the function of appellate courts in the United States is the concept that the court serves only to review allegations that errors of law were committed at the trial. In no sense can the appeal be considered a retrial of the entire case. Factual determinations made at a jury trial are not reviewable on appeal except when presented in the context of a legal question. Factual determinations made by a judge in cases tried without a jury are reviewable on appeal, but even in such cases, appellate courts are reluctant to set aside such determinations unless clearly erroneous.

The party appealing the judgment must specify the errors that allegedly occurred at the trial; generally, the appellate court will consider only those points advanced by the appealing party. Moreover, the court will, with few exceptions, refuse to consider an allegation of error, unless the issue had been raised during the initial trial.

Because appellate courts do not hear witnesses or permit the introduction of new evidence on appeal, it is necessary that the record of the trial be made available and include a transcript of the proceedings, original papers, and exhibits. Both parties are required to submit written "briefs" to the court containing legal precedents and the arguments in support of their contentions that error did or did not occur, and each party has an opportunity to present oral legal arguments supporting his position.

Most jurisdictions provide a second appellate court to which a party may appeal from an adverse decision of the first appellate court. The right to such a second appeal is usually limited to certain types of cases raising particularly important issues, and only a small percentage of litigants pursue a second appeal. In the U.S. Supreme Court, a petition to authorize an appeal in certain cases involving the public interest, when it is not available as a matter of right, is known as a petition for a writ of certiorari.

Civil-law appellate procedure. Appeals to intermediate appellate courts from courts of first instance are available quite broadly in Europe, frequently for all judgments exceeding a certain amount and at times for certain types of judgments, regardless of amount. This encourages appeals to intermediate appellate courts and explains their frequently very heavy case load.

Since the appeal involves a new hearing of the case, the procedure is essentially similar to that in use in courts of first instance, though entirely new claims may not be presented. In the case of a review of a nonfinal judgment, the appellate court frequently limits its review to an examination of the legal correctness of that judgment and then remands the case, so that proceedings in the court below may be completed. Occasionally, appellate courts are authorized to use the occasion of an appeal of a nonfinal judgment in order to decide the entire case themselves.

By way of contrast, appeals to the supreme courts of the various countries are generally limited to questions of law. The facts are not ordinarily reexamined, and no new evidence may be introduced. The procedure involves essentially the presentation of written or oral argument by counsel for both sides on the alleged substantive or procedural errors made by the lower court. In several countries, such as France and Italy, the partisan argument by the parties is augmented by independent argument by an officer of the Ministry of Justice representing the law as such. The court either affirms or reverses the judgment submitted to it for review. If it reverses, it does not, generally, substitute its own judgment for the erroneous judgment below but merely annuls the erroneous judgment and remands the case for new proceedings, frequently to a court different from that from which the case came. Review by supreme courts can usually be sought for all final (and sometimes even nonfinal) decisions of intermediate appellate courts, and frequently also of decisions of courts of first instance if no appeal to an intermediate appellate court is possible. No special permission of the

Appeals to
supreme
courts

Differences
between
common
law and
civil law

court analogous to the grant of certiorari is ordinarily required. Consequently, case loads are extremely heavy, and to handle them the full court does not usually sit together but instead is divided into panels. In important matters two or more panels may sit together. (P.E.H./Ma.E.O.)

Criminal procedure

The law of criminal procedure regulates the modes of apprehending, charging, and trying suspected offenders; the imposition of penalties on convicted offenders; and the methods of challenging the legality of conviction after judgment is entered. Litigation in this area frequently deals with conflicts of fundamental importance for the allocation of power between the state and its citizens.

PROCEDURE BEFORE TRIAL

The investigatory phase. When a criminal offense has been reported, the competent authority (the police, the public prosecutor, or the investigating magistrate) commences the criminal process by investigating the circumstances. In this phase, relevant evidence is collected and preserved for a possible trial. The suspect also has the right to collect evidence in his favour. In the civil-law countries of continental Europe, he can typically request the investigating authority to assist him in this endeavour; in common-law countries, the suspect is expected to take the initiative in preparing the case for his defense.

The role of the police. The police play a primary role in the investigation. They are responsible for interrogating suspects and witnesses, and they carry out arrests, searches, and seizures. In Anglo-American legal systems the police perform investigations on their own authority, whereas on the Continent they act under the formal supervision of public prosecutors or investigating magistrates.

The role of the magistrate. In some countries, such as France and Italy, a magistrate conducts the investigation in cases of serious criminal offense, personally hearing witnesses and directing police to perform such relevant acts as the seizure of evidence.

In many other jurisdictions, as in the United States and West Germany, magistrates do not organize or conduct the investigation. Their role is limited to authorizing particular acts of investigation involving serious invasions of civil rights—most important, instances of arrest, pretrial detention, search, seizure, and surveillance of mail and telecommunication. Generally, such acts are lawful only upon prior written judicial authorization (the warrant). Under U.S. law, warrants are issued only upon probable cause, that is, when there is evidence leading to a reasonable belief that the person to be arrested has committed a crime or that an object connected with criminal activity can be found at the place to be searched. Other legal systems employ less-stringent standards of suspicion.

When it is necessary for police to act on the spot—for example, because the suspect is about to escape or because he will destroy the contraband sought—they can take the proper measures without prior judicial authorization. In most cases, such provisional measures can or must be submitted later to judicial control.

The role of the prosecutor. Public prosecutors are lawyers appointed by the government as its representatives in criminal matters. In the United States, most state or county prosecutors are elected.

In some legal systems, as in West Germany, the prosecutor is formally responsible for conducting criminal investigations. In practice, however, his role is generally limited to advising and supervising police. Only in very serious or politically sensitive matters does he personally conduct the investigation.

The role of the suspect. Since the 19th century, the law has gradually recognized the suspect's autonomous position as a subject of the criminal process. His right to remain silent in order to avoid incriminating himself has, in principle, been acknowledged universally. However, few legal systems go so far as the United States, where, under the *Miranda v. Arizona* ruling of 1966, the defendant's statements will be excluded from evidence if he is not specifically warned of his right to remain silent before

interrogation while in police custody. In most countries, evidence of a confession is admissible in court unless the confession is shown to have been "involuntary"—for example, acquired by torture or threats.

On the other hand, the defendant has a universally recognized right to present to the court his view of the facts. In many jurisdictions, this right can be exercised even before the court decides whether there is sufficient evidence to hold a trial.

The role of defense counsel. The defense lawyer has a double function in the investigation phase of the criminal process: to assist the suspect in gathering exonerating evidence and to protect him from violations of his rights at the hands of law-enforcement personnel. All legal systems grant the suspect the right to the assistance of an attorney, and in many countries the suspect must be informed of this right before police interrogate him. If the suspect does not have the means to hire a lawyer, often the state will pay the attorney's fee or provide the suspect with state-employed counsel.

However, the law also restricts defense counsel's ability to carry out his functions. In some jurisdictions, as in France, the attorney has no right to be present when the suspect or a witness is interrogated by the police; only a few countries, such as the United States, grant the defense the right to compel witnesses on its behalf to appear in court. Moreover, in most jurisdictions the defense has no or only limited access to information gathered by the prosecution before the case reaches the court.

Pretrial detention. Incarceration of the suspect before trial most seriously impairs the preparation of an effective defense. Nevertheless, all legal systems permit pretrial detention, though under differing conditions.

In Anglo-American jurisdictions the rule is that suspects arrested and not released immediately for want of cause are held in custody. However, the suspect generally has a right to be released on a financial surety, or bail, the amount of which is set by the magistrate according to the individual circumstances of the case. The purpose of bail is to assure appearance of the suspect at the trial; hence, it will be forfeited if the suspect absconds. In appropriate cases the suspect can be released on his own recognizance (*i.e.*, without providing bail). Only under special circumstances—for example, when it is thought that the suspect might commit further offenses if released—can bail be denied altogether.

In continental Europe the law treats pretrial detention as the exception rather than the rule. The magistrate can remand the suspect to custody before trial only if this is necessary to prevent him from escaping, tampering with evidence, or committing further serious offenses. Even on the Continent, the law authorizes the court to release a suspect from custody if sufficient surety is posted.

The decision to prosecute. A formal accusation is universally regarded as an indispensable prerequisite for a criminal trial. It is typically the public prosecutor who, on the basis of the results of the investigation, determines whether to file a complaint and for which offense to bring charges.

Private prosecution. Private citizens, such as the victim of the offense, are not generally permitted to institute a criminal action, though the law on this point differs among jurisdictions. In the United States private criminal complaints are practically impossible. In England anyone can institute criminal proceedings for most offenses, but the director of public prosecutions can take over and discontinue prosecution at any time. In West Germany citizens can prosecute only for certain minor offenses such as libel and assault. In France victims of crime can combine criminal prosecution with civil claims for damages.

In many countries victims can prevent prosecution for certain offenses—*e.g.*, assault, libel, and some sexual offenses—by not filing a special request for public prosecution.

Grand jury. In the federal system of the United States, and in about half of the state systems, charges are brought not by the public prosecutor but by the grand jury, a group of 12 to 23 citizens selected by lot. The grand jury also has investigative authority, and it is to serve as

Bail

Defendants' rights

a protective shield against unwarranted prosecution. In practice, however, grand juries are usually dominated by the public prosecutors, who present the evidence to them.

Prosecutorial discretion. In all legal systems the prosecutor should bring an accusation only if he thinks that the available evidence, discounted by probable defense evidence, is so strong that the defendant is likely to be convicted after trial. In some countries, such as Italy, the prosecutor is required by law to bring charges whenever there is sufficient evidence for conviction. In other jurisdictions—for example, in the United States, France, and Japan—the public prosecutor has discretion whether or not to file a formal accusation; in effect, this means that he can informally grant clemency to an offender who would certainly be convicted in court. In still other countries, such as West Germany, prosecutorial discretion applies only to minor offenses, whereas prosecution of serious crimes is mandatory. To the extent the prosecutor has discretion, he can make the decision not to prosecute dependent upon certain conditions—e.g., that the offender pay restitution to the victim.

Plea bargaining. In some countries, such as the United States and Spain, the prosecutor's discretion extends to determining the crime with which the defendant is to be charged. Hence, in a case of armed robbery, the U.S. prosecutor may charge the suspect with armed robbery, simple robbery, assault, simple theft, or any combination of these offenses. All of these offenses carry quite different penalties, and normally the prosecutor charges the most serious offense that can be sustained by the evidence. However, since the cooperation of the defendant, especially in offering a plea of guilty, drastically shortens or simplifies the trial, prosecutors in some countries reduce charges on the condition that the defendant not contest the accusation in court. Especially in the United States, this creates a system of "plea bargaining," in which defense attorneys negotiate with prosecutors the charges (and resulting penalties) most acceptable to their clients. Similar transactions, though sometimes performed discreetly because of their dubious legality, occur in many other jurisdictions.

TRIAL PROCEDURE

Criminal courts. In most countries, two or three types of courts have jurisdiction in criminal matters. Petty offenses are usually dealt with by one professional judge; in England, however, two or more lay justices may sit in Magistrates' Court. Matters of greater importance are, in many countries, tried by panels of two or more judges. Often such panels consist of lawyers and lay judges, as in West Germany, where two laypersons sit with one to three jurists. The French *cour d'assises*, which hears serious criminal matters, is composed of three professional judges and nine lay assessors. Such "mixed courts" of professionals and ordinary citizens deliberate together and decide by majority vote, with lawyers and laypersons having one vote each.

By contrast, the jury system, a distinctive feature of the Anglo-American criminal process, involves a division of functions between the presiding judge and the laypersons sitting as jurors. The judge presides over the trial, determines the admissibility of evidence, and instructs the jury on the applicable law, but he does not participate in the deliberations of the jury. The jurors usually remain silent during trial but are autonomous in finding the verdict of guilty or not guilty.

The U.S. Constitution guarantees every defendant in a non-petty case the right to be tried before a jury; the defendant can also waive this right and have a professional judge sitting alone decide on the verdict. To ensure the impartiality of the jury, prosecution and defense can reject (in legal parlance, challenge) jurors whom they establish to be biased. Moreover, the defense (and in the United States the prosecution as well) has the right of peremptory challenge, in which it can challenge a number of jurors without having to give a reason.

Pretrial matters. In many legal systems, the court checks the accuracy of the accusation before admitting the case for trial. In France a special panel called the *chambre d'accusation* determines whether there is enough evidence

for the case to proceed; in England the Magistrate's Court makes the decision on "binding over" the defendant for trial; and in West Germany the trial court itself (sitting without lay assessors) decides whether there is sufficient evidence. In the Anglo-American system, the court holds a hearing to determine "probable cause" for trial; under continental law, courts usually make that determination on the basis of the documents assembled in the course of the investigation.

A characteristic feature of the Anglo-American criminal process is the opportunity for defendants to plead guilty or not guilty. Only if the defendant contests the accusation by pleading not guilty is a trial held. Otherwise, the court pronounces the defendant guilty as charged and goes on to determine the penalty. With few exceptions (as in Spain), continental law does not provide for such shortcuts to sentencing. Rather, a trial must be held even if the defendant has confessed guilt from the outset.

Publicity of the trial. Trials, as opposed to pretrial investigation, must be accessible to the public. This principle, embodied in the constitutions of several countries, is meant to protect the defendant; in the United States it is also based on the freedom of the press. Publicity does not mean that broadcasting of trials must be permitted; in most countries, it is not allowed.

In spectacular cases, great publicity can influence the court and work to the detriment of defendants. Most legal systems, therefore, permit the court to exclude the public from the trial (or from parts thereof) or to change the location in which the trial is to be held if either measure is necessary to protect the trial process from undue interference.

Presentation of evidence. In Anglo-American law the presentation of evidence is left to the parties. Witnesses are examined and cross-examined by counsel, not by the court. The function of the trial judge is to enforce the rules governing evidence and to ask supplementary questions if he feels that the parties have failed to clarify the facts. The defendant may testify as a witness if he chooses to, but he is not examined by the judge. Under continental law, by contrast, the presiding judge typically dominates the process of taking evidence. He is responsible for establishing the relevant facts by calling and questioning witnesses and for introducing real evidence. The judge also interrogates the defendant unless the latter chooses to remain silent. Attorneys for the prosecution and the defense ask additional questions of witnesses and summarize the evidence at the end of the trial.

Finding the verdict. A basic principle of both Anglo-American and continental procedures is that the defendant is presumed innocent unless and until his guilt has been established beyond a reasonable doubt. The burden of proof, therefore, rests upon the prosecution. On the Continent, this is true even in cases involving insanity, drunkenness, self-defense, or necessity. Anglo-American law regards these as "affirmative defenses" and requires the defendant to provide at least some evidence that they were a factor.

Courts in continental legal systems are not bound by any legal rules concerning the evaluation of evidence presented; rather, they are to follow their conscience in establishing guilt or innocence. The same is generally true for juries in the Anglo-American system; however, since juries are thought to be easily distracted from the real issues of the case, there is a complicated set of legal rules determining what evidence can be presented to juries. (See below *The law of evidence*.)

In the United States, jury verdicts must be unanimous; if the jury is unable to agree, a new trial before another jury can be held. In England, majority votes by margins of 10 to two or nine to one are acceptable after the jury has deliberated for at least two hours. As a corollary of the presumption of innocence, many continental systems require a specified majority of the judges to vote for a finding of guilty.

Sentencing. In continental systems, the court decides, on the basis of a single comprehensive trial, both on the guilt or innocence of the defendant and on the penalty if he is found guilty. Sentences are conclusively determined

Legal obligation to prosecute

Formation of the jury

The basic principle of criminal justice

by the court, with prison terms being subject to conditional release.

Anglo-American law provides for separate sentencing hearings, which typically take place a few weeks after the defendant has been found guilty of the charges. In the interim, social workers gather information on the offender's psychological and social background, which they present to the court. Usually, a single professional judge determines the sentence after hearing the defense (and, in the United States, the prosecution). In the United States, juries in several states make a recommendation with respect to capital punishment in cases where the death penalty is available as a sentence.

POST-CONVICTION PROCEDURE

Common law. In Anglo-American legal systems, a convicted defendant may move in the trial court to arrest judgment, or he may file a motion for a new trial. The legality of the conviction may also be challenged by appeal to a higher court. Criminal appeals were unknown in the traditional common law, but today they are universally granted by statute. In the United Kingdom, the Criminal Appeal Act of 1907 established an elaborate system of appellate procedure, proceeding from Magistrate's Courts all the way to the House of Lords, the supreme court of England. Extraordinary remedies available in English procedure include the writ of habeas corpus (determining the legality of holding the prisoner in custody) and the orders of mandamus (compelling an official to perform an act required by law), certiorari (requiring a lower court to present the trial record to a higher court), and prohibition (by which a higher court prohibits a lower court from exceeding its jurisdiction).

In the United States, a defendant convicted in a state or federal court can appeal to that state's (or the appropriate federal) appellate court. Subject to certain restrictions, the defendant can turn to the federal court system when his rights under the U.S. Constitution have been violated in state court. Review by the U.S. Supreme Court is discretionary; the court grants it only in cases of general significance by issuing a writ of certiorari to the court whose judgment is to be reviewed. Even after the regular avenues of appeal are exhausted, defendants in custody can at any time apply for a writ of habeas corpus, challenging the prison warden's right to keep the petitioner in custody and demanding his release. Since the warden's right usually depends on the validity of the criminal judgment, habeas corpus constitutes an indirect method of review. Legislation in the 1970s curtailed access to federal courts on the basis of habeas corpus.

While defendants enjoy a liberal right to appellate review in criminal matters, the prosecution generally cannot appeal an acquittal. This is due to a strict interpretation of the concept of double jeopardy, which forbids a defendant to be tried twice for the same act.

Appellate courts do not take evidence but only decide points of law on the basis of the record. Since juries do not give reasons for their verdicts, appeals are usually based on allegations of faulty procedure (in particular, the admission and exclusion of evidence) and on erroneous statements on the applicable law in the judge's instruction to the jury. The sentence is also subject to review in Britain and Canada but not in most of the United States.

Civil law. Appellate procedure on the Continent follows quite different rules. Most important, the prosecution as well as the defense can appeal a judgment, including the sentence. In some countries (e.g., West Germany) it is possible to demand a new trial in a higher court if the original trial was held by a single judge. In other cases, appellate courts review only matters of substantive or procedural law, including the question of whether the lower court did everything necessary to find the relevant facts. Continental trial courts usually write elaborate reasons for their judgments, and it is these reasons that form the objects of the appellate courts' scrutiny.

When appellate review is waived or exhausted, judgments are deemed final and can be executed. Final judgments can be overturned only if significant new evidence is found indicating that the decision was wrong. (H.-H.J./T.We.)

The law of evidence

To the end that court decisions are to be based on truth founded on evidence, a primary duty of courts is to conduct proper proceedings so as to hear and consider evidence. The so-called law of evidence is made up largely of procedural regulations concerning the proof and presentation of facts, whether involving the testimony of witnesses, the presentation of documents or physical objects, or the assertion of a foreign law. The many rules of evidence that have evolved under different legal systems have, in the main, been founded on experience and shaped by varying legal requirements of what constitutes admissible and sufficient proof. Although evidence, in this sense, has both legal and technical characteristics, judicial evidence has always been a human rather than a technical problem. During different periods and at different cultural stages, problems concerning evidence have been resolved by widely different methods. Since the means of acquiring evidence are clearly variable and delimited, they can result only in a degree of probability and not in an absolute truth in the philosophical sense. In common-law countries, civil cases require only preponderant probability and criminal cases, probability beyond reasonable doubt. In civil-law countries so much probability is required that reasonable doubts are excluded.

THE EARLY LAW OF EVIDENCE

Characteristic features of the law of evidence in earlier cultures were that no distinction was made between civil and criminal matters or between fact and law and that rational means of evidence were either unknown or little used. In general, the accused had to prove his innocence.

Nonrational sources of evidence. The appeal to supernatural powers was, of course, not evidence in the modern sense but an ordeal in which God was appealed to as the highest judge. The judges of the community determined what different kinds of ordeals were to be suffered, and frequently the ordeals involved threatening the accused with fire, a hot iron, or drowning. It may be that a certain awe associated with the two great elements of fire and water made them appear preeminently suitable for dangerous tests by which God himself was to pass on guilt or innocence. Trial by battle had much the same origin. To be sure, the powerful man relied on his strength, but it was also assumed that God would be on the side of right.

Semirational sources of evidence. The accused free person could offer to exonerate himself by oath. Under these circumstances, in contrast to the ordeals, it was not expected that God would rule immediately but rather that he would punish the perjurer at a later time. Nevertheless, there was ordinarily enough realism so that the mere oath of the accused person alone was not allowed. Rather, he was ordered to swear with a number of compurgators, or witnesses, who confirmed, so to speak, the oath of the person swearing. They stood as guarantees for his oath but never gave any testimony about the facts.

The significance of these first witnesses is seen in the use of the German word *Zeuge*, which now means "witness" but originally meant "drawn in." The witnesses were, in fact, "drawn in" to perform a legal act as instrumental witnesses. But they gave only their opinions and consequently did not testify about facts with which they were acquainted. Nevertheless, together with community witnesses, they paved the way for the more rational use of evidence.

The influence of Roman-canonical law. By the 13th century, ordeals were no longer used, though the custom of trial by battle lasted until the 14th and 15th centuries. The judicial machinery destroyed by dropping these sources of evidence could not be replaced by the oath of purgation alone. With the decline of chivalry, the flourishing of the towns, the further development of Christian theology, and the formation of states, both social and cultural conditions had changed. The law of evidence, along with much of the rest of the law of Europe, was influenced strongly by Roman-canonical law elaborated by jurists in northern Italian universities. Roman law introduced elements of common procedure that became known throughout the

Trial by
ordeal and
battle

Mechanisms of
appellate
review

continental European countries and became something of a uniting bond between them.

Under the new influence, evidence was, first of all, evaluated on a hierarchical basis. This accorded well with the assumption of scholastic philosophy that all the possibilities of life could be formally ordered through a system of a priori, abstract regulations. Since the law was based on the concept of the inequality of persons, not all persons were suitable as witnesses, and only the testimony of two or more suitable witnesses could supply proof.

The formal theory of evidence that grew out of this hierarchical evaluation left no option for the judge: in effect, he was required to be convinced after the designated number of witnesses had testified concordantly. A distinction was made between complete, half, and lesser portions of evidence, evading the problem posed by such a rigid system of evaluation. Since interrogation of witnesses was secret, abuses occurred on another level. These abuses were nourished by the notion that the confession was the best kind of evidence and that reliable confessions could be obtained by means of torture.

Despite these obvious drawbacks and limitations, through the ecclesiastical courts Roman-canonical law gained influence. It contributed much to the elimination of nonrational evidence from the courts, even though, given the formality of its application, it could result only in formal truths often not corresponding to reality.

COMPARATIVE SURVEY OF MODERN PRINCIPLES

A comparison of the principles of evidence under different legal traditions can best be made by examining the rights and obligations of the plaintiff and the defendant in civil proceedings and of the prosecutor and the accused in criminal proceedings. The position of the judge is also crucial. Historically, two systems developed.

The first, which follows what may be called the inquisitorial principle, had its origins in medieval Roman-canonical proceedings. It is distinguished by the active part played by the judge, who by virtue of his office, himself searches for the facts, listens to witnesses and experts, examines documents and orders the taking of evidence. In continental European countries, and those other countries that derive their law from them, this system has generally been retained for criminal proceedings. The prosecutor and the accused, of course, give their recital of the facts and indicate their evidence for specific assertions. But by virtue of his role in the case, the judge must make further investigations if he deems them necessary to obtain the truth. In some western European countries, there is a definite inclination toward employing this inquisitorial system in all legal proceedings that have, or could have, a substantial public legal impact; *e.g.*, matrimonial, status, administrative, social, labour, and financial matters.

The second system, which employs what are usually called accusatorial or adversary principles, is used in the common-law countries for all civil and criminal cases. In this system, the parties and their attorneys are primarily responsible for finding and presenting evidence. The judge does not himself investigate the facts. Only if the efforts of the parties are incomplete must the judge make inquiries with regard to questions that have remained unanswered.

In civil matters, most continental European countries follow a mixed system of both inquisitorial and adversarial principles. In some of these countries, the judge can, for example, hear witnesses who have not been designated by the parties, and in all countries he can, by virtue of his office, hear the parties and experts and order documentary evidence or the actual inspection of evidence. In contrast to criminal cases, the continental European judge is always bound by the motions and assertions of the parties.

Oral proceedings. Under both systems of presenting and obtaining evidence, oral proceedings are generally accepted. The written proceedings favoured during the Middle Ages have been abolished, although the parties prepare their lawsuits through briefs, and parts of the preliminary proceedings can be handled in writing. The interrogation of witnesses, however, is oral. Most civil-law countries do not permit any exceptions, while other countries, such as West Germany, permit written statements by witnesses in

special cases and with the consent of the parties. In the common-law countries an exception is made to the principle of oral proceedings for certain types of affidavits, and, particularly in civil cases, the practice has steadily gained in importance.

Direct interrogation of witnesses by the deciding court is an aspect of the law of evidence closely connected with oral proceedings. Generally, in continental European countries, witnesses are interrogated by the judges who decide the verdict, but a number of countries have an investigation procedure according to which another judge, or only one member of the judging body, interrogates the witnesses. Under both the inquisitorial and the accusatorial systems, the principle of direct interrogation is of special importance in the free consideration of evidence. In the common-law countries the function performed by the judge in this regard is handled by attorneys for the prosecution or defense, with the judge's role restricted almost entirely to overseeing the questioning.

One major influence that has shaped the law of evidence has been the jury system. At least one writer has said that law of evidence is the child of the jury. Oral proceedings, direct interrogation, and the public trial are much less problematic under the Anglo-American system than under the civil-law system to the extent that evidence is heard before the jury. But this system has spawned a large number of regulations for the admissibility of evidence in order to guarantee due process and fair procedure and to protect the jury from being misled. The initiative of the parties determines the handling of these regulations, for they must raise objections if, in their opinion, any of the numerous exclusionary rules is being violated. The judge then rules on the objection. By the complex working of this arrangement, the Anglo-American system has become more formalistic in many respects than the continental European system.

The burden of proof. The burden of proof is a manifold and somewhat ambiguous concept in the law of evidence.

The burden of producing evidence means that in general the party that cites specific facts for the substantiation of its claim also has the burden of producing the evidence to prove these facts. This burden depends on the substantive law governing the claim. Permissible presumptions and legal rules can shift the burden in various situations.

The burden of conviction, on the other hand, comes into play at the end of the hearing of evidence, if doubts remain. This is simply to recognize that the evidence is not sufficient to convince the jury or the judge and that, in general, the party having the burden of pleading and producing facts favourable to itself and of giving evidence also carries the so-called burden of conviction.

Whereas, in civil proceedings, it is generally the plaintiff who has the burden of proof for facts supporting a claim, unless this burden has been shifted to the defendant through rules or presumptions, in criminal proceedings it is the prosecution that bears the burden of proof for all relevant facts. What this means is that the defendant cannot be found guilty as long as proof has not been supplied or as long as doubts still remain. In continental European law, no distinction is made between civil and criminal cases with regard to the standard of proof. In both, such a high degree of probability is required that, to the degree that this is possible in the ordinary experience of life itself, doubts are excluded and probability approaches certitude. In the common-law countries the degree of probability required in civil cases is lower than that called for in criminal matters.

Relevance and admissibility. In civil proceedings in the common-law countries, evidence is both ascertained and simultaneously restricted by the assertions of the parties. If the allegations of one party are not disputed or contested by the other, or if the allegations are even admitted, then no proof is required. Proof would, in fact, be irrelevant. Evidence offered to prove assertions that are neither at issue nor probative of the matter at issue would also be irrelevant. The only evidence that is, therefore, relevant, is evidence that to some degree advances the inquiry and has a probative value for the decision. While continental European judges, in ordering the hearing of evidence or in

Influence

of proof in
civil and
criminal
proceed-
ings

deciding on evidence, indicate the facts to be proved and thereby strictly eliminate irrelevant facts, Anglo-American judges first give the parties an opportunity to furnish any evidence that they deem suitable. If, during the hearing of witnesses, irrelevant questions are put, they are rejected after the adversary has objected to them.

It has been said that relevance depends on logical considerations and that admissibility depends on the law. In contrast to civil law, the common law has developed a large number of rules governing the admissibility of evidence. Relevant evidence is not admissible, for example, if the witnesses are excluded from testifying because of incompetency, or if they are protected by privileges against self-incrimination, or in instances in which they would have to divulge confidential or professional communications that have a privileged status or government secrets, or, again, when the evidence is excluded by the rules against hearsay (see below *Sources of proof: Witnesses*).

In criminal cases in civil-law countries, relevance relates to such questions that are so far removed from the case that they have no evidence value at all. Admissions and confessions do not exclude further evidence. According to Anglo-American law, the accused may be a competent witness under the admissibility rules, but, in contrast to an ordinary witness, he has the privilege of not taking the witness stand. According to continental European law, the accused is neither a party nor a witness. He can be heard, but he cannot be forced to answer questions of fact. In general, Anglo-American rules of admissibility apply to criminal proceedings much as they apply to civil cases.

The free evaluation of evidence. Freedom to evaluate all the evidence produced was established in Roman law but fell into disuse as a principle during the time of the formalistic Roman-canonical law of evidence that characterized the Middle Ages. Remnants of the medieval formal theory of evidence survive in various countries.

In countries where remnants of the medieval formal theory of evidence are still preserved, the principle of free evaluation of the evidence by the judge generally dates from the French Revolution. The French introduced the concept of the judge's *conviction intime* (inner, deep-seated conviction) in contrast to rules of formal evidence that prescribed exactly when the evidence amounted to proof. The primacy this gave to the personal conviction of the judge meant that it was not even necessary to state the reasons for the inner conviction. This total dependence on the judge's discretion aroused a great deal of criticism, and, as a result, various judicial codes prescribed that in giving the grounds on which judgment was based, the judge had to specify in writing why he was convinced in each case. *Conviction intime* in its original sense is limited to the testimony of witnesses and experts and to the explanations of the parties. Both kinds of formal oaths made by parties to a case, the supplementary oath and the tendered oath, are still valid in civil-law countries, and both may lead to formal solutions, since the judge must follow the legal consequences of the oath. But these survivals of medieval formal evidence theory have been weakened. In France, for example, the judge's latitude under the principle of *conviction intime* has been extended to allow him to pass on the affirmation oath of the party, which formerly had to be given a certain value, regardless of his opinion of its worth. In other states, such as Austria, West Germany, and the Scandinavian countries, the formal oath of the parties was abolished and replaced by the free depositions of the parties. Even if the parties take an oath on their testimonies during this process, the judge is not bound by it but may still make his own evaluation of the evidence. In addition, some remnants of the formal evidence theory have been preserved with regard to documentary proof where rules of procedure contain presumptions as to the conclusiveness of certain documents. Since reliance on documentary evidence prevails in some countries, these formal evidence rules are still of special importance.

In Anglo-American law the problem of free evaluation of evidence can be understood through the institution of the jury. Obviously, the evidence must be convincing to the common sense of the jury members, who form their judgment on the basis of free conviction. The function of

the jury, however, is to decide questions of fact, rather than questions of law, which are left to the judge. The jury's verdict can be overturned by the judge if it is inconsistent with the evidence, or with his instructions as to the law governing the case. The judge's relationship to the jury therefore plays a role in the decisions, and there are difficult questions in which it is unclear whether the jury or the judge should consider the evidence. Some formal rules of evidence survive in Anglo-American law. In some cases evidence must be corroborated before it can constitute proof. In homicide cases, for example, a confession must be supported by additional evidence. In addition, evidence by witnesses is sometimes excluded by rules of admissibility.

SOURCES OF PROOF

According to Anglo-American law, the classic means of proof are witnesses, documents, and real evidence (derived from the actual inspection of objects). As a result of historical development, the status of witness was accorded to experts and to the parties in a civil lawsuit, and even to the accused in criminal proceedings. The development of continental European law has taken a different course. Parties cannot be witnesses, and evidence by experts is subject to special procedural rules. Consequently, there are essentially five separate sources of evidence: witnesses, parties, experts, documents, and real evidence.

Witnesses. The oral testimony of witnesses competes in a sense with documentary evidence to the extent that one may exclude or supplement the other. Under Anglo-American law, almost anyone can be a witness, including the parties and experts; even insane persons, children, and convicted felons may testify. Grounds once used for excluding such persons as witnesses are now used only to impeach their credibility. Continental European countries, as has been said, do not treat either the parties or experts as competent witnesses, and they are still suspicious of interested witnesses. Some of them, influenced by the Roman-based school, deny, on the whole, the capacity of those persons having a certain degree of relationship to the parties. Some consider insane persons incompetent to testify, others grant them the competency but exclude their testimony on the grounds of credibility. The capacity to be a witness does not depend on whether or not the person can testify about questions relevant to the specific case. In general, the tendency has been to utilize all persons who can testify about facts that will help to establish the truth. Competency as a witness has therefore been extended to as many persons as possible. On the other hand, many persons are protected by law from being forced to testify. This type of protection derives either from privilege, or from the right to refuse to give evidence, either case distinguishable from incapacity to testify. Whereas privilege or the right to refuse to give evidence may be either requested or waived, incapacity to testify takes effect automatically; i.e., it must always be officially considered by the court.

Privileges. Privileges under Anglo-American law must be distinguished from the right to refuse to give evidence under particular circumstances as it exists in continental European practice. The latter is granted to witnesses for either personal or objective reasons. The personal reasons are the same as those that result in incapacity to testify—i.e., relationship, affinity, and marriage. The objective reasons concern persons who, as a result of their profession (for example, clergymen, physicians, attorneys, journalists), have been put in possession of confidential facts. Such confidants have a limited right to refuse to give evidence so long as the person protected does not give his consent (the West German solution). In some cases they are not admitted as witnesses without the consent of the protected person (the Swedish solution). Thus the Swedish judge officially decides whether the protected person has given his consent, whereas the West German judge leaves the decision whether to testify up to the confidant. In addition, witnesses might refuse to testify if their testimony were to cause direct financial damage to themselves or to their families, or if it were to publicly disgrace them or expose them to criminal prosecution. All persons may make their own decision to testify, but judges are obliged

Competent witness

Conviction intime:
the judge's
opinion

to inform them about their specific rights in the matter. These procedural regulations have developed in order to avoid the situation in which the person protected becomes caught in a conflict between the truth and his personal interests. The interests of the protected person—perhaps partly out of realism—are thus given a higher value than the search for the facts.

The Anglo-American privileges differ from the continental European right to refuse to testify insofar as privileged persons cannot decide whether or not they wish to testify. They may only cite their privileges, and the judge decides if they must testify. Under a system that stresses the free evaluation of evidence, the obligation to testify is subject to only a very few exceptions.

The privilege against incriminating oneself has a twofold nature in Anglo-American law because, in civil proceedings, parties may appear as witnesses and, in criminal proceedings, the accused may appear as a witness. The privilege of an ordinary witness is considerably limited. He must submit to being designated and sworn in as a witness in all instances and must answer all questions except those that are self-incriminating. Consequently, either he or his attorney must sift out the incriminating questions that will evoke the privilege. This is not always easy, particularly since it is only the witness, and not the party or the party's attorney, who may cite the protecting privilege. Critics have called this privilege a sentimental institution, but it is worth noting, in this regard, that the privilege against self-incrimination is included in the U.S. Bill of Rights.

It has already been pointed out that in the common-law system, the accused in a criminal trial no longer lacks competence as a witness but may exercise the privilege of refusing to be called or sworn as a witness. Unlike ordinary witnesses, he may invoke this privilege with considerable latitude, but once he does decide to step into the witness box, he renounces his privilege and may be interrogated as if he were an ordinary witness. The question then arises whether the waiving of the privilege against self-incrimination is limited to testimony concerning crimes of which he presently stands accused, or whether he must answer all questions regarding criminal acts. It appears to have become fairly well established that the prosecutor can, in fact, interrogate the defendant about previous criminal offenses. In civil cases the parties have the same privilege for protection from self-incrimination as other witnesses; *i.e.*, they need not answer incriminating questions.

Privileges deriving from personal and professional relationships are generally not granted on principle, though historically a privilege for the protection of marital communications has developed. In England an 1853 law decreed that a husband could not be forced to testify concerning information that his wife may have given him during the course of the marriage. This, naturally, also applies to the wife. In the United States the courts contended that laws concerning testimony on matrimonial communications contained only a statement of the common law. Only the beneficiary of the privilege may cite it, and it is not applicable where criminal offenses by one spouse against the other or against the children are concerned or in the case of a divorce proceeding.

Attorneys are considered to be under an obligation to refuse to testify about confidential communications with their clients. The privilege, however, protects the client, not the attorney, and, therefore, the client may waive it. This privilege applies principally to the adversary system, in which, so to speak, the attorney is the client's champion.

Clergymen are likewise under obligation to refuse to answer questions concerning information given them in the secrecy of the confessional by believers. Again, the privilege protects the believer. This custom has been sanctioned by legislation in many U.S. states. In England, however, there is no common-law rule for this privilege.

Physicians, as a rule, must answer all questions since there is no common-law privilege regarding confidential information furnished by the patient. In some U.S. states an appropriate privilege has been created by legislation; again, it is the patient who is protected, and only he may waive the privilege.

Journalists, like physicians, occupy a position that is not entirely clear. In some jurisdictions they may refuse to testify about their sources of information, and in a number of U.S. states such a privilege has been specifically created by statute. In other U.S. states and in England the question does not yet seem to have been settled.

Swearing. The oath, perhaps the oldest means for encouraging truthful testimony, forms a link between court proceedings and religious belief since, in its usual form, witnesses swear by Almighty God that they are speaking the truth. Though the effectiveness of such an act has certainly diminished in secular societies, this appeal to God has for centuries been considered the surest means of obtaining truth. There are two kinds of oaths, the preliminary and the subsequent. In Anglo-American practice the witness is sworn in before testimony. Under the West German and other continental procedures, the swearing-in may occur after testimony as well. The latter method allows the judge to use his own discretion in individual cases as to whether or not the witness should be ordered to swear. In current West German practice, very few witnesses are sworn in for testimony in civil proceedings, whereas in criminal proceedings all witnesses have to swear. Some continental European countries allow witnesses who object to oaths to substitute a solemn affirmation, and Denmark has abolished all oaths in legal procedures. The oath of a witness does not have the formal effect of binding the judge or the jury. They must evaluate it and the testimony freely.

Examination and cross-examination. Judges and attorneys in common-law courts regard the opportunity to cross-examine as a guarantee of the reliability and completeness of testimony by a witness. Under the perfect operation of the adversary system it is not the judge but rather the parties or their attorneys who interrogate the witnesses. The plaintiff's attorney begins the "examination in chief," which is subject to a number of restrictions. Leading, misleading, and argumentative questions, for example, are not permitted. After the plaintiff's attorney concludes his interrogation, the defendant's attorney may cross-examine the same witness. This cross-examination generally consists of leading questions posed with the intent of weakening or invalidating the impression created by the direct testimony of the witness. The cross-examination must ordinarily be limited to subjects covered during direct interrogation. There is a recognizable tendency, however, for cross-examination to become as open-ended as possible. The plaintiff's attorney has the option, finally, to reestablish the credibility of his witness by reexamination. These interrogations are formally regulated and require a great deal of skill and experience on the part of the attorneys. Such formal questioning of the witness is unknown to the continental European rules of procedure, even though cross-examination is common. Continental rules of procedure require the judge to interrogate the witness first. Frequently, the witness begins with a free narration. Then, after the judge has finished his interrogation, the attorneys of both parties may question the witness. All this is done in an informal manner, and almost any question is permitted. In some countries the interrogation of witnesses is, however, rather formalistic because it is generally limited to questions concerning allegations specified in the evidence judgment. But here too, there is a tendency for the court to allow questions at its discretion.

Scientific examinations of witnesses are especially common in paternity and status proceedings with regard to blood-typing. These methods have now been so much improved that the suspicion of paternity may be definitely dismissed in many cases. In Germany and elsewhere, opinions based on biologic and hereditary evidence are used for these same purposes. The use of fingerprint and ballistics evidence, among other types, has become quite customary in criminal cases. In the United States, there are varying opinions about the admissibility of lie-detector tests as evidence. The results of such tests are not yet admissible in the continental European countries.

The hearsay rule. Hearsay is testimony based on what a witness has heard others say. The hearsay rule limiting this type of testimony is perhaps the most characteristic

Self-incrimination

Purpose of cross-examination

Professional confidentiality

feature of the Anglo-American law of evidence. It has also been said that, next to trial by jury, the hearsay rule constitutes the most important and original contribution of this system's practice.

Despite the obvious dangers involved in its use, free evaluation of the evidence furnished by hearsay testimony continues to be characteristic of continental European law. This somewhat surprising fact may be explained by reference to the historical development already traced here. Until the 19th century the medieval formal evidence theory strictly prescribed when the judge had to be convinced by the testimony of a witness. Moreover, there was no jury in the continental countries to be protected by rules of evidence and therefore no need to introduce rules of hearsay. When the formal evidence theory was replaced by the requirement that the judge freely consider the evidence, his discretion naturally extended to hearsay testimony.

The creation of a body of rules for the exclusion of hearsay evidence was motivated by the arguments that such testimony could tend to mislead the jury, that the hearsay observer, unlike the legal witness, was not under solemn oath and was inaccessible to cross-examination, that such testimony furnished third-hand evidence, and that it violated the best evidence rule (the rule that the best version possible of a written document be submitted as evidence).

The exceptions to the rule against hearsay

Over the years, exceptions to the prohibition of hearsay testimony had to be permitted, however, and these have become so numerous that the opinion has sometimes been expressed that no exhaustive list of such exceptions could even be compiled. The judge must decide in each case whether testimony based upon hearsay is admissible under an exception to the rule—a further indication that regulations governing the admissibility of evidence are far more important in Anglo-American law than in continental law. The most commonly cited exceptions to the rule of hearsay relate to statements made by dead or absent persons, statements in public documents, and to confessions and admissions by parties.

Confessions and admissions. Confessions, as a source of evidence, are distinguished from admissions. Whereas a confession is a complete acknowledgement of guilt in criminal proceedings, an admission is a statement of fact in either a civil or a criminal case. In former times, the confession was considered the ultimate form of evidence. As soon as the accused confessed—often under duress—no further proof was required. In time, involuntary confession came to be rejected as evidence under English law, and the burden of proving that a confession was voluntary lay with the prosecutor. In the United States the federal rule that confessions are inadmissible if obtained while the defendant was unlawfully detained has not gone quite so far, though the law is still in a state of considerable flux. Involuntary confessions, however, are not admissible for any purpose under Anglo-American law. In continental European law, on the other hand, confessions of the accused are always freely considered by the judge.

Differences between criminal and civil proceedings regarding admissions result mainly from the adversary principle governing civil proceedings. In Anglo-American procedure, if one party in a civil suit admits facts contrary to his interest, such an admission is conclusive and obviates the need for further evidence on the point. The same result follows in German or Swedish courts. Under the Roman-based laws of such countries as France, Italy, and Spain, an admission made before the court is a form of evidence that leads to conclusive proof binding upon the court. But admissions made out of court are subject to free evaluation by the judge and do not exclude further evidence. Only Soviet law gives no binding effect to admissions.

Party testimony. Oral testimony by the parties in civil proceedings was introduced in Austria in 1895. Norway followed suit in 1915, Denmark in 1919, Germany in 1933, and Sweden in 1948. Party testimony is generally heard in the same way as the evidence of witnesses, but there are some essential differences. In some countries, the interrogation of parties is a subsidiary source of evidence to be used only when all other means have been ex-

hausted; in others (e.g., Norway, Sweden, Austria, Brazil), parties are heard before witnesses. In some countries, both parties must be heard; in others, only one party may be heard upon motion of the opponent. The judge decides whether the parties are to be heard; this contrasts with the procedure with witnesses, who are heard only after having been nominated by the parties.

In most cases, the parties do not have to confirm their testimony by oath, but the court may decree that one of the parties must swear. In Swedish law, for example, the parties must solemnly declare that they have told the truth.

Expert evidence. Expert witnesses must have specialized knowledge, skill, or experience in the area of their testimony. For the most part, they do not testify concerning facts but draw inferences from them. With a few exceptions, they are treated in Anglo-American law as ordinary witnesses and are brought before the court by the parties in the same manner as other witnesses. Although ordinary witnesses are generally allowed to testify only concerning facts and not to express opinions, an exception to this rule is made for the expert, who must, of course, be allowed to give his opinion.

Generally speaking, anyone with special knowledge may be an expert in his respective field. In Anglo-American law, the expert is designated by the party, while in continental European law the court decides who may be an expert, generally selecting from a list on file in the court so as to guarantee that the experts designated are impartial. Experts may not, therefore, be cited by the parties.

The oral interrogation of experts is customary in Anglo-American law and proceeds, with a few exceptions, under the same rules for the interrogation of ordinary witnesses.

Under continental rules of procedure, on the other hand, expert opinions are generally given in written form. Experts are allowed a rather wide scope of discretion, especially when the opinion involves scientific findings that often cannot be checked by the judge. But under some continental European rules, the parties or their attorneys may request that the experts testify before the court to defend their written opinion and tell how they arrived at it.

Documentary evidence. Documentary evidence is in many respects considered better than the evidence furnished by witnesses, about which there has always been a certain amount of suspicion. Documentary evidence differs considerably from the evidence of witnesses and is dealt with under special rules.

Criteria for establishing the authenticity of documents are only important if authenticity is contested. This is often impossible, however, if a presumption favouring the authenticity of a public document exists—which it frequently does under continental European law. Under Anglo-American law, a party may serve the adversary with a written request to corroborate the authenticity of any relevant document. Direct evidence of authenticity may be gotten through the testimony of persons who signed the original documents. This is often impossible, however, and in this case circumstantial evidence is permitted. In some civil-law countries, documents are proved genuine by special proceedings. In other continental European countries, a document may be proved genuine by any type of evidence.

The obligation to present documents in the Anglo-American system derives from the best evidence rule. If the original document is in the hands of a third person or the opponent, the party that must supply proof can ask the court for a writ of *sub poena duces tecum* compelling the third party to produce the document in court. If the original is not produced after this, second-hand evidence of its existence is then permitted. In continental law, there is no similar obligation to produce documents. The adversary or third persons can only be ordered to do so if there is a positive obligation under the substantive law. Among European countries, only Sweden has developed any extensive obligation for the parties to produce documents.

Extrinsic proof of the contents of documents in Anglo-American law is admitted only in special cases, since oral evidence is inadmissible to vary, contradict, or add to the terms of a written agreement—a rule that makes many documents conclusive as evidence. The method of Anglo-

Qualifications of an expert witness

Proof of documentary evidence

American law in this particular area is consequently negative, since evidence outside the content of the document is in principle not admissible. Continental law follows the medieval method, by attributing a certain value as evidence to particular documents, which is binding on the judge.

The consideration of documentary evidence by the judge therefore tends to be restricted, since the document itself furnishes conclusive proof if evidence by reference to facts outside the document is inadmissible. In most continental laws, judges are bound by presumptions in this respect, and only in Swedish law are there no provisions restricting free judicial consideration of documentary evidence.

Real evidence. The remaining form of evidence is so-called real evidence, also known as demonstrative or objective evidence. This is naturally the most direct evidence, since the objects in question are inspected by the judge or jury themselves. Problems arise in this area over who is obliged to present objects for inspection or to actually undergo inspection. The use of the jury system in Anglo-American law has made it necessary that any real evidence be shown to be both logically relevant and completely genuine before it may be admitted as proof. The exhibit of real evidence may sometimes be directly connected with the case (for example, when a weapon is shown to the court), or it may involve something used to illustrate testimony, as, for example, a model or skeleton to clarify testimony about an injury. In any case, real evidence may not be accepted as legal proof unless it is authenticated by the testimony of witnesses. (H.N.)

Conflict of laws

Both civil and criminal procedure may have a variety of international aspects: the plaintiff and defendant may be foreign citizens or may reside outside the country of the court (called the forum state); evidence may have to be taken in a foreign country; or, finally, a decision rendered in one country may have to be enforced in another. Growing international activities, primarily for business purposes but also of a private nature, have decisively increased the practical relevance of these international aspects of procedural law.

Legal problems arising from the international aspects of civil and criminal proceedings are a result of the multiplicity of different sets of courts and different systems of law in the world. Each nation maintains its own set of courts in complete independence of every other nation, and each nation has its own set of laws, written or unwritten. The rules and provisions that deal with the international aspects of various national legal systems are called the law of conflict of laws.

DIVERSITY OF LAWS

Diversity of national and provincial laws

Diversity within countries. While in such countries as France, Sweden, Peru, or Japan one single system of law obtains for the whole country, diversity exists in many others, especially nations organized upon a federal pattern, such as the United States, Australia, Canada, and, to a minor degree, West Germany, Switzerland, and Mexico. The law of Illinois is not the same as that of New York, Louisiana, or Indiana; that of Quebec differs from that of Ontario or Newfoundland; that of Chihuahua is not quite the same as that of Michoacán. In West Germany and Switzerland the systems of private law are by and large uniform, but minor differences still exist among the *Länder* of Germany and among the Swiss cantons.

Even in countries whose political structure is of the unitary rather than the federal pattern, differences can be found. In the United Kingdom, for example, considerable differences exist between the laws of England, Scotland, the Isle of Man, the Channel Islands, and Northern Ireland.

Diversity of laws develops where a country is divided, such as Germany or Korea. Where a new country is formed, or where territory is annexed, legal unity may not be brought about at the same time. After the reannexation of Alsace-Lorraine by France in 1920, for example, German private law remained in effect there for many years; and when after World War I Poland was formed

out of parts of old Russia, Germany, and Austria, legal uniformity was not brought about until after the end of World War II.

Diversities of law within one country may also exist on an ethnic or religious basis. Such a situation has commonly existed in most countries of the Middle East; the laws concerning matters of the family, including succession upon death, remain different in India for Hindus, Muslims, Parsees, Buddhists, and other sects, and in Lebanon or Israel for Muslims, Jews, and the various groups of Christians. In the United States and Canada, American Indians are in several respects subject to their own tribal laws.

Diversity between countries. Because of the spread of Western civilization over the entire planet, the laws of modern nations present a considerable measure of similarity, at least with respect to business transactions between individuals and private enterprises. Owing to the endurance of social traditions or religious convictions that are still quite different in many parts of the world, there is much less harmony between the rules on personal status, family matters, and succession. The same is true for the rules of criminal law. In addition, economic regulations differ considerably, as is indicated by the contrasts between free-market economies and planned economies.

Rules on the conflict of laws. Wherever there is diversity of laws, be it within or between countries, rules are required that must deal with, and seek to mitigate, the consequences of that diversity. Although terminology is not uniform, in most countries these rules are generally called conflict of laws. However, within this broad field, which may cover all branches of the law, it is important to distinguish between two principal branches of the conflict of laws: private international law (dealing with civil procedure) and international criminal law.

PRIVATE INTERNATIONAL LAW

The name private international law, which is generally used in countries of European-continental tradition, and occasionally also in the United Kingdom, seems to indicate that it is a part of international law—that is, that system of law that is superior to all sovereign states and that, at least in theory, is uniform throughout the world. This view was commonly held for many centuries, and when the name private international law was coined in the 19th century it was meant to signify that the supranational body of international law consisted of two parts, public and private international law. While the former would determine the proper conduct of sovereign nations toward each other in both peace and war, the latter would, in a uniform way, tell all nations in what cases their courts ought or ought not to take jurisdiction, under what conditions foreign judgments were to be enforced or otherwise recognized, and in what cases the laws of one nation were to be applied rather than those of another.

Since the latter part of the 19th century, however, such a view has been considered an ideal rather than a true description of reality. Today, it is generally recognized that each nation determines not only what is to be its substantive law (its law of property, contracts, torts, family relations, succession, corporations, etc.) but also in what cases its courts are to have jurisdiction, under what conditions foreign judgments are to be recognized, and which country's law is to be applied in any particular case.

As on other matters, nations may, of course, conclude treaties, bilateral or multilateral, in which they assume in relations with each other the duty to deal with certain problems in an agreed way. Treaties of such a kind have been concluded between numerous states, especially among countries of Latin America and of continental Europe. The creation of various regional associations in western and eastern Europe, in the Middle East, and in Latin America has led to the conclusion of new multilateral conventions between the member states of these unions. The United States has concluded many bilateral treaties granting substantive or procedural rights to the citizens of each contracting state within the territory of the other. The countries of the Commonwealth are parties to numerous treaties with one another and with other nations, concerning foreign judgments and mutual rights

Public and private international law

of owning, disposing, and taking of property. In those numerous areas not covered by treaties, the rules of the conflict of laws of each nation are relevant. These rules differ from country to country since each state is sovereign in fixing and amending them. Even in France, West Germany, or Latin America, where the bulk of private law is contained in codes and other statutes, the statutory provisions on private international law are fragmentary, and for large parts of the field the law must be sought in the decisions of the courts. In all countries the writings of scholars have been of considerable influence.

The three principal issues

Among the rules of private international law, three important issues of international civil procedure arise in practice: (1) the problem of jurisdiction—that is, under which circumstances a case may be brought before the courts of a particular country or province; (2) international elements in the various stages of a judicial proceeding; and (3) the recognition and enforcement of foreign judicial decisions—that is, what weight, if any, is to be given in one country or province to the judgments and decisions of the courts of other countries or provinces.

Jurisdiction. If a person wishes to bring a civil lawsuit against another, he might conceivably bring the action in any country of the world. If, however, a citizen and resident of the United States, for example, were to sue a citizen and resident of Canada in Panama, a judgment obtained in Panama would be of no use to him unless the Canadian owned property in Panama that, if he did not pay, the U.S. citizen might attach there, or if the Panamanian judgment could be enforced in such other country or countries in which he happened to hold property. For this practical reason the problem of where to bring suit is thus tied up with that of the enforceability of foreign judgments. Even if a judgment might be of practical value to the plaintiff, however, he might find that the courts of the country in which he wished to bring his action would not receive it. As a matter of fact, all countries have limited their jurisdiction—that is, the scope of actions that they allow their courts to handle. Countries do not wish their courts to deal with lawsuits with which they have no proper contact, which might clog the calendars of their courts, or against which it would be unfair to compel a person to enter a defense on pain of having judgment by default rendered against him. Each country determines for itself when its courts should decide a civil lawsuit.

The limits of jurisdiction in civil suits

In composite countries, such as the United States, the United Kingdom, Canada, and Switzerland, rules also are necessary to determine in which of the several constituent states, provinces, or other parts a civil lawsuit may be brought. In some countries (for instance, West Germany) this determination is made by the national law. It may be left, however, to each of the constituent states or provinces to determine for itself the scope of litigation that it will allow its courts to decide. Such, at least on general principle, is the situation in the United States, where the state's freedom of determination is limited, however, by the "due process" clause of the Fourteenth Amendment to the federal Constitution, which in effect prohibits the state from exercising civil jurisdiction where it would be grossly unfair to do so. In the countries of the Commonwealth, the jurisdiction of the courts is also determined for each constituent part by its own law, but the principles of such determination do not differ widely from one another.

As a general principle, most countries or states agree that a case may be tried in their courts if both parties have consented to their jurisdiction. The plaintiff's consent simply appears from his commencing his action in the country or state in question; the consent of the defendant is presumed when, rather than objecting to the jurisdiction, he confesses judgment or begins to litigate on the merits of the controversy. Some countries, nevertheless, close their courts to a litigant whose case has no more substantial connection with them than the parties' consent. French courts, for instance, will not try a lawsuit between foreigners unless it arises out of a controversy that has some real connection with France, such as the breach of a contract to be performed in France, or a tort committed in France, or title to land situated in France. As another example, the courts of New York regard themselves as an "inconve-

nient forum" for suits between nonresidents concerning a tort committed outside New York. With few exceptions, Anglo-U.S. courts will not try controversies concerning title to, or trespass upon, land situated outside the state.

Generally, however, the problem of jurisdiction does not become acute unless the defendant objects to having the case tried in the country or province of the plaintiff's choosing, or unless he fails to appear. Different approaches to this problem of jurisdiction are followed in the continental European countries of the civil-law tradition and in those of the common-law, or Anglo-American, tradition. The former start from the idea that the proper place for a person to be sued is his domicile or residence. Apart from this principal venue, however, several others are available. For example, contentions over title to land must be sought where the land is situated. A suit arising out of an alleged tort may be brought in the place where the tort is alleged to have been committed, and a suit based upon breach of contract may be brought in the place in which it is alleged that the alleged contract was to be performed.

Some countries—for instance, West Germany—allow an absent defendant to be sued in their courts if he owns any property within the country. France keeps its courts open for suits of any kind brought by a French national against a foreigner. A large number of countries, including those adhering to the common-law tradition, allow a civil suit to be commenced by the attachment of property owned within the territory, the enforcement of a default judgment obtained being limited, however, to the assets thus attached.

In their general approach to the problem of jurisdiction, the common-law countries still proceed from the long-obsolete notion that a civil suit could be commenced only by the defendant's arrest by the sheriff. Consequently, an action can still be brought in any place in which the defendant is personally served with process, even though he may be there only for a few minutes to change airplanes. In modern times it has come to be widely held, however, that personal service upon the defendant is no longer an indispensable requirement of jurisdiction and that an individual may be sued in the country or state of his residence, even if the summons is not personally pressed upon him. A corporation can always be sued in the country or state in which it has been incorporated.

It is required, however, that an honest effort be made to give the defendant actual notice that a lawsuit is about to be brought against him. The mere publication of the summons in a newspaper or at the bulletin board of the court is not sufficient unless the address or identity of the defendant cannot be ascertained upon a reasonable effort.

States of the United States are now coming to allow their courts to exercise jurisdiction in cases having almost any kind of contact with the state. Generally, a corporation may be sued in any state in which it is simply "doing business," even though the case in question is totally unconnected with the state.

In both civil-law and common-law countries special rules apply for suits in which the plaintiff aims at a "judgment in rem." Rather than ordering a defendant to pay a certain sum of money or ordering him to do, or not to do, a certain act (such as deliver a deed to a piece of land or refrain from using a trademark), a judgment in rem produces by its own effect a change of the legal situation (for instance, the foreclosure of a mortgage, the removal of a cloud on a title to land, the dissolution of a marriage, the creation of an adoptive parent-child relationship). Lawsuits aiming at the court's changing the title to a piece of land can universally be brought nowhere but in the country or province in which the land is situated. Actions arising out of transactions connected with shipping can generally be brought in the port in which the ship in question happens to find itself. In the United States a suit for divorce can be brought in the state of the plaintiff's domicile or residence, for the establishment of which periods varying between a few weeks and several months in length are prescribed. In the British countries the traditional rule of exclusive jurisdiction of the domicile of the husband is weakening. Civil-law countries generally keep their divorce courts open to their nationals even if they reside abroad.

Special rules for judgments in rem

Proceedings. Even if a civil action can be properly brought before a court having jurisdiction, international aspects may have an impact on the course of the proceedings.

Deviations from a purely domestic proceeding may arise especially if one of the parties resides outside of the forum state. In order to commence an action, the plaintiff's complaint must be served upon the defendant. The question then arises how such service can be effected if the action is to be brought, for example, before an English court when the defendant resides in France. In this case, formal service of judicial documents is entrusted to state officers or bailiffs and is therefore regarded as an act of national sovereignty. Since no court or state authority may act outside the area or state of the court, service in another state requires assistance by public authorities in that state. The authorities, especially the judicial authorities of the state in which the defendant resides, must be requested to assist. Such international judicial assistance is usually rendered on condition of reciprocity; *i.e.*, only if the requesting state is prepared to honour a request for similar assistance. More certainty exists if both the requesting and the requested state are parties to a multilateral treaty on service of judicial documents.

A related issue will arise if the plaintiff cannot raise the funds for bringing his action or pursuing the proceedings. If he is a citizen of the forum state, he may be entitled to proceed *in forma pauperis* ("in the manner of a pauper"—*i.e.*, exempt from the usual costs of proceedings) or to obtain legal aid. However, the forum state is often not willing to bestow this benefit upon foreigners or persons residing abroad. Multilateral conventions seek to remove these difficulties by facilitating "international access to justice."

Another major difficulty to be overcome is in taking evidence outside the forum state when, for example, a witness living in Australia has to be heard in a divorce suit pending before a West German court. The problem and the solutions that have evolved are quite similar to those described above for the formal service of judicial documents outside the forum state.

Foreign judgments. If a creditor has obtained against his debtor a judgment for \$1,000 in Mexico or in Michigan, and his debtor does not have sufficient property in that country or state, can he enforce it in Illinois, where the debtor owns land, keeps a bank account, or owns other assets? If someone has brought and lost a lawsuit in New York, can he start it all over again in California or in Peru? If the marriage of Mr. and Mrs. Smith has been terminated by a decree of divorce of a court in Nevada, or by an act of the parliament of Canada, or by the order of a district governor in Norway, and Mr. Smith wishes to remarry in Wyoming or in South Africa, will he be given a license? If he remarries will his new marriage be valid or does he have to go to jail as a bigamist? If a citizen of the United States residing in Wisconsin adopts a child of German parents residing in Germany and the adoption has been confirmed by a court of Wisconsin, will the child inherit on the adopter's death a piece of land situated in Indiana or an account in a bank in Germany or in Switzerland?

Unless countries have bound each other by treaty mutually to enforce their civil judgments, each country is free as to whether or not, and, if at all, under what conditions, it wishes to enforce or otherwise recognize foreign judgments of the types indicated by the questions above. The attitudes of the several countries vary considerably in this respect, and the enforcement of foreign money judgments is not the same as the recognition of a judgment as a bar to the starting of a new suit all over again (*res judicata* effect), or the recognition of the termination of a marriage by a decree of divorce or of other changes of private legal relationships brought about by judicial act.

If, for example, an Illinois judgment for money is not promptly paid by the debtor, it can be enforced in Illinois by the attachment and sale of his property, the proceeds being turned over to the creditor. Such enforcement is generally the task of a public officer, such as a sheriff, who is empowered, where necessary, to break resistance with physical force. Although a sheriff knows well enough

the looks of a judgment of his own country or province, he cannot be expected, or even allowed, to go into action simply upon the basis of a paper purporting to be the judgment of a foreign country with whose judicial system, language, or even script he cannot be expected to be familiar. For the protection of the citizen as well as of himself, it is indispensable that, before the sheriff or other enforcement officer goes into action, the foreign judgment be transformed into a domestic one. Some countries, such as The Netherlands or Sweden, simply limit enforcement to domestic judgments. Even if the creditor has obtained a judgment abroad, he must start regular proceedings all over again, and the only advantage that the foreign judgment provides for him lies in the fact that the Dutch or Swedish court will be inclined to regard it as good, although in no way conclusive, evidence that his claim is well founded. In most other countries, however, a domestic judgment will be supplied by a domestic court without a reopening of the dispute about the merits of the creditor's claim. All that the domestic court will inquire into is the regularity of the proceedings in which the foreign judgment was obtained. For this transformation of a foreign into a domestic judgment, the majority of the civil-law countries provide a kind of special proceeding (*exequatur*) that is supposed to be, but is not always, simpler and less expensive than an ordinary civil lawsuit. In the common-law countries it is necessary to bring upon the foreign judgment an action that in outward form is a regular civil lawsuit but that is, at least in the normal case, simple and speedy. In the United Kingdom and the Commonwealth a simplified mode of domestication is furnished by agreements and statutes providing, in certain cases, for the simple registration in one law unit of judgments rendered in another. In the United States a similar method exists in the relations between those states that have adopted the Uniform Enforcement of Foreign Judgments Act. In the European Communities and in Scandinavia, multilateral treaties oblige signatory states to recognize and enforce judgments from other member states and provide for a simplified procedure for the domestication of the foreign judgment.

When a foreign judgment is not sought to be enforced by attachment of the debtor's property or similar measures, but when its *res judicata* effect is raised as a defense in a domestic lawsuit, or when the question is that of recognition of its law-changing effects, such as the termination of a marriage by a decree of divorce, it would seem to be unnecessary to require the formal transformation of the foreign into a domestic judgment by any special proceedings. Some countries (for instance, Italy and, to a more limited extent, France) nevertheless require such formal domestication for judgments purporting to affect the personal status of their nationals.

In the United States the Constitution provides that "full faith and credit shall be given in each state to the public acts, records and judicial proceedings of every other state." Under this clause the states, and by statute the territories, are obliged mutually to enforce their money judgments and to recognize the *res judicata* and law-changing effects of their judicial acts, provided the state by which the judgment was rendered was acting within the scope of its jurisdiction as defined by the Supreme Court of the United States. The only other defenses that might be raised are grave irregularity of the proceedings in which the judgment was obtained and, in certain cases, lack of finality.

In countries that follow the general principles of the common law, a foreign judgment usually is willingly enforced and otherwise recognized unless (1) the country by which it was rendered lacked jurisdiction according to the notions prevailing in the place where recognition is sought, or (2) the proceedings in which the judgment was obtained were tainted with fraud or were otherwise grossly unfair, or (3) the recognition or enforcement of the foreign judgment would seriously interfere with an important public policy of the country or state where recognition or enforcement is sought. In addition to these requirements, most civil-law countries (except, of course, those few in which foreign judgments as such are not enforced at all)

Judicial
assistance

The
recognition
and
enforce-
ment of
foreign
judgments

Prerequi-
sites for
recognition
of foreign
judgments

also demand reciprocity with the country seeking to have its judgment recognized.

Nowhere will a foreign judgment be enforced or recognized unless the country by which it was rendered had jurisdiction to do so under the notions obtaining where recognition is sought. These limits are sometimes wider, however, than those that a country will concede to others for the exercise of their jurisdictions. Whereas France, for instance, holds its courts open for all suits of a Frenchman against a foreigner, a U.S. or English court will not recognize a default judgment obtained in such an action unless the defendant was served with process in France or was a resident of France or had some other contact with that country that justifies his being sued in France.

In matters affecting personal status, especially divorce, civil-law countries generally recognize judgments rendered by the courts of the country of which the parties are nationals. Under the common law of England a decree of divorce will not be recognized unless it was rendered by the state of the domicile of the husband. After World War II, however, there were enacted in some parts of the Commonwealth statutes under which a wife living separately from her husband may also sue for divorce in the country or province of her residence, and a decree thus obtained is likely to be recognized in the other parts of the Commonwealth. Since 1971, the United Kingdom even recognizes a foreign divorce decree rendered in the country of which one of the spouses is a national.

In the United States the Supreme Court has determined that a divorce granted in one state must be recognized in all others if the state by which it was granted was the state of the true residence of the plaintiff or if the defendant actually participated in the proceedings without contesting the plaintiff's allegation of residence.

INTERNATIONAL CRIMINAL LAW

This young and less-developed branch of the conflict of laws has seen a tremendous growth in modern times. The growing importance of international criminal law is due, first, to the increased international mobility of people, giving rise to more criminal acts with a foreign element, such as traffic violations involving foreigners as offenders or victims. In addition, shrewd criminals and organized crime have discovered the increasing gap between the territorial limitations of police, prosecution, and court powers on the one hand and the easy and quick trans-border communication and movement of persons and assets on the other. The more important general issues of modern international criminal law are comparable to those of the conflict of laws of civil procedure and are therefore of three types: (1) jurisdiction—*i.e.*, the question of which authorities of which country may prosecute a criminal and bring him into court; (2) the international aspects of a criminal court proceeding; and (3) the recognition and enforcement of foreign judgments in criminal matters—*i.e.*, the value attached in state B to a judicial decision rendered in state A. Because of the marked differences between criminal and civil procedure, the problems and solutions of international criminal law differ from those of private international law in many important respects.

Jurisdiction. May a public prosecutor start a prosecution or may a criminal court open a judicial proceeding dealing with an offense that involves foreign elements? For instance, may a Swiss investigative or judicial authority open proceedings against a Frenchman? Does it make a difference whether this alleged offender resides in Switzerland, in France, or in Italy? Is it relevant whether the alleged act took place in Switzerland or outside Switzerland? Should one distinguish between a traffic accident, a theft, and a murder?

The basic principle for determining jurisdiction in criminal matters is that the authorities and courts of the state or province in which the offense was committed are competent to investigate and adjudicate it. This so-called principle of territoriality can be justified by both general and specific considerations. It is an important aspect of sovereignty that the authorities of a territory are responsible for preserving law and order in their area by protecting the integrity of the inhabitants and of their property

against attacks and by punishing offenders. In addition, it is most practicable to investigate and adjudicate offenses where they have occurred because local circumstances can easily be taken into account, and witnesses and other means of evidence usually are located at or near the place of commission. Territoriality is generally recognized as the defining principle of jurisdiction in international criminal law. Some countries, especially in the English-speaking world, even regard it as the exclusive basis of jurisdiction. Other countries extend the basic rule by a few narrow and specific additions for particular offenses, such as drug offenses, terroristic acts, or war crimes.

Two conventions in force for some members of the Council of Europe empower a contracting state A, on whose territory a person residing in contracting state B has committed an offense, to request the authorities of B to prosecute and adjudicate that offense under its criminal law. Paradoxically, these conventions were concluded in the interest of offenders, because they allow the authorities in the country of the offense to release the offender and request the country of residence to take over the prosecution and trial. Without the conventions, the police in the country of the offense would be compelled either to ask for securities or, in aggravated cases, to arrest the offender, at least until the trial was over and possibly even until he had served the sentence imposed for the offense.

Jurisdiction in criminal matters also has a personal aspect. Criminal trials, as distinct from trials of civil actions, will usually be continued only if the defendant appears before the court. His presence is almost indispensable for a fair trial. Since, for instance, a U.S. court or police officer cannot arrest a suspect outside the United States, the assistance of other countries for seeking, arresting, and delivering an alleged offender is required. For this purpose, bilateral and multilateral treaties provide, under certain conditions, for the extradition of suspects to the requesting country, which is usually the place where the offense was committed. One important restriction of the duty to extradite on which many countries insist protects nationals of the country requested; thus, the West German constitution prohibits the extradition of Germans to foreign countries. The purpose of this prohibition is not to make Germans immune from criminal trials for offenses committed abroad but to ensure them a trial before a German court. In order to achieve this, jurisdiction of German courts is extended beyond the basic principle of territoriality to include all offenses committed by Germans, even those committed abroad.

Proceedings. In a criminal proceeding, there are fewer complications caused by foreign elements than there are in civil proceedings, usually because the defendant is present at the trial. Nevertheless, he may require legal aid if he is too poor to pay for his defense. Or a foreign defendant or foreign witness may need an interpreter. These problems of access to the court are usually settled under the forum country's domestic rules of criminal procedure.

International cooperation is especially necessary where evidence has to be taken in a country outside the forum state. The most reliable way to obtain the necessary judicial assistance of foreign states is through treaties concluded between states. A convention of the Council of Europe, for example, makes judicial assistance in criminal matters obligatory for 18 member countries. Its opening provision binds the contracting states to afford one another, within the terms of the convention, "the widest measure of mutual assistance in proceedings in respect to offenses."

Foreign judgments. Generally speaking, the issues arising out of the international effects of a criminal judgment are comparable to those involved in determining the weight to be attached to a foreign judgment in civil matters. If a person has been convicted and sentenced in Turkey but before the end of the trial has fled the country, can he be brought back to Turkey to serve his sentence there? If he cannot be brought back to Turkey, will Italy, his present country of abode, be willing to enforce the payment of a penalty or even a prison sentence? Will the answer be different if the offender is an Italian residing in Italy? Less drastic, but certainly no less relevant, for the defendant is the question whether after an acquittal in

The principle of territoriality

Three principal issues

Enforcing
a sentence
imposed by
a foreign
court

France he may be prosecuted and convicted in Denmark for an offense based upon the same facts.

The stronger the intended effects of a foreign judgment, the less are states willing to give effect to it. The strongest effect of a criminal judgment is the enforcement of a sentence imposed by the court, and, contrary to the treatment of foreign judgments in civil matters, states are generally quite unwilling to enforce foreign prison sentences or even penalties. This situation can only be remedied by the conclusion of bilateral or multilateral treaties, of which many exist. The most common type provides for extradition of the convict to the country in which he has been convicted. Nineteen member countries of the Council of Europe, for example, are bound by a multilateral convention on mutual extradition. A more recent type of convention allows a contracting state A, where a resident of contracting state B has been convicted, to request the latter state to take over the person and make him serve in B the prison sentence imposed in A. Such a request usually serves the interests of the offender, especially if the penitentiary system of state A is not as well developed as that of state B. Such a transfer also helps to preserve the social and familial contacts of the offender and to facilitate his social rehabilitation. Usually state B will agree to enforcement of a foreign criminal sentence only if the offense is one that is punishable under the law of B also.

Lesser effects than enforcement of sentences are usually more acceptable to foreign states. The fact that a suspect has been acquitted or has been convicted and has served his sentence in one country is, in many other countries, recognized as a bar to a new prosecution or conviction for the same offense. In this way the double jeopardy rules of many national laws, barring a second proceeding on the same facts, is extended to the international level.

An earlier conviction for an offense in state A may have an adverse effect for a defendant who is later convicted for an offense of the same type in state B. This is true if, under the law of B, penalties may or must be increased for repeated offenses of the same type. In this case, too, a domestic rule (that penalizing recidivism) is extended to the international level, this time to the disadvantage of the defendant.

BIBLIOGRAPHY

Historical growth of procedural law: See LEOPOLD WENGER, *Institutes of the Roman Law of Civil Procedure*, rev. ed. (1940, reprinted 1986), the classic on the topic; JOHN P. DAWSON, *A History of Lay Judges* (1960), in disagreement with some of Wenger's conclusions, although not limited to Roman law, and *The Oracles of the Law* (1968, reprinted 1986), a complementary work on the history of professional judges; ARTHUR ENGELMANN *et al.*, *A History of Continental Civil Procedure* (1927, reprinted 1968; originally published in German, 1901), the classic text in English; ROBERT W. MILLAR, *Civil Procedure of the Trial Court in Historical Perspective* (1952), which discusses the history of Anglo-American trial procedure; and THEODORE F.T. PLUCKNETT, *A Concise History of the Common Law*, 5th ed. (1956), a general treatment of English legal history.

Civil procedure: M. CAPPELLETTI (ed.), *Access to Justice*, 40 vol. in 6 (1978-79), is a cooperative work by several contributors discussing problems and possibilities involved in attempts to secure access to justice for all; M. CAPPELLETTI (ed.), *Civil Procedure*, vol. 16 of *International Encyclopedia of Comparative Law* (1973-), issued in fascicles, is a scholarly discussion of all aspects of civil procedure by contributors from many countries; and CHARLES E. CLARK, *Procedure: The Handmaid of Justice* (1965), is a collection of significant essays.

Elements of civil procedure: American civil procedure is treated in KEVIN M. CLERMONT, *Civil Procedure* (1982); JACK FRIEDENTHAL, MARY KAY KANE, and ARTHUR R. MILLER, *Civil Procedure* (1985), a substantially more detailed discussion, mainly intended for students; FLEMING JAMES, JR., and GEOFFREY C. HAZARD, JR., *Civil Procedure*, 3rd ed. (1985), a discussion in some depth; JOSEPH H. KOFFLER and ALISON REPPY, *Handbook of Common Law Pleading* (1969), a discussion of earlier procedure; and HARVARD LAW REVIEW, *Essays on Civil Procedure* (1961, reissued 1967), a collection of valuable essays in the field.

Civil procedure in other countries is treated in M. CAPPELLETTI and JOSEPH M. PERILLO, *Civil Procedure in Italy* (1965), one of the best available treatments in English; RUTH BADER

GINSBURG and ANDERS BRUZELIUS, *Civil Procedure in Sweden* (1965), an indispensable work; TAKAOKI HATTORI and DAN FENNO HENDERSON, *Civil Procedure in Japan* (1983), a valuable discussion of modern procedure, published in loose-leaf format; and WILLIAM B. ODGERS, *Odgers' Principles of Pleading and Practice in Civil Actions in the High Court of Justice*, 22nd ed. by D.B. CASSON and I.H. DENNIS (1981), a standard work on England's civil procedure.

Treatments of special topics in civil procedure include EDWIN M. BORCHARD, *Declaratory Judgments*, 2nd ed. rev. (1941), the classic work; M. CAPPELLETTI, *Procédure orale et procédure écrite: Oral and Written Procedure in Civil Litigation* (1971), a comparative study based on reports from several countries, with a summary in English; and ROBERT C. CASAD, *Res Judicata in a Nutshell* (1976), an introduction to problems of effect of judgments.

Propaganda

Propaganda is the more or less systematic effort to manipulate other people's beliefs, attitudes, or actions by means of symbols (words, gestures, banners, monuments, music, clothing, insignia, hairstyles, designs on coins and postage stamps, and so forth). Deliberateness and a relatively heavy emphasis on manipulation distinguish propaganda from casual conversation or the free and easy exchange of ideas. The propagandist has a specified goal or set of goals. To achieve these he deliberately selects facts, arguments, and displays of symbols and presents them in ways he thinks will have the most effect. To maximize effect, he may omit pertinent facts or distort them, and he may try to divert the attention of the reactors (the people whom he is trying to sway) from everything but his own propaganda.

Comparatively deliberate selectivity and manipulation also distinguish propaganda from education. The educator tries to present various sides of an issue—the grounds for

doubting as well as the grounds for believing the statements he makes, and the disadvantages as well as the advantages of every conceivable course of action. Education aims to induce the reactor to collect and evaluate evidence for himself and assists him in learning the techniques for doing so. It must be noted, however, that a given propagandist may look upon himself as an educator, may believe that he is uttering the purest truth, that he is emphasizing or distorting certain aspects of the truth only to make a valid message more persuasive, and that the courses of action that he recommends are in fact the best actions that the reactor could take. By the same token, the reactor who regards the propagandist's message as self-evident truth may think of it as educational; this often seems to be the case with "true believers"—dogmatic reactors to dogmatic religious or social propaganda. "Education" for one person may be "propaganda" for another.

PROPAGANDA AND RELATED CONCEPTS

Connotations of the term propaganda. The word propaganda itself, as used in recent centuries, apparently derives from the title and work of the Congregatio de Propaganda Fide (Congregation for Propagation of the Faith), an organization of Roman Catholic cardinals founded in 1622 to carry on missionary work. To many Roman Catholics the word may therefore have, at least in missionary or ecclesiastical terms, a highly respectable connotation. But even to these persons, and certainly to many others, the term is often a dirty one tending to connote such things as the discredited atrocity stories and deceptively stated war aims of World Wars I and II, the operations of the Nazis' Ministry of Public Enlightenment and Propaganda, and the broken campaign promises of a thousand politicians. Also, it is reminiscent of countless instances of false and misleading advertising (especially in countries using Latin languages, in which *propagande commerciale* or some equivalent is a common term for commercial advertising).

To informed students of Communism, the term propaganda has yet another connotation, associated with the term agitation. The two terms were first used by the Marxist Georgy Plekhanov and later elaborated upon by Lenin in a pamphlet *What Is to Be Done?* (1902), in which he defined "propaganda" as the reasoned use of historical and scientific arguments to indoctrinate the educated and enlightened (the attentive and informed publics, in the language of today's social sciences); he defined "agitation" as the use of slogans, parables, and half-truths to exploit the grievances of the uneducated and the unreasonable. Since he regarded both strategies as absolutely essential to political victory, he twinned them in the term agitprop. Today every unit of a Communist party must have an agitprop section, and to the Communist, the use of propaganda in Lenin's sense is commendable and honest. Thus, a standard Soviet manual for teachers of social sciences is en-

titled *Propagandistu politekonomii* (*For the Propagandist of Political Economy*), and a pocket-sized booklet issued weekly to suggest timely slogans and brief arguments to be used in speeches and conversations among the masses is called *Bloknat agitatora* (*The Agitator's Notebook*).

Related terms. Related to the general sense of propaganda is the concept of "propaganda of the deed." This denotes taking nonsymbolic action (such as economic or coercive action), not for its direct effects but for its possible propagandistic effects. Examples of propaganda of the deed would include staging an atomic "test" or the public torture of a criminal for its presumable deterrent effect on others, or giving foreign "economic aid" primarily to influence the recipient's opinions or actions and without much intention of building up the recipient's economy.

Distinctions are sometimes made between overt propaganda, in which the propagandist and perhaps his backers are made known to the reactor, and covert propaganda, in which the source is secret or disguised. Covert propaganda might include such things as unsigned political advertisements, clandestine radio stations using false names, and statements by editors, politicians, or others who have been secretly bribed by governments, political backers, or business firms. Sophisticated diplomatic negotiation, legal argument, collective bargaining, commercial advertising, and political campaigns are of course quite likely to include considerable amounts of both overt and covert propaganda, accompanied by propaganda of the deed.

Another term related to propaganda is psychological warfare (sometimes abbreviated to "psychwar"), which is the prewar or wartime use of propaganda directed primarily at confusing or demoralizing enemy populations or troops, putting them off guard in the face of coming attacks, or inducing them to surrender.

Still another related concept is that of brainwashing. This term usually means intensive political indoctrination. It

Brainwashing

Agitprop:
agitation
and propa-
ganda

may involve long political lectures or discussions, long compulsory reading assignments, and so forth, sometimes in conjunction with efforts to reduce the reactor's resistance by exhausting him either physically through torture, overwork, or denial of sleep or psychologically through solitary confinement, threats, emotionally disturbing confrontations with interrogators or defected comrades, humiliation in front of fellow citizens, and the like. The term brainwashing has been widely used in sensational journalism to refer to such activities (and to many other activities) when they have allegedly been conducted by Maoists in China and elsewhere.

Another related word, advertising, has mainly commercial connotations, though it need not be restricted to this; political candidates, party programs, and positions on political issues may be "packaged" and "marketed" by advertising firms. The words promotion and public relations have wider, vaguer connotations and are often used to avoid the implications of "advertising" or "propaganda." "Publicity" and "publicism" often imply merely making a subject known to a public, without educational, propagandistic, or commercial intent.

Signs, symbols, and media used in contemporary propaganda. The 20th-century propagandist with money and imagination can use a very wide range of signs, symbols, and media to convey his message. Signs are simply stimuli—"information bits" capable of stimulating, in some way, the human organism. These include sounds, such as words, music, or a 21-gun salvo; gestures (a military salute, a thumbed nose); postures (a weary slump, folded arms, a sit-down, an aristocratic bearing); structures (a monument, a building); items of clothing (a uniform, a civilian suit); visual signs (a poster, a flag, a picket sign, a badge, a printed page, a commemorative postage stamp, a swastika scrawled on a wall); and so on and on.

The cover of *Time*, August 31, 1962, exemplifies propaganda against the construction of the Berlin wall by East Germany.

A symbol is a sign having a particular meaning for a given reactor. Two or more reactors may of course attach quite different meanings to the same symbol. Thus, to Nazis the swastika was a symbol of racial superiority and the crushing military might of the German folk; to some Asiatic and North American peoples it is a symbol of universal peace and happiness. Some Christians who find a cross reassuring may find a hammer and sickle displeasing and may derive no religious satisfaction at all from a Muslim crescent, a Hindu cow, or a Buddhist lotus.

The contemporary propagandist can employ elaborate social-scientific research facilities, unknown in previous epochs, to conduct opinion surveys and psychological interviews in efforts to learn the symbolic meanings of given signs for given reactors around the world and to discover what signs leave given reactors indifferent because, to them, these signs are without meaning.

Media are the means—the channels—used to convey signs and symbols to the intended reactor or reactors. A comprehensive inventory of media used in 20th-century propaganda could cover many pages. Written media include letters, handbills, posters, billboards, newspapers, magazines, books, and handwriting on walls and streets. Among audiovisual media, television may be the most powerful for many purposes. Television can convey a great many types of signs simultaneously; it can gain heavy impact from mutually reinforcing gestures, words, postures, and sounds and a background of symbolically significant leaders, celebrities, historic settings, architectures, flags, music, placards, maps, uniforms, insignia, cheering or jeering mobs or studio audiences, and staged assemblies of prestigious or powerful people. Other audiovisual media include public speakers, motion pictures, theatres, marching bands, mass demonstrations, picketing, face-to-face conversations between individuals, and "talking" exhibits at fairs, expositions, and art shows.

The larger the propaganda enterprise, the more important are such mass media as television and the press and also the organizational media—that is, pressure groups set up under leaders and technicians who are skilled in using many sorts of signs and media to convey messages to particular reactors. Vast systems of diverse organizations can be established in the hope of reaching leaders and followers of all groups (organized and unorganized) in a given area, such as a city, region, nation or coalition of nations, or the entire world. Pressure organizations are especially necessary, for example, in closely fought sales campaigns or political elections, especially in socially heterogeneous areas that have extremely divergent regional traditions, ethnic and linguistic backgrounds, and educational levels and very unequal income distributions. Diversities of these sorts make it necessary for products to be marketed in local terms and for political candidates to appear to be friends of each of perhaps a dozen or more mutually hostile ethnic groups, of the educated and the uneducated, and of the very wealthy as well as the poverty-stricken.

EVOLUTION OF THE THEORY OF PROPAGANDA

Early commentators and theories. The archaeological remains of ancient civilizations indicate that dazzling clothing and palaces, impressive statues and temples, magic tokens and insignia, and elaborate legal and religious arguments have been used for thousands of years, presumably to convince the common people of the purported greatness and supernatural prowess of kings and priests. Instructive legends and parables, easily memorized proverbs and lists of commandments (such as the *Analects* of Confucius, the Judaic Ten Commandments, the Hindu Laws of Manu, the Buddhists' Eightfold Noble Path), and highly selective chronicles of rulers' achievements have been used to enlist mass support for particular social and religious systems. Very probably, much of what was said in antiquity was sincere, in the sense that the underlying religious and social assumptions were so fully accepted that the warlords' spokesmen, the pharaohs' priests, and their audiences believed all or most of what was communicated and hence did not deliberate or theorize very much about alternative arguments or means of persuasion.

The systematic, detached, and deliberate analysis of

The nature of symbols

The nature of organizational media

The
Greco-
Roman
tradition of
rhetoric

propaganda, in the West, at least, may have begun in Athens about 500 bc, as the study of rhetoric (Greek: "the technique of orators"). The tricks of using sonorous and solemn language, carefully gauged humour, artful congeniality, appropriate mixtures of logical and illogical argument, and flattery of a jury or a mob were formulated from the actual practices of successful lawyers, demagogues, and politicians. Relatively ethical teachers such as Isocrates, Plato, and Aristotle compiled rules of rhetoric (1) to make their own arguments and those of their students more persuasive and (2) to design counter-propaganda against opponents and also (3) to teach their students how to detect the logical fallacies and emotional appeals of demagogues.

Early students of rhetoric also examined what today's analysts would call the problem of source credibility—what a speaker can say or do to convince his hearers that he is telling the truth, is well intentioned, is public-spirited, and so forth. For example, an Athenian lawyer defending an undersized man on trial for murder might instruct him to say to a jury: "Is it likely that an undersized man like me, so often ridiculed for being clumsy with a sword, would have attacked and killed this very tall war veteran who is famous everywhere for his swordsmanship?" But a tall and strong defendant might be told to invert the plea: "Would any man of my unusual height, who is rather well known to have slain 300 Persians in sword fights, have allowed himself to be drawn into a quarrel with this puny man—knowing full well that a jury of reasonable Athenians would be inclined from the start to hold me guilty if someone killed him?" So well did Greek rhetoricians analyze the arts of legal sophistry and political demagoguery that their efforts were imitated and further developed in Rome by such figures as Cicero and Quintilian. Aristotle's *Rhetoric* and similar works by others have, indeed, served as model texts for Western scholars and students until this day.

Hindu and
Chinese
traditions

There have been similar lines of thought in other major civilizations. In ancient India, the Buddha, and in ancient China, Confucius, both advocated, much as Plato had, the use of truthfulness, "good" rhetoric, and "proper" forms of speech and writing as means of persuading men, by both precept and example, to live the good life. Toward 400 bc in India, Kautilya, a Brahmin believed to have been chief minister to the emperor Candragupta Maurya, reputedly wrote the *Arthaśāstra* (*Principles of Politics*), a book of advice for rulers that has often been compared with Plato's *Republic* and Machiavelli's much later work *The Prince*. Kautilya discussed, in some detail, the use of psychological warfare, both overt and clandestine, in efforts to disrupt an enemy's army and capture his capital. Overtly, he said, the propagandists of a king should proclaim that he can do magic, that God and the wisest men are on his side, and that all who support his war aims will reap benefits. Covertly, his agents should infiltrate his enemies' and potential enemies' kingdoms, spreading defeatism and misleading news among their people, especially in capital cities, among leaders, and among the armed forces. In particular, a king should employ only Brahmins, unquestionably the holiest and wisest of men, as propagandists and diplomatic negotiators. These morally irreproachable experts should cultivate the goodwill of their king's friends, and of friends of his friends, and also should woo the enemies of his enemies. A king should not hesitate, however, to break any friendships or alliances that are later found to be disadvantageous.

Similar advice is found in *Ping-fa* (*The Art of War*) by the Chinese theorist Sun-tzu, who wrote at about the same time. "All warfare," he said, "is based on deception. Hence, when able to attack, we must seem unable; when using our forces, we must seem inactive; when we are near, we must make the enemy believe that we are far away; when far away, we must make him believe we are near. Hold out baits to entice the enemy. Feign disorder, and crush him."

The spread of all complex political systems and religions probably has been due very largely to a combination of earnest conviction and the deliberate use of propaganda. This mixture can be detected in the recasting in various

times and places of the legends of the Judaeo-Christian messiah, of heroes of the Hindu *Mahābhārata*, of the Buddha, of the ancestral Japanese Sun Goddess, of the lives of Muhammad and his relatives, of the Christian saints, of such Marxist heroes as Marx, Engels, Lenin, and Stalin, and even in the story of George Washington and the cherry tree.

Scattered and sometimes enlightening comment on political and religious propaganda has occurred in all major civilizations. In ancient Greece and Rome there was much writing on election tactics. In 16th-century Italy, Machiavelli discussed, very much like Kautilya and Sun-tzu, the uses of calculated piety and duplicity in peace and war. In Shakespeare's plays, Mark Antony and the Duke of Buckingham display the principles of propaganda and discuss them in words and concepts that anticipate the present-day behavioral scientist (see *Julius Caesar*, Act III and *Richard III*, Act III). They refer to such propaganda stratagems as the seizure and monopolization of propaganda initiatives, the displacement of guilt onto others (scapegoating), the presentation of oneself as morally superior, and the coordination of propaganda with violence and bribery.

Modern research and the evolution of current theories. After the decline of the ancient world, no elaborate systematic study of propaganda appeared for centuries—not until the Industrial Revolution had brought about mass production and raised hopes of immensely high profits through mass marketing. Toward the beginning of the 20th century, researchers began to undertake studies of the motivations of many types of consumers and of their responses to various kinds of salesmanship, advertising, and other marketing techniques. From the early 1930s on, there have been "consumer surveys" much in the manner of public-opinion surveys. Almost every conceivable variable affecting consumers' opinions, beliefs, suggestibilities, and behaviour has been investigated for every kind of group, subgroup, and culture in the major capitalist nations. Consumers' wants and habits are beginning to be studied in the same ways in the socialist countries—partly to promote economic efficiency and partly to prevent political unrest. Data on the wants and habits of voters as well as consumers are now being gathered in the same elaborate ways in many parts of the world.

Large quantities of such information on consumers and voters are stored and statistically processed by computers and are drawn upon for nationwide and international advertising campaigns costing billions of dollars annually. Such advertising—including political advertising—occupies a very high percentage of radio and television time and of newspaper, magazine, and billboard space in countries where it is permitted. By conservative estimates \$140,000,000 was spent in the U.S. presidential election of 1952, \$155,000,000 in that of 1956, \$175,000,000 in 1960, and \$200,000,000 in 1964. On paid media the Republican Party was estimated to have spent more than \$23,000,000 and the Democratic Party over \$25,000,000, for their presidential and vice presidential candidates in 1984. Critics have argued that advertising expenditures on such a scale, whether for deodorants or presidents, tend to waste society's resources and also to preclude effective competition by rival producers or politicians who cannot raise equally large amounts of money. A rising tide of consumer resistance and voter skepticism is leading to various attempts at consumer education, voter education, counterpropaganda, and proposals for regulatory legislation.

As far back as the early 1920s, there developed an awareness among many social critics that the extension of the vote and of enlarged purchasing power to more and more of the ignorant or ill-educated meant larger and larger opportunities for both demagogic and public-spirited propagandists to make headway by using fictions and myths, utopian appeals, and "the noble lie." Interest was aroused not only by the lingering horror of World War I and of the postwar settlements but also by publication of Ivan Pavlov's experiments on conditioned reflexes and of analyses of human motivations by various psychoanalysts. Freud's *Group Psychology and the Analysis of the Ego* (1922) was particularly relevant to the study of leaders, propagandists,

Sample
surveys
and
market
research

and followers, as were Walter Lippmann's *Public Opinion* (1922) and *The Phantom Public* (1925).

In 1927, an American political scientist, Harold D. Lasswell, published a now-famous book, *Propaganda Technique in the World War*, a dispassionate description and analysis of the massive propaganda campaigns conducted by all the major belligerents in World War I. This he followed with studies of Communist propaganda and of many other forms of communication. Within a few years, a great many other social scientists, along with historians, journalists, and psychologists, were producing a wide variety of publications purporting to analyze military, political, and commercial propaganda of many types. During the Nazi period and the period of World War II and the subsequent cold war between the U.S. and the Soviet Union, a great many researchers and writers, both skilled and unskilled, scholarly and unscholarly, were employed by governments, political movements, and business firms to conduct propaganda. Some of those who had scientific training designed very carefully controlled experiments or intelligence operations, attempting to quantify data on appeals of various types of propaganda to given reactors.

In the course of this theory building and research, the study of propaganda advanced a long way on the road from lore to science. Today several hundred more or less scholarly books and thousands of articles shed substantial light on the psychology, techniques, and effects of propaganda campaigns, major and minor.

In recent decades, nearly every significant government, political party, special-interest group, social movement, and big business firm in the advanced countries has developed its own corps of specialized researchers, propagandists, or "opinion managers" (sometimes referred to as information specialists, lobbyists, legislative representatives, or vice presidents in charge of public relations). Some have become members of parliaments, cabinets, and corporate boards of directors. The most expert among them sometimes are highly skilled or trained, or both, in history, psychiatry, politics, social psychology, survey research, and statistical inference.

Many of the bigger and wealthier propaganda agencies conduct (overtly and covertly) elaborate observations and opinion surveys, among samples of the leaders, the middle strata, and the rank and file of all social groups, big and little, whom they hope to influence. They tabulate many kinds of data concerning those contents of the press, films, television, and organizational media that reach given groups. They chart the responses of reactors, through time, by statistical formulas. They conduct "symbol campaigns" and "image-building" operations with mathematical calculation, using quantities of data that can be processed only by computers. To the ancient art of rhetoric, the "technique of orators," have been added the techniques of the psychopolitical analyst and the media man and the know-how of the administrators of giant advertising agencies, public relations firms, and governmental ministries of information that employ armies of analytic specialists and "symbol-handlers."

It is a commonplace among the highly educated that men in the mass—and even men on high educational and social levels—often react more favourably to utopian myths, wishful thinking, and nonrational residues of earlier experiences than they do to the sober analysis of facts. The average citizen who may be aware of being duped is not likely to have enough education, time, or economic means to defend himself against the massive organizations of opinion managers and hidden persuaders. Indeed, to affect them he would have to act through large organizations himself and to use, to some extent, the very means used by those he seeks to control. The still greater "curse of bigness" that may evolve in the future is viewed with increasing concern by many politically conscious people.

THE COMPONENTS OF PROPAGANDA

The contemporary propagandist employing behavioral theory tends to analyze his problem in terms of at least 10 questions:

1. What are the goals of the propaganda? (What changes are to be brought about? In whom? And when?)

2. What are the present and expected conditions in the world social system?

3. What are the present and expected conditions in each of the subsystems of the world social system (such as international regions, nations, lesser territories, interest groups)?

4. Who should distribute the propaganda—the propagandist or his agents?

5. What symbols should be used?

6. What media should be used?

7. Which reactors should the propaganda be aimed at?

8. How can the effects of the propaganda be measured?

9. By what countermeasures can opponents neutralize or suppress the propaganda?

10. How can such countermeasures be measured and dealt with?

In the present state of social science, this 10-part problem can be solved with only moderate confidence with respect to any really major propaganda campaign, even if one has a great deal of money for research. Yet if the propagandist is to proceed as rationally as possible, he needs the best answers that are available.

Goals. Goals are fairly easy to define if the propagandist simply wants to sell a relatively safe, useful, and simple good or service. When the propagandist aims to convert great numbers of people to a religion or a new social order or to induce extremely dangerous collective action like a war or revolution, however, the definition of goals becomes highly complex. It is complicated further by problems about "means-goals" or intermediate goals: probably the campaign will have to go on for a long time and will have to be planned in stages, phases, or waves. The propagandist may find it hard to specify, even to himself, exactly what beliefs, values, or actions he wants to bring about, by what points in time, among different sorts of people. Very large and firmly held complexes of values are involved, such as prestige, peace of mind, income, and even life itself or the military security of entire nations or regions—even, in modern times, the annihilation of all mankind. In such a situation, a mass of intricate and thorny value dilemmas arises: Is military or revolutionary victory worth the price of economic ruin? Can a desired degree of individual liberty be achieved without too much loss of social equality? Is a much quicker achievement of goals worth a much greater amount of human suffering? Are war crimes to be committed in order to win a battle? In short: What is the propagandist willing to risk, for what, across what periods of time?

Present and expected conditions in the world social system. Under modern conditions, each act of propaganda is apt to have effects in several parts of the world. Some of these may boomerang unexpectedly against the propagandist himself unless he can visualize the global system and its components and anticipate the problems that may arise. The global system, moreover, is inexorably changing. As population, trade, travel, education, and technology evolve, new centres of political, cultural, and economic power emerge. This social evolution, extremely rapid in current times, tends on balance to limit the use of more simplistic and parochial kinds of propaganda and increases the need for more sophisticated, scientifically formulated, and universalistic (world-oriented) types. If, for example, there is, as some theorists argue, an evolution everywhere from less rationality and scientism toward more and from the primacy of particularistic loyalties toward the primacy of a universalistic loyalty, is the propagandist to use appeals that resist such trends or accept them? If he resists, what is the cost? If his appeals are far ahead of his time, again what is the cost?

Present and expected conditions in subsystems. In many times and places in the past, the propagandist could profit handsomely by ignoring the welfare of a nation or the world and appealing to extremes of religious, racial, political, or economic fanaticism. This paid off very well, in the short run at least, within many subsystems. Today, however, this kind of propaganda can prove to be useless and even dangerous. The prudent propagandist has therefore to decide what mix of universalistic and particularistic symbolism will best serve his purposes at given times in

Propaganda specialists

Particularism versus universalism

given places. The choice is never an easy one: parochial or class-conscious or national groups may be aroused to the highest passions; and they are numerous and diverse and often highly incompatible with one another and with the imperatives of the nation or the world.

Propa-
ganda
“fronts”

The propagandist and his agents. The use of seemingly reputable, selfless, or neutral agents or so-called front organizations, while the propagandist himself remains behind the scenes, may greatly improve his prospects. If the authorities are after the propagandist, seeking to suppress his activities, he *must* stay underground and work through agents. But even in freer circumstances, he may wish someone else to speak for him. The propagandist, for instance, may not speak the reactors' language or idiom fluently. He may not know what they associate with given symbols. Or their cultural, racial, or religious feelings may bias them against him and thus tend to deny him a favourable hearing. In such cases the use of agents is inescapable. Thus, subsidizing a native news commentator or lecturer in a foreign country or furnishing propagandistic music for use by a foreign broadcasting station may be more effective than conducting one's own broadcasts. (There are exceptions, however. Many surveys have shown, for example, that news broadcasts by the British Broadcasting Corporation are considered by various foreign audiences to be more truthful than broadcasts originating in their own countries.) Furthermore, if the propaganda fails or is exposed for what it is, the agent can be publicly scapegoated while the real propagandist continues to operate and develop new stratagems. The prince, said Machiavelli, may openly and conspicuously bestow awards and honours and public offices; but he should have his agents carry out all actions that make a man unpopular, such as punishments, denunciations, dismissals, and assassinations.

A complicated modern campaign on a major scale is likely to be planned most successfully by a collective leadership—a team of broadly educated and skilled people who have had both practical experience in public affairs and extensive training in history, psychology, and the social sciences. The detachment, skepticism, and secularism of such persons may, however, cause them to be viewed with great suspicion by many reactors. It may be important, therefore, to keep the planners behind the scenes and to select intermediaries, front men, Trojan horses, and “dummy leaders” whom the reactors are more likely to listen to or appreciate.

Contemporary social-psychological research, dating from Freud's *Group Psychology and the Analysis of the Ego*, makes clear the wisdom of traditional insights concerning the supreme importance of leadership in any group, be it the family, the nation, or the world social system. The rank and file of any group, especially a big one, have been shown to be remarkably passive until aroused by quasi-parental leaders whom they admire and trust. It is hard to imagine the Gallic wars without Caesar, the psychoanalytic movement without Freud, the Nazis without Hitler, or the major Communist revolutions without Lenin and Mao Tse-tung and their politburos. These leaders were real, not dummies invented and packaged by image makers from an advertising agency or public relations firm. In the age of massive opinion researches, however, and with the aid of speech coaches and makeup artists and the magic impact of television, it has become increasingly possible for image makers to create front men who can affect the votes and other behaviour of very large percentages of a national audience. As one knowledgeable participant phrased it in 1970:

Image
makers

There are now four essential ingredients to a professionally managed political campaign: political polls, data processing, imagery, and money. The polls discover what the voter already believes, and data processing interprets and analyzes the depth of voters' attitudes. After that, an image of the candidate is tailored to meet the voters' demands and desires, and the whole package is then sold by massive expenditures of money in the advertising media, particularly television.

The candidate has become relatively unimportant as long as he can be properly managed. The candidate must be bright enough to handle the material furnished to him, but not too intelligent, because there is always the danger that an intelligent candidate may come up with unpopular or controversial

ideas of his own, and thereby destroy a carefully contrived campaign strategy. [Excerpt from a public address by Zoltan Ferency, chairman and gubernatorial candidate of the Democratic Party of Michigan, June 1970.]

Probably this is an overstatement, but it conveys the flavour of a great deal of contemporary political propaganda. Yet a dummy leader invented by an image maker may not always be invulnerable to counterpropaganda by a real leader, if one should turn up. Even a giant, expensive television campaign may not be able to conceal from all reactors the differences between a dummy and a bona fide leader with high political skills—a Franklin D. Roosevelt, for example, or a Jawaharlal Nehru—whose voice and gestures express a genuine and spontaneous concern for public policy and a determination to “wear no man's collar,” and who goes in for great numbers of face-to-face appearances that demonstrate that he has no need for a voice coach and a makeup artist.

Selection and presentation of symbols. The propagandist must realize that neither rational arguments nor catchy slogans can, by themselves, do much to influence human behaviour. A reactor's behaviour is also affected by at least four other variables. The first is the reactor's predispositions—that is, his stored memories of, and his past associations with, related symbols. These often cause the reactor to ignore the current inflow of symbols, to perceive them very selectively, or to rationalize them away. The second is the set of economic inducements (gifts, bribery, pay raises, threats of job loss, and so forth) which the propagandist or others may apply in conjunction with the symbols. The third is the set of physical inducements (love, violence, protection from violence) used by the propagandist or others. The fourth is the array of social pressures that may either encourage or inhibit the reactor in thinking or doing what the propagandist advocates. Even one who is well led and is predisposed to do what the propagandist wants may be prevented from acting by counterpressures within the surrounding social systems or groups of which he is a part.

In view of these predispositions and pressures, the skilled propagandist is careful to advocate chiefly those acts that he believes the reactor already wants to perform and is in fact able to perform. It is fruitless to call upon most people to perform acts that may involve a total loss of income or terrible physical danger—for example, to act openly upon Communist leanings in a totalitarian fascist country. To call upon reactors to do something extremely dangerous or hard is to risk having the propaganda branded as unrealistic. In such cases, it may be better to point to actions that the reactor can *avoid* taking—that is, to encourage him in acts of passive resistance. The propagandist will thereby both *seem* and *be* realistic in his demands upon the reactor, and the reactor will not be left with the feeling, “I agree with this message, but just what am I supposed to do about it?”

For maximum effect, the symbolic content of propaganda must be active, not passive, in tone. It must explicitly or implicitly recommend fairly specific actions to be performed by the reactor (“buy this,” “boycott that,” “vote for X,” “join Group Y,” “withdraw from Group Z”). Furthermore, because the ability of the human organism to receive and process symbols is strictly limited, the skillful propagandist attempts to substitute quality for quantity in his choice of symbols. A brief slogan or a picture or a pithy comment on some symbol that is emotion laden for the reactors may be worth ten thousand other words and cost much less. In efforts to economize symbol inputs, the propagandist attempts to make full use of the findings of all the behavioral sciences. He draws upon the psychoanalysts' studies of the bottled-up impulses in the unconscious mind; he consults the elaborate vocabulary counts produced by professors of education; he follows the headline news to determine what events and symbols probably are salient in reactors' minds at the moment; and he analyzes the information polls and attitude studies conducted by survey researchers.

There is substantial agreement among psychoanalysts that the psychological power of propaganda increases with use of what Lasswell termed the triple-appeal principle.

Predis-
positions and
induce-
ments

This principle states that a set of symbols is apt to be most persuasive if it appeals simultaneously to three elements of an individual's personality—elements that Freud labelled the ego, id, and superego. To appeal to the ego, the skilled propagandist will present the acts and thoughts that he desires to induce as if they were rational, advisable, wise, prudent, and expedient; in the same breath he says or implies that they are sure to produce pleasure and a sense of strength (an appeal to the id); concurrently he suggests that they are moral, righteous, and—if not altogether legal—decidedly more justifiable and humane than the law itself (an appeal to the superego, or conscience). Within any social system, the optimal blend of these components varies from individual to individual and from subgroup to subgroup: some individuals and subgroups love pleasure intensely and show few traces of guilt; others are quite pained by guilt; few are continuously eager to be rational or to take the trouble to become well informed. Some cautious individuals and subgroups like to believe that they never make a move without preanalyzing it; others enjoy throwing prudence to the winds. There are also changes in these blends through time: personalities change, as do the morals and customs of groups. In large collectivities like social classes, ethnic groups, or nations, the particular blends of these predispositions may vary greatly from stratum to stratum and subculture to subculture. Only the study of history and behavioral research can give the propagandist much guidance about such variations.

A propagandist is wise if, in addition to reiterating his support of ideas and policies that he knows the reactors already believe in, he includes among his images a variety of symbols associated with parents and parent surrogates. The child lives on in every adult, eternally seeking a loving father and mother. Hence the appeal of such familistic symbolisms as "the fatherland," "the mother country," "the Mother Church," "the Holy Father," "Mother Russia," and the large number of statesmen who are known as the "fathers of their countries." Also valuable are reassuring maternal figures like Queen Victoria of England, the Virgin Mary, and the Japanese Sun Goddess. In addition to parent symbols, it is usually well to associate one's propaganda with symbols of parent substitutes, who in some cases exert a more profound effect on children than do disappointing or nondescript parents: affectionate or amiable uncles (Uncle Sam, Uncle Ho Chi Minh); lively aunts (*la belle France*, Britannia, the Spanish Communist leader La Pasionaria, and Kuan-yin, the Chinese Goddess of Mercy); admired scholars and physicians (Karl Marx, Dr. Sun Yat-sen); politico-military heroes and role models (Abraham Lincoln, Winston Churchill, Mao Tse-tung, "the wise, mighty, and fatherly Stalin"); and, of course, saints (Joan of Arc, Mahatma Gandhi, Martin Luther King, the Buddha). A talented and well-symbolized leader or role model may achieve a parental or even godlike ascendancy (charisma) and magnify the impact of a message many times.

Media of propaganda. There are literally thousands of written, audiovisual, and organizational media that a 20th-century propagandist might use. All human groupings are potential organizational media, from the family and other small organizations through advertising and public relations firms, trade unions, churches and temples, theatres, readers of novels and poetry, special-interest groups, political parties and front organizations to the governmental structures of nations, international coalitions, and universal organizations like the United Nations and its agencies. From all this variety of media, the propagandist must choose those few media (especially leaders, role models, and organizations) to whose messages he thinks the intended reactors are especially attentive and receptive.

In recent years the communications revolution has brought about a massive, worldwide proliferation of school systems and of facilities for news gathering, publishing, broadcasting, holding meetings, and speechmaking. At present, almost everyone's mind is bombarded daily by far more media, symbols, and messages than the human organism can possibly pay attention to. The mind reels under noisy assortments of information bits about rival politicians, rival political programs and doctrines, new

technical discoveries, insistently advertised commercial products, and new views on morality, ecological horrors, and military nightmares. This sort of communication overload already has resulted in the alienation of millions of people from much of modern life. Overload and alienation can be expected to reach even higher levels in coming generations as still higher densities of population, intercultural contacts, and communication facilities cause economic, political, doctrinal, and commercial rivalries to become still more intense.

Research has demonstrated repeatedly that most reactors attempt, consciously or unconsciously, to cope with severe communication overload by developing three mechanisms: selective attention, selective perception, and selective recall. That is, they pay attention to only a few media; they fail (often unconsciously) to perceive therein any large proportion of the messages that they find uncongenial; and, having perceived, even after this screening, a certain number of unpleasing messages, they repress these in whole or in part (*i.e.*, cannot readily remember them). The contemporary propagandist therefore tries to find out: (1) what formative experiences and styles of education have predisposed his intended audiences to their current "media preferences"; (2) which of all the publications, television shows, leaders, and role models in the world they do in fact pay attention to; and (3) by which of these they are most influenced. These topics have thus become the subjects of vast amounts of commercial and academic research.

In most cases, reactors are found to pay the most attention to the publications, shows, leaders, and role models with whose views they already agree. People as a rule attend to communications not because they want to learn something new or reconsider their own philosophies of life but because they seek psychological reassurance about their existing beliefs and prejudices. When the propagandist does get their attention by putting his message into the few media they heed, he may discover that, to hold their attention, he must draft a message that does not depart very far from what they already want to believe. Despite the popular stereotypes about geniuses of politics, religion, or advertising whose brilliant propaganda converts the multitudes overnight, the plain fact is that even the most skilled propagandist must usually content himself with a very modest goal: packaging a message in such a way that much of it is familiar and reassuring to the intended reactors and only a little is so novel or true as to threaten them psychologically. Thus, revivalists have an *a priori* advantage over spokesmen of a modernized ethic, and conservative politicians an advantage over progressives. Propaganda that aims to induce major changes is certain to take great amounts of time, resources, patience, and indirection, except in times of revolutionary crisis when old beliefs have been shattered and new ones have not yet been provided. In ordinary periods (intercrisis periods), propaganda for changes, however worthy, is likely to be, in the words of the German sociologist Max Weber, "a slow boring of hard boards."

For reasons just indicated, the most effective media as a rule (for messages other than the simplest of commercial advertising) are not the impersonal mass media like newspapers and television but rather those few associations or organizations (reference groups) with which the individual feels identified or to which he aspires to relate his identity. Quite often the ordinary man not only avoids but actively distrusts the mass media or fails to understand their messages; but in the warmth of his reference groups he feels at home, assumes that he understands what is going on, and feels that he is sure to receive a certain degree of emotional response and personal protection. The foremost reference group, of course, is the family. But many other groups perform analogous functions—for instance, the group of sports fans, the church, the trade union, the alumni group, the clique or gang, the Communist cell. By influencing the key members of such a group, the propagandist may establish a "social relay" channel that can amplify his message. By concentrating thus on the few, he increases his chances of reaching the many—often far more effectively than he could through a plethora of mass

Communi-
cation
overload

Role
models
and
parental
symbols

Use of
reference
groups

meetings, paid broadcasts, handbills, or billboards and at much lower cost. Therefore, one important stratagem involves the combined use of mass media and reference-group channels—writing up materials for such media as news releases or broadcasts in ways designed specifically to reach specified groups (and especially their elites and leaders), who can then relay the messages to other sets of reactors.

The reactors (audiences). The audiences for the propagandist can be classified into: (1) those who are initially predisposed to react as the propagandist wishes, (2) those who are neutral or indifferent, and (3) those who are in opposition or perhaps even hostile.

As already indicated, propaganda is most apt to evoke the desired responses among those already in agreement with the propagandist's message. Neutrals or opponents are not apt to be much affected even by an intensive barrage of propaganda unless it is reinforced by nonpropagandistic inducements (economic or coercive acts) or by favourable social pressures. These facts, of course, are recognized by advocates of civil disobedience; their propagandists would contend that sloganeering and reasoned persuasion must be accompanied by sit-ins and other overt acts of passive resistance; they aim for a new climate of social pressure. These facts are also significantly recognized by Communist regimes; by controlling all means of production, they can offer great economic inducements or threaten a man's livelihood, thus making him a very attentive audience for propaganda. If these copressures are applied too strongly, however, they may become so distasteful to reactors that the associated propaganda will backfire.

Measurement of the effects of propaganda. The modern world is overrun with all kinds of competing propaganda and counterpropaganda and a vast variety of other symbolic activities, such as education, publishing, newscasting, and patriotic and religious observances. The problem of distinguishing between the effects of one's own propaganda and the effects of these other activities is often extremely difficult.

The ideal scientific method of measurement is the controlled experiment. Carefully selected samples of members of the intended audiences can be subjected to the propaganda while equivalent samples are not. Or the same message, clothed in different symbols—different mixes of sober argument and "casual" humour, different proportions of patriotic, ethnic, and religious rationalizations, different mixes of truth and the "noble lie," different proportions of propaganda and coercion—can be tested on comparable samples. Also, different media can be tested to determine, for example, whether results are better when reactors read the message in a newspaper, observe it in a spot commercial on television, or hear it wrapped snugly in a sermon. Obviously the number of possible variables and permutations in symbolism, media use, subgrouping of the audience, and so forth is extremely great in any complicated or long-drawn-out campaign. Therefore, the costs for the research experts and the fieldwork that are needed for thorough experimental pretests are often very high. Such pretests, however, may well save money in the end.

An alternative to controlled experimentation in the field is controlled experimentation in the laboratory. But it may be impossible to induce reactors who are truly representative of the intended audience to come to the laboratory at all. Moreover, in such an artificial environment their reactions may differ widely from the reactions that they would have to the same propaganda if reacting unself-consciously in their customary environment. For these and many other obvious reasons, the validity of laboratory pretests of propaganda must be viewed with the greatest caution.

Whether in the field or the laboratory, the value of all controlled experiments is seriously limited by the problem of "sleeping effects." These are long-delayed reactions that may not become visible until the propaganda has penetrated resistances and insinuated itself deep down into the reactor's mind—by which time the experiment may have been over for a long time. Another problem is that most people acutely dislike being guinea pigs and also dislike the word propaganda. If they find out that they are sub-

jects of a propagandistic experiment, the entire research program, and possibly the entire campaign of propaganda of which it is a part, may backfire.

Another research device is the panel interview—repeated interviewing, over a considerable period of time, of small sets of individuals considered more or less representative of the intended audiences. The object is to obtain (if possible, without their knowing it) a great deal of information about their life-styles, belief systems, value systems, media habits, opinion changes, heroes, role models, reference groups, and so forth. The propagandist hopes to use this information in planning ways to influence a much larger audience. Panel interviewing, if kept up long enough, may help in discovering sleeper effects and other delayed reactions. The very process of being "panel interviewed," however, produces an artificial environment that may induce defensiveness, suspiciousness, and even attempts to deceive the interviewer.

For many practical purposes, the best means of measuring—or perhaps one had better say estimating—the effects of propaganda is apt to be the method of extensive observation, guided of course by well-reasoned theory and inference. "Participant observers" can be stationed unobtrusively among the reactors. Voting statistics, market statistics, press reports, police reports, editorials, and the speeches or other activities of affected or potentially affected leaders can also give clues. Evidence on the size, composition, and behaviour of the intermediate audiences (such as elites) and the ultimate audiences (such as their followers) can be obtained from these various sources and from sample surveys. The statistics of readership or listenership for printed and telecommunications media may be available. If the media include public meetings, the number of people attending and the noise level and symbolic contents of cheering (and jeering) can be measured. Observers may also report their impressions of the moods of the audience and record comments overheard after the meeting. To some extent, symbols and leaders can be varied, and the different results compared.

Using methods known in recent years as content analysis, the propagandist can at least make reasonably dependable quantitative measurements of the symbolic contents of his own propaganda and of communications put out by others. He can count the numbers of column inches of printed space or seconds of radio or television time that were given to the propaganda. He can categorize and tabulate the symbols and themes in the propaganda. To estimate the implications of the propaganda for social policy, he can tabulate the relative numbers of expressed or implied demands for actions or attitude changes of various kinds. The 1970 edition of volume 1 of the *Great Soviet Encyclopedia*, for example, had no pictures of Stalin; in the previous edition, volume 1 had four pictures. Did this mean that a new father figure and role model was being created by the Soviet propagandists? Or did it indicate a return to the cult of older father figures such as Marx and Lenin? If so, what were the respective father figures' traits, considered psychoanalytically, and what are the political, economic, and military implications for Soviet policy?

By quantifying his data about contents, the propagandist can bring a high degree of precision into experiments using different propaganda contents aimed at the same results. He can also increase the accuracy of his research on the relative acceptability of information, advice, and opinion attributed to different sources. (Will given reactors be more impressed if they hear 50, 100, or 200 times that a given policy is endorsed—or denounced—by the president of the U.S., the premier of the U.S.S.R., or the pope?)

Very elaborate means of coding and of statistical analysis have been developed by various content analysts. Some count symbols, some count headlines, some count themes (sentences, propositions), some tabulate the frequencies with which various categories of "events data" (newspaper accounts of actual happenings) appear in some or all of the leading newspapers ("prestige papers") or television programs of the world. Some of these events data can be counted as supporting or reinforcing the propaganda, some as opposing or counteracting it. Whatever the methodology, content analysis in its more refined forms is an ex-

Use of

and
observa-
tion
techniques

Use of
experi-
ments

Use of
"content
analysis"

pensive process, demanding long and rigorous training of well-educated and extremely patient coders and analysts. And there remains the intricate problem of developing relevant measurements of the effects of different contents upon different reactors.

Countermeasures by opponents. Some countermeasures against propaganda include simply suppressing it by eliminating or jailing the propagandist, burning down his premises, intimidating his employees, buying him off, depriving him of his use of the media or the money that he needs for the media or for necessary research, and applying countless other coercive or economic pressures. It is also possible to use counterpropaganda, hoping that the truth (or at least some artful bit of counterpropaganda) will prevail.

One special type of counterpropaganda is "source exposure"—informing the audience that the propagandist is ill informed, is a criminal, or belongs to some group that is sure to be regarded by the audience as subversive, thereby undermining his credibility and perhaps his economic support. In the 1930s there was in the U.S. an Institute for Propaganda Analysis that tried to expose such propaganda techniques as "glittering generalities" or "namecalling" that certain propagandists were using. This countermeasure may have failed, however, because it was too intellectual and abstract and because it offered the audience no alternative leaders to follow or ideas to believe.

In many cases opponents of certain propagandists have succeeded in getting laws passed that have censored or suppressed propaganda or required registration and disclosure of the propagandists and of those who have paid them.

Measures against countermeasures. It is clear, then, that opponents may try to offset propaganda by taking direct action or by invoking covert pressures or community sanctions to bring it under control. The propagandist must therefore try to estimate in advance his opponents' intentions and capabilities and invent measures against their countermeasures. If he thinks that they will rely only on counterpropaganda, he can try to outwit them. If he thinks that they will withdraw advertising from his newspaper or radio station, he may try to get alternative supporters. If he expects vigilantes or police persecution, he can go underground and rely, as the Russian Communists did before 1917 and the Chinese before 1949, primarily on agitation through organizational media.

SOCIAL CONTROL OF PROPAGANDA

Democratic control of propaganda. Different sorts of politics, ranging from the democratic to the authoritarian, have attempted a variety of social controls over propaganda. In an ideal democracy, everyone would be free to make propaganda and free to oppose propaganda habitually through peaceful counterpropaganda. The democratic ideal assumes that, if a variety of propagandists are free to compete continuously and publicly, the ideas best for society will win out in the long run. This outcome would require that a majority of the general populace be reasonably well-educated, intelligent, public-spirited, and patient, and that they not be greatly confused or alienated by an excess of communication. A democratic system also presupposes that large quantities of dependable and relevant information will be inexpensively disseminated by relatively well-financed, public-spirited, and uncensored news gathering and educational agencies. The extent to which any existing national society actually conforms to this model is decidedly an open question. That the world social system does not is self-evident.

In efforts to guard against "pernicious" propaganda by hidden persuaders, modern democracies sometimes require that such propagandists as lobbyists and publishers register with public authorities and that propaganda and advertising be clearly labelled as such. The success of such measures, however, is only partial. In the U.S., for instance, publishers of journals using the second-class mails are required to issue periodic statements of ownership, circulation, and other information; thereby, at least the nominal owners and publishers become known—but those who subsidize or otherwise control them may not. In many places, paid political advertisements in newspa-

pers or on television are required to include the name of a sponsor—but the declared sponsor may be a "dummy" individual or organization whose actual backers remain undisclosed. Furthermore, agents of foreign governments or organizations engaged in propaganda in the U.S. are required to file forms with the U.S. Department of Justice, naming their principals and listing their own activities and finances—but it is impossible to know whether the data so filed are correct, complete, or significant. In many Western industrial nations, similar registrations and disclosures are required of those who circulate brochures inviting investors to buy stocks and bonds. This principle of disclosure, which appears so useful with respect to foreign agents and securities salesmen, is not often applied, however, to other media of propaganda. (In the U.S. the disclosure of certain types of political campaign advertisements and contributions is required, but the requirement is easily circumvented.) In many countries, claims made in propaganda (including advertising) about the contents or characteristics of foods and drugs and some other products are also subject to registration and to requirements of "plain labelling." In some places, consumer research organizations, privately or publicly supported, examine these claims rigorously and sometimes publish scientifically based counterpropaganda. Finally, there has been an increase in laws and customs requiring that equal space or time or a right of reply be rendered all major contenders in political campaigns or even major spokesmen differing on major issues of the day. In view of the apparently massive effects and the certainly massive expenses of political propaganda on television, there are many movements afoot in democracies to limit expenditures on campaign propaganda and to require networks to give time free of charge for even the minor parties, especially in the weeks immediately preceding elections. There have also been movements to require that political propaganda be halted for a specified number of days before the holding of an election—the idea being that a cooling-off period would allow voters to rest and reflect after the communication overload of the campaign period and would prevent politicians and their backers from using last-minute slander and sensationalism.

Authoritarian control of propaganda. In a highly authoritarian polity, the regime tries to monopolize for itself all opportunities to engage in propaganda, and often it will stop at nothing to crush any kind of counterpropaganda. How long and how completely such a policy can be implemented depends, among other things, on the amount of force that the regime can muster, on the thoroughness of its police work, and, perhaps most of all, on the level, type, and distribution of secular higher education. Secular higher education invariably promotes skepticism about claims that sound dogmatic or are made without evidence; and if such education is of a type that emphasizes humane and universalistic values, an ignorant or unreasonable authoritarian regime is not likely to please the educated for very long. If the educated engage in discreet counterpropaganda, they may in the end modify the regime.

World-level control of propaganda. One of the most serious and least understood problems of social control is above the national level, at the level of the world social system. At the world level there is an extremely dangerous lack of means of restraining or counteracting propaganda that fans the flames of international, interracial, and interreligious wars. The global system consists at present of a highly chaotic mixture of democratic, semidemocratic, and authoritarian subsystems. Many of these are controlled by leaders who are ill educated, ultranationalistic, and religiously, racially, or doctrinally fanatical. At present, every national regime asserts that its national sovereignty gives it the right to conduct any propaganda it cares to, however untrue such propaganda may be and however contradictory to the requirements of the world system. The most inflammatory of such propaganda usually takes the form of statements by prominent national leaders, often sensationalized and amplified by their own international broadcasts and sensationalized and amplified still further by media in the receiving countries. The only major remedy would lie, of course, in the slow spread of education for universalist

ganda

humanism. A first step toward this might be taken through the fostering of an energetic and highly enlightened press corps and educational establishment, doing all it can to provide the world's broadcasters, newspapers, and schools with factual information and illuminating editorials that could increase awareness of the world system as a whole. Informed leaders in world affairs are therefore becoming increasingly interested in the creation of world-level media and multinational bodies of reporters, researchers, editors, teachers, and other intellectuals committed to the unity of mankind.

BIBLIOGRAPHY. Annotated listings of books and articles of all times, countries, and languages, with respect to public opinion and the theory and practice of communication (including propaganda) appear in HAROLD D. LASSWELL, RALPH D. CASEY, and BRUCE L. SMITH (eds.), *Propaganda and Promotional Activities: An Annotated Bibliography* (1935, reprinted 1969); and in BRUCE L. SMITH, HAROLD D. LASSWELL, and RALPH D. CASEY, *Propaganda, Communication and Public Opinion: A Comprehensive Reference Guide* (1946). Further listings on general and international propaganda are in BRUCE L. SMITH and CHITRA M. SMITH, *International Communication and Political Opinion: A Guide to the Literature* (1956, reprinted 1972). Property Law

Like all law, property law seeks to articulate the principles, policies, and rules by which disputes are to be resolved and by which transactions may be structured so that disputes may be avoided. What distinguishes property law from other kinds of law is that the principles, policies, and rules of property law deal with the relationships between and among members of a society with respect to "things." The things may be tangible, such as land or a factory or a diamond ring, or they may be intangible, such as stocks and bonds or a bank account. Property law, then, deals with the allocation, use, and transfer of wealth and the objects of wealth. As such, it reflects the economy of the society in which it is found. Since it deals with the control and transfer of wealth between spouses and across generations, property law reflects the family structure of the society in which it is found. Since it deals with such fundamental issues as

the economy and the structure of the family, property law reflects the politics of the society in which it is found.

This article outlines the major systems of property law that have existed historically and that exist today. The principal focus is on the two major Western systems of law that have become dominant in the industrialized world: the Anglo-American system, derived from the English common law, and the "civil-law" system, which was developed on the European continent on the basis of Roman law. The focus is particularly on the different ways in which these systems attempt to resolve the conflicts that result from their historical tendency to regard absolute individual ownership of property as normative.

For coverage of related topics in the *Macropædia* and the *Micropædia*, see the *Propædia*, sections 551 and 553, and the *Index*.

The article is divided into the following sections:

Definition and scope

THE PROBLEM OF DEFINITION

Property is frequently defined as the rights of a person with respect to a thing. The difficulties with this definition have plagued speculative jurists in the West for the better part of a century. Speaking of the relationship of a person to a thing is of limited usefulness in legal discourse because a thing cannot bring or defend a lawsuit. The law does not deal with rights, privileges, powers, their correlatives and opposites, in the abstract; it deals with relationships between and among people.

With this in mind one may redefine the law of property as the complex of jural relationships between and among persons with respect to things. It is the sum of rights and duties, privileges and no-rights, powers and liabilities, disabilities and immunities that exist with respect to things.

What distinguishes property law from all other jural relationships is that the jural relationships of property law deal with things.

For purposes of this article, all tangible things are included within the realm of property law, even if a specific legal system denies the classification "property" to certain kinds of tangible things. Many, but not all, legal systems that recognize a separate category of property law also include within that category some intangible things, like stocks and bonds, but not other intangible things, like claims for compensation for wrongs (tort, delict). The definition of property law used here includes those intangible things that the legal system under discussion classifies as property.

This descriptive definition of property law makes it possible to say that there is no known legal system that does not have a law of property. A legal system may not have

a category that corresponds to property in Western legal systems, but every known legal system has some set of rules that deal with the relations among persons with respect at least to tangible things.

PROPERTY LAW AND THE CONCEPT OF PRIVATE PROPERTY

Etymology. The descriptive definition of property law adopted for this article is far removed from what the word *property* means in normal English usage: "an object of legal rights," or "possessions" or "wealth" collectively, frequently with strong connotations of individual ownership. The English word *property* derives either directly or through French *propriété* from Latin *proprietas*, which means "the peculiar nature or quality of a thing" and (in post-Augustan writing) "ownership." The word *proprietas* is derived from *proprius*, an adjective meaning "peculiar" or "own," as opposed to *communis*, "common," or *alienus*, "another's." *Proprius* itself is of uncertain etymology but is probably related to the Indo-European root that appears in Latin *pro*, *prae*, and *prope*, Greek *pró* and *prin*, and Sanskrit *pra*. The meaning of the root is suggested by the meanings of its derivatives: it is the core of meaning within a group of words that may be translated as "in front of," "before," "close to," and "on behalf of." Thus, even before it comes to be a legal term, "property" in the West expresses what distinguishes an individual or a thing from a group or from another. It is the face of one to other(s), what separates me from thee and ye, what lies in a person's view, or what has priority in time.

When the word *property* first appears in the English language, it is regularly used in either of the two senses of the Latin *proprietas*, or one easily derivable from them. Before the 17th century it is rare to find the word in its modern sense of an object of legal rights, and even where it is so found, the context almost always suggests a thing or group of things owned by an individual. The present descriptive definition of property law, then, abstracted from a relatively modern usage of the word *property* the body of law surrounding its object and then stripped the word of its normal connotation of individual ownership.

The Western tendency to agglomerate. If property law in the descriptive sense exists in all legal systems, the extraordinary diversity of the property systems of non-Western societies suggests that any concept of property other than the descriptive one is dependent on the culture in which it is found. Even in the West, as the discussion of the English word *property* shows, the concept has varied considerably over time.

Nonetheless, one tendency seems to characterize the legal concept of property, in the descriptive sense, in the West: a tendency to agglomerate in a single legal person, preferably the one currently in possession of the thing that is the object of the inquiry, the exclusive right to possess, privilege to use, and power to convey the thing. In the technical language of jural relationships, Western law tends to ascribe to the possessor of the thing: (1) the right to possess the thing with a duty in everyone else to stay off, (2) the privilege of using the thing with no right in anyone else to prevent that use (coupled with a right in the possessor to prevent others from using the thing), (3) a power to transfer any or all the possessor's rights, privileges, powers, and immunities to anyone else (who would in the technical language be described as liable to the exercise of the power), and (4) an immunity from change by anyone of those same rights, privileges, and powers (so that everyone else is disabled from changing them).

Basic tensions within the tendency. The tendency of Western property law to agglomerate in the possessor of a thing all rights, privileges, powers, and immunities concerning the thing has never been more than a tendency, because the tendency carries with it two inherent tensions. First, the exercise of the power to convey by any individual cannot begin to be full unless he can limit the power to convey of the individual to whom he conveys. The Earl of Arundel, for example, knows that his eldest son, the heir apparent of the earldom, is insane and likely to die childless. The earl wishes to give the barony of Grostok to his second son but to transfer the barony from his second son to his third son if his second son should become earl.

If the earl cannot do this, his power to convey the barony is less than full. If he can do this, the power of his second son to convey the barony will be less than full. (These are basically the facts of *The Duke of Norfolk's Case* [1682] 3 Ch. Cas. 1.)

The second tension is similar to the first. The privilege of one person to use his things, if exercised to the fullest, is likely to interfere with another's privilege to use his things. Two absolute privileges of use cannot coexist in proximity. The concept of proximity, moreover, has gained new meaning in the late 20th century, applying, for example, to a situation in which emissions of smoke may cause acid rain thousands of miles from the source of the emission.

Both tensions are likely to arise in situations in which the current possessor of the thing is being sued. The Duke of Norfolk's case will normally arise after both the earl and his heir are dead and the third son seeks to recover the barony from the second son, who has now inherited the earldom. The agglomerative tendency will favour the current possessor and may obscure the fact that ruling for the current possessor, the second son, will diminish the power to convey of all property holders. Similarly, cases of incompatible land use will normally result in the passive land user suing the active. For example, the victim of the acid rain will sue the factory emitting the smoke. Because the plaintiff in Western law generally has the burden of proof, the burden will be on the plaintiff to justify a limitation on the privilege of use of the defendant. If the issue is framed in these terms, the agglomerative tendency will favour the defendant and may even obscure the fact that the privilege of use of the plaintiff is equally at stake.

SCOPE OF THE ARTICLE

That the law has a tendency to agglomerate rights, privileges, and powers over a thing in a single individual is a commonplace on the European continent, where it has long been believed that the tendency was inherent in Roman law. That it is also a tendency in Anglo-American law is more controversial, because Anglo-American law recognizes more types of interests in things than does civil law. The first task, then, must be to show that the tendency exists generally in the West and to trace its history down to the present.

Second, the various rights, privileges, and powers associated with the term *property* must be analyzed in order to describe how the law categorizes the objects, subjects, and types of property interests, particularly possessory interests and interests denominated ownership; how it deals with privileges of use and limitations on such privileges; and how it deals with the acquisition and transfer of both possessory and use interests. The discussion closes with a theme adumbrated in the historical discussion—the future of the Western concept of property.

Relation to other branches of law. In nonindustrialized societies the complex of jural relations with respect to tangible things is intimately connected both with the economy of the society and with the family, at least the family as broadly conceived. In most such societies the economy and the family are also intimately connected. The tendency in industrialized societies, by contrast, is to divorce production from consumption—that is, the economy from the family. As a result, in the legal systems of the industrialized world, property used in production and property used within the family are divorced functionally and tend to be treated by different bodies of law.

Thus, although the descriptive definition of property employed in this article encompasses the American law of real estate, trusts and estates, family law (in part), sales of goods, negotiable instruments, secured transactions, securities (stocks and bonds), pensions, environmental protection, and patents, trademarks, and copyrights, only American lawyers who regularly deal with land or decedents' estates normally think of themselves as property lawyers. Those who deal with the other topics tend to think of themselves as family lawyers or commercial lawyers or corporate lawyers or environmental lawyers. Although some consideration is given here to all the branches of law that treat of tangible things and those intangibles that the system in question regards as property, the focus of

The Latin
root

Defini-
tion of
"agglomer-
ative
tendency"

discussion is on the two areas of property law that have the deepest roots in the West, the law concerning land and that concerning the allocation and transmission of property interests within the family.

Geographic scope. As noted above, the Anglo-American and civil-law systems have become dominant in the industrialized world, and property systems derived from one or the other of these systems are found in many countries in which industrialization is just beginning. Former British colonies and members of the British Commonwealth tend to use some version of the Anglo-American system, frequently with additional rules designed to accommodate indigenous religions, family structures, and systems of land tenure. Such, for example, is the situation on the Indian subcontinent. Countries that were colonized by continental Europeans tend to have a civil-law system, with the French or the closely related Spanish model tending to dominate. Such, for example, is the situation in most of Central and South America. Even countries that were never colonized tend to have a Western property system. Japan's, for example, is based on the German Civil Code. China's property system, on the other hand, remains relatively free of influence from the West, although even China's has been influenced by the codes of other socialist countries, and these are largely based on civil law with separate rules for property used in industrial and agricultural production.

The principal focus, then, is on the Anglo-American and civil-law systems that originated in western Europe. Specific examples from Anglo-American law come from the United States and England; specific examples from civil law come from France and Germany. Something is said about socialist legal systems where they differ notably from the two main systems. Occasional examples from some of the great religious legal systems are given and some generalizations made about other property systems of non-Western peoples. Here, however, illustrative examples must suffice. The focus is on land and property in the family in the Anglo-American and civil-law systems.

History and theory in the West

THE ANTHROPOLOGY OF PROPERTY

The evolutionary anthropology of the 19th century tended to see the emergence of absolutist individual property rights as a necessary and inevitable product of human development. Modern anthropology is considerably more cautious. The few generalizations that can be made on the basis of what is now known comparatively about the property practices of various societies, both historical and contemporary, do not seem to support a general evolutionary theory. But they can provide some starting points that help to explain certain features of the property systems that have emerged in the West.

First, almost all societies give individual members considerable control over some kinds of things. This normally includes the right to exclude most, if not all, other members of the society from those things, the privilege of using those things in a wide variety of ways, and the power to convey those things by gift or sale, at least *inter vivos*—that is, between living persons.

Second, every society has some kind of system for dealing with the things that were in the control of members who have died. These systems are frequently quite complicated. Some items may be buried or burned with the deceased; some may be taken by those in authority; but almost all societies, perhaps all, transfer at least some of those things from the control of the deceased to that of a member or members of his or her family (broadly conceived).

Third, there is a relationship between the economic system of the society and the types of things about which it has carefully worked out rules of property. A pastoral society, for example, is likely to have quite complicated rules and practices about the possession, use, and transfer of herds but may not have very complicated rules about land. On the other hand, an agricultural society is likely to have quite complicated rules about land but may devote correspondingly less attention to the rules about most kinds of movables.

Fourth, very few, if any, non-Western societies generalize about property in the way that Western legal systems do. Hence, the fact that most non-Western societies have some categories of things about which they have rules that look like the private-property rules of the West does not mean that the Western concept of private property is universal. What distinguishes the Western concept of private property from that found in the property systems of most, if not all, other societies is the fact that it is a default category; *i.e.*, Western legal systems regard individual ownership as the norm, derogations from which must be explained.

Modern anthropology has difficulty generalizing about history. Many non-Western societies have relatively short discoverable histories. The most dramatic change in the history of many non-Western societies has been their relatively recent contact with the West and with Western ideas. The fact that many non-Western societies have, as they have come in contact with the West, changed their property systems to make them more like those of the West does not indicate that such a change was inevitable, or even functional. It may be simply the result of the political and economic dominance of the Westerners who have come in contact with non-Western societies.

THE ORIGINS OF THE WESTERN IDEA OF PROPERTY

Deprived by modern anthropology of any notion that the Western idea of property can be shown to be an inevitable development of the forces of progress or civilization, one must look again at the emergence of the agglomerative tendency, which, as noted above, is characteristic of property law in the West.

Rome. In classical Roman law (c. AD 1–AD 250) the sum of rights, privileges, and powers a legal person could have in a thing was called *dominium*, ownership, or, less frequently, *proprietas* (though frequently enough for it to be clear that the two words were synonyms as legal terms). The classical Roman jurists do not say that their system tends to ascribe *proprietas* to the current possessor of the thing but that it did is clear enough. A number of Roman legal rules deny the label possession to the person who is in fact, though not legally, in possession in order to keep legal possession in the *proprietary*. Further, the person legally in possession is presumed to be the *proprietary*. This is clear enough from the procedural rules that require a person who is not peaceably in possession of a thing to establish affirmatively that his title is better than that of the peaceable possessor.

Once the Roman system had identified the *proprietary*, it was loath to let him convey anything less than all the rights, privileges, and powers that he had in the thing. Thus, full-use rights divorced from ownership (*usufructus*) could be given only to a living person, and that person could not convey those rights to another. The ability of an owner to agree to legally binding restrictions on his privilege of use (servitudes) was sharply limited. Moreover, anyone who found himself owning a thing jointly with others could require that thing be divided (“*nemo invitus ad communionem compellitur*”; “no one is forced to have common property with another”).

One might argue that the tendency toward absolute individual property rights in Roman law was more apparent than real. For example, classical Roman law never developed a remedy whereby an individual could, upon proof of ownership, specifically recover a thing. The owner could obtain a judicial declaration of his right to the thing, but the defendant could respond by paying damages. The Roman law of persons put extraordinary power over things in the hands of the head of the household (*paterfamilias*); indeed, this power was so extraordinary that an elaborate system (*peculium*) was necessary to allow slaves and sons in the power of their fathers to make binding legal transactions with things that were in fact but not in law their own. Moreover, land outside of Italy was owned not by individuals but by the Roman people collectively or by the emperor; yet individuals who had use rights in such land came to have control over it not far different from that of the owners of Italic land, even though they were not called owners. Finally, the sharp cleavage in Roman law between

civil-law
systems

Generaliza-
tions about
property
systems

public law and private law prevented the Romans from ever developing a legal notion of protection of property as against the state. This meant not only that property rights were not so absolute in Roman law as it might first seem but also that nothing prevented many of the sorts of conflicts about land use that in the later Anglo-American legal system were traditionally the subject of private tort suits or private agreements from being dealt with in Roman law as legislative or administrative matters.

Roman
inheritance

One may question, therefore, how different was the sum of Roman property rules in the descriptive sense of the term from that of legal systems where the agglomerative tendency in property law is less manifest. Nonetheless, the tendency itself existed to a marked extent in Roman legal thought about property. It is notable not only in the ways outlined above in which Roman legal thought focused on the interests of the owner of a thing to the expense of those of others but also in the fundamental separation that Roman law made between property law and the law of obligations (contract and delict). This latter separation was to become characteristic of all the Western legal systems, while the specific decisions that the Roman jurists made about what was to be characterized as a necessary part of ownership became characteristic of many Western legal systems, particularly the civil-law systems.

The existence of the agglomerative tendency in Roman legal thought has no obvious explanation in Roman political or philosophical thought other than the broadest of connections with general ideas of individual worth. Further, present-day knowledge of the relationship of Roman law to Roman society makes hazardous any attempt to explain the existence of the tendency on the basis of social causes. That the tendency, coupled with the Roman law of persons, favoured the property-holding classes, seems obvious. That it was a product of their power, particularly in the Republican period, is likely. A number of its manifestations, however, cannot easily be attributed to class interest, notably the law's refusal to allow family settlements of any but the most short-lived variety, the paucity of land-use control devices, and the failure of the law to develop any notion of protection of property against the state.

England. In medieval English law, the procedural system prevented any clear separation between property and obligation. It was not until the abolition of the forms of action in the 19th century that Anglo-American law was fully able to implement the distinction in the way the Romans had. It is therefore remarkable that English law prior to the abolition of the forms of action tended at critical junctures to move in directions similar to the Roman—namely, to agglomerate property rights in a single individual.

In England a notion of property in land emerged at the end of the 12th century from a mass of partly discretionary, partly customary, feudal rights and obligations. The way in which this happened was extraordinarily complex. What began as essentially an appellate jurisdiction, offered by the king in his court to ensure that a feudal lord did right by his men, ended with the free tenant being the owner of the land, in a quite modern sense, with the lord's rights limited to receipt of money payments.

Legislation at the end of the 13th century (statute *De Donis*, 1285) allowed a conveyor of land to limit its inheritance to the direct descendants of the conveyee and to claim it back if the conveyee's direct line died out (fee tail). In one of their few deviations from the principle of consolidating the power to convey in the present possessor of land, the English courts extended the scope of this legislation in the 14th century. In the middle of the 15th century, however, the courts reversed the trend and allowed the present possessor of entailed land to extinguish the interests of his descendants and of the conveyor (docking of entails by common recovery).

In the 16th century the process that had operated at the end of the 12th century to consolidate ownership rights in the free tenant was replicated for the copyholder, the descendants of those who held land by unfree tenure. The royal courts opened appellate jurisdiction to copyholders wronged by the unjust behaviour of their lords' courts,

and the end result was that the copyholder became the owner of what had heretofore been the lord's land in the eyes of the king's law. Once again, the lord's right in the land was reduced to the receipt of money payments.

The history of English land-use law in the medieval and Tudor periods has not been well explored. A more static society may have produced fewer land-use conflicts than does modern society. Such conflicts as there were may have been resolved in courts other than the central royal courts. The cases in the central royal courts, however, suggest, somewhat surprisingly, that the agglomerative tendency was working on behalf of the plaintiff and not the defendant in disputes over land use (nuisance actions).

Medieval
and Tudor
land-use
law

What protection a citizen's property received against the state in medieval England is a question that requires considerable translation for a world that knew neither citizens nor the state in the modern senses of the words. There are, however, intimations of a notion that property ought to receive some legal protection against the king. This may be an idea that underlies *Magna Carta* (1215). The statutes dating from the reign of Henry VIII (1509–47) that take property for public works are important both for their recognition of the state's power of eminent domain and for their provision for compensation to the owner whose property was taken.

The earliest manifestations of the agglomerative tendency in 12th-century England seem to have announced a fundamental change in the English social system. The man who was seised (*i.e.*, put in possession) of a freehold emerged as not far different from what one would nowadays call the owner of the property, and the rights of the lords of freeholders became more like those of taxing authorities. The rights of the nonfreeholders who held land of the free tenant, however, became obscured by the fact that they were not protected in the king's courts.

Current understanding both of the purpose and of the effect of this legal development is obscured by the fact that it is not possible to date precisely when the changes either in law or in society took place. It may be, as the legal historian S.F.C. Milsom has suggested, that the purpose of the intervention of the king's courts was to shore up a system that was weakening and that the intervention, by shifting jurisdiction from the lords' courts to the king's courts, had the unintended effect of destroying the previous system.

The tendency in the later Middle Ages to give greater power to convey to the present holder of the land at the expense of his power to convey in such a way as to deprive future generations of that same power has been seen as favouring the interests of lords. But that view does not explain the whole of a complex reality. Preservation of feudal revenues is certainly important to the understanding of such developments as the abolition of subinfeudation (statute *Quia Emptores*, 1290) and the requirement that legal title to land follow the right to its use (Statute of Uses, 1535), but it does not explain why the courts first extended and then restricted the power of the landowner to entail his land.

The Continent. The history of property law on the continent of Europe has not been as well explored as that in England. The collapse of Roman and then of Carolingian power led, in most areas on the Continent, to a situation not unlike that which prevailed in England before the emergence of the central royal courts in the late 12th century. As in England, land was bound up in a mass of partly discretionary, partly customary, feudal rights and obligations. England, however, was precocious in developing central royal courts as early as it did. In most areas of Europe lords' courts remained a significant force for a much longer period, even for free tenants.

The Roman idea of property was revived on the Continent as an intellectual matter before it came to have much practical force. Beginning in the 12th century, the study of Roman law in the universities led to a renewed awareness of Roman conceptions of property, and in many areas a mixture of Roman law and canon law, known as *jus commune* ("common law"), came to be authoritative in the absence of local law. The commentators on Roman law in the 14th and 15th centuries developed ways of

The influ-
ence of
Roman
law

describing the prevailing feudal forms of property-holding in terms of the Roman law (*dominium utile*; *quasi-possessio iuris*), and this process led to making these forms of property-holding more like the Roman. Further, Roman ideas were influential both because they were part of the equipment of every university-trained jurist and because they were part of the *jus commune*. By the end of the Middle Ages the property law of most European countries was still far from that of the Romans, but it was heading in that direction. Civil law was thus displaying the same agglomerative tendency noted in more detail for England.

Explaining the origins. So far a tendency has been identified that manifested itself with sufficient frequency to be worthy of being described as a fundamental tendency of property law in the West. How can this fundamental tendency be accounted for? Clearly, it antedates the philosophy of possessive individualism of the late 17th century, and it long antedates 19th-century liberalism, although it may not antedate certain general individualist trends in Western thought. Social causes may partially account for the tendency in Roman law; but if the dominus of Republican Rome was the most important element in the political system, the same can hardly be said to have been true of the ordinary freeholder of 13th-century England and even less of the copyholder of the 16th century.

To explain the tendency, something more basic is needed than the influence of a particular philosophical idea or the dominance of one social interest over another or even the product of a balancing of social interests. Both the Roman and the Anglo-American legal systems began as mechanisms for resolving disputes. Both systems began with possession of a thing by an individual. The convenience of assuming that that possessor had all the other rights, privileges, and powers one might have in a thing may go a long way to account for the presence of the tendency in both legal systems. The tendency began as an allocation of a burden of producing evidence of ownership. A dispute arose about a thing. Both systems began by determining who is possessed of it. They then assumed that that person had all the rights, privileges, and powers that go along with property until someone else could show that that was not the case.

Although Western legal systems are not unique in beginning as dispute-resolution mechanisms, the Western concept of property is, if not unique, certainly unusual. One may speculate that what makes this dispute-resolution device operate in favour of the individual property holder in the West is an accident of chronology: the coincidence of the emergence of systematic legal thinking (associated with professionalization) and a state of society that saw one individual's connection with a thing more clearly than it saw any group's connection with the thing. Thus, the notion of individual property emerges in both Roman and English law at a time when family ties to property were weakening and legal professionalization was occurring. In the Rome of the earliest jurists (c. 100 BC) the *gens* was ceasing to have the power over family property that it probably once had. In late 12th-century England, heirs were losing their power to control their ancestor's alienations. At the same time neither society was yet prepared to see the connections with the property of such groups as slaves and sons in paternal power in Rome or serfs in England. What caused this state of society, and how important it was that there existed general notions of individual autonomy and worth before the idea developed, is impossible to say. History reveals more of what happened to the tendency after it started than it does of how it started.

PROPERTY LAW AND THEORY IN THE EARLY MODERN PERIOD

Beginning in the 17th century, developments in property law both in England and on the Continent can be related to developments in speculative jurisprudence. Although general speculation about the nature of property is at least as old as Plato and Aristotle and property is considered, sometimes quite critically, in the writings of Church Fathers of the Latin West and medieval theologians, these writings had relatively little direct effect on the secular law.

The classical theories of property. In the early 17th cen-

tury the Dutch speculative jurist Hugo Grotius announced the theory of eminent domain. On the one hand, according to Grotius, the state did have the power to expropriate private property. On the other hand, for such a taking to be lawful, it had to be for a public purpose and had to be accompanied by the payment of just compensation to the individual whose property was taken. The idea was not new with Grotius, but he stated it in such a way that it became a commonplace of Western political thought.

In the late 17th century Samuel von Pufendorf refined a theory of the origins of property rights that had been in existence since ancient times. Property, Pufendorf said, is founded in the physical power manifested in seizing the object of property (occupation). In order, however, to convert the fact of physical power into a right, the sanction of the state is necessary. But the state cannot, Pufendorf seems to suggest, make a property right where physical possession is not present. Thus, both occupation and state sanction are necessary conditions for the legitimacy of property.

Pufendorf's contemporary John Locke had a different theory, again one that had considerable antecedents. What gives a man a right to a thing, according to Locke, is not simply his seizing of the object but rather the fact that he has mixed his labour with the thing in making it his own. This right to a thing arising out of labour is a natural right. It does not require state sanction in order to be valid. It should, however, be protected by the state. Indeed, property is fundamental to the contract that people make in forming the state, and for the state to deny the right to property is a breach of this contract.

The end of the 18th and the beginning of the 19th century saw the emergence, particularly in England, of a new set of ideas about property, influenced by ideas prominent in the Scottish Enlightenment but given a new and powerful twist by the utilitarian political philosopher Jeremy Bentham. Property, according to Bentham, is nothing but an expectation of protection created by the legislator and by settled practice. It is, however, an expectation that should be carefully respected. Since the function of the legislator is to maximize the sum of human felicity, he should know that rarely does any interference with property produce more felicity than it destroys.

Bentham's follower John Stuart Mill associated property with liberty and suggested that security of property is essential for man to maximize his potential for liberty. Modern economic theories of property that justify property on the ground that there must be an initial allocation of resources to allow the market to operate and on the ground that individual property rights minimize transaction costs derive from the tradition of Bentham and Mill.

On the Continent, thought about property took a somewhat different turn. Building on Immanuel Kant's categorical imperative that persons must always be treated as ends in themselves rather than as means, Georg Wilhelm Friedrich Hegel suggested that the same imperative applies to a person's property. The reason for this, according to Hegel, is that when someone extends his will to a thing, he makes that thing a part of himself. Protection of property is thus intimately connected with protection of the human will.

The middle of the 19th century saw the first concerted attacks on the institution of property since the time of the early Christians. *The Communist Manifesto* (1847) of Karl Marx and Friedrich Engels holds that property is nothing but a device in the social warfare between the capitalist and proletarian classes, the means by which the capitalist expropriates the labour of the proletarian and keeps him in slavery. Reform, according to Marx and Engels, would not come until the revolution, when property would be abolished.

Possessive individualism and the law. The 17th- and 18th-century theories of property, particularly Locke's, have been called possessive individualism. The importance of property in these theorists' overall conception of man and the state is undeniable. The extent to which possessive individualism manifested itself in the development of property law in the late 17th and 18th centuries is not so clear.

The theory of eminent domain

Hegel

In England, Sir William Blackstone's concept of property was curiously bifurcated. In a famous passage he lists property along with life and liberty as one of the absolute rights of Englishmen, but when he comes to restating the rules derived from this absolute private right, the tendency to absolutism is far less manifest. Blackstone's encomium of property reflects much that had been expressed before in the philosophy of possessive individualism, but it is not until the Fourth and Fifth Amendments to the U.S. Constitution in 1791 that one finds these ideas embodied as specific legal principles. And it was not until the second half of the 19th century that they received any substantial elaboration in American federal jurisprudence.

More careful research might be able to trace the influence of the ideas of the 17th- and 18th-century continental theorists of property in areas other than international law, about which most of them wrote. Prior to the French Revolution, however, it is hard to see any other specific legal manifestations of their theories.

What one does see in writings about property law on the Continent from the 16th through the 18th century, however, is the increasing dominance of ideas drawn from Roman law. In the 16th and 17th centuries local customary law was redacted into brief statements of rules. The redaction process itself had a tendency to magnify the influence of the *jus commune*, because what could not be found in the local custom was filled in with the *jus commune*. The local customs were then subjected to academic commentary that made use of the categories of Roman law, including the category of property. Finally, particularly in Germany, the entire corpus of scholarship on Roman law was brought to bear on local law, integrating it more fully into the European mainstream (a movement called *usus modernus pandectarum*).

Marxism, liberalism, and the law. Not surprisingly, relatively little of Marx's theory of property showed itself in property law until a Marxist revolution took place in Russia in the early 20th century. For utilitarianism and Hegelianism, and their combination in various forms of liberal thought, the evidence of influence is more pronounced as the 19th century progressed.

Nineteenth-century legal change. The beginning of the 19th century saw the promulgation in France of the Napoleonic Civil Code (1804), a systematic and comprehensive code of private noncommercial law that was to have great influence in the European codification movement which followed. The code is notable for its reluctance to recognize interests in property other than the owner's. This is probably to be accounted for by the fact that the codifiers were determined to abolish what they called feudalism—hereditary class privileges and all that was associated with them—and one of the characteristics of feudalism in the codifiers' minds was the recognition of multiple outstanding interests in land. While it is chronologically possible that the code's concept of property was influenced by utilitarian ideas, most of what is in the code can be adequately explained by the concept of property that the drafters of the code found in Roman law and in continental writing in the Roman law tradition.

Liberal conceptions of property seem to have influenced legal thought later in the 19th century. On the Continent the pandectists, a group of systematic jurists prominent in Germany, took the agglomerative tendency inherent in the Roman conception of property and developed it to a point that most modern commentators find goes far beyond what the Roman sources themselves suggest. Their ideas were embodied in the German Civil Code (effective 1900) and had substantial influence on the codes of other countries.

The tendency toward absolutism in matters of property is also remarkable in Anglo-American law on both sides of the Atlantic. The English Settled Land Acts (1882, 1890, 1925) gave considerably more power to the present holder of settled land than the common law had given him. The Married Women's Property Acts in both countries (England from 1857; United States from 1839) divided property within the marital unit by assigning it to one or the other spouse. The examples could easily be multiplied.

In the United States the influence of liberal ideas on

the development of the law of property can be seen most strongly in the substantial jurisprudence that emerged concerning the protection of property against the state. On the federal level, this development came after the passage of the Fourteenth Amendment to the U.S. Constitution in 1868. This amendment prohibits, among other things, any state from depriving a citizen of property without due process of law. Under this rubric, many types of economic and land-use regulations were struck down by the U.S. Supreme Court on the ground that they interfered with citizens' property rights.

As in the case of Roman law, so too in the case of 19th-century Anglo-American law, focusing on what is called property law may obscure the reality of the total law with respect to the possession, use, and conveyance of things. Thus, while the rights, privileges, and powers of the owner seemed to expand, other legal developments undercut them. For example, while the types of permissible easements (a property interest in land other than the owner's) were restricted in the 19th century, the English equity courts in the same period created a new form of obligation, now called equitable servitudes, which served the same function as easements and were not subject to the same restrictions (*Tulk v. Moxhay*, 2 Ph. 774 [Ch. 1848]). While the agglomerative tendency affected the law of trusts, the express trust resisted any attempt to defeat its basic division of legal from equitable title. Indeed, trusts were increasingly used as a form of holding newly important aggregations of personal property. Similarly, the increasing complexity of land-use conflicts led to an ever growing body of local land-use regulations, and the first comprehensive planning act was passed in England at the beginning of the 20th century (Housing, Town Planning, etc. Act of 1909).

Nineteenth-century legal thought. Perhaps because the category property told little of the real extent of the property holder's rights, privileges, and powers, the analytic jurists of the 19th and early 20th centuries were not so successful in constructing a system of "scientific" property law as they were in other areas of private law. Analytic jurisprudence in the Anglo-American realm tended to focus on the aspects of property law to which its technique was peculiarly adapted. Thus, the laws relating to common-law estates in land and future interests became the system of estates and future interests; the doctrine of perpetuities became the rule against perpetuities; and the doctrine about the three types of private land-use controls—easements, covenants, and equitable servitudes—was systematized. The first *Restatement of the Law of Property* in the United States (1936–44) limits itself to the two broad areas of estates and future interests (including the rule against perpetuities) and private land-use controls. Notably missing from the restaters' efforts were conveyancing law (except to the extent that it was included in estates and future interests), landlord and tenant law, public control of land use, and the law of natural resources.

Similarly on the Continent, the concept of possession received loving elaboration in the 19th century. In the hands of some pandectists it yielded striking echoes of Hegel's will theory. The various schemes of marital property were carefully delineated. Conveyancing, considered a matter for notaries rather than academic jurists, was largely ignored. Land-use regulation was left to public law and, hence, outside the ambit of those concerned with property.

The social situation. The social situation within which the law was operating changed markedly over the course of the 17th through the 19th centuries. In England in the 17th century the abolition of most of the lord's rights to receive money from his freehold tenants relegated the tension between the free landowner and his lord to the background, and a new tension emerged between the established country landowner seeking to perpetuate his family on his land and the newly wealthy man of commerce seeking to buy country land. While lordship remained a force on the Continent throughout the 18th century and in Germany into the 19th century, the same tension between noble and bourgeois was also apparent. The restrictions on the power to tie up land for long periods of time, which the law either invented or extended in

this period, favoured commercial interests. That the law stopped short, considerably short in the case of the Anglo-American law, of abolishing all restrictions on the power of the conveyee himself to convey is a product not only of a recognition of the tension in the fundamental tendency to agglomerate but also of the power of the countrymen and their conveyancers to influence the course of legal development.

Industrial
versus
agricultural
land uses

By the 19th century the conflict between the established landowner and the merchant gave way to a conflict between industrial and agricultural land uses, and the key issue was not the power to alienate land but the privilege to use it. In Anglo-American law the 19th-century courts gave broad scope to industrial development of land at the expense of adjoining residential and agricultural uses. The courts, however, at no time recognized an absolute privilege of land use, and this may be seen as a product both of the inherent tension in the fundamental tendency and also of the fact that the agricultural classes retained some social power. The developments on the Continent are less well known, principally because of the civil-law tendency to relegate land-use control to the area of public law and hence outside the purview of property.

The fundamental tendency revisited. As the need arose for a category to describe the sum of the rights, privileges, and powers that an individual could have with respect to a thing, the Romans, followed by the English, chose a noun derived from an adjective that means "own." The category at once described the concept and also the tendency. As time went on, the tendency took on an independent life. Western law excluded from the category property certain rights, privileges, and powers with respect to a thing because they existed in someone other than the property holder. In modern legal systems, though not in the Roman, property came to represent one of the rights of the individual against the state, perhaps originally because property had come to rest in the freeholder and not in his lord, and the king was the lord of all. The tendency was reinforced by philosophical ideas; social forces not only attached themselves to it but also arranged themselves around tensions within it.

In classical Roman law and in the late 19th and early 20th centuries, when the agglomerative tendency was at its strongest, the sum of rules pertaining to things undercut the tendency, but if one looked solely to the rules labeled property, the system of categorization obscured this fact. The question even was raised with regard to Roman law whether the strength of the tendency made any difference. One suspects that it did. In the United States in the 19th century, the categorization process clearly allowed the tendency to work in a more unfettered fashion than it would have if more conflicting interests had had to be reconciled under one category.

RECENT HISTORY OF THE WESTERN CONCEPT OF PROPERTY

The first half of the 20th century saw an extended debate in the United States about the extent of permissible state interference with property rights. One by one the more extreme doctrines of the late 19th and early 20th centuries were struck down. By the mid-1930s federal and state regulation of the economy could no longer be challenged on the ground that it constituted a deprivation of property rights without substantive due process of law, and direct restrictions on the use of property in the form of comprehensive zoning and planning ordinances had been sustained. Thus, the trend seemed clearly away from use of the property clauses of the Constitution to protect citizens against the state.

State interference
with
property
rights

Neither the United Kingdom nor the countries of the Continent make as much use of judicial review of public regulation as does the legal system of the United States, and neither the United Kingdom nor the Continent ever went as far as the United States in disabling the state from acting in areas that affected property rights. Both the United Kingdom and the Continent have strong traditions of protecting property rights against state interference, however, and despite these traditions the 20th century has seen increasing state regulation of property. The debates tend to be legislative rather than judicial, and, although

the regulators do not always win, over the course of the century they have won more than they have lost.

As part of their effort to permit greater regulation of property rights, the legal realists in the United States in the 1920s began to attack the categorization process itself. In both the public and the private law of property they found an easy mark, if only because the systematizers had been less successful there than in other areas of private law. Thus, in the late 20th century, the concept of property in the United States is a matter of controversy. The fundamental tendency has received a major setback in the field of public law, and the whole process of categorization with which the tendency has been associated is discredited.

In the United Kingdom and on the Continent, because property is less of a constitutional concept, it is less necessary to take a position about it. The growth of public regulatory law has meant that the concept of property may remain more or less intact but is of less relevance to the sum of rights, privileges, and powers with respect to things. Thus, in these countries modern controversies that strongly affect property in the descriptive sense are not always seen as involving property in the legal sense in the way that they are in the United States.

Objects, subjects, and types of possessory interests in property

Property law has been defined in this article as the sum of jural relationships with respect to things and things as all tangible things and those intangibles that the legal system in question classifies as property. This definition creates difficulties when one comes to describe property systems generally because it mixes a definition of things that is external to a given legal system with a definition of things that is dependent on the legal system in which it is found. The difficulty becomes more acute as one moves from general definition to subordinate levels of classification, for at these levels of classification, almost all the terms are specific to a given legal system or group of systems.

Most of these difficulties of bias in favour of one legal system or another can be avoided by acknowledging in advance where a particular scheme of classification comes from. The one used in this article is based on that employed in Western legal systems. Where the Anglo-American and the civil-law systems diverge, the categories of the Anglo-American system are considered first and are then compared functionally with those in the civil-law system.

The discussion begins by identifying the objects (things) and subjects (persons and groups) of the jural relationships with regard to things in Western legal systems generally. There follows a treatment of possession and ownership, categories that are closely related historically in the West. Then the discussion deals with divisions of ownership and in so doing contrasts the divided ownership system of the Anglo-American law with the devices in the civil-law system that achieve many of the same practical results while employing a quite different set of concepts. The section closes with the procedural protection of property interests.

OBJECTS

Classification of "things." The Roman jurist Gaius (c. AD 160) includes in his treatment of the law of things the acquisition and loss of individual things, succession (both testate and intestate, including legacies, with some references to what today would be called bankruptcy), and the acquisition and extinction of obligations (contracts and delicts). If one views Gaius' category of the law of things as equivalent to the descriptive definition of the law of property used in this article, then his category "property" is very broad indeed.

In civil-law systems today the term "property" applies to those tangible things that can be conveyed *inter vivos* and to a very few, if any, intangibles. Patrimony is a broader term. It includes everything that is the object of the law of succession. Obligations are defined in contradistinction to property. They do not receive the procedural protection that property interests receive, and the state is not as constrained in dealing with them as it is in dealing with property interests.

Property
patrimony,
and
obligations

Anglo-American law is generally less concerned with matters of definition than is the civil law. Except in the United States, where defining something as property automatically entitles it to constitutional protection, there is less discussion in the Anglo-American legal system of whether a given interest or a given thing should be classified as property or not. Nonetheless, Anglo-American law shows broadly the same characteristics as the civil law. Almost all tangible things are conceived of as being capable of supporting property interests; some intangibles are treated the same as tangibles, and some are not.

Within and without commerce. Of all things, Gaius says, some are of divine right (*divini juris*) and some are of human (*humani juris*). Of those that are of human right, some things are of public right (*publici juris*), and some things are things of individuals (*res singulorum*). Other Roman jurists further divided some of the things in Gaius' category of public right into things that by natural law are common to all (*res naturali jure communes omnium*) and things that belong to no one (*res nullius*). Some medieval jurists combined elements in the categories of things of divine right, things of public right, things of no one, and things common to all in a single category of things outside commerce (*res extra commercium*). These schemes point in somewhat different directions, but they all deal with the same core idea: some tangible things are withdrawn from the normal operations of property law. Modern jurists have attempted to categorize these things more precisely, though with no more success than the older jurists.

Religious things. The Roman category of things of divine right has generally been abolished in the West, and things that are dedicated to religious use are normally conceived of as the property of a state-established or state-recognized religious group. The religious group may, in turn, have internal rules that require that things associated with the religion be treated differently from other kinds of things. Roman Catholic canon law, for example, allows a diocesan bishop to relegate a church to profane uses only if he determines that serious reasons suggest that the church no longer be used for worship and that the good of souls will not be impaired; he must consult his presbyteral council and obtain the consent of those legitimately claiming rights in the church.

Non-Western legal systems, particularly religious legal systems, tend to retain a special category for things dedicated to religious or charitable use. Thus, in Hindu law the deity represented by an idol is regarded as owning the property dedicated to its use. Similarly, assets in an Islāmic waqf (foundation, charitable trust; see below) are regarded as belonging to God.

Things that cannot be possessed. A rather large group of tangible or at least perceptible things are withdrawn from commerce in most Western legal systems because of the difficulty of imagining how one could possess them. The ambient air, for example, is normally not the object of property. The effect of this doctrine has been to make air a free good, subject to pollution by anyone who has the capability of polluting it. Modern concerns with air pollution have led some commentators to suggest that recognizing property rights in the air might lead to more efficient control of air pollution.

Wild animals. All Western legal systems have special property rules about wild animals. Roman law, followed with some modifications by English law, held that wild animals belonged to no one until they were captured. Once captured the animal belonged to its captor unless the animal escaped and returned to its natural liberty. The capture of fish and game is regulated everywhere in the West, and some legal systems hold that such animals belong to the state unless and until they are captured in a manner conforming with the regulatory scheme.

Water. Water and the land under and bordering on water are everywhere in the West treated differently from other kinds of property. In Roman law navigable water and beaches were common to all. As in the case of wild animals, modern law in the West tends to give substantial power over water and land near water to the state. Beyond that the regimes vary substantially from jurisdiction to jurisdiction.

In England, navigable waterways are the highways of the monarch, open to all who have access to them. Access, however, is not guaranteed. Because private ownership extends from the low-water mark, the public has access to water and so may use it for navigation only if there is a public right-of-way leading to the water.

In the United States the same rules apply so far as access is concerned, but beaches may, depending on the jurisdiction, be subject to a public right of passage up to the high-water mark. The United States also has a well-developed law concerning the taking of water from a navigable or nonnavigable stream. In the eastern part of the United States the right to take water from a stream is dependent on ownership of lands adjoining the stream. In the western part of the country the right to take water tends to depend on having first taken it (prior appropriation). In both parts of the country public regulation has increasingly come to the fore, and the fact that water was historically not an object of private ownership has made it easier to introduce regulatory control over this resource.

Other natural resources. Other natural resources have, in some Western legal systems, been removed from normal private ownership. The tendency on the Continent is to make all minerals subject to state ownership or at least to extensive state control. Historically in England gold, silver, and lead were reserved to the crown. In the United States private ownership of minerals has been the rule, subject to considerable state regulation in the name of conservation. Just as the systems of private ownership with regard to water have tended to divide between those systems that award the water to the person who has it on his land and those that award it to the person who discovered or appropriated it, so, too, those Western systems that allow private ownership of minerals alternate between giving them to the landowner and giving them to the discoverer.

The human body. Throughout the West, the human body, living or dead, is not an object of private property. This fact has raised difficulties in many legal systems. For example, if the human body is not property, the question arises of what is happening when someone makes a gift of or sells blood or bodily organs or makes a testamentary disposition of his body for medical purposes. Many jurisdictions have special legislation on this topic, but the conceptual difficulty is by no means resolved.

Possession of tangible things. Possession of a tangible thing is, at least in the West, a concept that antedates conscious thought about law. Possession is a fact, the Roman jurists said, formed of an intention and a thing (*animus et corpus*). The thing was basically anything that was capable of being physically possessed; the intention was to hold it as one's own.

English law also had to deal with a fairly complicated social fact, seisin, the process by which a lord put his man in possession of a tenement. In English law the concept of seisin was also applied to tangible things other than land, things that were not subject to lordship. Together the two concepts of seisin came to equal something quite close to the Roman possession.

Any legal system that begins its property law with a concept of possession is going to have a property law biased in favour of tangible things. It is easy for Westerners to conceive of possessing almost anything that can be touched. It is far more difficult to conceive of possessing an abstraction like a right, a privilege, or a power. Westerners who are not lawyers will say that they possess their watches or their land; they will rarely say that they possess their bank accounts or the power to convey their land.

Possession of intangible things. Civil law, following Roman, has tended to deny the possibility of legal possession of anything that cannot be touched. English law, by contrast, and, following English law, Anglo-American systems generally are more open to the notion that one may be possessed of a right, a power, or a privilege.

Because possession is so fundamental to property in both Anglo-American and civil law, the civil-law systems' greater reluctance to recognize possessory interests in intangibles has important consequences for the way the two systems conceive of property rights. In the case of land,

Highways of the monarch

Seisin

civil law tends to give possession to the owner of the land and to be reluctant to recognize property rights in anyone other than the owner. Anglo-American law, however, recognizes multiple possessory rights in land and hence tends to speak not of ownership of the land but of ownership of an interest in land—*i.e.*, of an intangible legal abstraction in a tangible thing.

Although the abstraction of interests in land came early in the development of the English law, it was not until quite recently that Anglo-American jurisdictions recognized the possibility of divided possessory interests in movable property, and the English legal system may not recognize it to this day. Abstraction of contract rights and duties was also slow in developing. It was not until the 19th century that contract rights became freely assignable, and it was not until the same century that methods were developed whereby they could be protected against interference by third parties. Because contract rights were not assignable and because they could only be enforced against the maker of the contract, it was difficult to conceive of them as property. Bank accounts and stocks and bonds are simply standardized forms of contract rights, and so it was as difficult to conceive of them as property.

Negotiable
instru-
ments

The conceptual breakthrough came with regard to negotiable instruments. A promissory note (an agreement to pay back a loan), for example, made payable to the creditor "or order," is freely assignable by the creditor and by anyone to whom the creditor may assign it. The assignee (holder in due course) is also entitled to recover the debt even if the original creditor could not recover it (because, for example, it was part of a larger transaction in which the creditor had failed to perform his part).

Since the negotiable instrument is freely assignable and since it is enforceable without regard to the underlying transaction, it has two of the general characteristics of property: it is freely alienable and enforceable without regard to the relationship of the right-holder and the one against whom enforcement is sought. Negotiable instruments are thus sufficiently like property that Anglo-American law came to regard them as a species of property. Other forms of contract rights, such as bank accounts, followed. Today most forms of contract rights are treated for many purposes as property in Anglo-American law.

On the Continent historical development since the Middle Ages has moved away from the Romans' thing-oriented conception of property. The development came first in the doctrines about possession. While the medieval jurists recognized that one could not physically possess a right, they nonetheless developed possessory remedies for those who had been deprived of intangible rights that they had long enjoyed (quasi-possession of rights). The development, however, was aborted. The concept of quasi-possession of rights was associated with feudalism, in the context of which it had developed. With the abolition of feudal forms of property at the time of codification, the treatment of intangibles as property tended to be suppressed. Negotiable instruments, although they were (and are) recognized on the Continent, were treated in different kinds of courts. When codification came, they were not incorporated in the civil codes but were left in the commercial codes, and their use was frequently limited to those who could qualify as merchants.

This development could not last for long in a world in which contract rights are the principal means for the storage of value. The French civil lawyers, for example, soon came to recognize that it was possible to have a property interest in an intangible, and French developments in this regard have tended to parallel the Anglo-American. The German civil code, however, proved more intractable. The code specifically excludes the possibility of property in intangibles; so the development of property interests in contract rights in Germany has been devious. By the middle of the 20th century, however, German jurists had developed mechanisms whereby intangible rights and privileges could be transferred and protected in ways quite similar to property interests, despite the fact that they cannot be called property.

Government-granted rights as property. The 19th and 20th centuries have seen a great expansion of the types

of intangible rights granted by the government. The oldest of these are the exclusive rights given by the state to encourage and protect authors, inventors, manufacturers, and tradesmen. Copyright, the exclusive right to prohibit the copying of a piece of writing or a work of art or music, is almost universally regarded as a property right. In the Anglo-American system it may be enforced by an injunction—a characteristic of property rights generally. In most Western systems copyrights are freely assignable. They are normally protected against state interference in the manner of other forms of property. Patents, the government-granted right to the exclusive use of an invention, and trademarks, the government-granted exclusive right to market one's product with a given distinctive sign or symbol indicating its source, receive similar treatment in most Western countries.

The last generation has seen considerable debate in the West about whether property-like protection should be extended to other forms of government benefits. Modern Westerners are heavily dependent on the government. Most professions and many trades and businesses cannot operate without a government license. Citizens of virtually every Western country are protected against unemployment by a system of government insurance. Those who cannot work frequently subsist on government grants. Many of the elderly live on government pensions or other forms of social welfare. In many Western countries the government provides medical services or health insurance.

All these benefits have increased dramatically in number and importance over the course of the 20th century. By and large the law concerning them is treated by jurists as a matter of public or administrative law. While they are clearly as important or more important to the citizen than the traditional forms of property, it was not until 1964 that the American educator and lawyer Charles Reich suggested that the legal system should treat them like property. His suggestion was favourably received, at least for a period, by the courts in the United States. It then seemed to disappear from view.

In the United States it seems clear that the legislature may make a grant to an individual or group of individuals in such a way as to entitle that individual to property protection in the grant. The grant may then not be taken away without due process of law in a procedural sense. The grant may even be made in such a way that it cannot be taken without the payment of compensation. In other countries in the West the courts have been less involved in these public-law programs. It is perhaps all the more notable, therefore, that throughout the West there has been a tendency in recent years to make at least certain kinds of government grants more secure. As a general matter, government grants can be taken away for fewer reasons, and the process by which they can be taken away has become more elaborate.

The same tendency toward property-like treatment is also noticeable throughout the West with regard to certain kinds of arrangements between private citizens. Landlord-tenant law, for example, a traditional topic of property law at least in the descriptive sense, has tended to give greater security to the tenant (see below). Western law has also tended to give greater security to employees (who are not the holders of property rights even in the descriptive sense), requiring, for example, that an employer justify discharging a long-term employee. Employer-provided pension plans have come under increasing regulation. In the United States the Employees Retirement Income Security Act of 1974 (ERISA), for example, requires that after a period of time an employee's pension rights shall be deemed to have vested—*i.e.*, that the employee be entitled to a fixed amount from the pension plan, even if he quits his employment.

Movable and immovable property. If the distinction between tangible and intangible property has become increasingly blurred in Western law and if the category of intangible property seems to be increasingly expanding, the distinction between movable and immovable tangible things has remained relatively fixed. As noted above, Anglo-American property law began as a law concerning land. The actions that protected interests in land were real

The "new
property"

Real and
personal
actions

actions, real both in the sense that the interest claimed was notionally good against the whole world and real in the sense that the remedy afforded was the recovery of the land itself or the interest claimed in it. Movable objects, by contrast, were protected by personal actions—personal in the sense that one had to allege that the defendant had committed some wrong in order to recover and personal in the sense that money damages, not specific recovery of the thing, were normally the only available remedy. Reflecting these two types of actions, immovable property came to be called real property, and movable property, personal property.

Beginning from a law that made a radical distinction between interests in land and all other kinds of property, modern Anglo-American law has gradually come to view both kinds of property as similar. There remain, however, in many jurisdictions distinctions between the two that are more the product of the historical development than they are of any modern functional distinction. In almost all Anglo-American jurisdictions, for example, different forms of conveyance are used depending on whether the property conveyed is real or personal. The types of interests that may be recognized in the two also vary in many Anglo-American jurisdictions.

Modern civil law, by and large, has followed Roman law in minimizing the distinction between movables and immovables. Certain types of privileges of use are recognized only in land, but these tend to be interests that could not be had in a movable good, such as a right-of-way or a privilege to build. Conveyance of land may be somewhat different, but not radically different, from conveyance of movables. Statutes of limitation or periods of prescription may be longer for land than for movables. On the whole, however, the differences are not so great as they are in Anglo-American law.

All Western legal systems recognize that things attached to the land, such as trees or buildings, can become part of the land, so that they are automatically conveyed if the land is conveyed. Jurisdictions differ as to the extent to which it is possible for a landowner and someone else to agree that something built on the land will not become part of the land and as to the extent to which it is possible to convey something attached to the land separately from the land. Generally, the Anglo-American law of fixtures (things permanently attached to the land) pays more attention to the intent with which the attaching was done than does the civil law and gives greater freedom to convey fixtures separately from the land.

The law of
fixtures

SUBJECTS

The topic of the subjects of property rights has been greatly affected by the agglomerative tendency. Both Anglo-American and civil law sought a single legal person in whom the vast complex of property rights, privileges, and powers could be said to reside. Historical shifts in the law of persons (the recognition, for example, of more persons as being of equal status before the law) have created more persons to whom the agglomerative tendency could attach but have not defeated the tendency. The fact that modern law freely allows the creation of fictitious legal persons (corporations) has, if anything, exaggerated the tendency.

Single individuals. In both Anglo-American and civil law the paradigmatic holder of property is a single human person. The fact that in the West today far more wealth is held in some form of co-ownership or corporate ownership has not yet affected this paradigm.

Historically, property-holding capacity was quite limited, and the capacity freely to deal with property was even more limited. In classical Roman law, for example, only free adult male citizens not in paternal power were fully capable of holding and exercising property rights. Since paternal power lasted until the death of the parent or ancestor (there was no automatic emancipation), since a large percentage of the population were slaves, and since more than half the population were women and boys, very few people, in fact, qualified as subjects of full property rights. The situation in medieval England was not too different. Automatic emancipation at the age of 18 or 21 and the notion that adult unmarried women had prop-

erty-holding capacity somewhat expanded the number of persons having property-holding capacity, but serfs, aliens, children, and married women had limited property-holding capacity or capacity to deal with property.

The gradual abolition in Anglo-American and civil law of principles and rules based explicitly on personal status has made it easy to forget the limitations that still exist on property-holding capacity and on the capacity to deal with property. Thus, many Western jurisdictions still limit, in some way, the property-holding capacity of noncitizens. Many of the Western countries that have indigenous non-Western peoples living among them have separate rules concerning these peoples' property-holding capacity. Such regimes exist, for example, for American Indians who reside on reservations, at least with regard to tribal land.

Many citizens who are legally capable of holding property are not legally capable of dealing with it. In Western legal systems generally, children are recognized as capable of owning property, but they cannot deal with it without the consent of their parents or guardians. All Western legal systems have procedures whereby incompetent adults can be deprived of their capacity to deal with property. These procedures generally provide for the appointment of a guardian for the incompetent; the guardian is authorized to deal with the property on the incompetent's behalf.

Restrictions on both the property-holding capacity and the capacity to deal with property of competent adult women have largely been abolished in the West. Marital property regimes differ substantially, however, and although the trend is in the direction of equalizing the powers of husband and wife, full equalization of the power to deal with marital property has not been achieved in all Western jurisdictions.

The abolition of slavery and serfdom in the 18th and 19th centuries in the West has meant that with few exceptions competent Western adults are fully capable of holding and dealing with property. Having the capacity, of course, is not the same thing as having property. It is sometimes suggested that if the older law perpetuated inequalities by its explicit recognition of different statuses, the newer law may be doing the same thing by refusing to recognize real social inequalities.

Groups. Despite the tendency of Western legal systems to regard individual ownership as paradigmatic, all Western legal systems allow a number of different forms of group ownership. The categories offered below are not exhaustive, but they give some notion of the various forms of group ownership that may exist.

Concurrent individual owners. All Western legal systems recognize that a group of individuals may each have an undivided ownership interest in a thing. This is the norm, for example, when property is inherited by a group of siblings from a parent, but it is also possible for an individual owner to sell or give a piece of property to a group.

The two most commonly recognized forms of co-ownership in Anglo-American jurisdictions are joint tenancy and tenancy in common. In both forms of tenancy each tenant has the right to possess and the privilege to use the whole thing. If it is physically impracticable for them all to possess or to use the thing, they must agree among themselves who will have possession in fact, since all have possession in law. If they cannot agree, one or more of them may petition the court to have the thing partitioned among them. If partition in kind cannot be had, the court will order the thing sold and the proceeds to be divided among the erstwhile cotenants.

The two forms of cotenancy differ when it comes to succession and to the power to convey. In joint tenancy, if one of the joint tenants dies, the remaining tenants succeed to his share (moiety). In tenancy in common, if one of the tenants dies, his heirs or devisees succeed to his moiety. In joint tenancy, if one of the joint tenants conveys his moiety *inter vivos*, the conveyance destroys the survivorship interest of his cotenants so far as that moiety is concerned. The conveyee takes not as a joint tenant but as a tenant in common with the other tenants. In tenancy in common, however, conveyance operates like succession. The conveyee takes the same undivided interest that the conveying tenant had.

Civil-law systems recognize a form of co-ownership similar to the Anglo-American tenancy in common (*co-propriété; Miteigentum*). It is not possible in the civil-law systems to hold property in a form in which one's cotenants automatically succeed to it. French law, like Anglo-American, allows co-owners to demand partition of a cotenancy and is hostile to attempts to restrict this power. German law, however, has a form of cotenancy (*Gesamthand Eigentum*) in which the cotenants cannot partition the tenancy property, although they may alienate their shares. This form of cotenancy is used for many kinds of partnerships, including the partnership of coheirs that exists until the deceased's estate is settled and divided.

At English common law, partners held partnership property in their individual capacities. They were obliged to account to their partners for profits earned from it, but the ownership interest was in the partner individually, not in the partnership. The common-law rule prevails in England today. In many American jurisdictions, however, legislation allows the partners to hold partnership property in a form of cotenancy, known as tenancy in partnership, which is quite similar to the German *Gesamthand Eigentum*. Roman law treated ownership by partners in a way similar to the English common law, but that rule has, in general, not survived in the modern civil law. Those civil-law countries that do not recognize a form of ownership like the *Gesamthand Eigentum* tend, like the French, to recognize the property-holding capacity of the partnership itself. Thus, partnerships in these countries are treated like corporations (see below) for property-holding purposes.

Marital owners. English common law, after some hesitancy, adopted a regime of separate marital property. The wife had her property, the husband his. The only things that they owned together were things that had been conveyed to them together in a form of tenancy known as tenancy by the entirety (which still exists in a number of American jurisdictions). Tenancy by entirety is like joint tenancy in that the surviving spouse takes the whole of the property upon the death of the other spouse. It differs from joint tenancy in that it is not possible for one of the spouses to convey his or her interest so as to defeat the survivorship right of the other.

At common law, each spouse's separate property in land was subject to an expectancy in the other spouse. If the husband survived the wife and if a living child had been born to the marriage, the husband was entitled to curtesy, a life estate in all the lands of which his wife was seised during the marriage. If the wife survived the husband, she was entitled to dower, a life estate in one-third of all the land of which her husband was seised during the marriage.

The 19th-century Married Women's Property Acts had little effect on this basic system. The acts removed the husband's power to control his wife's property during the marriage, and they made it clear that the wife had the capacity to own personal property separate from her husband, but the basic scheme of separate property, curtesy, and dower remained.

What changed the system was the great increase in the amount of wealth held in personal property. Such property was the subject of neither dower nor curtesy. In the United States, although not in England, most jurisdictions provided for a forced share for widows. Under the forced-share system, the widow could waive her dower and any interest that she stood to take under her husband's will and take instead a share (normally a third or a half) of her husband's net estate.

The movement for equality for women in the latter half of the 20th century wrought another change in this system. Today, most American jurisdictions provide for a forced spousal share rather than simply a widow's share. Interests denominated dower and curtesy still exist in some jurisdictions, but they have been made sex-equal.

In the civil-law jurisdictions and in eight states of the United States, a different system of marital property prevails. As in the common-law system, husband and wife each have their separate property, but this is only the property they had prior to the marriage or property they received by gift or inheritance during the marriage. All property that is the result of earnings of either spouse

during the marriage is community property, as are, in some of the civil-law jurisdictions, all movables. Separate property descends to the heirs of the spouse who holds the property, but community property is generally divided in half upon the death of the first spouse to die. Half of it goes to the surviving spouse and half of it to the heirs of the first-dying spouse. Other community-property jurisdictions give the first-dying spouse's portion of the community to the surviving spouse, at least in the absence of a testamentary disposition to the contrary.

Both the common-law and the community-property systems arose at a time when divorce was not as common as it is today. In common-law property jurisdictions the tendency now is to allow the judge wide discretion to divide the property of a divorcing couple without regard to who holds title to what. In community-property jurisdictions the tendency is to divide the community and to leave the separate property with the spouse who has title to it.

The importance of marital property for the concept of property in the West cannot be overestimated. Although spouses have some power to change their marital property arrangements by private agreement, most married people in the West today live under a regime either of community property or of separate property subject to division upon divorce and to a forced share in the surviving spouse. One might well question to what extent any Westerner who is married can be said to have individual property when his or her spouse has so much of a stake in it.

Corporate owners. Throughout the West the vast bulk of productive assets are owned by fictitious legal persons (corporations, companies, *sociétés, Gesellschaften*), created under general incorporation statutes that allow such fictitious legal persons to engage in a wide variety of profit making and, frequently, of eleemosynary endeavours. This development is of relatively recent vintage, but it is so common today that it needs hardly to be stated.

What does need to be stated is the consequence of this fact for property law. If one asks who has the right to possession, privilege to use, and power to convey property of a corporation, the legal answer is that the corporation does, just as if it were an individual. But a corporation is not an individual; it is a fiction. People act collectively through a corporation. The seeming simplicity of corporate ownership masks a variety of interests.

Throughout the West the model of the corporation is that of shareholders owning the corporation. In the most common types of corporation the shareholders choose the directors of the corporation, who, in turn, choose the management of the corporation, who direct its day-to-day affairs. But the shareholders do not own the property of the corporation. They own a piece of the corporation itself; they have neither the right to possess, the privilege to use, nor the power to convey the corporation's property. Only if the corporation is liquidated, and after the corporation's creditors have been paid, are the shareholders able to claim any portion of the corporation's property.

Nor do the directors own the property of the corporation. According to the model, they manage the affairs of the corporation in a fiduciary capacity looking after the interests of the shareholders. They do have the right to possess, the privilege to use, and the power to convey the corporation's property, but they are subject to an overriding obligation to the shareholders. (Increasingly, in the modern world they may be subject to overriding obligations to others than the shareholders: creditors, workers, or the public at large.)

The managers of the corporation would seem to be the least likely candidates for the label owners of the corporation's property. According to the model, the managers are not the hired servants of the corporation. They are not only bound by fiduciary duties to the corporation, but they are also subject to the directors' control. But the larger and more complex the corporation, the more likely it is that the effective right to possess, privilege to use, and power to convey the property of the corporation will be exercised by the management of the corporation, with the express or tacit consent of the directors and with the much more notional consent of the shareholders.

Community or state owners. In every Western legal

Com-
munity
property

Tenancy
by
entirety

The
model of
a corpora-
tion

system certain tangible things, such as water, air, or wild animals (see above), are withdrawn from private ownership. Modern Western law tends to regard these things as belonging to the state or the community.

Furthermore, certain things that are not withdrawn from private ownership can at any time happen to belong to the community, to the state, or to some governmental entity. Some of these things, like public highways or public parks, may be open to the public generally, at least under certain conditions; some of them may be owned by the state in a manner quite similar to things that are in private ownership, like government office buildings or government-owned enterprises.

Finally, the community or the state may have interests in things that are owned privately by someone else. Offensive land uses may be abated by a public officer acting on behalf of the community or, in some situations, by any affected member of the community suing as private attorney general on behalf of the community. The number and types of land uses that are deemed offensive has increased notably throughout the West with the increase of concerns about the environment (see below).

The major difference between socialist legal systems and those of the West is that socialist legal systems reserve a large amount of property for community ownership. How much property is so reserved varies from socialist country to socialist country, and socialist legal systems are in a considerable state of flux. At the end of the 1980s, however, some or all of the following items were withdrawn from private ownership in most socialist countries: (1) the means of industrial production, or at least the basic means of production, (2) land (this varies considerably), (3) natural resources, (4) sources of energy, (5) the transportation infrastructure, (6) financial institutions (for example, banks and insurance companies), (7) cultural institutions (theatres, schools, the communications media), (8) rented houses, (9) public utilities, and (10) consumer goods manufactured by state-owned enterprises that have not yet been transferred to individuals.

The fact that this large amount of property is vested in the community does not mean that socialist governments manage it all. In all socialist countries much of this property is entrusted to entities that have some independence from the government, although they are subject to overall direction by the government. Such entities are generally of two types: state enterprises, which roughly correspond to government-owned corporations in the West, and cooperatives, which tend to operate in the fields of agriculture, fishing, crafts, consumer buying, or housing. In contrast to Western state-owned enterprises, socialist state enterprises generally do not have title to their property, but their ability to manage it makes their control over it not far different from that of Western state-owned corporations. In some socialist countries cooperatives may have title to the property that they use for their enterprise; in others it is simply entrusted to them.

THE CONCEPT OF OWNERSHIP

Everything must have an owner. It is tempting to define ownership as the sum of the possible rights, privileges, and powers that one might have in a thing. But it is rare in today's world for any one person to have all the legally possible rights, privileges, and powers in a thing. To say that one does not own a thing unless one has all possible interests in it would leave many things without an owner.

Western law has taken a different tack. It has tried to identify an owner or owners of everything. Many legal systems regard the state or the community as owner of those things for which no other owner can be identified. For those things that are the object of multiple and diverse interests, Western law will identify an owner or owners and then will say that the other interests are held by non-owners. The question, then, is how the owner is to be identified when the full panoply of property rights, privileges, and powers do not exist in one person.

Ownership and possession. Anglo-American law tends to identify ownership with the right to possession. Since Anglo-American law recognizes the possibility of multiple rights to possession, one must further qualify: the owner

of property is the one who has the right to possession that is better than anyone else's right to possession. As stated above, it is possible that more than one person can have this right concurrently; for example, it is possible to speak of cotenants as co-owners of the thing. As will be seen below, it is possible for the right to possession to be divided temporally, so that, for example, one person may own a life estate in the property, while another owns a remainder (a right to possession after the death of the life tenant).

The civil-law systems have a more univocal conception of ownership, but it too is closely associated with the right to possession. As in the Anglo-American system, it is possible for more than one person to have the best right to possession, so that co-owners are possible in the civil-law systems as they are in the Anglo-American. Civil-law systems are reluctant, however, to allow the division of the right to possession along temporal lines, so that in the life-estate-remainder example given above, the remainderman is deemed the owner, and the life tenant (usufructuary) possesses on behalf of the owner.

Because Western systems connect ownership with the right to possess, it is possible that the ownership of property will shift when the right to possession and possession in fact are separated for a long time. If person A leaves the tract of land that he owns in the woods, person B may enter into possession of it. That second possession is wrongful as to person A, but person A must act to recover his possession from person B within the period set down in the statute of limitations. In most Anglo-American jurisdictions the statute of limitations on actions to recover land is quite long, 10 or 20 years. But if person A fails to act within the limitations period, his action will be barred.

One may ask who then owns the land. In most Anglo-American jurisdictions the peaceable possessor of land has the right to possess that land against all except those who can show a better right to possession. But if person A's right to possession is barred by the statute of limitations, then his claim is not better than that of the peaceable possessor. Thus, the person who has actual possession of land for the limitations period acquires a right to possession good as against the whole world, including the true owner whose claim is now time-barred. This adverse possessor, then, becomes the true owner by passage of time.

In the civil-law countries the vocabulary is different, but the results are similar. With the passage of time (somewhat longer than in the Anglo-American systems), the possessor is said to acquire title by prescription, because the right of the former owner to bring an action to recover his ownership is barred.

The logical result of these last paragraphs has not been accepted with equanimity, particularly where the result would be to give ownership of the land to someone who has no legitimate claim to it. Both the Anglo-American and the civil-law systems purport to require more of the adverse possessor or the person who seeks to acquire title by prescription—that he be in good faith, for example, or that he have a claim of right. If, however, the claim of the true owner is indeed time-barred, then the only other alternative would be to hold that the land somehow belongs to no one. That possibility would violate the principle that everything must have an owner. In general, then, once the true owner's claim is time-barred, ownership devolves on the person who has the best possessory right.

Ownership as the absolute right to possession. One may thus define ownership in the same way that the legal philosopher Felix Cohen defined property: "That is property to which the following label can be attached: To the world: Keep off X unless you have my permission, which I may grant or withhold. Signed: Private citizen. Endorsed: The state." Cohen, however, goes on to warn that all the terms of the definition "shade off imperceptibly into other things." Consider, for example, the large range of possibilities encompassed in the phrase "permission, which I may grant or withhold." In all Western legal systems there are a number of situations in which the law will either assume that permission has been granted or will require the private citizen to grant his permission. The situations tend to be dramatic: Firefighters, for example, are usually allowed to enter private property to prevent the spread

Socialist

limitations

Possessory
rights
versus civil
rights

of a fire and frequently are authorized to destroy private property in order to prevent the spread of a fire.

In the 1960s a number of U.S. Supreme Court cases starkly posed the conflict between the property owner's right to exclude and civil rights, in the context of "sit-ins" in restaurants that were excluding customers on racial grounds. These cases suggested, if they did not quite hold, that in this context the possessory right of the restaurant owner would have to yield to the civil-rights claim of those sitting in. In the same period a number of courts held that owners of farms could not exclude visitors from agricultural migrant labour camps.

The conflict in these cases between property rights and civil rights was made starker by the practice in the United States of treating social issues as constitutional controversies. The issue, however, of the use of property to discriminate against members of the society whom the property owner disfavors is present throughout the Western world. Ultimately in the United States the problem of restaurant sit-ins was resolved by national legislation that made it the duty of anyone providing food or lodging to serve all comers without regard to race. Similar legislation exists in many Western countries, as does legislation allowing access to premises in which workers are employed.

DIVISIONS OF OWNERSHIP

Spatial divisions. All Western legal systems allow the owner of property to divide it along spatial lines. Such divisions may be unwise, for example, where the resulting piece of land has no access to a public right-of-way (see below). In the case of land, public regulation may prevent the division. The basic principle, however, is uncontroversial. If person A owns a piece of land or personal property, he is normally permitted to divide it, giving a piece of it to person B, and either keeping the other piece for himself or giving it to still a third person.

A somewhat different set of problems arises when the desired division is vertical rather than horizontal. By and large Anglo-American law allows such vertical divisions, so that one person may own the mineral strata underneath land, another the surface of the land, and the third the air rights. The civil-law systems have had some difficulty with this type of division of ownership, because of the medieval maxim: "Cuius est solum eius est usque ad coelum et usque ad inferos" ("Whoever owns the soil owns all the way to heaven and all the way to hell"). In both systems modern legislation has made possible, for example, ownership of an apartment on the 30th floor of a building. Condominium ownership is more complicated, because the condominium owner owns not only the area within the four walls of his apartment or house but also access rights and privileges to use common areas and utilities. Cooperative ownership avoids this complexity by having each of the cooperators own a share in a corporation. The corporation, in turn, allows the cooperators to possess their dwelling units, while retaining the title to all the property.

Temporal divisions. Anglo-American law is notorious for the number and complexity of temporal divisions of ownership it allows. The English law on the topic was considerably simplified in 1925, when it became impossible to have legal ownership divided temporally other than between landlord and tenant. English law, however, continues to allow complicated temporal divisions of beneficial interests in trusts, allowing, therefore, a temporal division in the equitable but not the legal ownership (see below). In many of the remaining Anglo-American jurisdictions, temporal division of the legal ownership of land is still possible, although increasingly undertaken by way of trust.

Life estate and remainder. One of the possible temporal divisions of ownership in Anglo-American law, the life estate and the remainder in fee, has already been considered. In such an arrangement the life tenant has the right to possess the land for his natural life. He may use the property, but he may not impair its capital value (commit waste). He may convey his interest, but he may convey no more than what he has, an interest limited by his life. Hence, his conveyee receives an estate limited by the life of the conveyor (estate pur autre vie). Common-law dower and curtesy are types of life estates.

The remainderman has a right to possession that commences upon the death of the life tenant. He may not use the land until the life tenant dies but may sue the life tenant if the life tenant commits waste. Since the remainderman's interest is an interest in fee, his interest will pass to his heirs or devisees if he dies before the life tenant. The remainderman may also convey his interest *inter vivos*, subject to the life estate. If the original owner in fee conveys a life estate to someone else and retains the rest of the property in himself, the retained interest is called a reversion. For most purposes reversions have the same characteristics as remainders.

A number of variations on the basic pattern of life estate and remainder are possible in Anglo-American law. There may, for example, be successive life estates: "to my wife Edith for her life, remainder to my son George for his life, remainder after George's death to George's children."

Contingent interests. Not only is it possible to create successive interests in land in Anglo-American law, it is also possible to create interests that are subject to express contingencies. Thus, in the example given above, the donor could make the remainder in George contingent upon George's having attained a specific age, say 21, at the time of the death of the previous life tenant.

Not only is it possible to make future interests subject to contingencies, it is also possible in most Anglo-American jurisdictions to make present interests in fee subject to contingencies. Thus, it is possible, for example, to grant a fee interest subject to the contingency that the land be used for school purposes and to provide for a forfeiture of the interest if it is not so used (fee simple determinable, fee simple subject to a condition subsequent).

The rule against perpetuities. The rule against perpetuities limits the number of successive interests that may be created in property by requiring that all interests vest, if at all, within lives in being plus 21 years. The operations of the concept of vesting are complicated, but basically the rule requires that any contingency with regard to a future interest must necessarily occur or fail to occur within the perpetuities period or else the interest will be held void from the beginning. For purposes of the rule, a contingency is not only an express contingency, such as the one in the example above that George have reached the age of 21, but also an implied contingency, such as the identification of George's children.

Both of the contingencies in the example given above meet the requirements of the rule. George is already a life in being, so he will obviously become 21 during his lifetime or fail to become 21. The children of George are not necessarily lives in being at the time of the grant, but they will all be identified during George's life (plus a possible period of gestation, which is allowed to extend the lives in being).

If, however, the gift had said "remainder to my children for their lives, remainder after the death of my last surviving child to my children's children," then the interest in the donor's grandchildren would be void under the rule. The donor could have another child after the effective date of the grant, which child could have a child more than 21 years after the donor, his wife, and all the child's living sibs were dead. That grandchild's interest, then, would vest outside the period of the rule. In most situations, the consequences of voiding the gift to the grandchildren will be to leave a reversion in fee in the grantor or his heirs, following the two valid life estates.

There are numerous modern proposals for reform of the technical operations of the rule against perpetuities. The details of its operation have changed over time and are likely to change further in the future. Its principle, however, has remained quite constant since *The Duke of Norfolk's Case* (see above). It compromises the conflict between the power to convey of the present holder of the property and the power to convey of those to whom the present holder conveys by allowing the present holder to restrain the power to alienate of those who are alive at the time he makes the conveyance and, in effect, that of their children until they reach the age of majority (21). After that full power of alienation must be allowed.

Civil law. Some, although not all, of the arrangements

The
concept of
vesting

Condo-
minium
and
cooperative
ownership

Usufruct

described above are possible in civil law. The major distinction between Anglo-American and civil law in this regard is that civil law normally does not regard such arrangements as involving divisions of ownership. Thus, the usufruct, the device in civil law that most closely corresponds to the life estate of the Anglo-American law, is regarded not as a form of ownership but as a right in the thing of another (*jus in re aliena*). Although the usufructuary normally does not have the right to possession in civil law, he is normally given possessory remedies against third-party wrongdoers. All in all one may question how different the practical position of the usufructuary is from that of the life tenant in Anglo-American law, despite the substantial conceptual differences between the two systems.

Even in the area of conditional gifts, the differences between the two systems are not as great as they might seem. True, in civil law the basic principle is that gifts cannot be conditioned. The donor must give outright or not at all. There are, however, exceptions in civil law that derive from the medieval Roman law of fideicommissary substitutions. The rules are complicated and vary from jurisdiction to jurisdiction. In the French system, for example, it is possible to make a will giving property to one's children and requiring that they turn it over to their children. In German law, it is possible to appoint successive heirs, so long as the succession occurs within 30 years of the death of the testator.

There is no equivalent in the civil law of the fee simple with a forfeiture clause. Thus, a grant subject to the condition that the land be used for school purposes is not possible in civil law, although there are ways of achieving similar results in civil law, at least for limited periods of time.

Landlord and tenant. In Anglo-American law present possessory interests less than the fee need not be limited to the life of the holder of the interest; they may also be limited to a specific term of years or to a renewable term. Such a transaction creates the relationship of landlord and tenant. The tenant may have a possessory interest for any specific term, such as a month, a year, 5 years, or 99 years. The tenant may also have an interest for a specific term that is renewed automatically unless the landlord or the tenant gives notice within a fixed period before the term expires (periodic tenancy). Thus, tenancies can be arranged, for example, from week-to-week, month-to-month, or year-to-year. It is also possible to have a tenancy for no fixed term but subject simply to the will of the landlord and tenant (tenancy at will). Either landlord or tenant may give notice to the other at any time to terminate the tenancy. (In many jurisdictions tenancies at will are subject to statutory regulation concerning the time of the notice to terminate, thus making them more like periodic tenancies.)

Similarly, civil law allows the creation of landlord-tenant relations. Although the categories of tenancies recognized in Anglo-American law do not exist in civil law, it is possible to create by private agreement most of the landlord-tenant arrangements that Anglo-American law recognizes. What is different in civil law is the conception of the relationship between landlord and tenant. In modern civil law, as in Roman law, the tenant does not have the right to possession, the landlord does. Since the landlord has a contractual obligation to allow the tenant to possess, the practical consequences of this conceptual distinction are not great. The most important area where the two systems differ is in the situation where the landlord sells his interest in the land to someone else. In Anglo-American law, the tenant has an enforceable possessory interest against his new landlord. In civil law, the tenant's remedy is against his old landlord. Even this difference has been narrowed by recent legislation in civil-law jurisdictions that allows tenants to sue third parties who interfere with their possession in fact.

Recent developments

Throughout the West in the second half of the 20th century there have been substantial changes in the law governing landlord-tenant relationships. These changes have most notably affected the law concerning residential tenancies, particularly tenancies in urban apartments. Some

jurisdictions have also made extensive changes in the law governing agricultural tenancies. By and large, the law of commercial tenancies has been left to private agreement. Commercial leases, therefore, continue to use traditional forms, with the terms being negotiated between the parties.

In the United States the changes in residential landlord-tenant law were initiated by the courts. Legislation has followed, confirming and frequently going beyond what the courts have done. In the rest of the West, the initiative has been taken by the legislatures, although the end results have been quite similar.

The principal changes are in four areas: security of tenure, legally imposed terms in the lease (particularly concerning the maintenance of the premises), regulation fixing rents, and direct government ownership of residential premises.

The law of landlord and tenant that the West inherited from the 19th century gave the tenant security of tenure only so long as the lease lasted. The parties could, of course, renew the lease once it was at an end, but such renewals required the consent of both landlord and tenant. In fact, however, residential leases tended to be renewed, with or without some adjustments in rent as the market dictated.

World War II precipitated a housing crisis throughout the West. The wartime economy did not produce enough new housing, and the end of the war saw a great increase in population. The end of the war also saw massive shifts in population to urban areas and great changes in patterns of land use. Landlords responded to these market forces by refusing to renew leases without sharp increases in rents or by refusing to renew leases at all, so that they might convert housing to more profitable uses.

Different jurisdictions in the West responded to this crisis in different ways. In England and on the European continent, where much of the housing stock had been destroyed in the war, direct provision of housing by the government began to play an important role in the housing market. There was also a tendency in these countries to fix the price of private rental housing and to require that private landlords renew leases so long as the tenant continued to pay the rent thus fixed.

In the United States more reliance was placed on the private market. Government-subsidized financing of housing encouraged construction of new housing by the private sector. Fixed rents existed in some jurisdictions but were intended as a temporary measure. Home ownership was, and remains, more common in the United States than it is in Europe.

In the United States, changes in the law of landlord and tenant came in the 1960s and early '70s, when the country came to focus on the deteriorated conditions of housing that existed for the urban poor, those who had been left behind as the middle class had moved to newly constructed housing in the suburbs. Urban housing for the poor was frequently maintained at levels far below what was required by local regulation (see below), but enforcement of these codes was sporadic.

Faced with this situation and with considerable legislative inertia, American courts came to read the provisions of the housing code into the lease. *Javins v. First Nat'l Realty Co.*, 428 F.2d 1071 (D.C. Cir. 1970), for example, requires that every residential lease have within it an unwaivable warranty of habitability, requiring the landlord to maintain the premises up to the standard of the local housing code. If the landlord does not maintain the premises up to this standard, the tenant may withhold rent and the landlord cannot evict him for nonpayment of rent.

Legislation in the 1970s tended to confirm the results of *Javins*. Other legislation and decisions gave residential tenants more security of tenure. A number of urban jurisdictions that had abandoned rent control reinstated it. While there are still considerable differences between the American and European patterns of regulation of the residential landlord-tenant relationship, the trend is toward convergence. Everywhere the essential terms of the relationship are increasingly fixed by law; the tenant's interest in his dwelling has become more secure, and the landlord is seen less as an owner than as the provider of a public utility. Recently a countertendency to rely more

Landlord and tenant

on market forces is observable throughout the West, but this has so far only modified the previous trend, it has not reversed it.

Divisions as to rights, privileges, and powers. *Trusts.* Anglo-American law recognizes another possible division of ownership, that between the power to manage property and the privilege of receiving the benefits from it. This division, known as the trust, is of great practical importance in Anglo-American law. The trust device is used in a wide variety of contexts, most notably in family settlements and in charitable gifts. In the area of family settlements it has largely replaced the legal life estate and remainder.

Fundamental to the notion of the trust is the division of ownership between legal and equitable. This division had its origins in separate English courts. The courts of common law recognized and enforced the legal ownership; the courts of equity recognized and enforced the equitable ownership. The conceptual division of the two types of ownership, however, survived the merger of the law and equity courts. Thus, today legal and equitable interests are usually enforced by the same courts, but they remain conceptually distinct.

Legal and equitable ownership

The basic distinction between legal and equitable ownership is quite simple. The legal owner of the property (trustee) has the right to possession, the privilege of use, and the power to convey those rights and privileges. The trustee thus looks to all the world like the owner of the property. He so looks to all the world except for one person, the beneficial owner (beneficiary, *cestui que trust*). As between the trustee and the beneficiary, the beneficiary gets all the benefits of the property. The trustee has a fiduciary duty to the beneficial owner to exercise his legal rights, privileges, and powers in such a way as to benefit not himself but the beneficiary. If the trustee fails to do this, the courts will require him to pay over what he has earned for himself to the beneficiary, and may, in extreme cases, remove him as legal owner and substitute another in his stead.

Divisions between legal and beneficial ownership are normally created by an express instrument of trust. The maker (settlor) of the trust will convey property to the trustee (who may be an individual or a corporation, such as a bank or trust company) and instruct the trustee to hold and manage the property for the benefit of one or more beneficiaries of the trust.

Trust instruments can be quite complicated. They may provide for succession among the trustees and for succession among the beneficiaries. They may give the trustee considerable discretion in managing the property and in paying out the benefits to the beneficiaries. In many jurisdictions the beneficiary's interest may be insulated from the claims of his creditors (spendthrift trust, protective trust). There are only three basic limits on private trusts in Anglo-American law. The first is that there must be some diversity between the legal and the beneficial owners. If they are or become identical, the interests merge and the trust is dissolved. The second limitation is that the beneficiaries must be identifiable. The third is that the power of the beneficiaries to dissolve the trust cannot be suspended for longer than the perpetuities period. Thus, future interests in a trust, like future interests at law, must vest within a life or lives in being at the creation of the irrevocable character of the trust plus 21 years.

In the arrangement described above, the donor gave property to his spouse, Edith, for her life, remainder for life to his child George, if George reached the age of 21, with a remainder after George's death to George's children. This arrangement could be accomplished by means of a trust. The donor (settlor) would give the property in trust to a trustee with the following instructions: (1) pay the income from the property to Edith for her life, (2) upon Edith's death, accumulate the income or expend it on behalf of George until George reaches the age of 21, (3) when George has reached the age of 21, pay the income to George during his lifetime, and (4) upon George's death, divide the principal of the trust among George's then-living children.

Using a trust rather than the legal life-estate-remainder arrangement allows a separation of the management of

assets from the enjoyment of them. Getting assets into the hands of professional or semiprofessional managers frequently allows them to be managed more competently than they would be by some or all of the beneficiaries. Further, the assets themselves are not locked into the arrangement. If it makes sense to sell a piece of land or to shift a portfolio from bonds to stocks, the trustee does this, and he can give good title to the assets. In the legal life-estate-remainder arrangement all the holders of interests in the assets have to consent to the conveyance of the property, a cumbersome procedure at best and particularly difficult when some of the beneficiaries are minors or are unascertained. Further still, use of the trust allows the beneficial interest in property to pass from generation to generation without the property having to pass through probate, an awkward and time-consuming process in many Anglo-American jurisdictions. Finally, use of the trust sometimes allows for a savings in taxes.

There is no precise equivalent of the trust in civil law. (Islamic law knows an institution, the *waqf*, that is somewhat like the Anglo-American trust.) Some modern civil-law systems have created an institution like the trust, but this has normally been by adapting trust ideas from the Anglo-American system rather than by developing native ideas.

Civil-law parallels to the trust

Most of the uses to which the Anglo-American trust is put are achieved in civil law in other ways. For example, the charitable trust of Anglo-American law has a quite close analogy in the civil-law foundation (*fondation*, *Stiftung*). Of the purposes for private express trusts mentioned above, lawyers on the Continent get professional management for assets by turning them over to managers who are paid a fee for their services. Since the number of possible outstanding interests in a given piece of property is more limited in the civil law than it is in Anglo-American, it is less necessary to have a trustee who can give good title to the whole of the property. Probate avoidance is rarely an issue on the Continent, because civil-law systems of probate are normally far less cumbersome than the Anglo-American systems. Thus, as in so many other areas in comparative Western law, it turns out that some of the needs that the Anglo-American trust serves are not needs in the civil-law systems because of structural differences in the systems and that the remaining needs are served by other devices.

Security interests in property. Another division of the rights, privileges, and powers of ownership exists in all Western legal systems—the division that occurs when an owner makes use of his thing as security for a loan or other obligation. Both English common law and Roman law recognized a number of different ways in which property could be used to secure a transaction. In general, the devices used at common law transferred ownership or a real right in the thing to the creditor, while those used in Roman law kept the ownership of the thing in the debtor. The focus, then, of the development of the common law was on ensuring that the debtor got his ownership back if he discharged the obligation, while the focus of the development of Roman law was on ensuring that the creditor's rights were protected if the thing ended up in the hands of some third party.

From these two quite different starting points a long course of development in both the Anglo-American and civil-law systems has arrived at a point where, despite great differences in vocabulary and conceptualization about property used in a secured transaction, there is considerably less difference in practical result. Both systems recognize arrangements between debtor and creditor in which the ownership of the thing is nominally transferred to the creditor, but the creditor's ability to deal with the thing is limited in such a way that the ownership will revert to the debtor so long as the debtor discharges his obligation. Both systems also recognize arrangements in which the creditor does not receive an ownership interest in the property but where he receives sufficient rights against the debtor so that he is secure if the debtor does not discharge his obligation.

In both systems the most complicated, and historically the most important, security devices have to do with land—

Mortgages

the mortgage of the common law and the *hypothec* of the civil law. In the mortgage of the common law the debtor (mortgagor) conveyed his land to the creditor (mortgagee) subject to the condition that the land would automatically revert back to the debtor if the debtor discharged his obligation by a certain date. The debtor, however, remained in possession of the land, and the practice of allowing the debtor to remain in possession became an obligation of the creditor to allow the debtor to possess the land and finally a right in the debtor to possess the land so long as the debtor was not in default on the debt. If the debtor defaulted, the creditor's right to possess became perfected, and he could enter and use the land for himself or sell it as he wished. The debtor's interests were extinguished.

The equity courts intervened on the side of the debtor. Equity first gave the debtor a right to redeem the property by paying the amount that was owing, even if he had defaulted on the debt. In order to sell the property, creditors were forced to bring an action in equity to foreclose the debtor's equity of redemption. As a condition of foreclosure, equity gave the debtor a right to the proceeds of the sale to the extent that the sale realized more than the outstanding debt. Legislation in the 19th century extended the debtor's right to redeem even after the creditor had foreclosed. Finally, in some jurisdictions, legislation required that the creditor sell the property after he had foreclosed, and in some of these jurisdictions the sale had to be conducted by a public official.

At common law the debtor could not transfer legal title to his property to third persons because he did not own it. (He could, however, convey his equity of redemption.) This meant that a purchaser in good faith might end up with nothing even though the mortgagor looked to all the world like the owner of the property (he was in possession and could normally produce evidence that the property had been transferred to him by a previous owner). In order to protect third-party purchasers, most Anglo-American jurisdictions have public offices in which mortgage transactions can be recorded (see below). Under the prevailing legislation, the purchaser who takes in good faith from a mortgagor in possession acquires good title against the mortgagee unless the mortgage is recorded.

In most Anglo-American jurisdictions these developments in mortgage law have led to a reconceptualization of the mortgage itself. If the mortgagor has the right to possession, an equity of redemption, and the power to convey good title to the land (subject to the mortgage if the transaction is recorded), his interest looks more like that of an owner than do those of the creditor, despite the fact that the mortgage deed says that the creditor is the owner. Other jurisdictions retain the notion that the creditor is the owner subject to all the qualifications offered above. There is little practical difference in result in the two types of jurisdiction.

Starting from very different premises the civil-law systems have arrived at much the same result. The debtor has the right to possession and privilege of use of the property unless and until he defaults. If he defaults, the creditor may, depending on the jurisdiction, either take possession of the property or force a sale of it. The debtor's interest in the proceeds of the sale over and above the outstanding amount of the debt is everywhere protected. In some jurisdictions the debtor may also be given a grace period within which he can redeem the property after default. Registration of security interests is virtually universal. If the interest is registered, the creditor's interest survives any transfer of the property, even to a good-faith purchaser without actual notice of the security interest.

Security
interests in
movables

Security interests in movables have a somewhat different history. In the Anglo-American system security interests in personal property were developed largely by the equity courts, aided in the 19th and 20th centuries by legislation. The result is a quite complex branch of what is normally called commercial law. Suffice it to say here that it is possible to have arrangements much like a mortgage whereby the debtor retains possession of the property subject to a security interest in the creditor (chattel mortgage or conditional sale) or to have the creditor take possession of the property subject to the debtor's right to redeem it by

paying the debt (pledge or pawn). In some jurisdictions, notably England, the debtor will lease the property from the creditor (who is also normally the seller), his title becoming absolute when the payments have been made (hire purchase). In the United States the differences among the various types of personal property security agreements have been considerably reduced by uniform legislation that deals with all of them under one heading.

On the Continent the pledge or pawn (*pignus*) was historically the chief security device for movables. Under this device the right to possession of the movable was in the creditor, although possession in fact might not be. Financing devices for merchants are handled in separate codes of commercial law, where the devices tend to be similar to those of the Anglo-American chattel mortgage or conditional sale. Modern consumer credit law has produced a number of devices, some of them representing developments from the civil law of pledge, some more closely resembling the English hire purchase.

PROTECTION OF PROPERTY INTERESTS

Public law protections of property. *Criminal.* If person A takes the property of person B without his permission and with the intent permanently to deprive him of it, that is theft, a concept that is universal in the West. In the Anglo-American systems today theft is everywhere a crime, the penalty normally being dependent on the value of the thing stolen and the circumstances under which the taking occurs. Modern Anglo-American criminal codes tend to subdivide theft in ways that reflect their common-law background. Larceny is the simple taking of personal property or money from the possession of another with the intent permanently to deprive the possessor of it. Burglary is larceny aggravated by the fact that it is achieved by breaking and entering premises in order to accomplish it. Robbery is larceny aggravated by the fact that it is achieved by the exercise of force or threats of force against the possessor. Embezzlement is a wrongful taking of property by someone (like a bank clerk) who is already rightfully in possession of it.

The civil-law criminal codes do not observe the Anglo-American distinction between larceny and embezzlement. Otherwise, the criminal prosecution of theft in civil law is quite similar to that in the Anglo-American systems. An intent to deprive (*animus furandi*) is required. The penalty will vary depending on the value of the thing stolen and will be aggravated if the theft is accompanied by wrongfully entering premises or by the exercise of force.

Land cannot be stolen in either Anglo-American or civil law. Wrongful entry onto land may be punished in Anglo-American law by statutes regulating criminal trespass. Deliberate damage to another's land may also be punished criminally, particularly under modern regulatory statutes concerning the environment.

Regulatory. The 20th century has seen the rise of an extensive body of regulatory law concerning the use of property, particularly of land. This law is treated in more detail below, but it is well to point out here that the effect of such regulatory law is to protect the property interests of those members of the community whose property would be adversely affected by the land use proscribed by the regulation. Thus, if an environmental law prohibits the emission of pollutants from a smokestack, that law protects the interests of those on whose land the pollutants would otherwise descend.

In some circumstances some Western jurisdictions allow those adversely affected by the violation of such regulations to sue the violators directly. In other circumstances and in other jurisdictions such standing to sue is not allowed, but the adversely affected individual may bring an administrative proceeding to compel enforcement of these regulations. Even if no private enforcement is allowed, the facts that the regulation exists and that its enforcement by public authorities can normally be expected changes the property interests, in the definitional sense, not only of the property owner whose privilege of use is limited by the regulation but also of those who are benefited by the regulation.

Private law protections of property. The protection of

property in civil procedure has a long history in both the Anglo-American and civil-law systems. Both procedures are strongly affected by the fundamental distinction that Roman law made between actions in personam and those in rem and by the distinction that the medieval civilians made between actions to establish ownership (petitory actions) and those to recover possession (possessory actions).

Ejectment

Anglo-American law. In the Anglo-American systems the basic action for vindication of an ownership interest in land is usually a modern action derived from the common-law action of ejectment. This action results in the successful plaintiff being restored to the physical possession of the land. After some controversy, still not completely settled, it was decided that the plaintiff in ejectment need not prove title good as against the whole world but simply a relatively better right to possession than the defendant. The operations of this action thus fit into the Anglo-American concept of ownership as a relatively better right to possession.

For the owner seeking a judicial declaration of his title to land, most of the Anglo-American systems provide an action derived from the equity action to quiet title. This results in a declaratory judgment as to the state of the title. The procedural difficulties of bringing this action make it a decided second best to ejectment, but sometimes it is the only remedy available (where, for example, the plaintiff is already in possession but the defendant claims ownership or some lesser interest and hence is hampering the market value of the plaintiff's land).

As a general matter, where the action of ejectment is not available, equity courts, or their modern descendants, will protect the plaintiff who has established that he has a property interest in land by issuing an injunction against the defendant who is interfering with the interest.

Because the action of ejectment tries the better right to possession, separate possessory actions for land are no longer a main feature of Anglo-American law. Most jurisdictions do, however, have a statutory possessory action, derived from the English statutes of forcible entry and detainer, in which an owner or prior peaceable possessor can recover possession from one who has taken or who detains possession without pretense of right. These actions are frequently used by landlords to recover possession from tenants who have held over after the terms of their leases have expired and are occasionally used by peaceable possessors who have been ousted from their possession by force.

Possession of land is also protected in the Anglo-American system by civil actions of trespass. Technically, trespass is a personal action, and the successful plaintiff recovers only money damages. Since such actions frequently rest on the right to possession, however, they were used in the past, and in some jurisdictions are used today, to try title.

Trover and replevin

Historically, the Anglo-American system had no real action to vindicate ownership of movables. Though still technically personal actions, actions concerning movable property have been expanded in Anglo-American law, so that today they serve most of the purposes of the old real actions of the land law. In England, conversion, a descendant of the common-law trover action, is used, coupled with the possibility that in some situations (normally in the case of unique movables) the court may specifically decree the restoration of the thing itself. In the United States the common-law action of replevin was changed to allow the same purpose to be achieved.

Civil law. Roman law had an action of *rei vindicatio*, whereby the plaintiff could claim ownership of any thing, movable or immovable. It could be brought only against someone who was withholding possession of the thing from the plaintiff, and it required the proof of ownership by derivation of title from the conceded owner or by demonstrating that the quite strict requirements of usucapion had been met. (Usucapion, a type of prescription, required that the person claiming it have uninterrupted possession of a movable for a year or of an immovable for two years, that he have acquired it in good faith, and that he have a just cause for his acquisition. This last requirement effectively limited usucapion to cases of defective sales and certain types of official orders.) Roman

law also offered an *actio publiciana* to the person who had fulfilled all the requirements of usucapion except that the prescriptive period had not run out. A third action, the *actio negatoria*, protected the owner in possession against the claims of one out of possession, allowing the owner to obtain what was in effect a declaratory judgment as to his rights.

Roman procedure for protecting possession was sharply distinguished from the actions that protected ownership. The interdict *unde vi* protected the peaceable possessor of land who was dispossessed by force; the interdicts *utrubi* and *uti possidetis* protected the possessor either of movables or immovables whose possession was being disturbed by some third party.

Modern civil-law systems retain the distinction that Roman law made between petitory and possessory actions, but the tendency in both cases is toward a procedure of relative rather than absolute rights. Thus, for example, the modern French revendication, while still nominally an action that tries absolute ownership, has in practice become an action that tries relatively better title between the plaintiff and the defendant. Similarly, the French possessory actions of *réintégration* and *complainte* are available to almost any peaceable possessor to recover something of which he was dispossessed by someone whose claim to possession is inferior to his. The results in the German system are similar, although the German scheme of actions is somewhat closer to that of Roman law. German law also knows an action to correct the *Grundbuch* (see below), which has a somewhat similar function to that of the Anglo-American quiet title action.

Use of property interests

The previous section focused on the right to possession of property. This section focuses on the privilege of use of property—the extent to which the law allows an owner or possessor of property to use the property and how an owner or possessor of property may grant privileges of use to others. The fact that person A's privilege of using his property inevitably conflicts with person B's privilege of using his, if their properties are located near each other, has led throughout the West to extensive limitations on the privilege of use, first in the area of private law and, increasingly today, in the area of public law.

NUISANCE LAW AND CONTINENTAL PARALLELS

At English common law the basic limitations on the privilege of use of property were incorporated in the law of nuisance, the action that a landowner could bring if his privilege of using his land was being interfered with. Historically, nuisance law seems to have been deeply conservative; existing land uses were protected against more recent ones. A hierarchy of land uses favoured residential uses over agricultural and agricultural over industrial. (Commercial uses were sometimes placed after residential, sometimes after agricultural.) The maxim “sic utere tuo ut alienum non laedas” (“use your own thing so as not to harm that of another”) expressed this conservative tendency, though it hardly offered a precise solvent for difficult cases.

Today, nuisance law is still used in the Anglo-American system as a means of resolving land-use disputes. The hierarchy of land uses is still employed, tacitly if not expressly; the maxim is still occasionally quoted, and at least in close cases the land use that is prior in time will prevail over subsequent ones. What has changed about nuisance law is the fact that today the element of judicial discretion in resolving the basically unresolvable conflict between two equally privileged land uses is more frankly recognized.

Nuisance is defined as the substantial interference with the plaintiff's use of his land by the unreasonable conduct of the defendant. Each of the qualifying words in the definition can lead to an exercise of judicial discretion. One may ask, for example, whether the harm caused by the defendant's activity is substantial. A judgment is called for, aided, of course, by precedent, but always unique to the given case. Hazards to health, offenses to the sense of smell or hearing, and demonstrated economic loss are

Nuisance

frequently found to be substantial harms. Offenses to the sense of sight and injuries to peculiarly sensitive activities (such as maintaining a mink farm) are much less likely to be found substantial.

The second stage in determining that a nuisance exists requires a finding that the defendant's activity was unreasonable. Unreasonable conduct is a relative matter. It may be unreasonable to engage in heavy manufacturing in a residential area and perfectly reasonable to do so in an industrial area. The care with which the defendant conducts his activities is of relevance, but it is not decisive.

Once a nuisance is found, there still must be, in most jurisdictions, a "balancing of the equities" to determine whether the defendant will be enjoined from his activities or whether the plaintiff will have to content himself with money damages. In recent cases, economic considerations have come to the fore in making this determination. Thus, in a celebrated New York case, the court refused to enjoin the operations of a cement plant that represented a \$45 million investment and a large number of jobs for a small community but instead awarded money damages to the nearby residents calculated on the basis of the reduction in the capital value of their houses that would result from the continued presence of the smoke-emitting plant (*Boomer v. Atlantic Cement Co.*, 26 N.Y.2d 219, 257 N.E.2d 870 [1970]).

Unlike the English common law, Roman law had no single action whereby a plaintiff could complain of his neighbour's interference with his land use. Various private actions did exist by which a plaintiff could complain of particular noisome land uses, but the jurists never seem to have generalized about them.

The adoption by modern civil law of the Roman conception of ownership and of substantial parts of the Roman scheme of actions has meant that modern civil law also lacks a unified protection of the privilege of use like that of the Anglo-American nuisance law. In France this lack has been made up by the development of the concept of *abus de droit* ("abuse of right"). The concept has been extensively used in situations where the defendant has employed his land in a given way in order to interfere with his neighbour's land use. The paradigm case came from Colmar in the middle of the 19th century, when the defendant built a large and totally unnecessary chimney on the roof of his house in order to block the light to his neighbour's windows (2 mai 1855, D.1856.2.9). From there the concept has developed so that it may be used in situations where the motives of the defendant are not so obviously malicious as they were in the Colmar case, but it has never involved the French judiciary as much in land-use questions as has the Anglo-American. German law, on the other hand, has developed a concept similar to that of Anglo-American nuisance law, based on the general requirement in the code that one act in good faith and on a specific provision dealing with smoke and noise.

PRIVATE LAND-USE CONTROL: SERVITUDES

Both Roman law and English common law recognized that an owner of land could voluntarily part with a right or privilege with regard to his land so that a neighbour might use the land in a way that would otherwise be actionable. The classic case is the right-of-way, whereby an owner agrees to allow a neighbour to cross his land in order to allow the neighbour to reach his own land. What distinguishes the right-of-way and similar interests from the myriad types of enforceable agreements not to sue is that the right-of-way is a real right; that is, if it is properly created, the right-of-way will remain in effect even when the owner of the burdened land has transferred the land to another.

Today the category of *jura in re aliena* ("rights in the thing of another") is broader in Anglo-American systems than it is in the civil law. The developments, however, were not entirely independent of each other. The similarity in the two bodies of law will become even more noticeable if, as has been proposed, American law comes to abandon its traditional distinctions between and among easements, profits, real covenants, and equitable servitudes and adopts instead, like the civil law, a general category of servitudes.

Easements and profits. An easement in Anglo-American law is a privilege to do something on the land of another or to do something on one's own land that would otherwise be actionable by one's neighbours (affirmative easement). Exceptionally, it is the right to prevent a landowner from doing something on his land that he would otherwise be privileged to do (negative easement). Examples of affirmative easements include rights-of-way, the privilege of using land for pasture, the privilege of using a wall as a party wall, the privilege of flooding land, and the privilege of maintaining a nuisance on one's own land (for example, a garbage dump or an airport). Examples of negative easements are more restricted. It is sometimes said that there are only four such easements: two being the right to prevent one's neighbour from obstructing the light and the air that normally come to one's property, the third being the right to prevent him from undermining the support for a building, and the fourth being the right to prevent him from changing the course of an artificial stream.

Historically, and in some jurisdictions today, easements had to be appurtenant: the land benefited by the easement (dominant tenement) and the land burdened by the easement (servient tenement), in most situations, had to be adjacent to each other. A separate category of privileges, known as profits, was recognized, and these could be held in gross; *i.e.*, the holder of the profit did not have to be the owner of the adjacent land. Profits gave the holder the privilege of taking something from the burdened land, like timber, game, minerals, or water. The recognition by most Anglo-American jurisdictions that affirmative easements can be held in gross has led to the gradual abandonment of the distinction between affirmative easements and profits.

Easements may be created by grant, by implication, or by prescription. Normally, the owner of the burdened land will grant the easement expressly. Recordation may be necessary in order to have the grant bind third parties (see below). Where the owner has divided land in such a way that the conveyee has no convenient means of access except across the land retained by the conveyor, the conveyor will be presumed to have given the conveyee a right-of-way across the retained land (easement by implication). The same will often be presumed where the conveyor has left himself totally landlocked (easement by necessity). (In a few jurisdictions statutes compel the same result.) Implication will also be found where there were pipes or paths on the undivided parcel that suggest that the parties to the transaction that divided the parcel intended to subject one parcel to an easement in favour of another. Finally, the continuous and uncontested use of an easement for the period of prescription (normally, the statute of limitations for ejectment actions) can give rise to an easement by prescription.

Real covenants. The common law recognized that under certain circumstances a promise could be made to "run with the land," so that the owner of the estate burdened by the promise would have a duty to perform it. The promise could be either negative (a promise not to do something, like not using the land for commercial purposes) or affirmative (a promise to do something, like maintaining a fence or paying an assessment to a homeowners' association). The conditions under which such covenants would run with the land were, and perhaps still are, complicated. In many jurisdictions the precise contents of the doctrine are not clearly defined. This is because the enforcement of covenants by means of injunction, the equitable servitude discussed in the next section, has largely taken over, as a practical matter, for covenants that run with the land at law.

Equitable servitudes. The equitable servitude is an invention of the English equity courts in the 19th century. This device allows the enforcement of promises (usually negative promises) that neither fall within the traditional types of negative easements nor meet the traditional requirements of covenants that run with the land against the successors in title to the land owned by the original promisors. What is required is that the content of the promise "touch and concern the land," a requirement that allows the court to make a policy determination that a

Creation of easements

Right-of-way

particular class of promises should be permitted to burden the land and that the person against whom enforcement is sought took the burdened land with notice of the promise. This notice will typically arise from the fact that the instrument in which the promise was made is on the public record, but it has been held that a uniform scheme of development of parcels of land that were once under common ownership is enough to put the purchaser of one of the parcels on notice to inquire whether a promise to develop in this way was made.

The equitable servitude has been of great importance in land development in Anglo-American jurisdictions. By use of this device land can be developed according to a uniform scheme (residences only, residences of a certain size, even residences with a required style of architecture). The use of the equitable servitude as a device for private land-use control is one of the reasons why public regulation of land use is a relatively recent phenomenon in the United States.

Civil law. The Roman law of real servitudes was not well developed. The rustic praedial servitudes consisted of three types of rights-of-way (*iter*, *via*, *actus*) and one type of water right (*aquaeductus*); the urban praedial servitudes were principally concerned with light to and support of buildings. A generally restrictive attitude towards servitudes is also manifest in the modern civil law. In French law it is not possible to create a servitude that benefits a person rather than a tenement or piece of land; *i.e.*, a servitude must have both a dominant and servient tenement. There can be no servitude requiring the owner of the servient tenement to do something. Within these limits French law allows a servitude to be created for any purpose. The German law is broader. It recognizes the possibility that servitudes may be created to benefit a person rather than a particular piece of land, although the benefit may last no longer than the lifetime of the beneficiary. As in French law there does not seem to be any way in German law to compel the owner of the servient tenement to do something. Thus, there is no category in civil law corresponding to the Anglo-American affirmative real covenant, and the category of equitable servitudes is unnecessary because the general category of servitudes is broader.

In French law the methods of creating servitudes are remarkably similar to the methods of creating easements in Anglo-American law. German law makes less use of prescription and implication of servitudes than does Anglo-American law, probably because of its reliance on the *Grundbuch* (see below). Both the French and German systems recognize a right-of-way of necessity (*enclave*; *Notweg*). The parcels need not originally have been in common ownership, but the landowner seeking a way of necessity must compensate the owner of the servient tenement.

Servitude law is not used in civil-law countries as extensively as it is used in Anglo-American. This is probably because civil-law jurisdictions developed public controls on land use earlier than did most Anglo-American jurisdictions.

PUBLIC REGULATION OF LAND USE

Urban planning was known in the ancient world, and particular regulations of land use designed to ensure the health, safety, or sensibilities of neighbours appear wherever human beings live in reasonably close proximity. The amount, however, of such regulation has increased dramatically in the 20th century. As a result, zoning and planning law has become a topic of general concern to the legal profession. The 20th is probably the first century in which it is possible to outline a body of general principles of zoning and planning law rather than simply listing the types of regulations that one or another jurisdiction has seen fit to enact.

Zoning and planning law is also an area in which the basic distinction between Anglo-American and civil law is not particularly useful. Although the concept of public nuisance does not seem to exist in civil law and the constitutional protection given to "property" in the United States has given rise to a somewhat unusual set of limita-

tions on the power of government to regulate land use, the overall picture of public control of land use in the West is more notable for its similarities than for its differences.

Public nuisance. In Anglo-American law the concept of public nuisance serves as a bridge between the private law of nuisance and the avowedly public law of zoning and eminent domain. The concept of public nuisance is closest to that of private nuisance in situations in which a public officer, acting on behalf of the community, brings suit to abate a nuisance that differs from a private nuisance only in that it affects a large number of people. The concept of public nuisance is further removed from that of private nuisance when legislative bodies declare that certain kinds of land use are public nuisances as a matter of law. Traditional legislatively declared public nuisances include the maintenance of houses of prostitution or illegal gambling establishments and illegal sales or consumption of alcoholic beverages. The direct link between public nuisance and zoning and planning law is provided by the fact that in many Anglo-American jurisdictions violations of zoning law are automatically public nuisances. Thus, constructing a building without obtaining the requisite public approval is automatically a public nuisance, which may be abated by the public prosecutor.

Civil law lacks the concept of public nuisance. Civil law, of course, has a large number of prohibited land uses like those described above, and civil law prohibits the construction of buildings without obtaining the requisite permits. Whether the absence of the concept of public nuisance leads to any real differences in result may be doubted. The concept of public nuisance in Anglo-American law has frequently been criticized as being too broad to afford much predictability of decision.

Direct regulation. *Zoning and planning.* In the 19th century urban areas expanded rapidly throughout the West. Industrialization introduced many new types of land uses, uses that frequently were annoying, dangerous, or injurious to the health of those engaged in more traditional residential, commercial, and agricultural activities. The invention and rapid spread of the automobile created problems of traffic control far exceeding anything that the age of the horse-and-buggy had produced. Fire and police protection in urban areas, the provision of such public services as trash collection, and the provision of water, gas, and electricity were rendered difficult, if not impossible, by the chaotic growth of many areas.

Throughout the West the response to these problems was to regulate development. By and large existing structures and land uses were allowed to remain, but new structures and new land uses were subjected to increasingly stringent regulation. The fact that only new structures and uses are subject to regulation is characteristic of all modern Western forms of land-use control, whether it is deemed constitutionally impermissible to require landowners to change existing uses or whether it is simply politically inexpedient to do so.

In virtually all jurisdictions the key regulatory device is the requirement that new construction or substantial rehabilitation of old structures not be undertaken until official permission is obtained (building permit, *permit de construire*, *Baugenehmigung*). The landowner seeking the permit will present to the authorities a set of plans for the proposed construction. These plans are examined to determine if they meet two conceptually distinct sets of requirements. The first set of requirements is the building code. This code requires that all buildings or all buildings of a certain type (*e.g.*, multiple residences) conform to regulations concerning the types of materials used, fire safety, and the use of water and electricity within the building. Particularly for buildings designed for human habitation there are normally additional requirements concerning such matters as the amount of space per occupant, lighting, ventilation, plumbing, or electrical service. Some jurisdictions have a housing code in addition to the building code. The housing code frequently operates retroactively; *i.e.*, it sets out minimum requirements for any building in which human beings reside, whether or not it is newly constructed.

The second set of requirements is the zoning code, in a

Servitudes
in civil law

Zoning
and plan-
ning law

Building
and zoning
codes

more restricted sense. The zoning code lays out a series of requirements for construction and land use within particular areas (zones) of the jurisdiction. Zones may be either inclusive or exclusive. If the zones are inclusive, a hierarchy of land uses is created, usually ranging from the least to the most offensive uses. The typical pattern in urban areas begins with the establishment of residential uses and extends to commercial uses and finally to industrial uses. The characteristic of inclusive zoning is that in any given zone the use designated for that zone will be permitted and also any use conceived as being higher—i.e., less offensive. In exclusive zoning, which is less common, only the designated use is permitted in the given zone.

Modern zoning is characterized by a multiplication of districts. Districts will be designated not only for particular types of uses but also for height and density control. The broad types of uses mentioned above may be elaborately subdivided. Residential districts, for example, may be further subdivided into residential districts for single-family detached houses, for single-family row houses, for two-family houses, for more than two-family houses, and for apartment buildings of given types. Height may be limited by stories or by measurement; open space may be required by setback limitations or by limiting the amount of the site that may be covered by the building; density may be controlled by limiting the ratio of floor area in the building to the area of the site.

Planning
and
process

The establishment of a comprehensive zoning code requires a considerable amount of planning. A full-scale plan, sometimes called a master plan, requires an accurate inventory of the population and of the land-use patterns existing in the area, economic and demographic predictions of what the future is likely to bring, a thorough understanding of the infrastructure that these future changes will require, and considerable imagination in determining what uses should be encouraged and what uses discouraged and where. Such an elaborate plan is normally not legally required before an initial zoning map is drawn. On the other hand, some planning is required, not only as a practical matter but also as a means of fulfilling the universal requirement that the zoning meet some minimum standard of rationality.

The typical statutory scheme vests a given local governmental body with the power to adopt a zoning plan for the region under its control. Public hearings and publication of the proposed plan for comment are frequently required. Property owners aggrieved by the plan are normally given an opportunity to obtain some kind of review of the decisions of the local governmental body. In the Anglo-American jurisdictions this review is normally had in the regular court system, although administrative review may have to be pursued before recourse to the courts is had. In the civil-law jurisdictions review is normally had in separate administrative courts. Both systems tend to give local governmental bodies considerable discretion in making their determinations.

Environmental and historical controls. Both environmental regulation and regulation designed to achieve preservation of historic buildings and districts have greatly increased in the 20th century, particularly since World War II. Broadly speaking, environmental regulations fall into two types: (1) those which limit, frequently by some scientific measure, the amount of a given toxin or pollutant that may be emitted into the air or into the water supply and (2) those that attempt to preserve natural areas in their natural form. Examples of the first type of regulation are the federal clean air and air quality acts in the United States and the Rhine Compact in Europe. Examples of the second type of regulation are the state wetlands preservation acts in the United States and the scenic designation districts in Europe.

Historical preservation regulation normally tightly controls changes in the exterior appearance of buildings. It may leave the building owner with the option of reconfiguring the interior of the building in such a way that he can continue to earn a return on the building, or it may require the preservation of the interior of the building as well. In some areas, if the building cannot be made profitable and still comply with the regulations, the

government may be required to pay the building owner compensation or purchase the building from the owner.

Eminent domain. The concept of eminent domain dates back to at least the early 17th century. It states that the sovereign may take private property for public use, but only upon the payment of just compensation. Many instances of the use of the eminent domain power are universal throughout the West and uncontroversial. Governmental bodies everywhere take pieces of land from private owners in order to construct public roads, build government buildings, or install public services, such as electric wires, or water, gas, and sewer pipes.

In the 20th century there has been a considerable increase in the use of the eminent domain power. As noted above, either as a legal or as a political matter, land-use regulation normally operates only prospectively. For this reason major changes in the type of land use existing in a given area or in the quality and quantity of the buildings are most often accomplished by use of the eminent domain power. Urban renewal projects are a familiar example. Here, a governmental body condemns an entire area, frequently one containing a number of substandard buildings and inappropriately mixed land uses, and then razes the area. The governmental body may then either develop the area itself or sell the parcels to private developers on the condition that they develop them according to a plan devised by the governmental body.

Another use of the condemnation power occurs when a governmental body condemns the development rights in a given parcel of property. This may be done because there are doubts about the body's authority to proceed by way of regulation, because there are political objections to its doing so, or because the body wants to achieve greater flexibility. The current land use may continue so long as the owner wants to continue it, but no further development can take place without permission of the governmental body.

Whatever interest the governmental body takes, it is required to pay just compensation for it. Just compensation is normally defined as the fair market value of the land or interest taken. While there is considerable variation in just-compensation law and even more variation in what is actually awarded, the fair-market-value standard rarely gives the landowner full compensation for the economic loss that he suffers as a result of the taking. Just compensation rarely includes such items as loss of goodwill, moving costs, or counsel fees. Where the landowner retains land in the area and the value of that land is increased because of the public improvement, the increase in value is frequently deducted from the compensation the landowner receives. Thus, even in a situation where the government's obligation to pay compensation is conceded, the person whose land is condemned pays for the privilege of being a citizen of the community in which the land lies.

Just-
compensa-
tion law

Limitations on government action. The notion that some losses by a private owner as a result of government action must be borne by him as part of the cost of living in a community is key to understanding how various jurisdictions determine when a governmental unit must proceed by using the eminent domain power and when it may proceed by way of regulation. Clearly, all government regulations affecting the use of land can have an adverse economic impact on the owner of the land, yet no Western legal system requires that all such economic losses be compensated. Some economic losses must be compensated; some need not be compensated. The question, increasingly debated as regulation of land use becomes more pervasive, is how to draw the line between those that must be compensated and those that need not be.

Every Western jurisdiction requires that, where the government takes property permanently for some public use, some compensation must be paid. But few, if any, Western jurisdictions require that compensation be paid when the government enacts a regulation concerning the prospective use of the land, even if the enactment of that regulation substantially decreases the market value of the land. Where and how the line will be drawn between these extremes varies considerably from jurisdiction to jurisdiction.

The United States probably has the most developed law

on this topic because the enforcement of the provisions of the U.S. Constitution that protect property interests from governmental interference has long been committed to the courts. In the United States two competing and overlapping theories are employed to distinguish "takings," which must be compensated, from "regulations," for which compensation need not be paid: (1) Where a governmental body invades the possessory interest of the landowner, compensation must be paid. There are exceptions to this principle, as, for example, in cases where the invasion of the possessory interest is for a short period and justifiable on grounds of protecting public health or safety or where it is unintentional; but the fact that a governmental body has invaded a landowner's possessory interest is a good predictor that a court will require that compensation be paid. (2) Where the government has not invaded a possessory interest of the landowner but has regulated his use of his property in such a way that no viable use of the property remains, compensation will frequently be required. This principle is considerably more controversial than the first, but it has been followed often enough that it, too, is a good predictor of judicial decisions.

The problem with the second principle is that it is dependent on the particular configuration of the property interests in question. Thus, a regulation that requires that mining operations be conducted in such a way as not to cause subsidence of the surface of the land would not deprive the owner of the entire tract of land of all use because he could continue to use the surface, nor would it deprive the owner of a deep mine of all possible use, since he could conduct his operations in such a way as to avoid the subsidence, but it would deprive the person who owned only a mine close to the surface of all use, since he could not mine without causing subsidence of the surface. (These are basically the facts of *Pennsylvania Coal Co. v. Mahon*, 260 U.S. 393 [1922].)

Compensation law in France and Germany

By and large the French legal system requires compensation only in those situations where the government has permanently deprived a landowner of the possession of his property. The concept of "regulatory taking" does not exist in French law. German law, however, because of the constitutional protection given to property since World War II, has developed a considerable jurisprudence on the topic. By and large the German developments have run a course parallel to those in the United States.

Acquisition and transfer of property interests

Conceptually the creation of a property interest *de novo* and its transfer from one person to another have little in common. The first topic concerns the initial allocation of resources and is closely connected with various theories about the origin of property. The second topic involves the more mundane world of everyday legal transactions. Practically, however, the two topics are closely related. Very few tangible things today do not have an owner. Thus, creation of an original title frequently depends on the extinction of another title, either of another private owner or of the state.

ORIGINAL ACQUISITION

First possession. Speculative jurisprudence, particularly in the 17th and 18th centuries, posited the creation of original titles in a remote period by the physical seizure by individuals of things from a common stock. The theory was based on the fact that most legal systems, including all Western ones, recognize the possibility that an original title can be created by the appropriation of certain kinds of physical things that have no private owner. Wild animals are a notable example. Similarly, tangible personal property lost or abandoned by its owner will frequently become the property of the finder, though regulation may require that in order for the finder to perfect his title he must turn the property over to a public authority for a period of time so as to allow the losing owner an opportunity to reclaim it.

The concept of discovery (meaning discovery by Europeans) played a considerable role in the establishment of European sovereignty over areas of the New World during

the age of exploration (1450 to 1650). Survivals of ideas derived from this period may be seen in countries where the discovery of valuable mineral resources, particularly on public land, will give the discoverer some right to the minerals, although that right is frequently less than full ownership of them.

The concept of discovery also plays a role in the creation of rights in intangible intellectual property. Patents are normally awarded to the person who can demonstrate that he has invented something that has previously not been known. Copyrights are given to the author, the creator of a literary, musical, or artistic work. Trademarks are normally dependent on being the first to use or to register the mark.

Patent,
copyright,
and
trademark

Accession. The concepts of accession, specification, and confusion all involve situations in which something new is made out of something old and that which is old belongs to two different people. In most legal systems, the owner of a cow will own the calf without regard to who owns the bull, and the owner of a field will own the plants that grow in it without regard to who owned the seed or who planted it (accession). In many legal systems, if person A makes a silver plate out of person B's silver ingot, the plate will belong to person A (specification), but if person A decorates the plate of person B, even if that greatly increases its value, the plate will belong to person B, although person B may have to compensate person A for his labour. Finally, if one person's wheat becomes commingled with that of another in the same bin in such a way that the two cannot be separated, the ownership of the wheat will probably depend on who had the larger portion to start with, with the owner of what was originally the smaller portion being relegated to a right to compensation (confusion).

Adverse possession, prescription, and expropriation. In the section on ownership and possession (see above), the related concepts of adverse possession and prescription are discussed. A number of possible rules are buried in the two concepts. One might say, for example, that the expiration of the statute of limitations simply bars the action, but it does not bar the right (limitation of actions, strictly speaking). Alternatively, one might say that the passage of the statutory period bars both the action and the right but does not create any new right in the adverse possessor (extinctive prescription). Or one might say that the adverse possessor, or the one who has fulfilled the requirements for prescription, acquires the title of the one whose title is time-barred (acquisitive prescription, strictly speaking). Both Anglo-American and civil law generally take the more extreme position that, once the rights of the original owner have been extinguished, the person who has prescribed or adversely possessed against those rights has a new original title. At a minimum this means that the new owner may prove his title without having to show how the previous owner acquired his title. It may also mean that he is not subject to restrictions that the original owner may have agreed to.

The exercise of the power of eminent domain also normally results in a new title in the sovereign.

Privileges conferred by public authorities. The foregoing discussion makes it clear that the state has the power throughout the West to create new forms of property. The state may be limited by convention or the constitution when it comes to reallocating property already in private hands, but the state is free to transfer to individuals property that it has and also to create new types of rights that will count as property rights.

DERIVATIVE ACQUISITION

Granted that a property right, privilege, or power exists in a private person, it may be asked whether that right, power, or privilege can be transferred to someone else. The general assumption in Western law is that it can be. Freedom of contract and freedom of alienation of property are the twin foundations of a market economy, and despite the extensive regulation and socialization of the market economies of the West, the basic principle has remained unimpaired. Freedom of alienation is less characteristic of socialist economies and legal systems and of non-Western economies and legal systems. Nonetheless, even these sys-

The
promise
to alienate
property

tems allow alienation in a wide variety of circumstances.

Contract and conveyance. Any legal system that distinguishes between property and obligation (as do all Western systems) will distinguish between a promise to alienate property and the alienation itself. The promise may be fully enforceable between the parties; it may even affect the rights of third parties, at least those who know of the promise. But until the property is transferred, the original owner has a real right in the property (good, notionally, against the whole world), and the promisee has simply an enforceable obligation to have the property transferred.

In many transactions the contract and conveyance take place simultaneously so that the distinction between the two makes no practical difference. If person A buys a watch at a jeweler's, pays for it, and walks out of the store with it on his wrist, both a contract of sale and a conveyance of the watch have taken place; there is no need to distinguish between the two. If, however, person A does not pay for the watch but wears it out of the store and then transfers it to some third person, it becomes important to know whether the jeweler still owned the watch when it was transferred (in which case the jeweler may recover it from the third person) or whether person A owned the watch (in which case the third person now owns it, and the jeweler's sole remedy is against person A). Similarly, if person A pays for the watch but leaves it with the jeweler to have a strap put on it, and the jeweler transfers it to some third party before person A comes back to pick it up, it becomes important to know whether the jeweler still owned the watch (in which case the third party now owns it and person A's sole remedy is against the jeweler) or whether person A owned the watch as soon as he paid for it (in which case he may recover the watch from the third party, and his remedy, if any, will be against the jeweler).

In the example given above there are three possible points at which the title to the property could pass: (1) when the contract between the jeweler and person A was formed (normally when they have agreed on a price and a thing to be sold), (2) when person A paid for the watch, or (3) when the jeweler handed over the watch to him. As a general matter, Western law takes the first or the third position and leaves the second possibility to private agreement between the parties. Thus, in the absence of agreement to the contrary, Western law generally provides that transfer of title takes place either when a valid agreement to transfer is made or when the thing is delivered to the conveyee.

Registration and recordation. In the example of the watch, the distinction between contract and conveyance became important as soon as the rights of a third person became involved. But from the point of view of the third party any one of the three suggested rules about conveyance might be unsatisfactory, because it may be difficult for the third party to know whether a contract has been formed, a payment under it has been made, or even whether the property has been delivered to the purchaser as owner, as opposed to as borrower or hirer. To protect third parties in these situations, many legal systems provide for the registration or recordation of transactions, particularly transactions involving items of great value (such as airplanes or boats or cars) or items of great durability (such as land).

Types of
registration
systems

Registration systems fall into two general types. The first type provides for the registration of title. Under this system transfer of title does not take place unless and until the transfer is registered in the system. This is the system of the German *Grundbuch*, in which titles to land are registered, and of the systems for registration of automobile titles that prevail in the United States. The other type of system is a recording system. Under such a system a transfer is effective even if it is not recorded, but a good-faith purchaser who relies on the record is not protected unless the transaction is recorded. Under this system the previous owner who the record shows is still the owner has the power to convey good title to an innocent third party unless and until the new owner records the transaction. This is the system that prevails in most jurisdictions in the United States for land and under the French system

of registration for transfers of land. The English land registration system is more like the German system than it is like the French or the American.

Sales. In Anglo-American law three things must be established about a conveyance before the law applicable to it can be determined: (1) whether it is a sale or a gift, (2) whether it is of personal (movable) or real (immovable) property, and (3) whether it is immediately effective between living parties (*inter vivos*) or will take effect only upon the death of the conveyor (testamentary). Whereas *inter vivos* sales and *inter vivos* gifts of movables are treated quite differently, the conveyancing aspects of *inter vivos* sales and *inter vivos* gifts of immovables are quite similar. Testamentary sales of either movables or immovables are rare, and testamentary gifts of movables and of immovables are treated similarly. In civil law the distinction between conveyances of movables and conveyances of immovables is far less important than it is in Anglo-American law, whereas the distinction between sales and gifts of immovables is more important than it is in Anglo-American law.

Movables. In both Anglo-American and civil law the sale of a movable is both a contract and a conveyance. In both Anglo-American and French law the contract also serves to transfer the title to the thing unless the parties agree otherwise. German law, on the other hand, following Roman law, requires that there be a handing over of the thing from the seller to the buyer before title may pass. Indeed, in German law title to the thing will pass even if there is no valid contract of sale, so long as the parties intend to transfer ownership of the thing.

The difference between the Anglo-American and French systems, on the one hand, and the German, on the other, can be exaggerated. The number of situations in which there is intent to transfer ownership of a thing in German law without there being a valid contract of sale (or gift, see below) is small. Further, German law allows the transferor and transferee to agree that the transferor will remain in physical possession of the goods, even though title has passed to the purchaser. Thus, in the example given above where the watch remained with the jeweler to have the strap put on it, all three systems would probably hold that title had passed to the purchaser, but the German system would require evidence that the purchaser and the seller had agreed that the seller retain possession in fact on behalf of the new owner, the purchaser.

Despite the fact that all three systems probably would hold that the purchaser had good title to the watch even though the seller retained physical possession of it, all three systems, somewhat surprisingly, would probably protect the third party to whom the jeweler transferred it. All three systems hold as a basic principle that one cannot transfer more rights in a thing than one has (*nemo dat quod non habet; nemo plus iuris ad alium transferre potest quam ipse habet*), but all three systems recognize numerous exceptions to this principle, particularly in the case of movables. Both the French and German systems recognize that the actual possessor of movable goods (with the notable exception of stolen goods) may give good title, at least to a good-faith purchaser. The Anglo-American system is narrower in this regard, but, at least in the United States, someone who entrusts his goods to a merchant, such as the jeweler in this case, who regularly deals in such goods, is liable to lose his title to the person to whom the merchant sells the goods.

Sale of immovables. Sale of real property in Anglo-American law is radically different from the sale of goods. The Statute of Frauds of 1677, which in one form or another is in effect in all Anglo-American jurisdictions, requires that the transfer of most types of interests in land be made by a writing (deed). Contracts for the sale of land also have to be evidenced by a writing, but unless the contract and the transfer are evidenced by the same piece of writing (something that in practice is very rare), the contract will not suffice to transfer the title to real property.

In practice, the sale of real property is always preceded by a contract. The contract will fix the price and other terms of the arrangement and will normally fix a date (the "law day") on which the seller is to appear with a deed to

The Statute
of Frauds

the property conveying "good and merchantable title" and the buyer is to appear with the purchase price. A contract for the sale of land is specifically enforceable. If either side fails to perform, the other party, if ready, willing, and able to perform, may compel the performance. But the ability to compel the performance is not the same thing as having legal (as opposed to equitable) title to the property. That only happens when the conveyance is made—i.e., when the seller delivers the deed to the buyer. The period intervening between the contract and the conveyance is normally occupied by the buyer's obtaining financing for the purchase and the seller's obtaining evidence, based on the public record or on his own muniments of title, that he has merchantable title to the property.

In French law a contract of sale of an immovable passes title to the immovable. Subsequent registration serves to protect that title against third-party purchasers in good faith from the original vendor. In German law the contract of sale and the transfer are conceptually distinct, but in practice they are frequently merged in the same transaction. The transfer of title is not valid as to third parties, or even between the parties themselves, until the transaction is registered in the *Grundbuch*.

In both the French and German systems the time between the contract and its ultimate consummation is markedly shorter than it is in the Anglo-American system. This may be explained in part by the fact that the public recording and registration systems are more effective (despite the differences in how they operate) and by the fact that in both systems there are fewer possible outstanding interests in land. Another explanation of the differences between Anglo-American and civil-law conveyancing practices would look to the differences in the ways that real estate transactions are financed.

Gifts. In Anglo-American law a promise to make a gift is not a binding contract, because it lacks the essential element of consideration (the requirement that to be valid a contract must involve a bargained-for exchange). By contrast, in civil law a contract to make a gift is valid if it is accompanied by certain formalities and if it does not violate the expectancies that the close relatives of the donor have in the property. It is not surprising, then, that donative transactions operate in civil law in much the same way as do sale transactions.

Inter vivos. Lacking the contract to make the gift valid, Anglo-American law has long puzzled over the donative conveyance of movables. Traditional doctrine holds that there has to be delivery, a transfer of possession of the thing accompanied by donative intent on the part of the donor, and acceptance by the donee. Acceptance will be presumed, but evidence of both delivery and donative intent has long been thought to be essential. The contortions that this doctrine produces, particularly in situations where the donative intent is clear but the thing in question is awkward or impossible to deliver, have long been noted by courts and commentators alike. Recently, Anglo-American courts seem to be increasingly willing to allow the delivery of a writing embodying a statement of the gift to substitute for the delivery of the thing itself.

Gifts of real property have caused less difficulty in Anglo-American jurisdictions. It is well established that a writing (deed) is necessary for the transfer of title to real estate; it is common for deeds to recite at least nominal consideration, but no preliminary contract is required for title to pass. Recording of the deed is necessary to make it binding as to subsequent good-faith purchasers from (but not donees of) the same donor.

In civil law a promise of a gift is binding if it is notarized and if it does not deprive the donor's expectant heirs of their obligatory share in his estate. In French law the contract alone suffices to transfer the property. In German law, as in the case of sale, there must be transfer of possession or an agreement that the donor retain possession on behalf of the donee if the thing is movable or an entry in the *Grundbuch* if the thing is immovable. Thus, in civil law *inter vivos* transfers by way of gift parallel those by way of sale, with the important exception that gifts of either movables or immovables may be subject to the overriding interests of the donor's expectant heirs.

Testaments. Western law generally permits a property owner not only to transfer his property while he is alive but also to transfer the property that he owns at his death. This is done by a document called a will or testament. A will is revocable at any time before the testator's death, but if he dies without having changed it, it comes into effect. Thus, the principal characteristic of the will in Western legal systems is its ambulatory nature. It confers no rights on the beneficiaries at the time it is executed but only at the time of the testator's death, and it transfers not the property that the testator owns when he makes the will but rather what he owns at the time of his death.

On this much both the Anglo-American and civil-law systems are in agreement. Beyond this they differ substantially, largely for historical reasons. Decedents' estates are administered quite differently in the two systems, and there are substantial differences in the amount of freedom of disposition that each system gives the deceased. These differences are considered in the next section.

While the form required for a valid will varies from jurisdiction to jurisdiction, a few common principles are observable: in most civil-law jurisdictions and in some Anglo-American jurisdictions a document entirely in the writing of the testator (holograph), signed and dated by the testator, will constitute a valid will. In France and Germany such wills are quite common, perhaps even the norm, and they are normally executed after seeking advice from a notary. In those Anglo-American jurisdictions in which they are valid, their use is far less common than in civil-law countries, and they are almost never recommended by professionals.

Both Anglo-American and civil-law jurisdictions also make use of a formal will, derived from the Roman testament. The characteristic of such a will is that it must be witnessed by a certain number (generally two or three in modern law) of disinterested witnesses. It is normally prepared by a professional, a notary on the Continent or a solicitor or other lawyer in the Anglo-American jurisdictions, and it tends to formality of language.

Many Western jurisdictions will excuse some of the formalities required for will making in certain circumstances. Soldiers' and sailors' wills, for example, are frequently effective with fewer than the usual formalities, and oral wills (nuncupative wills) at least of certain types of property may be valid if made under certain circumstances, such as when the testator is dying. The nuncupative will is related to, though conceptually distinct from, the *causa mortis* gift, a device that exists in most Anglo-American and in some civil-law jurisdictions.

Succession. After a long historical development Western legal systems have come to regard succession to property by relatives of the deceased as normal. Succession by the wider community is regarded as abnormal, something that happens only when no near kin can be found and when the deceased has made no other disposition of his property. Taxation of the passage of property at death, though nearly universal in the West, is not regarded as a form of succession but as a public-law element engrafted onto the system.

Executors and universal succession. As noted above, civil-law systems of succession differ markedly from those in Anglo-American countries. In Anglo-American countries the death of a property holder initiates a period in which his assets are in transition. The deceased's will, if he made one, must be probated (proven) in a court. The court appoints a personal representative of the deceased. In many jurisdictions, if the personal representative has been named in the will, he is called the executor of the will. If no personal representative is named in the will, if the personal representative named in the will fails to qualify or declines to serve, or if there is no will, the personal representative appointed by the court is called the administrator of the estate. The personal representative then marshals the deceased's assets, pays the deceased's debts and the taxes on his estate, and distributes the balance to those named in the will or those entitled to the assets by law.

Title to the deceased's personal property passes to the personal representative, subject to his fiduciary responsibility

The form
of a will

Donative
transac-
tions

to discharge the obligations of the estate and distribute the balance to those entitled to it. At common law and in a number of Anglo-American jurisdictions today, title to real property passes immediately upon death to those who succeed to it, but since the real property is also liable to the payment of the deceased's debts and taxes, the title is normally not marketable until the estate is closed. Thus, as a practical matter, the deceased's estate constitutes an entity held by the personal representative until the distribution is made.

Universal succession

Civil-law systems generally avoid the hiatus period characteristic of Anglo-American estate administration. By and large civil-law systems provide for universal succession, a term derived from Roman law, which means that the heirs succeed immediately to both the assets and the liabilities of the deceased. They are responsible for paying the debts and taxes and any legacies that may lawfully be charged against the estate. Personal representatives are not unknown in civil law, but they generally play a less important role than do those in the Anglo-American systems.

Freedom of testation and legitim. Another major difference between Anglo-American and civil-law systems of succession is that wills, though important, are less important in civil law than they are in the Anglo-American system. In civil law someone who dies leaving a spouse or close kin (descendants or ascendants) may effectively dispose of only a portion of his estate by will. The rest must go to the statutory heirs (*réserve héréditaire, legitim*). Wills remain important in the civil-law systems, however, both because the disposable share of the estate may amount to a large monetary sum and because the statutory share of the heirs tends to be viewed in monetary terms. Thus, the will may direct that certain assets be given to certain members of the family, so long as each member receives the value to which he or she is entitled under the statute.

Anglo-American law affords, at least in theory, greater freedom of testation. In England a deceased may dispose of his entire estate by will to the detriment of his spouse and children, subject however to contravention by a court upon petition of the spouse or children if they are not adequately provided for. In the United States a deceased may generally not disinherit his spouse but may disinherit his children, even if this leaves them without any means of support.

Theoretical possibilities, however, do not determine practical realities. Many Americans, for example, avoid the probate system entirely, either because they make lifetime dispositions of their property (for example, in trust) or because their heirs behave as if universal succession were in fact in place; *i.e.*, the heirs divide the property among themselves and pay the creditors and the tax collector out of their own pockets. Similarly, there seems to be little pressure to change the amount of freedom of testation offered to many Anglo-American testators because that freedom is rarely used to disinherit spouses or children. (Perhaps the most common form of American will is one that gives the surviving spouse everything, usually with the tacit understanding that he or she will give anything left over to the children on his or her death.)

Patterns of intestate succession. Patterns of intestate succession vary markedly from jurisdiction to jurisdiction in the West, although the differences tend to be ones of detail and not of principle. The typical Anglo-American intestacy statute gives the surviving spouse a half or a third of the property, with the remaining half or two-thirds going to the children of the deceased, the children of any deceased child dividing their parent's share among them (representation). In the absence of a surviving spouse, the children (or their representatives) take all. In the absence of children, the surviving spouse takes all or shares his or her portion with the deceased's parents. Beyond that the patterns vary, but almost all provide for succession by the deceased's next of kin, at least so long as he left grandparents or descendants of grandparents. If no one survives in these categories, some modern systems give the property to the state; others continue the search for blood relatives of the deceased.

Civil-law patterns do not vary greatly, though they tend to give less to the surviving spouse because he or she is

presumed to have a share of the community property (see above). The French system is notable for the fact that it divides the deceased's property between his maternal and paternal kin, if there are no descendants. The German system is more like the Anglo-American.

Historically in the West illegitimate children were totally excluded from inheritance. Modern Western legal systems have come increasingly to recognize inheritance rights of illegitimates, although not all systems give them equal rights with legitimates.

Inheritance rights of illegitimate children

English law did not recognize adoption until 1926. Modern Anglo-American law has come to recognize adopted children as, in most jurisdictions and for the most part, equal in inheritance rights to natural children. The civil law has had less difficulty recognizing the rights of adopted children because Roman law freely allowed adoption.

Nonconsensual transfers. Western law generally recognizes some situations in which transfers of property are made without the consent of the property holder. By far the most important of these are the situations in which a property holder may be forced to give up his property to someone to whom he owes money. As a general matter, in Western legal systems a creditor may reach any property which the debtor has the power voluntarily to transfer. Thus, even in the absence of a mortgage or a pledge, a person's general creditors may reach and execute upon any property that he could convey voluntarily to them. The property that the general creditor can reach varies considerably from jurisdiction to jurisdiction. Many jurisdictions exempt certain kinds of property from execution by creditors. The "debtor states" of the United States are particularly notable for the amount and character of the property that may be so exempt. The jurisdictions also differ widely in the extent to which they require court supervision of the process of seizing a debtor's property. Some will allow it upon very little showing; others require a quite elaborate process.

As mentioned above, co-owners in many jurisdictions are able to force the judicial sale of the property that they hold, particularly if partition in kind is not possible.

Although acquisitive prescription or expropriation (see above) can be viewed as involuntary transfers, they are technically probably better viewed as the creation of new titles by the state and the extinction of old ones. There are, however, some situations in which this analysis will not suffice. In the Anglo-American system a court of equity has considerable discretion to deny an injunction and remit the complainant to money damages. Where this happens, a property right is in effect forcibly sold by the property holder, who must be satisfied with money damages. The same problem does not seem to have arisen in civil-law systems, but a similar result can occur in the civil law when a landowner claims a way of necessity.

The Western concept of property: assessment

One of the striking results of this survey of property law in the West has been to recognize the extent to which the differences between the civil-law systems and the Anglo-American systems are not of great practical significance. Despite substantial differences in the history of the two systems—differences that are still manifest today in the different vocabulary and different devices that the two systems use to solve legal problems—it was frequently possible to say either that the two systems arrive at the same practical result or that the practical results in the two systems are converging.

The tendency toward convergence

This fact should not be surprising. As said above, property law is intimately connected with the economy of the society, with its family structure, and with its political system. Commentators have long noted that the industrialized, bureaucratic democracies of the West have become increasingly interdependent and increasingly like each other as the 20th century has progressed. To the extent that the differences between the Anglo-American and civil-law systems are based on historical differences that are not reflected in the modern societies, one should expect that these societies would tend toward the same legal solutions despite their differences in conceptual starting points.

This tendency toward convergence has been aided by the fact that most of the changes noted above have come by way of legislation (e.g., landlord and tenant). Legislation in the West has traditionally been able to change the conceptual scheme that history has imposed on the law. Most of these legislative changes have also come about in the area denominated public law (e.g., land-use regulation). Public law operates largely free of the historical differences in conceptualization that characterize the private law of the Anglo-American and civil-law systems. As public law has become increasingly important for property law in the definitional sense, the practical results in the two systems have been able to come closer together.

The last decades of the 20th century have also seen a progressive eroding of both the legal concept and the practical importance of private property in the West. Attacks on the concept of private property itself are more common in the United States than in other countries, both because of the American constitutional tradition of protecting property and also because the United States has made more changes in its law by way of judicial decision. American judges are forced, in a way that legislators are not, to make their decisions in the context of traditional property law.

In the United States, then, examples of direct attacks on the concept of property are easy to find. The "sit-in" cases and the cases involving access to migrant labour camps (referred to above) were expressly framed as conflicts between "property rights" and "civil rights" and left a strong suggestion that a humane society could hardly prefer the former to the latter. In a quite different area of law, many judges and commentators expressly characterized the judicial changes in the law of landlord and tenant as a triumph of contract over property concepts. A number of academic writers have suggested that property rules, with their characteristic injunctive remedy, interfere with the achievement of allocational efficiency and should be replaced by liability rules; damages, they argue, should be awarded for the violation of property rights rather than specific performance.

The only recent academic development that suggests anything other than a dim future for the concept of private property in the United States was the attempt to apply the concept of property to a citizen's expectation that he would continue to be the recipient of government benefits. As noted above, the idea found favour with the courts for a while but then seemed to be lost from view.

Most of these developments are evident throughout the Western world, although their relationship to the concept of private property has not always been put as sharply as in the United States. Thus, the problem of access to restaurants or places of employment is in many Western countries subject to regulation similar to that which exists in the United States, but the regulations are perceived as "public law" regulations of business and hence outside the scope of the "private law" of property. Landlord and tenant law has been reformed again and again in the West in the 20th century. The question of the appropriate remedy to defend property rights has appeared wherever thinking about law in the manner of a new subspecialty, that of law and economics, has been felt. The security of job, pension, insurance, and welfare are standard political and legal issues throughout the Western world.

Other developments suggest that the institution, if not the concept, of private property is in trouble throughout the West. A new body of regulatory law designed to protect the environment has greatly restricted the traditional privileges of owners of resources to use them to their advantage. Further, and perhaps in the long run most significantly, family ties are weakening throughout the West. Divorce rates are at an all-time high. Birth rates are declining, particularly among the middle class. Finally, continuing high discount rates, whether accompanied by inflation or not, and heavy taxation on private accumulations of wealth and particularly on its passage from generation to generation have affected the attitudes and practices of many Westerners with regard to the use of traditional forms of property as a source of personal financial security. While the concept of private property

itself is not directly involved in these developments, the traditional devices that property law offers for ensuring the financial security of present and future generations are made increasingly irrelevant by these developments.

Some of these modern developments directly involve the agglomerative tendency characteristic of the Western concept of property. One may, for example, consider the developments in landlord-tenant law. The landlord is the owner; all that the lease purports to do, in the Anglo-American system, is to convey possession to the tenant for a term, and, in the civil-law countries, to create in the landlord an obligation to allow the tenant the use of the premises for a particular period. The agglomerative tendency would dictate that the tenant should be entitled to no more than was conveyed to him or to no more than bargained for. To the extent that the modern developments give the tenant more, they undercut the tendency. The agglomerative tendency is also involved in the conflict between property rights and civil rights because the tendency would lead one to define the right to exclude broadly and to require that it be protected even where it is being used discriminatorily. To the extent that modern law has reached a different result, it has, once again, undercut the tendency.

Some of these modern developments involve tensions inherent in the agglomerative tendency. Perhaps the only reason that increasing environmental regulation is not always perceived as simply a variant on the old land-use problem is that adverse environmental effects are sufficiently diffused that it is difficult to see that it is the property of those who feel the effect that is at stake. The academic controversy over property rules versus liability rules involves the same tension. The economic approach suggests that, once the law has chosen one land use in preference to another, it should compromise with the nonfavoured land use by giving the favoured use less than full remedies.

Neither the agglomerative tendency nor the tensions within it are involved in the changes in the family or in the controversy over the security of employment and government benefits, but the two may be related and their product affects the role, at least of traditional property, in the society. Traditional property operates in a family context and serves to support the role of the family in providing security for its members. If family ties are weakening and if traditional property cannot provide security against exogenous economic forces, people will look elsewhere for their security. They will look, for example, to their employment or to government benefits. As these, in turn, become more the focus of attention and more secure, traditional property and the security that it provides within the family will be further weakened. It is perhaps for this reason that the different compromises the Anglo-American and civil-law systems made historically between the power to convey of present holders and the power to convey of the conveyee have remained more stable in the West than have those about land use. They have remained stable because private settlements are increasingly irrelevant to the financial security of most of the population.

Thus, although nothing concerning the descriptive definition of property used in this article is at stake in these modern controversies and developments, the concept and the institution of property has changed fundamentally in the West in the last generations. Coming as these developments do, at a time of the decay of liberalism, one may fairly ask whether these developments indicate a change not only from the extremes to which the agglomerative tendency was brought during the 19th and early 20th centuries but also whether they indicate a reversal of the fundamental tendency itself. That is an issue that only the next century can resolve.

Theory: Surveys of classical and of early modern theories of property law are found in J. ROLAND PENNOCK and JOHN W. CHAPMAN (eds.), *Property* (1980), which includes a look at the future of the Western concept of property in CHARLES DONAHUE, JR., "The Future of the Concept of Property Predicted from Its Past," pp. 28-68; RICHARD TUCK, *Natural Rights Theories: Their Origin and Development* (1979); and RICHARD SCHLATTER, *Private Property: The History of an Idea* (1951, reprinted 1973).

Specific modern legal systems: For American developments, see ROGER A. CUNNINGHAM, WILLIAM B. STOEUCK, and DALE A. WHITMAN, *The Law of Property* (1984); RAY ANDREWS BROWN, *The Law of Personal Property*, 3rd ed., rev. by WALTER B. RAUSHENBUSH (1975); RICHARD R. POWELL, *The Law of Real Property*, rev. by PATRICK J. ROHAN (1949-), a multi-volume classic treatise, still being updated with supplements; and A. JAMES CASNER (ed.), *American Law of Property*, 7 vol. in 8 (1952-54). For England, see FREDERICK H. LAWSON and BERNARD RUDDEN, *The Law of Property*, 2nd ed. (1982); KEVIN GRAY, *Elements of Land Law* (1987); ROBERT MEGARRY and H.W.R. WADE, *The Law of Real Property*, 5th ed. (1984); and J. CROSSLEY VAINES, *Crossley Vaines' Personal Property*, 5th ed., rev. by E.L.G. TYLER and N.E. PALMER (1973). French law is reviewed in MAURICE S. AMOS, *Amos & Walton's Introduction to French Law*, 3rd ed., rev. by FREDERICK H. LAWSON, A.E. ANTON, and L. NEVILLE BROWN (1967); CHRISTIAN LARROUMET, *Droit civil*, vol. 2: *Les Biens, droits réels principaux* (1985); GABRIEL MARTY and PIERRE RAYNAUD, *Les Biens*, 2nd ed. (1980), and *Les Régimes matrimoniaux*, 2nd ed. (1985); and MARCEL PLANIOL and GEORGES RIPERT, *Traité pratique de droit civil français*, 2nd ed., 14 vol. (1952-62).

For Germany, see NORBERT HORN, HEIN KÖTZ, and HANS G. LESER, *German Private and Commercial Law*, trans. from German (1982); E.J. COHN, *Manual of German Law*, 2nd rev. ed., 2 vol. (1968); ERNST WOLF, *Lehrbuch des Sachenrechts*, 2nd ed. (1979); LUDWIG ENNECCERUS, THEODORE KIPP, and MARTIN WOLFF (eds.), *Lehrbuch des bürgerlichen Rechts*, vol. 1 in 2: *Allgemeiner Teil des bürgerlichen Rechts*, 15th ed., rev. by H.C. NIPPERDEY (1959-60), vol. 3: *Sachenrecht*, 10th ed., rev. by MARTIN WOLFF and L. RAISER (1957), and vol. 5: *Erbrecht*, 13th ed., rev. by HELMUT COING (1978); and KURT REBMANN and FRANZ-JÜRGEN SÄCKER (eds.), *Münchener Kommentar zum Bürgerlichen Gesetzbuch*, 2nd ed. (1984-), planned for 7 vol., some multipart, of which 5 had been published by 1989.

Specific studies: Following are works discussing other topics, listed in the order they are treated in the text. The vocabulary of jural relationships is presented in WESLEY N. HOFFELD, *Fundamental Legal Conceptions as Applied in Judicial Reasoning: And Other Legal Essays*, ed. by WALTER WHEELER COOK (1923), available also in later abridged editions. For non-Western systems of property, see chapter 2, "Structural Variations in Property Law," published as a separate fascicle of the incomplete vol. 6 of the *International Encyclopedia of Comparative Law*, covering Islamic, Hindu, and African law, as well as that of socialist countries; and MAX GLUCKMAN, *The Ideas in Barotse*

Jurisprudence (1965, reprinted with a new preface and amendments, 1972).

Evolutionary anthropology and the development of the concept of property are addressed in FRIEDRICH ENGELS, *The Origin of the Family, Private Property, and the State* (1902, originally published in German, 1884), also available in many later editions and translations; HENRY SUMNER MAINE, *Ancient Law: Its Connection with the Early History of Society, and Its Relation to Modern Ideas* (1861), available in many later editions; PETER STEIN, *Legal Evolution: The Story of an Idea* (1980); and ALAN WATSON, *The Evolution of Law* (1985).

S.F.C. MILSOM, *The Legal Framework of English Feudalism* (1976, reprinted 1986), examines the tradition of land tenure; D.R. COQUILLETTE, "Mosses from an Old Manse: Another Look at Some Historic Property Cases About the Environment," *Cornell Law Review* 64:761-821 (June 1979), discusses the nuisance law; WILLIAM B. STOEUCK, "A General Theory of Eminent Domain," *Washington Law Review* 47:553-608 (August 1972), traces the history of the governmental authority over private property; and DAVID J. SEIPP, "Bracton, the Year Books and the 'Transformation of Elementary Legal Ideas' in the Early Common Law," *Law and History Review* 7:175-217 (Spring 1989), analyzes the concept of property in Bracton. On "possessive individualism," see C.B. MACPHERSON, *The Political Theory of Possessive Individualism: Hobbes to Locke* (1962, reprinted 1985). GEORGE L. HASKINS, "Extending the Grasp of the Dead Hand: Reflections on the Origins of the Rule Against Perpetuities," *University of Pennsylvania Law Review* 126:19-46 (November 1977), explores social conflicts in connection with this rule. See also J.H.C. MORRIS and W. BARTON LEACH, *The Rule Against Perpetuities*, 2nd ed. (1962, reprinted 1986); and RONALD H. MAUDSLEY, *The Modern Law of Perpetuities* (1979). C. REICH, "The New Property," *Yale Law Journal* 73(5):733-787 (April 1964), looks at government-granted rights as "property." Property and personal financial security are the topic of MARY ANN GLENDON, *The New Family and the New Property* (1981), and *The Transformation of Family Law: State, Law, and Family in the United States and Western Europe* (1989), focusing on marital property. For corporate property, see ADOLF A. BERLE and GARDINER C. MEANS, *The Modern Corporation and Private Property*, rev. ed. (1968).

Definitions of ownership are given in FELIX S. COHEN, "Dialogue on Private Property," *Rutgers Law Review* 9(2):357-387 (Winter 1954); and A.M. HONORÉ, "Ownership," ch. 5, pp. 107-147 in A.G. GUEST (ed.), *Oxford Essays in Jurisprudence* (1961). Modern legal relations between landlord and tenant are examined in CHARLES DONAHUE, JR., "Change in the American Law of Landlord and Tenant," *Modern Law Review* 37:242-263 (May 1974). For trusts, see AUSTIN WAKEMAN SCOTT, *The Law of Trusts*, 3rd ed., 6 vol. (1967), with a 4th ed., by AUSTIN WAKEMAN SCOTT and WILLIAM FRANKLIN FRATCHER, appearing in parts since 1987. Civil-law functional equivalents of the trust are discussed in CHRISTIAN DE WULF, *The Trust and Corresponding Institutions in the Civil Law* (1965). FRANCIS ALLEN, "Offenses Against Property," pp. 57-76 in LOUIS B. SCHWARTZ (ed.), *Crime and the American Penal System* (1962), studies the protection of property in criminal law. DONALD G. HAGMAN and JULIAN CONRAD JUERGENSEMEYER, *Urban Planning and Land Development Control Law*, 2nd ed. (1986); and J.F. GARNER and N.P. GRAVELLS (eds.), *Planning Law in Western Europe*, 2nd rev. ed. (1986), deal with public control of land use. Constitutional protection of property is the subject of BRUCE A. ACKERMAN, *Private Property and the Constitution* (1977). A comparative treatment of gifts (both inter vivos and testamentary) is offered in JOHN P. DAWSON, *Gifts and Promises: Continental and American Law Compared* (1980). American wills are examined in M.L. FELLOWS et al., "An Empirical Study of the Illinois Statutory Estate Plan," *University of Illinois Law Forum* 1976:714-745 (1976). Property from the perspective of law and economics is presented in G. CALABRESI and A.D. MELAMED, "Property Rules, Liability Rules, and Inalienability: One View of the Cathedral," *Harvard Law Review* 85:1089-1128 (April 1972); and A.M. POLINSKY, "Controlling Externalities and Protecting Entitlements: Property Right, Liability Rule, and Tax-Subsidy Approaches," *Journal of Legal Studies* 8(1):1-48 (January 1979).

(Ch.D.)

Protestantism

Protestantism, beginning in northern Europe in the early 16th century in reaction to medieval Roman Catholic doctrines and practices, became, along with Roman Catholicism and Eastern Orthodoxy, one of three major forces in Christianity. After a series of European religious wars, and especially in the 19th century, it spread rapidly in various forms throughout the world. Wherever Protestantism gained a foothold, it influenced, to a greater or lesser extent, the social, economic, political, and cultural life of the area.

This article treats the history of the Protestant movement

and the teachings, practices, and organizational principles both common among and peculiar to the respective Protestant denominations. For further treatment of the life and works of the two principal Reformation leaders, see CALVINISM, CALVIN AND; LUTHER. See also *Micropædia* for biographical treatment of other Reformers (e.g., John Knox; Thomas Müntzer; Huldrych Zwingli).

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 811, 827, and 961, and the *Index*.

The article is divided into the following sections:

HISTORY OF THE PROTESTANT MOVEMENT

Origin of the term Protestant

Protestantism was given its name at the Diet of Speyer in 1529. At that imperial assembly the Roman Catholic princes of Germany, along with the Holy Roman emperor Charles V, rescinded most of what toleration had been granted to the followers of Martin Luther three years earlier. On April 19, 1529, a protest was read against this decision, on behalf of 14 free cities of Germany and six Lutheran princes, who declared that the decision did not bind them because they were not a party to it, and that if forced to choose between obedience to God and obedience to Caesar they must choose obedience to God. They appealed from the diet to a general council of all Christendom or to a congress of the whole German nation. Those who made this protest became known as Protestants. The name was adopted not by the protesters but by their opponents, and gradually it was applied as a general

description to those who adhered to the tenets of the Reformation, especially to those living outside Germany. In Germany the adherents of the Reformation preferred the name evangelicals and in France Huguenots.

The name Protestant was attached not only to the disciples of Luther (c. 1483–1546) but also to the Swiss disciples of Huldrych Zwingli (1484–1531) and later of John Calvin (1509–64). The Swiss Reformers and their followers in Holland, England, and Scotland, especially after the 17th century, preferred the name Reformed.

In the 16th century the name Protestant was used primarily in connection with the two great schools of thought that arose in the Reformation, the Lutheran and the Reformed. In England in the early 17th century the word Protestant was used in the sense of "orthodox Protestant," as opposed to those who were regarded by Anglicans as

unorthodox, such as the Baptists or the Quakers. Roman Catholics, however, used it for all who claimed to be Christian but opposed Catholicism (except the Eastern churches). They therefore included under the term Baptists, Quakers, and Catholic-minded Anglicans. Before the year 1700 this broad usage was accepted, though the word was not yet applied to Unitarians. The English Toleration Act of 1689 was entitled "an Act for exempting their Majesties' Protestant subjects dissenting from the Church of England." But the act provided only for the toleration of the opinions known in England as "orthodox dissent" and conceded nothing to Unitarians. Throughout the 18th century the word Protestant was still defined in relation to the historical reference of the 16th-century Reformation. Samuel Johnson's dictionary (1755), which is characteristic of other dictionaries in that age, defines the word thus: "one of those who adhere to them, who, at the beginning of the reformation, protested against the errors of the church of Rome." (W.O.C.)

The context of the late medieval church

The Protestant Reformation occurred against the background of long developments and rich ferment in the Roman Catholic Church and the world of the late Middle Ages. For two reasons it has been difficult to gain perspective on those times. Catholic historians had an interest

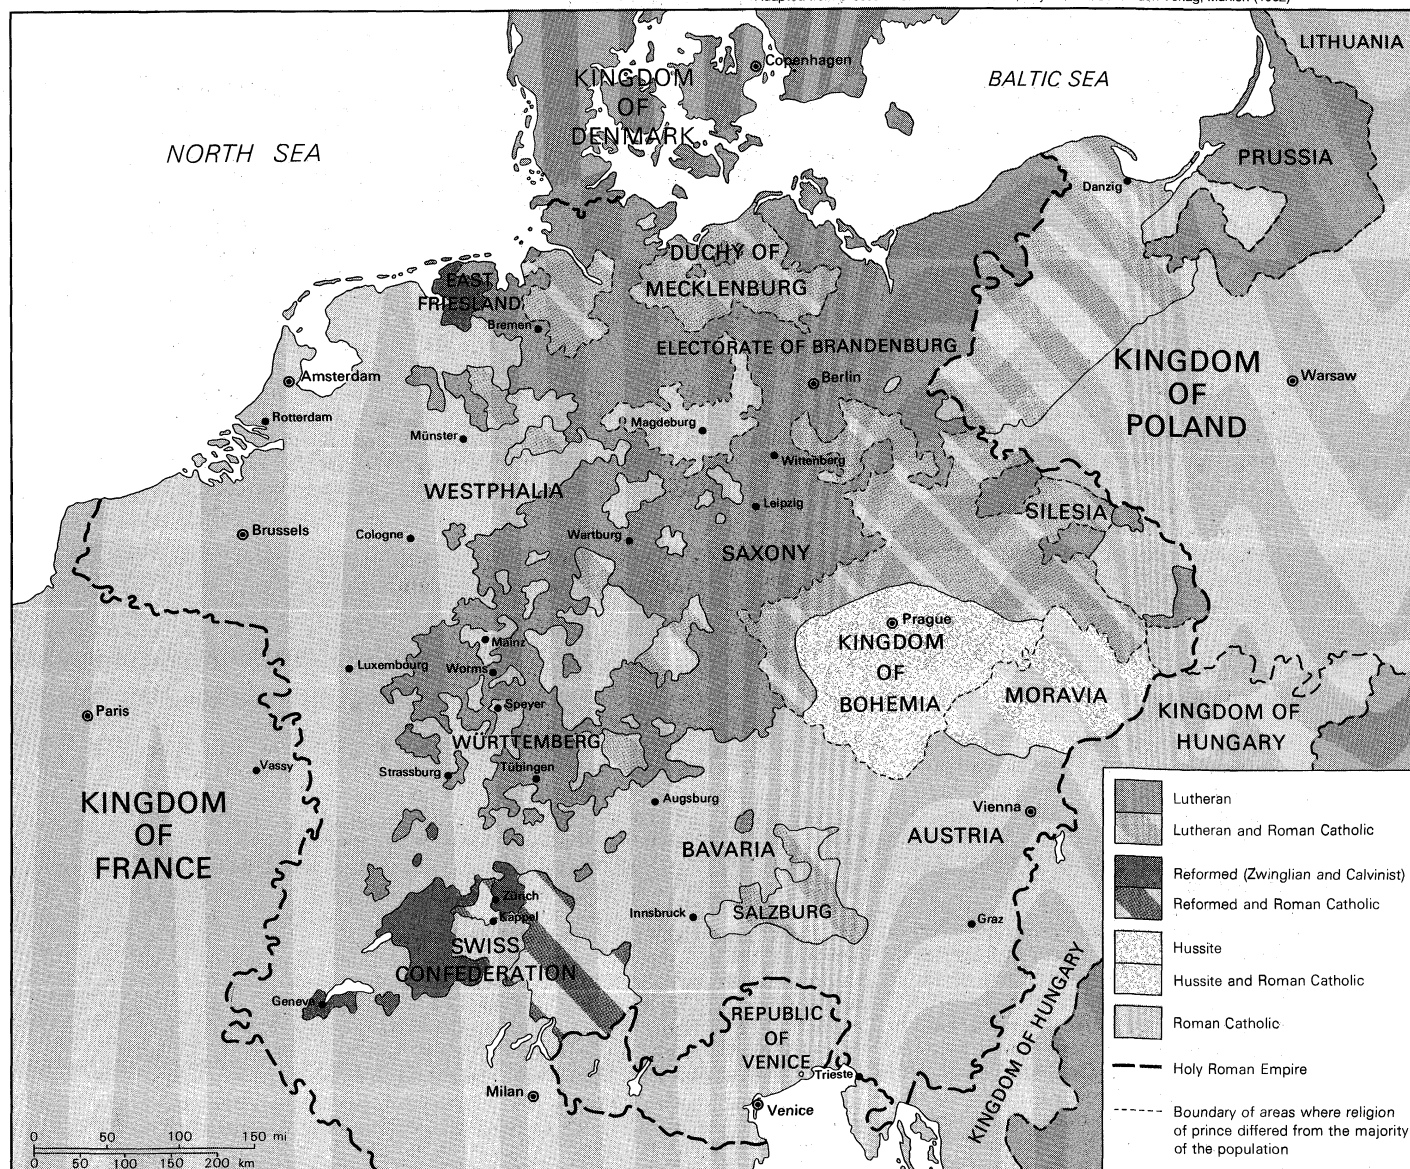

in showing how much reform was occurring before and apart from the radical disrupters of the 16th century, the Protestant reformers. Protestant historians, on the other hand, portrayed the late medieval church in the most negative terms to show the necessity of the Reformation, which consequently came to look like a complete break with a corrupt past.

The other reason for difficulty in understanding stems from the fact that the 15th-century agents of change were not "Pre-Reformers"; they neither anticipated Protestantism nor acquired their importance only from the subsequent Reformation. The events of that period were also not "Pre-Reformation" happenings but had an identity and meaning of their own.

There has always been agreement on the fact that there were reform developments and ferment in the 15th-century church all the way from Spain and Italy northward through Germany, France, and England. Some of these were directed against abuses by the papacy, the clergy, and monks and nuns. The pious, for example, abhorred Innocent VIII (1484-92), who performed marriage ceremonies for his own illegitimate children in the Vatican, and Alexander VI (1492-1503), who was and was seen to be depraved. The public was also increasingly aware of and angered by luxurious papal projects, for which funds were exacted.

The distaste for the papacy increased at a time of rising

nationalist spirits. The popes, who had long intervened in the politics of Germany, France, and England, faced setbacks when the monarchies in each country acquired new power. The sovereigns found a need to assert this power against the papacy and, in most cases, against local clerical representatives of the church.

At this time of rising national consciousness there appeared a generation of theologians who remained entirely within the context of medieval Roman Catholicism but who engaged in fundamental criticisms of it. Thus William of Ockham (d. 1349?) spoke up as a reformer within the Franciscan order. He wished to return this religious order to the ideal of poverty, which it had in large part abandoned. As part of his reform he maintained that Pope John XXII was heretical. Ockham saw the papacy and empire as independent but related governments or realms. When the church was in danger of heresy, lay people—princes and commoners alike—must come to its rescue. This meant, in the present case, reform.

In England, John Wycliffe engaged in similar struggles, which weakened papal power and the hold of the medieval church. Wycliffe also traded on national consciousness, which he directed toward reform of the church. His instrument was the moral law of the Bible. Wycliffe gave impetus to its translation, and in 1380 he helped make it available to rulers and ruled alike, though he always granted uncommon spiritual authority to the king.

In Bohemia, Jan Hus, who became rector of the University of Prague, used that school as his base to criticize a luxury-minded clergy. He also exploited national feelings and came to argue that the pope had no right to use the temporal sword. Hus's bold accusations led to his death by burning at the Council of Constance in 1415.

Alongside a piety that combined moral revulsion with national feelings, Christian humanism was a further sign of stirring in the late medieval church. In Italy, Lorenzo Valla (1407–57) used his sophisticated techniques of historical inquiry to expose a number of forgeries that had given the papacy many of its powers and much of its domain. In Germany, Johannes Reuchlin (1455–1522) studied Greek and Hebrew, the biblical languages, and fought for the rights of scholars to question traditional claims of the church. In Holland, Desiderius Erasmus (1466/69–1536), who remained a Roman Catholic, used his vast learning and his satiric pen to question the practices of the church.

Still another factor that disturbed a complacent late medieval church was a flowering of mysticism in the spirit of Meister Eckehart (d. 1327/28) or Johann Tauler (d.

1361). These people of profound devotion gained followers who sought and claimed to have a direct access to God, bypassing many of the church's rites and practices. Reformers like Martin Luther were to speak well of some of these devotionalists and to translate their writings.

While the Reformers attacked people in high places, they also regarded the Catholicism of ordinary people as being in need of reform. Devotion to the Virgin Mary had come to look superstitious to them as well as to occur at the expense of devotion to Christ. Such practices as pilgrims visiting shrines or parishioners regarding relics of saints with awe seemed to perpetuate a kind of paganism under a Christian veneer. The pestilences and plagues of the 14th century had bred an inordinate fear of death, which led to the exploitation of simple people by a church that was, in effect, offering salvation for sale. By the turn of the 16th century much of Europe was ripe for reforms that Catholicism could neither open itself up to nor contain.

(M.E.M.)

The continental Reformation: Germany, Switzerland, and France

THE ROLE OF LUTHER

Luther said that what differentiated him from previous reformers was that they attacked the life, he the doctrine of the church. Whereas they denounced the sins of churchmen, he was disillusioned by the whole scholastic scheme of redemption. The assumption was that man could erase his sins one by one through confession and absolution in the sacrament of penance. Luther discovered that he could not remember or even recognize all of his sins, and the attempt to dispose of them one by one was like trying to cure smallpox by picking off the scabs. Indeed, he believed that the whole man was sick. The church, however, held that the individual was not too sick to make up for bad deeds by some good deeds. God gave to all a measure of grace. If human beings lay hold of it and did the best they could, God would reward them with a further gift of grace with which they could perform deeds of genuine merit, which would give them credit before God. Human beings might even die with more than enough credits for salvation. These extra credits constituted a treasury of the merits of the saints, from which the pope could make transfers to those whose accounts were in arrears. The transfer was called an indulgence and for this, in Luther's day, the grateful recipient made a contribution to the church.

Ockham's
reform
efforts

The
indulgence
system and
its effects

This arrangement proved to be a popular way of raising money particularly because, unlike tithes, it was voluntary and could provoke no resentment. By this means crusades, cathedrals, hospitals, and even bridges were financed. At first the indulgence, according to the Germanic law of commutation of a physical punishment to a fine, applied only to penalties imposed by the church on earth. Then it was extended to penalties imposed by God in purgatory. In Luther's day immediate release from purgatory was being offered, and the remission not only of penalties but even of sins was assured. Thus the indulgence encroached upon the sacrament of penance.

Luther was desperately in earnest about his standing before God and Christ. The woodcuts of Christ the Judge on a rainbow consigning the damned to hell filled him with terror. He believed the monastic life to be the way par excellence to acquire those extra merits that would more than balance his account. He became a monk and subjected himself to rigorous asceticism, but he could never reach the assurance that a sinful pygmy like himself could ever stand before the inexorable justice and majesty of God. Continual recourse to the confessional simply convinced him of the fundamental sickness of the whole man. He began then to question the goodness of a God who would make human beings so weak and then damn them for what they could not help. Relief came through the study of the Psalms. Luther found the 22nd Psalm particularly revealing because it contains the words quoted by Christ upon the cross, "My God, my God, why hast thou forsaken me?" Evidently then, Christ, being without sin, so identified himself with sinful humanity as to feel himself estranged from God. Christ the Judge seated upon the rainbow had become Christ the Derelict upon the cross, and here the wrath and the mercy of God could find their point of meeting so that God was able to forgive those utterly devoid of merit. He could justify the unjust, and this required of man only that he accept the gift of God in faith. This was the doctrine of justification by faith, which became the watchword of the Reformation.

What this insight meant for the doctrine of indulgences is at once apparent. The great offense was not the financial aspect but rather the very notion that human beings dared to engage in bookkeeping with God. Luther by now had become a professor at the University of Wittenberg and also a pastor. His parishioners were obtaining the indulgences issued by Albert, the new archbishop of Mainz, half of the proceeds to be retained by him as reimbursement for his installation fee as archbishop, the other half to go to the pope for the building of the Basilica of St. Peter's at Rome. For this indulgence Albert made unprecedented claims. If the indulgence were on behalf of the donor himself, he would receive preferential treatment in case of future sin, if for someone else already in purgatory, he need not be contrite for his own sin. Remission was promised not only of penalties but also of sins, and the vendor of the indulgences offered immediate release from purgatory.

Ninety-five
Theses

Against these instructions Luther launched his Ninety-five Theses on All Saints' Day of the year 1517. In the theses he presented three main points. The first concerned financial abuses; for example, if the pope realized the poverty of the German people, he would rather that St. Peter's lay in ashes than that it should be built out of the blood and hide of his sheep. The second focused attention on doctrinal abuses; for example, the pope had no jurisdiction over purgatory and if he did, he should empty the place free of charge. The third attacked religious abuses; for example, the treasury of the merits of the saints was denied by implication in the assertion that the treasury of the church was the gospel. This was the crucial point. When the papacy pronounced Luther's position heretical, he countered by denying the infallibility of popes and for good measure of councils also. Scripture was declared to be the only basis of authority.

Luther found support in many quarters. Already a widespread liberal Catholic evangelical reform sought to correct the moral abuses such as clerical concubinage, financial extortion, and pluralism (*i.e.*, the holding of several benefices by one man) and ridiculed the popular

superstitions associated with the cult of the saints and their relics, religious pilgrimages, and the like. This movement had representatives in all lands, notably John Colet in England, Jacques Lefèvre in France, Francisco Jiménez de Cisneros in Spain, Juan de Valdés in Naples, and, above all, Erasmus of Rotterdam. Erasmus found nothing amiss in Luther's theses except that he had been too tart as to purgatory, and when the cry of heresy was raised against Luther, he wrote to the elector Frederick III the Wise, Luther's prince, telling him that as a Christian ruler he was obligated to see to it that his subject should have a fair hearing.

Another party that rallied to Luther was that of the German nationalists led by Ulrich von Hutten, who aspired to convert the Holy Roman Empire into a German national state. This program would entail the suppression of the whole system of prince-bishops and could never be achieved without a war with the papacy. Luther was hailed because of his attack on the papacy, though he would not condone the program of violence.

Yet despite the support from these parties, Luther would have been speedily crushed had Pope Leo X taken seriously the religious side of his office. The secularization of the papacy saved Luther, and he destroyed the secularization of the papacy. At the moment when Luther appeared to be foredoomed, an election for the office of Holy Roman emperor was pending. It was elective and any European prince was eligible, including Henry VIII of England, Francis I of France, Charles I of Spain. The Pope wished none of them because the position entailed control over Germany, and the augmentation of power to one of the three would destroy the balance of power. His preference was for a minor prince, and none fitted the role better than Luther's protector, Frederick the Wise of Saxony. In consequence the Pope dallied in the case of Luther and even after Charles was elected, the Pope was willing to play Frederick against him. Not until June 1520, nearly three years after the Ninety-five Theses, was Luther summoned to submit within 60 days. The time was reckoned from the date of the actual delivery of the bull to the person named. So great was the obstruction to Rome on the part even of German bishops that the bull was not handed to Luther until October 10.

He employed the summer of 1520 to bring out some of the great manifestos of the Reformation. The *Address to*

Reaction
of Pope
Leo X

the Christian Nobility of the German Nation called upon the ruling class in Germany, including the emperor, in whom Luther had not yet lost confidence, to reform the church in externals by returning to apostolic poverty and simplicity. This appeal to the civil power to reform the church was a return to the earlier practice of the Middle Ages when emperors more than once had deposed and replaced unworthy popes. Luther argued that the papacy of his day was only 400 years old, meaning that it was the Gregorian reform that had given the church its lead in matters political, encroaching thereby on the sphere of the magistrate on the ground that the lowliest priest did more for mankind than the loftiest king. Luther countered with the doctrine of the priesthood of all believers, including Christian magistrates. Any layman was spiritually a priest, though not vocationally a parson. The Christian ruler, then, being himself a priest, could reform the church in externals, as the church might excommunicate him in spirituals. The liberal Catholic reformers could sympathize with this program except for the identification of the papacy with Antichrist. This savoured of the medieval sects.

The sacraments as defined in *The Babylonian Captivity*

Another tract dealt with the sacraments. The title was *The Babylonian Captivity*, meaning that the sacraments themselves had been taken captive by the church. Luther reduced the number of the sacraments from seven to practically two. The seven were baptism, the Eucharist or mass, penance, confirmation, ordination, marriage, and extreme unction. Luther defined a sacrament as rite instituted by Christ himself. By this token only baptism and the Eucharist were strictly sacraments and penance only as confession. Extreme unction, that is anointing with oil those on the verge of death, was dropped entirely. Confirmation went out for a time but was later restored. Ordination continued as a rite of the church. Penance included contrition, confession, and satisfaction. Luther felt that none could be sure of genuine contrition, none could make satisfaction. Confession was wholesome but should be voluntary and could be made to any fellow Christian. Marriage was not a Christian sacrament, because it was not instituted by Christ but by God in the garden of Eden, and valid not only for Christians but also for Turks and Jews. Baptism was to be administered but once only and to babies on the ground of their dormant faith.

This left the mass, and at this point Luther gave the greatest offense. The wine, he asserted, should be given to the laity as well as the bread, as in the Hussite practice. No masses should be said for the dead by the priest alone without communicants, because the Eucharist involved fellowship not only with Christ but also with believers. The most drastic change was that Luther denied the doctrine of transubstantiation, according to which, at the pronouncement of the words of institution, the elements of bread and wine, though retaining their accidents of colour, shape, and taste, nevertheless lost their substance, which was replaced by the substance of the body of Christ as God. This Luther denied, saying that no change was wrought by the words of Christ.

The doctrine of Real Presence

Luther, nevertheless, believed that the body of Christ was physically present upon the altar because Christ said, "This is my body." Therefore, in some inexplicable manner, his body must be "with, in, and under" the elements. But if no change was wrought, how did his body come to be on the altar? Because his body was everywhere. But if everywhere, why especially there? Because in view of human limitations God had decreed two modes of self-disclosure, the preaching of the Word and the administration of the sacrament. There the eyes of the believer were opened. This view undercut sacerdotalism, since the words of the priest did not bring the body of Christ to the altar. The undercutting of sacerdotalism destroyed the hierarchical structure of society culminating in the papacy.

But what was to be done with Luther? On December 10, instead of submitting, he defiantly burned the papal bull together with a copy of the canon law. The normal course would then have been to excommunicate him outright, but Frederick the Wise insisted that he be given a fair hearing. The natural body to pass judgment would have been a council of the church. But the popes were the greatest obstructionists when it came to calling a council

Luther and Hus distributing the sacramental bread and wine to the Elector of Saxony and his family. Woodcut by an unknown artist.

because they feared the revival of conciliarism, which in the previous century bade fair to convert the church into a constitutional monarchy. There would have been no Council of Trent save for Luther. Only after another 20 years, when the spread of his teaching left no other expedients, was a council convened. Consequently, his hearing had to be before a secular tribunal, the Diet of the empire meeting at Worms in the winter and spring of 1521. Since this was a secular tribunal the attempt was made to prove that he was not simply a heretic but also a rebel whose views were more subversive of the civil than of the ecclesiastical order, because he was undermining the very principle of authority. Luther was brought before the Diet and given an opportunity to repudiate his books. Had he disclaimed the one on the sacraments, the other points might have been negotiated. He acknowledged them all. Would he then disclaim some of their teaching? Who was he to reject the teaching of the ages? Let him give an answer without horns, to which he replied: "I will answer without horns and without teeth. Unless I am convicted by Scripture and plain reason—I do not accept the authority of popes and councils, for they have contradicted each other—my conscience is captive to the Word of God, I cannot and I will not recant anything, for to go against conscience is neither right nor safe. God help me. Amen." The Emperor then placed Luther under the imperial ban. The bull of excommunication by the church was formally released only later. Frederick the Wise at this point intervened and wafted Luther away to a place of hiding.

Diet of Worms

Luther was concealed for a year at the castle of the Wartburg. During this enforced withdrawal he made perhaps his greatest contribution in that he translated the whole of the New Testament from the Greek text of Erasmus into an idiomatic, pungent, powerful German. In many respects his German helped to create the idiomatic. Nothing did so much to win popular adherence to his teaching as the dissemination of this translation.

But some were not so convinced. Many of the liberal Catholic reformers, like Erasmus, recoiled from Luther's paradoxes, from his confidence that his interpretation of Scripture was correct, from his acceptance of the doctrine of predestination, which makes of God a tyrant when he elects some and damns others regardless of their behaviour. The German national movement collapsed. Then in Luther's own circle variant forms of Protestantism arose, which in the aggregate are variously described as the left wing of the Reformation or as the radical Reformation. The terminology does not matter so much as the recognition that no neat classification is possible.

Müntzer

RADICAL REFORMERS RELATED TO LUTHER'S REFORM

Two figures emerging in Luther's circle are significant by way of anticipation. One was Karlstadt (c. 1477/81–1541), who drew the radical inference from the dualism of flesh and spirit that art and music should be abolished as external aids to religion and the Presence of Christ's body on the altar should be interpreted in a spiritual sense. His program issued in iconoclastic riots. He extended Luther's doctrine of the priesthood of all believers to mean that all laymen were pastors. If one person was assigned the tasks of a parson, he should dress like others and, like others, should work with his hands. The clergy not only might but must marry. The sabbath should be strictly observed. This program anticipated the Puritan movement. It entailed a blending of spiritualism and legalism. The sensory aids to religion were to be discarded by those advanced in the spiritual life and then snatched away by laws from those still weak.

A much more disquieting figure than Karlstadt was Thomas Müntzer (c. 1490–1525), a man of learning and a creative firebrand, who may be regarded not as the progenitor but as the first formulator of the concept of the Protestant Holy Commonwealth. He believed that the elect, those predestined by God for salvation, could be sufficiently identified to compose a definite group. Luther denied the possibility of distinguishing the elect from the nonelect. Müntzer's test was the new birth in the spirit. The test was not for him an absolute mark, and he recognized that among the wheat there might be some weeds, yet he accepted it as an adequate test for the formation of a community bound together by a covenant. The mission of this group was to set up the Kingdom of God on Earth, the Holy Commonwealth, by wiping out the ungodly. In the attempt they would have to endure suffering, and here Müntzer drew from German mysticism the theme of walking in Christ's steps toward the cross. But the trial would end in triumph, for the Lord Jesus would speedily come to vindicate his saints and erect his Kingdom. There are obviously incompatibles here, the way of suffering and the infliction of suffering, the feverish activity of man to achieve that which will be established by God. But logical incompatibles fuse at high emotional temperatures. Müntzer appealed to the Saxon princes to implement his program, but they banished him. He found a hearing among the revolting peasants and led them at the Battle of Frankenhausen, where they were butchered and he captured and beheaded. Luther execrated his memory because he seized the sword in defense of the gospel. The Marxists have exalted him as the prophet of social revolution because he was the only one of the Reformers who had a deep feeling for the sufferings of the socially oppressed. In grasping the sword he did not essentially differ from Huldrych Zwingli, Gaspard de Coligny, or Oliver Cromwell.

ZWINGLI AND HIS INFLUENCE

Huldrych Zwingli (1484–1531), the great figure in Swiss Protestantism, was in fact if anything more committed to military action than Müntzer because he fell as a combatant with sword and helmet on the field of battle. He became a Reformer independently of Luther, with whom he was entirely in accord as to justification by faith and predestination. At certain points Zwingli drew from Erasmus and Karlstadt, notably with respect to the disparagement of the sensory aids to religion. Zwingli, though an accomplished musician, considered that the function of music was to put the babies to sleep rather than to worship God. The organ was dismantled and the images removed from the cathedral at Zürich. The Lord's Supper was understood by Zwingli in his most extreme period simply as a memorial of Christ's death and, on the part of the recipient, as a public declaration of faith with more significance for the members of the congregation who saw him take his stand than for his own spiritual life. Zwingli could the more readily retain the baptism of infants because it was simply a recognition that the child belongs to the people of God as the child in the Old Testament belonged by circumcision to Israel. The analogy with Judaism applied at many points, for Zwingli regarded the

Christian congregation as the new Israel of God, an elect people, reasonably identifiable, not as with Müntzer by the new birth but by adherence to the faith. This company could be called theocratic in the sense that it was under the rule of God, whom church and state should alike serve in close collaboration. The identification of the whole populace of Zürich with this elect people was the more tenable because those not in accord with the ideal were disposed to leave. Zwingli approved of even an aggressive war to forestall interference from the Roman Catholic cantons. In the second war of Kappel he fell in 1531.

In Zwingli's circle arose the group who formed the mainstay of the radical Reformation. They shared with Zwingli, and with all the reformers to a degree, the desire to restore the church to the primitive pattern, but they were more drastic in their restitution. Manifestly the early church had not been allied with the state. Luther, Zwingli, and other Reformers saw no sense in forcing the church back into the period when the state was hostile and the Christians were persecuted. After the state became Christian, there could very well be a close alliance, as indeed there had been in ancient Israel.

The Anabaptists. The radicals restricted their biblicism to the New Testament and espoused three tenets therefrom that have come to be axiomatic in the United States: the separation of church and state, the voluntary church, and religious liberty. They were called Anabaptists on the ground that, having rejected infant baptism, they rebaptized adults previously baptized. But they called themselves simply Baptists, denying that they repeated baptism since the dipping of babies was no baptism at all. Baptism, they held, did not itself regenerate but was only the outward sign of an inner experience, the rebirth in the spirit, of which only an adult was capable. The Anabaptists, so-called, also believed in the possibility of a Christian society whose members were marked both by the conversion experience and also by a highly disciplined deportment. In obedience to the New Testament they repudiated swearing oaths and recourse to violence, whether in war or at the hands of the magistrate. The saints should withdraw from the wicked world.

This whole program obviously had political and social aspects and was a threat to that society or any other, for no society, save that of a small sect, has ever renounced the use of the sword. The Anabaptists were marked for extermination by Catholics and Protestants alike. One of their first leaders, Felix Manz, was drowned in Zürich in 1527. The Diet of Speyer in 1529, at which the Lutherans protested, subjected the Anabaptists to the penalty of death with the concurrence of the Lutherans. Persecution in the first decade eliminated the leaders, most of them educated and moderate men. Less temperate spirits came to the fore, sustaining their courage by setting dates for the speedy coming of the Lord. One band, composed mainly of Anabaptists, took over the town of Münster in Westphalia in 1534 and, contrary to the tenets of their fellows, seized the sword and, in accord with Old Testament practice, restored polygamy. The town was captured by Catholics and Lutherans conjoined and the leaders were executed. Persecution everywhere intensified.

Other groups. In Holland Menno Simons (c. 1496–1561), the founder of the Mennonites, repudiated violence, polygamy, and the setting of dates for the coming of the Lord and returned to the teaching of the early founders. The Mennonites survived partly by reason of accommodation to military service in Holland, partly by migration first to eastern Europe and then to the Americas. Another group, named Hutterites from Jakob Hutter (died 1536), was allowed to form communal colonies in Moravia on the estates of tolerant feudal nobles who were willing to drop the demand for military service in return for excellent craftsmanship in field and shop. Because of subsequent persecution these groups also migrated to the New World. The Swiss branch, which survives in the United States, is called the Amish. The entire pattern of ideas has reappeared in various combinations in subsequent history, not only among the Church of the Brethren and the Quakers but among all of the free churches disclaiming a state connection.

THE ROLE OF CALVIN

Another form of Protestantism was Calvinism, named for John Calvin (1509–64), a Frenchman educated in humanist and legal studies, who in consequence of a conversion to the Protestant reform had to flee France. In Basel, at the age of 27, he brought out the first edition of his *Institutes of the Christian Religion*, which in successive expansions became for centuries the manual of Protestant theology. Calvin was in basic agreement with Luther as to justification by faith and the sole authority of Scripture. On the sacrament of the Lord's Supper he took a mediating position between the radical Swiss and the Lutheran view. Thus he believed that the body of Christ was not everywhere present, but that his spirit was universal and there was a genuine communion with the risen Lord. Calvin took a middle view likewise with respect to music and art. He favoured congregational singing of the Psalms, and this became a characteristic mark of the Huguenots in France and the Presbyterians in Scotland and the New World. As to art, he rejected the images of saints and the crucifix (that is, the body of Christ upon the cross), but allowed a plain cross. These modifications do not refute the generalization that Calvinism was alien to art and music in the service of religion but not in the secular sphere.

As over against Luther, there was a shift of emphasis in Calvin, whose *Institutes* did not begin with justification by faith but with the knowledge of God. Luther found refuge from the terror of God's dispensations in the mercy of Christ. Calvin could the more calmly contemplate the frightfulness of God's judgments because they would not descend upon the elect. Luther, as noted, saw no way of knowing who were the elect. He could not be sure of himself and throughout his life had a continual struggle for faith and assurance. Calvin had certain approximate and attainable tests. He did not require the experience of the new birth, which is so inward and intangible, though to be sure later Calvinism moved away from him on this point and agonized over the marks of election. For Calvin there were three tests: the profession of faith, as with Zwingli; a rigorously disciplined Christian deportment, as with the Anabaptists; and a love of the sacraments, which meant the Lord's Supper since infant baptism was not to be repeated. If a person could meet these three tests let him assume his election and stop worrying.

If one could achieve such assurance, what an enormous release of energy to be directed to the glory of God and the erection on Earth of some semblance of a holy commonwealth! The term became common in New England. Calvin's own statement was that "the Church reformed is the kingdom of God." Calvin saw more of a possibility of its realization through the efforts of the elect because he muted the expectation of the imminent return of the Lord. The service of the Kingdom did not require a particular vocation. Any worthy occupation is a divine calling demanding unrelenting zeal. Luther had emphasized the secular callings as over against the monastic, which in the Middle Ages alone had been called a vocation. With Calvin the point was not so much that one should accept one's lot and rejoice in the assigned task, however menial, as that the work would contribute to the larger realization of the Christian society.

Calvin had a concrete opportunity for the realization of his ideal, albeit at first only on a small scale. The city of Geneva had recently thrown off the authority of the bishop and of the duke of Savoy and had not yet joined the Protestant Swiss Confederation, though aided in the fight for liberation by the Protestant city of Bern. Through the Bernese, Protestant preachers began to evangelize Geneva. The city was threatened by civil war. The bellicose preacher Guillaume Farel, unable himself to contain the violence he had helped to unleash, laid hold of Calvin merely passing through the city and impressed him into the unwelcome task of leadership. After turbulent years, a banishment and a recall, he was able for the last two decades of his life to direct the city that John Knox considered "the most godly since the days of the apostles." There was actually scarcely a feature of Thomas More's *Utopia* that Geneva did not seek to realize.

The program, despite all the turbulence, was the more

attainable because of a selective process with respect to the population. At the outset all the Catholics who would not submit to the new regime had to leave. Among those who remained, excommunication from the church, if not removed within six months, meant banishment from the city. Control over excommunication, after a long struggle, came to be entirely in the hands of the church. The state, having long suffered from the abuse of excommunication for political purposes, was loath to concede to the church exclusive control. Abortive attempts to achieve independence had been made by the Protestant churches at Basel and Strassburg. Calvin succeeded, with the result that one who was not in the graces of the church could not for long be a member of the community. A further factor ensuring a select constituency was the influx of 6,000 refugees from France, Italy, Spain, and, for a time, from England into a city of 13,000. Thus in Geneva, church, state, and community came to be one. The ministers and the magistrates with differentiated functions were alike the servants of God in the erection of this new Israel; and the comparison with ancient Israel was the more striking and the inner cohesion the more intensified because Geneva also was begirt by foes, the duke of Savoy and the duke of Alba, like the old Canaanites and Philistines.

CALVINISM IN FRANCE

The situation in France with respect to the Reformation was not altogether dissimilar to that in Germany because, although the decentralization of government was not as great, some of the French provinces enjoyed a considerable autonomy, particularly in the south, and it was in the Midi and French Navarre that the Protestant movement had its initial strength. Then, too, noble houses were continually conspiring to manipulate or eviscerate the monarchy. The religious issues came to be intertwined with the political ambitions. The ruling houses, first the Valois from Francis I through Henry III and then the Bourbon, beginning with Henry IV, sought to secure the stability of the land and the throne by quelling religious strife either by the extermination or toleration of minorities.

The ground was better prepared for the reform of the church in France than in Germany because of the efforts of liberal Catholics such as the scholar Jacques Lefèvre d'Étaples and the bishop of Meaux, Guillaume Briçonnet. King Francis I and his sister Margaret of Angoulême not infrequently intervened to save humanist reformers from the menaces of the obscurantists, and Margaret's daughter, Jeanne d'Albret, the queen of Navarre, a feudatory of France, provided an asylum for the persecuted in her domain, though she did not herself espouse the Huguenot cause until 1560. When Lutheran teaching first began to infiltrate France, Francis I, who would not abet heresy, fluctuated in his policy of repression, depending on whether he desired a political alliance with the pope, the Turk, or the German Lutherans. The year 1534 precipitated a crisis when placards were posted in Paris savagely attacking the mass. Severe repression followed. Bishop Briçonnet made his submission. Farel fled to Geneva, Lefèvre to Strassburg, Calvin to Basel. Under Henry II, the son of Francis, repression was intensified, particularly when in 1559 France and Spain made peace and thus each was free to devote attention to the suppression of heresy at home. The persecution of the Huguenots, as the Protestants came to be called in France, would have been intense save for the death of the King in a tournament.

At this point the rivalry of the noble houses injected itself more overtly into the religious struggle. The crown, with its alternating policy of eradication or recognition, was flanked by two extreme houses for whom the religious issue was of intense concern. The House of Guise was so Catholic as to be willing to call in Spanish aid, and the family of Admiral Coligny so Huguenot as to be willing to court help from England and even from Germany. Under Francis II the Guises were in the ascendant because the queen, later queen of Scots, was of that house. Some of the Huguenots, foreseeing the suppression in store, hatched the Conspiracy of Amboise, an attempted assassination of the leaders of the Guise party and transferral of power to the House of Bourbon.

The
Huguenots
and the
French
religious
wars

This was plainly rebellion and acutely raised a problem with which the Protestants had long been wrestling. The Lutherans had had to face it earlier when the Diet of Augsburg in 1530 gave them a year in which to submit on pain of war. The Lutheran princes then had formed the Schmalkaldic League to resist arms with arms. Luther was loath to condone any use of the sword in defense of the Gospel and absolutely forbade any recourse to violence on the part of a private citizen against the magistrates. This was his reason for disapproval of the Peasants' War. But now the jurists pointed out to Luther that the emperor was an elected ruler and that if he transgressed against the true religion he might be brought to book by the electors, who also were magistrates. Thus arose the doctrine of the right of resistance of the lower magistrate against the higher. The concept lost its pertinence in Germany after the Peace of Augsburg in 1555, which granted toleration to the Lutherans in the territories where they were predominant. Minorities in Lutheran and Catholic lands were granted the right of migration without loss of goods.

But the Calvinists were not included in the peace, and the problem of armed resistance again became acute in France. Calvin would not condone the Conspiracy of Amboise because it was not led by a lower magistrate. The term was now applied to the princes of the blood in line for succession to the throne. This meant the House of Bourbon. The Conspiracy of Amboise failed. Francis II died, and was succeeded by his brother, the young Charles IX. The queen mother, Catherine de Médicis, took the lead and sought to avert religious war by granting the Huguenots limited toleration in restricted areas in the edict of 1562. When François, duc de Guise, discovered the Huguenots worshipping outside the prescribed limits, as he claimed, he opened fire. The Massacre of Vassy set off the wars. The Huguenots now were led by a prince of the blood, Louis I, 1st prince de Condé, of the House of Bourbon. Calvin approved. There followed three inconclusive wars. Condé was killed in the first and François, duc de Guise, was assassinated. His son, now Henri, duc de Guise, believed in the complicity of Coligny, the new leader of the Huguenots. At the end of 10 years of indecisive conflict, Catherine made another effort at a settlement to be cemented by the marriage of Henry of Navarre, a Bourbon, the son of Jeanne d'Albret and the hope of the Huguenots, and her own daughter Margaret (Marguerite de Valois), a Catholic. The leaders of all parties came to Paris for the wedding. The Duke of Guise made an attempt on the life of Coligny, which failed. Then the Guise, with the connivance of Catherine and her son Charles, who panicked,

tried to wipe out all of the leaders of the Huguenot party in the Massacre of St. Bartholomew's Day in August 1572. Other massacres followed in the provinces.

Charles IX was succeeded by his brother, Henry III, two years later (1574). Such was the revulsion against the massacre that the King could rule only by forming an alliance with the Huguenot Henry of Navarre. A fanatical Catholic was thereby so outraged that he assassinated the King. Both sides had abandoned the fiction of the inferior magistrate and had gone in unabashedly for popular revolution. Henry of Navarre then became Henry IV, but he was unable to take Paris and rule France so long as he was a Protestant. In order to pacify the land he made his submission to Rome and promulgated an edict of toleration for the Huguenots, the Edict of Nantes, in 1598. It gave them liberty of worship again in limited areas but full rights of participation in public life. The edict remained in force until the revocation in 1685.

The Reformation in England and Scotland

HENRY VIII AND THE SEPARATION FROM ROME

In the meantime the Reformation had taken hold in England. The beginning there was political rather than religious, a quarrel between the king and the pope of the sort that had occurred in the Middle Ages without resulting in a permanent schism, and might not have in this instance save for the total European situation. The dispute had its root in the assumption that the king was a national stallion expected to provide an heir to the throne. England did not have the Salic law, which in France forbade female succession, but England had just emerged from the Wars of the Roses and the fear was not unwarranted that the struggle might be resumed if there were not a male succession. Catherine of Aragon, the queen of Henry VIII, had borne him numerous children of whom only one survived, the princess Mary, and more were not to be expected. The ordinary procedure in such a case was to discover some flaw in the marriage that would allow an annulment or, in the terminology of that day, a divorce. In this instance the flaw was not difficult to find, because Catherine had been married to Henry's brother Arthur, and the law of England, following the prohibition in the book of Leviticus, forbade the marriage of a man with his deceased brother's widow. At the time of the marriage the pope had given a dispensation to cover this infraction of the rule. The question now was whether the pope had the authority to dispense from the divine law. Catherine said there had been no need for a dispensation because

In the Musée Cantonal des Beaux-Arts, Lausanne, Switz.

her marriage to Arthur had not been consummated and there had been no impediment to her marriage to Henry. The knot would have been cut by some casuistry had Catherine not been the aunt of Emperor Charles V, who was not prepared to see her cast aside in favour of another wife, and who controlled the pope. Clement VII, wishing neither to provoke the emperor nor to alienate the king, dallied so long that Henry took the matter into his own hands, repudiated papal authority, and in 1534 set up the Anglican Church with the king as the supreme head. The spiritual head was the archbishop of Canterbury, now Thomas Cranmer, who married Henry to Anne Boleyn. She bore the princess Elizabeth. By still another wife Henry did have a son who succeeded as Edward VI.

Although the basic concern of Henry was political, the alterations in the structure of the church gave scope for a reformation religious in character. Part of the impulse came from the survivals of Lollardy, part from the Lutheran movement on the Continent, and even more from the Christian humanism represented by Erasmus. The major changes under Henry were the suppression of the monasteries, the introduction of the Bible in the vernacular in the parish churches, and permission to the clergy to marry, though this was later revoked. The resistance to Henry's program was not formidable and the executions resulting were not numerous. Henry was impartial in burning some Lutherans who would not submit to his later reactionary legislation and toward some Catholics who would not accept the royal supremacy over the church, notably John Fisher and Thomas More.

On his ascension to the throne in 1547, young Edward VI was hailed by Cranmer and other Protestants as England's Josiah, the young 7th-century-BC king of Judah who enforced the Deuteronomic reform. Edward, it was held, would rid the land of idolatry so that England might be blessed. Protestantism advanced rapidly during his reign through the systematic reformation of doctrine, worship, and discipline—the three external marks of the true church. A reformed confession of faith and a prayer book were adopted, but the reformation of the ecclesiastical laws that would have defined the basis of discipline was blocked in Parliament by the most powerful of the English nobility.

The death of Edward and England's return to Roman Catholicism in 1553 under Queen Mary was interpreted by Protestants as a judgment by God upon a nation that had not taken the Reformation seriously enough. Many, including Cranmer, died as martyrs to the Protestant cause. Others fled to the European continent. Those in exile experimented with more radical forms of worship and discipline. Leading clergymen published material justifying rebellion against an idolatrous ruler. Many saw in Geneva, which was a haven for English exiles, a working model of a disciplined church. Exiles produced two large volumes of incalculable consequence for English religious thought. John Foxe's *Actes and Monuments*, popularly known as *The Book of Martyrs*, and the Geneva Bible were the most popular books in England for many years after they were published. They provided a view of England as an elect nation chosen by God to bring the power of the Antichrist (understood to be the pope) to an end. An England obedient to God would receive his favour. Otherwise, it would experience his plagues.

Elizabeth I, beginning her rule in 1558, was hailed as the glorious Deborah (12th-century-BC Israelite leader), the "restorer of Israel." She did not restore it far enough for English Protestants, however. Two statutes promulgated in her first year—the Act of Supremacy, stating that the queen was "supreme governor" of the Church of England, and the Act of Uniformity, ensuring that English worship should follow *The Book of Common Prayer*—defined the nature of the English religious establishment. In 1563 the primary church legislative body, the Convocations of Canterbury and York, defined standard doctrine in the Thirty-nine Articles, but attempts in the Convocation to reform the prayerbook further and to produce a reformed discipline failed. Defeated there, the reformers came to rely more on Parliament, where they could always depend on strong support.

THE ROLE OF JOHN KNOX

In Scotland the Reformation is associated with the name of John Knox, who declared that one celebration of the mass is worse than a cup of poison. He faced the very real threat that Mary, Queen of Scots, would do for Scotland what Mary Tudor had done for England. Therefore Knox defied her to her face in matters of religion and, though a commoner, addressed her as if he were all Scotland. He very nearly was, because in the period prior to 1560 many an obscure evangelist had converted the lowlands largely to the religion of John Calvin. The church had been given a Presbyterian structure, culminating in a General Assembly, which had actually as great and perhaps a greater influence than the Parliament. Because of her follies, and very probably her crimes (complicity in the murder of her husband), Mary had to seek asylum in England. There she became the focus of plots on the life of Elizabeth until Parliament decreed her execution. Presbyterianism came to be established in Scotland, and this very fact alone made possible the union of Scotland with England. Union of Protestant England with a Catholic Scotland would have been unthinkable.

Knox is frequently reproached for his intolerance in regarding one celebration of the mass as worse than a cup of poison, but one must remember that the year 1560 marked the peak of polarization between the confessions. Similar intolerance had been mounting at Rome. Paul III, after an abortive attempt at reform, had introduced the Roman Inquisition in 1542. His successor, Paul IV, placed everything that Erasmus had ever written on the Index. The Council of Trent began its sittings in 1545, introducing rigidity in dogma and austerity in morals. The Protestant views of justification by faith alone, the Lord's Supper, and the propriety of clerical marriage were sharply rejected. All deviation within the Catholic fold was rigidly suppressed. When Carranza, the archbishop of Toledo, returned to Spain in 1559, after assisting Mary in the restoration of Catholicism in England, he arrived in time for the last great auto-da-fé of the Lutherans. Himself under suspicion for ideas no more heretical than those of Erasmus, he was incarcerated for 17 years in the prison of the Inquisition. The liberal cardinal Giovanni Morone was imprisoned during the pontificate by Paul IV, and under Pius V, Pietro Carnesecchi, an Erasmian and one-time secretary of Clement VII, was burned in Rome. John Knox and Pope Pius V represent the acme of divergence between the confessions. (R.H.B./J.C.S./Ed.)

Council
of Trent

THE RISE OF PURITANISM

Origins. Despite Elizabeth I's conservatism the Protestant reformers in England began to see their programs and ideas take hold more firmly during her reign. The movement known as Puritanism was part of this growing Protestant influence in English society in the late 16th and early 17th centuries.

Puritanism first emerged as a distinct movement in a controversy over clerical vestments and liturgical practices. Immediately following the Elizabethan Settlement, a practical latitude existed for Protestant clergy to wear what they chose while leading worship. Many preachers took this opportunity to do away with the formal attire as well as other practices traditionally associated with the Roman Catholic mass. But in 1564 Queen Elizabeth demanded that Matthew Parker, the archbishop of Canterbury, enforce uniformity in the liturgy. He did so somewhat reluctantly with the publication of his *Advertisements* in 1566. Those who refused to wear the now prescribed garb came to be considered collectively, and with scorn, as "Puritans" or "precisians" for their unwillingness to submit in these seemingly minor points to the supremacy of the queen.

Aside from vestments and liturgy the form of church government was a second controversial issue among Elizabethan English Protestants. In 1570 Thomas Cartwright (1535–1603) delivered a series of lectures at Cambridge University proposing that presbyterian government, or government by local councils of clergy and laity, might be an improvement over the current system of archbishops, bishops, and appointments. Cartwright was dismissed for his opinions and fled to Geneva. Two years later John

Thomas
Cartwright

The external
marks
of the
church

Field and Thomas Wilcox anonymously published an *Admonition to the Parliament*, which pushed Cartwright's ideas even further. In reply John Whitgift, vice-chancellor at Cambridge, maintained that the government of the church should be suited to the government of the state and that episcopal government best suited monarchy. In this dispute most Puritans shied away from extremes and supported some form of episcopacy, but a small number went beyond even Cartwright and Field in seeking to effect immediately a "reformation without tarrying for any." These Separatists broke with the established parish system to set up voluntary congregations that covenanted with God and with themselves, chose ministers by common consent, and put into practice the Puritan marks of the true church. Robert Browne (d. 1633) was an early advocate of the Separatist mentality.

The leaders of the Puritan movement, however, including Cartwright (who had returned to England in 1585) and Field, repudiated the Separatists and sought to set up "presbyterianism in episcopacy," or a "church within the church." This compromise between presbyterianism and episcopacy was preferred by the most prominent Puritans, and they began to institute such a system by means of informal public meetings of clergy and laity to expound and discuss the Bible. These meetings were called "prophesyings," and they were favoured for their educational value to the rural population by Edmund Grindal, who had succeeded Parker as archbishop of Canterbury in 1576. But the prophesyings were also the occasions for local Puritan clergy, laity, and gentry to mobilize, and they were viewed by Elizabeth, in the context of the more radical groups, as a political threat. An increasingly clear alliance between Puritans and certain factions within Parliament did not allay Elizabeth's fears.

Thus, the Queen ordered Grindal to suppress the prophesyings. When he refused, Elizabeth effectively suspended him from the exercise of his office. This suspension further alienated Puritans. Meetings continued, often in a modified form, called *classis* or conferences, which were loosely coordinated by John Field in London. Following Grindal's death in 1583, John Whitgift, Cartwright's old opponent, advanced to Canterbury. Whitgift had no hesitation in closing down the prophesyings, but he proceeded with caution in formal prosecution of Puritans. Extended ecclesiastical hearings by the Court of High Commission, under the leadership of John Aylmer, and civil proceedings by the Star Chamber were accompanied by the imprisonment of only a few of the most prominent Puritans.

Whitgift's policy, along with the death of Field and other Puritan leaders between 1588 and 1590, effectively ended any grand plan for a continuing reformation of the English Church under Elizabeth. The generally moderate Elizabethan Puritan movement was over, and the forces of reform dispersed into various parties and programs ranging from nonseparating congregationalism (as advocated by William Ames) to open subversion of the established hierarchy as in the anonymous Marprelate Tracts (1588–89). Despite failure to promote reform in matters of church structure, the Puritan spirit continued to spread throughout the society. Protestants with Puritan sympathies controlled colleges and professorships at Oxford and Cambridge, had the ears of many leaders in the House of Commons, and worked tirelessly as preachers and pastors to continue the preaching of Protestantism in its distinctively "hot" Puritan form to the laity. (M.E.M.)

Puritanism under the Stuarts (1603–49). *Events under James I.* Puritan hopes were raised when James VI of Scotland succeeded Elizabeth as James I of England in 1603. James was known to be Calvinist in theology, and he had once signed the Negative Confession of 1581 favouring the Puritan position. In 1603 the Millenary Petition (with a claimed thousand signatures) presented Puritan grievances to the King, and in 1604 the Hampton Court Conference was held to deal with them. The petitioners were sadly in error in their estimate of the King, who had learned by personal experience to resent Presbyterian clericalism. At Hampton Court he coined the phrase, "no bishop, no king." Outmaneuvered in the conference, the Puritans were made to appear petty in their requests.

As a seal upon the Hampton Court Conference James appointed Richard Bancroft to be Whitgift's successor as archbishop of Canterbury and encouraged the Convocation of 1604 to draw up the *Constitutions and Canons* against Nonconformists. Conformity in ecclesiastical matters became a pattern in areas where forms of nonconformity had survived under Elizabeth. Though a number of the clergy were deprived of their positions, others took evasive action and got by with minimal conformity. Members of Parliament supported them in their position by arguing that since the canons had not been ratified by Parliament they did not have the force of law.

Puritans remained under pressure, but men of Puritan sympathies still came close to the seat of power in James's reign. The enforced reading from pulpits of James's *Book of Sports*, dealing with recreations permissible on Sundays, in 1618, however, was a further affront to those who espoused strict observance of the sabbath, making compromise more difficult.

Increasing numbers of Separatist groups could not accept compromise, and in 1607 a congregation from Scrooby, Eng., fled to Holland and then migrated on the *Mayflower* to establish the Plymouth Colony on the shore of Cape Cod Bay in 1620.

Events under Charles I. Despite the presence of controversy, Puritan and non-Puritan Protestants under Elizabeth and James had been united by adherence to a broadly Calvinistic theology of grace. Much of Whitgift's restraint in handling Puritans, for instance, can be traced to the prevailing Calvinist consensus he shared with the Nonconformists. Even as late as 1618 the English delegation to the Synod of Dort supported the strongly Calvinistic decisions of that body. Under Charles I, however, this consensus broke down, driving yet another rift into the Church of England. Anti-Puritanism in matters of liturgy and organization became linked with anti-Calvinism in theology.

The leaders of the anti-Puritan and anti-Calvinist party, notably Richard Montagu, whose *New Gagg for an Old Goose* (1624) first linked Calvinism with the abusive term "Puritan," drew upon the development of Arminianism in Holland. Arminians stressed God's universal offer of salvation to mankind in contrast to the Calvinistic doctrine according to which God predestined a few to salvation, with the rest of humanity reprobated or damned. Early English Arminians added to this an increased reverence for the sacraments and liturgical ceremony. Richard Neile, bishop of Durham, was the first significant patron of Arminians among the hierarchy, but by the time William Laud was appointed bishop of London in 1628, he was the acknowledged leader of the anti-Puritan party. London was regarded as the stronghold of Puritanism, and a policy of thorough anti-Puritanism was begun there. Men who were not Separatists found their positions increasingly difficult to maintain.

Laud, who became archbishop of Canterbury in 1633, was clearly a favourite of Charles. He oversaw the advance of Arminians to influential positions in the church and subtly promoted the propagation of Arminian theology. His fortunes began to turn, however, when he attempted to introduce into the Church of Scotland a liturgy comparable to the Anglican *Book of Common Prayer*. When "Laud's Liturgy" was introduced at the Church of St. Giles at Edinburgh, a riot broke out leading to a popular uprising that restored Presbyterianism in Scotland.

Charles sought to put down the Scots, but his armies were no match for the Scottish forces. In 1640 he was faced with an army of occupation in northern England demanding money as a part of its settlement. Short of funds, Charles was forced to call Parliament, without which he had been trying to rule since 1629.

Religion played perhaps the key role in the parliamentary elections, and Calvinists came to dominate the Commons. Puritans, who had been increasingly alienated from the ecclesiastical and civil hierarchy since the mid-1620s, suddenly saw an opportunity to return the Church of England to its original doctrinal system and to carry out reforms that had been held in check since the Elizabethan Settlement. Arminianism in theology, liturgy, and government was linked in the popular mind with Catholicism,

as fears of a Spanish conspiracy to undermine Protestant England became widespread. The first act of the Long Parliament, as it came to be called (1640–53), was to set aside Nov. 17, 1640, as a day of fasting and humiliation. Cornelius Burges and Stephen Marshall were appointed to preach that day to members of Parliament. Their sermons urged the nation to renew its covenant with God in order to bring about true religion through the maintenance of “an able, godly, faithful, zealous, profitable, preaching ministry in every parish church and chapel throughout England and Wales” and through the establishment of a civil magistracy that would be “ever at hand to back such a ministry.”

Hundreds of similar sermons were preached on monthly fast days and on other occasions before Parliament during the next few years, urging the people to adopt true doctrine, pure worship, and the maintenance of discipline as a means to claim God’s blessing so that England might become “our Jerusalem, a praise in the midst of the earth.”

Civil war. In the course of his reign it had become apparent that Charles himself was the patron of Arminians and their attempt to redefine the doctrine of the Church of England. Arminians in turn favoured Charles’s causes against Puritans and Parliament. This alliance held despite increasing pressure on Charles to cooperate with Parliament on economic and military matters. The resulting civil war between the forces of the King and the troops of Parliament was hardly just a religious struggle between Arminians and Calvinists, but conflict over religion played an undeniably large role in bringing about the Puritan Revolution. As Protestantism split, so did English society.

Fighting broke out in 1642, and after the first battles members of Parliament called together a committee of over a hundred clergymen from all over England to advise them on “the good government of the Church.” This body, the Westminster Assembly of Divines, convened on July 1, 1643, and continued daily meetings for more than five years.

A majority of the Puritan clergy of England probably would still have opted for a modified episcopal church government. Parliament, however, needed Scotland’s military help. It adopted the Solemn League and Covenant, which committed the Westminster Assembly to develop a church polity close to Scotland’s presbyterian form. A small, determined Assembly group of “Dissenting Brethren” held out for the freedom of the congregation, or “Independency,” as opposed to the power of presbytery. Others, called Erastians, wanted to limit the offenses under the power of church discipline. Because both groups had support in Parliament, the reform of church government and discipline was frustrated.

Dissent within the assembly was negligible compared with dissent outside it. Pamphlets by John Milton, Roger Williams, and others schooled in Puritanism pleaded for greater freedom of the press and of religion. Such dissent was supported in the New Model Army, a Parliamentary army of 22,000 men organized and disciplined under Sir Thomas Fairfax (1612–71) as commander in chief and Oliver Cromwell (1599–1658), and the real power in England was passing to the military leaders who had defeated all Royalist forces. Late in 1648 the victors feared that the Westminster Assembly and Parliament would reach a compromise with the defeated Charles that would destroy their gains for Puritanism. In December 1648 Parliament was purged of members unsatisfactory to the Army, and in January 1649 King Charles was tried and executed.

The age of Cromwell (1649–60). Both Parliament and the assembly continued to sit on a “rump” basis (containing only a remnant after the purges), and Oliver Cromwell emerged as England’s Lord Protector. Cromwell was a typical Puritan in that he saw the judgment and mercy of God in events. Military successes to him were definite signs of the blessing of God upon his work.

The Independent clergyman John Owen guided the religious settlement under Cromwell. He maintained that the “reformation of England shall be more glorious than of any Nation in the world, being carried on, neither by might nor power, but only by the spirit of the Lord of Hosts.” Error was a problem for both Cromwell and

Owen, but, as Owen expressed it, it was better for 500 errors to be scattered among individuals than for one error to have power and jurisdiction over all others.

Such was the basis for a pluralistic religious settlement in England under the Commonwealth in which parish churches were led by men of Presbyterian, Independent, Baptist, or other opinions. Jews were permitted to live in England. But it was unacceptable for such groups as Roman Catholics or Unitarians to hold religious views publicly. Cromwell was personally willing to tolerate *The Book of Common Prayer*, but his Parliament was not. Voluntary associations of churches were formed, such as the Worcestershire Association, to keep up a semblance of church order among churches and pastors of differing persuasions.

In the upheaval brought on by the wars radical groups appeared that both challenged and advanced the Puritan vision of the New Jerusalem. The Levellers (a republican and democratic political party) in the New Model Army in 1647 and 1648 interpreted the liberty that comes from the free grace of God offered to all men in Christ as having direct implications for political democracy. The Diggers (agrarian communists) in 1649 planted crops on common land, first at St. George’s Hill near Kingston and later at Cobham Manor, also near Kingston, to encourage God to bring soon the day when all men would live in an unstructured community of love with a communal economy. The Fifth Monarchy Men (an extreme Puritan millennialist sect) in 1649 presented their message of no compromise with the old political structures and advocated a new structure, composed of saints joined together in congregations with ascending representative assemblies, to bring all men under the kingship of Jesus Christ. As distinct units these groups were short-lived. A more enduring group was founded by George Fox (1624–91) as the Society of Friends, or Quakers, which pushed the Puritan logic disallowing any remnants of popery to its ultimate limit with a program of no ministers, no sacraments, and no liturgy. Puritanism had never been a monolithic movement, and accession to power had brought the factions to bear. The limits of the Puritan spirit of reform showed clearly in the widespread persecution of the Quakers.

The Restoration (1660–85). After the death of Cromwell chaos threatened, and in the interest of order even some Puritans supported the restoration of Charles II. They hoped for a modified episcopal government, such as had been suggested in 1641 by the archbishop of Armagh, James Ussher (1581–1656). Such a proposal was satisfactory to many Episcopalians, Presbyterians, and Independents. When some veterans of the Westminster Assembly went to Holland in 1660 to meet with Charles before he returned, the King made it clear that there would be modifications to satisfy “tender consciences.”

These Puritans were outmaneuvered in their attempt to obtain a comprehensive church, however, by those who favoured the strict episcopal pattern. A new Act of Uniformity was passed on May 19, 1662, by the Cavalier Parliament. The act required reordination of many pastors, gave unconditional consent to *The Book of Common Prayer*, advocated the taking of the oath of canonical obedience, and renounced the Solemn League and Covenant. Between 1660 and when the act was enforced on Aug. 24, 1662, almost 2,000 Puritan ministers were ejected from their positions.

As a result of the Act of Uniformity, English Puritanism entered the period of the Great Persecution. The Conventicle Act of 1664 punished any person over 16 years of age for attending a religious meeting not conducted according to *The Book of Common Prayer*. The Five Mile Act of 1665 prohibited any ejected minister from living within five miles of a corporate town or any place where he had formerly served. Still, some Puritans did not give up the idea of comprehension (inclusiveness of various persuasions). There were conferences with sympathetic bishops and brief periods of indulgence for Puritans to preach, but fines and jailings set the tone. Puritanism became a form of Nonconformist Protestantism.

During the short reign of Charles’s Roman Catholic brother, James II (1685–88), fear of Roman Catholic

tyranny united politically both establishment and Non-conformist Protestants. This new unity brought about the "Glorious Revolution" (1688), establishing William and Mary on the throne. The last attempt at comprehension failed to receive approval by either Parliament or the Convocation under the new rulers. In 1689 England's religious solution was defined by an Act of Toleration that continued the established church as episcopal but also made it possible for dissenting groups to have licensed chapels. The Puritan goal to further reform the nation as a whole was transmuted into the more individualistic spiritual concerns of Pietism or else the more secular concerns of the Age of Reason.

Puritanism in the English colonies. *Virginia.* A decade before the landing of the *Mayflower* (1620) in Massachusetts a strong Puritan influence was planted in Virginia. Leaders of the Virginia Company who settled Jamestown in 1607 saw themselves in a covenant relation to God, and they carefully read the message of their successes and failures. A typical Puritan vision was held by the Virginia settler Sir Thomas Dale. His strict application of severe laws disciplining the Jamestown community in 1611 probably saved the colony from extinction, but he also earned a reputation as a tyrant. Dale thought of himself as a labourer in the vineyard of the Lord, as a member of Israel building up a "heavenly New Jerusalem." Like Oliver Cromwell later, whom he resembled, Dale interpreted his military success as a direct sign of God's lending "a helping hand."

Puritan clergymen saw excellent opportunity for their cause in Virginia. The Reverend Alexander Whitaker, the "apostle of Virginia," wrote to his London Puritan cousin in 1614, "But I much more muse, that so few of our English ministers, that were so hot against the surplice and subscription, come hither where neither is spoken of." The church in Virginia, however, became more directly aligned with the English establishment when the settlements were made into a royal colony in 1624.

Massachusetts Bay. In New England, however, the Puritans had their greatest opportunity. Between 1628 and 1640 the Massachusetts Bay Colony was developed as a covenant community. Governor John Winthrop stated the case concisely in his lay sermon on board the *Arbella* before the colonists landed,

Thus stands the cause between God and us; we are entered into covenant with Him for this work; we have taken out a commission; the Lord hath given us leave to draw our own articles. . . . Now if the Lord shall be pleased to hear us and bring us in peace to the place we desire, then hath He ratified this covenant and sealed our Commission, [and] will expect a strict performance of the articles contained in it.

Lack of performance of the articles, in this view, would bring down the wrath of God.

The pattern for church organization in the colony was determined by John Cotton, who pursued "that very Middle-way" between English Separatism and the Presbyterian form of government. Unlike the Separatists he held the Church of England to be a true church, though blemished; and unlike the Presbyterians he held that there should be no ecclesiastical authority between the congregation and the Lordship of Christ. Cotton proposed that the church maintain its purity by permitting only those who could make a "declaration of their experience of a work of grace" to be members. Cotton's plan ensured that church government should be in the hands of the elect, the chosen of God.

Taking their cue from Thomas Cartwright, the Puritans of the Bay Colony fashioned the civil commonwealth according to the framework of the church. Only the elect could vote and rule in the commonwealth. The church was not itself to govern, but it was the means through which were prepared "instruments both to rule and to choose rulers." Biblical law was the primary law for the ordering of both church and state.

The colony prospered; thus it seemed evident that God was blessing Puritan performance. As a result the leadership could not take kindly to those who were publicly critical of their basic program. Hence Roger Williams in 1635 and Anne Hutchinson in 1638 were banished from

the colony in spite of their ability to declare experience of the work of grace.

More troublesome than these dissenters were persons such as Mary Dyer. She and other Quakers who returned again and again after being punished and banished were finally hanged. It was difficult for the state to keep the church pure.

In order to head off a possible new form of church government dictated from England at the time of the Westminster Assembly, churches from the four Puritan colonies of Massachusetts Bay, Plymouth, Connecticut, and New Haven met in a voluntary synod in 1648. They adopted the Cambridge Platform, in which the congregational form of church government was worked out in detail. The standard for church membership came under question when it was found that numbers of second-generation residents could not testify to the experience of grace in their lives. This resulted in the Half-Way Covenant of 1657 and 1662 that permitted baptized, moral, and orthodox persons to share in the privileges of church membership except for partaking of communion.

Late in the 17th century it was apparent to all that the ideal commonwealth was not being maintained. Ministers pointed to wars with the Indians and other problems as signs of God's judgment. Visitation by demonic powers in the form of witches was believable to people expecting the wrath of God. The Salem witchcraft trials and hangings took place in 1692 at a period of declining confidence in the old ideal.

Other colonies. Massachusetts Bay, Plymouth, Connecticut, and New Haven were variations on the main theme of realizing the Holy Commonwealth in America. Roger Williams and the other founders of Rhode Island must also be regarded as Puritans with the "one principle, that every one should have liberty to worship God according to the light of their consciences."

William Penn's "holy experiment" in Pennsylvania represented another Puritan variation, only this time under Quaker norms. When Penn came into the ownership of this vast tract of land, he saw it as a mandate from God to form an ideal commonwealth. In New Jersey, Puritans from the New Haven colony who were dissatisfied with the Half-Way Covenant sought to reestablish the pristine Puritan community at Newark. Maryland, which had been established under Roman Catholic auspices, soon had a strong Puritan majority among its settlers.

There was no colony in which the Puritan influence was not strong in one form or another. One estimate is that 85 percent of the churches in the original 13 colonies were Puritan in spirit.

The expansion of the Reformation in Europe

By the middle of the 16th century Lutheranism was dominant in northern Europe. Württemberg, after the restoration of Duke Ulrich, adopted the reform in 1534. The outstanding Reformer was Johannes Brenz and the great centre Tübingen. Brandenburg, with Berlin as its capital, embraced the reform in 1539. In that same year ducal Saxony, until then vehemently Catholic, changed sides. Elisabeth of Braunschweig, also in that year, became a convert, but only after long turbulence did her faith prevail in the land. Very significant for the north as a whole was the stand taken by Albert of Prussia, who was a member of the Polish Diet and whose wife was Danish. He secularized the Teutonic Knights and in 1525 acknowledged himself a Lutheran. In the Scandinavian lands Denmark toyed with Lutheranism as early as the 1520s, but not until 1539 was the Danish Church established on a national basis with the king as the head and the clergy as leaders in matters of faith. Norway followed Denmark. The Diet of Västerås officially declared what had for some time been true, namely, that Sweden was an evangelical state. The outstanding Swedish Reformers were the brothers Olaus and Laurentius Petri. Finland, under Swedish rule, followed suit. The Reformer there was Mikael Agricola, called "the father of written Finnish." The Baltic states of Livonia and Estonia were officially Lutheran in 1554. Subsequently ravished by the Russians,

anism in
northern
Europe

portions of these lands united with Sweden, Denmark, and Poland. Lutheranism survived. Toward the east, Austria under the Habsburgs could enjoy no state support for the evangelical movement, which nevertheless gained adherents. In Moravia, as noted, the Hutterites established their colonies under tolerant magnates.

Eastern Europe was a seedbed for even more radical varieties of Protestantism, because kings were weak, nobles strong, and cities few, and because religious pluralism had long existed. Poland acquired a large German Lutheran population when the Danzig area came under Polish control, and a large contingent of the Bohemian Brethren migrated to Poland when the Habsburg ruler attempted their extermination. Several of the Polish noblemen adopted their pacifism and would wear only swords made of wood. To Poland also flocked the Italian anti-Trinitarians, having been granted an asylum, perhaps merely because they were Italian, by the Italian queen of Poland, Bona Sforza. Named Socinians from their leader, Faustus Socinus, they flourished until dissipated by the Counter-Reformation. Much more extensive was the Calvinist influx not only into Poland but into the whole of eastern Europe. This variety of Protestantism appealed to those of non-German stock because it was not German and no longer markedly French, as well as because of its revolutionary temper and republican sentiments. The Compact of Warsaw in 1573 called the *Pax Dissidentium* ("The Peace of Those Who Differ") granted toleration to Roman Catholics, Lutherans, Calvinists, and Bohemian Brethren, but not to the Socinians.

In Hungary, the Turkish victory at the Battle of Mohács in 1526 brought about a division of the land into three sections, the northwest ruled by the Habsburg Ferdinand, the eastern province of Transylvania under Zápolya, and the area of Buda under the Turk. Even before this date Lutheranism had made inroads not only in the German but also in the Magyar sections. Subsequently Calvinism made even greater gains. The anti-Trinitarians found a permanent locus in Transylvania. The weakness of the government and the diversity of religion in this whole area made for a large degree of toleration.

The Reformation gained no lasting hold in Spain and Italy. In Spain the main reason for this must be found in the conflicts of the previous century when the Christians were striving to achieve political, cultural, and religious unification by converting or expelling the unbelievers, the Jews and the Moors. The Inquisition was introduced in 1482 to root out all remnants of Jewish practices among the Marranos, the Jewish converts to Christianity. The non-Christian Jews were expelled in 1492. Then Granada fell and the same process was applied to the Moriscos, the Moorish converts, and the unconverted Moors, after a century, also were expelled. Because the process had thus far been successful, the pressures were relaxed, and Spain enjoyed a decade of Erasmian liberalism in the 1520s. But with the infiltration of Lutheranism the machinery of repression again was brought into force.

In Italy sectarian and heretical movements had proliferated in the late Middle Ages. But one by one they had been crushed, and the Italians may well have felt that such rebellions were futile. Furthermore, the friars preached moral rather than doctrinal reform as Luther had done. Another consideration was that the new monastic orders, the Capuchins, Theatines, and Jesuits, gained papal favour and became a mighty force in counteracting Protestant infiltration, which nevertheless did take place. Venice was a centre, with its branch house of the Lutheran banking family of Fugger, and so was Lucca. At Naples the Spanish mystic Valdés, though not a Protestant, expounded a piety of the type of the liberal Catholic reform, and some of his followers were attracted to the movements coming from beyond the Alps. Calvinism gained a hold. But the Roman Inquisition, as above noted, was established in 1542, and those with Protestant leanings either made cloisters of their own hearts, or went to the stake, or crossed the mountains into permanent exile. The most radical theological views of the Reformation were those propounded by the Spanish and Italian anti-Trinitarians.

(R.H.B./J.C.S./M.E.M.)

Protestant renewal and the rise of the denominations

THE SETTING FOR RENEWAL

Survival of a mystical tradition. The Thirty Years' War (1618–48) must be seen as one of the circumstances out of which the desire for spiritual renewal emerged. Although modern historical research has modified the exaggerated contemporary accounts of the war's effects, it is unquestioned that distress was widespread and profound. In some places the economy was reduced to barter, schools were closed, churches were burned, the sick and needy were forgotten. Not unexpectedly spiritual and moral deterioration accompanied the physical destruction. Drunkenness, sexual license, thievery, and greed were the despair of faithful pastors and earnest laymen.

During the war some notable signs of renewal began to appear. There reemerged, for example, an interest in the earlier devotional literature, some of which reflected the pious mysticism associated with such names as Johannes Tauler (c. 1300–61), Thomas à Kempis (c. 1380–1471), and other German, Dutch, and even Spanish authors. The mystical tradition had lived on into the Reformation century and found representatives in Kaspar Schwenckfeld (1489–1561), Valentin Weigel (1533–88), and Jakob Böhme (1575–1624). Although both Lutherans and Calvinists opposed these mystics, many of their religious and theological ideas were subsequently absorbed by orthodox theologians.

Catholic recovery of Protestant territories. After the Peace of Westphalia in 1648 that ended the war, Catholicism regained some territories from Lutheran Protestantism: first, because the rise of toleration was somewhat more rapid in Protestant countries than in Catholic lands and, second, because Louis XIV identified French power with universal French acceptance of the Roman Catholic faith. In 1685 he revoked the Edict of Nantes and expelled thousands of Huguenots, who fled to England, Holland, or Germany, much to the advantage of those countries. Several of the French refugees became prominent in English religious life, and in Prussia groups of them founded flourishing congregations known as the French Reformed. In 1702 a determined group of Huguenots in the mountains of the Cévennes in France, known as the Camisards, rose in rebellion but was suppressed by military power two years later. There was a further small outbreak of war in 1709. For a time the few surviving Huguenot congregations met only in secret. They were led by Antoine Court (1695–1760), who secured ordination from Zürich and founded (1730) a college at Lausanne to train pastors. French Protestants barely held out until the French Revolution, after which they had a revival.

France gained Alsace in 1648. This enabled Catholics to increase rapidly, and Protestants decreased in strength. Strassburg, once one of the leading cities of the Protestant Reformation, returned its cathedral to the Catholics (1681) and became a town with a large Catholic population. Louis XIV ruled the Palatinate for nine years and allowed the French Catholics to share the churches with the Protestants; though he was compelled to surrender the country at the Treaty of Rijswijk (1697) to the Holy Roman Empire, a clause (the *Simultaneum*) of the treaty (added at the last moment and not recognized by the Protestants) preserved certain legal rights and endowments of Catholics in Protestant churches. As a result of France's greater power Protestant authority in the Rhineland between Switzerland and the Netherlands diminished.

Another shock to Protestantism was the conversion of Augustus II, elector of Saxony, to Roman Catholicism in 1697. It appeared as though Protestantism was not even safe in its original home. The conversion involved political motives; Augustus was a candidate for the throne of Poland and was loyal to his new allegiance, assisting the Roman Catholic Church in Poland and also, somewhat, in Saxony; but such assistance had no effect on the Lutheranism of Saxony.

Protestant scholasticism. The second half of the 17th century was at once the high age of Protestant systematic orthodoxy and the age when the first signs of its dis-

Renewed interest in the mystical tradition

solution appeared. The axioms of the Reformation were worked out in a great and systematic body of doctrine.

The theologians defended and the pastors taught Luther's or Calvin's dogmatic systems—relying also upon authoritative sources such as the Formula of Concord (1577) in Lutheranism or the conclusions of the Synod of Dort (1618) in Calvinism—which were extended and made into a tradition. Even when the system was not of the ordinary Protestant tradition, it was generally worked out in many volumes, based upon coherent axioms, defended against all assailants, appealing always to reason and to biblical authority and seldom to feeling or conscience. This age has sometimes been known as the age of Protestant scholasticism. But that pejorative term came from a posterity that would no longer accept the axioms on which the systems were founded. These were the last scriptural theologians before the period of the Enlightenment, when the understanding of Scripture was altered. The old axioms were changed by Pietism, science, and philosophy.

THE RISE OF PIETISM

Influences from English Puritanism reached the Continent through the translation of works by Richard Baxter (1615–91), Lewis Bayly (1565–1631), and John Bunyan (1628–88). Most frequently read were Baxter's *A Call to the Unconverted*, Bayly's *The Practice of Piety*, and Bunyan's *Pilgrim's Progress*.

Dutch Pietism, influenced by the Englishman William Ames (1576–1633) whose *Medulla Sacrae Theologiae* (1623) and *De Conscientia* (1630) were basic textbooks for "federal theology" and Puritan casuistry in England and New England, was represented by Willem Teellinck, Johannes Cocceius, Gisbert Voetius, and Jodocus van Lodensteijn. Impulses from these men became a part of the reform movement that had already appeared in German Lutheran circles and was to be known as "Reform Orthodoxy." Older historians of Pietism, notably Albrecht Ritschl, paid little or no attention to this reform phenomenon within Lutheranism. Ritschl saw Pietism as an alien mysticism uncongenial to the spirit of both Luther and the 17th-century theologians. More recent scholars (E. Benz, M. Schmidt, H. Leube, F.W. Kantzenbach) have exposed the Ritschlian prejudice and deepened the understanding of the role played by such representatives of "Reform Orthodoxy" as Johann Arndt (1555–1621) and Johann Dannhauer (1603–66). The "pectoral [heart] theology" of these orthodox Lutherans found its highest expression and widest audience in the writings of Arndt,

who, rather than Philipp Jakob Spener, can be called the "father of Pietism." His chief work, *Four Books on True Christianity* (1606–10), was soon being read in countless homes. Although Arndt developed devotionally the *unio mystica* (mystical union), a 17th-century Lutheran doctrinal addition to the *ordo salutis* (order of salvation), the central Arndtian theme was not that of mystical union. Rather, he stressed repentance, regeneration, and the new life, and this was the very essence of Pietism.

Alongside the orthodox piety of the 17th century one of the most significant contributions to spiritual renewal was the rich treasures of Lutheran hymnody. Examples from this classical period of church song are the works of Philipp Nicolai (1556–1608; "Wake, Awake" and "How Brightly Beams the Morning Star!"), Paul Gerhardt (1607–76; "O Sacred Head Now Wounded," "O How Shall I Receive Thee," "Put Thou Thy Trust in God"); and Martin Rinkart (1586–1649; "Now Thank We All Our God").

Pietism in the 17th century. The various streams of concern for renewal converged in the life and work of Spener (1635–1705). In 1666, after having earned his theological doctorate at Strasbourg, he was called to be Senior of the clergy in Frankfurt am Main, where he was soon distressed by the conspicuous worldliness of the city. His sermons urged repentance and renewal, and each Sunday afternoon he held catechism classes for both children and adults. This led to efforts to revitalize the rite of confirmation, which, since the days of Martin Bucer, had been practiced in the Church of Hesse (Frankfurt).

The origin of the so-called *collegia pietatis* (assembly of piety) has been traced to a sermon of 1669, in which Spener exhorted the laity to come together on Sunday afternoon not to drink, play cards, or gamble, as was the custom among Frankfurt's smart set, but to review the morning's sermon and to engage in devotional reading and conversation "about the divine mysteries." The next year, at the request of a few parishioners, such meetings were held each Sunday and Wednesday at Spener's home. Although some of the Frankfurt ministers, over whom Spener was superintendent, took a dim view of the *collegia pietatis*, the practice flourished and in time became a distinguishing feature of the movement. Those who attended the conventicles were soon called Pietists.

In a relatively short time, Spener became a household name in Germany. Through his writings and extensive correspondence, especially with men in high places, Spener came to be called "the spiritual counselor of all Germany." Most significant was the publication in 1675 of his *Pia*

Philipp
Jakob
Spener
and the
*collegia
pietatis*

Desideria (Pious Desires). The book's first part reviewed the low estate of the church. He charged civil authorities, who since before the Peace of Augsburg (1555) were the de jure heads of the church, with irresponsible caesaropapism (doctrine of state control over church). He likewise flayed the clergy, many of whom were scandalous and self-seeking, often confusing assent to "true doctrine" with faith. The laymen, too, he claimed, were not blameless. Drunkenness must not be excused as a German peccadillo; prostitution, adultery, fornication, homosexuality, thievery, and assault must be rooted out lest people lose God's promised salvation. The second part of the work reminded readers of the possibility of better conditions in the church: "... we can have no doubt that God promised His church here on earth a better state than this." When the full number of heathen (Gentiles) had been brought in, God would even convert the Jews. But the fulfillment of these hopes was not to be achieved by sitting with folded hands. Part three, therefore, set forth a six-point reform program:

1. The Word of God—the whole Bible, not merely the pericopes (biblical texts used in a set sequence in worship services)—must be made known widely through public and private reading, group study (conventicles under the guidance of pastors), and family devotions.

2. There should be a reactivation of Luther's idea of the priesthood of believers, which included not only the "rights of the laity" but also responsibility toward one's fellow men.

3. People should be taught that Christianity consists not only in knowing God's will but also in doing it, especially by implementing the command to love one's neighbour.

4. Religious controversies with unbelievers and heretics unfortunately may be necessary. If they cannot be avoided, they should be entered prayerfully and with love for those in error.

5. Theological education must be reformed. Professors must see that future pastors are not only theologically learned but spiritually committed.

6. Finally, preaching should have edification and the cultivation of inner piety as its goal.

Initially the *Pia Desideria* was received with enthusiasm and given wide acclaim. Some clergymen, however, felt threatened by the implications of the reform program's emphasis on the laity. Professors resented Spener's criticism of scholastic theology and advocacy of curricular reform. Spener's response was to emphasize more and more the *collegia pietatis*. Contrary to Spener's wishes the conventicles in time became divisive and abrasively donatistic (referring to the Early Church heresy that held that priests must be morally righteous or the sacraments would not be valid), tending to develop into "little churches within the church" (*ecclesiolae in ecclesia*). In an attempt to stem separatism and other questionable attitudes, Spener wrote tracts that expounded the doctrines of the spiritual priesthood (1677) and ecclesiology (1684). In the latter he argued that despite the faults of the church its teachings were not false and separation from services and sacraments was wrong.

Spener's influence had spread widely by 1686. In many circles, not least among the nobility, he was praised and imitated. In other quarters his emphases produced vigorous and, in many instances, unjust criticism. Weary of opposition and controversies, Spener accepted a call to be the court chaplain in Dresden, where he was soon disillusioned by the unresponsiveness and vulgarity of the court and the hostility of the pastors in this stronghold of orthodoxy. Two items of special significance from the Dresden period should be noted: (1) There he wrote his *Impediments to Theological Study* (1690), which was hardly calculated to win friends at the famous Saxon University of Leipzig; (2) there, too, he made the acquaintance of a young instructor, August Hermann Francke (1663–1727), who was to become in a sense Spener's successor and the second great leader of Pietism.

By 1691 Spener welcomed a call from the elector of Brandenburg, who soon brought in other Pietists, opened his domain to persecuted French Huguenots, and made Berlin a strong spiritual centre, thus taking religious lead-

ership away from rival Saxony. All of this was enhanced by the founding of a new university at Halle (1694), the theological faculty of which became, with Spener's and Francke's influence, the academic centre of Pietism.

Spener's years in Berlin were not without bitterness. The conflict between Orthodoxists and Pietists had mounted to a high pitch. The theological faculty at Wittenberg, for example, charged Spener with 284 deviations and prayed that God would save "our Lutheran Zion" from the ravages of pietistic heresies.

During his last years Spener collected and edited several volumes of his papers (*Theologische Bedencken*), continued his friendship with and support of Francke at Halle, and, significantly, served as a sponsor at the baptism of Nikolaus von Zinzendorf, who was to lead evangelical Pietism in a new direction. Spener died on Feb. 5, 1705.

Meanwhile, Francke became the central figure of Pietism. During his student years at Leipzig he had been engaged in group Bible study, being one of the organizers of a *collegium philobiblicum* (assembly of Bible lovers), dedicated largely to the scholarly rather than devotional approach to the Scriptures. A religious experience in 1687 led Francke to make conversion—characterized by a severe penitential struggle and commitment to holy living—the norm for distinguishing the true Christians from unbelievers. Francke's Pietism, going beyond the spirit of Spener, came to stress a legalistic and ascetic way of life. Under Francke's leadership (he became professor in 1698) Halle became famous not only for its university but for the many "Halle institutions" that sprang up: an orphan asylum with affiliated schools, a publishing house and Bible institute, a Collegium Orientale Theologicum (Oriental College of Theology) for linguistic training of missionaries, and an infirmary that the medical faculty welcomed as compensation for the university's lack of a clinic. All of this gave to Halle and Franckean Pietism an energetic and activist character.

Pietism in the 18th century. *Central Europe and England.* One of Francke's institutions in Halle was the *paedagogium* (1698), which was intended for the education of boys whose well-to-do parents lived at a distance. Nikolaus Ludwig, Graf von Zinzendorf (1700–60) attended the Halle boarding school from 1710 to 1716. Having been drawn earlier to Spener, his godfather, Zinzendorf was now greatly stimulated by Francke. As a 14-year-old lad he organized the "Order of the Grain of Mustard Seed," whose youthful members pledged themselves to reach out in ever-expanding love to "the whole human race."

By 1721 Zinzendorf had settled down on his estate (Berthelsdorf) near the Bohemian border, where he brought believers together in a nonseparatist *ecclesiola in ecclesia*, which denied the Halle Pietists' demand for penitential remorse as a mark of "heart religion." Zinzendorf formulated the slogan that came to play such a great role in the history of revivals: "Come as you are. It is only necessary to believe in the atonement of Christ."

A small band of Moravian exiles took refuge on his estate in 1722. Looking upon this event as an opportunity to realize his cherished project of "the Mustard Seed," he gave up his position in the Saxon civil service and welcomed other Moravian refugees. They, like Zinzendorf, had been primarily influenced by Pietism and had only a hazy idea that their ancestors were Hussites. Zinzendorf soon organized the colony, now called Herrnhut, into the community of the Bohemian Brethren. They were not to separate from the Lutheran Church of Saxony. They would attend services in the village church at Berthelsdorf and call upon the local pastor for ministerial acts; but they were to look upon themselves as "the salt" of the earth, an *ecclesiola* from which "heart religion" would be disseminated throughout Christendom. Under Zinzendorf's "superintendency" the Herrnhut Brethren became more and more a distinct church, the reborn Moravian Church, or Unitas Fratrum. Although Zinzendorf received a license as a minister in 1734 and three years later was consecrated bishop, he left Herrnhut under pressure in 1736, traveling in western Germany, England, and America. The chief centres of his missionary work in Pennsylvania were Germantown and Bethlehem. He returned to Herrnhut in

The six-point reform program

Court chaplain in Dresden

Herrnhut

1749 and presided over the Church of the Brethren until his death (1760).

The influence of the Moravians on the Evangelical Awakening in England was significant. By 1775 there were 15 Moravian congregations in England, and it was in one of these that John Wesley, founder of Methodism, had his famous "Aldersgate Street Experience" (1738) as he was listening to a Moravian preacher reading Luther's *Preface to the Romans*:

while he was describing the change which God works in the heart through faith in Christ, I felt my heart strangely warmed. I felt that I did trust in Christ . . . and an assurance was given me that he had taken away my sins."

He allied himself with the Moravian society in Fetter Lane, London, and the same year journeyed to Hernnuth to learn at first hand about the people to whom he owed so much. Although Wesley later parted from the Moravians, his initial experience of saving grace in the company of the Brethren shaped the wide-reaching evangelical movement that associated the names of the two Wesleys (John and Charles) and George Whitefield.

Germany. A slightly different type of Pietism appeared in Württemberg, where Spener had established relations with Swabian churchmen. Avoiding the extremes of Franckean Pietism, it accepted conventicles but opposed all temptation to separatism and sought an evangelical, as opposed to legalistic, sanctification of life in the congregations. Interested in academic theology and a scholarly study of the Scriptures, the leader of Württemberg Pietism, Johann Albrecht Bengel (1687–1752), was a pioneer in textual criticism and biblical, in contradistinction to systematic, theology. His *Gnomon Novi Testamenti* (1752; "Interpretation of the New Testament") was widely distributed in the Lutheran and English world; a fresh approach to the Bible by its emphasis on *Heilsgeschichte* (the history of salvation).

Radical
Pietism

Radical Pietism always lurked beneath the surface of Evangelical Pietism. The appeal to mystical and emotional experiences and the depiction of the church as "unholy Babylon" were common characteristics of Radical Pietism. Difficult to trace historically because of a tendency to flare up spontaneously, it can nevertheless be divided into two main forms. The first was a fanatic sectarianism in which ecstatic and visionary elements were dominant. A favourite doctrine was chiliasm (referring to the thousand-year reign of Christ at the end of history), in which the *apocatastasis* (the eventual salvation of all men) played a large role. Somewhat different but still under the first rubric were the "inspired congregations," whose inspiration was expressed in convulsive physical phenomena accompanied with glossolalia, "speaking in tongues." The second main form was "separatistic" or "nonchurch" and emphasized the "inner light." Because the "inner light" and human reason were often identified, the advocates of "Spiritual Pietism" tended to move toward Rationalism (see below). Chief among these men were Gottfried Arnold (1666–1714), Johann Konrad Dippel (1673–1734), and Gerhard Tersteegen (1697–1769).

18th-century Pietism in Scandinavia, Russia, and America. *Denmark/Norway.* As in Germany, the age of orthodoxy in the Dano-Norwegian kingdom had its deeply spiritual side, which came to expression in men like Bishop Jens Dinesen Jersin (died 1632) and Holger Rosenkrantz (died 1642), both of whom taught the necessity of pious living. Also, as in Germany, the "reform orthodoxy" was evidenced in hymns, especially those of Thomas Kingo (1634–1703). Pietism, as such, arrived in Copenhagen at the turn of the century and was welcomed, strangely enough, by the unpietistic king Frederick IV. It was during his reign (1699–1730) that the royal chaplain, the German R.J. Lütken, was able to give status to pietistic pastors and to win the King for the cause of missions in India. The King initiated a search for missionaries and, finding none in his domain, he turned to Germany, where Lütken's contacts brought about the connection with two young Halle-trained Pietists, Bartholomäus Ziegenbalg (1683–1719) and Heinrich Plütschau (1678–1747). Ordained at Copenhagen in 1705, these men became the founders of the famous Tamil mission at Tranquebar,

Pietistic
mis-
sionary
activity

India, and stimulated foreign mission interest among the Halle Pietists. To this period belongs the Christian work among the semipagan Lapps in northern Norway carried on by the Norwegian Pietist Thomas von Westen. Another Norwegian, Hans Egede, became the pioneer missionary in Greenland. King Christian VI, known as the "Pietist on the throne," gave support to numerous pietistic causes: an orphan home and schools modeled after Halle, a missionary institute, and even conventicles (the 1741 decree permitted them only under pastoral leadership). The name of Erik Pontoppidan, court preacher at Copenhagen and later bishop of Bergen in Norway, was to have enduring significance largely because of his excellent exposition of Luther's catechism, entitled *Truth unto Godliness*. Virtually a national reader for many generations, especially in Norway, this "layman's dogmatics" combined Law and Gospel, orthodoxy and Pietism, in such a manner that its power persisted into 20th-century American Lutheranism.

Sweden, Finland, and Russia. Original royal opposition to Pietism in Sweden was softened only after Francke personally visited King Charles XII on his Russian campaign. Meanwhile, Swedish students at Halle returned to their homeland imbued with Francke's ideas and practices. Following the defeat of Charles XII at Poltava in Russia (1709), thousands of Swedish prisoners of war were quartered in Siberia. Many sought comfort in religion under the leadership of a Swedish Pietist, J. Cederhielm. Correspondence with Halle and the writings of Francke and Arndt produced a strong pietistic movement in the prison camps from which only 5,000 of the original 30,000 captives were able to return to Sweden by 1724. The zealous returnees carried their pietistic convictions back to Swedish parishes. In a short time both church and government looked upon Pietism as a threat to national unity. The result was the Conventicle Act of 1726, which retarded Pietism and held Swedish church life to conventional forms for the next century. Finns as well as Swedes had followed Charles XII to defeat. Those who returned from Russia were the apostles of a religious awakening. For a time the literature of Pietism was influential, but due to the Conventicle Act of 1726 (Finland was partially a Swedish domain), its role was somewhat limited.

Pietism in
Siberian
prison
camps

Meanwhile, Pietism came to the Russian-occupied Baltic states, where it experienced greater freedom than under the Swedes. From the foreign quarter of Moscow, inhabited mainly by German Lutherans, the work of Francke reached Peter the Great and some of his government ministers.

America. In 1703 three pastors from New Sweden on the Delaware River ordained Justus Falckner, a Halle-educated Pietist, for service among the Dutch Lutherans in New York. Most of the Dutch Lutherans were of Pietist orientation, as were the many Germans from the Rhineland and Southern German valleys. These "Palatines," who settled in New York and Pennsylvania, and the famous refugee Salzburger, who settled in Georgia, came via London where the Pietist court chaplain M. Ziegenhagen assisted them on their way to America. Accompanying the Salzburger were two Francke-selected pastors, J.M. Boltzius and I.C. Gronau, who naturally shaped the spiritual life of the Georgia settlement. Zinzendorf's visit to America (1741–42) led to a clash between his type of Pietism and that of Halle, represented by Henry Melchior Mühlberg (1711–87). The victory belonged to Mühlberg, who became the organizing genius and spiritual leader, later called "The Patriarch of American Lutheranism."

RATIONALISM

The first signs of a Rationalist movement, which was to have as powerful an influence on Protestantism as the Pietists had had, may be traced back to those few who at the end of the 16th century attacked Calvinism on grounds of reason. In Leyden, the Netherlands, Jacobus Arminius (1560–1609) reacted against Calvinist doctrines of predestination (God's foreordaining men to heaven or hell). Though anyone not a Calvinist after a time came to be called Arminian, there were groups so designated in Holland and England that had members who were more marked by their use of reason in theology than by their

opposition to Calvin. In England the enemies of such liberal theologians gave them the name Latitudinarians. The so-called Latitudinarians sought to maintain church unity based upon a few fundamental articles of faith and otherwise to allow for a wide diversity of doctrine, polity, and ways of worship. Their best representatives were the Cambridge Platonists—philosophical theologians at Cambridge (c. 1640–80)—who claimed that reason is the reflection of the divine mind in the soul.

During the 17th century philosophy, hitherto considered a handmaid to theology, was expanded beyond the limits of Aristotelian philosophy and the Bible and—partly due to natural science and partly due to the reflections of thinkers from Francis Bacon (1561–1626) and René Descartes (1596–1650) onward—developed its independence. The successes of science, especially to be noted in the work of Sir Isaac Newton (1642–1727), persuaded many men of the power of reason and, by 1680, of the necessity that all things be tested by reason, including even those realms of the conscience or spirit that hitherto had been thought inaccessible to reason. The signs of the age of Rationalism were the rapid decline of belief in witchcraft; the slow and painful rise of a belief in toleration; a more widespread symbolic comprehension of conceptions like heaven and hell; and the recognition of the small size of the planet Earth within the universe. On the Continent Benedict de Spinoza (1632–77) and G.W. Leibniz (1646–1716), and in England John Locke (1632–1704), were regarded as the philosophers of the age. Among the German theologians Christian Wolff (1679–1754) of Halle approached theology almost as if it were a form of mathematics, seeking for a truth that would be incontrovertible among all reasonable men. Under prompting from Pietists of Halle, he was expelled from Prussia in 1723. But before Wolff's death Rationalist theologians had displaced the Pietists in control of Halle University and had made it the centre of Rationalist theology among Protestants.

In England the same trend among the disciples of John Locke issued in the Deists (especially John Toland, 1670–1722) for whom Christianity was never mysterious and was understood only as a republication of the natural religion of the human race. Like Wolff and his disciples the English Deists had no permanent influence on the history of Protestantism, except by forcing the theologians to answer them and thereby to treat the philosophy of religion with seriousness. The most important of all the answers to the Deists lay in the work of Bishop Joseph Butler (1692–1752), whose sermons and *Analogy of Religion* formed the most cogent defense of the basis of Christian philosophy known in that age.

Rationalist theology, contemporaneous though certainly not in harmony with Pietism and evangelicalism, began to modify or even destroy the traditional orthodoxies—i.e., Lutheran or Calvinist—of the later Reformation. The Rationalist theologians insisted that goodness in God could not be different in kind from goodness in men and therefore that God cannot do what in a man would be immoral. Though for the most part they accepted the miracles of the New Testament—until toward the end of the 18th century—the Rationalists were critical of miracles outside the New Testament, since they suspected everything that did not fit their mechanistic view of the universe.

EVANGELICALISM IN ENGLAND AND THE COLONIES

Methodism. Similar to the Pietists in Germany was the evangelical, or Methodist (named from the use of methodical study and devotion), movement in England led by John Wesley. While a fellow of Lincoln College, Oxford, Wesley gathered a group of earnest students of the Bible about him, made a missionary expedition to Georgia, and became a friend of the Moravians. Like the Pietists he laid much emphasis upon the necessity of conversion and devoted the remainder of his life to evangelistic preaching in England. He did not intend any separation, but the parish system of the Church of England as then organized was incapable of adjustment to his plan of free evangelism and lay preachers. In 1744 Wesley held the first conference of his preachers; soon this became an annual conference, the governing body of the Methodist societies, and was given

a legal constitution in 1784. The Methodist movement had remarkable success, especially where the Church of England was failing—in the industrial parishes, in the deep countryside, in little hamlets, and in hilly country, such as Wales, Cumberland, Yorkshire, and Cornwall. In 1768 Methodist emigrants in the American colonies opened a chapel in New York, and thereafter the movement spread rapidly in the United States. It also succeeded in French-speaking cantons of Switzerland.

The Methodist movement seized upon the elements of feeling and conscience that Protestant orthodoxy had tended to neglect. It gave a renewed and devotional impetus to the doctrines of grace and justification and to the tradition of moral earnestness, which had once appeared in Puritanism but which had temporarily faded during the reaction against Puritanism in the middle and late 17th century. In England it slowly began to strengthen the tradition of free churchmanship over against the tradition of the established church, though for a century or more many English Methodists believed themselves to be much nearer the Anglican Church from which they had issued than any other body of English Protestants. It enabled hymns—hitherto confined (except for metrical Psalms) to the Lutheran churches—slowly to be accepted in other Protestants bodies, such as the Church of England, the Congregationalists, and the Baptists. The evangelical movement of the 18th century produced several of the most eminent of Christian hymn writers, especially Philip Doddridge (1702–51) and Charles Wesley (1707–88).

Though John Wesley himself had not been Calvinist, in Wales the Methodists retained both the name and the theology of Calvinistic Methodists. In the United States Methodism made even more rapid progress.

The Great Awakening. Churches in the 13 colonies of the American states practiced the Congregational or Baptist church polity on a scale not known in Europe. The small Anabaptist groups had required evidence of faith, and this sometimes meant public testimony to the experience of conversion. In the larger congregations of America a similar testimony—because it was given to a wider circle—became more evident, more solemn, and at times more emotional. The pastors of the Calvinistic tradition of New England, trying to escape from the religion of forms and to seek the religion of the heart, gave unusual stress to the necessity for an immediate experience of salvation. Pastors found that under certain conditions a wave of emotion could sweep through an entire congregation and believed that they could here observe conversion and its subsequent issue in a better life. The movement owed something to the German Pietist T.J. Frelinghuysen (1691–c. 1748) and something to John Wesley's colleague George Whitefield (1714–70). The chief mind at the beginning of the Great Awakening, however, was that of an intellectual mystic rather than of a conventional Calvinist preacher. Jonathan Edwards (1703–58) was the Congregational pastor at Northampton in Massachusetts, where the conversions began in 1734–35. In the middle years of the 18th century waves of revivals and conversions spread through the colonies. Though the revivals were led by Congregationalists and Presbyterians, many small, independent, Bible-centred groups, which often professed allegiance to Baptist teaching, came into being because of the revivals. As Wesley in England and Zinzendorf in Germany had been forced to carry their new methods outside the established churches of their lands, so too were the American revivalistic leaders.

The movement was not native to America. But the conditions of the American frontier gave this kind of evangelicalism a new vigour, and from America it permanently influenced the future development of Protestantism. In the towns and new cities with moving populations, Protestantism found methods that became a feature of evangelical endeavours to reach the unregenerate or the unchurched crowds of the coming industrial cities.

LEGACIES OF THE AMERICAN AND FRENCH REVOLUTIONS

The American Revolution and the French Revolution changed the history of Western society and within it the history of the Protestant movement. The American Con-

Jonathan
Edwards

stitution, with its inferred separation of state and churches, owed something to the 'spirit of free churchmanship that had been inherited from colonial days, something to the religious mixture of immigrants continually arriving from Europe, something to the reaction against the "Church and King" alliance that prevailed in Britain, and something to the secular spirit of the Enlightenment. With the French Revolution and Napoleon, the idea of the secular state became an ideal for many European liberals, especially among the anticlericals in Roman Catholic countries. The American pattern was probably more influential than the Napoleonic in Protestant Europe. The Protestant states of Germany, Scandinavia, the Netherlands, Switzerland, England, and Scotland, which were all accustomed to established Protestant churches, for a time met no strong demand anywhere for disestablishment. In all those countries the members of the free, or dissenting, churches were able to secure complete toleration and civil rights during the 19th century, but in no Protestant country was the formal link between state and an established church totally broken during the 19th century, except in Ireland (1871) and in Wales (1914-19), where the Church of England was a minority. At least as an outward and historical form, however, established churches remained in England, Scotland, and all the Scandinavian countries.

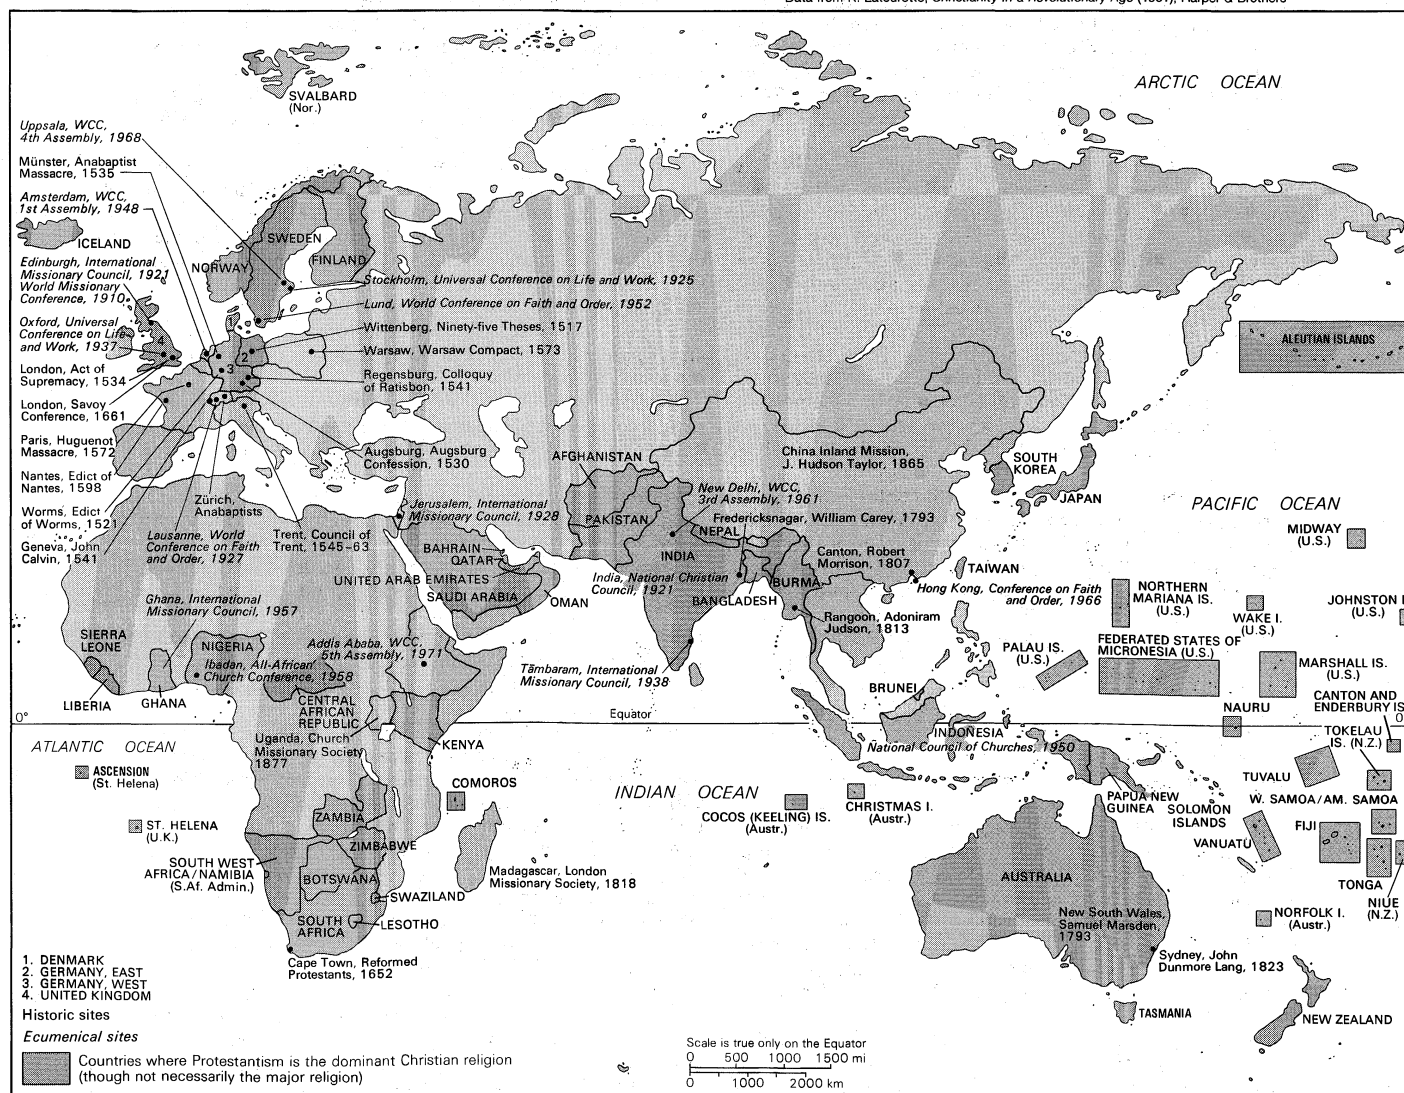

MOVEMENTS TOWARD REUNION

Early in the 19th century the greatest acts leading to reunion since the Reformation were initiated. During the

later 17th century the states of Europe—especially as they allowed more than one denomination—moved slowly toward toleration for all men as long as they were good citizens. The Christian leaders, especially of the new Rational, or Latitudinarian, school, sought to show that the doctrines that divided Protestants from each other (if not Protestants from Catholics) mattered less than the truths upon which they agreed. Among the Lutheran and Reformed, the German theologian George Calixtus (1586-1656) already had sought to prove their essential unity by showing that the doctrines that divided them were not essential to faith. A Scotsman, John Durie (1596-1680), traveled from England to eastern Germany and from Sweden to Switzerland on practical endeavours to persuade churchmen to unite. In 1631 the Huguenot Synod of Charenton (France) agreed to accept Lutherans who married Reformed or were godparents, without compelling them to abandon their special beliefs, on the ground that there was a sufficient agreement in the essential gospel between the Lutheran and Reformed. Lutherans (except for Calixtus and his school) could not take this view. Neither Calixtus nor Durie had much influence. Leibniz and the French Roman Catholic bishop Jacques Bénigne Bossuet (1627-1704) corresponded about the possibility of union between Catholics and Protestants, but in vain. In Prussia, with a mainly Lutheran population and a dynasty of Reformed princes, the policy of reconciliation became more effective. In 1708 King Frederick I built a "union-church" in Berlin, with the Lutheran Catechism and the Heidelberg

Pre-19th-century efforts at reunion

The Prussian Union

Catechism side by side on the altar. In 1817, in a Prussia stimulated by the national revival that followed the fall of Napoleon (1815), King Frederick William III (1770–1840) used the third centenary of the Reformation to unite the Lutheran and Reformed of Prussia by royal decree (the Prussian Union), and despite resistance the union was slowly accepted by the majority of Prussian congregations. Other, though not all, German states succeeded in uniting their Protestant communities about the same time. Many of the more conservative Lutherans, rejecting the Prussian Union, emigrated to the United States.

THE REVIVAL OF PIETISM

Germany. Before and for some time after 1815 an awakening occurred in Germany as a reaction against the Enlightenment. In philosophy, literature, and music it found expression in German Idealism and Romanticism. In the congregations the reaction took the form of Pietism. Pietistic orthodoxism and biblicism continued to live on among “the quiet in the land.” Some solitary thinkers with pronounced religious interests sought to preserve and awaken genuine Christianity and to point out the banality of the Enlightenment. Among these was Johann Georg Hamann (1730–88), a theologian given to brilliant paradoxical thought, who understood Luther’s *theologia crucis* (theology of the cross) better than any other 18th-century person. Matthias Claudius (1740–1815) was another representative of the antirationalist mood of the dawn of the 19th century. Johann Friedrich Oberlin (1740–1826) mixed his biblicistic piety with a concern for social missions. J.A. Urlsperger (1728–1806) sought to promote piety by organizing the Christentumsgesellschaft (“A Society for Christianity”), the German counterpart of the British Society for Promoting Christian Knowledge. Out of it grew the Basel Mission Society. G.C. Storr (1746–1804) and J.F. Flatt (1759–1821) represented the “Old Tübingen school” of biblical Supernaturalism.

It was in such a climate that the revival of Pietism occurred. Many of the people involved in it were not interested, at least in the beginning, in reviving former confessional differences. They were satisfied with being known as “Christians” or “evangelicals.” But in time some of these new Pietists, influenced by Romanticism’s admiration for the past, began to assert the need of linking their pietistic interests with the traditional confessional heritage of the church. True religion (Pietism), they argued, is really Lutheranism properly understood. Thus beginning with a renewal of heart religion (Pietism), they came to a neoconfessionalism.

There were three discernible “schools” in this revival of Lutheranism. “The Repristination Theology” (*i.e.*, restoration of earlier norms) made the 17th-century orthodoxy normative for the interpretation of Martin Luther and the confessions, and it fought the rising historical-critical approach to the Bible by affirming the verbal inspiration and inerrancy of the original manuscripts (autographs) of the Scriptures. Ernst Wilhelm Hengstenberg (1802–69) was the champion of this school of “Old Lutherans.” A second group, the Neo-Lutherans, felt that the Repristinationists, though not basically wrong, needed correction and improvement especially in their view of the church, the ministry, and the sacraments. These Neo-Lutherans (“high churchmen”), influenced by Romanticism, were the German counterpart of the Oxford Movement in England. Chief exponents were August Vilmar (1800–68) and Wilhelm Löhe (1808–72), the latter having strong influence in American Lutheranism. The third group, the so-called Erlangen school, rejected Rationalism, Repristination, and Romantic catholicizing of the church. They asserted that theology must see the relationship of faith to history, thus providing a new setting for understanding both the Bible and the Lutheran confessions. Chief representatives were Gottfried Thomasius (1802–75) and J.C.K. von Hofmann (1810–77).

Denmark. The Spener-Francke tradition of Pietism survived the age of Rationalism in Denmark by being nurtured here and there by pietistic pastors and congregations, especially in rural Jutland. The rebirth of Danish spiritual life and the conquest of Rationalism in the first

half of the 19th century, however, came not from Pietism but from the religious and cultural impact of N.F.S. Grundtvig (1783–1872) and Søren Kierkegaard (1813–55). Both of these men were profoundly religious and at times may have sounded like Pietists, but neither had any essential sympathy for Pietism. Grundtvig was in fact definitely opposed to Pietism, while Kierkegaard, though stressing “the individual” and his existential involvement in the truth, found little time for Pietism as such. The actual renaissance of Pietism in Denmark was associated with the Inner Mission Society (established in the 1850s) and its leader Vilhelm Beck (1829–1901), who, deeply influenced by Kierkegaard’s *Øieblikket* (“The Present Moment”), brought some of his emphases into the church that Kierkegaard so bitterly criticized.

Norway. Nineteenth-century Pietism in Norway may be seen in three episodes: (1) the life and work of Hans Nielsen Hauge (1771–1824), (2) the pietistic confessionism of Gisle Johnson (1822–94), and (3) the conflict over liberal theology (*c.* 1875–1908). Hauge was a layman theologically untrained but at home in the Bible, Luther’s catechism, and the works of Arndt, Pontoppidan, and Kingo. Converted in 1796, his sense of mission eventually produced a national revival. Hauge and Haugeanism, though sharply critical of the established church, became an example of conventicle Christianity within the framework of the state church. Arrested no fewer than 10 times for violation of the long-neglected Conventicle Act of 1741, Hauge’s final imprisonment lasted from 1804 to 1811. Although he thought of himself solely as a religious awakener, Hauge and his movement contributed to the sociopolitical revival in Norway through the influence of laymen who had been trained in an activist type of Pietism. A characteristic feature of Haugeanism was its concept of a person’s daily work as a divine calling. Imitating Hauge’s example, many Haugeans became successful businessmen, shippers, and farmers.

The second figure in Norwegian Pietism gave his name to a revival that occurred in the 1850s, the Johnsonian Awakening. Influenced by the German “Erlangen school,” Johnson was joined on the theological faculty in Christiania (Oslo) by a staunch Hengstenbergian Repristinationist, C.P. Caspari, a converted German Jew. The Johnsonian Awakening, unlike the lay-oriented Haugean movement, was consciously directed toward pastors and church leaders. It produced powerful lay organizations that promoted inner and foreign missions.

The third phase of Norwegian Pietism was manifested in the conflict over theological liberalism during the last quarter of the 19th century. Increasingly the university-oriented Norwegian intellectuals—clergy and lay—were drawn toward liberal positivism, historical relativism, and progressive optimism, the whole structure of which was based on natural science and biblical criticism. The orthodox Pietists of the Johnsonian school led the attack on the liberal professors now dominating the theological faculty. By the turn of the century the idea of establishing a faculty independent of state control and supported by the faithful in the congregations was born. This was realized in 1908 when the Menighetsfakultetet (the Congregational Faculty) was created.

Sweden. Like Norway, Sweden was visited with a variety of pietistic movements in the 19th century. The first was militant revivalism in northern Sweden, where Moravian Herrnhuters interested in Lapland missions merged their enthusiasms with those of pietistic Lutherans and together were called the “Old Pietists.” Lay conventicles, encouraged by some clergymen, emphasized devotional reading of the liturgy, the Bible, and Luther’s and Arndt’s sermons. The movement, called the *Läsare* (“The Readers”), soon came under attack, resulting in the emigration of a group under Erik Jansson to Bishop Hill, Ill. A second revival in the first half of the century was associated with the name of Henrik Schartau (1757–1825), who was pastor and dean at Lund, Swed. What distinguished Schartauism as a revival movement was its strong churchly character. It was catechetical, liturgical, orthodox, and anti-conventicle. Yet its profound piety produced an awakening in south-west Sweden, the results of which were still noticeable in

Grundtvig and Kierkegaard

The Johnsonian Awakening

Schartauism

the 20th century. The third revival occurred toward the middle of the century under the leadership of Carl Olof Rosenius (1816–68), a lay preacher strongly influenced by George Scott, an English Methodist evangelist. Rosenian Pietism, or the “New Evangelism,” as it was called, made much of “objective justification,” appealing to sinners to “Come as you are.” Again, as in Denmark and Norway, a healthy inner mission society was one of the fruits of revival, the National Missionary Society. Following the death of Rosenius, leadership came into the hands of Paul Peter Waldenström (1838–1917), whose subjective views of the atonement led to the formation of the Swedish Mission Covenant Church (1878).

Generally speaking, the two Swedish universities, Lund and Uppsala, represented high and low churchism respectively. The latter viewpoint influenced Parliament to allow the Church of Sweden its own Convocation (1865) with lay representation.

North America. The great 19th-century German and Scandinavian immigration began in 1839–40. The first Germans to arrive were “Old Lutherans” from Prussia whose original pietistic impulses had given way to a high-church confessionalism of the Hengstenbergian and “New Lutheranism” line. Colonies of about 1,000 “Old Lutherans” under J.A.A. Grabau settled in the vicinity of Buffalo and others in and around Milwaukee. They were the forerunners of the Buffalo Synod (1845). Saxon immigrants, under Martin Stephan and Carl F.W. Walther likewise arrived in 1839 and settled near St. Louis to become by 1847 the Missouri Synod. Stephan had practiced conventicle Pietism in Germany and had influenced Walther and others in this direction. Walther and other Missouri Synod leaders later moved to a staunch confessionalism that left little room for conventional Pietism. The Norwegians, who also arrived in 1839, were almost entirely of the Haugean persuasion, one of their first leaders, Elling Eielsen (1804–83), being an extremely legalistic lay follower of Hauge. Most of the subsequent waves of immigrants were sympathetic to Pietism, the laity inclining toward Haugeanism, the clergy towards Johnsonianism. The Danish immigrants, fewer in number, eventually split over the question of Pietism. The anti-Pietists, or Grundtvigians, were known as “the Happy Danes,” while the pietistic, inner-mission disciples of Beck were denominated “the Sad Danes.” The Swedish-Americans reflected “Läsare” and Rosenian Pietism initially, but after the Evangelical Lutheran Augustana Synod was formed in 1860 it soon began to evidence a churchly type of Pietism that perhaps could be traced to Schartaivism.

THE ERA OF PROTESTANT EXPANSION

Toleration. The great Protestant advance depended in part on the existence of the secular state and toleration. As late as 1715 the Austrian government had denied all protection of the law to the numerous Hungarian Protestants. But after the French Revolution the few survivals of this old church–state unity were rapidly whittled away. Even in countries in which one church was established, all churches were given some form of protection; Protestant groups could spread, though slowly and under difficulty, in Spain or Italy. Even in tsarist Russia, which did not recognize toleration, Baptists obtained a foothold from which they were to build the second largest Christian denomination of Soviet Russia. Wherever western European and American ideas were influential, Protestant evangelists could work fairly freely, especially in the colonial territories of Africa and India.

Though the secular state thus helped Protestant (and Roman Catholic) expansion and variety, it also confronted all churches with urgent new problems. The American pattern, in which the state must have no constitutional connection with religion, stemmed as much from the old Congregational tradition as from the ideas of the Enlightenment and was never antireligious in intention. It was influential among the older churches of Europe. In Protestant countries where state and church had been in alliance since the Reformation the effect was twofold: the state became more neutral in its attitude toward the leading denominations of its territory; and the state church

pressed harder toward independence from all forms of state control. Lutheran Germany produced a strong movement toward independence in the mid-19th century. In Scotland the evangelical movement demanded independence from the state in the appointment of ministers to parishes, and when this was refused by the courts and by the government, nearly half the Church of Scotland (1843) under the leadership of Thomas Chalmers (1780–1847) left the established church to found the Free Church of Scotland. The two churches continued side by side (until their eventual reunion in 1929). In Switzerland a Reformed theologian, Alexandre-Rodolphe Vinet (1797–1847), pressed for the separation of church and state and in 1845 founded the Free Church.

In England the move toward independence in a state church was a feature of the Oxford Movement, founded by John Henry Newman (1801–90) in 1833. Here the movement took a course unique in Protestantism. It asserted independence by emphasizing all the Catholic elements within the traditional heritage of Protestantism and so created a school of thought that, though remaining within a Protestant Church, came close to repudiating the Protestant tradition as it was then commonly understood in Europe and America. Newman himself became a Roman Catholic in 1845 and was made a cardinal in 1879. Under the leadership of the survivors the Oxford Movement brought about a transformation in the worship, organization, and teaching of the Church of England within the traditional polity of an established and Protestant church. The remarkable sign of this change was the revival from 1840 on of nunneries and from 1860 on of monasteries.

In German Lutheranism, under the influence of Pietism, Theodor Fliedner (1800–64) established in 1836 a “mother-house” for deaconesses that became a model for the many successor diaconate orders in Germany, Scandinavia, and the United States. These were the first such to appear in Protestant communities since the dissolution of monastic communities during the Reformation. In the mid-20th century France produced a celebrated community at Taizé devoted to ecumenical prayer and study.

On the whole the trend was always, though slowly, toward a free church in a free state. A few powerful conservative theorists, especially Friedrich Julius Stahl (1802–61) among German Lutherans, strenuously defended one version or another of the old link between throne and altar and the necessity for a single privileged church if revolution or rationalism were to be avoided. These theorists were usually viewed, however, as survivals from a past age. Much more powerful and contemporary were the theorists who, in resisting the trend toward denominationalism and pluralism, saw the church as the religious side of the nation and therefore wanted to broaden its doctrines and liberalize its polity. In England Frederick Denison Maurice defended the established church upon these liberal lines; and in Denmark, more easily because the population was so largely Lutheran, N.F.S. Grundtvig shrank from every form of denomination or confessionalism and wanted to make Christianity the spiritual aspect of Danish national life. Grundtvig’s movement had extraordinary success; but Denmark, and to a lesser extent Sweden and Norway, were exceptions to the trend. The older Protestant churches steadily moved farther away from the state and unsteadily but gradually secured more autonomy in their organization.

The rise of American Protestant influence in the world. Since the 16th century the two centres of Protestant political power had been Germany and England. With German unity effected under Prussia and the rise to world power of Britain, the political force of Protestantism was stronger during the 19th century than at any time since the Reformation. But about 1860 it began to be clear that a third force was emerging in the United States. After 1820 American frontier conditions helped to extend the variety of Protestant forces, and denominations such as the Disciples of Christ, formed in 1832 from revivalist groups, arose. These Protestant denominations in time extended their influence beyond America. Many of the immigrants to America were Catholic, and in time the largest single denomination in the United States was to be

Movement

Church–
state rela-
tionships

the Roman Catholic. But the tone of American leadership and culture remained Anglo-Saxon, liberal, and Protestant. Many Germans and Scandinavians, usually of the Lutheran persuasion, emigrated to America, and American Lutheranism expanded until it became a centre of Lutheran life and thought of a weight equal to the original homes of Lutheranism in Germany and Scandinavia. Because the Lutheran leadership came largely from European pietistic groups, the American Lutheran churches tended to be more conservative in theology and discipline than the churches in Germany. The element of revivalism in American Christianity continued throughout the 19th century and helped the concept of a personal Christian faith to penetrate deeply into the American way of life.

The spread of missions. With the background of European strength in Germany and Britain, with the rising strength of the United States, and with the longest period of peace that Europe had ever known, the Protestant churches entered their greatest period of expansion. Confronted at home by the new cities, they developed social services on a scale hitherto unknown, such as in hospitals, orphanages, temperance work, care of the old, extension of education to the young and to working adults, Sunday schools, boys' and men's clubs in city slums, and the countless organizations demanded by the new city life of the 19th century. Abroad they carried Protestantism effectively into all those parts of Africa that were not under French or Portuguese influence, so that in southern Africa the Bantu became largely a federation of Protestant peoples. In India British and American missionaries steadily increased the strength of the newer Indian Christian churches. In China Christianity had been hitherto confined to the seaports and the survivors of Roman Catholic missions in the 17th century; but now a variety of evangelical groups, mostly financed from England or America and led by the China Inland Mission (founded 1865), created congregations deep in the interior of China. Japan had been closed to Christianity since 1630, and after its reopening in 1859 American and British missionaries created Japanese Christian churches. American missionaries developed Protestant congregations in the countries of South and Central America. All of the main Protestant denominations—Lutherans, Presbyterians, Anglicans, Congregationalists, Baptists, Methodists—developed into worldwide bodies, and all suffered strain in adjusting their organizations to meet these extraordinary new needs.

REVIVALISM IN THE 19TH CENTURY

One of the most prominent features of Protestantism in the 19th century was the development of revivalist methods to meet the needs of an industrial and urban society. Although many urban poor seldom went to church, they listened to evangelical preachers in halls or theatres, or on street corners. Methodists and Baptists, familiar with revivalistic methods, made many strides forward, especially in the United States. Their efforts were not confined to reaching the working class. The English Baptist Charles H. Spurgeon (1834–92) secured a large audience in London and helped to make the ministry of Protestant dissent very powerful. His mission was for the most part to the educated rather than to the urban poor. For the lowest end of the social scale, a former Methodist preacher, William Booth (1829–1912), and his wife, Catherine, created in east London the agency of evangelism that was known from 1878 as the Salvation Army. They directed their mission to the men on the street corners, using brass bands and even dancing to attract attention. They differed from the Methodist revivalist tradition, from which they had sprung, by their belief in the necessity of a strong central government under a "general" appointed for life, and by abandoning the use of sacraments. At first they met much hostility and even persecution, but by the end of the 19th century the Salvation Army had securely established its place in British life and had become a worldwide organization.

In Sweden a Methodist preacher influenced Karl Olof Rosenius (1816–68), who introduced revivalism into Swedish Lutheranism. He and some disciples also were influenced by the movement that stemmed from Zinzen-

dorf. Though there were links with Pietism, the new movement was quite unlike the little groups of Pietism. The Pietists wanted to gather men to salvation out of the world, whereas the Bornholmers (as they later came to be called in Denmark because of a famous episode in evangelism on the island of Bornholm) wanted to declare salvation to the world. The movement had effects in Norway and Denmark and in the Lutheran Church—the Missouri Synod in the United States—but never became as separate as the Salvation Army.

In the United States the development of revivalism was particularly marked in the expansion of the moving frontier. The memory of the Great Awakening (c. 1725–50) was always powerful, and in halls of cities as well as in the camps of the west, revivalistic preaching methods were effective. Protestantism was exceptionally strong because, in many cases, immigrant groups found in religion that link with their historic past that secular society could not for the time give them. Famous evangelists appeared to meet the need of the cities, especially Charles Grandison Finney (1792–1875) and Dwight Lyman Moody (1837–99).

Thus, some of the evangelistic power in Protestantism of the 19th century was drawn away from the traditional churches of the Reformation—Lutheran, Calvinist, and Anglican—and tended to create new forms of church life and new organizations. These almost always used lay preachers, were far more concerned with bringing the individual to conversion and little concerned with church order, and were sometimes content if they could draw a soul to Christ without worrying if it were drawn into a historical Christian community as understood since the Reformation. Consequently they developed a tendency, not common before the Pietist movement, to identify Protestantism with individualism in religion. Because the evangelistic endeavours subsequently produced separate organizations, the separate denominations and the varieties of Christianity that still called themselves—and with justice—Protestant were rapidly increased.

The secular state allowed or even stimulated the Protestant churches to establish further and powerful varieties of religious groups. Among radical Protestants several important groups or new churches emerged, and several of them were apocalyptic, owing their origin to expectations of the Second Coming of Christ. In Britain appeared the Plymouth Brethren, founded in 1827 by John Nelson Darby (1800–82), who separated themselves from the world in preparation for the imminent coming of the Lord. The Catholic Apostolic Church, formed in 1832 largely by the Scotsman Edward Irving, likewise prepared for an imminent coming. Apocalyptic groups and sects were successfully established in the United States, probably because of the absence in new areas of any settled or habitual church polity. The Seventh-day Adventists were founded by William Miller (1782–1849) of New York, again with an expectation of an immediate end of the world. Though not self-proclaimed Protestants, the Mormons (Church of Jesus Christ of the Latter-day Saints), founded by Joseph Smith (1805–44), came out of a parallel waiting upon the end. Another set of groups arose from the revival of faith healing, the most important being the Christian Scientists, founded in 1879 by Mary Baker Eddy (1821–1910), who set up her first church in Boston.

NEW ISSUES FACING PROTESTANTISM IN THE 19TH CENTURY

Churches and social change. Attacks on the churches during the 19th century (and after) were twofold: social and intellectual. Rapidly growing cities and industry created a proletariat estranged from religious life. Many of the political leaders, especially in Europe, claimed that the churches were bulwarks of that order of society which must be overthrown if justice was to be secured for the working class. Some of the earlier forms of socialism were atheistic or at least deistic and suspected free churches as fiercely as they suspected an alliance between altar and throne. Social and economic thinkers, such as Karl Marx (1818–83), argued that religion was the opium of the people, that it bade human beings to be content with their lot when they ought to be discontented.

In response to such views, in nearly every European

Gospel

country, Catholic or Protestant, there came into existence groups of "Christian Socialists," who believed (at least) in the doctrine that workers had a right to social and economic justice and that a Christian ought in conscience to work toward those political conditions that would achieve more social justice for them. Except for these basic views the Christian Socialists varied greatly in their outlook and ideas, whether political or theological. Adolf Stöcker (1835–1909), a court preacher in Berlin, was an anti-Semitic radical politician; and Charles Kingsley (1819–75), a clergyman novelist in England, was a warmhearted conservative who deeply sympathized with and understood the working class. The most profound of all the Christian Socialists was Frederick Denison Maurice (1805–72), a theologian of King's College in London until he was ejected in 1853, then a London pastor, and finally a professor of moral philosophy at Cambridge.

But in England and America the radical wing of Protestants—especially Baptists and primitive Methodists—did as much for the workers' religion as the intellectual leadership of a few Anglican theologians. In some cases the endeavours made Socialist parties possible for the Christian voter; in others they persuaded Christian voters or politicians—without actually voting for a Socialist party—to adopt policies that led toward a welfare state. Nevertheless, they made Christians more conscious of a social responsibility. In America the Social Gospel excited much influence in the churches at the end of the 19th century, and its most influential leader was a Baptist, Walter Rauschenbusch (1861–1918). Whereas in Catholic countries political parties arose that especially appealed to Christian voters and often used the word Christian in their name, in all the Protestant countries all political parties needed to appeal to Christian voters, and few avowedly secular parties had political success.

Biblical criticism. Besides political, social, and economic criticism, Protestantism was encountering an intellectual onslaught on Christianity. There were thinkers who declared that the advance of science and of history proved the Bible, and therefore Christianity, untrue. The question of biblical criticism was first posed in the German universities; *i.e.*, whether a man might be a Christian and even a good Christian though he held some parts of the Bible to be not true. This became the great question for Protestantism, if not for all Christendom, in the 19th century. On the one hand Protestantism stood by the Bible and declared that the truth of God came from the Bible. On the other it rested in part on a fundamental conviction of the liberty of the human spirit as it encountered the Bible. Protestantism was thus seldom friendly to the tactic of meeting argument merely by excommunication or by the blunt exercise of church authority. The theological faculties of German universities, being state faculties and not church institutions, suffered much internal stress, but they arrived at last at the conviction that reasoned criticism—even when it produced conclusions opposed to traditional Christian thinking—should be met rather by refutation than by way of authority. Thus German Protestantism showed at length an elasticity, or open-mindedness, in the face of new knowledge, which was as influential in the development of the Christian churches as the original insights of the Reformation. Owing in part to this German example, the Protestant churches of the main tradition—Lutheran, Reformed, Anglican, Congregational, Methodist, and many Baptist communities—adjusted themselves relatively easily (from the intellectual point of view) to the advances of science, to the idea of evolution, and to progress in anthropology and comparative religion.

Influence
of philo-
sophical
thought on
biblical
criticism

In such a flux of ideas, with the Protestant tradition seemingly under attack from Protestants, there was naturally a wide variety of approaches, both in philosophy and history. There was an opinion, represented by the German philosopher G.W.F. Hegel (1770–1831), that Christianity should be restated as a form of Idealistic philosophy. This view was influential for a time in Germany and afterward among Oxford philosophers of later Victorian England. Such restatements were subjected to destructive attacks, of which the most powerful were published by the

Danish philosopher Søren Kierkegaard, chiefly because such reasoned philosophy failed altogether to account for the depths and tragedies of human existence. An earlier opinion sought to base the justification of Christian faith in the religious feelings commonly found in humanity. A German philosopher, F.D.E. Schleiermacher (1768–1834), sought to infer the Christian and biblical system of thought from an examination of human religious experience. Schleiermacher's attempt had much influence on Protestant thought. Throughout the 19th century the appeal to religious experience was fundamental to liberal Protestant thinking, especially in the attempt to meet the views of modern science. Probably the most important of the successors of Schleiermacher was Albrecht Ritschl, who wholly rejected the ideas of Hegel and the philosophers; he distinguished himself sharply from Schleiermacher by repudiating general religious experience and by resting all his thought upon the special moral impact made by the New Testament on the Christian community. Between 1870 and 1918 the Ritschlian school was one of the leading theological schools of thought within the Protestant churches.

Meanwhile, scholars made long strides in the study and exposition of the Bible. Freed from the necessity of defending every one of its details as historical truth, professors at Protestant universities were able to put the books of the Bible into a historical setting. This made an important difference in the study of the New Testament but was a revolution so far as the Old Testament was concerned, where the entire earlier accepted chronology was changed. German Rationalist or Hegelian historians were the first to study the problems with freedom. Ferdinand Christian Baur (1792–1860) of the University of Tübingen applied the methods of Hegelian philosophy to the documents of the New Testament, which he conceived to be products of the clash between the Jewish Christians led by Peter and the Gentile Christians led by Paul. This theory, known as the Tübingen theory, soon receded in influence; but in aid of this theory Baur expounded the texts with such ability as to make his study a landmark in the study of the Bible. Among a large number of excellent biblical students, Joseph Barber Lightfoot (1828–89) of Cambridge finally demolished the Tübingen theory by showing the 1st-century origin of most of the New Testament texts; and Adolf von Harnack (1851–1930) of Berlin by the end of the century summarized the results of a century that was revolutionary in the area of biblical study.

criticism of
the Bible

Protestantism in the 20th century

MAINSTREAM PROTESTANTISM

The war of 1914–18 broke Europe's waning self-confidence in the merits of its own civilization. Since it was fought between Christian nations, it weakened worldwide Christianity. The seizure of power by a formally atheist government in Russia in 1917 brought a new negative pressure into the world of Christendom and sharpened the social and working class conflicts of western Europe and America. During the following 40 years the Protestant churches suffered inestimable losses.

Germany under Adolf Hitler (in power 1933–45) professed to save Europe from the threat of Bolshevism; and the Nazi rule was at first welcomed by many German churchmen. Disillusionment was not slow to follow. From September 1933 there already existed a partial schism between churchmen willing to cooperate with the government in church matters—especially over the Aryan clause that demanded that no Jew should hold office in the church—and those, led by Martin Niemöller, who were not willing to cooperate in church matters. With the support of the state-aided Lutheran churches in the south (Bavaria and Württemberg), Niemöller's group was able to form the Confessing (or Confessional) Church, and the schism was made manifest when the Confessing Church held the Synod of Barmen in May–June 1934. For a time the Confessing Church was strong throughout Germany; but when the German government provided a less doctrinaire government under the minister of church affairs Hanns Kerrl, the Confessing Church was itself divided—

The effect
of Nazi
control in
Germany

into those who were willing to cooperate and Niemöller's men, who were not willing to cooperate because it was a church government imposed by the Nazi government. At the Synod of Bad Oeynhausen (February 1936) the Confessing Church broke up and was never again so strong. In the later stages, especially during World War II when the extreme Nazis secured complete control of Hitler's government, the churches came under increasing pressure and toward the end were struggling in some areas to survive. Bishop Theophil Wurm of Württemberg was a leader in protesting to the government against its inhumane activities, and Pastor Heinrich Grüber, until his arrest, ran the Büro Grüber, which sought to evacuate and protect Jews. Some church leaders, notably the theologian Dietrich Bonhoeffer, paid with their lives for their associations with resistance to the Nazi government.

The results
of World
War II

The end of the war saw Russian armies in control of eastern Europe and Germany divided. All the churches in the area came under pressure. Most Germans were evacuated or deported from the three Baltic states of Lithuania, Estonia, and Latvia. Although Lutheran communities remained there, they were subjected to persecution, especially under the rule of Stalin. The Lutherans in Transylvania (Romania) and the Reformed in Hungary came under less severe pressure but were much diminished in numbers. The Protestants of Czechoslovakia, led by the theologian Joseph Hromádka, succeeded in maintaining more dialogue with Marxist thinkers than did Protestants elsewhere in Europe. From the viewpoint of Protestant strength the greatest losses were suffered through the division of Germany. The settlement between the victorious powers gave large areas of former German-speaking (and largely Lutheran) areas to Poland, and many (approximately 8,000,000) Germans were expelled; most went to western Germany. The East German state, as constructed in 1945, included Wittenberg and most of the original Protestant homeland. East Germany (the German Democratic Republic) was the sole country in which a Marxist government ruled a largely (70 percent) Protestant population. For a time the Lutheran churches were the chief link between East and West Germany and the annual meeting, or *Kirchentag*, the single expression of a lost German unity. But the building of the Berlin Wall in 1961 stopped this communication and isolated the East German churches. Despite governmental pressure, especially in relation to money, education, and church building, and in the national (and anti-Christian) form of youth dedication, the East German Protestants worked courageously and flourished. The 450th anniversary of the Reformation on Oct. 31, 1967, showed how strong a hold the Protestant churches still had over the affections of a large number of people.

In Russia, before the Revolution of 1917 a deeply Orthodox state, the 40 years after the Revolution witnessed a growth in the Baptist community. The flexibility and simplicity of Baptist organization made it in some respects more suitable to activity under difficult legal conditions. In the years after Stalin's death in 1953 there was evidence of rapid advance; but after 1960 the Baptist communities, like the Orthodox, again came under pressure, which at times was severe.

The effect
of the
decline of
the British
Empire

The material losses that Great Britain suffered in World War II and the end of the British Empire in the years after 1947 had serious effects on the Protestant churches in former British territories. The home country could no longer provide money and human resources to the overseas churches on the same scale, and in a few areas church government was handed over to leaders who were not ready to take over church leadership. But in other areas the change of status for Britain hastened the process of change in leadership that had been proceeding slowly; and some of the failing resources were supplemented from elsewhere, especially from the United States, Canada, and Australia. Thus the so-called younger churches came to be a new fact of world Christianity, led by men who no longer saw the history of Christianity solely through European eyes and had an impatience partly derived from a different attitude to the Christian past. This was to be of primary importance in the ecumenical movement. Meanwhile, the

secularizing trend of a technological age assailed the old European churches and had an even greater effect upon the areas where the younger churches ministered.

The growth of mainline Protestantism in sub-Saharan Africa, as of Lutheranism in South West Africa/Namibia or Anglicanism in South Africa—as well as of the Pentecostal and Evangelical churches and sects in South America and Asia—helped compensate for losses in Europe and North America. Because of conversions and population growth the Protestant church actually increased in size as it changed its scope and ethos.

There were also surprising survivals and reappearances of Protestantism in areas of the world where its demise had been foreseen. Thus, in 1948–49 the Communist seizure of power in China effectively ended Protestant missions there. By 1951 there were hardly any European missionaries in the country, and the Chinese churches had to stand without outside aid. They came under severe pressure, especially during the so-called Cultural Revolution in the 1960s and '70s. They could no longer evangelize and sought barely to survive. The partial reopening of China to the West and the cautious measures granting more freedom of religion and speech beginning in the late 1970s and the 1980s led to new contacts between Chinese Protestants and Westerners. It was estimated that several million Protestants and other Christians had endured the suppression and persecution of the two previous decades, and, however uncertain their futures remained, they represented a vital group of churches.

CONSERVATIVE AND EVANGELISTIC FORMS OF PROTESTANTISM

The most important movements in 20th-century Protestantism took root in soil that most call conservative, and some of their founding had a reactionary character. At the same time not all members of these movements wished to be typed as conservative. Their forward-looking and exuberant expressions of faith displayed more radical outlooks. The three main movements are usually called Pentecostalism, Fundamentalism, and Evangelicalism. The first has been of immeasurable importance in the spread of Protestantism beyond its historic European home.

Pentecostalism. Pentecostalism emerged out of Wesleyan Holiness movements at the turn of the century in the United States. In 1901 in Topeka, Kan., and in 1906 in Los Angeles, there were particularly notable manifestations of various phenomena that characterize the movement. Central to these is glossolalia, "speaking in tongues." This is a form of unexpressed speech whose agents "yield" themselves to the Lord. Normally the syllables they speak or sing are unintelligible, though some claim that they speak in recognizable foreign tongues as the disciples of Jesus did at the first Pentecost, from which the movement derives its name. Pentecostals believe that they must experience a "second baptism," beyond water baptism, in which the Holy Spirit comes to them. They not only speak in tongues but also interpret them; they prophesy; many engage in healings, claiming that miraculous healings did not cease after the apostolic period, as many other Christians claim they did.

Speaking
in tongues

The Pentecostal movement in the United States was often Southern, associated with the "Bible Belt," and developed among the rural poor whites or urban blacks. After the mid-20th century, through fast-growing denominations like the Assemblies of God, Pentecostalism emerged as one of the most visible forms of Protestantism and became increasingly acceptable to the middle classes. After 1960 the movement spread into mainstream churches like the Episcopal, Lutheran, and Presbyterian, where participants often called it a "charismatic" movement.

Pentecostalism had its greatest success in the Caribbean, Latin America, and sub-Saharan Africa. There many prophetic movements erupted, in which Christians adopted emotional forms of worship and healing. Pentecostalism in these parts of the world was often the religion of the poor, bringing hope to people in nations that were emerging from colonialism. The Pentecostals, building on the work done by missionaries a century earlier, were not often anti-American or anti-European, as some liberation

movements were. In fact, they often accented "otherworldliness" and avoided politics or identified with conservative and even repressive regimes.

Fundamentalism. The second major movement, Fundamentalism, combined late 19th-century premillennialism with more or less rationalistic defenses of biblical inerrancy. It took its name from a sequence of tracts called *The Fundamentals* that were issued between 1910 and 1915 in the United States, and the movement became institutionalized in 1919 and 1920, as Fundamentalism became a formal and militant party in denominational conflict in the United States.

The most obvious causes for the rise of Fundamentalism were the spread of Darwinian evolutionary theory and its acceptance in the more liberal parts of the Protestant churches as well as the higher criticism of the Bible. Fundamentalists in the United States felt that these two movements were subverting seminaries, bureaus, mission boards, and pulpits in the northern branches of denominations like the Baptists and Presbyterians. The Scopes trial in 1925, in which the Fundamentalist champion William Jennings Bryan fought against the teaching of evolution in schools and defended the Genesis record as being scientific, coincided with the climactic denominational battles in those two churches.

The Scopes trial

The Fundamentalists tended to lose the political battles but survived with their own network of Bible colleges, radio programs, and publishing ventures. In the early 1940s they regrouped into several competitive Fundamentalist organizations that steadily gained followers, visibility, morale, and assertiveness. They prospered most when they moved from a generally passive political posture to open participation, particularly in support of Ronald Reagan's successful presidential bids in 1980 and 1984.

Groups like the Moral Majority, founded by Fundamentalist evangelist Jerry Falwell, demonstrated how effective the television ministry of the movement could be. The Fundamentalists concentrated political energies on opposition to abortion, support of an amendment that would permit prayer in public schools, and identification with the causes of Israel and a strong military defense budget.

Evangelicalism. The third movement is Evangelicalism. Focused for decades in the ministry of figures like evangelist Billy Graham and journals like *Christianity Today*, this conservative and evangelistic group tended to agree with Fundamentalism on cardinal doctrines: the virgin birth, substitutionary atonement, and physical resurrection of Jesus. Most Evangelicals insisted on some version of biblical inerrancy, but gradually more and more scholars of the movement questioned whether that was the best way to assert faith in biblical authority. Nor did all agree with those Fundamentalists who stressed premillennialism.

Evangelicals, however, were more moderate than Fundamentalists; they agreed with the older-style Fundamentalists in substance but differed in style. They found Fundamentalists to be too negative about culture, too withdrawn into sects, too rude and blustery and judgmental. When Evangelicals formed the National Association of Evangelicals in 1942, they were attacked from the Fundamentalist right much as they attacked the mainstream moderates and liberals. Most of them preferred to see themselves not as well-mannered Fundamentalists but rather as perpetrators of the 19th-century Protestant mainstream.

To that end the Evangelicals increasingly reentered the world of cultural, social, and political engagement. Rather than build Bible schools, they concentrated on liberal arts colleges. Some Evangelicals even engaged in radical social programs and criticized conservative Protestantism's over-identification with militarism and unfettered capitalism. They also acquired considerable if slightly unpredictable political power in the United States and elsewhere.

Evangelicals also tended to be ecumenical; Billy Graham welcomed Catholic and mainstream Protestant leaders on his platforms, and he prayed with many kinds of Christians whom Fundamentalists would shun. Whereas Fundamentalists and Pentecostals had counterparts in the Third World, Evangelicals tended to form international movements and hold conferences designed to bring Christians of many nations together.

While Fundamentalists usually split off into churches of their own, millions of Evangelicals remained connected to mainstream denominations and increasingly moved fully into the mainstream. But they always endeavoured to keep alive their doctrinal distinctiveness and their passion for witnessing to Christ.

THEOLOGICAL MOVEMENTS WITHIN PROTESTANTISM

Meanwhile, a certain reaction could be observed in the Protestant tradition of theology. This was partly due to a general doubt about European liberalism after World War I and particularly due, in its further development, to a reaction against attempts by the Nazis to use liberal theology for some of their views of society.

In both the 19th and 20th centuries liberal theology met much criticism on the ground that it narrowed Christianity to the limits of what men believed themselves to be experiencing or turned what was objective truth into subjective feeling. Though himself no conservative, Kierkegaard was the most extreme of these critics. All the conservative theologians—including the earliest members of the Oxford Movement in England, the evangelical tradition generally, and those many who stood by the inerrant word of the Bible and in the 20th century came to be called by the name Fundamentalist—opposed the liberals on the same grounds. But in the 20th century there was a reaction even within the liberal camp. Beginning in 1918 a reaction against all theologies emphasizing religious experience was led by Karl Barth of Basel and Emil Brunner of Zürich. This theological movement, called Neoorthodoxy, widely influenced Protestant thinking in Europe and America. Barth and his disciples regarded their work as a reassertion of the true sovereignty of Scripture and as a return to the authentic principles of the Reformation. In America Reinhold Niebuhr was almost as influential in reacting against liberal Christian philosophies as they applied to society and to man. Yet that the questions the older theologians had sought to meet still remained was shown by the influence exerted by the German theologian Rudolf Bultmann of Marburg, who sought to "demythologize" the New Testament by discovering its core truths and thus allowing its significance for faith to be more fully disclosed. Refugees from Nazi Germany, such as Paul Tillich, interpreted European developments to Americans.

The rise of Neo-orthodoxy

The Neoorthodox synthesis did not outlast the generation of the giants who gave voice to it, and Protestant theology after the mid-1960s was in disarray. Europe lost its hegemony, though certain theologians, among them Jürgen Moltmann, began to take elements of Neoorthodoxy and combine them into variously described movements, such as "theology of hope," "political theology," "theology of revolution," or Protestant versions of "liberation theology." Espoused in the Third World by theologians who stressed witness to the fact that God sides with the oppressed and the poor or in the United States by feminists or black theologians who developed new interpretations of biblical and traditional texts, these theologies called into question what seemed to be the patriarchalism, elitism, and racism of much earlier academic theology.

Numerous movements adopting liberation theologies co-existed. In general they shared a tendency to particularize Protestant thought. One approach was to make much of cultural contexts. Thus, there was African or Asian, feminist or black theology. In all these cases interpretations were perceived as coloured by the "pre-understanding" people or groups brought to the reading of the texts. Another approach was to focus on "narrative theology" or "story theology" in an effort to move from abstract theology to concrete understandings centring on people. Finally, thanks to the rise of Pentecostalism and Fundamentalism, there developed across the Protestant spectrum fresh attention to the doctrine of the Holy Spirit and to eschatology, the teaching about "the last things."

THE ECUMENICAL MOVEMENT

The ecumenical movement was in origin exclusively Protestant (though Eastern Orthodox leaders soon took part) and was at first largely dominated by Protestant thinking. Its origins lay principally in (1) the new speed

of transport across the world and the movement of populations that mixed the denominations as never before; (2) the world reach of traditional denominations; (3) the variety of religion within the United States and the problems that such a variety created; and (4) the younger churches of Africa and Asia and their contempt for barriers raised by events of European history for which they felt no special concern. There was always a strong link with the missions, and an American Methodist missionary leader, John R. Mott, whose travels did as much as anything to transform the various ecumenical endeavours into a single organization, represented in his own person the harmony of missionary zeal with desire for Christian unity. A conference at Edinburgh in 1910, which marks the beginning of the movement proper, was a World Missionary Conference. From it sprang conferences on life and work (led by the Swedish Lutheran archbishop Nathan Söderblom), dealing with practical problems, as well as conferences on faith and order, at which theologians sought to examine their theological differences with sympathy. In the beginning Roman Catholics refused to participate; the Eastern Orthodox participated only through exiles in the Western dispersion; and the Nazi government refused to allow Germans to go far in participating. By the end of World War

II in 1945 it was evident that there was a new atmosphere, and the World Council of Churches was formally constituted at the Amsterdam conference in 1948. The entire movement depended for most of its money and for part of its drive on the Americans; but its headquarters was in Geneva, and, under the guidance of its first General Secretary, Netherlands Reformed administrator W.A. Visser 't Hooft, it never lost sight of the fact that the traditional problems of divided Christian Europe had to be met if it was to succeed.

In the years after 1948 the ecumenical movement brought Protestants into an ever-growing dialogue with the Eastern Orthodox and the Roman Catholics. After John XXIII became pope in 1958, the Roman Catholics at last began to participate in the ecumenical movement. Although the definitions of the second Vatican Council (1962-65) were unacceptable to most Protestants, they had a breadth quite unlike the definitions of the first Vatican Council in 1870 and encouraged those (usually liberal) Protestants who hoped in time to lower this greatest of barriers raised by the 16th century.

For specific information on ecumenical efforts in the second half of the 20th century, see the entries on individual denominations below. (E.C.N./M.E.M./W.O.C.)

Formation of the World Council of Churches

THE PROTESTANT HERITAGE

The basic doctrines of Protestantism at the Reformation, in addition to those of the creeds, were: justification by grace alone through faith alone; the priesthood of all believers; the supremacy of Holy Scripture in matters of faith and order. There has been variation in sacramental doctrine among Protestants, but the limitation of the number to the two "sacraments of the Gospel," baptism and Holy Communion, has been almost universal.

In theory Protestantism has stood throughout its history for a principle of protest that calls under judgment not only the beliefs and institutions of others but also one's own movements and causes. On those grounds, however, most students of Protestantism would recognize that the Protestant tradition has not been substantially more successful than have other faiths at remaining self-critical or at rising above institutional self-defensiveness.

Within the spectrum of non-Roman Catholic Western Christianity a great variety of doctrinal views and polities have been expressed. Not all Western non-Roman Catholic Christians have been ready to be included in Protestantism. Some Anglicans and Lutherans, for instance, have been so eager to stress their continuity with the historic Roman Catholic Church and their distance from extreme Protestantism that they have asked for separate designations. Courtesy suggests that such appeals be taken seriously; however, ultimately habits of speech and sociological usage tend to predominate and, despite their protestations, these groups are usually included in the Protestant cluster.

Teaching, worship, and organization

COMMON PRINCIPLES AND PRACTICES OF THE MAGISTERIAL REFORMERS AND THEIR SUCCESSORS

Justification by grace through faith. The original Protestant leaders united in their contention that what separated them from the Roman Catholicism of their day was their teaching that man is justified by grace through faith. Devotion to this teaching has been central to Protestantism throughout its history. Although there have been subtle variations in the differing Protestant church bodies, a core of shared belief was at first easily discernible.

Concern for "justification" was related to the obsession that in the 16th century was often expressed in terms of finding oneself on good terms with God. The metaphors were drawn from the courts of law. Aware of its shortcomings, its ignorance, its sin, and its guilt, mankind saw itself standing before a bar of justice presided over by God. Without help, the individual could expect nothing but God's wrath and condemnation. This meant that he

would perish everlastingly, and his present life would be full of torment. Yet the Bible also presented mankind with a picture of a loving and gracious God, who may very well desire happiness for all. The question then was: how could the individual be sure that God would reveal his gracious, and not his wrathful, side? How could he have the confidence that he was included in the positive loving action of God?

The teaching of the Reformers becomes most intelligible when seen against the Western Catholic doctrines (*e.g.*, sin, grace, atonement), as they saw them. In the Protestant view the late medieval Catholic teaching held that a human being was brought back to God only when so much grace had been infused into his soul that he merited the favour of God. God could not have been expected to accept someone who was unacceptable, but he could impart something that would make humans acceptable. This something was grace, and its flow depended upon the merits of God's perfect Son, the man Jesus Christ. The church, according to medieval Catholicism, in a sense controlled the flow through the sacramental system and through its hierarchy.

To the Reformers the Roman Catholic sacramental system seemed to be part of a transaction that was always going on between man and God. In it, people made sacrifices designed to appease and please God. They would attend the mass, bring offerings, show sorrow, do penance—which might involve self-punishment or compensatory good works—until God would be gracious. The leaders of the church, from priests through bishops and popes, mediated the transaction. The Reformers believed that such an arrangement could easily be misused as a political instrument for forcing rulers to comply with the church's wishes and as a personal instrument for keeping people in uncertainty or terror. It was this vision of Catholicism that helped inspire the Protestant leadership to rebel and to define justification in other terms.

The terms for this Protestant teaching came from the Bible, especially from the New Testament, and even more so from the writings of St. Paul. In St. Paul they saw a religious hero and thinker who had endured a spiritual quest similar to their own. He could be described as having been brought up in a legalistic version of Judaism, a system in which he was constantly striving to please God by following his Law, particularly as set forth in the Old Testament through the Ten Commandments. Yet Paul failed and was assailed by doubts about his worthiness and his salvation. His conversion meant a radical turning and a free acceptance of God's favour "in Christ." This meant that in faith a person could be so identified with

Influence of the writings of St. Paul

Concern for "justification"

Jesus Christ that when God looked at him, he saw instead the merit that Christ had won through his self-sacrifice on the cross. God looked, in short, at the sinner; but he did not see the sinner. He saw his perfect Son. So he could declare the person righteous; he could justify him—even though the person was still a sinner.

When taken out of the historical context of St. Paul's teachings in the letters to the Romans or the Galatians and transferred to their own times, the Reformers' teaching of justification relied heavily on the work of the Holy Spirit. The Holy Spirit, in effect, made Christ's action contemporaneous with the sinner's quest. God was working now on behalf of those in need. Through preaching, humanity learned of Jesus Christ's sacrifice and death. If the individual believed this historical narrative and, more importantly, if by the power of the Holy Spirit he believed that it was told and enacted for him, he stood before God in a new light. Grace was not infused into him to the point that he became acceptable and pleasing to God. Instead, while the individual was still a sinner, God accepted him favourably and justified him. Christ's death on the cross was then the only "transaction" that mattered between God and man. The sacraments reinforced the relation and brought new grace, but no pretense was made that the human subject had achieved satisfaction before God or produced enough merit to inspire God to act.

In the Reformers' view the new situation was one of freedom. Whereas Catholics constantly stood in fear as to whether they had provided enough merits, had achieved enough good works, or had pleased the church as God's bargaining agent, the Reformers' version had the believers standing before God completely freed of these nagging questions. They were liberated both from the terrors of sin, death, and the devil, on one hand, and, on the other hand, from the enslaving pride that went with the belief of human beings that they had achieved or at least had substantially cooperated in their own salvation.

This left the Reformers with a serious question, one to which their Roman Catholic opponents regularly referred. What had happened in this teaching of justification and freedom to the biblical accent on good works? Jesus himself, in the Synoptic Gospels (Matthew, Mark, and Luke), was constantly preoccupied with the effort of making people better, of having them bring forth "good fruit." Even Paul shared such concerns. Had the Protestant movement slighted these concerns in its desire to free human beings from the necessity of merits and good works?

The literature of Protestantism is rich in its expression of answers to such questions. The Reformers were virtually unanimous: good works did not produce appeasement of God or salvation, yet they inevitably flowed from the forgiven heart and were always the consequence of the justified person's life. The Law of God could never be used as the saving path along which human beings walked, as a sort of obstacle path or road map to God. Instead, the Law of God measured human shortcomings and judged them. A gracious God acting through his Gospel brought human beings back to him.

The Reformers' vision of human beings implied in such teachings was doubled-sided. They believed that from God's point of view the justified person was so identified with Jesus Christ that he shared Christ's perfection. The same person, throughout all his life, left to his own devices or when seen by God apart from Christ's sacrificial work, remained a sinner. The difference came through God's gracious initiative; nothing that a person did started the process of his justification. To the eyes of many in subsequent generations the result was an apparently pessimistic and gloomy view of human potential in Protestantism. The will was bound, apart from God's loving activity. No merits or good works would satisfy God. Sometimes the phrase total depravity was used to describe the human condition, though it must be said that the term had connotations in the 16th century that were different from those that it has today. It was used not so much to provide lurid connotations for descriptions of the depth of sin but rather to describe its extent; man as a total being was in trouble. Even good works, piety, religiousness, and efforts, apart from justification by grace through faith, fell under

God's curse. On the other hand, the justified sinner could be described in the most lavish terms, as one who could be "as Christ" or even sometimes "a Christ."

Those who have heard this Protestant teaching outlined through the centuries have regularly seen the difficulties it raises insofar as the portrait of God's character is concerned. Protestants never came up with logically satisfying answers to the resultant questions, though they were convinced that they were faithful witnesses to biblical teachings concerning the mystery of God's nature. The central question: if everything depended upon God's initiative and yet the majority of people are not saved, does this not mean that God is responsible for creating humans only to have them suffer; is he not guilty of the worst kind of cruelty by being the sole agent of their damnation?

In facing the question Protestant leaders differed slightly from each other. Some said that whenever people were saved, it was to God's credit; whenever they were lost, it was through their own fault. They were free to hear the Word; they were free to respond and accept the gift of grace in Christ; their own hardness of heart kept them from freedom and new life. Others ran the risk of presenting cruel pictures of God's nature and action in their interest to witness to his sovereignty and initiative. The view that God predestined some people to be saved and others to be damned was called "double predestination." Some theologians argued that God did this predestining before humans fell into sin; others saw it as a new act of God consequent upon man's fall. Those Protestant parties that were generally non-Calvinist in outlook were usually less systematic and less logical in their statements. The non-Calvinists taught a doctrine called "single predestination." They shared the Calvinists' affirmation of God's total responsibility for human salvation; but they tended to be silent or to relegate to the area of mystery and unanswerable questions the issue of how God could then be other than responsible for human damnation. In general the Protestants saw themselves to be more successful at preserving the teaching of God's sovereignty and the corollary of human helplessness than they were at making his character attractive to all. They saw themselves overcoming this problem in biblical terms by a stress on his loving relation to humanity in sending his own Son, Jesus Christ, to suffer on its behalf.

The "priesthood of all believers." If the teaching of justification had important consequences for the doctrines of God and of man in Protestantism, it was of at least equal import for any statement of the meaning of the church and especially of the relations between clergy and laity. The medieval system, sacramental and hierarchical, in effect gave the priests a monopoly in monitoring the transaction between God and man. The Protestant teaching of justification broke this, down and the Protestant leaders reverted to what they held to be the biblical view, that all believers have a share in spreading the word of grace and the acts of forgiveness. The result was an emphasis not on the privileges of a priestly caste but rather on "the priesthood of all believers."

The Reformers viewed this teaching as based on the free-flowing sense of authority that existed between Christ and his Apostles, who had been pictured in the Gospels as being active apart from an elaborate clerical church order. At the same time they believed that their doctrine would effectively displace the Roman Catholic hierarchical thought and action. Now all people were to be enjoined to take responsibility for each other's salvation; any Christian could represent the needs of all others before God. Originally the priesthood of all believers was an enlargement of the view that all Christians had intercessory powers, that they could all pray for one another. But it came to refer to the Protestant view of an equality of status between clergy and laity and to the common calling of all Christians to be agents of God's Word and grace.

The affirmation of the priesthood of all believers had widespread implications in society. In Protestant areas and nations the privileges of the clergy were limited and the scope of lay activity enlarged. All believers shared a "vocation" (calling), and priestly vocations were not considered to be more meritorious or nobler than lay vocations.

Man's freedom and the problem of "good works"

Man as simultaneously righteous and sinful

Predestination

Priesthood and coresponsibility

Monastic vocations were almost entirely swept away, and restorations of the monastic ideal have been rare and exceptional in Protestant history. Protestants kept, for the most part, a rite of ordination (though some Anabaptists dispensed with all acts that seemed to imply separation between a ministry of ordained persons and laymen) but did not regularly view it as a sacrament. That is to say, ordination conferred no special grace on men. In part a ministry was kept on a pragmatic basis; the clergy were to tend to the business of studying and preaching the Word, properly administering the sacraments, and caring professionally for the health of the church. A set-aside ministry was also derived from biblical precedent in the Book of Acts and early Christian letters.

Protestants, while acknowledging their belief in the equality of laymen and clerics in the priesthood of all believers, have not always seen themselves as particularly successful in clarifying the laity's role. In most cases laymen were not to be the preachers in public worship, and administration of the sacraments usually remained in clerical hands. By demanding of preachers expertise at expounding the Bible, Protestants often have made educational requirements a basis for ordained ministry, at the expense of a full lay involvement. Yet their views did greatly enhance both the theological and practical status of laymen, when contrasted to the situation in medieval Catholicism.

If all believers were priests, then no single church could monopolize the mediation of grace, since Protestants saw that there were believers in all churches, Roman Catholic and Protestant, Lutheran or Calvinist or Anglican. As a result the teachings inherited from medieval Catholicism about the visible and the invisible church were called into question. To many Reformers, most notably Luther, the church was always visible because it was made up of people. But its limits and borders were invisible since one could not examine the heart of others to determine exactly who were the true believers and who were the faithless. This inability to define the boundaries of the church led other Reformers, among them Calvin, to continue to employ the distinction between a visible church and an invisible one, the latter referring to the people who were saved, even if they were in churches where full doctrinal purity had not been achieved. People see the visible, humanly organized church of Christ, but they cannot simply identify this with the Bible's one, holy, catholic, and apostolic church, which is properly discerned only by God and hence invisible to humans. The visible church, in the Reformers' view, almost certainly contained a mixture of members of the invisible church, on the one hand, and hypocrites, or false believers, on the other.

Authority of the Word. Justification by grace through faith and the priesthood of all believers were affirmations that challenged the inherited Roman Catholic views of authority because they seriously undercut the monopoly of the hierarchy in the system of grace. Downgrading the medieval system of authority left a vacuum that Protestantism hastened to fill. Full of variety and pluralism as the movement was from the first, it was rarely characterized by a love of anarchy or indiscipline, and the Reformers set to work at once to establish the locale and extent of authority in the church and the believer's life. Almost unanimously they saw final authority to reside in the Word of God, which tended in the minds of many to be simply equated with the Bible. The need of the Protestant movement to redefine authority enhanced its view of Scripture just as, one might argue, the rediscovery of scriptural teaching was seen to be the primary impetus behind the Protestant movement.

Later generations of Protestant thinkers sometimes resorted to scholastic philosophical definitions similar to those of the medieval Catholic theologians; in such definitions justification became the material (or substantive) principle of the Reformation, while the matter of scriptural authority became the equally important formal (or structural) principle. In some epochs debate about the nature of the Word of God or the Bible was even more preoccupying than was discussion of justification. Protestants often have portrayed medieval Catholicism as being a nonbiblical or even an antibiblical faith, one that denied the Bible to the

laity. The expense of reproducing manuscripts led many libraries to chain books to the wall, and the Bible chained to the wall entered Protestant mythology as a symbol of the denial of lay access to the Bible in Roman Catholicism. In many circles Protestantism has been celebrated as a religion of the "open Bible" in opposition to the closed book of Catholicism.

Mythology aside, Protestants without exception concentrated on biblical teaching, and this led to a new passion for translating the Bible into the vernacular and disseminating it as widely as possible, an activity aided by the almost simultaneous invention of movable type and the resultant progress in printing technology. It was to be put into the hands of as many ministers and laymen as possible. Thus, they also had to be taught to read, and the Protestant movement claims some credit for hastening the modern impetus toward the ideal of universal literacy. While the Bible was ordinarily read in the churches and interpretation was shaped by the old and new traditions of these churches (Anglicans read the Bible's teachings on apostolic succession in a way different from that of Anabaptists, for example), what came to be called "the right of private judgment" was often exalted.

While Protestants could agree that the Word of God was authoritative in matters of faith and that the Bible as the book inspired by the Holy Spirit had unique status, they did not agree on all interpretations of the Scripture, nor did they unite in a single doctrine of scriptural authority. The Anabaptists, and later the Quakers, stressed an immediate experience of God and thus tended to qualify the importance of the Bible in shaping Christian life. But even among the Lutherans, Calvinists, and Anglicans there were differences of opinion about the Bible.

Latter-day Protestant Fundamentalists have argued that scriptural authority, if it is to be believable and if it is indeed the Word of an all-knowing, perfect God, dare not be described as including errors, even errors in historical or geographic detail. They have backed up this contention with citations from John Calvin and Martin Luther. At the same time, subsequent Protestant contenders for a more open and critical attitude toward biblical literature are equally capable of citing the Reformers—Luther, for example. Luther often spoke of the Bible as "the cradle in which Christ lies" and as a book that derives its authority from Christ and not from an a priori (presumed) doctrine of inerrant inspiration. Their argument concludes that Luther could quite freely relegate some books of the Bible to secondary status or criticize the argument of others, even as he could complain of Paul's grammar or illogical argumentation, and point to errors of detail. Part of the confusion on this matter results from the fact that the Reformers in their era did not see questions regarding truth in the same terms as they have been recognized in the later scientific world, and, also, they could accept the full and governing authority of the Bible without elaborating theories concerning its perfection in detail.

The unquestionable elevation of the Bible as the authority in matters of faith led to a corollary downgrading of other authorities in the church. The hierarchy, and especially the pope, were hardest hit, and papal authority was denied in almost every sector of Protestantism. In place of papal authority more regard came to be paid, at least by conservative reformers, to the Fathers (doctrinal teachers and interpreters) of the early church, who were sometimes cited in the confessional writings of the various Protestant bodies. The Fathers were revered as guides rather than as final authorities. Similarly, a critical attitude toward councils of the church came to prevail. On the one hand, it was widely asserted that councils can quite often and do err, and historical studies pointed to contradictions between various conciliar statements and to unsubstantiated assertions by past councils. On the other hand, many formulas and creedal statements of the ecumenical councils, particularly as these referred to the Trinity or to the Person and work of Jesus Christ, were highly regarded, and many Protestant churches took the chief creedal statements of past councils into their own official body of teaching.

Canon law, the inherited body of legal materials that regulated faith and morals, quite naturally also suffered

because of the high regard for the Bible. In most Protestant circles it was difficult to make legislation binding upon conscience unless it was based on clearly affirmed biblical legal teaching; more important, accent on the Gospel of grace led most Protestants to want to undervalue the whole role of law in the life of the church. At the same time, new church order soon developed, and it must be said that Protestants often acted as legalistically as did the Roman Catholics, whom they were repudiating. Most Protestant bodies, notably the Anglicans, developed their own versions of canon law or rules of church order and discipline.

The ongoing reformation of the church. The church that is to be judged not by the pope but by a normative Bible, that is grounded in a priesthood of all believers and critically affirmative of Church Fathers and councils, and that rejects inherited codes of canon law differed vastly from medieval Catholicism. In few respects did it differ more than in its establishment of the principle of an ongoing reformation. While most of the Reformers, once established, tended to resist extensions of reformation that would jeopardize their status and definition, almost all Protestants, at least nominally, assented to the idea that *ecclesia reformata semper reformanda*—i.e., that the church was always reformed and always in need of further reformation. The Protestant movement, then, was conceived as an unfinished product, constantly to be judged by a reading of the Bible, its polity continually subject to debate, its policy open to ongoing appraisal and change. It was in that climate that the sacramental teaching of Protestant churches was argued and developed.

Emphasis on the sacraments. On few points did Protestants disagree more than in their interpretation of the sacraments, but they did unite in their rejection of some aspects of Roman Catholic teaching. Since attack on the sacramental-hierarchical system of salvation was at the heart of their reform, almost nothing of it survived intact. In place of the churchly system the new accent fell on limiting sacramental teaching to those acts clearly commanded by Christ and connected with his promise in the Scriptures. One can argue that, since "sacrament" was not a biblical term, the debate had to do simply with definitions. Most Protestants defined sacraments, then, as acts that impart grace and the new life. They must combine the Word of God and some visible means (like bread, wine, and water); they must have been established by God and instituted by Christ. On these terms, five of the seven chief Roman Catholic sacraments failed to meet the definitional tests: marriage, ordination, confirmation, penance (now called repentance), and extreme unction (now called anointing of the sick). Not in every case did Protestants abolish these acts from their rites, but they ruled them out as sacraments. Thus the Protestant teaching on marriage was normally as "high" as Catholic doctrine and may be considered quasi-sacramental. But it was seen chiefly as a civil act blessed by the church, and it did not convey grace to the participants, nor was there a visible "means."

Though Protestants—with a few exceptions, chiefly Anabaptist and Quaker—had little difficulty limiting the number of sacraments and perpetuating a high regard for those that survived the change in definition, they were far apart in their understandings of what went on in sacramental acts. Basically three views were debated. To the "right," as one might call it, was the Lutheran view, which critics considered as being quite close to Roman Catholicism. Luther seemed to bring with him something of a medieval worldview, in which symbols of the material world were transparent to another invisible, divine order. This attitude made it possible for him to make much of the material objects in the sacraments. When he connected them with biblical words, he was able to say of bread and wine that these are the body and blood of Christ, and of baptism, that it effected a change in the believers' status before God.

At the "left" was the view of Huldrych Zwingli and other Swiss Reformers, who accented the spiritual side and downgraded the material. In some respects they shared more of what has come to be considered a modern view of matter and spirit, in which the symbols were opaque,

disengaged from an invisible "other order." Such teaching meant that what mattered most in the sacraments was the following of Christ's commands, the reminiscence of his participation in the world of his disciples, and the spiritual intentions brought to the acts of believers. For Zwingli the bread and the wine were symbols that merely represented the body and blood of Christ, and baptism was more a sign of a Covenant with God than a supernatural imparting of grace. Between the Lutheran and Zwinglian views were Calvinist and Anglican attitudes and definitions. All Reformers agreed, however, in their criticism of the Roman Catholic teaching called "transubstantiation," which held that the actual "substance" of the bread and wine in the Lord's Supper was turned into the body and blood of Christ. But they did not agree over the alternatives to that teaching, and debate over the sacrament did as much as any other theological factor to contribute to internal Protestant division.

Relationship between the community of the baptized and the political community. Equally varied were the attitudes toward civil authority among the various Protestant parties. Martin Luther expressed what in theory could have been a most radical theological view of the separation of civil and religious realms through his doctrine of "the two kingdoms." He could reduce his teaching virtually to an aphorism: God's Gospel ruled in the churchly realm and his Law ruled in the civil society. To rule the church by the Law or the civil realm by the Gospel would be to bring legalism to the sphere of grace and sentimentalism into the orbit of justice and thus dethrone God and enthrone Satan. In practice, however, the Lutheran Reformation worked to keep its ties to the civil order and was the established religion wherever it predominated in Germany and Scandinavia. In many territories princes actually took on the superintending roles that bishops had known in Roman Catholicism.

John Calvin made less of a theoretical effort to separate civil and religious realms. Under his plan Geneva was to be a theocracy in which the saints would rule. God's covenanted community was to be based on his Law, as revealed in the Scripture. Consequently, no detail of civil or community life was too remote, too secular, or too petty to escape inclusion by the Calvinists in the ecclesiastical sphere of supervision or regulation. Zwingli taught a variation of this version, one that asked the Christian to be a zealot or patriot in the civil society—a teaching that he confirmed with his blood, for he was killed in battle in 1531. In the Anglican approach there was also no attempt to separate the civil and religious realms; in England the church was given the mandate to press conscientious matters upon the sovereign and other civil authorities. These established Protestant views were to be subverted or countered by radical Reformers who did want a separation from civil spheres. These views were also constantly revised with the rise of the modern secular state.

Modes of expression of the ideas of the magisterial Reformers and their successors. Protestantism was forced to find means to propagate and sustain itself through time. Reformers had removed many of the inherited props or means and developed, within a century, parallel structures of most of those that had been repudiated along with Roman Catholicism. Lacking papal authority, canon law, and "international" connection with civil authority (as there had been in the old Holy Roman Empire), along with the binding power of church councils or a single philosophy on the basis of which to argue their case, they came up with alternatives or surrogates for most of these, though the new systems were more varied than the at least nominally homogeneous Catholic skein.

Most notable among the structural necessities was the formulation of "confessions," or creedal statements—and Protestants met frequently and regularly to write them—by which they could define their positions for the benefit of their adherents and their opponents. The Lutheran Augsburg Confession (1530), Reformed documents such as the Second Helvetic Confession (1566) and the Westminster Confession (1646), Anglican affirmations such as the Thirty-nine Articles (1563), and Anabaptist confessions such as that of Dordrecht (1632), all gave evidence

Separation
of church
and state

The
sacraments
com-
manded by
Christ

Protestant
confes-
sions

of the Protestant impulse to define their positions. The Protestant leaders recognized that their movement could not long exist or continue with the fervour and ferment of first-generational impulses.

Liturgies
and hymns

Confessions of the church appealed to the minds of theologians, the administrative passions of leaders, and the legalistic spirit of those who would impose them as doctrinal standards, but they did not warm believers' hearts. Thus, Protestant leaders had to concern themselves with the affective side of church life in order to hold the attention of masses of people and to give them opportunity to express their faith and life in God. The chief instruments to achieve these aims were liturgies and hymns. The inherited liturgies included much of the Roman Catholic sacramental teaching. As such they were given over too much to an accent on the sacrificial character of the mass and thus had to be purged. Conservative Reformers retained the shell, or outline, at least, of these formulas for worship, though they took great pains to bring both these outlines and the nuances of expression into line with what they considered to be a more evangelical teaching. Since worship is perhaps the chief public expression of gathered Christians, all Reformers had to give attention to its detail.

Luther initiated the process with his *Formula Missae* ("Formula of the Mass") of 1523, a service that retained the Latin language; but he soon devised (in 1526) a *Deutsche Messe* ("German Mass"), a vernacular and folk expression of greater informality. At about the same time Zwingli was producing a Reformed order with two liturgies for the Word and the Lord's Supper in 1525, soon to be followed by Martin Bucer's work on Psalms and church practice in 1539 and Calvin's *Form of Church Prayers* in 1542 and 1545. The Anglicans were preserving stately forms of worship used in subsequent centuries, chiefly in *The Book of Common Prayer* of 1549 and 1552, and in Scotland John Knox helped formulate Presbyterian worship in *The Forms of Prayers* in 1556.

While Protestant orders were somewhat less ceremonial than the Roman Catholic liturgies they replaced, the human impulse to routinize ceremonies prevailed, and almost everywhere these forms for worship took on a more or less formal character. They differed from Catholicism chiefly in their elevation of the act of preaching the Word of God. Preaching was viewed as the means of grace whereby men were encouraged to repent and accept the grace of God through faith in Christ, just as the sermon was used to shape the community and give guidance. For some this accent on preaching meant a downgrading of the Lord's Supper; for others there was to be a parity, with the sacrament providing a necessary parallel means of conveying grace. Communion "in both kinds," with reception of both bread and wine, prevailed (whereas in the Catholicism of the era of the Reformers the cup was withheld from the laity), and, except in Anabaptist circles, the Catholic practice of infant baptism by means other than total immersion was retained. The Protestants, for the most part, took over existing Roman Catholic church buildings for worship, or they met in academic or civil halls or homes; but as time passed, they also took responsibility for erecting church buildings.

Hymnody played a major role in giving voice to Reformation sentiment, never more successfully than in Martin Luther's "A Mighty Fortress Is Our God," which came to be called "the battle hymn of the Reformation." The Genevan Reformation and the Presbyterian churches tended to prefer simple and sometimes stolid hymnody in the form of rephrased and parsed psalms, such as The Genevan Psalter of 1562. The rejection of hymns and attention to sung versions of Scripture also prevailed in early Anglicanism, not so much because of principle but because of the failure of Anglican Reformers to devote themselves to the propagation of their movement through song. The great tradition of Protestant hymn writing developed later, in the 18th and early 19th centuries.

Systematic
theologies
and
dogmatics

Liturgies and hymns appealed to the heart and soul, but Protestant theologians also addressed the mind through an impressive outpouring of works in systematic theology and dogmatics. Calvin was the supreme systematizer of first and second generation Protestantism, and his *In-*

stitutes of the Christian Religion (1536) is a classic on even the shortest shelves of Christian doctrinal literature. Luther was, of course, a first-rate theologian, but he made considerably less effort to be systematic, and his scores of volumes of theology usually grew out of comments on issues that agitated him or inspired or disturbed his movement at any moment. His disciple and colleague Philipp Melancthon, in the *Loci Communes* of 1521, was much more concerned with systematic discipline.

In the 17th century the Protestant movement tended toward more rigid doctrinal expressions, as individuals interpreted the confessional statements of the earlier century with an almost fanatic attention to detail. Huge works of Lutheran and Reformed dogmatics poured forth from presses, most of them based on a kind of Protestant reversion to the type of scholastic philosophy that had prevailed in the late medieval period. Leaders in the period of Lutheran orthodoxy were Martin Chemnitz (1522–86) and Johann Gerhard (1582–1637); Reformed Orthodoxy was marked by the scholarship of Theodore Beza (1519–1605) or, in England, men like William Perkins (1558–1602). The ponderous and often lifeless writings of lesser orthodoxists than these were often expressions of internecine Protestant warfare. Debates raged over the sacraments, over the two natures of Christ, over the relations of ecclesiastical and civil realms, and over the part man played in salvation. Almost never did these debates lead to concord, and despite occasional irenic figures, such as Georg Calixtus (1586–1656) or Hugo Grotius, Protestantism was fated to remain divided, at least until the ecumenical movement in the 20th century began to produce new amity and common purpose or assent.

COMMON PRINCIPLES AND PRACTICES OF THE RADICAL REFORMERS AND THEIR SUCCESSORS

The interpretation of Protestantism up to this point has been, with only a few noted exceptions, based on the majority view among the 16th-century Protestant movements. No single term adequately covers the Lutheran-Calvinist-Anglican complex, though "magisterial," "establishment," "mainline," "conservative," and "classical" have frequently been applied to these movements. Of considerable parallel significance was the Protestant activity of another, and even more complicated, cluster of movements, for which also no single term can be agreed upon. Some historians speak of "the radical" Reformation or "the left wing of the Reformation"; others have concentrated on components, such as the Anabaptist-sectarian or the spiritual-mystic or the rationalist-unitarian versions. In almost every case, these were the expressions of the economically and socially deprived classes in the 16th-century societies, though their latter-day heirs have sometimes known or sought the favour of civil authority and social arbiters.

The "radical" Reformation was radical in that it deliberately chose to repudiate as much as possible of traditional Roman Catholicism in various acts of "restitution" of what it held to be the obscured and eclipsed but true original apostolic church. The "conservative" or "magisterial" Reformation, on the other hand, tended to keep whatever it could of the medieval ecclesiastical tradition and to affirm continuities in the life of the church wherever possible.

The varieties of radical expressions are rich and bewildering. They grew in virtually every Protestant land, sometimes as an extension of the logic of the conservative Reformation but more often as original movements bearing a logic of restitution all their own. The radical Reformation also occurred in Catholic territories, such as Italy, where the mainline Protestant movement never knew much success. In Lutheran circles men like Karlstadt and Thomas Müntzer set out, in Luther's prime years, to shatter much of what he wanted to retain and to carry reform in new directions. Debates over the Lord's Supper and baptism led to new radical movements in Switzerland, southern Germany, and Bohemia-Moravia. In Strassburg a significant group of radicals, including Kaspar Schwenckfeld, Melchior Hofmann, and Sebastian Franck, gathered around 1529. The north of Germany and the Netherlands were havens of early Anabaptism (re-baptism), and in the southern Netherlands Menno Si-

reform
movements

mons spread the movement that has come to be called Mennonitism. In Poland and eastern Europe the radical Reformation often took spiritualist and unitarian (anti-Trinitarian) turns, as it did in Italy. "Radical reform" was also behind some of the Puritan and separatist movements in England. Because they were by nature competitive, free-formed, and varied, it is difficult to generalize about the radical Reformation movements, but some assertions common to major segments are possible, and the study of these movements is important because of the role they were to play in shaping modern Protestantism, especially as it developed in North America.

The gathered church. The radical Reformers were united in their opposition to established Protestantism's view of ecclesiastical continuity with the church of Christ in every age. The mainstream Reformers were radical in their rejection of what they regarded to be false teaching in the medieval church and almost never had kind words to say about any of its forms. But they did believe that God had kept a body of faithful teachers and respondents through the millennium or so after what they considered to be the "fall" of the church during the closing years of the Roman Empire, and this view of the succession of believers was integral to their doctrine of the church. Just as emphatic was rejection of this view in radical circles. Some radicals were willing and eager to trace a kind of continuity from John the Baptist down to the 16th century, but it was significant that they found virtually every evidence of true faith only in the sectarian movements that had separated themselves from official Roman Catholicism or that were condemned, harassed, and persecuted by Catholics. Among these were the Waldensians (a medieval religious movement espousing voluntary poverty and lay preaching); the Albigensians, also called Cathars (medieval sect espousing dualism and asceticism); some forms of Spiritual Franciscanism (branch of the Franciscan order espousing poverty); and other reform movements of the Middle Ages. Just as often, however, radicals taught that the true church had died not long after Christ and had to be restored as if from the foundation itself.

The repudiation of continuity was paralleled by rejection of a tie between the civil and ecclesiastical realms. The bond between these two, in the era of the Roman emperor Constantine (d. 337), was viewed by the radical Reformers as the root of the church's fall and later vicissitudes or death. From that experience, it was argued, the church ought to have learned not to let the spiritual infection of political authority prevail nor to permit any one to be regarded as a member of the church without an explicit personal affirmation of faith. In a widely used phrase, the church was to be "the believer's church," made up of assenting and consenting people of decision who chose to respond to God's Covenant. This view appeared in contrast to the view held by those who argued that baptism of infants, who of course could not make personal decisions, conferred church membership and that, thus, virtually entire populations of territories could be members.

The keystone of the concept of the believer's church is that people voluntarily choose to be members. No one can be coerced into it nor can one become a member automatically, as it were, through a sacramental act. It was on this ground that infant baptism was condemned by almost all radical Reformers. A result of this accent on voluntarism has been a strong stress on the will of the believer and the giving of a voice to all believers in the questions of the governance and destiny of the church.

The theological counterpart to the teachings that disengaged radical Protestantism from Catholic continuity or established life was the view that no human authority determined modes of church life. The church is Christ's, and not man's. As such it seeks to transcend territorial, racial, and ethnic bounds in theory, even if it is rarely consistent or successful in practice. As Christ's church it is capable of representing him fully in each place, and thus local governance or authority, and even autonomy, was universally stressed.

The radical Reformation almost always restored the sense of an apostolate (missionary outreach), whereas the conservative Reformers had often neglected the importance

of a sense of witness and missionary activity, and some of them had even ruled it out from the church's present-day mandate. Anabaptists and spiritualists and "free" church (non-state) advocates tended to be missionary, even if this meant a kind of subversion of established Protestant churches, filled as these were—in radicals' eyes—with unbelievers or inadequate believers.

Relationships between church and state. Churches as disengaged as these were from established structures were in principle devoted to, and in practice successful in adhering to, ideas that called for sharp distinctions between Christian and non-Christian, sacred and secular, religious and worldly life. This is not to say that radicals took no interest in the civil or social realm; they often did, indeed. But they brought a special viewpoint. They were "eschatological"; that is, they almost always were moved by dramatic views of the future, in which Christ would come again or the Kingdom or Day of the Lord would be announced to change everything. Worldly conditions were temporary and were judged by the saints as ephemeral and corrupting, even if they found it necessary to live with or to employ earthly instruments in the meantime. At the same time, for the sake of the freedom and purity of the believer's church, its members advocated separation from the civil realm, permitting no intrusion by civil authorities in church affairs and seeking no direct involvement in administration of the state by ecclesiastical figures.

Because such a large number of radicals believed that Christ's new order was imminent, they generally took a negative view of most human means of facing problems. Many of them advocated a rejection of warfare and saw in the Gospels a support of pacifist positions. The modern "peace church" witness of Mennonites, Brethren, and Quakers was born of this impulse. Paradoxically, there were other radicals (such as Müntzer) who on occasion saw violence and warfare as legitimate means for them to help hasten Christ's new order.

Church discipline. Separation between the church and the world and membership based on clear commitment made it possible for radicals to insist on higher standards of church membership and stricter means of church discipline than could their magisterial counterparts. Social control was more feasible in these smaller and well-defined groups than in the established churches, and "the ban," as a form of excommunication, was the instrument which supported discipline. The use of the ban meant expulsion from the congregation of believers and, with it, social exclusion. The ban was not conceived as merely a punitive measure; brotherly admonition and discipline were to continue, with the hope that the wayward could be rescued.

Believers' baptism. A special word must be said concerning baptism since it gave its name Anabaptism to part of the movement and was one of the radicals' most dramatic points differentiating them from the rest of Protestantism. Infant baptism, from the radicals' viewpoint, cheapened the standard of church membership and was not clearly designated or foreseen in the New Testament documents that chartered the church. Michael Sattler (c. 1500–27), Menno Simons, and Balthasar Hubmaier (1485–1528) led the opposition to infant baptism. Radicals would follow Jesus, who underwent baptism as an adult, and they also would be "buried" (in water) with him, as St. Paul said baptized people would be. "New birth" would come from this act, and the reborn believers would restore the church.

Doctrine of the ministry. The concept of ministry was also changed more drastically in radical groups than in the more established Protestant circles. When priests became Lutherans, Calvinists, or Anglicans, there could be a rather subtle transition in their calling. The Anabaptists and spiritual Reformers, however, wanted a clean break with the past. The minister was viewed chiefly as a prophet, not as priest. As an agent of a new order, anticipating Christ's fulfilled Kingdom, he was not to care about earthly prerogatives or routines. Some men, such as Menno Simons, believed that the only way to take on the new ministerial vocation was to repudiate their Roman Catholic ordination. But such conversions from Catholic to radical clergy were rare, and the radical wing of the

church"

Reformation more frequently expressed its views on the ministry by simply placing a low valuation on ordination. The classical Reformers wanted university-trained, theologically expert ministers. The radicals, on the other hand, permitted laymen to be ministers: leaders such as Kaspar Schwenckfeld and Konrad Grebel (c. 1498–1526) were probably never ordained.

The suffering of persecution. The radical Reformation and the believer's church were made up of people who were prepared to suffer for their faith at the hands of both civil authorities and Catholic and other Protestant ecclesiastical leaders. The story of the rise of Anabaptism is one of persecution, of exiles and fugitives, and of a pilgrim church. The story of the rationalist form of Reformation, as in the case of Michael Servetus (anti-Trinitarian; c. 1511–53), often ended in something that can be called a Protestant Inquisition, in which men died for their ideas. Though some erratic personalities may have revealed a desire for martyrdom, more characteristic were those who upheld the idea of patterning one's life after Jesus, the great example. He had not known status or security and was eventually condemned to death; how could his true followers evade a similar path?

Doctrinal variations. Doctrinal varieties among the radicals were many, and it is hardly fair to cluster the various emphases. Certain features stand out, however. First of all, the role of Christ, central to Protestant Christianity, shifted subtly but significantly. The emphasis on Christ's priestly work, in which he brought sacrifice for men before the altar of God, was displaced by a new regard for his prophetic role. He had thundered against the powers of religion and civil society, against established forces, and against the rich; so would his followers. He was seen less as an agent in a divine-human transaction culminating in death on the cross as a sacrifice, and more as the supreme exemplar and leader.

The radicals spoke critically of scholastic philosophy and the intellectualized theology built upon it, and therefore they displayed a distaste for the more arcane expressions of classical theology. Faustus Socinus (1539–1604) in Poland and Michael Servetus in Strassburg became shapers of modern Unitarianism. They believed that the doctrine of the Trinity was an unscriptural abstraction and that simple monotheism could best be protected if Christ were not defined as a full expression of the Godhead. Unitarianism remained a distinctly minority emphasis in the radical Reformation. The Bible was usually highly regarded, but whereas the magisterial Reformers tended to see it in the context of tradition, the radicals stressed contemporary personal experience and often allowed for or claimed new special revelation.

Protestantism's influence in the modern world

INFLUENCE ON NATIONALISM

Protestantism eventually became the majority faith throughout northwestern Europe and in England and English-speaking America. From there, in the great 19th-century Protestant missionary movement, it was carried into all parts of the world, joining Roman Catholicism as a minority presence in Asia and Africa and at the same time also establishing beachheads in largely Catholic Latin America. It is impossible to separate Protestantism from the general history of the North Atlantic nations, where it was firmly established for centuries and where its "free" churches or, after "separation of church and state," its voluntary churches, still predominated.

Thus it is possible to speak of Protestantism's contribution to modern nationalism. It shared in shaping this force initially by helping bring to an end the Holy Roman Empire, which was disintegrating already at the time of the Reformation but which finally collapsed in 1806. The old *corpus Christianum* (Christian body; i.e., Christian society) did not survive; the presence of Protestantism spelled the doom of an international, transterritorial, unified Christianity under one head. Protestantism's desire to cultivate literacy and to spread regard for the vernacular served to remove the Latin linguistic bond of older Christendom and to encourage the rise of national boundaries

based on languages. All but the radicals tended to make much of loyalty to the existing state, and Protestants often provided an ideological base for each new state as it rose to self-consciousness—as was the case in Prussia or in the United States.

INFLUENCE ON THE ARTS

Protestant attitudes toward the arts have been ambivalent and therefore have produced mixed results. For the most part, Reformed and spiritualist Protestants have been uneasy about the arts, fearing lest the symbol be confused with the reality—and lest, therefore, the symbol be idolized and the reality forgotten. Thus Calvin and Zwingli found little place for the visual arts, though Luther showed interest and was a friend of some artists of his time, including Lucas Cranach. Luther also revealed a more affirmative attitude toward music than did the Swiss Reformers, though through the centuries most of Protestantism encouraged the use of music. When Protestant historians want to point to past glories in the aesthetic realm, they cite men like John Milton in literature, Rembrandt in painting, and Johann Sebastian Bach in music, though such a group has few heirs in more recent centuries.

ECUMENICAL CONCERNS

While it is clear that Protestantism by nature had to allow for great variety, not all Protestants have rested content with division and separation. They were caught between two biblical mandates. One commanded them to seek the truth and not to express full fellowship with those they considered to be in error. The other stressed the values of Christian unity as a witness in the mission of the church and as a foretaste of the eschatological, or fulfilled, life of Christians when, all agreed, they will all be one. The ferment of the 16th century and the doctrinal formulations of the 17th century led to ever-increasing divisions and hardening of lines or positions. The 18th-century Enlightenment, which in its British and German forms lived off and fought against Protestantism just as the French forms similarly related to Roman Catholicism, tended to breed a spirit of consensus. The Enlightenment placed an exceedingly high value on toleration of differences even as its spokesmen worked for agreement on doctrines based on a search for what they viewed as natural in reason and law. Such a tendency inevitably served to minimize doctrinal differences among Protestants.

The 20th century, however, has seen more effort toward producing consensus than did the previous three and a half centuries. The modern ecumenical movement, today thoroughly Protestant-Catholic-Orthodox in its outlook, was first born and institutionalized on Protestant soil by men who saw the mission of the church frustrated by competition and division. Beleaguered, huddled together like sheep in a storm, to use a familiar picture, they sought each other's company.

At the same time modern transportation and communication techniques effectively reduced their world and made uniting symbols accessible. A theological recovery was fused with a new vision of common tasks to produce a Protestantism eager for common statement and often for common action in an ecumenical era. The ecumenical movement has led to denominational mergers and to conciliar organizations, on both confessional and transconfessional lines.

In the meantime, the openness of Roman Catholicism, particularly exemplified in the career of Pope John XXIII (1881–1963), led to new amity and concord between Protestants and Roman Catholics. In the last third of the 20th century both of the old warring parties, without formally repudiating their polemical positions of the 16th century, have tended to move beyond their terms and to find new bases for meeting. Modern Catholic biblical commentators speak in what sounds much like Protestant terms of grace and faith. Protestants have new appreciation for a Roman Catholic view of the interconnectedness of the components of the church. More and more, Protestants view the Scriptures as rooted in a tradition and tradition as rooted in the Scriptures. Thus they have a new sympathy for Catholic views of tradition—even as some Catholics

criticize unreflective responses to ecclesiastical authority on coercive lines in their own communion. Protestants and Eastern Orthodox Christians, generally spatially quite separated, have begun to understand each other through agencies and organizations such as the World Council of Churches.

CONCLUSION

"The end
of the
Protestant
era"

In the latter half of the 20th century many heirs of Protestantism, among them the philosophical theologian Paul Tillich, began to speak of "the end of the Protestant era," or of the times as being "post-Protestant." This does not mean that they all wavered in their faith in Protestantism's general witness. Tillich, for one, argued that "the Protestant principle" of prophetic criticism had to be included in any authentic expression of church life and that it was a genuine value in the secular world. But these thinkers believed that the cultural dominance of Protestantism on its own historic soil was waning.

From the Renaissance onward and increasingly during the Enlightenment the adherents of Protestantism saw their thought-world repeatedly challenged on many fronts. During the 19th century, with the rise of industrialism and urbanization, a changing world presented new problems to societies and cultures shaped by traditional Protestantism. Meanwhile, ideologues, some of whom were avowed "god-killers," rose up on Protestantism's territory to challenge its deepest beliefs: the economic theorist Karl Marx, the evolutionary theorist Charles Darwin, and the philosophical nihilist Friedrich Nietzsche, to take only three examples, were thoroughly at home with the Protestant experience and were able to use it as a foil to develop many of their own views.

In the 20th century Protestantism has become uncertain about its "foreign mission" of expansion in a postcolonialist, anti-imperialist world. The modern appreciation for values in non-Christian religions has led many Protestants to adopt positive attitudes toward these at the expense of the desire to extirpate or displace them with an expanding Protestantism. Totalitarian forces, particularly in Nazi Germany, absorbed some Protestant emphases and

changed them beyond recognition, or they persecuted those Protestants who radically opposed suppression.

The attractions of modern life, secularization, and a crisis of faith all have contributed to a general Protestant decline, beginning with a measurable decrease in church membership, first on the Continent in the 19th century and then in England around the turn of the century. Therefore, while huge majorities of the population (as in Scandinavia and England) are baptized members of established Protestant churches, only a small percentage of these are attendants at worship services or responsive to the disciplines and mandates of the church. Those who use church attendance and support of ecclesiastical appeals as indicators of Protestant fortunes unite with those who see that Protestant dogma no longer defines belief, and its divisions no longer excite Western man—and then note the end of the Protestant era.

On the other hand, Protestantism is deeply integrated into so many elements of Western culture that it can be expected to continue to assert subtle influence. It has experienced ebb and flow or revival and decline periodically and now may be going through an extended period of decline. Yet even to speak in these terms may betray a Western provincialism that does not do justice to major trends. Countering all phenomena that elicit words about decline are at least two forces. One is the strength of conservative and evangelistic forms of Protestantism: Pentecostalism, Evangelicalism, and Fundamentalism. While historical antecedents of these movements were often world-denying, sectarian, and withdrawn, late 20th-century versions include men and women eager to shape their surrounding culture. They give evidence that they may be doing so, or may begin to do so, in forms that not many would have foreseen a few decades ago.

The other compensatory force is the growth of Protestantism in sub-Saharan Africa, Latin America, and many parts of Asia. Some of these new Protestant churches have begun to take indigenous forms that have little to do with the forms initially introduced by missionary forces and to witness far beyond Protestantism's conventional Western bases. (M.E.M.)

THE MAJOR PROTESTANT DENOMINATIONS

Lutheran churches

Lutheran churches are those religious bodies that trace their distinctive interpretation of the Christian Gospel to Martin Luther and the 16th-century movements that issued from his reform. They take their place alongside Anglican and Calvinist communions to make up one of the three major branches of Protestantism.

The Lutheran churches, originally in Germany but quickly spreading to Scandinavia, did not wish to be called after their founder. He had seen his work as an evangelical (*i.e.*, Gospel-centred) reform within the Western Catholic church. The name Lutheran came from opponents of Luther and his reforms, but the epithet eventually came to be turned into a badge of honour among partisans of the reformer's interpretation.

The
Church
of the
Augsburg
Confession

Still, many of the leaders attempted to adopt other terms such as "Evangelical," which has subsequently become part of the official name of the church in various nations and territories. Others preferred, and prefer, to be called The Church of the Augsburg Confession, a title that recalls the Lutheran document presented by evangelicals to the emperor at the Diet of Augsburg in 1530. In the 20th century many have chosen to speak of their church as an "evangelical Catholic" movement, yet "Lutheran" they became and remain.

For several decades after 1530 this oldest and largest Protestant body hardly broke the European geographic bounds that were set for it. It was a negligible force in Presbyterian Scotland, Anglican England, the Reformed Lowlands and Switzerland, or in Catholic France, Spain, and Italy. There were early Lutheran movements in central Europe, as in Hungary, where the Reformed came to

dominate in 1543, and in Transylvania. But Lutheranism prospered most in the many territories that were eventually to make up modern Germany and then the northern lands: Finland, Sweden, Norway, Denmark, and Iceland.

From this significant but well-defined territory, Lutheranism moved with substantial numbers into North America after the 1740s and in the 19th century from European and North American bases into much of the rest of the world. Still, most of its theological, intellectual, cultural, and political expression as well as the major trends in its development are best measured from northern Europe and especially from the German territories that it shared with Reformed and Roman Catholic Christians.

Lutherans claim to see their movement centred in the understanding that, thanks to the saving activity of God in Jesus Christ, they are themselves "justified by grace through faith." Early Lutherans invoked this theme against both Catholic and Reformed Christianity, both of which, though on differing grounds, they professed to see stressing salvation in part through good works or moral earnestness. This would be an endeavour to help the believer make a claim upon God and thus, thought Lutherans, would deprive Christians of the security of faith and would arrogate to human beings activities that belonged only to God. In Lutheranism the bond between God and the redeemed was entirely at God's initiative and through God's grace. The believer trusts this God. With most other Protestants, Lutherans based their teachings not on churchly authority but on the divinely inspired Bible.

Justifi-
cation
by grace
through
faith

HISTORY

The post-Reformation in Germany. A generation after Luther the churches and territories that followed him

theologically took part in a diet that produced the Peace of Augsburg (1555). This action accepted the principle *cuius regio, eius religio*, which meant that whoever governed a region determined its religion. It was a far remove from the modern policy of separation of church and state, for which the reformers could have taken little credit. Instead there developed what is often called "territorialism" in confessional life. Where once there had been one empire and one church, there now were numerous nations or principalities, each with its own official church.

The confessional church on territorial grounds compromised the very nature of a confession, which was to have been a freely accepted creedal statement. When a ruler chose to take his people into Lutheranism, they had to follow or suffer penalty, no matter what their deepest convictions. Yet if they had to accept territorial conformity, they were free to change the character of its faith through time. Lutheranism passed through numerous phases and appeared to be quite different in each.

Conventionally Lutheranism has been seen as having passed through a series of rather clearly defined stages, with movements of thought and practice termed Orthodoxy, Pietism, the Enlightenment, and the like. This convention points to complex realities with sufficient accuracy and thus serves well for understanding the complex movement after more than four and a half centuries.

Orthodoxy. Orthodoxy came to dominate first. Whatever the ordinary people who rejected Catholic "work-righteousness" and were attentive to "grace" and "faith" were thinking, their pastoral and professorial leaders—and, for that matter, their princes, for politics was much involved in the new definition—grappled with orthodoxy in doctrine and practice. They did so perhaps out of a Germanic love for order and precision and more clearly because the first generation of Lutherans had left them with a rather unstable mix with which they had to deal.

One strand, most faithful to Luther himself, was more ready to live with the risky faith and the paradoxes that coloured his preaching and life, but it then converted the experience of such faith into rather rigid doctrine. In the second generation these "Gnesio-Lutherans" or "Genuine Lutherans," who gathered at centres like the university at Jena, followed impulses to bring order and precision to bear on the thought and the creeds they had inherited. In the eyes of many historians this party lost much of the drama and dynamic of Luther's witness. But it was also a belligerent faction, one that brought passion to its claims on orthodoxy.

Philippists Its opponents were called Philippists, after Philipp Melancthon, the chief scholar at Luther's side and the author of the Augsburg Confession itself. Melancthon was a humanist with a pacific outlook, who appeared to be a compromiser, as did his intellectual heirs, in the eyes of the Gnesio-Lutherans. They accused Philippists of "synergism," the contention that human beings could cooperate in the work of salvation. They also saw Reformed tinges in the Philippists' doctrine of the Lord's Supper.

By 1577 leaders of the Lutheran parties had agreed on a statement called the Formula of Concord and in 1580 sealed the Lutheran confessions in the *Book of Concord*, which has been respected ever since and holds varying degrees of authority in Lutheran churches. In the century following, Lutheran scholars, led typically by Johann Gerhard, wrote the multivolumed *Loci Theologici*, code names for books that stressed a proper doctrine or place for all Christian teachings. Scholastic in style, these books of dogma characteristically began with arguments proving the existence of God and the full authority of the verbally inerrant Bible.

Pietism. Orthodoxy bred reaction, and this Orthodoxy, soon perceived as rather sterile, did not satisfy pastors and people alike. From the 1670s into the 1760s Pietism flourished, originating again at universities, such as Halle, and spreading from thence to other schools and congregations. As the name implies, this movement stressed the piety of the individual or of the small groups of Lutherans who gathered as smaller "churches within the church" for prayer, Bible reading, moral scrutiny, and works of charity. Philipp Jakob Spener, a leader among the Pietists, wanted

to remain orthodox but nonetheless engaged in criticism of what Pietists saw to be the barren larger Lutheran church of which they remained a part.

Pietism downplayed doctrinal definition and led to movements that helped make up the 18th-century German Enlightenment. The tendency of Pietism was to minimize supernatural and miraculous elements in Christianity and to stress reason and morality. Although ordinary worshippers seem to have been sustained by the Scriptures, hymns, and liturgies that retained these elements, scholars of Lutheranism initiated radical theological traditions that have characterized German universities ever since.

19th-century developments. In the 19th century the Enlightenment lived on in more romantic forms that gave a greater place to emotions. Some of these were philosophically idealistic, some Germanically nationalistic. At least two schools should be singled out. One, in the tradition of G.W.F. Hegel, saw Christian development against a huge screen of "thesis" and "antithesis," and under the great historian F.C. Baur at Tübingen posed Hebraic versus Hellenic, Catholic versus Protestant motifs and movements. This school began to cast doubt on fact and event in history and soon began to speak in terms of biblical myth. Out of it issued radical movements that led to theological extremism, as found in D.F. Strauss's *Life of Jesus Critically Examined*, an essay on the impossibility of writing a life of Jesus.

The second school, in a Neo-Kantian spirit, stressed biblical fact and event and issued in a quest for the historical Jesus. Under Albrecht Ritschl a number of Lutheran and Reformed theologians developed a theology that stressed morality and the will. Out of their efforts came the well-known late 19th-century German liberal theology with its devotion to Jesus as teacher and doer of good.

Thus a kind of intellectual schism emerged among 19th-century German Lutherans; one school pioneered in the application of historical methods to biblical studies, developing what came to be known as higher criticism of the Bible, while the other, in a conservative reaction, established more pietistic training centres for the clergy.

Events on the political level also caused schism. Frederick William III's successful efforts to form a Prussian Union church with the Reformed in 1817, while at first meeting with approval, soon prompted a critical reaction. Dissension came partly over Frederick William's new church order, according to which the territorial regent was placed into the position of chief bishop of the church, not because he was the head of state but because he was the person of highest status in the congregation. This decision was in violation of the Lutheran tradition regarding the relationship of church and state, and "confessionalists," who that year celebrated the third centenary of the Lutheran Reformation, promoted "back to Luther" movements. Some Lutherans refused to become part of the Union and formed the "Old Lutheran" church; others chose emigration.

Much of Lutheranism, however, remained obedient to the civil order, perpetuating a tradition begun by Luther himself. After the break with Rome, Luther had remained closely tied to the growth of German nationalism and welcomed the protection of German princes. Many of these became, in effect, "prince-bishops," with considerable church power. The Lutheran churches came to be established by law and supported by taxes in Scandinavia and in many parts of Germany. Further, Luther had a fear of anarchy and a predisposition to grant considerable power to the state as an instrument of order. While he himself was "civilly disobedient" in the face of the emperor in the 1520s, neither his theological vision nor his personal inclination led him to endorse revolution or radical critique of the state. Lutheranism, therefore, was generally obedient to the civil order, and its clergymen were often cast in roles that made them seem to be lower-level civil servants.

Lutheranism in eastern Europe and Scandinavia. Lutheranism was carried rather quickly from Germany to Bohemia and Austria, Poland and Hungary (where it remained a minority party), and then to the Scandinavian nations. There much of the proselytizing impulse

Higher criticism of the Bible

Lutheranism and civil obedience

came through universities, especially when scholars from north European schools studied in Germany and carried Lutheran ideas back north. Already in the 1520s and 1530s Denmark made its move to Lutheranism under the influence of its successive kings. A former monk, Hans Tausen, who became a convinced Lutheran, was the major theological influence.

Norway was in many ways a dependency of Denmark, when around 1525 King Frederick I encouraged Lutheran preaching in Bergen. Norway followed Denmark into the orbit of Augsburg Confessionalism, as did Iceland, by importing Lutheranism from Denmark. Sweden's political restlessness similarly led that emerging nation to turn Lutheran under King Gustav I Vasa after 1523. Olaus Petri, a student at Wittenberg during the years of Luther's reform, brought conviction and passion to the task of spreading Lutheran ideas in Sweden. Although the King and Petri or his reformer colleagues often were in conflict, Petri's reformation ideas prospered. In Finland, Michael Agricola, still another former Wittenberg student, translated the New Testament and books of worship and helped Finland make a transition to Lutheranism before his death in 1557.

Scandinavian universities and churches generally followed developments parallel to those in Germany, albeit with a special accent on 19th-century Pietist revivals in Norway and Sweden that would make their impact through immigration to America. The major drama of Scandinavian Lutheranism occurred in 19th-century Denmark. There N.F.S. Grundtvig represented a romantic "folk-church movement," and Hans Martensen a kind of official church idealism. Søren Kierkegaard issued a devastating critique of both in the name of an existentialist encounter with Jesus, bypassing established and, he thought, dead Christendom.

Lutheranism in North America. American Lutheranism inherited both the Orthodox Confessionalism and the Pietism of the Continent. Enlightenment rationalism, however, was rarely advocated. The Lutherans began to go in large numbers to New York, the Carolinas, and especially Pennsylvania in the 1740s, where they were often gathered by the Lutheran patriarch Henry Melchior Muhlenberg. Many who went to America were poor, and some arrived as exiles or protesters against imposed conformity. Handicapped by their relatively late arrival and the fact that they spoke languages other than English and tended to live in rural enclaves, they had less impact on politics and culture than might be assumed, given the record of their counterparts in Europe.

Because Lutherans came from many nations, spoke many different languages, were propelled by a variety of motives, and were guided by leaders either unaware of or competitive with one another (as, for instance, "Pietists" versus "Confessionalists"), they tended to be isolated. As they became aware of one another, they became contentious. In the mid-19th century, for instance, a shaping influence was Samuel S. Schmucker, a Gettysburg (Pennsylvania) Seminary professor, who advocated Americanization and cooperation with the Reformed evangelical churches. Partly in reaction the more Lutheran Confessional-minded Charles Porterfield Krauth, also at Gettysburg, stressed Lutheran distinctives. More militant in his defense of 17th-century orthodoxy was the great shaper of the Missouri Synod, Carl F.W. Walther, who was president of both the synod and its principal seminary, Concordia, at St. Louis. Walther advocated a policy that forbade Lutherans from communing or praying together if their synods were not in complete doctrinal agreement with one another.

The majority of American Lutherans were of German descent and were often suspect in the Anglo-Saxon milieu. They did not, in the main, support Prohibition and other Protestant social causes. Some retained the German language and were, generally falsely, suspected of German loyalties during World War I. In response they set out to prove themselves superpatriots and after the war they became more Americanized than before.

Through two centuries American Lutherans gathered about 8,000,000 Christians into scores of church bodies. In the 20th century, especially after 1918, they had a

tendency to merge, and 5,500,000 of them united three bodies to become the Evangelical Lutheran Church in America (ELCA) in 1988. The largest non-ELCA group was the 2,500,000-member Lutheran Church-Missouri Synod, which saw trends toward liberalism and ecumenical expression in the larger body that it did not welcome. Canadian Lutheranism, about 300,000 strong, is divided chiefly into two bodies parallel to the ELCA and the Missouri Synod in the United States and is strongest in Ontario and the Western provinces.

In the United States the ELCA constituency is chiefly northern. One large wing thrives in and around the states where Lutheranism first arrived: Pennsylvania, New York, Virginia, the Carolinas. Another resulted from 19th-century immigrations from Scandinavia and Germany to the upper Midwest, with Minnesota having the largest number. The Missouri Synod has less strength in the East and is strongest also in the upper Midwest and around the Great Lakes. After World War II, partly through population mobility and partly through conscious efforts to found new congregations, Lutheranism came to be more of a national presence.

Lutherans in America developed an extensive network of seminaries, beginning at Gettysburg and Philadelphia, when it was seen that they could not depend upon clergy sent by agencies in Germany and Scandinavia. Most Lutheran groups founded colleges of their own, many of which remain strong church-related liberal arts institutions. The Missouri Synod and a smaller and still more isolated Wisconsin Synod established a flourishing network of parochial elementary and, in some cases, high schools. Originally these were shaped by a defensive mentality bent on sheltering the young from public school life. In more recent decades the schools have tended to attract non-Lutheran constituencies and to see themselves less as competition than as complements to public schools.

Lutheranism in the 20th century. In the 20th century, after the moral collapse of World War I, Lutherans along with the continental Reformed reacted against the humanistic liberalism that they felt failed to do justice to the radical difference between the divine and the human. There was a revival of biblical theology, often on existentialist grounds, as in the work of Rudolf Bultmann at Marburg, W.Ger. Historians like Karl Holl helped inaugurate a Luther renaissance. In Sweden Gustaf Aulen and Anders Nygren inspired theological revivals that stressed certain profound motifs in Christian and Lutheran thought.

To its shame much of Lutheranism was silent or even concurrent when Hitler came to power and provided some intellectuals and some pastors for Nazi Church ("German Christian") leadership. At the same time some of the neo-orthodox Lutherans joined with the Reformed in 1934 to establish a Confessing Church. In Martin Niemöller and Dietrich Bonhoeffer in Germany, Kaj Munk in Denmark, and Bishop Eivind Berggrav in Norway it brought forth anti-Nazi heroes and, in some cases, martyrs.

"Mission fields" around the world—established in the 19th century from the Continent and from North America chiefly in the first half of the 20th century—later became younger churches. After the middle of the 20th century many of these showed a vitality that was disappearing or had gone from churches in Europe. Although in Europe church attendance was ordinarily very low, in South West Africa/Namibia and elsewhere in Africa thousands gathered to worship and to use their churchly vision for meeting their political problems. Thus in South West Africa/Namibia, a territory under the domain of South Africa but seeking independence, Lutheran church people participated in the leadership of revolutionary organizations, thereby developing a pattern different from the characteristic Lutheran one of passivity in politics or conservatism in the face of change.

In its northern homelands Lutheranism was anything but an expanding force after the mid-20th century. Yet through the Lutheran World Federation and countless vital agencies and institutions Lutherans continued to find ways of expressing the faith they had heard Martin Luther proclaim. They also took responsible parts in the formal ecumenical movement of the century in their endeavor-

Divisions among Lutherans

our to stress both their "evangelical" and their "catholic" sides. (M.E.M.)

TEACHINGS

Lutheran Confessions. The official teaching of the Lutheran churches is that of the *Book of Concord* (1580), which contains the three ancient creeds (Apostles', Nicene, and Athanasian), the Augsburg Confession, the Apology of the Augsburg Confession, Luther's Schmalkaldic Articles, Luther's Small and Large Catechism, Melancthon's "Treatise on the Power and Primacy of the Pope," and the Formula of Concord. Of these Lutheran symbols only the Augsburg Confession and Luther's Small Catechism are accepted by all Lutheran churches. No general confessions of faith were adopted after 1580 by the Lutheran churches, although other doctrinal statements have served a confessional purpose for particular churches.

Partly because of the circumstances of its composition and partly because the Reformers understood their work to be a restoration of Christianity amidst contemporary corruptions, the Augsburg Confession emphasizes the continuity of the Lutheran teaching with the ancient Christian Church.

Justification. The teaching centres in the Gospel, or "justification": the doctrine that men "are justified freely on account of Christ through faith when they believe that they are received into grace and their sins forgiven on account of Christ, who by his death made satisfaction for our sins"; God "imputes [this faith] as righteousness in his sight" (Augsburg Confession, IV). Modern Lutheran theologians, among them Rudolf Bultmann and Paul Tillich, have applied this doctrine about grace to doubt as well as to guilt and have called attention to the change in the cultural and religious situation since the 16th century. Thus, Tillich interpreted justification through faith as a person's accepting his having been accepted in spite of unacceptability.

This doctrine ("the article by which the church stands or falls") provides the key for understanding the Bible (Apology, IV, 3-5) as a book that has two kinds of content—law and promises. Law demands a perfect inward as well as outward obedience to the divine will, which reason can never achieve. As such it drives men to despair, but the despair is conquered by the promise that God justifies the unjust man. This means that in Lutheran theology, in the act of being justified before God, the human being recognizes no positive or constructive role for the law. "The law always accuses," always destroys what the sinner had thought would impress God. God then effects a new creation by producing the new and justified person in Christ. Theologically, the doctrine of justification gives a Christocentric (*i.e.*, what honours Christ) stress and a practical (*i.e.*, whether afflicted consciences are consoled) emphasis to the other articles of faith.

Human nature. Lutheranism has a doctrine of human nature that defines the natural state as one in which humans do not fear or love God and are self-seeking. Human beings have freedom of will concerning the outward observance of laws (civic righteousness) but not before God (where they are inevitably unrighteous). They have a knowledge of God but not a true knowledge (they think, for example, that righteousness is what God has rather than what God gives).

Similarly, the meaning of predestination is to be sought not in the hidden counsel of God but in his revelation (Formula of Concord, Epitome XI). Lutheran teaching differs from the Calvinist double predestination by accepting the formal inconsistency of saying that believers are predestined to salvation without saying that unbelievers are predestined to damnation, for the purpose of the article on predestination is to console the troubled conscience. The mechanism of predestination has been the subject of controversy within Lutheranism (whether the decision of God is made "in view of faith"), but the basic position expressed in the symbols has been maintained.

Church, sacraments, and ministry. In opposition to the claim that the Roman Catholic Church was the only legitimate ecclesiastical organization, as well as to the biblicist demand to restructure the Christian Church according

to the New Testament pattern, the Augsburg Confession (Art. VII) defines the church as the "congregation of saints [believers] in which the gospel is purely taught and the sacraments rightly administered." "Gospel" is interpreted to mean that God justifies believers on account of Christ, not on account of their merits (Augsburg Confession, V). Right administration includes the practice of communion under both kinds (bread and cup). For the unity of the church it is sufficient to agree concerning the gospel and administration of the sacraments. This is the formula Lutherans use to build ecumenical relations with other churches. But it also brings difficulties, for the meaning and degree of "agreement" are always difficult to define and measure.

Luther regarded the church as essentially hidden or invisible. Although it is as weak and sinful an institution as any other one, it is possible to believe that God works in and through the church because it is founded on God's word.

This doctrine has undergone transformations since the 16th century. Orthodoxy and Pietism understood the invisibility of the church to mean that only God knows who among the assembled people are true believers (the invisible church as distinguished from the visible congregation). In the 19th century a sacramental-institutional conception was formulated by some Lutheran theologians (*e.g.*, the German leader Wilhelm Löhe), a congregational conception by others (*e.g.*, the conservative American C.F.W. Walther), a national or folk conception by still others (*e.g.*, the Danish leader N.F.S. Grundtvig), and a historical-evolutionary conception (*i.e.*, the church as the first actualization of the Kingdom of God to be progressively realized in history) by others. Though these differences radically divided the Lutheran bodies in the 19th century, particularly in America, today Lutherans tend to live with different conceptions of church polity without letting such matters divide them.

Of the three sacraments (baptism, Lord's Supper, penitence-absolution) recognized by Luther and the Lutheran confessional writings, which are called symbols, in the *Book of Concord*, the Lutheran churches generally hold to two by combining absolution in part with baptism (daily repentance is the repeated actualization of baptism) and in part with the Lord's Supper (confession and absolution). The criterion used in determining the number of sacraments was that they were actions instituted by Christ and connected with God's promise (Apology XIII). The symbols do not define the relation between word and sacraments except to say that they come together, and both have the effect of creating and strengthening faith. This is a rejection of the view that sacraments are effective *ex opere operato* (operative apart from faith) and that they are only memorial actions.

The Formula of Concord's teaching on the Lord's Supper is that Christ is bodily present "in, with, and under the bread and wine" (Solid Declaration, 35 ff., adopting Luther's terminology over Melancthon's "with the bread and wine"). The Formula of Concord left open the question whether Christ is present in the sacrament because he is present everywhere, as one party contended, or whether he is present in the sacrament because he chooses to be.

In the 19th century some Lutherans (*e.g.*, Gottfried Thomasius) distinguished word and sacrament by saying that the sacraments are intended for man's natural life as the word is for his conscious personal life. This view in some cases was carried so far (*e.g.*, in Martensen and Friedrich Stahl) as to subordinate the word (as the presentation of salvation) to the sacrament (as the participation in salvation).

The ministry is conceived of as a service in word and sacrament but not a special status. Every baptized Christian is a priest by status (universal priesthood of believers), but the public preaching and administration of sacraments devolves upon "rightly called" ministers, who are priests by office.

Church and state. The Lutheran churches generally have understood the relation of church and state on the basis of God's two ways of ruling in the world (two kingdoms). Through the "laws, orders, and estates" of the world God rules by compelling external obedience through

The church

The sacraments

Book of Concord

Law and Gospel

fear and threat of punishment. Through preaching and sacrament he rules in apparent weakness by converting the human heart. This conception has provided Lutherans with a basis for understanding the constitutional separation of state and church in the United States.

The two
domains of
power and
grace

The two domains of power and grace are interdependent because the word alone cannot preserve peace and justice—the civil government must even protect the freedom of the church to proclaim the Gospel—and civil power cannot effect salvation. Lutheranism has rejected the view that civil power is of itself evil, as well as the view that civil obedience has merit for salvation in the sight of God.

To define a citizen's relation to government one may say that in ordinary circumstances a Christian obeys the powers that be (except in matters of faith) as the agent of God's rule. But if a law or government is unjust, a Christian has the right and duty to resist it, passively accepting the consequences of disobedience for himself but actively defending his fellow man against that law or government. If the government is tyrannical, a Christian not only resists but rebels. Those Christians who also are holders of civil power have an obligation to resist and oppose misuse of such power by other rulers (as the territorial princes opposed the emperor in Luther's time). Lutheran scholars are not in complete agreement, but many would associate this view with Luther himself. In the 20th century it was developed by figures like the Norwegian bishop Eivind Berggrav, who resisted the Nazis.

In the 19th century the romantic view of the national state as expressing the spirit of a people was widely influential, but later it became suspect because of the demonic character of nationalism in the 20th century.

Scripture and tradition. The Lutheran Confessions, unlike the Reformed, have no article on Scripture, although the Formula of Concord does designate the Scriptures of the Old and New Testaments as the "sole and most certain rule" for judging teachings and teachers.

Toward tradition the attitude of Luther and the confessions was conservative; they retained whatever did not conflict with the Gospel of justification through faith. They viewed the written tradition of the church fathers as useful for interpreting the Scriptures but not as a source or norm of teaching. Some Lutheran theologians in the 19th century developed an organic view of the relation of the two (*i.e.*, Scripture contains a truth that is unfolded in the course of history) not unlike that of the Roman Catholics Johann Möhler and John Henry Newman.

Ethics. Lutheran teaching on ethics is determined by the perspective of the two kingdoms—the domain of law is not to be confused with that of the Gospel—and by the relation of faith and love implicit in justification. Works of love are the result, rather than the condition, of faith. Human beings have freedom from concern with self by the act of God and are enabled to direct their concern to other human beings. The works a person is to do are specified in part by his status in the world (as parent, ruler, subject, and other roles). Though early Lutherans thought of status in more natural terms (as "orders of creation"), recent Lutherans have given the concept a historical reference (*e.g.*, a person's particular destiny). A person's calling is to do well whatever his status requires. A second factor defining the works a person is to do is the concrete need of fellow human beings.

Man's
works

Controversies. Lutheran teaching has been shaped in part by the theological controversies in its history, almost all of which were at one time divisive. They had to do with such questions as the relation between divine and human agency (synergistic controversy, predestinarian controversy); whether works are indifferent, necessary, or dangerous for salvation (antinomian controversy, Majoristic controversy); whether in a state of confessional disagreement any questions are neutral (adiaphoristic controversy); what the nature of the sacramental presence is; whether the divine power resides in the Scriptures only when they are being used or also apart from their use (Rathmann controversy); what are sufficient grounds for church unity (syncretistic controversy); and whether God's election of believers is made "in view of faith" or not (predestinarian controversy).

WORSHIP AND ORGANIZATION

Liturgy and music. The worship service also was affected by the theology of the Reformers. Luther's "German Mass" of 1526 reflects changes that began about 1523. Apart from shifting the emphasis from sacrifice to thanksgiving, Luther's chief innovation here was to take the words of institution out of the framework of prayer and make of them a proclamation of the Gospel. This change has been preserved to the present day, although there is now a tendency to put the words again into a eucharistic prayer.

Because of the Reformers' emphasis upon the importance of the word, the sermon took an essential place in the service. Preaching is usually based upon a biblical text, a biblical story or doctrine, or a theological theme. Partly in reaction to the 19th century, there is an effort to keep preaching biblically oriented, though not necessarily tied to specified texts.

The term *mass*, at first retained, is not normally used except in the Church of Sweden (*högmessa*) as a name for the main service of worship. The other minor services disappeared from use during the 17th century, though some have been recovered in the liturgical reforms of the last century. Only Matins and Vespers are used with any regularity.

The basic order of service in most Lutheran churches is the same. It consists of two main portions (preaching and sacrament) in which the Kyrie, Introit, Gloria, Credo, and Agnus Dei are incorporated. Under the impact of the liturgical movement in the 20th century the didactic emphasis has given way to an emphasis on celebration in the service. Liturgical revisions (Swedish order of 1942, German of 1954, in the United States in 1941, 1958, and 1978) have brought an even greater uniformity in the basic order. They have also restored communion as a normal part of the regular Sunday service.

Lutherans observe two sacraments, baptism and the Lord's Supper (communion, Eucharist). The common practice is to baptize children and adults who have not been baptized previously. The frequency of communion has increased in recent years, but there are still many congregations where it is celebrated only once a month or less often. Though the usual practice has been that only those who have been confirmed may participate in the Eucharist, in 1970 the Lutheran Church in America and the American Lutheran Church approved participation for 10-year-old baptized children, whether they have been confirmed or not.

The rites of the Lutheran churches are confirmation, ordination, marriage, and burial. In the rite of confirmation (usually between the ages of 10 and 15) a member makes public profession of the faith received in baptism. In the rite of marriage the church ceremony may replace the civil ceremony or it may serve as an invocation of blessing on the civil ceremony. Ordination of the clergy does not endow its members with a special character or give them a special status, but it sets them apart for the particular office of preaching the word and administering the sacraments. This rite is interpreted either institutionally (*i.e.*, preaching is an order instituted by Christ and transmitted from generation to generation [succession]) or congregationally (*i.e.*, the congregations call certain of their members to assume the functions of preaching and administering the sacraments for them). In 1970 the Lutheran Church in America and the American Lutheran Church approved the ordination of women, a practice carried over in the Evangelical Lutheran Church in America, which came into being from a merger in 1988. There is no sacrament of extreme unction, but there is a burial service for the dead.

An important role was played in the Reformation by hymns, which not only conveyed the evangelical teaching but also allowed for popular participation in the church services. The best-known Lutheran hymns come from the period of the 16th and 17th centuries (*e.g.*, "A Mighty Fortress Is Our God" by Luther, "All Glory Be to God on High" by Nikolaus Decius, "O Sacred Head Now Wounded" by Paul Gerhardt, "Wake, Awake, for Night Is Flying" by Philipp Nicolai, "Now Thank We All Our

The
service,
sacra-
ments,
and rites

Hymnody

God" by Martin Rinkart). But each nation has made its contribution (e.g., Thomas Kingo in Denmark and Norway), and Lutheran hymnals today include hymns from many ages, nations, and communions.

Among the composers of choral music (cantatas, motets, masses, settings of the Passion of Christ) Johann Sebastian Bach ranks highest (e.g., *Mass in B Minor*, *St. Matthew Passion*, and *St. John Passion*). But other composers of importance were Michael Praetorius, Heinrich Schütz, and Dietrich Buxtehude. To this music should also be added the Scandinavian folk tunes (e.g., L.M. Lindeman in Norway).

Education. Education of the laity and clergy was an early problem for the Reformers. The means developed to meet it have had a formative influence on Lutheranism to the present day.

To instruct the people in Christian teaching, Luther not only translated the Bible into the vernacular but also wrote his Small and Large Catechisms (1528–29). The small one was to be used by heads of households to instruct those under their care. It includes not only the three parts that had been in use before (the Ten Commandments, the Creed, and the Lord's Prayer) but also three additional parts on baptism, the Lord's Supper, and absolution. Each topic in the various parts is connected with an explanation in the form of an answer to the question, "What does this mean?"—a device Luther used in order to avoid mechanical memorization.

The Small Catechism, with various expositions, has remained a basic instructional tool in the Lutheran churches, though it has been supplemented by other materials (e.g., Bible courses, Sunday school literature, projects).

In the 20th century efforts have been made to connect the secular world and the Christian tradition by establishing institutions such as the academies for laity in Europe (which provide opportunity for regular meetings of persons from specific vocations to discuss the relevance of Christianity to those vocations) and the church colleges in the United States.

Organization. The polity of the Lutheran churches varies from country to country. The Church of Sweden has maintained the episcopal succession unbroken, and congregations there are given great freedom to appoint their own pastors. The Danish Church lost but later regained the episcopacy. In Norway there is a closer tie between church and state than in the other Scandinavian countries. Since 1869, by an arrangement with Russia, the Finnish Church is independent of state control but is supported by public funds.

Until the end of World War I the churches in Germany were under secular authority, administered by a commission of laity and clergy, a system that grew out of the emergency situation of the Reformation. After the collapse of the government in 1918, the churches drew up new constitutions placing the congregations under a General Synod in some provinces and under a bishop in others; and the several provincial churches (*Landeskirchen*) were united in the German Evangelical Church Federation (1922). At the end of World War II, after the conflicts under Hitler, the Evangelical Church in Germany was organized under Bishop Theophil Wurm and Pastor Martin Niemöller, adopting the Declaration of Barmen (1934) as a binding statement. The United Evangelical Lutheran Church of Germany, formed in 1948, became a unit within the Evangelical Church in Germany.

In the United States the Lutheran churches have the same denominational standing as other churches. The polity is congregational, but in a complex form in which congregations yield some authority to synods on regional and national levels. Elected heads are called presidents in some Lutheran bodies, but in the largest, the Evangelical Lutheran Church of America, they are bishops.

Besides these larger Lutheran churches there are a number of Lutheran free churches in Europe (e.g., Evangelical Lutheran [Old Lutheran] Church, Germany) and in the United States (e.g., Church of the Lutheran Confession), which have complete congregational autonomy.

The Lutheran World Federation, established in 1947, is a cooperative organization. (R.P.S./M.E.M.)

Reformed and Presbyterian churches

Reformed and Presbyterian churches share a common origin in the Reformation in 16th-century Switzerland. Reformed is the term identifying churches regarded as Calvinistic in doctrine. The term presbyterian designates a collegial type of church government by pastors and by lay leaders called elders, or presbyters, from the New Testament term *presbyteroi*. Presbyters govern through a series of representative consistories, from the local congregation to area and national organizations, commonly termed sessions, presbyteries, synods, and assemblies.

A slogan for the Lutheran Reformation was "by faith alone." Reformed Christians added the principle "to God alone the glory." Reformed Christians emphasized that God's word alone and no mere human opinion should be the norm for faith. "To God alone the glory" determined attitudes toward church government and worship, the design and furnishing of church buildings, and even secular authority. Reformed churches are confessional in nature, and during the 16th and early 17th centuries a number of manifestos of faith were written. Some of these confessions were theses for debate, such as Zwingli's *Sixty-Seven Articles* of 1523. Others, such as the Zurich Consensus of 1549, sought unity between groups on controversial doctrines. The very names of the Geneva, Helvetic, French, Belgic, and Scots confessions indicate the relationship of Reformed churches to the rising sense of nationhood in 16th-century Europe. A harmony of confessions prepared in 1581 shows the agreement among national churches as well as between Reformed confessions and the Lutheran Augsburg Confession. Some national confessions had international significance. The Second Helvetic Confession became standard for churches in countries east of Switzerland. The Heidelberg Catechism had great importance in the churches of the Netherlands and wherever the Dutch settled. The Westminster Confession of Faith, produced in 1648 by a committee appointed by the English Parliament, had its greatest influence among Presbyterian and Congregational churches outside of England.

HISTORY

This section treats developments within the Reformed and Presbyterian churches after the Reformation. For a discussion of the emergence of these churches, see above *History of the Protestant movement*.

After the Reformation in Europe. *Reformed churches in eastern Europe.* Reformed Christianity in eastern Europe had great strength among Hungarians. By 1576 the government of the Hungarian Reformed Church emerged with superintending bishops chosen by church councils of pastors and elders. In 1606 István (Stephan) Bocskay, prince of Transylvania, secured recognition of the rights of Hungarian Reformed churches in territories under both Habsburg and Turkish rule, and Reformed faith was identified with Hungarian nationalism. The Transylvanian town of Debrecen became known as the Calvinist Rome. Transylvania, a sovereign state at the Peace of Westphalia ending the Thirty Years' War in 1648, fell under Habsburg domination later in the century. This resulted in a Counter-Reformation against Protestants, which was lightened by toleration in 1781 and equality under the law in 1881. Partitioning of Hungary in 1919 and 1945 left a significant number of continuing Hungarian Reformed churches in Romania, Czechoslovakia, the Soviet Union, and Yugoslavia as well as in the present state of Hungary.

The Thirty Years' War was devastating to the Hussite Unity of Brethren in Bohemia, who had identified with the Reformed tradition during the Reformation. Protestantism survived underground until limited toleration came in 1781. Two Czech Brethren denominations exist in present-day Czechoslovakia. A Christian Peace Movement, which has gained international significance, developed from these churches in Prague during the 1950s.

Though Poland produced an influential Reformed theologian in Jan Łaski (d. 1560), the Counter-Reformation reduced Reformed churches to the status of a small sect in Poland by the 17th century. In 1648 there were still more than 200 Reformed congregations, but by the late 20th

Meaning of Presbyterian and Reformed

The catechisms

century there were only eight congregations in Poland, five in Lithuania, and one in Latvia.

Congregational churches in Bulgaria and Evangelical churches in Greece are members of the World Alliance of Reformed Churches.

Revocation of the Edict of Nantes *Reformed churches in France.* French Calvinists, or Huguenots, set the pattern for presbyterian organization on a national level at a synod of the Reformed Church of France in 1559. During the religious wars of the next decades they developed a theory of resistance to the unjust state, but the end of effective resistance came with the fall of La Rochelle in 1628. Huguenots remained as a weakened, tolerated minority in France. On Oct. 18, 1685, Louis XIV revoked the Edict of Nantes, which had granted Huguenots limited toleration. At least 250,000 French Protestants emigrated to Prussia, Holland, England, and America. After the suppression of the Camisard (French Protestant peasant) revolt in 1715, Louis XIV announced the end of the practice of Protestantism in France. Yet that very year a group met in Nîmes to plan restoration of the Reformed Church. With the 1789 French Revolution equality under the law came to Protestants. Napoleon placed Reformed congregations under state control, with pastors on state salary.

A national synod did not meet again until 1848. At that time a free Evangelical Synod was organized, separating from the state-recognized church over the issue of state support. In 1905 state support of the old synod was withdrawn, and the two synods were united in 1938.

When Alsace was annexed to France in 1648 a number of Reformed Christians were brought into the French nation. But the Reformed Church in Alsace-Lorraine, whose history has been different from that of the Reformed Church of France, remained a separate organization. Outside of French-speaking Switzerland, French Reformed churches are the largest Protestant group in the Latin countries of Europe, each having a Reformed Church. French Reformed Christians have played a role in the World Council of Churches, in liturgical and theological renewal, in relating the church to technology and urbanization, and in Catholic-Protestant and Communist-Christian dialogue.

Reformed churches in Germany. The Peace of Westphalia in 1648 established the legality of Reformed churches in German states, according to the pleasure of the ruling prince. At the end of the 17th century Reformed Christians in the Palatinate faced an attempt at their destruction. Many fled to the Netherlands, America, and Prussia, where Reformed churches were established. The Hohenzollern Elector of Brandenburg was converted to Calvinism in 1609. Hohenzollern rulers permitted the establishment of Reformed churches among refugees and also continued Reformed churches in territories that came later under Prussian rule.

Frederick William III of Prussia in 1817 proposed a union of Reformed and Lutheran churches. Reformed theologian Friedrich Schleiermacher led ministers in support of this union but shared with them a concern for the loss of Reformed systems of self-government to monarchical absolutism. The union became a pattern for a majority of Protestants in Germany. Distinctively Reformed territorial churches are still to be found in northwestern West Germany. The Reformed Church of Anhalt, now in East Germany, joined in the union Evangelical Church in 1981.

The Barmen Confession A Reformed Alliance was organized in Germany in 1884 to preserve the Reformed heritage. A synod held in Altona in January 1934 drew up a confession in opposition to Nazi corruption of the Gospel. This led to the Barmen Synod of May 1934 in which Christians of Lutheran, Union, and Reformed background joined in the Barmen Confession of Faith. This confession was the basis for resistance to Hitler by the Confessing Church. After World War II the Confessing Church ceased, but its work has continued to be an inspiration to churches in both West and East Germany. The Reformed Alliance is still active in West Germany, and there is a Reformed Conference in East Germany.

Reformed churches in England and Wales. The failure of the Puritans either to complete establishment of a presbyterian system during the Westminster Assembly in

1648 or to continue a looser arrangement of independent churches under Cromwell opened the way in 1660 to an episcopal restoration in the Church of England. Those Reformed Christians who could not accept this became persecuted Nonconformists. The Glorious Revolution of 1688–89, which expelled the Roman Catholic sovereign James II, gave English Presbyterians, Independents, and Baptists limited toleration outside the state church. Many Presbyterian congregations became Unitarian during the next century. This movement was checked by the Evangelical Awakening of the 18th century, which reinvigorated the Nonconformist groups.

The free-church spirit changed the Reformed ethical emphasis on parish discipline to formation of voluntary societies dedicated to preserve the sabbath, to suppress vice, to abolish slavery, and to work for moral reform.

In 1972 the United Reformed Church was formed out of the Congregational Union of England and Wales and the Presbyterian Church of England. The Presbyterian (Calvinistic/Methodist) Church of Wales, formed in the 18th century, has a substantial membership.

Reformed churches in Scotland and Ireland. The refusal of the Episcopal bishops of the Church of Scotland to accept the legitimacy of William and Mary in 1688 resulted in presbyterian government for the church. State interference in the appointment of pastors along with evangelicalism gave rise to secessionist movements in the 18th century, culminating in 1843 in a major schism and the formation of the Free Church of Scotland under Thomas Chalmers. In 1900 secession and free churches became the United Free Church, which in turn reunited with the Church of Scotland in 1929.

In Ireland the Presbyterian Church has roots both among Scottish settlers and also among English Puritans of the early 17th century. Although the church is represented in all of Ireland, most of its membership resides in Northern Ireland, where Irish nationalism is a crucial issue.

Reformed churches in The Netherlands and in Switzerland. The Peace of Westphalia in 1648 ended the Eighty Years' War for the independence of the Netherlands. The Reformed Church, which was identified with Dutch nationalism, constituted the majority church within a nation that had remarkable tolerance for religious minorities.

Closer state control of the church followed the Napoleonic era. This and an enervated theology prompted two secessions from the Dutch Reformed Church, the first in the 1830s and the second in the 1880s. These secession churches united as the Gereformeerde Kerken in The Netherlands, which exist alongside the traditional Hervormde Kerk. Abraham Kuyper, the scholarly neo-Calvinist leader of the second of these secessions, served as prime minister of The Netherlands with a conservative coalition in Parliament from 1901 to 1905. The two main bodies of Reformed Protestantism in The Netherlands cooperate on many levels.

Nineteenth-century evangelical secession and 20th-century reunion occurred in Swiss Reformed churches, which continue to be organized along cantonal lines. A Christian Socialist movement was developed in the early 20th century. Karl Barth and Emil Brunner, whose theological influence went far beyond Switzerland and the Reformed tradition, emerged from that movement with less utopian political realism.

Reformed and Presbyterian churches in the United States. *The colonial period.* Persons of Reformed background were important in directing the political and religious course of the 13 American colonies. In 1611 Alexander Whitaker, son of a Reformed theologian, began to establish churches in Virginia. Elder William Brewster, in the 1620 Plymouth Colony, used the writings of the English Presbyterian Thomas Cartwright as his guide in church government. A Dutch Reformed Church was organized on Manhattan Island in 1628, and the Massachusetts Bay Colony in 1630 was a new model Reformed church and commonwealth. In the 17th century Waldensian refugees came to Staten Island, and Huguenots settled in New York and New England. These were followed by Scots-Irish immigrants, who settled throughout the colonies, and by German Reformed refugees from the Palatinate.

Secessionist movements

The 18th-century Great Awakening—led by Calvinist preachers Jonathan Edwards, Theodore Frelinghuysen, George Whitefield, and Gilbert Tennent—encouraged an evangelical Christianity often at odds with establishment attitudes. Hence revival-seasoned clergy learned to fight for the free expression of religion. These evangelicals joined with deists in supporting religious liberty in the constitutional foundation of the United States.

Calvinist
culture

The 19th century. Most religious groups in the new nation had a Calvinist viewpoint and pattern of life, favouring constructive activity rather than idle enjoyment. Art, music, literature, and recreation were approved only if edifying. Sunday was a quiet day with minimal farm chores, freedom from business cares, Sunday school, church, and conversation among friends. A disciplined nation might receive the blessing of God and enjoy peace and prosperity. Revivalism was seen as the means by which people could be brought under the Lord's discipline. Revivals then bore fruit not only in disciplined souls but also in movements for women's rights, abolition of slavery, and temperance. Saving souls and building a better world came to be two aspects of the Kingdom of Christ in America.

The 20th century. After the Civil War (1861–65) conflict developed between those who adapted Darwinism to theology and those who saw evolution as a threat to biblical authority, between those who championed higher biblical criticism and those who opposed it. This conflict peaked in a fundamentalist-modernist controversy in the 1920s with fundamentalists withdrawing to the edges of American denominational life. In the 1980s television preachers gave the fundamentalist perspective not only new popularity but also political significance.

Mainline denominations, however, have been in numerical decline. Reformed Christianity is still concerned about achieving a more just society and at the same time is working for the redemption of individuals. There is debate over goals and methods.

Reformed and Presbyterian world mission. *Asia.* In 1622 an institute was founded in Leiden (the Netherlands) to prepare missionaries for the Dutch Indonesian colonies. Building upon work begun by Catholics, Presbyterian missionaries established churches in Indonesia that by the late 20th century comprised at least one-third of all Asian Reformed and Presbyterian Christians.

Presby-
terian
churches in
Korea

Presbyterian churches in Korea have been established for more than 100 years and are second in Asian membership to the Reformed churches of Indonesia. Not only have these churches grown rapidly in South Korea, but through immigration they constitute the fastest growing segment of Presbyterian churches in the United States. Identified with Korean nationalism in the past, these churches have found themselves in tension with the government of South Korea. In 1986 contact was made with Presbyterian Christians in North Korea after 40 years of isolation.

The strong Presbyterian Church in Taiwan has been identified more with the native Taiwanese than with church members coming from mainland China after 1945. Conflict with the government has resulted in the jailing of Taiwanese Presbyterian leaders.

Presbyterian and Reformed churches exist in Japan, Thailand, Malaysia, Singapore, Burma, India, Pakistan, Iran, Syria, and Lebanon. There is also a strong Presbyterian and Reformed component in larger United churches in Japan, the Philippines, India, and China. With new tolerance in the 1980s in the People's Republic of China, a resurgence of the United Protestant Church of Christ in China has taken place. Church buildings have been reopened and new congregations formed.

Africa. Reformed churches in Africa date from Dutch settlement in South Africa in 1652 as well as from settlements by Huguenot and German Reformed refugees somewhat later. With British occupation in South Africa in 1806 Scots brought Presbyterianism. By the late 20th century half of the Presbyterian and Reformed membership in Africa was in the Republic of South Africa. White Dutch Reformed churches have been closely identified with the government policy of apartheid. At the meeting of the World Alliance of Reformed Churches in Ottawa, Can., in 1982 apartheid was declared heresy. Two of the

white Reformed denominations then were suspended from the alliance, and the Reverend Allan Boesak, a Colored Reformed pastor and leader of the anti-apartheid forces, was named president of the World Alliance. A confessional statement, the Kairos Document, drawn up in 1985 by Reformed, Congregationalist, Presbyterian, and other church leaders, affirmed a theology unconditionally opposed to the state theology of South Africa. It has been compared to the 1934 Barmen Confession in Germany calling for resistance to the state.

Other African nations with large Presbyterian church membership include Madagascar, Kenya, Zaire, Cameroon, Malawi, Egypt, and Ghana. Churches from 16 other African nations belong to the World Alliance.

Other areas. In Canada, Australia, and New Zealand, as well as in the Pacific Islands and West Indies where there were former British colonies, there are both Presbyterian churches and United or Uniting churches with Presbyterian components.

In 10 countries of Latin America there are member churches of the World Alliance, but half of the Presbyterian and Reformed membership is found in Brazil. Since most of the Presbyterian membership in these countries is of middle-class background, liberation theologies that identify with the concerns and needs of the poor have created controversy. There is a small but vigorous Presbyterian-Reformed Church in Cuba.

The success of the world mission can be seen in the vanguard of Reformed theology. For most of the 20th century influential Reformed theologians included such white, male, North Atlantic leaders as Barth, Brunner, John and D.M. Baillie, Reinhold and H. Richard Niebuhr, Hendrik Kraemer, and Jürgen Moltmann. This type of leadership has begun to make room for theologians from Asia, Latin America, and Africa, such as C.S. Song, Kosuke Koyama, Mariane Katoppo, Yong-Bok Kim, Elsa Tamez, and Allan Boesak. Reformed theology has become global.

Global
theology

Reformed Christians in the ecumenical movement. Since the time of Martin Bucer and John Calvin the Reformed movement has had leaders who were untiring in efforts toward church unity. In the 17th century the Scot John Dury and the Czech John Amos Comenius were notable for their ecumenical efforts. While later Pietism and Evangelicalism divided churches, people were also encouraged to put aside differences for common goals. Mission societies received support and sent missionaries from diverse denominational backgrounds. In the past 150 years Presbyterian and Reformed churches have not only reunited among themselves but also have formed close links with churches of other historical backgrounds. In the United States discussion and the adoption of consensus papers have taken place since 1961 by a Consultation on Church Union that included Reformed, Presbyterian, Congregational, Methodist, Episcopal, and Disciples churches.

The World Council of Churches was organized in 1948. Reformed and Presbyterian churches participate in local and regional councils of churches and interfaith groups. Since the second Vatican Council (1962–65), called by Pope John XXIII, there has been increased dialogue with Roman Catholics. The insights coming through ecumenical and interfaith relationships make for more global, more dynamic, and more relevant teaching and practice in Reformed and Presbyterian churches.

TEACHINGS

Doctrines. Reformed churches consider themselves to be the Roman Catholic Church reformed. Calvin in his *Institutes* spoke of the holy Catholic Church as mother of all the godly. Bullinger in the Second Helvetic Confession made it clear that Reformed churches condemn what is contrary to ecumenical creeds. Interpretations of the early Church Fathers and decrees and canons of councils "were not to be despised, but we modestly dissent from them when they are found to set down things differing from, or altogether contrary to, the Scriptures." Universal articles of Christian faith, such as the doctrines of the Trinity, the humanity and divinity of Christ, and the sin of man and the saving work of Christ, are affirmed in Reformed faith.

Reformed churches share with Lutheran and other

Justification by grace through faith

Protestant communions the concept of justification by grace through faith as central to the Gospel. The essence of faith is God's forgiving love coming as a gift through Jesus Christ. As with Lutherans, the true treasure of the church is this good news of the grace of God. Scripture is the authoritative witness of the good news, but, as was stated in the Westminster Confession, "authority thereof is from the inward work of the Holy Spirit, bearing witness by and with the word in our hearts." Calvin said: "There is no doubt that faith is a light of the Holy Spirit through which our understandings are enlightened and our hearts are confirmed in a sure persuasion." Such understanding is shared by Lutheran and Reformed Christians.

The church and the sacraments. Calvin tried unsuccessfully to mediate between the Lutherans and Zwinglians, holding that Zwingli had been more concerned to show how Christ was not present than how he was and affirming, with Luther, the real presence of the resurrected Christ in communion. In the 1980s Lutheran and Reformed churches in Europe and the United States came to recognize each other's ministries of word and sacrament.

Both Calvin and Bucer, more than Luther, were concerned to keep the "profane" from receiving communion. This encouraged the development of church discipline, and the use of elders to oversee discipline within the parish became a feature of Reformed church life. In the struggle to maintain that discipline, Calvin's successor, Theodore Beza, asserted that the presbyterian form of government was ordained by Christ.

Scripture and tradition. Before the Reformation, humanists rejected arguments that appealed to the authority of church tradition. They made the authority of Scripture central in the church. Following them, Reformed Christians insisted that no authority in the church was on a level with Scripture; by Scripture all tradition was to be judged.

Church and state. The position in the Swiss Reformation was that church and state should render reciprocal service yet remain distinct. The church invisible consisted of God's elect, but the membership of a visible church approximated the population of the corresponding state. Beyond borders national churches kept communion with each other in spite of differences of custom.

Obedience was required of Christians, even to unworthy rulers, unless the ruler commanded disobedience to God. On such occasions, God rather than man must be obeyed. But even then, the private individual should not actively resist the ruler. It was the responsibility of lesser magistrates to bring such rulers into line. Sixteenth-century resistance of Huguenots in France, Protestants in Scotland, and Puritans in England was justified on this basis.

English Puritans asserted that the government of the state should be patterned after their form of government in the church. This teaching was one source of modern constitutional government. Another source in Reformed tradition was the belief that no one person should be trusted with unlimited power, a doctrine James Madison built into the U.S. Constitution.

There has been a constant Reformed hope that the kingdoms of this world may be brought closer to the will of God and that this would result in a better justice for all. This view requires that church people become involved in politics.

The sovereignty of God and double predestination. There has been no argument in Reformed theology about the positive side of the doctrine of predestination concerning the election of those whom God wills to save. Difference of opinion, however, arose over whether God determines who is reprobated. Bullinger did not believe that it was God's will that "one of these little ones should perish." He maintained that Christians should always hope for the best for all. Calvin affirmed "double" predestination, meaning that both reprobation and election are within the active will of God. His reason found this appalling but scriptural. To call God, thereby, unjust was to judge One who is the very standard of justice.

In his *Institutes* Calvin discussed predestination in the context of the love and grace of Jesus Christ. Later theologians expounded predestination more abstractly as an aspect of God's sovereignty. Arminianism rose in protest

to this. The defenders of double predestination thought that Arminianism would cut the nerve of the Protestant doctrine of justification by grace alone and lead people back to popery. Hence, at Dort in 1618, double predestination was affirmed as Reformed orthodoxy.

WORSHIP AND ORGANIZATION

Liturgy. In the Reformation earlier liturgies were modified by using the vernacular, removing anything that implied the reenacting of sacrifice in the mass, providing for congregational confession, and emphasizing the preaching of the word. Following Erasmus' recommendation, the singing of Psalms became characteristic of Reformed worship. While most Reformed churches today use a broad spectrum of vocal music, some hold exclusively to Psalms.

Stress on preaching reached its peak among English Puritans. Some clergy preached two hours on an Old Testament text on Sunday morning, two hours on a New Testament text in the afternoon, and devoted the evening to discussion of the day's sermons with the congregation. Calvin held that the Eucharist should be celebrated weekly, though others believed that it was too sacred for such frequent use. Care was taken to instruct participants and to prepare them for confession. The Eucharist was served around a table.

In the 20th century attention has been given to relating worship to the social and material needs of human beings as well as to communicating the word to human hearts and minds. At the Iona Community in Scotland, for example, where worship is directed to those intending to work in economically deprived areas, and at the Taizé Community in France new forms of worship are being developed. In recent years there has been emphasis upon celebration in response to the good news of God, a greater appreciation of the arts in worship than in the past, and a concern for inclusive language.

Religious education. The requirements of Reformed life have demanded an educated clergy and an informed laity. Besides academic training for pastors, the early practice was for them to meet often and for one to interpret Scripture and for the others to engage in critical discussion. Queen Elizabeth I suppressed the custom in England, for she believed that four sermons a year were quite enough and that gatherings of pastors might be subversive.

Lay education was accomplished through preaching the word and teaching the catechism, such as Calvin's Little Catechism, which was designed for teaching the young. Others, such as the Westminster Larger Catechism, were used to instruct pastors and teachers. More recently catechetical instruction has given way to inductive forms of education, with emphasis on the age level at which instruction takes place. There is also concern to relate the Christian faith to the daily life of the larger community.

Present organization of Reformed and Presbyterian churches. In Presbyterian churches a local congregation is ruled internally by a session moderated by the pastor and composed of laity (elders) elected from the congregation. A presbytery formed of pastors and elders representing each congregation rules over local congregations on a district level. In other Reformed churches the district association has less power and the local congregation more than in Presbyterian churches. In Hungarian Reformed churches a presiding bishop moderates the presbytery.

Beyond the district level are regional synods or conferences and national assemblies. These bodies are usually composed of an equal number of clergy and laity. Since 1875 there has been a World Alliance of Reformed Churches, which was joined in 1970 at Nairobi, Kenya, by the International Congregational Council to form the World Alliance of Reformed Churches (Presbyterian and Congregational). There are about 160 member denominations.

Although a few Reformed groups still have a special relationship to the government of their nation, there is little difference in practice between established and free Reformed churches.

Social ethics. Reformation leaders were involved in the total life of their communities. Calvin's relation to the education, health and welfare services, refugee settlement,

Music and sermons

industry, finance, and politics of Geneva is well documented. The historian R.H. Tawney, impressed by this, has called Calvin a "Christian socialist." The English Puritans believed that if they could reshape the political and church life of the nation, God's blessing would come upon the land instead of war, famine, and pestilence. Concern to achieve greater social justice for humankind has been normative among Presbyterian and Reformed churches. Such concern in the past has been seen as resulting sometimes in petty rules and harsh administration, but in new forms that concern is still a living force.

Types of Reformed piety. In Zwingli, Calvin, William the Silent, and Cromwell, a classic type of Reformed piety was manifest. Those persons saw themselves as God's instruments in redeeming human affairs, even at cost to themselves, and they had high expectations of others. Living under God's mercy, they showed little fear of the powers of this world and were ready to make choices on a pragmatic basis.

In a less heroic mold were Reformed Christians who did not expect to change history but who encouraged the development of godliness in those about them, beginning with themselves. The increasing emphasis in the late 16th century upon the personal experience of saving faith helped the Reformed tradition to become a nursery for Pietism in the late 17th and 18th centuries. Along with a more confessional orthodoxy and a more rationalistic liberalism, such Pietism remains to the present. A new style of worldly Christianity is emerging with Christ, standing for and with the oppressed, as the model. (J.C.S.)

Anglican Communion

Anglicanism refers to the form of Christianity practiced by the churches of the Anglican Communion. This loosely organized family of religious bodies represents offspring of the Church of England, one of the major branches of the 16th-century Protestant Reformation. It is a form of Christianity that includes features of both Protestantism and Catholicism. It prizes traditional worship and structure but operates autonomously and flexibly in different locales. Anglicans possess few firm rules but a cluster of historic pieties and procedural loyalties. *The Book of Common Prayer*, a compilation of the church's liturgical forms originally issued in the 16th century, represented the achievement of autonomy from Rome and remains the hallmark of Anglican identity. The prayer book derives from ancient English spirituality and embodies the uniqueness of Anglican Christianity.

HISTORY

Christianity in England. The Church of England, mother church of the Anglican Communion, has had a long history. When Christianity began in England is uncertain, but it probably was not later than the early 3rd century. The church was well enough established by the 4th century to send three British bishops—of Londinium (London), Eboracum (York), and Colonia Linum (Lincoln)—to the Council of Arles (in modern France) in 314. In the 5th century, after the Romans had withdrawn from and the Anglo-Saxons had invaded Britain, illud performed missionary work in Wales and Patrick in Ireland. Though isolated from continental Christianity in the 5th and 6th centuries, Christianity in the British Isles grew due to the influence of monasticism. About 563 Columba founded an influential monastic community on the island of Iona off Scotland. In 597 a monk named Augustine went to England at the request of Pope Gregory the Great to oversee the development of English Christianity. Augustine's archbishopric at Canterbury soon became the symbolic seat of England's church. Subsequent mission work, such as that of Aidan around 634 in northern England, solidified the church's life. The early Catholic Church in England was a distinctive fusion of Romano-British, Celtic, and Roman influences. It retained powerful centres in the monasteries and lived in tension with the medieval monarchy. The martyrdom of Thomas Becket demonstrated the church's concern to preserve its integrity over the throne in the 12th century. The writings of John

Wycliffe (d. 1384) questioned the form of the medieval church and became an early protest against Rome's control over England's church.

Under King Henry VIII in the 16th century the Church of England broke with the pope. Henry wished no Reformation but intended to substitute his royal authority over the English Church for that of Rome. Upon Henry's death Archbishop Thomas Cranmer began changes that allied the Church of England with the Reformation. His *Book of Common Prayer*, which appeared first in 1549, revised traditional forms of worship to incorporate Protestant ideas. When Elizabeth I assumed the throne in 1558 the Reformation in England triumphed. The theologian John Jewel (1522–71) wrote that England's church had returned to ancient precedent. Richard Hooker (1554?–1600) offered a defense of English Church order against Puritans and Catholics in England. In the 17th century Puritan opposition achieved powerful political form. But the Restoration of 1660 ended the Puritan commonwealth and began more than a century of great influence for the Church of England. Until the early 19th century it dominated England's religious life and became closely allied with the power of the throne.

The Church of England became a considerable social and spiritual force, its piety permeating English life. The church generated impressive forms of philanthropy, and clergy commonly performed the duties of civil servants. Anglican influence spread to colonial areas in India and North America. But the church's hold on English religious life began to wane in the 18th century despite impressive reform efforts. John Wesley, Charles Simeon, John Newton, and other Evangelical clergy prompted a surge of new religious fervour. Evangelical laity such as William Wilberforce and the Clapham Sect fought slavery and encouraged social reform. In the early 19th century the Anglo-Catholic (High Church) Oxford Movement led by John Henry Newman, John Keble, and E.B. Pusey attempted a recovery of ancient liturgy and a response to social concerns. The church made impressive efforts to encompass the diversity of modern English life while retaining its traditional identity.

Developments in worldwide Anglicanism. From the time of the Reformation the Church of England expanded, following the routes of British exploration and colonization. It served native peoples and expatriates alike, and all initially considered themselves loyal to the see of Canterbury. The Church of England's great missionary societies were important agents of its growth beyond England. The Society for Promoting Christian Knowledge, founded in 1699, the Society for the Propagation of the Gospel in Foreign Parts, 1701, and the Church Missionary Society, begun in 1799, achieved global identity. These societies undertook mission work among indigenous people of English colonies and began the process of transferring authority in church matters to local leadership. Anglicanism thus came to function as a decentralized body of national churches loyal to one another and to the forms of faith inherited from the Church of England.

Social and political circumstances often hastened the development of autonomy. The American Revolution compelled the organization of the Episcopal Church, which completed its structure by 1789. The first American bishop, Samuel Seabury, was consecrated in Scotland in 1784. The Anglican Church of Canada had its own separate organization in 1893, though it was known as the Church of England in Canada until 1959, just as the Anglican Church of Australia continues to be so designated.

Initially Anglicanism's growth followed the outline of the British Empire. Vigorous missionary work produced strong church life in such diverse places as Nigeria, Kenya, South Africa, India, and Australia. In China and Japan, British, American, and Canadian Anglicans combined their efforts. The church left an impressive legacy of educational institutions and medical facilities. Here and there native peoples became clergy and even bishops. Samuel Crowther of Nigeria became the first black bishop in 1864.

Consolidation and indigenization characterized later Anglican mission. By the late 19th century Anglican bishops began meeting once a decade for the Lambeth Conference

Missionary efforts of the English Church

Development of local autonomy

Bishop
Colenso

at the archbishop of Canterbury's residence in London. The immediate cause of the initial meeting in 1867 was a controversy that arose in one of the colonial churches. The archbishop of Cape Town, Robert Gray (who was High Church, or traditionalist), wanted the bishop of Natal, John Colenso (who was Low Church, or evangelical), to be arraigned on charges of heresy for holding what were then regarded as advanced views of the creation stories in the opening chapters of Genesis. The controversy centring on Bishop Colenso aroused intense feelings and anxieties over a wide range of issues—doctrinal, personal, and organizational—among all the Anglican churches throughout the world. Bishop Colenso was convicted and deposed in the church courts but upon appeal to the civil courts of England won his case and retained his church properties. What began as a jurisdictional dispute in South Africa became a matter of concern for all Anglicans. The issue of the relationship between the church's various branches required clarification. Lacking an authoritative centre, however, Anglicans have continued to rely upon consultation and consensus to coordinate matters of belief and practice.

The end of colonialism and the rise of newly independent nations compelled Anglicans to rethink their identity and mission. Once the church of the colonizer, Anglicanism has spawned a host of self-directing churches linked by common form and historic allegiance to the Church of England. In most cases Anglicanism has been able to adapt in an affirmative way to new and changing social circumstances. In 1947 Anglicans joined several Christian bodies to create the Church of South India, a unique ecumenical union. Frequently Anglicans have been articulate opponents of injustice. Archbishop Janani Luwum of Uganda was martyred for opposition to the rule of Idi Amin. In South Africa the Anglican Church has consistently opposed apartheid, and Archbishop Desmond Tutu won the Nobel Prize for Peace for 1984 for his stand on behalf of racial equality. Anglicans rarely become revolutionaries, for the church views its task as working through existing structures for justice.

The Church of England has evolved a similar posture since the mid-19th century. Still the nation's official church, it has experienced attrition and attempted to redefine its place in English life. A succession of powerful leaders have enhanced the church's claim of being the nation's soul. In the latter 19th century Christian Socialism was an effort to draw compassionate attention to social problems. Sparked by the theologian F.D. Maurice, the movement later was led by clergy such as Stewart Headlam and Henry Scott Holland. In the 20th century Archbishop William Temple underscored that the church was a community of worship in step with modern life. The scholar and lay theologian C.S. Lewis restated the tenets of Christian belief in a sensitive response to modern doubt, and John A.T. Robinson affirmed the searching quality of modern Christian experience.

TEACHINGS

The
Lambeth
Quadrilat-
eral

Doctrinal views. What has come to be known as the Lambeth Quadrilateral defines Anglicanism's essential beliefs. First suggested by an American, William Reed Huntington, in 1870, the Quadrilateral stated four marks essential to the Anglican conception of Christian identity—Scripture, the Nicene Creed, baptism and Holy Communion, and the episcopate. The Lambeth Conference of 1930 further clarified the nature of Anglicanism when it described the Anglican Communion as:

a fellowship within the One Holy Catholic and Apostolic Church, of those duly constituted Dioceses, Provinces or Regional Churches in communion with the See of Canterbury, which uphold and propagate the . . . faith and order as they are generally set forth in the Book of Common Prayer . . . ; promote within each of their territories a national expression of Christian faith, life and worship; and are bound together not by a central legislative and executive authority, but by mutual loyalty sustained through the common counsel of the Bishops in conference.

The Anglican Communion thus holds to the Catholic faith as expounded by the Holy Scriptures and by the early Church Fathers. It respects the authority of the state but

does not submit to it; and it equally respects the freedom of the individual. In its relationship to the world the Anglican Communion does not seek to evade the challenges of the world or to live a life separate from it. Basing its doctrines on the Bible, the Anglican Communion allows a remarkable latitude of interpretation by both clergy and laymen.

Though the Church of England holds close to the spirit of the Thirty-nine Articles (a 16th-century doctrinal document that allows for broad interpretations), subscription to them is not required of the laity, and adherence by the clergy is expected only in a general way. Other churches or councils of the Anglican Communion take different views of the Articles, but none regards them as having, for example, the status of the historic statements of belief as set forth in the Apostles' or Nicene creed, nor do they accord them the status given to other 16th-century doctrinal statements, such as the Augsburg Confession of the Lutheran churches or the Westminster Confession of the Reformed and Presbyterian churches.

The ministry. Anglicans accept a threefold order of ministry, which consists of bishops, priests, and deacons. Though holding to the view of succession from the Apostles, Anglicans are not committed to any one theory regarding the conveyance of that ministry. Anglicans attempt to balance the clerical point of view with forms of authority that include the laity. Even bishops rarely are able to function without the advice and consent of other clergy and laity.

Bishops,
priests, and
deacons

WORSHIP AND ORGANIZATION

Anglican worship. Worship is the centre of Anglican life. Anglicans view their tradition as a broad form of public prayer, and they attempt to encompass diverse Christian styles in a traditional context. Although the prayer book is the most apparent mark of Anglican identity, it has undergone many revisions and wears national guises. The prayer book of 1662 represents the official version in the Church of England, but a 1928 version and a later Alternative Service Book are commonly used.

A few overseas Anglicans still rely upon the English prayer book of 1662, but most have their own versions, increasingly in languages other than English. All forms hold to the essential, historic elements of the prayer book but incorporate local idioms. In recent years there has been a recovery of ancient liturgical styles and vestments and a heightened emphasis upon the Eucharist as the central act of Christian worship. Experimental rites have appeared in different parts of the Anglican world. Change in Anglican worship has meant increased variety, new roles for laity, and a tendency toward freedom of expression while holding to the essence of the church's traditional forms.

Comprehensiveness in doctrine and practice. Often said to be the middle way between Roman Catholic and Protestant churches, the Anglican Communion is comprehensive in matters of doctrine and practice. While asserting the importance of the apostolic succession of bishops and *The Book of Common Prayer*, it nevertheless allows a considerable degree of flexibility in most doctrinal and liturgical matters. Thus, within the communion there are several schools of thought and practice, including High Church, Anglo-Catholic, Low Church, evangelical, and others. The various churches of the Anglican Communion, though autonomous, are bound together by a common heritage and common doctrinal and liturgical concerns, and there has always been a considerable amount of interchange of ecclesiastical personnel.

Authority and structure. Having no central authority and no one person, such as the pope of the Roman Catholic Church, from whom it can expect final authority, the Anglican Communion consists of national, autonomous churches that are bound together by intangible links best described as ties of loyalty between the see of Canterbury and each other. Although the archbishop of Canterbury is respected throughout the Communion and his words carry great moral authority, he exercises no jurisdiction over any part of the Communion other than over the diocese of Canterbury and over the Church of England as a whole through the authority vested in synods

Role of the
archbishop
of Can-
terbury

and convocations. Like a family the Anglican Communion changes its form and shape, increasing when new provinces (areas of jurisdiction) are formed and decreasing when schemes of union with non-Anglican churches are consummated. The basic unit of the Anglican Communion is the diocese, a geographic area over which a bishop presides. Dioceses generally form part of a larger unit known as a province, but even these are far from uniform in configuration. A province, for example, may be part of an autonomous church: the Anglican church in Australia has five provinces and the one in Canada four; the churches of England and Ireland have two each; and the Protestant Episcopal Church in the United States of America has nine. Some provinces, however, include whole countries, such as Japan, South Africa, West Africa, Kenya, Uganda, and Tanzania; other provinces cover a number of countries, such as the provinces of Central Africa, the West Indies, and the Southern Cone of America. On occasion, one diocese covers a whole country or even several countries, such as the diocese of Polynesia.

Titles of
Anglican
ecclesi-
astical
leaders

Variations occur in the titles of the heads of the various provinces or national churches. England has two archbishops (Canterbury and York), known as metropolitans, as does Ireland. Canada has a primate (who has no province) and four metropolitans; Australia has five archbishops, one of whom—while having jurisdiction over a province—is known as the primate. The Church of Japan and the Episcopal Church of Brazil each has a primate who also has a diocese, and the United States has a presiding bishop and a primate, both without a diocese. To complicate organizational matters, the Scottish Episcopal Church has a primus (primate), and the Protestant Episcopal Church in the United States has presidents (who are elected only for three-year periods) of its nine provinces. Several branches of the church exist apart from provincial or national churches, though usually in reliance upon either the Church of England or the Episcopal Church in the United States. A number of dioceses in Central America, such as Guatemala, Honduras, Nicaragua, and El Salvador, participate in the Episcopal Church, though with the goal of eventual autonomy in a Central American province. The Church in Hong Kong is a special adjunct to the Council of the Church of East Asia, and the Church of Bermuda is an extra-provincial see of the Church of England. In some areas, such as China (Three Self Movement), India (Church of North India and Church of South India), and Pakistan, Anglicans have participated in the creation of ecumenical forms of church union.

Internal developments. The mother church of the Anglican Communion, the Church of England, has maintained close connections with the state; it has representative bishops in the House of Lords and can properly be called the established church, even though, contrary to much popular opinion, it is in no sense supported financially by the state. The Church of England itself is without question the church of the English people, even though many of the country's citizens do not so regard it. Only in England do Anglicans comprise a majority, accounting for more than one-half of the world Anglican population.

Apart from its assured position in the life of England, the Anglican Communion has never had much of a worldwide structure. Indeed, the Anglican Communion has been characterized by its lack of structured cohesion. Even meetings of Anglican Church leaders have been restricted, except in very recent times, to the meetings of the Lambeth conferences, which are held only once every 10 years, and to Pan-Anglican congresses, which involve clergy and laity as well as bishops. Only three such meetings have been held in the 20th century: in London in 1908, Minneapolis, Minn., in 1954, and Toronto in 1963. At two- or three-year intervals between Lambeth conferences meetings of the Anglican Consultative Council are held. While it has no real authority, the council gives cohesion to the Anglican Communion between Lambeth conferences. The council replaced the Lambeth Consultative Body, whose members were the primates or presiding bishops of the various national churches and also replaced the Advisory Council on Missionary Strategy, which came into being after World War II. The Lambeth Conference

Anglican
Con-
sul-
ta-
tive
Council

of 1968 recommended formation of the Anglican Consultative Council, and that body has assumed primary responsibility for coordinating the global Anglican network. The council is an advisory body of about 60 members, including bishops, clergy, and lay people. It shares information, coordinates policy, and develops unified mission strategies. Though lacking binding authority, the council has the archbishop of Canterbury as its president, and it increases the Anglican tendency toward consultation in matters of faith and life. The Lambeth Conference of 1978 recommended that the primates (heads) of all Anglican provinces meet regularly, and they have since done so in various countries of the Anglican Communion.

The importance of conversation among Anglicans has been underscored by the extent of change in some branches of the Anglican Communion. In the second half of the 20th century most churches of the Anglican world revised their versions of *The Book of Common Prayer*. Decentralized and autonomous, Anglican branches have this freedom, although they are constrained by a sense of coordinating their efforts. In the United States revision of the Episcopal Church's prayer book was extensive. The new prayer book of 1979 incorporated years of liturgical study, of trial drafts, and of discussion. It offered unprecedented liturgical options, including use of modern English liturgies and opportunities for informal worship. The book generated controversy, which abated only slowly.

Equally controversial was the admission of women to the church's priesthood and the prospect of women bishops. Women had been ordained priests in Hong Kong in 1944 and in 1971. By the mid-1970s large numbers of women in various parts of the Anglican world called for the priesthood to be opened to them. The impact was greatest in the United States and Canada, where women became a significant percentage of seminary students. American Episcopalians approved women as priests in 1976 after heated debate. While several other Anglican churches took a similar course, the Church of England hesitated to study and to debate the issue. Opponents of the ordination of women feared the loss of the church's Catholic heritage. Advocates saw a chance for Anglican leadership in expanding the ministries open to women in the church. The Lambeth Conference of 1988 confronted the possibility that a woman would be chosen bishop in the United States, forcing the issue of women's ministries into the international context.

Global mission has remained a priority for Anglicans, but the gradual penetration of Latin America has been a recent feature. While recognizing and respecting the pervasive influence of Roman Catholicism in the area, Anglicans have found a niche among unchurched people. Social mission, education, and provision of indigenous leaders have characterized this phase of Anglican expansion. There has also been impressive growth in Africa and Asia, all sparked by indigenous leadership, and Anglicanism has thus become as much a non-Western as a Western form of Christianity.

Relations with other churches. Because the Anglican Communion consists of a cluster of related churches, it does not, as a worldwide Communion, have membership in the World Council of Churches; each of the Anglican churches, however, holds such membership. This type of ecumenical relationship is in keeping with one of the consistent goals of Anglicanism. Anglicans see themselves as catalysts for Christian unity, and the Anglican blend of Catholic liturgy and Protestant procedure affords the basis of broad ecumenical encounter. Within Anglicanism there is a common point with virtually all other expressions of the Christian faith. Anglicans readily engage Roman Catholic, Orthodox, and Protestant leaders in theological discussion and joint liturgy. Ecumenical processes involving the Catholic Church have been regular and intensive, though without prospect of organic reunion. The Anglican/Roman Catholic International Theological Commission has met regularly as have committees involving the Lutheran and Reformed traditions. For Anglicans ecumenical discussion is the appropriate context for advancing Christian mission.

World Anglicanism. The Anglican Communion has tried to establish itself as the middle way in Christianity,

attempting to bridge the gulfs between Protestant, Roman Catholic, and Eastern Orthodox churches. In 1947 Anglican dioceses were included in the new Church of South India, a communion that also included mission churches of the Methodists and Congregationalists. In other areas the Anglican Communion has special interchurch relations, as with the Lusitanian Church in Portugal, the Mar Thoma Syrian Church in India, the Old Catholic churches in Europe and the United States, the Philippine Independent Church, and the Spanish Reformed Episcopal Church. In the United States Anglicans took part in the Consultation on Church Union. In 1974 the Church of England and English Roman Catholics, Baptists, United Reformed, and Methodists agreed to form a national commission for discussions about practical reunion. Statements issued by Archbishop of Canterbury Robert Runcie and Pope John Paul II following a historic meeting between the two in England in 1982 emphasized the importance of the reconciliation effort.

(R.S.De./W.L.Sa.)

Baptists

Baptists are Protestant Christians who share the basic beliefs of most Protestants but who insist that only believers should be baptized and that it should be done by immersion rather than by the sprinkling or pouring of water. (This view, however, is shared by others who are not Baptists.) Although Baptists do not constitute a single church or denominational structure, most adhere to a congregational form of church government. Some Baptists lay stress upon having no human founder, no human authority, and no human creed.

HISTORY

Origins. Some Baptists believe that there has been an unbroken succession of Baptist churches from the days of John the Baptist and the Apostles of Christ. Others trace their origin to the Anabaptists (a 16th-century Protestant movement; see above *History of the Protestant movement*) on the European continent. Most scholars, however, agree that Baptists, as an English-speaking denomination, originated within 17th-century Puritanism as an offshoot of Congregationalism.

There were two groups in early Baptist life: the Particular Baptists and the General Baptists. The Particular Baptists adhered to the doctrine of a particular atonement—that Christ died only for an elect—and were strongly Calvinist (following the Reformation teachings of John Calvin) in orientation; the General Baptists held to the doctrine of a general atonement—that Christ died for all people and not only for an elect—and represented the more moderate Calvinism of Jacobus Arminius, a 17th-century Dutch theologian. The two currents were also distinguished by a difference in churchmanship related to their respective points of origin. The General Baptists had emerged from the English Separatists, whereas the Particular Baptists had their roots in non-Separatist independency.

Both the Separatists and the non-Separatists were congregationalist. They shared the same convictions with regard to the nature and government of the church. They believed that church life should be ordered according to the pattern of the New Testament churches, and to them this meant that churches should be self-governing bodies composed of believers only.

They differed, however, in their attitude toward the Church of England. The Separatists contended that the Church of England was a false church and insisted that the break with it must be complete. The non-Separatists, more ecumenical in spirit, sought to maintain some bond of unity among Christians. While they believed that it was necessary to separate themselves from the corruption of parish churches, they also believed that it would be a breach of Christian charity to refuse all forms of communication and fellowship. While many non-Separatists withdrew and established a worship of their own, they would not go so far as to assert that the parish churches were devoid of all marks of a true church.

Growth in England and abroad. Although the Particular Baptists were to represent the major continuing Baptist

tradition, the General Baptists were first to appear. In 1608 religious persecution induced a group of Lincolnshire Separatists to seek asylum in Holland. A contingent settled in Amsterdam with John Smyth (or Smith), a Cambridge graduate, as their minister; another group moved to Leiden under the leadership of John Robinson. When the question of baptism arose during a debate on the meaning of church membership, Smyth concluded that, if the Separatist contention that “churches of the apostolic constitution consisted of saints only” was correct, then baptism should be restricted to believers only. This, he contended, was the practice of the New Testament churches, for he could find no scriptural support for baptizing infants. Smyth published his views in *The Character of the Beast* (1609) and in the same year proceeded to baptize first himself and then 36 others, who joined him in forming a Baptist church. Shortly thereafter Smyth became aware of a Mennonite (Anabaptist) community in Amsterdam and began to question his act of baptizing himself. This could be justified, he concluded, only if there was no true church from which a valid baptism could be obtained. After some investigation Smyth recommended union with them. This was resisted by Thomas Helwys and other members of the group, who returned to England in 1611 or 1612 and established a Baptist church in London. The parent group in Amsterdam soon disappeared.

The Particular Baptists stemmed from a non-Separatist church that was established in 1616 by Henry Jacob at Southwark, across the Thames from London. In 1638 a number of its members withdrew under the leadership of John Spilsbury to form the first Particular Baptist Church.

The two decades from 1640 to 1660 constituted the great period of early Baptist growth. Baptist preachers won many adherents around the campfires of the Puritan leader Oliver Cromwell’s army. The greatest gains were made by the Particular Baptists, while the General Baptists suffered defections to the Quakers. After the Restoration of the Stuarts in 1660 both groups were subjected to severe disabilities until these were somewhat relaxed by the Act of Toleration of 1689.

During the following decades the vitality of the General Baptists was drained by the inroads of skepticism, and their churches generally dwindled and died or became Unitarian. The Particular Baptists retreated into a defensive, rigid hyper-Calvinism. Among the Particular Baptists in England renewal came as a result of the influence of the Evangelical Revival, with a new surge of growth initiated by the activity of the English Baptist clergymen Andrew Fuller, Robert Hall, and William Carey. Carey, in 1792, formed the English Baptist Missionary Society—the beginning of the modern foreign missionary movement in the English-speaking world—and became its first missionary to India. A New Connection General Baptist group, Wesleyan in theology, was formed in 1770, and a century later, in 1891, it united with the Particular Baptists to form the Baptist Union of Great Britain and Ireland.

By the end of the 19th century Baptists, together with the other Nonconformist churches, were reaching the peak of their influence in Great Britain, numbering among their preachers several men with international reputations. Baptist influence was closely tied to the fortunes of the Liberal Party, of which the Baptist David Lloyd George was a conspicuous leader. After World War I English Baptists began to decline in influence and numbers.

Baptist churches were established in Australia (1831) and New Zealand (1854) by missionaries of the English Baptist Missionary Society. In Canada, Baptist beginnings date from the activity of Ebenezer Moulton, a Baptist immigrant from Massachusetts who organized a church in Nova Scotia in 1763. In Ontario the earliest Baptist churches were formed by United Empire Loyalists who crossed the border after the American Revolution, while other churches were established by immigrant Baptists from Scotland and by missionaries from Vermont and New York.

Development in the United States. Baptist churches in the English colonies of North America were largely indigenous in origin, being the product of the leftward movement that was occurring among the colonial Puritans at

The question of baptism

Particular Baptists and General Baptists

Survival and expansion of Particular Baptists

the same time as it was in England. While some emigrants went to the New World as Baptists, it was more typical for them to adopt Baptist views after their arrival in the colonies, as happened in the case of Henry Dunster, the first president of Harvard College, and Roger Williams.

Colonial period. The first Baptist Church in North America was established at Providence in 1639 by Roger Williams shortly after his banishment from the Massachusetts Bay Colony. Although Williams' general Calvinist theological position was roughly analogous to that of Spilbury, prior to becoming a Baptist he had adopted the narrower Separatist view of the church. Williams soon came to the conclusion that all churches, including the newly established church at Providence, lacked a proper foundation, and that this defect could be remedied only by a new apostolic dispensation, when new apostles would appear to reestablish the true church.

The defection of Williams left the church with no strong leadership and thus made it possible for it to be reorganized on a General Baptist platform in 1652. There was scattered General Baptist activity throughout the colonies, but the only large cluster of General Baptists was in Rhode Island, where the churches were united into an association in 1670. The early General Baptists never gained great strength. Most of their churches decayed, and some, including the Providence church, were reorganized as Particular Baptist churches. The half dozen churches that survived never entered the mainstream of American Baptist life and exerted little influence upon its development.

The earliest strong Particular Baptist centre in the colonies was at Newport, R.I., where, between 1641 and 1648, a church that had been gathered by the physician and minister John Clarke adopted Baptist views. Except for a church that had a brief existence at Kittery, Maine, there were only two other Particular Baptist churches in New England for the better part of a century. One was at Swansea, Mass.; the other was organized at Boston in 1665. Another Particular Baptist church was established at Charleston, S.C., in 1683 or 1684.

The centre of Particular Baptist activity in early America was in the Middle Colonies. In 1707 five churches in New Jersey, Pennsylvania, and Delaware were united to form the Philadelphia Baptist Association, and through the association they embarked upon vigorous missionary activity. By 1760 the Philadelphia association included churches located in the present states of Connecticut, New York, New Jersey, Pennsylvania, Delaware, Virginia, and West Virginia; and by 1767 further multiplication of churches had necessitated the formation of two subsidiary associations, the Warren in New England and the Ketochton in Virginia. The Philadelphia association also provided leadership in organizing the Charleston Association in the Carolinas in 1751.

Although this intercolonial Particular Baptist body provided leadership for the growth that characterized American Baptist life during the decades immediately preceding the American Revolution, that growth was largely a product of an 18th-century religious revival known as the Great Awakening. Though they participated directly in the Awakening only during its last phase in the South, Baptists attracted large numbers of recruits from among those who had been "awakened" by the preaching of others. In addition to strengthening and multiplying the "regular" Baptist churches, the Awakening in New England produced a group of revivalistic Baptists, known as Separate Baptists, who soon coalesced with the older New England Baptist churches. In the South, however, they maintained a separate existence for a longer period of time. Shubael Stearns, a New England Separate Baptist, migrated to Sandy Creek, N.C., in 1755 and initiated a revival that quickly penetrated the entire Piedmont region. The churches he organized were brought together in 1758 to form the Sandy Creek Association. Doctrinally these churches did not differ from the older "regular" Baptist churches, but what the older churches saw as their emotional excesses and ecclesiastical irregularities created considerable tension between the two groups. By 1787, however, a reconciliation had been effected.

In several of the colonies, Baptists laboured under legal

disabilities. The public whipping of Obadiah Holmes in 1651 for his refusal to pay a fine that had been imposed for holding an unlawful meeting in Lynn, Mass., caused John Clarke to write his *Ill News from New England* (1652). Fourteen years later Baptists of Boston were fined, imprisoned, and denied the use of a meetinghouse they had erected. Payment of taxes for support of the established church was a cause of continuing controversy in New England, while the necessity to secure licenses to preach became an inflammatory issue in Virginia.

In the 19th century. The problem of travel had made it difficult for the Philadelphia association to serve as a bond uniting Baptists, and the rapid multiplication of churches made it impossible. It has been estimated that immediately before the American Revolution there were 494 Baptist congregations; 20 years later, in 1795, Isaac Backus estimated the number at 1,152. The initial expedient of the Philadelphia association had been to organize subsidiary associations, but during the war the churches, left to their own devices, proceeded to organize independent associations. By 1800 there were at least 48 local associations, and the main problem was to fashion a national body to unite the churches. The final impetus in this direction came from an interest in foreign missions. Among the first missionaries of the newly organized Congregational mission board were Adoniram Judson and Luther Rice, who had been sent to India. On shipboard they became convinced by a study of the Scriptures that only believers should be baptized. Upon arrival at Calcutta, Judson went on to Burma, while Rice returned home to enlist support among American Baptists. As a result of Rice's efforts a General Convention of the Baptist denomination was formed in 1814. Its scope was almost immediately broadened to include, in addition to the foreign mission interest, a concern for home missions, education, and the publication of religious periodicals. In 1826 the General Convention once again was restricted to foreign mission activities, and in the course of time it became known as the American Baptist Foreign Mission Society. Other denominational interests were served by the formation of additional societies with similar specialized concerns, such as the American Baptist Home Mission Society and the American Baptist Publication Society.

The unity achieved through these societies was disrupted by the slavery controversy. During the decade prior to 1845 various compromises between the proslavery and antislavery parties in the denomination were attempted, but they proved to be unsatisfactory. As a result a Southern Baptist Convention was organized at Augusta, Ga., in 1845. Although its constitution provided for boards of home and foreign missions, education, and publication, its energies were devoted largely to foreign missions. Consequently, the American Baptist Home Mission Society and the American Baptist Publication Society continued to operate in the South after the Civil War. Later the Southern Baptist Convention began to develop its own home mission and publication work and to protest the intrusion of the older societies in the South. The final separation between Baptists of South and North was formalized in 1907 by the organization of the Northern Baptist Convention (in 1950 renamed the American Baptist Convention and after 1972 called the American Baptist Churches in the U.S.A.), which brought together the older societies and accepted a regional allocation of territory between the Northern and Southern conventions.

Development of black churches. Black churches constitute a major segment of American Baptist life. Many slaves were converted and became members of Baptist churches during the Great Awakening. While there were black Baptist churches prior to the Civil War, they rapidly multiplied following the Emancipation Proclamation (1863), an edict freeing the slaves in the United States. State and regional conventions were formed, and the National Baptist Convention was organized in 1880. By 1900 black Baptists outnumbered black adherents of all other denominations. Throughout the Jim Crow years of segregation and exclusion from most aspects of American life, black churches were the focal point of black communal life. In the civil rights struggle of the 1960s the major leadership,

Formation
of General
Convention

National
Baptist
Convention

Philadel-
phia
Baptist
Associa-
tion

including that provided by Martin Luther King, Jr., came out of black churches.

Developments in education. From the beginning American Baptists displayed an interest in an educated ministry. The Philadelphia association in the 18th century collected funds to help finance the education of ministerial candidates. Hopewell Academy was established in 1756, and in 1764 Brown University was founded in Rhode Island midway between Nova Scotia and Georgia. After 1800 educational institutions multiplied rapidly. The educational advance culminated in 1891 in the founding of the University of Chicago.

During the 20th century. After 1900 Baptists were troubled by theological controversies that led to the formation of several new Baptist groups. Some of the tensions arose over questions of structure of church organization, some arose over refusals to adopt an authoritative creedal statement, some were created by converts among new immigrants, and some were the product of dissatisfaction with the affiliation of the American Baptist Convention with interdenominational and ecumenical bodies. Questions of organizational structure were involved in the formation of the American Baptist Association in 1905 by churches located primarily in Oklahoma, Texas, and Arkansas. Two other groups were products of the Fundamentalist controversy: the General Association of Regular Baptist Churches, organized in 1932; and the Conservative Baptist Association of America (1947).

During the post-World War II period the Southern Baptist Convention abandoned its regional limitations. Because of increasing mobility of population, it became necessary for the convention to follow its members to the growing urban centres of the North and West. By the second half of the 20th century Southern Baptists had become the largest Protestant body in the United States, and their churches were located in every part of the country.

Following World War II Southern Baptists increasingly isolated themselves from other Christian churches, feeling no need to cooperate with them in common enterprises. During these years they also developed centralized operations through the boards and agencies of the Convention. Participation in the "Cooperative (mission) Program" and utilization of the materials and activities supplied by the Sunday School Board became badges of loyalty. These programs were carefully devised and eminently successful in promoting numerical growth.

Meanwhile, dissident Southern Baptists, based initially in the old southwest of Tennessee, Mississippi, Louisiana, Arkansas, and especially Texas, began to become influential elsewhere. They were heirs of an older isolationism that had long been kept in check but gained major new impetus from a radical fundamentalism developing strength in the South after World War II. Led by a small coterie of Texas strategists, the dissidents put a plan into operation in 1979 by which they gained control of and imposed their views on the bureaucracy and theological seminaries of the Southern Baptist Convention. No room for a difference of opinion was left except at the local level.

Growth outside the United States. While Baptists have been troubled by divisive tendencies during the 20th century, there has also been a tendency toward greater unity and cohesiveness through the Baptist World Alliance. The 19th century was a period of great Baptist missionary activity. The endeavour in Asia was led by William Carey in India, Adoniram Judson in Burma, and Timothy Richard in China. The initial Baptist presence in Africa began in 1793 when David George, a former slave from South Carolina, reached Sierra Leone by way of Halifax, N.S. More organized activity was initiated in 1819 by black Baptists of Richmond, Va., who sent Lott Cary to Sierra Leone in 1821 and then shifted his base of operations to Liberia in 1824. By the late 20th century there were major concentrations of Baptists in Zaire, Nigeria, and Cameroon. Of later origin is the Baptist community in Latin America.

The pioneer Baptist in Europe was Johann Gerhard Oncken, who organized a church at Hamburg in 1834. Oncken had become acquainted with Barnas Sears of Colgate Theological Seminary, who was studying in Germany, and with six others he was baptized by Sears. From

this centre, evangelistic activity was extended throughout Germany, and missions were established elsewhere in eastern Europe. Baptist activity was initiated independently in France, Italy, and Spain. Swedish Baptist beginnings date from the conversion of Gustaf W. Schroeder, a sailor baptized in New York in 1844, and Frederick O. Nilsson, also a sailor, who was baptized by Oncken in 1847.

The expansion of the Baptist community in Asia, Africa, Latin America, and Europe led to the formation of the Baptist World Alliance in London in 1905. The purpose of the alliance is to provide mutual encouragement, exchange of information, coordination of activities, and consciousness of the larger Baptist fellowship.

The most notable growth occurred in Russia, where a Russian Baptist Union was formed in 1884 as the result of influences stemming from Oncken. Another Baptist body, the Union of Evangelical Christians, was organized in 1908 by a Russian who had come under the influence of English Baptists. Persecution of Baptists, which had been severe, was relaxed in 1905, and within the remaining disabilities a moderate growth occurred. The Revolution of 1917, with its proclamation of liberty of conscience, marked the beginning of a period of astonishing advance: by 1927 the Russian Baptist Union numbered some 500,000 adherents, while the Union of Evangelical Christians embraced more than 4,000,000. The Soviet constitution of 1929 subjected them to pressure once again, however. Membership in the two groups, which combined in 1944 to form the All-Union Council of Evangelical Christians-Baptists in the U.S.S.R., declined sharply, but an estimated membership of more than 500,000 in the 1980s testified to the tenacity with which these believers held their faith.

TEACHINGS

History. Initially Baptists were characterized theologically by strong to moderate Calvinism. The dominant continuing tradition in both England and the United States was Particular Baptist. By 1800 this older tradition was beginning to be replaced by evangelical doctrines fashioned by the leaders of the evangelical revival in England and the Great Awakening in the United States. By 1900 the older Calvinism had almost completely disappeared, and Evangelicalism was dominant. The conciliatory tendency of Evangelicalism and its almost complete preoccupation with "heart religion" and the experience of conversion largely denuded it of any solid theological structure, thereby opening the door to a new theological current that subsequently became known as Modernism. Modernism, which was an attempt to adjust the Christian faith to the new intellectual climate, made large inroads among the Baptists of England and the United States during the early years of the 20th century, and Baptists provided many outstanding leaders of the movement, including Shailer Mathews and Harry Emerson Fosdick. Many people regarded these views as a threat to the uniqueness of the Christian revelation, and the counter-reaction that was precipitated became known as Fundamentalism (a movement emphasizing biblical literalism).

As a result of the controversy that followed, many Baptists developed a distaste for theology and became content to find their unity as Baptists in promoting denominational enterprises. By 1950, outside the South, both Modernists and Fundamentalists were becoming disenchanted with their positions in the controversy, and it was from among adherents of both camps that a more creative theological encounter began to take place. While the majority of Baptists remained nontheological in their interests and concerns, there were many signs that Baptist leadership was increasingly recognizing the necessity for renewed theological inquiry.

Contents. The unity and coherence of the Baptists is based on six distinguishing, although not necessarily distinctive, convictions they hold in common.

1. The supreme authority of the Bible in all matters of faith and practice. Baptists are a non-creedal people, and their ultimate appeal always has been to the Scriptures rather than to any confession of faith that they may have published from time to time to make known their commonly accepted views.

Developments in Russia

Central aspects of Baptist doctrine

Fundamentalist Southern Baptists

2. Believer's baptism. This is the most conspicuous conviction of Baptists. They hold that if baptism is the badge or mark of a Christian, and if a Christian is a believer in whom faith has been awakened, then baptism rightly administered must be a baptism of believers only. Furthermore, if the Christian life is a sharing in the life, death, and resurrection of Christ, if it involves a dying to the old life and a rising in newness of life, then the act of baptism must reflect these terms. The sign must be consonant with that which it signifies. It is for this latter reason that Baptists were led to insist upon immersion as the apostolic form of the rite.

3. Churches composed of believers only. Baptists reject the idea of a territorial or parish church and insist that a church is composed only of those who have been gathered by Christ and who have placed their trust in him. Thus the membership of a church is restricted to those who—in terms of a charitable judgment—give clear evidence of their Christian faith and experience.

4. Equality of all Christians in the life of the church. By the doctrine of the priesthood of all believers Baptists not only understand that the individual Christian may serve as a minister to other members but also that each church member has equal rights and privileges in determining the affairs of the church. Pastors have special responsibilities, derived from the consent of the church, which only they can discharge, but they have no unique priestly status.

5. Independence of the local church. By this principle Baptists affirm that a properly constituted congregation is fully equipped to minister Christ and need not derive its authority from any source, other than Christ, outside its own life. Baptists, however, have not generally understood that a local church is autonomous in the sense that it is isolated and detached from other churches. As individual Christians are bound to pray for one another and to maintain communion with one another, so particular churches are under similar obligation. Thus, the individual churches testify to their unity in Christ by forming associations and conventions.

6. Separation of church and state. From the time of Smyth, Baptists have insisted that a church must be free to be Christ's church, determining its own life and charting its own course in obedience to Christ without outside interference. Thus Smyth asserted that the

magistrate is not by virtue of his office to meddle with religion or matters of conscience, to force and compel men to this or that form of religion or doctrine, but to leave Christian religion free to every man's conscience.

Baptists were in the forefront of the struggle for religious freedom in both England and the United States. They cherished the liberty established in early Rhode Island, and they played an important role in securing the adoption of the "no religious test" clause in the U.S. Constitution and the guarantees embodied in the First Amendment.

Few Baptists have been willing to become so sectarian as to deny the Christian name to other denominations. With the exception of the Southern Baptists, most Baptists cooperate fully in interdenominational and ecumenical bodies, including the World Council of Churches.

WORSHIP AND ORGANIZATION

Baptist worship is hardly distinguishable from the worship of the older Puritan denominations (Presbyterians and Congregationalists) of England and the United States. It centres largely on the exposition of the Scriptures in a sermon and emphasizes extemporaneous, rather than set, prayers. Hymn singing also is one of the characteristic features of worship. Communion, received in the pews, is customarily a monthly observance.

Baptists insist that the fundamental authority, under Christ, is vested in the local congregation of believers, which admits and excludes members, calls and ordains pastors, and orders its common life in accord with what it understands to be the mind of Christ. These congregations are linked together in cooperative bodies—regional associations, state conventions, and national conventions—to which they send their delegates or messengers. The larger bodies, it is insisted, have no control or authority over a

local church; they exist only to implement the common concerns of the local churches.

The pattern of organization of the local church has been undergoing change during the 20th century. Traditionally the pastor was the leader and moderator of the congregation, but there has been a tendency to regard the pastor as an employed agent of the congregation and to elect a lay member to serve as moderator at corporate meetings of the church. Traditionally the deacons' functions were to assist the pastor and to serve as agents to execute the will of the congregation in matters both temporal and spiritual; there has been a tendency, however, to multiply the number of church officers by the creation of boards of trustees, boards of education, boards of missions, and boards of evangelism. Traditionally decisions were made by the congregation in a church meeting, but there has been a tendency to delegate decision making to various boards. The relationship of local churches to the cooperative bodies has been undergoing similar change, and this has occasioned continuing discussion among all Baptist groups. (W.S.H.)

Congregationalists

Congregationalists are members of a group of churches that arose in England in the late 16th and 17th centuries. Originally they were frequently called Independents, as they still are in Welsh-speaking communities. The main centres of Congregationalism traditionally were in Britain and the United States, but in the 20th century Congregationalists have joined with others to form united churches in these and several other countries.

Congregationalism has occupied a position among the churches somewhere between Presbyterianism and the more radical Protestants, such as non-Fundamentalist Baptists and Quakers. Its distinctive emphasis has been on the right and responsibility of each properly organized congregation to make its own decisions about its own affairs, without having to submit them to the judgment of any higher human authority. Although this was not always true in the early days in America, Congregationalists have generally been distrustful of state establishment of religion and have been workers for civil and religious liberty. Their emphasis on the rights of the particular congregation and on freedom of conscience arose historically from their strong Protestant convictions concerning the sovereignty of God and the priesthood of all believers. This attitude has given them an openness of outlook that has led many of them to theological and social liberalism and to active participation in the ecumenical movement.

HISTORY

England. The "Congregational way" came into prominence in English life during the 17th-century Civil War, but its origins lie in 16th-century Separatism. Robert Browne is sometimes taken as its founder, but he was an erratic character who changed his views more than once. Congregational ideas were in the air, finding expression independently of him. The Separatists (those advocating separation from rather than reform of the Church of England) were severely persecuted under Elizabeth I; three of them—John Greenwood, Henry Barrow, and John Penry—were the first Congregational martyrs. Some of the Separatists settled in Holland to escape persecution, and it was from among these that the *Mayflower* Separatists later set sail for the New World (see below, *United States*).

At the time of the Long Parliament, beginning in 1641, many exiles returned to England, and the Independents, as they were now called, became increasingly active. They were particularly influential in the army, having Oliver Cromwell himself associated with them. They began to move away from the Presbyterians, with whom they had initially cooperated, and to draw closer to the Baptists and the Fifth Monarchy Men (a Puritan millennialist sect). They reached the peak of their influence during the Commonwealth in the 1650s, and their leaders, Hugh Peter, John Owen, and Thomas Goodwin, held positions of eminence. With the death of Cromwell (1658) they lacked the conviction and power of initiative to hold the country

The
Separatists

together, and in the confused period before the recall of King Charles II in 1660 their political influence collapsed.

The advent of Charles II was a disaster for Congregationalists, and the Act of Uniformity of 1662 was the first of a series of determined efforts to root them out from English life. "Black Bartholomew," St. Bartholomew's Day, Aug. 24, 1662, when some 2,000 ministers of various Protestant groups who rejected the authority of the Church of England were ejected from their livings, has always been regarded as a great turning point in the history of English Dissent. All Nonconformists were subjected to a persecution that, although severe, was not so intense as to imperil their existence. In this time John Owen and others produced some of the classical statements of Congregational belief; John Milton produced his greatest poems; and John Bunyan, although his closest affinities were with the Baptists, imprinted some of the characteristic religious attitudes of the Dissenters indelibly on the English consciousness.

The accession of William and Mary in 1688 and the consequent Toleration Act of 1689 meant that the survival of the Congregationalists was assured, although still under civil disabilities. Their fears were renewed by the advent of Queen Anne (1702). The Occasional Conformity Act (1711) forbade Dissenters from qualifying for public office by occasionally taking communion at the Anglican parish church, and the Schism Act (1714) was directed against their schools. The death of Queen Anne in 1714, before the Schism Act could be fully implemented, was considered providential by the Dissenters. They supported the new regime and the Whig ascendancy and for the next 50 years enjoyed a modest prosperity. Most of them belonged to the economically independent sections of society and lived in London and the older provincial towns. They were especially active in education. After 1662 Dissenters were debarred from the universities, and many ejected ministers started small schools and colleges called academies, which gradually became more numerous and influential. Their curricula, influenced by the educational theories of Francis Bacon and John Amos Comenius, were more relevant than those of the comatose universities, and they were the precursors of many later educational developments.

Religious zeal was declining as the 17th century waned, and rationalism became more influential. Deism and Arrianism (a heresy denying the divinity of Christ) were widespread, the latter especially among the Presbyterians, some of whom gradually became Unitarian. That Congregationalism did not go the same way was in no small measure due to the influence of Philip Doddridge, minister of Northampton, who was a theologian, pastor, social reformer, educationist, and author of the devotional classic *The Rise and Progress of Religion in the Soul* (1745).

The quality of Congregationalism in the early 18th century has sometimes been disparaged, but its limitations were those of a small community in the aftermath of a period of great intensity of experience. A change came with the rise of Methodism and the Evangelical Revival (c. 1750–1815), which had a profound, if unobtrusive, influence on Congregationalism. Many ministers were deeply affected by the revival, and many people who were reached by the Methodist preaching found their way into the already existing Congregational churches. Thus the great evangelist George Whitefield had close relations with Congregationalism, and many of the churches founded by Selina Hastings, countess of Huntingdon, a leading figure in the revival, made and long retained a connection with Congregationalism. By 1815 the character of Congregationalism had been significantly changed in an Evangelical direction, especially in the developing industrial areas of Lancashire and Yorkshire.

The outstanding result of the Evangelical Revival in Congregationalism was the founding of the London Missionary Society (1795). Its purpose was not so much the spreading of Congregationalism overseas as the proclaiming of "the glorious gospel of the blessed God," leaving the churches it founded to find their own form. Its main support was always Congregational, and it has now been incorporated into the Council for World Mission of the United Reformed Church. Through its agency, churches

have been established in Africa, Madagascar, India, China, Papua New Guinea, and on islands in the South Seas. Many of these are now united in wider bodies, of which the most notable is the Church of South India.

In the first half of the 19th century Congregationalism was involved in a period of expansion and consolidation. Increased numbers brought many poorer people into the churches, and a new political and social radicalism began to emerge. Voluntarism, which opposed the state support of denominational education, and the Liberation Society, which advocated disestablishment, found widespread support. The Congregational Union of England and Wales, linking the churches in a national organization, was founded in 1832 and the Colonial (later the Commonwealth) Missionary Society, for promoting Congregationalism in the English-speaking colonies, in 1836.

Congregational churches shared fully in the ecclesiastical prosperity of the Victorian era. Many new buildings were erected, often in ambitious Gothic style, and the cult of the popular preacher developed. Able ministers, among whom R.W. Dale of Birmingham was outstanding, deeply influenced the public life of Victorian cities. The links of the churches with the Liberal Party were greatly strengthened, and the civic disabilities of Dissenters were steadily removed. Thriving churches in new suburbs developed into hives of social, philanthropic, and educational activity. The picture of the philistine (unimaginative) Dissenters drawn by the poet and critic Matthew Arnold in *Culture and Anarchy* (1869) contained a measure of truth, but the work's lack of historical perspective led it to underestimate the zeal for self-improvement and the desire for a richer life that existed in Victorian Congregationalism.

The Liberal victory of 1906 represented the peak of the social and political influence of Congregationalism. After that, Congregational churches shared in the institutional decline of most British churches, but they continued to show theological and cultural vitality. In October 1972 the majority of English Congregationalists and Presbyterians united to form the new United Reformed Church, which was joined in 1981 by the Churches of Christ, the small British counterpart of the American Disciples of Christ.

Wales, Ireland, and Scotland. Welsh-speaking Congregational churches did not join the United Reformed Church but have their separate organization in the Union of Welsh Independents. These churches grew up originally in the countryside but transplanted themselves with remarkable success to the developing industrial valleys in the 19th century. The churches have been strong centres of distinctively Welsh culture, and their ministers have often been national leaders. Their influence diminished in the 20th century as population moved away from old centres of strength, but Welsh Congregationalists maintain their tradition of preaching, poetry, and hymnody.

Congregationalism in Scotland has been less prominent, and in Ireland it has struck only a very small root. In Scotland it arose in the 19th century out of dissatisfaction with the lack of missionary zeal of the Church of Scotland and soon united with a similar group called the Evangelical Union. Numerically small, it has made a distinctively liberal contribution to Scottish life and has given many notable sons to the church-at-large, among them the missionaries David Livingstone and Robert Moffat and the writer George MacDonald, as well as Peter Taylor Forsyth.

United States. It was in the United States that Congregationalism achieved its greatest public influence and numerical strength, and, through the New England experiment, in setting up communities based on Congregational-type religious principles, it was a major factor in determining the character of the nation. The New England settlement had two roots, in the Separatism of Plymouth Colony and in the Puritanism of Massachusetts Bay. The first Separatists came on the *Mayflower* in 1620 from the exiled church at Leiden, Holland. The Puritans wished to reform the Church of England rather than to leave it, and they left England in order to build a "godly commonwealth" that would be an example to old England of what a new England, truly reformed according to the Word of God, might be. They were closer in spirit to the English Presbyterians than to the Separatists, but there

Persecution of Nonconformists

Links with the Liberal Party

Influence of Methodism and Evangelical Revival

The New England experiment

was enough affinity between the two groups to enable them to live together in comparative harmony and to reject more radical leaders such as Roger Williams and Anne Hutchinson. In 1648 the two groups united to produce the Cambridge Platform, a declaration of faith that accepted the theological position of the Westminster Confession but maintained a Congregational polity. (The English Congregationalists produced a similar statement, the Savoy Declaration, in 1658.)

The original experiment demanded a radical commitment of an intellectual and spiritual intensity that made the New England colony unique in history. As the community became established and a second generation grew up, it became difficult to maintain the high standard, and the rigorous conditions for church membership had to be relaxed. This need found expression in the famous Half-Way Covenant, which said that those who had been baptized but could not enter into full church membership on the basis of the kind of religious experience considered appropriate were accepted as church members but not admitted to communion or allowed to have voting rights.

The community was keenly interested in education from the outset, and one of its earliest acts was to start a college to maintain the succession of learned ministers. Thus was founded Harvard College (1636), the first of a long line of colleges begun under Congregational auspices in America.

The Great Awakening

The gradual loss of religious fervour caused great distress and self-questioning to the Congregational leaders, but a quickening of new life came with the 18th-century Great Awakening, the widespread revival movement that started in 1734 under the influence of Jonathan Edwards. The Awakening, however, threw into relief the differences emerging between two wings in Congregationalism. On the one side were those who maintained the Calvinist tradition, creatively restated by Edwards and his followers, with a greater emphasis on the affective elements in religion. On the other was a rapidly growing Unitarianism, parallel to a similar movement in England. By the early 19th century many of the oldest Congregational churches had become Unitarian, including 12 of the 14 in Boston. Unitarianism was not so prevalent in Connecticut, where Congregationalism had quickly taken root and remained the established church until well into the 19th century.

Although the loss to Unitarianism was serious, Congregationalism remained vigorous in the 19th century and was active in the westward expansion of the nation. The Presbyterians were almost nonexistent in New England but strong in the Middle Atlantic states, where Congregationalism had little root. The two bodies adopted a Plan of Union in 1801 for joint missionary activity in the developing territories. One of the reasons for the ultimate breakdown of this arrangement after half a century was the growing liberalism of Congregationalism. The characteristic theologian of this period was Horace Bushnell, who challenged the traditional substitutionary view of the Atonement (that Christ's suffering and death atoned for man's sins), and whose well-known book, *Christian Nurture* (1847), questioned the necessity of the classical conversion experience. Such influential preachers as Henry Ward Beecher and Washington Gladden popularized similar ideas. The so-called Kansas City Creed of 1913 summed up the liberalism of this period, which represented a radical break with the Calvinist past.

American Congregationalists have engaged in widespread missionary activity, particularly in the Middle East and in China before the Communist Revolution. A national Congregational organization was formed in 1871, and powerful Boards for Home Missions and Education were established, through which Northern Congregationalists did a great deal for black education in the South, where there were hardly any indigenous Congregational churches.

United Church of Christ

Modern American Congregationalism has shown itself singularly ready to unite with other churches. Union with a relatively small body called the Christian Church, which was concentrated in the upper South, was achieved between the world wars, and a more notable union was achieved with the Evangelical and Reformed Church in 1961. This was a strong community of German Lutheran and Reformed background, which claimed the eminent

theologians Reinhold Niebuhr and Paul Tillich among its ministers. The new church body is known as the United Church of Christ. A minority of Congregational churches refused to join the union, and these remain separate.

Congregationalism has not succeeded in becoming a popular worldwide form of church life, although it has been represented in most English-speaking countries. Congregationalists were prominent in the formation of the Church of South India in 1947. They have also become part of the United Church of Canada and of the Uniting Church in Australia. Through the International Congregational Council, united with the Reformed Alliance since 1970, they have had fraternal ties with churches of similar outlook in Europe, notably the Remonstrant Brotherhood of Holland and the Swedish Mission Covenant Church.

TEACHINGS

Throughout their history Congregationalists have shared the faith and general outlook of evangelical Protestantism in the English-speaking countries, but normally in a more liberalized way than would be customary among their nearest neighbours, the Presbyterians, the Methodists, and the Baptists. The English historian Bernard Manning once described their position as decentralized Calvinism, in contrast to the centralized Calvinism of Presbyterians. That description contains much truth about their doctrines and general outlook until well into the 19th century, but it underestimates the Congregational emphasis on the free movement of the Spirit. This provides a link with the Quakers and partly explains the Congregational distrust of giving binding authority to creedal statements. The other part of their distrust is explained by their anxiety to accord supreme authority to Scripture. They have not been slow to produce declarations of faith. In addition to the Savoy Declaration, the Cambridge Platform, and the Kansas City Creed already mentioned, lengthy statements have also been produced both by the United Church of Christ and by the English Congregationalists. No great authority is claimed for any of these, and in recent generations most Congregationalists have regarded the primitive confession, "Jesus is Lord," as a sufficient basis for membership.

Distrust of binding creedal statements

Similarly, they have always stressed the importance of freedom. Even in the days of their Cromwellian triumph they were tolerant by the standards of the time, and through the activities of the Protestant Dissenting Deputies, who had the right of direct access to the monarch, they contributed greatly in the 18th century to the establishment of the rights of minorities in England. Both in England and America the long-faced and repressive Puritan of tradition owes as much to the caricatures of political opponents and literary rebels as to actual fact.

WORSHIP AND ORGANIZATION

Practices. Congregationalism has always attached importance to preaching because the Word of God as declared in Scripture is regarded as constitutive of the church. Baptism and the Lord's Supper are considered to be the only sacraments instituted by Christ. Infants are baptized, normally by sprinkling. The Lord's Supper is normally celebrated once or twice a month and has not always been given a central place, often following a preaching service after a brief interval in which many of the congregation leave. In recent times, the unity of sermon and sacrament as parts of the same service has been much more strongly emphasized, and there has been a tendency to assimilate Congregational and Presbyterian practice to each other. Traditionally public prayer has been extempore, but in the 20th century service books and set forms have been increasingly used. Since the 18th century and the work of the great Congregationalist hymn writer Isaac Watts, hymns have featured prominently in Congregational worship. The English compilation, *Congregational Praise* (1951), worthily maintained the tradition.

Polity. The distinctive organizational tenet of Congregationalism has been that of the spiritual autonomy of the particular congregation. The congregation, however, is not thought of as any casual gathering of Christians but as a settled body with a well-defined constitution and proper offices that has tried to order itself in harmony with the

The Congregational principle

New Testament understanding of the nature of the church. The claim is made that if a church in a particular place possesses the Bible, the sacraments, a properly called and appointed minister and deacons, and members who have made a genuine Christian profession, no earthly body can be more fully the church than this. It follows that, as it is responsible to God for its life in that place, so it must have freedom to discern and obey God's will for itself, with no dictation from outside. Although this view carries with it respect for the rights of the individual conscience, it is not spiritual individualism but an attempt to treat the visible and corporate character of the church as concretely as possible.

It has always been recognized that this principle did not involve ecclesiastical isolation. "The communion of the churches with each other" was a frequent 17th-century theme. But the precise way in which churches should be related to the association and councils through which they expressed their communion has often caused uneasy debate. In the 19th century, thinking about this relation was affected by the individualism of the age, while in the more centralized and mobile 20th century, with the widespread movement toward mergers and redeployment, the positive role of councils has been stressed. The authentic Congregational principle would appear to be that, whatever adaptations of organization may be necessary in changing circumstances, responsibility and the freedom to fulfill it must always be as specific and personal as possible.

The
"gathered"
church

The idea of the "gathered" church is integral to traditional Congregationalism. It is a recognition that the primary agent in church foundation is not human but God's Spirit. Arising in protest against the Anglican territorial conception of the church, according to which all residents of a particular neighbourhood should be counted as members of the local Anglican church, it insisted that it was the duty and privilege of the believer to discover who else in the vicinity was called by Christ and then to walk together with them in church order, which was thought of not primarily as a matter of organization but of common style of life. Where the state or prelate tries to impose another principle, "the crown rights of the Redeemer" (Christ) in his church—a great phrase among Congregationalists—are impugned. How far the principle of the gathered church can be honestly applied in churches with large formal memberships is a problem modern Congregationalists have not solved, but great responsibilities remain with particular churches. All members are deemed to have equal rights and are expected to exercise them through membership of a church meeting that is empowered to deal with all matters pertaining to that particular church's life. Church meetings have not always been very vigorous and, especially in the United States, many of their powers have been delegated to officers or committees, but efforts have been made to restore them to their important place.

Ordination to the Congregational ministry has been through the ratification of the call of the individual by acceptance for training by the churches acting together, and then by the call from a particular church to act as its minister. This practice has been retained in most of the new united churches. The churches corporately set standards of training, which, particularly in the United States and Canada, is frequently conducted in interdenominational seminaries or universities.

Associa-
tions or
unions of
churches

Until new patterns were established by mergers, nearly all Congregational churches were linked together in association or unions on local, provincial, and national levels. In recent times these have appointed superintendent ministers or moderators, who exercise a general ministry to the churches over a large area; but it would be misleading to think of their role as equivalent to that of diocesan bishops, since they are not regarded as the sources of ecclesiastical order and have no formal authority over independent churches. It is a Congregational principle that the service of the Word and the sacraments, rather than one's place in a system of ecclesiastical administration, confers authority on a minister.

All offices in Congregational churches were open to women before it became widespread practice. The first woman was ordained in 1917. Churches are mainly fi-

nanced by the contributions of members. There are substantial denominational funds for ensuring minimum stipends to finance missionary work and pensions, but even these depend heavily on contributions from the churches as well as on endowments.

Congregationalism in the modern world. Congregationalism has flourished most in settled communities of manageable size, in provincial cities, or in the substantial suburbs of larger cities. It has played a prominent part in the civic life of such places, especially in the 19th century, and it has proved itself a rich seedbed for educational and cultural aspirations. It has not itself always enjoyed the fruits of these aspirations because many of the children it has produced have moved on to spheres where the organized churches have found difficulty in keeping pace with them. Many prominent American and English politicians have been Congregationalists, among them Hubert Humphrey and Harold Wilson. John Milton and Robert Browning stand closest to the distinctive Congregationalist outlook among the numerous major artists of Congregationalist connection or upbringing.

Congregationalism has clearly not succeeded in establishing itself as one of the major forms of churchmanship in the modern world. Congregational ideas and practices have, however, had a deep influence on many other churches. Congregationalism has also been a major factor in shaping the institutions and the general culture of the United States and, to a lesser degree, of Britain and the Commonwealth. Its expansion and vitality in England in the 19th century were closely linked with the rise of new middle-class groups, but with the increase of social mobility, the centralization of business organizations, and the decline of the continuity of family style of life from one generation to the next, its churches have suffered heavily in deterioration of numbers and direct social influence. The decline has not been as marked in the United States, where Congregational churches have shared in the general ecclesiastical prosperity, although even there they have not expanded at anything like the rate of most other large groups of churches. Most of the historic Congregational churches are now incorporated in reunited churches belonging to the Reformed family. Whether what is distinctive in Congregationalism can be effectively maintained under the pressure of modern urban mobility in more centrally organized churches is to be determined. (D.T.J.)

Influence
and decline

Friends

Friends (or Quakers) are a Christian group that arose in mid-17th-century England, dedicated to living in accordance with the "Inward Light," or direct inward apprehension of God, without creeds, clergy, or other ecclesiastical forms. As most powerfully expressed by George Fox (1624–91), Friends felt that their "experimental" discovery of God would lead to the purification of all of Christendom. It did not; but Friends founded one American colony and were dominant for a time in several others, and though their numbers are now comparatively small, they continue to make disproportionate contributions to science, industry, and especially to the Christian effort for social reform.

HISTORY
