The situation has been complicated by the fact that the history of Shakespeare criticism and the stage history of his plays have run parallel but separate courses. It is fair to say that, from about the mid-18th century onward, there has been a constant tension between the critics and the theatres regarding treatment of Shakespeare. Although Dr. Johnson was the contemporary of David Garrick, Coleridge and Hazlitt the contemporaries of Edmund Kean, Dowden of Sir Henry Irving, and Bradley of Beerbohm Tree, the links between these critics and actors were not notably strong. Theatregoers were usually impressed by character impersonations rendered by virtuoso actors, while readers became more and more impressed by an awareness and admiration of the special artistic form of the plays. Rather than by stage performances, Shakespeare criticism was influenced by the dominant literary forms of each age: by the self-revelatory poem of the Romantic period, the psychological and ethical novel of the Victorians, the fragmentary revelations of the human condition in 20th-century poetry. It is a platitude that each age finds what it wants to find in Shakespeare. It will only see what it can. It can only see what it must. But Shakespeare critics, if criticism is to be in a healthy condition, must pay more than lip service to that fact. However deeply embedded in its contemporary situation, good criticism, like all intellectual feats, is a leaping out of the situation. The history of Shakespeare criticism is a subject of more than scholarly interest. It is a cautionary tale. Sometimes it is an awful warning.

The progress of Shakespeare criticism. As a basis for the criticism of an author's work, it is reasonable to begin by inquiring how his contemporaries assessed his achievement. But contemporary literary criticism was surprisingly silent about the plays actually being written (though critics were reasonably articulate about the plays they thought ought to be written). Collections of references made to Shakespeare later, during the 17th century, show that many important writers paid little attention to him. Ben Jonson's reputation was, for a variety of reasons, probably superior for the first half of the century. He was, moreover, the most vocal literary critic of the early 17th century, and he thought of Shakespeare as a naturally gifted writer, who failed to discipline himself. From his criticism derived the distinction between "nature" and "art" that for long proved to be a pertinacious and unproductive theme of Shakespeare criticism. It was further encouraged by John Milton, when he contrasted Jonson's "learned sock" with Shakespeare's "native wood-notes wild" (which refers to the comedies but came to be treated as a general statement, especially the epithet "wild"). A good deal of the spirit of Ben Jonson's cavillings, rather than his magnificent praise in the poem prefixed to the Folio of 1623, was continued by later 17th-century and 18th-century critics, censuring Shakespeare's carelessness, his artistic "faults."

John Dryden (died 1700) was the first great critic of Shakespeare. Much concerned with his own art as a dramatist, he judged Shakespeare in a practical spirit. For 100 years after him, the best literary criticism of Shakespeare was an elaboration and clarification of his opinions. Dryden on some occasions praised Shakespeare in the highest terms and boldly defended the English tradition of the theatre, maintaining that, if it was contrary to the revered classical precepts of Aristotle, it was only because Aristotle had not seen English plays; had he seen them, his precepts would have been different. Dryden nevertheless at times attributes artistic "faults" to Shakespeare, judging him according to Neoclassical principles of taste that derived from France and soon prevailed throughout Europe. Shakespeare's dramatic art was so different from that of the admired tragedy of the times (that of Corneille and Racine) that it was difficult for a critic to defend or interpret it in reasonable terms. The gravest charge was the absence of "poetical justice" in Shakespeare's plays. Although some of the better 18th-century critics, such as Joseph Addison and Dr. Johnson, saw the limitations of "poetical justice" as an artistic theory, they nevertheless generally felt that the ending of *King Lear,* especially, was intolerable, offending all sense of natural justice by the death of Cordelia. The play was thus given a "happy ending"—one congruent with "poetical justice"—by the poet and playwright Nahum Tate: Lear was restored to his authority, and Cordelia and Edgar were to be married and could look forward to a prosperous reign over a united Britain. This change was approved by Dr. Johnson, and the revised play held the stage for generations and was the only form of *King Lear* performed on the stage until the mid-19th century.

In the early 18th century the cumbrous folio editions were replaced by more convenient editions, prepared for the

Pope's theory that Shakespeare's natural genius was hampered by writing for the theatre

reader. Nicholas Rowe, in a six-volume edition of 1709, tidied up the text of the plays, adding scene divisions, lists of dramatis personae, indications of locality, and so on. Rowe was himself a practicing and successful dramatist, and on the whole he gave a good lead to the dramatic criticism of the plays. The preface to Alexander Pope's edition of 1725, however, had an unhappy influence on criticism. Shakespeare's natural genius, he felt, was hampered by his association with a working theatre. Pope fully accepted the artistic form of Shakespeare's writings as due to their being stage plays. But he regarded this as a grave disadvantage and the source of their artistic defectiveness. Lewis Theobald took the opposing view to Pope's, claiming that it was an advantage of Shakespeare that he belonged to the theatrical profession. Dr. Johnson similarly realized that methods of producing the plays on the stage influenced the kind of illusion created. In the splendid preface to his edition (1765), Johnson dismissed, once and for all in English criticism, the Neoclassical theories of "decorum," the "unities," and the mutual exclusiveness of tragedy and comedy—theories now seen as irrelevant to Shakespeare's art and as having confused the discussion of it. In many ways Johnson was the source of the notion of Shakespeare as a realistic dramatist, whose mingling of tragic and comic scenes was justified as "exhibiting the real state of sublunary nature," in which laughter and tears, rejoicing and misery, are found side by side.

Johnson censured Shakespeare as a dramatic artist for his lack of morality. Shakespeare, he wrote, "sacrifices virtue to convenience, and is so much more careful to please than to instruct, that he seems to write without any moral purpose." Later critics have felt compelled to controvert or to circumvent such a judgment. But Johnson's preface, if it did not give the discussion of Shakespeare's artistry a fresh start, cleared away some of the dead or irrelevant doctrines.

During the rest of the 18th century, after Johnson, it was scholarship rather than criticism that advanced in England. The best of literary criticism of the time was in the discovery of new subtleties in Shakespeare, especially in characterization; indeed, the acceptance of Shakespeare as a dramatic artist largely came about through his evident powers of characterization (to which probably the growth of the realistic novel in the 18th century had made readers more sensitive), and inadequate attention was paid to other aspects of his dramatic craftsmanship. There was nothing in England comparable to the brilliant Shakespeare criticism of Lessing, Goethe, and August von Schlegel in Germany. The latter's essay on *Romeo and Juliet* of 1797 demonstrated that, apart from a few witticisms, nothing could be taken away from the play, nothing added, nothing rearranged without mutilating the work of art and confusing the author's intentions. Here modern Shakespeare criticism begins. Indeed, from the time of Lessing, in the 18th century, to the mid-19th century, German critics and scholars made substantial and original contributions to the interpretation of Shakespeare, indicating Shakespeare's superlative artistry, at a time when in England he was admired more as a great poet and a brilliant observer of mankind than as a disciplined artist.

Coleridge's critical opinions

Samuel Taylor Coleridge, the greatest English critic of Shakespeare, vigorously denied that he had been affected by Schlegel (though he acknowledged the influence of Lessing), but there are many similarities between the two. His criticism—which has to be put together from reports of his lectures, from his notebooks, and from memories of his conversation, for he never succeeded in writing an organized book on Shakespeare—at first censured Shakespeare's lack of artistry, but in his lectures, given from 1810 onward, and in his *Biographia Literaria* (1817), he demonstrated that Shakespeare's "irregularities" were in fact the manifestations of a subtle intelligence. It was the purpose of criticism to reveal the reasons why the plays are as they are. Shakespeare was a penetrating psychologist and a profound philosopher; but Coleridge claimed that he was an even greater artist, and his artistry was seen to be "unconscious" or "organic," not contrived. Thus the dominant literary forms of Coleridge's age, which were those of self-revelatory poetry, influenced the criticism of the age: Hamlet was felt to speak with the voice and feeling of Shakespeare, and, as for the sonnets, William Wordsworth, whose greatest achievement was writing a long poem on the growth of his own mind, explained that Shakespeare "unlocked his heart" in his sonnets.

These critical opinions were inclined to degenerate in inferior hands in the course of the 19th century: the belief in Shakespeare's all-pervading artistry led to oversubtle interpretations; the enthusiasm for character analysis led to excessive biography writing outside the strictly dramatic framework; and the acknowledged assessment of Shakespeare's keen intelligence led to his being associated with almost every school of thought in religion, politics, morals, psychology, and metaphysics. Nevertheless, it was the great achievement of the Romantics to have freed criticism from preoccupation with the "beauties" and "faults" in Shakespeare and to have devoted themselves instead to interpreting the delight that people had always felt in the plays, whether as readers or theatregoers. Shakespeare's "faults" now became "problems," and it was regarded an achievement in literary criticism to have found an explanation for some hitherto difficult or irreconcilable detail in a play. Many of the most brilliant writers of Europe were critics of Shakespeare; and their utterances (whether or not they may be regarded as having correctly interpreted Shakespeare) are notable as recording the impressions he made upon great minds.

SHAKESPEARE'S INFLUENCE

Today Shakespeare's plays are performed throughout the world, and all kinds of new, experimental work finds inspiration in them: " . . . in the second half of the twentieth century in England," wrote the innovative theatre director Peter Brook, "we are faced with the infuriating fact that Shakespeare is still our model."

Shakespeare's influence on English theatre was evident from the start. John Webster, Philip Massinger, and John Ford are among the better known dramatists who borrowed openly from his plays. His influence is evident on Restoration dramatists, especially Thomas Otway, John Dryden, and William Congreve. John Osborne, Harold Pinter, Samuel Beckett, and George Bernard Shaw are among 20th-century writers in whose works Shakespearean echoes are to be found. Many writers have taken over Shakespeare's plots and characters: Shaw rewrote the last act of *Cymbeline,* Tom Stoppard invented characters to set against parts of *Hamlet* in *Rosencrantz and Guildenstern Are Dead* (1968), and Edward Bond used *King Lear* as the starting point for his own *Lear* (1971).

Influence on European theatre

Shakespeare has also influenced dramatists and theatre directors outside his own country. In Germany, English acting troupes were welcomed early in the 17th century, and the German version of *Hamlet, Der bestrafte Brudermord* ("Fratricide Punished"), testifes to the immediate influence of that play. His influence on later European dramatists ranges from a running allusion to Hamlet in Anton Chekhov's play *The Seagull* to imitation and parody of *Richard III* in Bertolt Brecht's *Arturo Ui,* adaptation of *King John* by Max Frisch, and André Gide's translation and simplification of *Hamlet.*

Shakespeare's influence on actors since his own day has been almost as widespread. Many European and American actors have had their greatest successes in Shakespearean roles. In England very few actors or actresses reach preeminence without acting in his plays. Each player has the opportunity to make a part his own. This is not because Shakespeare has created only outlines for others to fill but because he left so many and varied invitations for the actor to call upon his deepest, most personal resources.

Theatre directors and designers after Shakespeare's time, with every technical stage resource at their command, have returned repeatedly to his plays, which give opportunity for spectacle and finesse, ritual and realism, music and controlled quietness. Their intrinsic theatricality, too, has led to adaptations into very different media: into opera (as Verdi's *Otello*) and ballet (as versions of *Romeo and Juliet* from several nations); into sound recordings, television programs, and films. Musicals have been made of the comedies (as *Kiss Me Kate* from *The Taming of the Shrew*); even a tragedy, *Othello,* was the inspiration of a "rock" musical in 1971 called *Catch My Soul,* while *Macbeth* has yielded a political-satire show called *Macbird!* (1967).

Shakespeare has Hamlet say that the aim of theatre performance is to "hold the mirror up to nature," and this is what the history of his plays, from their first production to the latest, shows that he has, preeminently, achieved.

MAJOR WORKS

PLAYS: (probable dates of performance given): *2 Henry VI, 3 Henry VI* (1589–91); *1 Henry VI* (1591–92); *Richard III, The Comedy of Errors* (1592–93); *Titus Andronicus, The Taming of the Shrew* (1593–94); *The Two Gentlemen of Verona, Love's Labour's Lost, Romeo and Juliet* (1594–95); *Richard II, A Midsummer Night's Dream* (1595–96); *King John, The Merchant of Venice* (1596–97); *1 Henry IV, 2 Henry IV* (1597–98); *Much Ado About Nothing, Henry V* (1598–99); *Julius Caesar, As You Like It* (1599–1600); *Hamlet, The Merry Wives of Windsor* (1600–01); *Twelfth Night, Troilus and Cressida* (1601–02); *All's Well That Ends Well* (1602–03); *Measure for Measure, Othello* (1604–05); *King Lear, Macbeth* (1605–06); *Antony and Cleopatra* (1606–07); *Coriolanus, Timon of Athens* (1607–08); *Pericles* (1608–09); *Cymbeline* (1609–10); *The Winter's Tale* (1610–11); *The Tempest* (1611–12); *Henry VIII* (1612–13).

POEMS: (dates of publication given): *Venus and Adonis* (1593); *The Rape of Lucrece* (1594); "The Phoenix and the Turtle" (1601); *Sonnets* with "A Lovers complaint" (1609).

BIBLIOGRAPHY

Modern editions: Among one-volume editions of Shakespeare's *Works* are those by GEORGE L. KITTREDGE (1936; rev. by IRVING RIBNER, 1971); PETER ALEXANDER (1951); HARDIN CRAIG (1951; rev. by CRAIG and DAVID BEVINGTON, 1973); and CHARLES J. SISSON (1954). Editions giving one volume for each play include ALFRED HARBAGE (gen. ed.), *The Pelican Shakespeare,* rev. ed. (1969); SYLVAN BARNET (gen. ed.), *The Signet Classic Shakespeare,* 27 vol. (1963–66); the revision of *The Arden Shakespeare,* ed. by UNA ELLIS-FERMOR *et al.* (1951–); and T.J.B. SPENCER (gen. ed.), *The New Penguin Shakespeare.* The *New Cambridge Edition* (gen. eds., SIR A.T. QUILLER-COUCH, J.D. WILSON, *et al.*) is also one volume for each play, but the early publications of the comedies and some histories are now considered eccentric. The *New Variorum Edition,* started by HORACE HOWARD FURNESS in 1871, is still in progress, and the completeness of its textual apparatus and notes ensures continual usefulness.

Textual studies: WALTER EBISCH and LEVIN L. SCHÜCKING compiled a comprehensive *Shakespeare Bibliography* (1931, reissued 1973; supplemented in 1937 for the years 1930–35). The account is updated by GORDON R. SMITH, *A Classified Shakespeare Bibliography, 1936–1958* (1963). JAMES G. MCMANAWAY, *A Selective Bibliography of Shakespeare: Editions, Textual Studies, Commentaries* (1975), covers more than 4,500 items published between 1930 and 1970, mainly in English. The *Shakespeare Quarterly* publishes an annual classified bibliography, while the *Shakespeare Survey* publishes annual accounts of "Contributions to Shakespearian Study," as well as retrospective articles on work done on particular aspects. JOHN BARTLETT, *A New and Complete Concordance . . . to Shakespeare* (1894); and C.T. ONIONS, *A Shakespeare Glossary,* 2nd ed. rev. (1919), are both still most useful reference works and are kept in print. On textual criticism as applied to Shakespeare, the following works represent modern thinking and practice: FREDSON BOWERS, *Bibliography and Textual Criticism* (1964), and *On Editing Shakespeare* (1966); WALTER W. GREG, *The Editorial Problem in Shakespeare,* 3rd ed. (1954), and *The Shakespeare First Folio* (1955); CHARLTON HINMAN, *The Printing and Proof-Reading of the First Folio of Shakespeare,* 2 vol. (1963); E.A.J. HONIGMANN, *The Stability of Shakespeare's Text* (1965); RONALD B. MCKERROW, *An Introduction to Bibliography for Literary Students* (1927, reissued 1967); ALFRED W. POLLARD, *Shakespeare Folios and Quartos: A Study in the Bibliography of Shakespeare's Plays, 1594–1685* (1909, reprinted 1970); ALICE WALKER, *Textual Problems of the First Folio* (1953, reprinted 1978); and FRANK P. WILSON, *Shakespeare and the New Bibliography,* rev. ed. by HELEN GARDNER (1970). Facsimile editions of quartos and folio, which are necessary for any close work on textual problems, have been edited by WALTER W. GREG *et al., Shakespeare Quarto Facsimilies* (1939–66); and by CHARLTON HINMAN, *The First Folio of Shakespeare* (1968).

Biographies: A lively account of the various efforts that have been made to write a biography of Shakespeare from the available materials, with the help of imaginative interpretation, is SAMUEL SCHOENBAUM, *Shakespeare's Lives* (1970). See also Schoenbaum's collections of documents, paintings, and other records: *William Shakespeare: A Documentary Life* (1975); *Shakespeare: The Globe and the World* (1979); and *William Shakespeare: Records and Images* (1981). The first detailed life of Shakespeare was written by NICHOLAS ROWE, *Some Account of the Life of Mr. William Shakespear* (1709; photographic facsimile, 1967). EDMOND MALONE from 1780 onward added much new material; his final account is in the 1821 Variorum Edition. The best of the 19th-century biographies were J.O. HALLIWELL-PHILLIPPS, *Outlines of the Life of Shakespeare* (1881; last revision, 1887); and SIDNEY LEE, *A Life of William Shakespeare* (1898; 14th ed., 1931). A standard work is E.K. CHAMBERS, *William Shakespeare: A Study of Facts and Problems,* 2 vol. (1930), of which there is a useful abridgement by CHARLES WILLIAMS, *A Short Life of Shakespeare with Sources* (1933). More recent works are EDGAR I. FRIPP, *Shakespeare, Man and Artist,* 2 vol. (1938, reissued 1964); PETER ALEXANDER, *Shakespeare's Life and Art* (1939, reprinted 1979); HAZELTON SPENCER, *The Art and Life of William Shakespeare* (1940, reprinted 1970); M.M. REESE, *Shakespeare: His World and His Work,* rev. ed. (1980); GERALD E. BENTLEY, *Shakespeare: A Biographical Handbook* (1961), supplemented by his *Profession of Dramatist in Shakespeare's Time, 1590–1642* (1971); MURIEL C. BRADBROOK, *Shakespeare: The Poet in His World* (1978), with emphasis on the plays; EMRYS JONES, *The Origins of Shakespeare* (1977), a study of mid-Tudor influences on Shakespeare; PETER QUENNELL, *Shakespeare* (1963); and A.L. ROWSE, *William Shakespeare* (1963). Studies of special aspects of the life and environment include JOHN LESLIE HOTSON, *Shakespeare Versus Shallow* (1931, reprinted 1970); THOMAS W. BALDWIN, *William Shakspere's Petty School* (1943, reissued 1973), and *William Shakspere's Small Latine and Lesse Greeke,* 2 vol. (1944, reprinted 1966); and MARK ECCLES, *Shakespeare in Warwickshire* (1961). A valuable collection of background material is contained in *Shakespeare's England: An Account of the Life and Manners of His Age,* ed. by SIDNEY LEE and C.T. ONIONS, 2 vol. (1916). Also helpful are E.M.W. TILLYARD, *The Elizabethan World Picture* (1943, reprinted 1973); and *Shakespeare in His Own Age,* ed. by ALLARDYCE NICOLL (1964, reissued 1976). Standard works on the theatre of Shakespeare's professional life are E.K. CHAMBERS, *The Elizabethan Stage,* 4 vol. (1923, reprinted 1974); and GLYNNE WICKHAM, *Early English Stages 1300–1660* (vol. 2 on 1576–1600, published in two parts, 1963–72; 2nd ed., 1980–). Other helpful studies are ALFRED HARBAGE, *Shakespeare's Audience* (1941, reissued 1969); ALOIS M. NAGLER, *Shakespeare's Stage* (1958, reissued 1981); and BERNARD BECKERMAN, *Shakespeare at the Globe, 1599–1609* (1962). Special aspects of the environment that throw light on the mentality of the dramatist are RICHMOND NOBLE, *Shakespeare's Biblical Knowledge and Use of the Book of Common Prayer* (1935, reissued 1977); R. MUSHAT FRYE, *Shakespeare and Christian Doctrine* (1963); PAUL A. JORGENSEN, *Shakespeare's Military World* (1956, reissued 1973); GEORGE W. KEETON, *Shakespeare's Legal and Political Background* (1967); and KATHARINE M. BRIGGS, *The Anatomy of Puck* (1959, reprinted 1977), and *Pale Hecate's Team* (1962, reprinted 1977), on belief in fairies and witchcraft. A survey of the theories that someone other than William Shakespeare of Stratford-upon-Avon was the author of the plays published under his name has been written by H.N. GIBSON, *The Shakespeare Claimants: A Critical Survey of the Four Principal Theories Concerning the Authorship of the Shakespearean Plays* (1962, reprinted 1971).

See also REGINALD C. CHURCHILL, *Shakespeare and His Betters* (1958); and FRANK W. WADSWORTH, *The Poacher from Stratford* (1958). The possibility of cryptic messages in the plays was conclusively investigated in WILLIAM F. and E.S. FRIEDMAN, *The Shakespearean Ciphers Examined* (1957). The following are some of the principal exponents of the theories: (*Bacon*): EDWIN DURNING-LAWRENCE, *Bacon Is Shake-speare* (1910, reprinted 1971); and A.B. CORNWALL, *Francis the First, Unacknowledged King of Great Britain and Ireland . . .* (1936); see also J.M. ROBERTSON, *The Baconian Heresy* (1913, reprinted 1970). (*Edward de Vere, 17th Earl of Oxford, 1550–1604*): J. THOMAS LOONEY, *"Shakespeare" Identified* (1920; 3rd ed. 1974); PERCY ALLEN, *The Case for Edward de Vere . . . as William Shakespeare* (1930); HILDA AMPHLETT, *Who Was Shakespeare?* (1955, reprinted 1970); and GILBERT SLATER, *Seven Shakespeares* (1931, reprinted 1978), which proposes Oxford and a group of his collaborators. (*6th Earl of Derby*): ABEL LEFRANC, *Sous le masque de "William Shakespeare,"* 2 vol. (1918–19), and *À la découverte de Shakespeare,* 2 vol. (1945–50). (*Marlowe*): CALVIN HOFFMAN, *The Man Who Was Shakespeare* (1955).

Critical studies: Opinion about Shakespeare up to 1700 is collected in *The Shakespeare Allusion-Book,* ed. by JOHN MUNRO, 2 vol. (1909), rev. by EDMUND K. CHAMBERS (1932, reprinted 1970); and in GERALD E. BENTLEY, *Shakespeare and Jonson: Their Reputations in the Seventeenth Century Compared* (1945, reissued 1965). Eighteenth-century criticism is surveyed in DAVID NICHOL SMITH, *Shakespeare in the Eighteenth Century* (1928, reprinted 1978), and in his collection of *Eighteenth Century Essays on Shakespeare* (1903; 2nd ed., 1963); his anthology *Shakespeare Criticism: A Selection* (1916), includes work up to about 1825. BRIAN VICKERS, *Shakespeare: The Critical Heritage,* 6 vol. (1974–81), is an anthology covering the years 1623 to 1801. Dr. Johnson's criticism has been conveniently excerpted in *Johnson on Shakespeare,* ed. by WALTER RALEIGH (1908), and *Samuel Johnson on Shakespeare,* ed. by W.K. WIMSATT (1960). THOMAS M. RAYSOR prepared the standard edition of *Coleridge's Shakespearean Criticism* (1930; 2nd ed., 2 vol., 1960); but a useful compilation is *Coleridge on Shakespeare,* ed. by TERENCE HAWKES (1969). These can be supplemented by *Coleridge on Shakespeare: The Text of the Lectures of 1811–12,* ed. by R.A. FOAKES (1971). General surveys of the development of criticism are given by LOUIS MARDER, *His Exits and His Entrances* (1963); ALFRED HARBAGE, *Conceptions of Shakespeare* (1966); ARTHUR M. EASTMAN, *A Short History of Shakespearean Criticism* (1968, reissued 1974); and RAYMOND POWELL, *Shakespeare and the Critics' Debate* (1980). The best brief accounts are by T.S. ELIOT and J. ISAACS, "Shakespearian Criticism," in *A Companion to Shakespeare Studies,* ed. by HARLEY GRANVILLE-BARKER and G.B. HARRISON (1934, reprinted 1960); and by M.A. SHAABER, "Shakespeare Criticism: Dryden to Bradley," and STANLEY WELLS, "Shakespeare Criticism Since Bradley," in *A New Companion to Shakespeare Studies,* ed. by KENNETH MUIR and SAMUEL SCHOENBAUM (1971). The situation outside Britain may be studied in *Shakespeare in Europe,* a collection edited by OSWALD LE WINTER (1963). PATRICK MURRAY, *The Shakespearian Scene: Some Twentieth-Century Perspectives* (1969), gives a shrewd survey of modern criticism. NORMAN RABKIN, *Shakespeare and the Problem of Meaning* (1981), discusses the inevitably differing interpretations of the plays. Several 20th-century works may be regarded as having had a substantial effect on the criticism of Shakespeare. HARLEY GRANVILLE-BARKER, *Prefaces to Shakespeare* (5 series, 1929–47; 4 vol., 1963), set the plays firmly in their theatrical environment. Enquiries into the artistic conventions of Shakespeare's time were the basis of the criticism of LEVEN L. SCHÜCKING, *Character Problems in Shakespeare's Plays* (1922, reissued 1959; originally published in German, 1919); ELMER E. STOLL, *Art and Artifice in Shakespeare* (1933, reissued 1968); OSCAR J. CAMPBELL, *Shakespeare's Satire* (1943, reprinted 1971); and WILLIAM W. LAWRENCE, *Shakespeare's Problem Comedies,* 2nd ed. (1969). G. WILSON KNIGHT, *The Wheel of Fire* (1930; 4th rev. ed., 1949, reissued 1977), *The Imperial Theme* (1931; 3rd ed., 1968, reprinted 1972), *The Shakespearian Tempest* (1932; 3rd ed., 1953, reissued 1971), and later books; and L.C. KNIGHTS, *How Many Children Had Lady Macbeth?* (1933, reprinted 1973), showed how Shakespeare achieved poetical and symbolic effects. The study of Shakespeare's imagery is well represented by the pioneer work of CAROLINE F.E. SPURGEON, *Shakespeare's Imagery and What It Tells Us* (1935, reissued 1977); WOLFGANG CLEMEN, *The Development of Shakespeare's Imagery* (1951; 2nd ed., 1977); and ROBERT B. HEILMAN, *This Great Stage: Image and Structure in King Lear* (1948), and *Magic in the Web: Action and Language in Othello* (1956, reprinted 1977). S. VISWANATHAN, *The Shakespearean Play As Poem: A Critical Tradition in Perspective* (1980), concentrates on the work of Knight, Knights, and Spurgeon. An understanding of the intellectual and social background of the plays was advanced by WILLARD FARNHAM, *The Medieval Origin of Elizabethan Tragedy* (1936, reissued 1970), and *Shakespeare's Tragic Frontier* (1950, reprinted 1973); HARDIN CRAIG, *The Enchanted Glass: The Elizabethan Mind in Literature* (1936, reissued 1975); C.L. BARBER, *Shakespeare's Festive Comedy* (1959, reissued 1972); THEODORE SPENCER, *Shakespeare and the Nature of Man,* 2nd ed. (1949, reissued 1974); L.B. CAMPBELL, *Shakespeare's "Histories": Mirrors of Elizabethan Policy* (1947, reissued 1978); and SUKANTA CHAUDHURI, *Infirm Glory: Shakespeare and the Renaissance Image of Man* (1981).

Some of the notable explorations of the artistry of the plays are MADELEINE DORAN, *Endeavors of Art* (1954); BERTRAND EVANS, *Shakespeare's Comedies* (1960); and ANNE RIGHTER, *Shakespeare and the Idea of the Play* (1962). JAN KOTT, *Shakespeare, Our Contemporary* (1964; originally published in Polish, 1962), has been very widely read and influential on theatrical productions.

(J.R.Br./T.Sp./Ed.)

Shanghai

Shanghai (Wade-Giles romanization Shang-hai, Pinyin Shanghai), whose name literally means "on the sea," is one of the world's largest seaports and a major industrial and commercial centre of the People's Republic of China. It is located on the coast of the East China Sea between the mouth of the Yangtze River to the north and the bays of Hangchow and Yü-p'an to the south. The municipality covers a total area of 2,383 square miles (6,185 square kilometres), which includes the city itself, surrounding suburbs, and an agricultural hinterland; it is also China's most populous urban area.

Shanghai was the first Chinese port to be opened to Western trade, and it long dominated the nation's commerce. Since the Communist victory in 1949, however, it has become an industrial giant whose products supply China's growing domestic demands. The city has also undergone extensive physical changes with the establishment of industrial suburbs and housing complexes, the improvement of public works, and the provision of parks and other recreational facilities. Shanghai has attempted to eradicate the economic and psychological legacies of its exploited past through physical and social transformation to support its major role in the modernization of China.

The article is divided into the following sections:

Physical and human geography

THE LANDSCAPE

Site. The province-level municipality (*shih*) of Shanghai is bordered by Kiangsu Province on the north and west and Chekiang Province on the south. It includes the city of Shanghai; the nine mainland counties (*hsien*) of Pao-shan, Chia-ting, Ch'ing-p'u, Sung-chiang, Chin-shan (Chu-ching), Shang-hai (Hsin-chuang), Feng-hsien (Nan-ch'iao), Nan-hui, and Ch'uan-sha; and approximately 30 islands in the mouth of the Yangtze and offshore to the southeast in the East China Sea. The largest island, Ch'ung-ming, has an area of 270 square miles (700 square kilometres), extends more than 40 miles (65 kilometres) upstream from the mouth of the Yangtze, and is the 10th county in the greater Shanghai Municipality.

The city's composition

The mainland portion of the city lies on an almost level deltaic plain with an average elevation of 10 to 16 feet (three to five metres) above sea level. It is crisscrossed by an intricate network of canals and waterways that connect the municipality with the T'ai Hu region to the west.

Climate. The city's maritime location fosters a mild climate characterized by minimal seasonal contrast. The average annual temperature is about 58° F (14° C); the July maximum averages about 80° F (27° C), and the average January minimum is about 37° F (3° C). About 45 inches (1,140 millimetres) of precipitation fall annually, with the heaviest rainfall in June and the lightest in December.

Layout. As China's main industrial centre, Shanghai has serious air, water, and noise pollution. Industrial relocation and construction in the suburbs since the 1950s initially helped alleviate central city air pollution, although high population density and mixed industrial-residential land use continued to cause problems. The Wu-sung (Suchou) Chiang (River) and Huang-p'u Chiang, which flow through the city, are severely polluted from industrial discharges, domestic sewage, and ships' wastes; nonetheless, the Huang-p'u is Shanghai's main water source. Environmental protection and urban cleanliness is enhanced by industrial and solid waste resource recovery operations run by a municipal corporation. More than 1,000 different materials are recycled, including plastic, chemical fibre, and residues, machine components, oil and grease, rags, human hair, and animal bones.

The municipality radiates toward the north, west, and south from the confluence of the Wu-sung, and the Huang-p'u, a tributary of the Yangtze. Surrounding the central core is a transitional zone on both banks of the Huang-p'u, which encompasses a partially rural area of about 160 square miles. The suburban industrial complexes of Wu-sung to the north and Minhsing to the south were annexed in 1980. The banks of the Wu-sung, an important inland waterway connection to the interior hinterland, are occupied by a westward arterial extension of the transitional zone. To the south, however, the transitional zone terminates abruptly a few miles south of the central Shanghai urban core, at the Huang-p'u. P'u-tung, directly east across the Huang-p'u from the central business district, was founded in 1870 as one of the earliest industrial areas; it was also notorious as the city's most extensive and appalling slum. Several of the post-1949 industrial workers' residential complexes are now located there, and it is part of the Huang-p'u district.

Downtown Shanghai. The physical perspective of downtown Shanghai is much the same as in the pre-Communist period. Because of the policy of developing integrated residential and industrial complexes in suburban areas, central city development and renewal has been given low priority. Many of the pre-World War II buildings, which housed foreign commercial concerns and diplomatic missions, still dominate the area.

Extending southward and westward from the confluence of the Wu-sung and Huang-p'u rivers, central Shanghai has a gridded street pattern and includes the area originally contained within the British concession. The area is bounded on the east along the Huang-p'u by Chung-shan Tung Lu (Chung-shan Tung Road); on the west by Hsi-tsang Chung Lu; and on the south by Yen-an Tung Lu, which was built on the former Yang-ching-p'ang Canal that separated the British from the French concessions. Chung-shan Tung Lu has several hotels, the central administrative offices of Shanghai, and a residence for foreign seamen. The main commercial artery, Nan-ching Tung Lu, runs westward from the eastern road. On this street are located Shanghai's largest retail establishment—the Shanghai Number One Department Store—as well as restaurants, hotels, and the central communications and telegraph building.

The Hung-k'ou district lies to the north and east of the Wu-sung Chiang. It was originally developed by American and Japanese concessionaires and in 1863 was combined with the British concession to the south to create the International Settlement. It is an important industrial area, with shipyards and factories spread out along the bank of the Huang-p'u in the eastern section of the district.

The Bund, a wide boulevard of buildings along the Huang-p'u Chiang in Shanghai.

Peter Carmichael—Aspect Picture Library

Its best known building, the Shang-hai Ta-hsia (Shanghai Mansions Hotel), overlooks the Huang-p'u.

The old Chinese city, which is now part of central Shanghai, is characterized by a random and labyrinthine street pattern. Until the early 20th century the area was surrounded by a three-mile wall. It is now circumscribed by the two streets of Jen-min Lu and Chung-hua Lu, which follow the course of the original wall; and it is bisected by the main north–south artery, Ho-nan Nan Lu (South Ho-nan Road).

Western Shanghai is primarily residential in character and is the site of the Industrial Exhibition Hall. To the southwest, the district of Hsü-hui, formerly Ziccawei, became a centre of Christian missionary activity in China in the 17th century. During the late 1800s, Jesuit priests established a major library, a printing establishment, an orphanage, and a meteorological observatory in the area.

Land-use patterns in metropolitan Shanghai mirror pre-1949 real-estate market conditions. Much of the high-value land given over to industrial plants, warehouses, and transport facilities lies close to the Huang-p'u and Wu-sung rivers. South of the Wu-sung, which is traversed by about 20 bridges within the city, residential areas extend south from the industrial strip to the Huang-p'u. North of the Wu-sung, residential areas are less clearly demarcated, and there is a more gradual merging of city and country in the transitional zone. Continuous urban settlement is bounded on the north by the two major east–west arteries of Chung-shan Pei Lu and Ssu-ping Lu.

Retail trade is concentrated in the old central business district, although the volume of trade conducted there has diminished with the establishment of the industrial satellite towns and villages on the periphery of Shanghai.

Housing. Shanghai has made considerable progress since 1949 in providing housing for its growing population. Construction of integrated, self-sufficient residential complexes in conjunction with industrial, agricultural, and commercial development throughout metropolitan and suburban Shanghai has helped disperse population from the overcrowded central city and has led to dramatic changes in the urban and suburban landscape. Thousands of families in urban districts, however, remain inadequately housed, and shanties persist in some areas.

The concept of state-supported housing was introduced in 1951 with the development of Ts'ao-yang Hsin Ts'un (Ts'ao-yang New Village) in an existing industrial zone on Shanghai's western periphery. Following the construction of the Ts'ao-yang Hsin Ts'un, many other residential complexes have been built. Some of them were constructed with the partial support of government bureaus or industrial enterprises to satisfy the needs of their employees. Two of the earliest complexes in this category were the Railroad Village and the Post and Telegraph Village.

Five major housing developments were built in the former slum area of Yang-shu-p'u. These include the villages of An-shan, K'ung-chiang, Ch'ang-pai, Feng-ch'eng, and the Feng-nan Erh Ts'un. Other complexes are those at P'eng-p'u, Chen-ju, I-ch'uan, Jih-hui, and Chiang-wan. Some of these are in relatively remote suburban locations in the transitional and hinterland zones near older rural marketing centres. The P'eng-p'u workers' housing project is typical. Those who work in nearby factories live in a garden-apartment complex that includes apartment buildings, administrative offices, workshops, clinics, and a nursery. The adjacent fields supply wheat, clover, beans, cabbage, melons, and rapeseed (for cooking oil) for consumption by the inhabitants of the complex.

THE PEOPLE

The greater municipality can be divided into three distinct population zones—the densely populated central city, the transitional zones, and the rural hinterland, which is one of the world's most densely settled agricultural areas.

Within metropolitan Shanghai, there are few, if any, concentrations of ethnic minority groups. The majority of the population is of Han Chinese origin.

THE ECONOMY

China's leading industrial centre

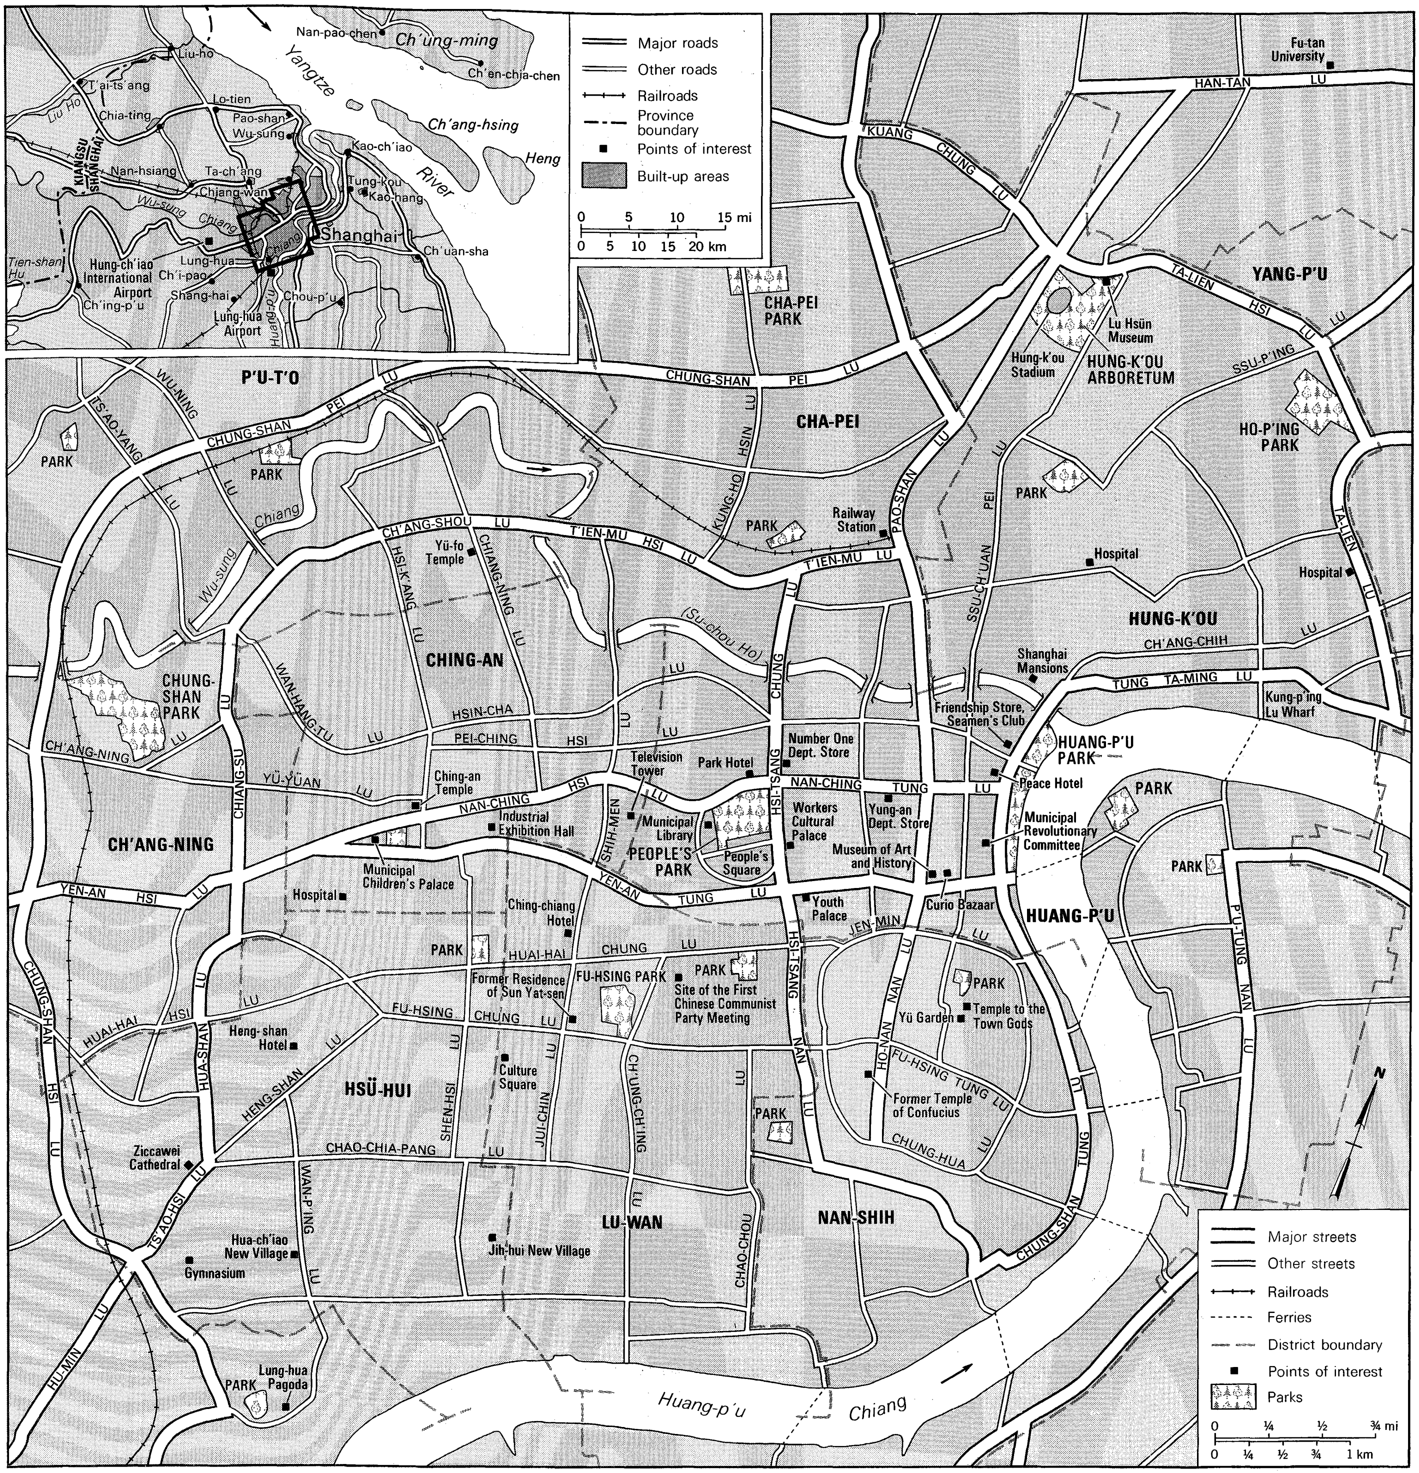
Industry. Shanghai has become the nation's leading industrial and manufacturing centre because of a distinctive combination of factors. These include the availability of a large, highly skilled, and technologically innovative work force; a well-grounded and broadly based scientific-research establishment supportive of industry; a tradition of cooperation among producers; and excellent internal and external communication and supply facilities.

The iron and steel industry was one of the earliest to be established in China. In the 1950s the blast-furnace capacity of the industry was enlarged, and attempts were made to integrate the operations of the iron and steel industry more closely with the machine-manufacturing industry.

Shanghai's machine and machine tool industry is especially important in China's modernization plans. Among the varieties of industrial equipment produced are multiple-use lathes, wire-drawing dies, and manufacturing equipment for assembling computers and other electronic devices, precision instruments, and polymer synthetics.

The chemical and petrochemical industries are almost fully integrated, and there is increasing cooperation among individual plants in the production and supply of chemical raw materials for plastics, synthetic fibres, dyes, paint, pharmaceuticals, agricultural pesticides, chemical fertilizers, synthetic detergents, and refined petroleum products. Heavy industry (especially metallurgical and chemical) predominated until the late 1970s. Light industry is now favoured in an effort to reduce pollution, alleviate transport congestion, and compensate for energy and raw material shortages associated with heavy industry.

The textile industry has been reorganized to assure efficient utilization of the mills' productive capacity at all stages of the manufacturing process. The textile mills cooperate in their use of raw materials and have estab-



Central Shanghai and (inset) its metropolitan area.

lished cooperative relationships with plants that manufacture rubber shoes, tires, zippers, industrial abrasives, and conveyor belts.

Shanghai is also a primary source of a wide variety of consumer goods such as watches, cameras, radios, fountain pens, glassware, stationery products, leather goods, and hardware. Factories producing such goods have made a special effort to meet consumer demands and to produce durable and attractive products.

Commerce. The retail trade in manufactured consumer goods is managed by the First Commercial Bureau. A number of commercial corporations under the Bureau are responsible, in turn, for the wholesaling, distribution, and warehousing of specific commodity groups. A separate corporation manages the larger retail stores, while the smaller retail establishments and some specialized wholesaling organizations are controlled by local commerce bureaus in the various districts of the city.

Banking operations

Finance and trade. Shanghai's two major banks—the People's Construction Bank and the Bank of China—function as administrative organs of the Ministry of Finance. They are responsible for the disbursement and management of capital investment funds for state enterprises. Two British banks, the Hong Kong and Shanghai Banking Corporation and the Chartered Bank, along with other foreign banks, maintain Shanghai branch offices that underwrite foreign trade transactions and exchange foreign currency in connection with trading operations. Remittances from Chinese living abroad (mainly in Hong Kong and in a number of Southeast Asian countries) are managed and collected by several overseas Chinese banks.

Industrial products are exported from Shanghai to all parts of China. Imports are mainly unprocessed food grains, petroleum and coal, construction materials, and such industrial raw materials as pig iron, salt, raw cotton, tobacco, and oils. In domestic trade, Shanghai still imports more than it exports. In foreign trade, however, the value of exported commodities exceeds that of imported goods, and the proportion of manufactured exports is steadily increasing.

The port of Shanghai

Transportation. Shanghai is China's major transport centre. The central city is both a sea and river port, with the Huang-p'u Chiang serving as an excellent harbour; at high tide, oceangoing vessels can sail up the river to the city.

In the early 1950s, the harbour was divided into a number of specialized sections. P'u-tung, on the east bank of the Huang-p'u and in the Huang-p'u district, is used for the storage of bulk commodities and for transportation maintenance and repair facilities, while P'u-hsi, in the Nan-shih District on the west bank, and Fu-hsing Tao (Fu-hsing Island) are the sites of general cargo wharves. Kao-yang Lu Wharf and I-hui contain general and bulk cargo wharves, and the Wu-sung Chiang is lined with riverine and small-craft terminals and cargo-handling facilities. Ocean terminals were constructed after 1952 at Jih-hui Chiang, south of the city, and at Chang-hua-peng, to the north at Wu-sung; a third passenger-and-freight terminal for Yangtze River and coastal traffic was opened in 1982.

Heavily used inland-waterway connections, via the Wu-sung Chiang, and an extensive canal network are maintained with Su-chou (Soochow), Wu-hsi, and Yang-chou in Kiangsu Province, and with Hang-chou (Hangchow), in Chekiang Province.

Railway facilities

The railway network reflects the efforts that have been made since 1949 to reorient the city's industrial economy to balance export and domestic development needs. Before World War II, Shanghai was the terminus of two major rail lines south of the Yangtze—the Hu-ning line, from Nanking to Shanghai, and the Hu-han-jung line, from Shanghai to the port of Ning-po in Chekiang Province. A short spur line also ran from Shanghai to Wu-sung. Additional spur lines, built since 1949, connect the industrial districts to the main trunk routes. These spurs include the Wen-tsao-pin and Min-hang lines and several short spurs emanating from Nan-hsiang (just west of the central city) to Ho-chia-wan, Peng-p'u, T'ao-p'u, and the Shanghai General Petrochemical Plant at Jinshanwei to the south.

Shanghai is served by two airports. The older Lung-hua Airport, a few miles south of the city, is used mainly for domestic flights; the Hung-ch'iao International Airport, southwest of Shanghai, is one of China's busiest. Intraurban transport by electric trolleybus, trolley, and motorbus has been substantially improved since 1949.

ADMINISTRATIVE AND SOCIAL CONDITIONS

Government. As a first-order, province-level administrative unit, Shanghai Municipality is, in theory, directly controlled by the central government in Peking. It is difficult, however, to gauge the precise nature of this relationship. Since the Cultural Revolution of the late 1960s, China's administrative apparatus at all levels of the hierarchy has been in a process of readjustment so as to bring governmental organization in line with political reality. In 1967, at the beginning of the Cultural Revolution, the Shanghai Municipal Revolutionary Committee was established as the top governing body in the municipality after a chaotic period in which a number of popular-based revolutionary organizations seized control of the city for brief periods. The committee at that time was composed of representatives of the army, the mass revolutionary organizations, and some former Communist Party officials. By the mid-1970s, this was replaced by a municipal government made up of commissions, offices, and bureaus responsible to the Shanghai People's Congress, an elected body. These units serve both policy advisory and administrative functions and function as administrative links to both the national government in Peking as well as the local governing bodies.

Public utilities. Modern public works improvements include the installation and improvement of drainage and sewage treatment facilities, public water supply systems, street lights, and public refuse bins. Roads have been widened and repaired, flood walls constructed in low-lying areas subject to tidal inundation, and housing built. The sea walls surrounding Shanghai have also been strengthened and enlarged; two long sea walls extend east of the Huang-p'u for a total of more than 13 miles (21 kilometres).

Shanghai is also one of China's major electric power generating centres. Electricity can be generated by coal-fired thermal plants, and the Shanghai area is linked via a major transmission network with Nanking to the northwest and with Hangchow and Hsin-an-chiang (the site of a hydroelectric generating facility) in Chekiang Province to the southwest. China's largest gas works is located at Lung-hua. Increased energy demands for industry and domestic use in the early 1980s led to a decision by the national authorities to construct one of China's first two nuclear power plants in Shanghai.

Health. Shanghai's health-care facilities range from thousands of small clinics associated with factories, schools, retail establishments, and government offices to numerous major research and teaching hospitals. Most hospitals have facilities for practicing and teaching both traditional Chinese and Western medicine. Medical schools have concentrated on the training of "barefoot" doctors, practitioners with sufficient medical skills to supply basic care to people in rural areas.

Education. Shanghai is China's leading centre of higher education and scientific research. There are numerous universities and other institutions of higher learning—including Fu-tan, Chiao-t'ung, T'ung-chi, and the Hua-tung Shih-fan Ta-hsueh—as well as technical and higher education institutes. Many factories have affiliated work-study colleges to equip workers for more highly skilled jobs. In 1960 the Shanghai Municipal Part-Work Part-Study Industrial University was established through the cooperation of more than 1,000 industrial establishments. A large segment of the city's total work force is enrolled in one of these schools.

Work and college programs

The Shanghai Branch of the Chinese Academy of Sciences, China's leading scientific research and development body, is located in Shanghai. During the Cultural Revolution, practical applications of scientific work in agriculture and industry were encouraged. Since the late 1970s, extensive research investments have been made in such high technology areas as nuclear energy, computers, semiconductors, laser and infrared technology, and satellites.

CULTURAL LIFE

Shanghai's cultural attractions include museums, historical sites, and scenic gardens. The Shanghai Museum of Art and History houses an extensive collection of bronzes, ceramics, and other artifacts dating over several thousand years. The Shanghai Revolutionary History Memorial Hall displays photographs and objects that trace the city's evolution. The Ta Shih-chieh ("Great World"), founded in the 1920s, is Shanghai's leading theatrical centre and offers folk operas, dance performances, plays, story readings, and specialized entertainment forms typical of China's national minority groups. The city also has many workers' and children's recreational clubs and several large motion picture theatres, including the Kuang-ming Theatre.

The old Chinese city houses the 16th-century Yü-Yuan Garden (Garden of the Mandarin Yü), an outstanding example of late Ming garden architecture, and the Former Temple of Confucius. Other points of attraction are the Ch'ing dynasty Lung-hua Pagoda, the Industrial Exhibition Hall, and the tomb and former residence of Lu Hsün, a 20th-century revolutionary writer.

The major publishing houses of Shanghai are a branch of the People's Literature Publishing House (at Peking) and the People's Educational Publishing House. In addition to the large branch of the library of the Chinese Academy of Sciences, Shanghai has numerous other libraries. Shanghai's art and music schools include a branch of the Central Conservatory (Tientsin), the Shanghai Conservatory, and the Shanghai Institute of Drama. There is also a variety of professional performing arts troupes, including ballet and opera companies, symphonies, and puppet troupes.

Parks, open spaces, and playing fields were notably expanded after 1949. Two of the earliest to be opened for public use were the People's Park in central Shanghai and the Huang-p'u Park on the shore of the Huang-p'u Chiang. Every section of the city has large parks and playing fields. Among the largest are the Hung-k'ou Arboretum and Stadium in the north; the Peace Park and Ho-p'ing Park and playing field in the northeast; the P'u-tung Park in eastern Shanghai, the Hu-nan and Fu-hsing parks in the south, and the Chung-shan Park on the western periphery of the central city.

History

EVOLUTION OF THE CITY

As late as the 5th to 7th century AD the Shanghai area, then known as Shen or Hu Tu, was sparsely populated and undeveloped. Despite the steady southward progression of Chinese settlement, the exposed deltaic position of the area retarded its economic growth.

The city's origins

During the Sung dynasty (960–1126) Shanghai emerged from its somnolent state as a small, isolated fishing village. The area to the west around T'ai Hu (T'ai Lake) had developed a self-sustaining agricultural economy on protected reclaimed land and was stimulated by an increase in population resulting from the southward migration of Chinese fleeing the invading Mongols in the north. The natural advantages of Shanghai as a deepwater port and shipping centre were recognized as coastal and inland shipping expanded rapidly. By the beginning of the 11th century, a customs office was established; and by the end of the 13th century, Shanghai was designated as a county seat and placed under the jurisdiction of Kiangsu Province.

During the Ming dynasty (1368–1644), roughly 70 percent of the cultivated acreage around Shanghai was given to the production of cotton to feed the city's cotton- and silk-spinning industry. By the middle of the 18th century there were more than 20,000 persons employed as cotton spinners.

The impact of Western imperialism

After the 1850s, the predominantly agricultural focus of the economy was quickly transformed. At this time the city became the major Chinese base for commercial imperialism by nations of the West. Following their humiliating defeat by Great Britain in 1842, the Chinese surrendered Shanghai and signed the Treaty of Nanking, which opened the city to unrestricted foreign trade. The British, French, and Americans took possession of designated areas in the city within which they were granted special rights and privileges, and the Japanese received a concession in 1895 under the terms of the Treaty of Shimonoseki.

The opening of Shanghai to foreign business immediately led to the establishment of major European banks and multipurpose commercial houses. The city's prospects as a leading centre of foreign trade were further enhanced when Canton, a rival port in the southeastern coastal province of Kwangtung, was cut off from its hinterland by the Taiping Rebellion (1850–64). Impelled by this potential threat to the uninterrupted expansion of their commercial operations in China, the British obtained rights of navigation on the Yangtze in 1857. As the natural outlet for the vast hinterland of the Lower Yangtze, Shanghai rapidly grew to become China's leading port and by 1860 accounted for about 25 percent of the total shipping tonnage entering and departing the country.

Shanghai did not, however, show promise of becoming a major industrial centre until the 1890s. Except for the Chiang-nan Arsenal organized by the Ch'ing dynasty (1644–1911) in the early 1860s, most industrial enterprises were small-scale offshoots of the larger foreign trading houses. As the flow of foreign capital steadily increased after the Sino-Japanese War of 1894–95, light industries were established within the foreign concessions, which took advantage of Shanghai's ample and cheap labour supply, local raw materials, and inexpensive power.

THE 20TH CENTURY

By contrast, local Chinese investment in Shanghai's industry was minimal until World War I diverted foreign capital from China. From 1914 through the early 1920s, Chinese investors were able to gain a tenuous foothold in the scramble to develop the industrial economy. This initial involvement was short-lived, however, as the post-World War I resurgence of Western and Japanese economic imperialism—followed closely by the Depression of the 1930s—overwhelmed many of the newly established Chinese industries. Competition became difficult, as cheaper foreign goods were dumped on the Shanghai market, and labour was attracted to relatively higher paying jobs in foreign-owned factories. Prior to the Sino-Japanese War of 1937–45 the Japanese had gained control over about half of the city's yarn-spinning and textile-weaving capacity.

Founding of the Chinese Communist Party

The 1920s was also a period of growing political awareness in Shanghai. Members of the working class, students, and intellectuals became increasingly politicized as foreign domination of the city's economic and political life became ever more oppressive. When the agreements signed by the United Kingdom, the United States, and Japan at the Washington Conference of 1922 failed to satisfy Chinese demands, boycotts of foreign goods were instituted. The Chinese Communist Party was founded in Shanghai in 1921, and four years later the Communist Party led the "May 30" uprising of students and workers. This massive political demonstration was directed against feudalism, capitalism, and official connivance in foreign imperialistic ventures. The student–worker coalition actively supported the Nationalist armies under Chiang Kai-shek, but the coalition and the Communist Party were violently suppressed by the Nationalists in 1927.

Shanghai was occupied by the Japanese during the Sino-Japanese War of 1937–45, and the city's industrial plants suffered extensive war damage. In the brief interim before the fall of Shanghai to the People's Liberation Army (PLA) in 1949, the city's economy suffered even greater dislocation through the haphazard proliferation of small, inefficient shop industries, rampant inflation, and the absence of any overall plan for industrial reconstruction.

After 1949 Shanghai's development was temporarily slowed because of the emphasis on internal regional development, especially during the period up to 1960 when close cooperation was maintained with the Soviet Union. With the cooling of relations after 1960, Shanghai has resumed its key position as China's leading scientific and technological research centre, with the nation's most highly skilled labour force.

BIBLIOGRAPHY. RHOADS MURPHEY, *Shanghai: Key to Modern China* (1953), is an authoritative study of Shanghai's pre-World War II political and economic organization. For the post-1949 period, NEALE HUNTER, *Shanghai Journal* (1969), recounts the author's experiences as an English teacher in the Shanghai Foreign Language Institute during the Cultural Revolution. Scholarly accounts of the organization and management of Shanghai's industry, trade, and financial institutions through the 1960s may be found in AUDREY G. DONNITHORNE, *China's Economic System* (1967); and BARRY M. RICHMAN, *Industrial Society in Communist China* (1969). Economic and political developments are treated in CHRISTOPHER HOWE, "The Level and Structure of Employment and the Sources of Labor Supply in Shanghai, 1949–1957," and LYNN T. WHITE III, "Shanghai's Polity in Cultural Revolution," in J.W. LEWIS (ed.), *The City in Communist China* (1971). A carefully documented collection of papers on Shanghai's political life, economic development, cultural and ideological milieu, and spatial development is brought together by CHRISTOPHER HOWE (ed.), *Shanghai: Revolution and Development in an Asian Metropolis* (1981). LYNN T. WHITE III, *Careers in Shanghai: The Social Guidance of Personal Energies in a Developing Chinese City, 1949–1966* (1978), examines political and social influences on career choices in relation to national goals. (B.Bo.)

Shintō

Shintō is the name given to indigenous religious beliefs and practices of Japan. The word Shintō literally means "the way of *kami*" (*kami* means "mystical," "superior," or "divine," generally sacred or divine power, specifically the various gods or deities); it came into use in order to distinguish indigenous Japanese beliefs from Buddhism, which had been introduced into Japan in the 6th century AD. Shintō has no founder, no official sacred scriptures, and no dogma, but it has preserved its ethos throughout the ages.

This article is divided into the following sections:

NATURE AND VARIETIES

Shintō consists of the traditional Japanese religious practices as well as the beliefs and life attitudes that are in accord with these practices. Shintō is more readily observed in the social life of the Japanese people and in their personal motivations than in a pattern of formal belief or philosophy. It remains closely connected with the Japanese value system and the Japanese people's ways of thinking and acting.

Three major types of Shintō

Shintō can be roughly classified into the following three major types: Shrine Shintō, Sect Shintō, and Folk Shintō. Shrine Shintō (Jinja Shintō), which has been in existence from the beginning of Japanese history to the present day, constitutes a main current of Shintō tradition. Shrine Shintō includes within its structure the now defunct State Shintō (Kokka Shintō)—based on the total identity of religion and state—and has close relations with the Japanese Imperial family. Sect Shintō (Kyōha Shintō) is a relatively new movement consisting of 13 major sects that originated in Japan around the 19th century. Each sect was organized into a religious body by either a founder or a systematizer. Folk Shintō (Minzoku Shintō) is an aspect of Japanese folk belief that is closely connected with the other types of Shintō. It has no formal organizational structure nor doctrinal formulation but is centred in the veneration of small roadside images and in the agricultural rites of rural families. These three types of Shintō are interrelated: Folk Shintō exists as the substructure of Shintō faith, and a Sect Shintō follower is usually also a parishioner (*ujiko*) of a particular Shintō shrine.

HISTORY TO 1900

Much remains unknown about religion in Japan during the Paleolithic and Neolithic ages. It is unlikely, however, that the religion of these ages has any direct connection with Shintō. Yayoi culture, which originated in the northern area of the island of Kyushu in about the 3rd or 2nd century BC, is directly related to later Japanese culture and hence to Shintō. Among the primary Yayoi religious phenomena were agricultural rites and shamanism.

Early clan religion and ceremonies. In ancient times small states were gradually formed at various places. By the middle of the 4th century AD a nation with an ancestor of the present Imperial Household as its head had probably been established. The constituent unit of society at that time was the *uji* (clan or family), and the head of each *uji* was in charge of worshipping the clan's *ujigami*—its particular tutelary or guardian deity. The prayer for good harvest in spring and the harvest ceremony in autumn were two major festivals honouring the *ujigami.* Divination, water purification, and lustration (ceremonial purification), which are all mentioned in the Japanese classics, became popular, and people started to build shrines for their *kami.*

Kami

Ancient Shintō was polytheistic. People found *kami* in nature, which ruled seas or mountains, as well as in outstanding men. They also believed in *kami* of ideas such as growth, creation, and judgment. Though each clan made the tutelary *kami* the core of its unity, such *kami* were not necessarily the ancestral deities of the clan. Sometimes *kami* of nature and *kami* of ideas were regarded as their tutelary *kami.*

Two different views of the world were present in ancient Shintō. One was the three-dimensional view in which the Plain of High Heaven (Takama no Hara, the *kami*'s world), Middle Land (Nakatsukuni, the present world), and the Hades (Yomi no Kuni, the world after death) were arranged in vertical order. The other view was a two-dimensional one in which this world and the Perpetual Country (Tokoyo, a utopian place far beyond the sea) existed in horizontal order. Though the three-dimensional view of the world (which is also characteristic of North Siberian and Mongolian shamanistic culture) became the representative view observed in Japanese myths, the two-dimensional view of the world (which is also present in Southeast Asian culture) was dominant among the populace.

Early Chinese influences on Shintō. Confucianism is believed to have reached Japan in the 5th century AD, and by the 7th century it had spread among the people,

By courtesy of the Japan National Tourist Organization

Procession at Tōshō-gū (Tōshō Shrine) Festival at Nikkō, Japan, May 17–18.

together with Chinese Taoism and Yin-Yang (harmony of two basic forces of nature) philosophy. All of these stimulated the development of Shintō ethical teachings. With the gradual centralization of political power, Shintō began to develop as a national cult as well. Myths of various clans were combined and reorganized into a pan-Japanese mythology with the Imperial Household as its centre. The *kami* of the Imperial Household and the tutelary *kami* of powerful clans became the *kami* of the whole nation and people, and offerings were made by the state every year. Such practices were systematized supposedly around the start of the Taika-era reforms in 645. By the beginning of the 10th century about 3,000 shrines throughout Japan were receiving state offerings. As the power of the central government declined, however, the system ceased to be effective, and after the 13th century only a limited number of important shrines continued to receive the Imperial offerings. Later, after the Meiji Restoration in 1868, the old system was revived.

The encounter with Buddhism. Buddhism was first introduced into Japan in AD 538 and developed gradually. In the 8th century there emerged tendencies to interpret Shintō from a Buddhist viewpoint. Shintō *kami* were viewed as protectors of Buddhism; hence shrines for tutelary *kami* were built within the precincts of Buddhist temples. *Kami* were made equivalent to *deva* (the Buddhist Sanskrit term for "gods") who rank highest in the Realm of Ignorance, according to Buddhist notions. Thus *kami,* like other creatures, were said to be suffering because they were unable to escape the endless cycle of transmigration; help was therefore offered to *kami* in the form of Buddhist discipline. Buddhist temples were even built within Shintō shrine precincts, and Buddhist *sūtras* (scriptures) were read in front of *kami.* By the late 8th century *kami* were thought to be avatars, or incarnations, of Buddhas and *bodhisattvas. Bodhisattva* names were given to *kami,* and Buddhist statues were placed even in the inner sanctuaries of Shintō shrines. In some cases Buddhist priests were in charge of the management of Shintō shrines.

Shintō–Buddhist syncretism

From the beginning of the Kamakura period (1192–1333), theories of Shintō–Buddhist amalgamation were formulated. The most important of the syncretic schools to emerge were Ryōbu (Dual Aspect) Shintō and Sannō Ichijitsu (One Truth of Sannō) Shintō. According to Ryōbu Shintō—also called Shingon Shintō—the two realms of the universe in Shingon Buddhist teachings corresponded to the *kami* Amaterasu Ōmikami and Toyuke (Toyouke) Ōkami enshrined at the Ise-daijingū (Grand Shrine of Ise, commonly called Ise-jingū, or Ise Shrine) in Mie Prefecture. The theorists of Sannō Ichijitsu Shintō—also called Tendai Shintō—interpreted the Tendai belief in the central, or absolute, truth of the universe (*i.e.,* the fundamental Buddha-nature) as being equivalent to the Shintō concept that the sun goddess Amaterasu was the source of the universe. These two sects brought various Buddhist rituals into Shintō. Buddhistic Shintō was popular for several centuries and was highly influential until its extinction at the Meiji Restoration.

Shintō reaction against Buddhism. Ise, or Watarai, Shintō was the first theoretical school of anti-Buddhistic Shintō in that it attempted to exclude Buddhist accretions and also tried to formulate a pure Japanese version. Watarai Shintō appeared in Ise during the 13th century as a reaction against the Shintō–Buddhist amalgamation. Konton (chaos), or Kizen (non-being), was the basic *kami* of the universe for Watarai Shintō and was regarded as the basis of all beings, including the Buddhas and *bodhisattvas.* Purification, which had been practiced since the time of ancient Shintō, was given much deeper spiritual meanings. *Shōjiki* (defined as uprightness or righteousness) and prayers were emphasized as the means by which to be united with *kami.*

Yoshida Shintō, a school in Kyōto that also emerged during the 13th century, inherited various aspects of Watarai Shintō and also showed some Taoist influence. The school's doctrines were largely the work of Yoshida Kanetomo (1435–1511). Its fundamental *kami* (the source of all things and beings in the universe) was Taigen Sonjin (the Great Exalted One). According to its teaching, if one is truly purified, his heart can be the *kami*'s abode. The ideal of inner purification was a mysterious state of mind in which one worshipped the *kami* that lived in one's own heart. Although the Watarai and Yoshida schools were thus free of Buddhistic theories, the influence of Chinese thought was still very much present.

Neo-Confucian Shintō. In 1603 the Tokugawa shogunate was founded in Edo (Tokyo), and contact between Shintō and Confucianism was resumed. Scholars tried to interpret Shintō from the standpoint of Neo-Confucianism, emphasizing the unity of Shintō and Confucian teachings. Schools emerged based on the teachings of the Chinese philosophers Chu Hsi and Wang Yang-ming, and Neo-Confucianism became an official subject of study for warriors. Yoshikawa Koretaru (1616–94) and Yamazaki Ansai (1619–82) were two representative scholars of Confucian Shintō. They added Neo-Confucian interpretations to the traditional theories of Watarai Shintō, and each established a new school. The T'ai Chi (Supreme Ultimate) concept of Neo-Confucianism was regarded as identical with the first *kami* of the *Nihon shoki,* or *Nihon-gi* ("Chronicles of Japan"). One of the characteristics of Yoshikawa's theories was his emphasis on political philosophy. Imperial virtues (wisdom, benevolence, and courage), symbolized by the Sanshu no Jingi (Three Sacred Treasures), and national ethics, such as loyalty and filial piety, constituted the way to rule the state. Yamazaki Ansai further developed this tendency and advocated both mystic pietism and ardent emperor worship.

Yoshikawa Koretaru and Yamazaki Ansai

Fukko Shintō. Fukko (Restoration, or Revival) Shintō is one of the Kokugaku (National Learning) movements that started toward the end of the 17th century. Advocates of this school maintained that the norms of Shintō should not be sought in Buddhist or Confucian interpretations but in the beliefs and life-attitudes of their ancestors as clarified by philological study of the Japanese classics. Motoori Norinaga (1730–1801) represented this school. His emphasis was on the belief in *musubi* (the mystical power of becoming or of creation), which had been popular in ancient Shintō, and on a this-worldly view of life, which anticipated the eternal progress of the world in ever-changing mutations. These beliefs, together with the inculcation of respect for the Imperial line and the teaching of absolute faith—according to which all problems beyond human capability were turned over to *kami*—exercised great influence on modern Shintō doctrines.

The most important successor of Motoori in the field of Shintō was Hirata Atsutane (1776–1843), who showed the influence of Roman Catholic teachings in some respects—derived from the writings of Jesuits in China—by advancing the idea of a creator god and retribution for ethical and religious failings in another world. These doctrines, however, were not accepted into the main current of Shintō. Hirata developed the philological studies started by Motoori and trained many capable disciples. He also wrote prayers, worked out formulas for family cults of tutelary *kami* and ancestors, and promoted Shintō practices. His spirituality, reverence for the emperor, and desire to restore the Imperial regime based on the spirit of ancient Shintō enlisted many supporters and served as one of the factors in bringing about the Meiji Restoration in 1868.

Formation of Sect Shintō. At the fall of the Tokugawa shogunate in 1867, new religious movements emerged out of the social confusion and unrest of the people. What these new movements taught differed widely: some were based on mountain-worship groups, which were half Buddhist and half Shintō; some placed emphasis on purification and ascetic practices; and some combined Confucian and Shintō teachings. New religious movements—such as Kurozumi-kyō (in this sense *kyō* means "religion," or "religious body"), founded by Kurozumi Munetada (1780–1850); Konkō-kyō (Konkō is the religious name of the founder of this group and means, literally, "golden light") by Kawate Bunjirō (1814–83); and Tenri-kyō (*tenri* means "divine reason or wisdom") by Nakayama Miki (1798–1887)—were based mostly on individual religious experiences and aimed at healing diseases or spiritual salvation. These sectarian Shintō groups, numbering 13 during the

Meiji period (1868–1912), were stimulated and influenced by Restoration Shintō. They can be classified as follows:

1. Revival Shintō sects: Izumo-ōyashiro-kyō (or Taisha-kyō), Shintō-taikyō, Shinri-kyō
2. Confucian sects: Shintō Shūsei-ha, Shintō Taisei-ha
3. Purification sects: Shinshū-kyō, Misogi-kyō
4. Mountain worship sects: Jikkō-kyō, Fusō-kyō, Ontake-kyō (or Mitake-kyō)
5. "Faith-healing" sects: Kurozumi-kyō, Konkō-kyō, Tenri-kyō

SHINTŌ LITERATURE AND MYTHOLOGY

Kojiki and *Nihon-gi* (*Nihon shoki*)

Shintō has no founder. When the Japanese people and Japanese culture became aware of themselves, Shintō was already there. Nor has it any official scripture that can be compared to the Bible in Christianity or to the Qur'ān in Islām. The *Kojiki* ("Records of Ancient Matters") and the *Nihon-gi,* or *Nihon shoki* ("Chronicles of Japan") are regarded in a sense as sacred books of Shintō. They were written in AD 712 and 720, respectively, and are compilations of the oral traditions of ancient Shintō. But they are also books about the history, topography, and literature of ancient Japan. It is possible to construct Shintō doctrines from them by interpreting the myths and religious practices they describe.

Stories partially similar to those found in Japanese mythology can be found in the myths of Southeast Asia; and in the style of description in Japanese myths some Chinese influence is detectable. The core of the mythology, however, consists of tales about the sun goddess Amaterasu Ōmikami, the ancestress of the Imperial Household, and tales of how her direct descendants unified the Japanese people under their authority. In the beginning, according to Japanese mythology, a certain number of *kami* simply emerged, and a pair of *kami,* Izanagi and Izanami, gave birth to the Japanese islands, as well as to the *kami* who became ancestors of the various clans. Amaterasu, the ruler of Takama no Hara; the moon god Tsukiyomi no Kami; and Susanoo (Susanowo) no Mikoto, the brother of Amaterasu, were the most important among them. A descendant of Amaterasu, Jimmu, is said to have become the first emperor of Japan. Japanese mythology says that the Three Sacred Treasures (the mirror, the sword, and the jewels), which are still the most revered symbols of the Imperial Household, were first given by Amaterasu to her grandson. The Inner Shrine (Naikū) of the Ise-jingū is dedicated to this ancestral goddess and is the most venerated shrine in Shintō.

The Japanese classics also contain myths and legends concerning the "800 myriads of *kami*" (*yao-yorozu no kami;* literally, *yao* equals 800 and *yorozu* 10,000). Some of them are the tutelary deities of clans and later became the tutelary *kami* of their respective local communities. Many others, however, are not enshrined in sanctuaries and have no direct connections with the actual Shintō faith. Little attention was paid to Shintō mythology until the development of Restoration Shintō, and even after that it has remained well understood only by Shintō priests and scholars.

DOCTRINES

Kami and *makoto*

Concept of the sacred. At the core of Shintō are beliefs in the mysterious creating and harmonizing power (*musubi*) of *kami* and in the truthful way or will (*makoto*) of *kami.* The nature of *kami* cannot be fully explained in words because *kami* transcends the cognitive faculty of man. Devoted followers, however, are able to understand *kami* through faith and usually recognize various *kami* in polytheistic form.

Parishioners of a shrine believe in their tutelary *kami* as the source of human life and existence. Each *kami* has a divine personality and responds to truthful prayers. The *kami* also reveals *makoto* to people and guides them to live in accordance with it. In traditional Japanese thought, truth manifests itself in empirical existence and undergoes transformation in infinite varieties in time and space. *Makoto* is not an abstract ideology. It can be recognized every moment in every individual thing in the encounter between man and *kami.*

In Shintō all the deities are said to cooperate with one another, and life lived in accordance with a *kami's* will is believed to produce a mystical power that gains the protection, cooperation, and approval of all the particular *kami.*

Precepts of truthfulness and purification. As the basic attitude toward life, Shintō emphasizes *makoto no kokoro* ("heart of truth"), or *magokoro* ("true heart"), which is usually translated as "sincerity, pure heart, uprightness." This attitude follows from the revelation of the truthfulness of *kami* in man. It is, generally, the sincere attitude of a person in doing his best in the work he has chosen or in his relationship with others, and the ultimate source of such a life-attitude lies in man's awareness of the divine.

Although Shintō ethics do not ignore individual moral virtues such as loyalty, filial piety, love, and faithfulness, it is generally considered more important to seek for *magokoro,* which constitutes the dynamic life-attitude that brings forth these virtues. In ancient scriptures *magokoro* was interpreted as "bright and pure mind" or "bright, pure, upright, and sincere mind." Purification, physical and spiritual, is stressed even in contemporary Shintō to produce such a state of mind. It is a necessary means to make communion between *kami* and man possible and to enable individuals to accept the blessings of *kami.*

Nature of man and other beliefs. In Shintō it is commonly said that "Man is *kami's* child." First, this means that a person was given his life by *kami* and that his nature is therefore sacred. Second, it means that daily life is made possible by *kami,* and, accordingly, the personality and life of people are worthy of respect. An individual must revere the basic human rights of everyone (regardless of race, nationality, and other distinctions) as well as his own. The concept of original sin is not found in Shintō. On the contrary, man is considered to have a primarily divine nature. In actuality, however, this sacred nature is seldom revealed in man. Purification is considered symbolically to remove the dust and impurities that cover one's inner mind.

Role of the individual in the history of his family

Shintō is described as a religion of *tsunagari* ("continuity or communion"). The Japanese, while recognizing each man as an individual personality, do not take him as a solitary being separated from others. On the contrary, he is regarded as the bearer of a long, continuous history that comes down from his ancestors and continues in his descendants. He is also considered as a responsible constituent of various social groups.

Motoori Norinaga stated that the human world keeps growing and developing while continuously changing. Similarly Japanese mythology speaks of an eternity of history in the divine edict of Amaterasu. In its view of history, Shintō adheres to the cyclical approach, according to which there is a constant recurrence of historical patterns. Shintō does not have the concept of the "last day": there is no end of the world or of history. One of the divine edicts of Amaterasu says:

> This Reed-plain-1,500-autumns-fair-rice-ear Land is the region which my descendants shall be lords of. Do thou, my August Grandchild, proceed thither and govern it. Go! and may prosperity attend thy dynasty, and may it, like Heaven and Earth, endure forever.

Modern Shintōists interpret this edict as revealing the eternal development of history as well as the eternity of the dynasty. From the viewpoint of finite individuals, Shintōists also stress *naka-ima* ("middle present"), which repeatedly appears in the Imperial edicts of the 8th century. According to this point of view, the present moment is the most valuable of all conceivable times. In order to participate directly in the eternal development of the world, it is required of Shintōists to live fully each moment of life, making it as worthy as possible.

Historically, the *ujigami* of each local community played an important role in combining and harmonizing different elements and powers. The Imperial system, which has been supported by the Shintō political philosophy, is an example of unity and harmony assuming the highest cultural and social position in the nation. After the Meiji Restoration (1868), Shintō was used as a means of spiritually unifying the people during repeated wars. Since the end of World War II the age-old desire for peace has been restressed. *The General Principles of Shintō Life* proclaimed by the Association of Shintō Shrines in 1956 has the following article: "In accordance with the Emperor's will, let us be harmonious and peaceful, and pray for the nation's development as well as the world's co-prosperity."

RITUAL PRACTICES AND INSTITUTIONS

Matsuri

Shintō does not have a weekly religious service. People visit shrines at their convenience. Some may go to the shrines on the first and 15th of each month and on the occasions of rites or festivals (*matsuri*), which take place several times a year. Devotees, however, may pay respect to the shrine every morning.

Rites of passage. Various Shintō rites of passage are observed in Japan. The first visit of a newborn baby to the tutelary *kami,* which occurs 30 to 100 days after birth, is to initiate the baby as a new adherent. The Shichi-go-san (Seven-Five-Three) festival on November 15 is the occasion for boys of five years and girls of three and seven years of age to visit the shrine to give thanks for *kami*'s protection and to pray for their healthy growth. January 15 is Adults' Day. Youth in the village used to join the local young men's association on this day. At present it is the commemoration day for those Japanese who have attained their 20th year. The Japanese usually have their wedding ceremonies in Shintō style and pronounce their wedding vows to *kami.* Shintō funeral ceremonies, however, are not popular. The majority of the Japanese are Buddhist and Shintōist at the same time and have their funerals in Buddhist style. A traditional Japanese house has two family altars: one, Shintō, for their tutelary *kami* and the goddess Amaterasu Ōmikami, and another, Buddhist, for the family ancestors. Pure Shintō families, however, will have all ceremonies and services in Shintō style. There are other Shintō *matsuri* concerning occupations or daily life, such as a ceremony of purifying a building site or for setting up the framework for a new building, a firing or purifying ceremony for the boilers in a new factory, a completion ceremony for a construction works, or a launching ceremony for a new ship.

Varieties of festival, worship, and prayer. Each Shintō shrine has several major festivals each year, including the Spring Festival (Haru Matsuri, or Toshigoi Matsuri; Prayer for Good Harvest Festival), Autumn Festival (Aki Matsuri, or Niiname-sai; Harvest Festival), an Annual Festival (Rei-sai) and the Divine Procession (Shinkō-sai). The Divine Procession usually takes place on the day of the Annual Festival, and miniature shrines (*mikoshi*) carried on the shoulders are transported through the district. The order of rituals at a grand festival is usually as follows: (1) Purification rites (*harae*)—commonly held at a corner of the shrine precincts before participants come into the shrine but sometimes held within the shrine before beginning a ceremony. (2) Adoration—the chief priest and all the congregation bow to the altar. (3) Opening of the door of the inner sanctuary (by the chief priest). (4) Presentation of food offerings—rice, sake wine, rice cakes, fish, seaweed, vegetables, salt, water, etc., are offered but animal meat is not because of the taboo on shedding blood in the sacred area. In the past cooked food was usually offered to *kami,* but nowadays uncooked food is more often used. In accordance with this change, the idea of entertaining *kami* changed to that of thanksgiving. (5) Prayer—the chief priest recites prayers (*norito*) modelled on ancient Shintō prayers. These prayers were compiled in the early 10th century and were based on the old belief that spoken words had spiritual potency. (6) Sacred music and dance. (7) General offering—participants in the festival make symbolic offerings using little branches of the evergreen sacred tree to which strips of white paper are tied. (8) Taking offerings away. (9) Shutting the door of the inner sanctuary. (10) Final adoration. (11) Feast (*naorai*).

Ritual at festivals

By courtesy of the Izumo-taisha

Inner sanctuary (centre background) of the Grand Shrine of Izumo (Izumo-taisha), dedicated to Ōkuninushi no Kami.

In the olden days *naorai,* a symbolic action in which participants held communion with *kami* by having the same food offered to the deity, came in the middle of the festival ceremony. The custom is still observed sometimes at the Imperial Household and at some old shrines, but it is more common to have communion with *kami* by drinking the offered sake after the festival. Since World War II it has become popular to have a brief sermon or speech before the feast.

Most Shintō festivals are observed generally in accordance with the above-mentioned order. On such occasions as the Annual Festival, various special rites may be held; *e.g.,* special water purification (*misogi*) and confinement in shrines for devotional purposes (*o-komori*), the procession of a sacred palanquin (*o-miyuki*) or of boats (*funa matsuri*), a ceremonial feast (*tōya matsuri*), sumo wrestling, horseback riding (*kurabe-uma*), archery (*matoi*), a lion dance (*shishi mai*), and a rice planting festival (*o-taue matsuri*).

Shintai and *mitama-shiro*

Types of shrines. A simple torii (gateway) stands at the entrance of the shrine precincts (see Tōshō-gū illustration). After proceeding on the main approach, a visitor will come to an ablution basin where the hands are washed and the mouth is rinsed. Usually he will make a small offering at the oratory (*haiden*) and pray. Sometimes a visitor may ask the priest to conduct rites of passage or to offer special prayers. The most important shrine building is the main, or inner, sanctuary (*honden*), in which a sacred symbol called *shintai* ("*kami* body") or *mitama-shiro* ("divine spirit's symbol") is enshrined. The usual symbol is a mirror, but sometimes it is a wooden image, a sword, or some other object. In any case, it is carefully wrapped and placed in a container. It is forbidden to see it: only the chief priest is allowed inside the inner sanctuary.

In the beginning Shintō had no shrine buildings. At each festival people placed a tree symbol at a sacred site, or they built a temporary shrine to invite *kami.* Later they began to construct permanent shrines where *kami* were said to stay permanently. The *honden* of the Inner Shrine at Ise and of Izumo-taisha (Grand Shrine of Izumo, in Shimane Prefecture) illustrate two representative archetypes of shrine construction. The style of the former probably developed from that of a storehouse for crops, especially for rice, and the style of the latter from ancient house construction. In the course of time, variations of shrine architecture were adopted and additional buildings were attached in front of the *honden.* The *honden* and *haiden* are in many cases connected by a hall of offering (*heiden*) where prayers are usually recited. Large shrines also have a hall for liturgical dancing (*kaguraden*).

Other practices and institutions. *Ujigami* belief is the most popular form of Shintō in Japan. Originally referring to the *kami* of an ancient clan, after the 13th century *ujigami* was used in the sense of the tutelary *kami* of a local community, and all the members in the community were that *kami*'s adherents (*ujiko*). Even today a *ujiko* group consists of the majority of the residents in a given community. A Shintōist, however, can believe at the same time in shrines other than his own local shrine. It was only after World War II that some large shrines also started to organize believers' groups (*sūkeisha*). The Believers' Association of the Meiji Shrine, for instance, has a substantial membership living in and around Tokyo.

Kokugakuin University in Tokyo and Kōgakkan University at Ise are the primary training centres for Shintō priests. Though anyone who goes through certain training processes may be a priest (or a priestess), many priests are, in fact, from the families of hereditary Shintō priests.

SHINTŌ RELIGIOUS ARTS

The Japanese from ancient times have valued emotional and aesthetic intuitions in expressing and appreciating their religious experiences. They found symbols of *kami* in natural beauty and the forces of nature, and they developed explicitly religious poetry, architecture, and visual arts. Shrine precincts are covered with green trees and are places of a serene and solemn atmosphere, which is effective in calming worshippers' minds. In the larger shrines, surrounded by expansive woods with mountains as their background, a harmony of nature and architecture may be achieved. Ise-jingū and Izumo-taisha still retain the ancient architectural styles. After the 9th century an intricate form of shrine construction was developed adopting both Buddhist and Chinese architectural styles and techniques. The curving roof style is one example. Unpainted timbers are most frequently used, but wherever Buddhistic Shintō was popular, Chinese vermilion-lacquered shrines were also built.

Torii: the sacred gates

A torii always stands in front of a shrine. Various kinds of torii can be seen in Japan, but their function is always the same: to divide the sacred precincts from the secular area. A pair of sacred stone animals called *komainu* ("Korean dogs") or *karajishi* ("Chinese lions") are placed in front of a shrine. Originally they served to protect the sacred buildings from evil and defilements. After the 9th century they were used for ornamental purposes on ceremonial occasions at the Imperial Court and later came to be used at various shrines generally. Some of the stone lanterns (*ishidōrō*) used at the shrines are works of art. The dedicator's name and the year are inscribed on the lanterns to inform viewers of the long tradition of faith and to urge them to maintain it.

Compared with Buddhist statuary, visual representations of *kami* are not outstanding either in their quality or quantity. Images of *kami* were, in fact, not used in ancient Shintō until after the introduction of Buddhism into Japan. These are placed in the innermost part of the *honden* and are not the objects of direct worship by the people. *Kami* icons are not worshipped at shrines.

The history of the shrine, its construction arrangements, and ritual processions are recorded in picture scrolls (*emakimono*), and at the older shrines there are many votive pictures (*ema*)—small wooden picture plaques—that have been dedicated over the years by worshippers. Other articles, such as specimens of calligraphy, sculpture, swords, and arms, dedicated by the Imperial families, nobles, or feudal lords, are also kept at shrines. Several hundred such items and shrine constructions have been designated by the Japanese government as national treasures and important cultural properties.

Religious music and dance

The traditional religious music and dance of shrines were performed for the purpose of entertaining and appeasing *kami,* rather than to praise them. *Gagaku* (literally, "elegant music") involves both vocal and instrumental music, specifically for wind, percussion, and stringed instruments. *Gagaku* with dance is called *bugaku. Gagaku* was patronized by the Imperial Household as court music and was much appreciated by the upper classes from the 9th to the 11th century. Later some of the more solemn and graceful pieces were used as ritualistic music by shrines and temples. Today *gagaku* is widely performed at larger shrines. The authentic tradition of *gagaku* has been transmitted by the Bureau of Music (Gagaku-ryō, now called Gakubu) of the Imperial Household (established in 701).

Apart from *gagaku* there are also *kagura* (a form of indigenous religious music and dance based on blessing and purification), *ta-asobi* (a New Year's dance-pantomime of the cycle of rice cultivation), and *shishi mai,* which developed originally from magico-religious dances, and are now danced for purification and as prayers. *Matsuri-bayashi* is a gay lively music with flutes and drums to accompany divine processions. Some organizations of both Shrine and Sect Shintō have recently begun to compose solemn religious songs to praise *kami,* making use of Western musical forms. (See also EAST ASIAN ARTS.)

POLITICAL AND SOCIAL ROLES

Until the end of World War II, Shintō was closely related to the state. Offerings to *kami* were made every year by the government and the Imperial Household, and prayers were offered for the safety of the state and people. The *matsuri-goto* (the affairs of worship) offered by the emperor from olden days included not only ceremonies for *kami* but also for ordinary matters of state. "Shintō ceremonies and political affairs are one and the same" was the motto of officials. Administrators were required to have a religious conscience and develop political activities with *magokoro.*

This tradition was maintained as an undercurrent throughout Japanese history. Villagers prayed to the tutelary *kami* of the community for their peace and welfare and promoted unity among themselves with village festivals. After the Meiji Restoration, the government treated Shintō like a state religion and revived the system of national shrines, which dated from the 10th century. In order to propagate Revival Shintō as the foundation of the national structure, they initiated the "great promulgation movement" in which the emperor was respected like *kami.* Although the Japanese constitution enacted in 1889 guaranteed freedom of faith under certain conditions, priority was, in fact, given to Shintō. In elementary schools Shintō was taught to children, and most of the national holidays were related to Shintō festivals. Shintō of this nature was called State Shintō and came under the control of the Bureau of Shrines in the Ministry of Home Affairs.

Relation of State and Sect Shintō

State Shintō was regarded as a state cult and a national ethic and not as "a religion." The free interpretation of its teachings by individual Shintō priests was discouraged. Priests of the national shrines were prohibited from preaching and presiding over Shintō funerals. By 1945 there were 218 national and approximately 110,000 local shrines. The number of Sect Shintō groups was limited to 13 after the organization of Tenri-kyō. Legally these 13 sects were treated as general religious bodies, similar to Buddhism and Christianity, and came under the supervision of the Ministry of Education.

After the end of World War II, the Supreme Commander for the Allied Powers ordered the Japanese government to disestablish State Shintō. All government financial support from public funds and all official affiliation with Shintō and Shintō shrines were also discontinued. State rites performed by the emperor were henceforth to be regarded as the private religious practices of the Imperial family. These rulings were carried into the new Japanese constitution that was enacted in 1947. Presently, Shrine Shintō is faced with two serious problems. The first is determining how the traditional unifying function of Shintō can be promoted in local communities or in the nation without interfering with freedom of faith. The second is the necessity of harmonizing Shintō with rapid modernization, especially in organizing believers and dealing with human problems or the meaning of life.

The number of Shintō shrines has been decreasing since the beginning of the Meiji era, in part because a municipal unification plan in 1889 called for the shrines of tutelary *kami* to be combined with the municipality. The great majority of shrines belong to the Association of Shintō Shrines, established in 1946, and most of the others are independent or belong to small groups.

About 15 percent of 16,251 Sect Shintō churches were damaged during World War II. Although they were not affected by the occupation policies after the war, many sects, in fact, went through difficult years because of unrest among the people and disunion within their own organizations. In the late 20th century, Tenri-kyō in particular was most active among the Sect Shintō groups and was extending its missionary activities overseas to nations in East Asia and in North and South America, and also to other areas.

PLACE OF SHINTŌ IN JAPANESE AND WORLD RELIGION

Shintō together with Buddhism is closely related both culturally and socially to the life of the Japanese people. Its relationships to other religions in Japan are generally cooperative and harmonious. Most Shintōists believe that cooperation between different religions could contribute to world peace, but this is not to imply a facile religious syncretism. Shintōists insist on maintaining their own characteristics and inner depth while working toward the peaceful coexistence of human beings.

(N.H.)

Sikhism

Sikhism is the religion of an Indian group founded in the Punjab (or Pañjāb) in the late 15th century AD by Gurū Nānak. Its members are known as Sikhs. The great majority of Sikhs live in the state of Punjab. Most of the remainder are in Haryāna state and Delhi or are scattered in other parts of India. Some Sikhs have also settled in Malaysia, Singapore, East Africa, the United Kingdom, the United States, and Canada. The word Sikh is derived from the Pāli *sikkha* or Sanskrit *śiṣya,* meaning "disciple." Sikhs are disciples of their Ten Gurūs (religious teachers), beginning with Nānak (1469–1539) and ending with Gobind Singh (1666–1708).

This article is divided into the following sections:

HISTORY AND BACKGROUND

Religious and cultural origins. Sikhism was a historical development of the Hindu Vaiṣṇava Bhakti movement—a devotional movement among followers of the god Vishnu—that began in Tamil country and was introduced to the north by Rāmānuja (traditionally, 1017–1137). In the 14th and 15th centuries, and after prolonged confrontation with Islām, the movement spread across the Indo-Gangetic Plain. The Bhaktas (devotees) maintained that God, though known by many names and beyond comprehension, is the one and the only reality; that all else is illusion (*māyā*); and that the best way to approach God is through repetition of his name (Sanskrit *nāma*), singing hymns of praise (Punjabi *kīrtan*), and meditation under the guidance of a Gurū. Traditional Hindu religion and society were hierarchically structured; the Bhakti movement opposed the Brahmin hegemony over religious ritual and the caste system.

Hindu Vaiṣṇava and Islāmic Ṣūfī origins

Kabīr (1440–1518), a medieval mystic poet and religious synthesist, was the link between Hindu Bhakti and Islāmic Ṣūfism (mysticism), which had gained a large following among Indian Muslims. Ṣūfīs (mystics) also believed in singing hymns and in meditation under guidance of a leader. They welcomed non-Muslims in their hospices. Sikhism drew inspiration from both Bhaktas and Ṣūfīs.

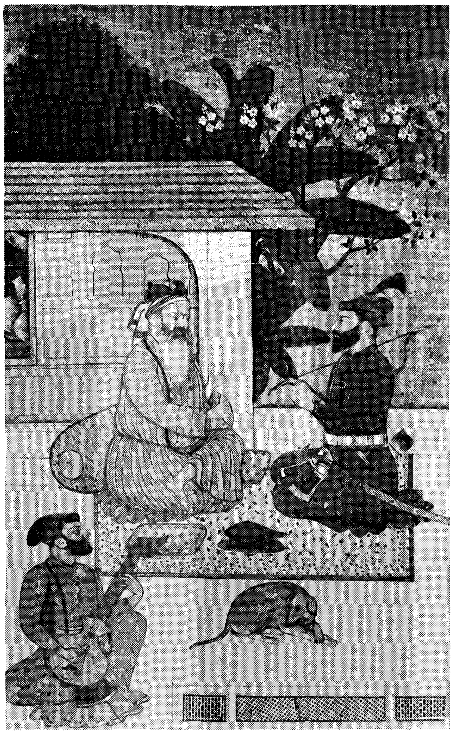
The Ten Gurūs: Nānak and his tradition. Nānak was born in 1469 in the village of Rāi Bhoi dī Talvaṇḍī, 40 miles (65 kilometres) from Lahore (in present-day Pakistan). His father was a revenue collector belonging to the Bedī (conversant with the Vedas—the revealed scriptures of Hinduism) subcaste of Kṣatriyas (Warriors). Nānak received an education in traditional Hindu lore and in the rudiments of Islām. Early in life he began associating with holy men. For a time he worked as the accountant of the Afghān chieftain at Sultānpur. There a Muslim family servant, Mardānā, who was also a rebec player, joined him. Nānak began to compose hymns. Mardānā put them to music and the two organized community hymn singing. They organized a canteen where Muslims, as well as Hindus of different castes, could eat together. At Sultānpur, Nānak had his first vision of God, in which he was ordered to preach to mankind. He disappeared while bathing in a stream. When he reappeared on the third day, he proclaimed: "There is no Hindu, there is no Mussulman."

Sikh tradition relates that Nānak also undertook four long voyages: east as far as Assam; south through the Tamil country to Ceylon; north to Ladakh and Tibet; and west as far as Mecca, Medina, and Baghdad. He spent the last years of his life in Kartārpur (in present-day Pakistan), where he raised the first Sikh temple. He nominated one of his disciples, Aṅgad, as his successor.

Aṅgad (Gurū 1539–52) was followed by another disciple, Amar Dās (Gurū 1552–74), who later nominated his son-in-law, Rām Dās Soḍhī (Gurū 1574–81) as his successor. Thereafter, the office of Gurū remained in the Soḍhī family. Rām Dās was succeeded by his youngest son, Arjun Mal (Gurū 1581–1606), who, before his death by torture in Lahore on May 30, 1606, nominated his son Hargobind (Gurū 1606–44). The seventh Gurū, Har Rāī (Gurū 1644–61), was Hargobind's grandson, who, after his tenure, nominated his young son Hari Krishen (Gurū 1661–64), who died of smallpox at the age of eight. Tegh Bahādur (Gurū 1664–75), who succeeded him, was the son of the sixth Gurū, Hargobind. Before his execution in Delhi on November 11, 1675, Tegh Bahādur passed succession to his son, Gobind Rāī (Gurū 1675–1708).

The founding of the Khālsā. The execution of two Gurūs and persecution by the Mughals compelled the Sikhs to take to arms. This was given religious sanction when, on the Hindu New Year's Day (April 13, 1699), Gobind Rāī baptized five Sikhs into a new fraternity he called the Khālsā, meaning the "Pure" (from the Persian *khāleṣ,* also meaning "pure"), and gave himself and them a common surname, Singh ("Lion"). Kaur ("Lioness") is the corresponding name given to all Sikh women. Gobind Singh's military career was not very successful. He lost most of his followers, including his four sons. He was hounded out of the Punjab and assassinated at Nānded (now in Mahārāshtra) on October 7, 1708. Before his death he declared the succession of Gurūs at an end. The military leadership of the Sikhs devolved upon Bandā Singh Bahādur. For

The surname Singh



The first Sikh Gurū, Nānak, conversing with the 10th and last Gurū, Gobind Singh. The imaginary meeting is expressive of the religion's development from a pacifist to a militant brotherhood. Painting of the Guler school, *c.* 1820. In the collection of Mohan Singh, Punjab, India.

eight years Bandā defied the Mughals and devastated large tracts of eastern central Punjab, until he was captured and, along with 700 of his followers, executed in Delhi in the summer of 1716.

For a few years the Khālsā disappeared into the hills. But when Mughal power was weakened by the incursion in 1738–39 of the Persian Nāder Shāh, they reemerged into the plains. They organized themselves under *misl*s (from Persian *mēsāl,* meaning both "example" and "equal") and began to extract protection money from towns and villages. The series of invasions between 1747 and 1769 that were led by Aḥmad Shāh Durrānī completely disrupted Mughal administration. In the battle of Panipat in 1761, the Afghāns destroyed rising Marāthā power in the north. The power vacuum thus created allowed the Sikhs to establish themselves as the rulers of the Punjab.

The Sikh Empire of Ranjit Singh. In the years of turmoil between the Persian and Afghān invasions, Sikh *misl*s had operated in loosely defined areas. Two main divisions emerged: Cis-Sutlej, the area between the Sutlej and the Yamuna rivers, and the Trans-Sutlej, between the Sutlej and the Indus rivers. In 1761 Sikhs wrested the capital city of Lahore from the Mughal governor.

Ranjit Singh

Ranjit Singh's (1780–1839) *misl,* the Śukerchakīās, was based at Gujrānwāla, north of Lahore. Ranjit took possession of the capital in 1799 and two years later had himself crowned maharaja of the Punjab. The English, who had advanced beyond Delhi, took the Cis-Sutlej states under their protection and compelled Ranjit Singh to accept the Sutlej River as the southeastern limit of his kingdom. There, after Ranjit Singh systematically brought the Trans-Sutlej region under his suzerainty, he took Multan in 1818 and Kashmir in 1819. In the following winter he extended his domain north and west beyond the Indus River into the land of the Pathans.

Ranjit Singh then began modernizing his army by employing European officers to train his troops. This army defeated the Pathans and Afghāns and extended Sikh power to the Khyber Pass.

Relations between the Sikhs and the British. After taking the Cis-Sutlej states under their protection, the British began to make plans for extending their empire up to the Indus River. Even during Ranjit Singh's lifetime they had been interfering in the affairs of Afghanistan, and they had persuaded him to join in an Anglo-Sikh expedition to Kabul. After the death of Ranjit Singh the Sikh kingdom disintegrated rapidly. Ranjit's eldest son and successor, Kharak Singh, was deposed by his own son, Naonihal Singh, and died of excessive use of opium. On the same day, Naonihal Singh was mortally injured when a gateway collapsed on his head. Kharak Singh's widow, Chand Kaur, occupied the throne for a few months until she was deposed and later murdered by Ranjit Singh's second son, Sher Singh. On September 15, 1843, Sher Singh, his son Pratap Singh, and Chief Minister Dhian Singh Dogra were murdered by Chand Kaur's kinsmen, who in their turn were slain by Dhian Singh's son, Hira Singh Dogra. Ranjit Singh's youngest son, Dalip Singh, was proclaimed maharaja with his mother, Jindan Kaur, as regent and Hira Singh Dogra as prime minister. Power passed, however, into the hands of the pañcāyat (elected council) of the Khālsā Army, which compelled the Dogra to flee Lahore and then slew him in flight.

The British began to move their troops to the Sikh frontier and made preparations to cross the Sutlej. On December 11, 1845, the Khālsā Army began crossing the river to intercept a British force led by their commander-in-chief and the governor general. In a series of bitterly contested battles at Mudki (December 18), Fīroz Shāh (Fīrozpur; December 21–22), Alīwāl (January 28, 1846), and Sobrāon (February 10)—often called the First Sikh War—the Khālsā were defeated. The British annexed the territory between the Sutlej and Beās rivers; forced the Sikhs to reduce their army; and, on their failure to pay a large war indemnity, forced them to cede Jammu and Kashmir, which were then sold to Gulab Singh Dogra. A British resident was posted at Lahore to administer the rest of the Sikh kingdom during the minority of Dalip Singh.

Administrative measures taken by the resident aroused resentment among the people. The banishment of Jindan Kaur, the queen mother, on charges of conspiracy brought matters to a head in the winter of 1848 and touched off a general Sikh uprising, also referred to as the Second Sikh War. A bloody but inconclusive battle was fought at Chiliānwāla (January 13, 1849); however, at Gujrāt (February 21, 1849) the Khālsā were totally defeated and laid down their arms. The Sikh kingdom was annexed, and Maharaja Dalip Singh was exiled from the Punjab.

Sikh role in the Indian Mutiny

After many years of chaos, the Punjab was administered efficiently and fairly. Consequently, when the Indian Mutiny broke out in 1857, the province stayed loyal to the British, and the Sikhs took a prominent role in suppressing the Mutiny. For this loyalty and help they were rewarded by grants of land. The proportion of Sikhs in the British Army was increased. A regulation was passed requiring Sikh soldiers to observe Khālsā traditions. With the reclamation of desert lands through an extensive system of canals, unprecedented prosperity came to the Punjab. Sikhs were the most favoured settlers. Sikh loyalty was evidenced in World War I, in which Sikhs formed more than one-fifth of the British Indian Army.

The depression that followed the war led to widespread disturbances, climaxed in the killing, on April 13, 1919, at Amritsar of almost 400 people. Sikhs also clashed with the authorities over the possession of their *gurdwārā*s (temples), which were under the control of hereditary priests. The Sikh masses turned from their British connection to join Gandhi's freedom movement. The progressive introduction of democratic reforms further reduced their earlier privileged status under British rule. Their participation on the British side in World War II was considerably less enthusiastic than it had been in 1914–18.

When the subcontinent was partitioned into India and Pakistan in 1947, the Sikh population was divided equally on both sides of the boundary line. Since the partition had been preceded by savage Sikh–Muslim riots, some 2,500,000 Sikhs were compelled to leave Pakistan.

Sikhism since 1947. The government of free India abolished privileges previously extended by the British to religious minorities, including the Sikhs. Thus, the proportion of Sikhs in defense and civil services declined. The partition also adversely affected the Sikh agricultural classes, who had abandoned rich farmlands in Pakistan and changed places with Muslims of east Punjab whose holdings were much smaller. The decline in their fortunes nurtured a sense of grievance and gave birth to agitation for a Punjabi-speaking province in India in which Sikhs would form a majority of the population. This demand was conceded after the Indo-Pakistan War in 1965.

Increased wheat production during the 1970s brought unprecedented prosperity to Sikh farmers. Material improvement was accompanied by the growth of Sikh fundamentalism under the leadership of Jarnail Singh Bhindranwale. Tension increased between Sikhs and Hindus as the Akālī Religious Party (Shiromanī Akālī Dal; SAD), the predominant Sikh political party, began demanding more political and economic advantages for Sikhs.

By the early 1980s the demands of the SAD had become strongly militant, and there was an escalation in sectarian violence. The Indian government responded by arresting and imprisoning thousands of Sikhs. Armed bands, under the direction of Bhindranwale, spread a reign of terror throughout the Punjab region. Matters came to a head in 1984, when Bhindranwale and his followers entrenched themselves in the compound of the Harimandir (Golden Temple). In June the Indian Army launched an assault on the temple that killed several hundred Sikhs (including Bhindranwale) and resulted in heavy damage to the temple buildings. In October Indian Prime Minister Indira Gandhi was assassinated by two Sikh members of her bodyguard, touching off widespread Hindu violence against Sikhs. These two events caused deep resentment in the Sikh community and fueled the movement demanding the establishment of a separate Sikh state.

SIKH LITERATURE, MYTH, AND LORE

Canonical and noncanonical literature. The earliest source materials on Nānak are the *janam-sākhīs* ("life stories"), written 50 to 80 years after the death of the Gurū. Most Sikh scholars reject them and rely instead on the Gurū's compositions incorporated in the *Ādi Granth* and the *Vārs* (heroic ballads) composed by Bhāī Gurdās (died 1629). Neither Nānak's hymns nor Gurdās' *Vārs* are specific regarding the events of Nānak's life. Other historical writings date from the 18th and the 19th centuries.

The canonical work

There is only one canonical work: the *Ādi Granth* ("First Book") compiled by the fifth Gurū, Arjun, in 1604. There are at least three recensions (versions) of the *Ādi Granth* that differ from each other in minor detail. The version accepted by Sikhs as authentic is said to have been revised by Gobind Singh in 1704. The *Ādi Granth* contains nearly 6,000 hymns composed by the first five Gurūs: Nānak (974), Aṅgad (62), Amar Dās (907), Rām Dās (679), and Arjun (2,218). Gobind incorporated 115 hymns of his father, Tegh Bahādur, in it. Besides these compositions, the *Ādi Granth* contains hymns of the Bhakta saints and Muslim Ṣūfīs, notably Farīd and Kabir, and of a few of the bards attached to the courts of the Gurūs.

The *Dasam Granth* ("Tenth Book") is a compilation of writings ascribed to Gobind Singh. Scholars are not agreed on the authenticity of the contents of this *Granth,* and it is not accorded the same sanctity as the *Ādi Granth.* Traditions of the Khālsā are contained in the *Rahatnāmās* (codes of conduct) by contemporaries of Gobind Singh.

Myths and lore. Although the Gurūs themselves disclaimed miraculous powers, a vast body of *sākhīs* ("stories") recounting such miracles grew up, and with them *gurdwārās* (temples) commemorating the sites where they were performed. It also became an article of belief that the spirit of one Gurū passed to his successor "as one lamp lights another." This notion gained confirmation through the fact that the Gurūs used the same poetic pseudonym, "Nānak," in their compositions.

A composition about which little is known, but which has played an important role in Sikh affairs, is a collection of prophecies, *Sau Sākhī* ("Hundred Stories"), ascribed to Gobind Singh. Various versions are known to have been published prophesying changes of regimes and the advent of a redeemer who will spread Sikhism over the globe.

SIKH DOCTRINES, PRACTICES, AND INSTITUTIONS

Use of Hindu cosmogony

Doctrines. *Views on the nature of man and the universe.* Speculation on the origin of the cosmos is largely derived from Hindu texts. Sikhs accept the cyclic Hindu theory of *saṃsāra*—birth, death, and rebirth—and *karma,* whereby the nature of one's life is determined by his actions in a previous life. Humans are, therefore, equal to all other creatures, except insofar as they are sentient. Human birth is the one opportunity to escape *saṃsāra* and attain salvation.

Concept of the Khālsā. Khālsā is a concept of a "chosen" race of soldier-saints committed to a Spartan code of conduct (consisting of abstinence from liquor, tobacco, and narcotics and devotion to a life of prayer) and a crusade for *dharmayudha*—the battle for righteousness. The number five has always had mystic significance in the Punjab—"land of the five rivers." "Where there are five, there am I," wrote Gobind Singh. The first Khālsā were *pañj piyāres*—the five beloved ones. The ideal goal of all young Sikhs is to take *pahul* ("baptism") and thus become Khālsā. The *sahajdhārī* ("slow-adopter") is assumed to be preparing himself gradually for the initiation.

The notion of the five Ks. The five emblems of the Khālsā, all beginning with the letter *k,* have no scriptural basis but are mentioned in the *Rahatnāmās,* written by Gobind Singh's contemporaries. The most important of the Ks is *keṣa* ("hair"), which the Khālsā must retain unshorn. A Khālsā who cuts off his hair is a *patit* ("renegade"). The sanctity of unshorn hair is older than Gurū Gobind Singh—the founder of the Khālsā—for many of the earlier Gurūs also followed the tradition (common among certain sects of Hindu ascetics as well) of letting their hair and beards grow. The other four Ks are *kaṅghā* ("comb"); *kacch* ("drawers"), worn by soldiers; *kirpān* ("sabre"); and *kārā* ("bracelet") of steel, commonly worn on the right arm. The usually accepted explanation of the *kārā* is that it is the Gurū's charm against evil—a variation of the Hindu *rakhri* tied by sisters on the wrist of their brothers to keep them from harm.

Monotheism. Unity of the Godhead is emphasized in Sikhism. Nānak used the Hindu Vedāntic concept of *om,* the mystic syllable, as a symbol of God. To this he added the qualifications of singleness and creativity and thus constructed the symbol *ik* ("one") *om kār* ("creator"), which was later given figurative representation as ੴ. The opening lines of his morning prayer, *Japjī,* called the Mul Mantra ("Root Belief") of Sikhism, define God as the One, the Truth, the Creator, immortal, and omnipresent. God is also formless (*niraṇkār*) and beyond human comprehension. Sikh scriptures use many names, both Hindu and Muslim, for God. Nānak's favourite names were Sat-Kartār ("True Creator") and Sat-Nām ("True Name"). Later the word Wāh-Gurū ("Hail Gurū") was added and is now the Sikh synonym for God.

Concepts of spiritual authority. The sole repository of spiritual authority is the *Ādi Granth.* In the event of disputes, a conclave is summoned to meet at the Akāl Takht ("Throne of the Timeless"), a building erected by the sixth Gurū, Hargobind, facing the Harimandir temple in Amritsar. Resolutions passed at the Akāl Takht have spiritual sanction. Sikh religion and politics have always been intimately connected, and belief in a Sikh state is an article of faith. "Raj karey Ga Khālsā—"the Khālsā shall rule"—is chanted at the conclusion of every service.

Aniconic orientation and anti-ritualism

Views on idolatry and rituals. Sikhism forbids representation of God in pictures and the worship of idols. Nevertheless the *Ādi Granth* itself has become an object of intense ceremonial reverence and as such is known as *Granth Sahib* ("The *Granth* Personified"). *Granth Sahib* is "roused" in the morning and placed under an awning draped in fineries. Devotees do obeisance and place offerings before it. In the evening it is put to rest for the night. On festival days it is taken in procession through the streets. Most rituals centre on the *Ādi Granth.* The nonstop recitation from cover to cover by a relay of readers (*akhand-path*), which takes two days and nights, has become popular.

Social consequences of beliefs. The main consequence of Sikh belief has been a gradual breaking away from the

Sikh social structure

Hindu social system and the development of Sikh separatism. The singular worship of the *Ādi Granth* excludes worship of all other objects common among Hindus (*i.e.,* the Sun, rivers, trees, etc.) and also puts a stop to the practice of ritual purifications and pilgrimages to the Ganges. Since every Sikh is entitled to read the scripture, Sikhs do not have a priestly caste similar to the Brahmans in Hinduism. Sikh insistence on commensality (eating together) at the *Gurū ka laṅgar* ("kitchen of the Gurū") destroyed the traditional Hindu pattern of caste among them and substituted a far less rigid social structure. Sikhs are grouped into three broad categories based largely on ethnic differences: Jāṭs (agricultural tribes), non-Jāṭs (erstwhile Brahmans, Kṣatriyas, and Vaiśyas—the three highest groups of the traditional Hindu social system), and Mazahabis (untouchables). The Jāṭs, though low in the caste hierarchy, are preeminent; the Mazahabis, though converts from Hindu outcastes (untouchables outside the caste system), and still discriminated against, have a much higher status than untouchables in Hindu society. This three-tiered system is in a state of flux: among the educated urban classes it is breaking up, but in the villages a form of apartheid persists (see also SOCIAL DIFFERENTIATION: *Social stratification: Caste*).

Practices and institutions. *The Gurū and the disciple.* The guidance of the Gurū toward the attainment of *mokṣa*—release—is absolutely essential. The Gurū or the Satgurū—true Gurū—is accorded a status only a shade below that of God. His function is to point the way to the realization of the truth, to explain the nature of reality, and to give the disciple the gift of the divine word (*nām-dān*). Although the line of Gurūs ended with Gobind Singh and Sikhs regard the *Ādi Granth* as their "living" Gurū, the practice of attaching oneself to a *sant* ("saint") and elevating him to a status of a Gurū has persisted and is widely practiced.

Recitation of Nāma. Sikhism is often described as *nām-mārga* ("the way of *nāma*") because it emphasizes the constant repetition (*jap*) of the name of God and the *gurbāni* (the divine hymns of the Gurūs). *Nāma* cleanses the soul of sin and conquers the source of evil, *haumain* ("I am")—the ego. Thus tamed, the ego becomes a weapon with which one overcomes lust, anger, greed, attachment, and pride. *Nāma* stills the wandering mind and induces a super-conscious stillness (*divya dṛṣṭi*), opens the *dasam duār* ("10th gate"—the body has only nine natural orifices) through which enters divine light; and thus a person attains the state of absolute bliss.

Rites of passage and other ceremonies. No specific rites are prescribed for birth, but the practice of chanting the first five verses of Nānak's *Japjī* is observed among some Sikhs when a child is born. A few days later the child is brought to the *gurdwārā*. The *Ādi Granth* is opened and the child given a name beginning with the first letter of the first word on the left page. When a child has learned some Gurmukhi script he is initiated into reading the *Ādi Granth.* The most important ceremony is that of *pahul* ("baptism"), usually administered at puberty. The initiate takes *amrit* ("nectar") and is admitted to the Khālsā fraternity. During a Sikh marriage ceremony (*anand karaj*), the groom and bride are required to go around the *Ādi Granth* four times to the chanting of wedding hymns. On death, there is continual chanting of hymns until the body is prepared for cremation. A final *ardāsā* ("supplicatory") prayer is said before the funeral pyre is lit. Ashes of the dead are usually immersed in the Beās at Kīratpur—or in one of the Hindu sacred rivers, preferably the Ganges.

Pilgrimage places

Sacred times and places. Early hours of the dawn are ambrosial hours (*amritvelā*) most appropriate for prayer and meditation. Though not specifically prescribed as such, *gurdwārā*s with historical associations are, in fact, places of pilgrimage. Preeminent among them is the Harimandir at Amritsar, the holiest shrine of the Sikhs. Nankāna, the birthplace of Nānak (now in Pakistan), comes second. There are also five thrones (Akāl Takhts) that are accorded special sanctity; these are at Amritsar, Anandpur, Patiāla, Patna, and Nānded. The last four are the places associated with Gobind Singh. From all of them, proclamations can be made to all the Khālsā.

The first Sikh place of worship was built by Nānak at Kartārpur and was, like Hindu temples, known as *dharamsālā* ("place of faith"). At a later stage, a Sikh temple was called a *gurdwārā,* meaning "gateway to the Gurū." There are more than 200 historical *gurdwārā*s associated with the Gurūs, which are controlled by the Shiromanī Gurdwārā Prabaṅdhak Committee (SGPC) set up by the Sikh Gurdwārās Act of 1925.

In addition to historical *gurdwārā*s, every place with a sizable Sikh population is likely to have a *gurdwārā* of its own. In well-to-do homes, a room is often set apart for this purpose. The only object of worship is the *Ādi Granth.* Sikhs observe all festivals celebrated by the Hindus of northern India. In addition, they celebrate the birthdays of the first and the last Gurūs and the martyrdom of the fifth (Arjun) and the ninth (Tegh Bahādur). The biggest fair is on the first of Baisākh (mid-April), which is also the birthday of the Khālsā itself.

The Khālsā Saṅgat. The Saṅgat ("Congregation") is usually called the Sādh-saṅgat ("Congregation of Holy Men") and thus is invested with sanctity. The Saṅgat in each *gurdwārā* elects its own governing body, and decisions are taken by vote. As a rule women do not participate in the deliberations. The SGPC at Amritsar is the general governing body of Sikhism.

Minor subgroups and orders

Sectarian differences. The first dissenters from the mainstream of Sikhism—known as the Udāsīs—were followers of Nānak's elder son, Śri Chand. The order inclined toward asceticism and later furnished priests (*mahants*) for *gurdwārā*s. They were ousted from control by the SGPC in 1925. Followers of Rām Rāī, who was passed over by his father, Har Rāī (seventh Gurū), in favour of a younger son, Hari Krishen (eighth Gurū), broke away to become Rām Rāiyās. They have their headquarters in Dehra Dūn, Uttar Pradesh.

Khālsā who do not believe that the line of Gurūs ended with Gobind Singh have continued the tradition of having a living Gurū. Among these, the Bandaī Khālsā (followers of Bandā Bahādur) are now extinct, but the Nāmdhārīs and Niraṅkārīs worship living Gurūs.

Sikh welfare and educational institutions. The SGPC is the chief welfare organization of the Sikhs. The Sikh Educational Conferences, meeting annually since 1908, are the chief educational organizations credited with the establishment of a large number of schools. In 1965 two socioreligious organizations, the Gurū Gobind Singh Foundation and the Gurū Nānak Foundation, endowed many university chairs for the study of Sikhism and the publication of material on Sikh history and religion.

BIBLIOGRAPHY. JOSEPH D. CUNNINGHAM, *History of the Sikhs,* 2nd ed. (1853), was the first scholarly work on the Sikhs up to the first Anglo-Sikh war of 1845–46. His interpretation of Sikhism as an eclectic Hindu-Muslim faith remained unquestioned until McLeod's work in 1968. Cunningham was censured for suggesting that British designs on the Sikh kingdom provoked Sikh aggression. MAX A. MACAULIFFE, *The Sikh Religion,* 6 vol. (1909, reissued 1963) is a compilation of all the legends about the Sikh Gurūs based on *janam-sākhī*s and on saints whose writings are in the Sikh scriptures; full of literal translations of Sikh hymns. SHER SINGH, *Philosophy of Sikhism* (1944), is a scholarly work interpreting Sikhism as an offshoot of Vaiṣṇavite Hinduism. A selection of hymns from the *Ādi Granth* and Gobind Singh's *Dasam Granth* carried out by a panel of Sikh scholars may be found in *Selections from the Sacred Writings of the Sikhs,* trans. by TRILOCHAN SINGH *et al.* (1960). KHUSHWANT SINGH, *A History of the Sikhs,* 2 vol. (1963–66), interprets Sikhism as an aspect of Punjabi nationalism, and his *Ranjit Singh, Maharajah of the Punjab* (1963) is a biography based on Persian, Punjabi, and English sources. W.H. MCLEOD, *Gurū Nānak and the Sikh Religion* (1968, reissued 1976), casts serious doubt on source material on the life of Nānak, rejects the theory of Sikhism as an eclectic faith, and asserts that it is a branch of Hindu Vaiṣṇavism tinged with yogism. His *Evolution of the Sikh Community* (1976) is an excellent history and analysis. W. OWEN COLE and PIARA SINGH SAMBHI, *The Sikhs: Their Religious Beliefs and Practices* (1978), is an introduction, and Cole's *Sikhism and Its Indian Context: 1469–1708* (1984) explores the relations between early Sikhism and other Indian religious beliefs and practices. INDIA, *White Paper on the Punjab Agitation* (1984), deals with the storming of the Golden Temple by the Indian Army.

(K.S.)

Slavery

There is no consensus on what a slave was or on how the institution of slavery should be defined. Nevertheless, there is general agreement among historians, anthropologists, economists, sociologists, and others who study slavery that most of the following characteristics should be present in order to term a person a slave. The slave was a species of property; thus, he belonged to someone else. In some societies slaves were considered movable property, in others immovable property, like real estate. They were objects of the law, not its subjects. Thus, like an ox or an ax, the slave was not ordinarily held responsible for what he did. He was not personally liable for torts or contracts. The slave usually had few rights and always fewer than his owner, but there were not many societies in which he had absolutely none. As there are limits in most societies on the extent to which animals may be abused, so there were limits in most societies on how much a slave could be abused. The slave was removed from lines of natal descent. Legally and often socially he had no kin. No relatives could stand up for his rights or get vengeance for him. As an "outsider," "marginal individual," or "socially dead person" in the society where he was enslaved, his rights to participate in political decision making and other social activities were fewer than those enjoyed by his owner. The product of a slave's labour could be claimed by someone else, who also frequently had the right to control his physical reproduction.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 513.

This article is divided into the following sections:

Slavery was a form of dependent labour performed by a nonfamily member. The slave was deprived of personal liberty and the right to move about geographically as he desired. There were likely to be limits on his capacity to make choices with regard to his occupation and sexual partners as well. Slavery was usually, but not always, involuntary. If not all of these characterizations in their most restrictive forms applied to a slave, the slave regime in that place is likely to be characterized as "mild"; if almost all of them did, then it ordinarily would be characterized as "severe."

Sources for slaves

Slaves were generated in many ways. Probably the most frequent was capture in war, either by design, as a form of incentive to warriors, or as an accidental by-product, as a way of disposing of enemy troops or civilians. Others were kidnapped on slave-raiding or piracy expeditions. Many slaves were the offspring of slaves. Some people were enslaved as a punishment for crime or debt, others were sold into slavery by their parents, other relatives, or even spouses, sometimes to satisfy debts, sometimes to escape starvation. A variant on the selling of children was the exposure, either real or fictitious, of unwanted children, who were then rescued by others and made slaves. Another source of slavery was self-sale, undertaken sometimes to obtain an elite position, sometimes to escape destitution.

Slavery existed in a large number of past societies whose general characteristics are well-known. It was rare among primitive peoples, such as the hunter-gatherer societies, because for slavery to flourish, social differentiation or stratification was essential. Also essential was an economic surplus, for slaves were often consumption goods who themselves had to be maintained rather than productive assets who generated income for their owner. Surplus was also essential in slave systems where the owners expected economic gain from slave ownership.

Ordinarily there had to be a perceived labour shortage, for otherwise it is unlikely that most people would bother to acquire or to keep slaves. Free land, and more generally, open resources, were often a prerequisite for slavery; in most cases where there were no open resources, nonslaves could be found who would fulfill the same social functions at lower cost. Last, some centralized governmental institutions willing to enforce slave laws had to exist, or else the property aspects of slavery were likely to be chimerical. Most of these conditions had to be present in order for slavery to exist in a society; if they all were, until the abolition movement of the 19th century swept throughout most of the world, it was almost certain that slavery would be present. Although slavery existed almost everywhere, it seems to have been especially important in the development of two of the world's major civilizations, Western (including ancient Greece and Rome) and Islāmic.

Two types of slavery

There have been two basic types of slavery throughout recorded history. The most common has been what is called household, patriarchal, or domestic slavery. Although domestic slaves occasionally worked outside the household, for example, in haying or harvesting, their primary function was that of menials who served their owners in their homes or wherever else the owners might be, such as in military service. Slaves often were a consumption-oriented status symbol for their owners, who in many societies spent much of their surplus on slaves. Household slaves sometimes merged in varying degrees with the families of their owners, so that boys became adopted sons or women became concubines or wives who gave birth to heirs. Temple slavery, state slavery, and military slavery were relatively rare and distinct from domestic slavery, but in a very broad outline they can be categorized as the household slaves of a temple or the state.

The other major type of slavery was productive slavery. It was relatively infrequent and occurred primarily in classical Athenian Greece and Rome and in the post-Columbian circum-Caribbean New World. It also was found in 9th-century Iraq, among the Kwakiutl Indians of the American Northwest, and in a few areas of sub-Saharan Africa in the 19th century. Although slaves also were employed in the household, slavery in all of those societies seems to have existed predominantly to produce marketable commodities in mines or on plantations.

A major theoretical issue is the relationship between productive slavery and the status of a society as a slave or a slave-owning society. In a slave society, slaves composed a significant portion (at least 20–30 percent) of the total population, and much of that society's energies were mobilized toward getting and keeping slaves. In addition the institution of slavery had a significant impact on the society's institutions, such as the family, and on its social thought, law, and economy. It seems clear that it was quite possible for a slave society to exist without productive slavery; the known historical examples were concentrated in Africa and Asia. It is also clear that most of the slave societies have been concentrated in Western (including Greece and Rome) and Islāmic civilizations. In a slave-owning society slaves were present, but in smaller numbers, and they were much less the focus of the society's energies.

Distinction between slavery and serfdom

Slavery was a species of dependent labour differentiated from other forms primarily by the fact that in any society it was the most degrading and most severe. Slavery was the prototype of a relationship defined by domination and power. But throughout the centuries man has invented other forms of dependent labour besides slavery, including serfdom, indentured labour, and peonage. The term serfdom is much overused, often where it is not appropriate (always as an appellation of opprobrium). In the past a serf usually was an agriculturalist, whereas, depending upon the society, a slave could be employed in almost any occupation. Canonically, serfdom was the dependent condition of much of the western and central European peasantry from the time of the decline of the Roman Empire until the era of the French Revolution. This included a "second enserfment" that swept over central and some of eastern Europe in the 15th and 16th centuries. Russia did not know the "first enserfment"; serfdom began there gradually in the mid-15th century, was completed by 1649, and lasted until 1906. Whether the term serfdom appropriately describes the condition of the peasantry in other contexts is a matter of vigorous contention. Be that as it may, the serf was also distinguished from the slave by the fact that he was usually the subject of the law—*i.e.,* he had some rights, whereas the slave, the object of the law, had significantly fewer rights. The serf, moreover, was usually bound to the land (the most significant exception was the Russian serf between about 1700 and 1861), whereas the slave was always bound to his owner; *i.e.,* he had to live where his owner told him to, and he often could be sold by his owner at any time. The serf usually owned his means of production (grain, livestock, implements) except the land, whereas the slave owned nothing, often not even the clothes on his back. The serf's right to marry off his lord's estate often was restricted, but the master's interference in his reproductive and family life ordinarily was much less than was the case for the slave. Serfs could be called upon by the state to pay taxes, to perform corvée labour on roads, and to serve in the army, but slaves usually were exempt from all of those obligations.

A person became an indentured servant by borrowing money and then voluntarily agreeing to work off the debt during a specified term. In some societies indentured servants probably differed little from debt slaves (*i.e.,* persons who initially were unable to pay off obligations and thus were forced to work them off at an amount per year specified by law). Debt slaves, however, were regarded as criminals (essentially thieves) and thus liable to harsher treatment. Perhaps as many as half of all the white settlers in North America were indentured servants, who agreed to work for someone (the purchaser of the indenture) upon arrival to pay for their passage. Some indentured servants alleged that they were treated worse than slaves; the economic logic of the situation was that slave owners thought of their slaves as a long-term investment whose value would drop if maltreated, whereas the short-term (typically four years) indentured servants could be abused almost to death because their masters had only a brief interest in them. Practices varied, but indenture contracts sometimes specified that the servants were to be set free with a sum of money, sometimes a plot of land, perhaps even a spouse, whereas for manumitted slaves the terms usually depended more on the generosity of the owner.

Peons

Peons were either persons forced to work off debts or criminals. Peons, who were the Latin-American variant of debt slaves, were forced to work for their creditors to pay off what they owed. They tended to merge with felons because people in both categories were considered criminals, and that was especially true in societies where money fines were the main sanction and form of restitution for crimes. Thus, the felon who could not pay his fine was an insolvent debtor. The debt peon had to work for his creditor, and the labour of the criminal peon was sold by the state to a third party. Peons had even less recourse to the law for bad treatment than did indentured servants, and the terms of manumission for the former typically were less favourable than for the latter.

HISTORICAL SURVEY

The origins of slavery are lost to human memory. It is sometimes hypothesized that at some moment it was decided that persons detained for a crime or as a result of warfare would be more useful if put to work in some way rather than if killed outright and discarded or eaten. But both if and when that first occurred is unknown.

Slavery in China

Slave-owning societies. Slavery is known to have existed as early as the Shang dynasty (18th–12th century BC) in China. It has been studied thoroughly in ancient Han China (206 BC–AD 25), where perhaps 5 percent of the population was enslaved. Slavery continued to be a feature of Chinese society down to the 20th century. For most of that period it appears that slaves were generated in the same ways they were elsewhere, including capture in war, slave raiding, and the sale of insolvent debtors. In addition, the Chinese practiced self-sale into slavery, the sale of women and children (to satisfy debts or because the seller could not feed them), and the sale of the relatives of executed criminals. Finally, kidnapping seems to have produced a regular flow of slaves at some times. The go-between or middleman was an important figure in the sale of local people into slavery; he provided the distance that made such slaves into outsiders, for the purchasers did not know their origins. Chinese family boundaries were relatively permeable, and some owners established kinlike relations with their slaves; male slaves were appointed as heirs when no natural offspring existed. As was also the case in other slave-owning societies, slaves in China were often luxury consumption items who constituted a drain on the economy. The reasons China never developed into a slave society are many and complex, but certainly an abundance of non-slave labour at low prices was one of the major ones.

Korea had a very large slave population, ranging from a third to half of the entire population for most of the millennium between the Silla period and the mid-18th century. Most of the Korean slaves were indigenously generated. In spite of their numbers, slaves seem to have had little impact on other institutions, and thus the society can be categorized as a slave-owning one.

Slavery existed in ancient India, where it is recorded in the Sanskrit Laws of Manu of the 1st century BC. The institution was little documented until the British colonials in the 19th century made it an object of study because of their desire to abolish it. In 1841 there were an estimated 8,000,000 or 9,000,000 slaves in India, many of whom were agrestic or predial slaves, that is, slaves who were attached to the land they worked on but who nevertheless could be alienated from it. Malabar had the largest proportion of slaves, about 15 percent of the total population. The agrestic slaves initially were subjugated communities. The remainder of the slaves was recruited individually by purchase from dealers or parents or by self-sale of the starving, and they can be classified as household slaves. Slavery in Hindu India was complicated by the slave owners' ritual need to know the origins of their slaves, which explains why most of them were of indigenous origin. Although there were exceptions, slaves were owned primarily for prestige.

Slavery was widely practiced in other areas of Asia as well. A quarter to a third of the population of some areas of Thailand and Burma were slaves in the 17th through the 19th centuries and in the late 19th and early 20th centuries, respectively. But not enough is known about them to say that they definitely were slave societies.

Other societies in the Philippines, Nepal, Malaya, Indonesia, and Japan are known to have had slavery from ancient until fairly recent times. The same was true among the various peoples inhabiting the Asian parts of the modern Soviet Union: the peoples of Sogdiana, Khorezm, and other advanced civilizations of Central Asia; the Mongols, the Kalmyks, the Kazakhs; and the numerous Turkic peoples, most of whom converted to Islām.

Slave-owning societies in the New World

In the New World some of the best-documented slave-owning societies were the Klamath and Pawnee and the fishing societies, such as the Yurok, that lived along the coast from what is now Alaska to California. Life was easy in many of those societies, and slaves are known to have sometimes been consumption goods that were simply killed in potlatches.

Other Amerindians, such as the Creek of Georgia, the Comanche of Texas, the Callinago of Dominica, the Tupinambá of Brazil, the Inca of the Andes, and the Tehuelche of Patagonia, also owned slaves. Among the Aztecs of Mexico, slavery generally seems to have been relatively mild. People got into the institution through self-sale and capture and could buy their way out relatively easily. Slaves were often used as porters in the absence of draft animals in Mesoamerica. The fate of other slaves was less pleasant: chattels purchased from the Mayans and others were sacrificed in massive numbers. Some of the sacrifices may have been eaten by the social elite.

In England about 10 percent of the population entered in Domesday Book in 1086 were slaves, with the proportion reaching as much as 20 percent in some places. Slaves were also prominent in Scandinavia during the Viking era, AD 800–1050, when slaves for use at home and for sale in the international slave markets were a major object of raids. Slaves also were present in significant numbers in Scandinavia both before and after the Viking era.

Continental Europe—France, Germany, Poland, Lithuania, and Russia—all knew slavery. Rus was essentially founded as a by-product of slave raiding by the Vikings passing from Scandinavia to Byzantium in the 9th century, and slavery remained a major institution there until the early 1720s, when the state converted the household slaves into house serfs in order to put them on the tax rolls. House serfs were freed from their lords by an edict of Tsar Alexander II in 1861. Many scholars argue that the Soviets reinstituted a form of state slavery in the Gulag camps that flourished until 1956.

Slavery was much in evidence in the Middle East from the beginning of recorded history. It was treated as a prominent institution in the Babylonian Code of Hammurabi of *c.* 1750 BC. Slaves were present in ancient Egypt and are known to have been murdered to accompany their deceased owners into the afterlife. It once was believed that slaves built the great pyramids, but contemporary scholarly opinion is that the pyramids were constructed by peasants when they were not occupied by agriculture. Slaves are also mentioned prominently in the Bible among the Hebrews in Palestine and their neighbours.

Slaves were owned in all Islāmic societies, both sedentary and nomadic, ranging from Arabia in the centre to North Africa in the west and to what is now Pakistan and Indonesia in the east. Some Islāmic states, such as the Ottoman Empire, the Crimean Khanate, and the Sokoto caliphate, must be termed slave societies because slaves there were very important numerically as well as a focus of the polities' energies.

Slavery in black Africa

Slaves have been owned in black Africa throughout recorded history. In many areas there were large-scale slave societies, while in others there were slave-owning societies. Slavery was practiced everywhere even before the rise of Islām, and black slaves exported from Africa were widely traded throughout the Islāmic world. Approximately 18,000,000 Africans were delivered into the Islāmic trans-Saharan and Indian Ocean slave trades between 650 and 1905. In the second half of the 15th century Europeans began to trade along the west coast of Africa, and by 1867 between 7,000,000 and 10,000,000 Africans had been shipped as slaves to the New World. Although some areas of Africa were depleted by slave raiding, on balance the African population grew after the establishment of the transatlantic slave trade because of new food crops introduced from the New World, particularly manioc, corn (maize), and possibly peanuts (groundnuts). The relationship between African and New World slavery was highly complementary. African slave owners demanded primarily women and children for labour and lineage incorporation and tended to kill males because they were troublesome and likely to flee. The transatlantic trade, on the other hand, demanded primarily adult males for labour and thus saved from certain death many adult males who otherwise would have been slaughtered outright by their African captors. After the end of the transatlantic trade, a few African societies at the end of the 19th century put captured males to productive work as slaves, but this usually was not the case before that time.

Athenian slave society

Slave societies. The first known major slave society was that of Athens. In the early Archaic period the elite worked its estates with the labour of fellow citizens in bondage (often for debt). After the lawgiver Solon abolished citizen slavery about 594 BC, wealthy Athenians came to rely on enslaved peoples from outside Attica. The prolonged wars with the Persians and other peoples provided many slaves, but the majority of slaves were acquired through regular trade with non-Greek peoples around the Aegean. At the time of classical Athens (the 5th through the 3rd centuries BC) slaves constituted about a third of the population. A particularly noteworthy locus of slave employment was the Laurium silver mines, where private individuals could pick out a lode and put their slaves to mining it. As in all other slave societies, it was the profitability of slavery that determined its preeminence in Athens. (Also important were political conditions that made the gross exploitation of citizens impossible.) Slaves were responsible for the prosperity of Athens and the leisure of the aristocrats, who had time to create the high culture now considered the beginning of Western civilization. The existence of large-scale slavery was also responsible, it seems logical to believe, for the Athenians' thoughts on freedom that are considered a central part of the Western heritage. Athenian slave society was finally destroyed by Philip II of Macedonia at the battle of Chaeronea (338 BC), when, on the motion of Lycurgus, many (but not all) slaves were freed.

Roman slave society

The next major slave society was Roman Italy between about the 2nd century BC and the 4th century AD. Initially Rome was a polity consisting primarily of small farmers. But the process of creating the empire took them away from their farms for extended periods, and the prolonged wars of conquest in Spain and the eastern Mediterranean during the 3rd and 2nd centuries BC created a great flood of captives. Nothing was more logical than to put the captives to work farming, especially the olives and grapes that created much of the prosperity of the late republic and the principate. Slaves and freedmen were responsible for much of the empire's commodity production, and in the early principate they ran its governmental bureaus as well. The conditions were right to put the captives to work: private ownership of land; developed commodity production and markets; a perceived shortage of internal labour supply; and an appropriate moral, political, and legal climate. Roughly 30 percent of the population was enslaved. Roman slave society ended as the slaves were legally converted into coloni, or serfs, and the lands became populated and the frontiers so remote that finding great numbers of outsider slaves was increasingly difficult.

Some lesser Islāmic slave societies are also of interest. One is the Baghdad caliphate founded in the 7th and lasting through the 10th century. Many tens of thousands of military captives were imported from Sogdiana, Khazaria, and other Central Asian locales. In the 9th and 10th centuries several tens of thousands of black Zanj slaves were imported from Zanzibar to Lower Iraq, where they constituted more than half the total population and were put to work to clear saline lands for irrigation and to cultivate sugar. More long-term was the slavery practiced in the Crimean Khanate between roughly 1475 and its liquidation by the Russian empress Catherine the Great in 1783. The Crimean Tatar society was based on raiding the neighbouring Slavic and Caucasian sedentary societies and selling the captives into the slave markets of Eurasia. Approximately 75 percent of the Crimean population consisted of slaves or freedmen, and much of the free population was highly predatory, engaged either in the gathering of slaves or in the selling of them. It is known that for every slave the Crimeans sold in the market, they killed outright several other people during their raids, and a couple more died on the way to the slave market. The reasons for the transition of the Crimean Khanate from a slave-owning society to a slave society have not been studied in detail. Probable reasons, however, include the combination of high demand for slaves throughout the Islāmic world, the defenselessness of the sedentary agricultural Slavs and others, and the existence of a relatively poor class of Crimean horsemen, who were led by a predatory elite that got rich by slave raiding. Crimean Tatar slave raids into Muscovy were greatly curtailed by the building of a series of walls along the frontier in the years 1636–53 and ultimately by the liquidation of the khanate in 1783.

Slavery in the Ottoman Empire

It is probable that the Ottoman Empire, and especially its centre in Turkey, should be termed a slave society. Slaves from both the white Slavic north and the black African south flowed into Turkish cities for half a millennium after the Turks seized control of much of the Balkans in the 14th century. The proportion of the population that was slave ranged from about one-fifth in Istanbul, the capital, to much less in remoter provincial areas. Perhaps only people such as the slave owners of the circum-Caribbean sugar islands and the American South were as preoccupied with slaves as were the Ottomans.

Slaves in the Ottoman Empire served in various capacities. They were janissary soldiers (see below), and they ran the empire, manned its ships, generated much of its handicraft product, and served as domestic servants and in harems. Contemporaries believed that the absolute power of the ruler was based on his military and administrative slaves. The Tanzimat enlightenment movement of the mid-19th century initiated the abolition of slavery; by the 1890s only a few slaves were being smuggled illegally into the empire, and the slave population was greatly reduced.

Other prominent Islāmic slave societies were on the east coast of Africa in the 19th century. The Arab-Swahili slave systems have been well-studied, and it is known that, depending on the date, 65 to 90 percent of the population of Zanzibar was enslaved. Close to 90 percent of the population on the Kenya coast was also enslaved, and in Madagascar half the population was enslaved. It may be assumed that similar situations prevailed elsewhere in the vicinity and also earlier, but studies to verify the proposition have not been undertaken.

Another notable Islāmic slave society was that of the Sokoto caliphate formed by Hausas in sub-Saharan Africa (northern Nigeria and Cameroon) in the 19th century. At least half the population was enslaved. That was only the most notable of the Fulani jihad states of the western and central Sudan, where between 1750 and 1900 from one- to two-thirds of the entire population consisted of slaves. In Islāmic Ghana, between 1076 and 1600, about a third of the population were slaves. The same was true among other early states of the western Sudan, including Mali (1200–1500), Segou (1720–1861), and Songhai (1464–1720). It should be noted that slavery was prominent in Ghana and Mali, and presumably elsewhere in Africa in areas for which information is not available, long before the beginnings of the transatlantic slave trade. The population of the notorious slave-trading state of the central Sudan, Ouidah (Whydah), was half-slave in the 19th century. It was about a third in Kanem (1600–1800) and perhaps 40 percent in Bornu (1580–1890). Most slaves probably were acquired by raiding neighbouring peoples, but others entered slavery because of criminal convictions or defaulting on debts (often not their own); subsequently, many of those people were sold into the international slave trade. After the limiting and then abolition of the transatlantic slave trade, a number of these African societies put slaves to work in activities such as mining gold and raising peanuts, coconuts (palm oil), sesame, and millet for the market.

Among some of the various Islāmic Berber Tuareg peoples of the Sahara and Sahel, slavery persisted at least until 1975. The proportions of slaves ranged from around 15 percent among the Adrar to perhaps 75 percent among the Gurma. In Senegambia, between 1300 and 1900, about a third of the population consisted of slaves. In Sierra Leone in the 19th century close to half the population was enslaved. In the Vai Paramount chiefdoms in the 19th century as much as three-quarters of the population consisted of slaves. Among the Ashanti and Yoruba a third were enslaved. In the 19th century over half the population consisted of slaves among the Duala of the Cameroon, the Ibo and other peoples of the lower Niger, the Kongo, and the Kasanje kingdom and Chokwe of Angola.

Caribbean slave societies

The best-known slave societies were those of the circum-Caribbean world. Slave imports to the islands of the Caribbean began in the early 16th century. Initially the islands often were settled as well by numerous indentured labourers and other Europeans, but following the triumph after 1645 of the sugar revolution (initially undertaken because superior Virginia tobacco had left the Barbadian planters with nothing to sell) and after the nature of the disease climate became known to Europeans, they came to be inhabited almost exclusively by imported African slaves. In time the estate owners moved to England, and the sugar plantations were managed by sometimes unstable and unsavoury Europeans who, with the aid of black overseers and drivers, controlled masses of slaves. About two-thirds of all slaves shipped across the Atlantic ended up in sugar colonies. By 1680 in Barbados the average plantation had about 60 slaves, and in Jamaica in 1832 about 150. The sugar plantations were among the contemporary world's largest and most profitable enterprises, paying about 10 percent on invested capital and on some occasions, such as in Barbados in the 1650s, as much as 40 to 50 percent. The proportions of slaves on the islands ranged from more than a third in Cuba, which went into the sugar and gang-labour business on a large scale only after the local planters had gained control in 1789, to 90 percent and more on Jamaica in 1730, Antigua in 1775, and Grenada up to 1834.

Slaves were of varying importance in Mesoamerica and on the South American continent. Initially slaves were imported because of a labour shortage, aggravated by the high death rate of the indigenous population after the introduction of European diseases in the early 16th century. They were brought in at first to mine gold, and they were shifted to silver mining or simply let go when gold was exhausted in the mid-16th century. In Brazil, where sugar had been tried even before its planting in the Caribbean, the coffee bush was imported from Arabia or Ethiopia via Indonesia, and it had an impact similar to that of sugar in the Caribbean. Around 1800 about half the population of Brazil consisted of slaves, but that percentage declined to about 33 percent in 1850 and to 15 percent after the shutting off of imports around 1850 combined with free immigration to raise the proportion of Europeans. In some parts of Brazil, such as Pernambuco, some two-thirds of the population consisted of Africans and their offspring.

The final circum-Caribbean slave society was what became the southern United States. Slaves first were brought to Virginia in 1619. Subsequently, Africans were transshipped to North America from the Caribbean in increasing numbers. Initially, however, the English relied for their dependent labour primarily on indentured servants from the mother country. But in the two decades of the 1660s and 1670s the laws of slave ownership were clarified (for example, Africans who converted to Christianity did no longer have to be manumitted), and the price of servants may have increased because of rising wage rates in prospering England; soon thereafter African slaves replaced English indentured labourers. Tobacco initially was the profitable crop that occupied most slaves in the Chesapeake. The invention of the cotton gin by Eli Whitney in 1793 changed the situation, and thereafter cotton culture created a huge demand for slaves, especially after the opening of the New South (Alabama, Mississippi, Louisiana, and Texas). By 1850 nearly two-thirds of the plantation slaves were engaged in the production of cotton. Cotton could be grown profitably on smaller plots than could sugar, with the result that in 1860 the average cotton plantation had only about 35 slaves, not all of

Cotton culture and slavery

whom produced cotton. During the reign of "King Cotton," about 40 percent of the Southern population consisted of black slaves; the percentage of slaves rose as high as 64 percent in South Carolina in 1720 and 55 percent in Mississippi in 1810 and 1860. More than 36 percent of all the New World slaves in 1825 were in the southern United States. Like Rome and the Sokoto caliphate, the South was totally transformed by the presence of slavery. Slavery generated profits comparable to those from other investments and was only ended as a consequence of the War Between the States.

The international slave trade. Organized commerce began in the Neolithic Period, and it may be assumed that slaves were not far behind high-value items such as amber and salt in becoming commodities. Even among relatively simple peoples one can trace the international slave trade. Thus such a trade was going on among the peoples of Siberia before the arrival of the Russians in the 16th and 17th centuries. The slaves so traded were neighbouring people captured in warfare, who were then shipped to distant points where they would be without kin and whence they would be unlikely to flee. Similar commerce in slaves occurred on nearly all continents and provided the bulk of household slaves throughout the world.

Slave raiding

The international slave trades that provided much of the chattel for the slave societies flowed out of the great "population reservoirs." Two such reservoirs were the Slavs and contiguous agriculturalist Iranians from antiquity to the 19th century and the sub-Saharan Africans from around the beginning of the Christian Era to the middle of the 20th century. A third such reservoir probably was the Germanic, Celtic, and Romance peoples who lived north of the Roman Republic and Empire and who half a millennium later became the victims of the Vikings' slave raids. The dynamics of these raids were as follows: A large demand for slave labour prompted neighbouring peoples (typically migratory or nomadic in habit) to prey on the sedentary agriculturalists living in the reservoir. The raiders developed techniques, of which surprise was perhaps the major one, that put the settled peoples at a disadvantage, for they never knew when and where the raiders might strike. Populations in the reservoir could be completely depleted, as happened to the East Slavs living in the steppe south of the Oka and between the Volga and the Dnepr rivers from 1240 to the 1590s, or they could migrate half a continent away to escape the slave raiders, as did the Ndembu in Africa. Ruthenians, frontier Poles, Caucasians, and numerous African peoples were sorely depleted by slave raids. One alternative was to fight back, as did the Muscovite Russians and the Baya of Adamawa (now northern Cameroon in West Africa), and the consequence in both instances was the creation of an authoritarian garrison state.

The international slave trades developed into elaborate networks. For example, in the 9th and 10th centuries Vikings and Russian merchants took East Slavic slaves into the Baltic. They were then gathered in Denmark for further transshipment and sold to Jewish and Arabic slave traders, who took them to Verdun and León. There some of the males were castrated. From those places the slaves were sold to harems throughout Moorish Spain and North Africa. In the 9th century the Baghdad caliphate got slaves from western Europe via Marseille, Venice, and Prague; Slavic and Turkic slaves from eastern Europe and Central Asia via Derbent, Itil, Khorezm, and Samarkand; and African slaves via Mombasa, Zanzibar, the Sudan, and the Sahara. The Mongols in the 13th century brought their slaves first to Karakorum, whence they were sold throughout Asia, and then later to Sarai on the Lower Volga, whence they were retailed throughout much of Eurasia. Following the breakup of the Golden Horde, the Crimean Tatars took their chattel to Kefe (Feodosiya) in the Crimea, whence it was transported across the Black Sea and sold throughout the Ottoman Empire and elsewhere. Arabs developed similar supply networks out of black Africa across the Sahara, across the Red Sea (from Ethiopia and Somalia), and out of East Africa, which supplied the Islāmic world and the Indian Ocean region with human chattel.

The transatlantic slave trade

Beginning around 1500 a similar process occurred along the coast of West Africa to supply the transatlantic slave trade. The Africans were captured by other Africans in raids and then transported to the coast; one may assume that the number of casualties of African slave raiding was nearly as high as that of Crimean Tatar slave raiding. The captives, primarily adult males, were assembled on the coast by African rulers and kept in holding pens until wholesaled to European ship captains who sailed up and down the coast looking for slave cargo. (As stated above, the women and children often were not sent to the coast for export but were kept by the Africans themselves, often for incorporation into their lineages.) African rulers, who did not allow the Europeans to move inland, often conducted their wholesale business on the coast, such as at Ouidah in Dahomey (now Benin). (Because of the disease climate the Europeans also were reluctant, even unable, to move inland until the mid-19th century.) But African rulers did everything they could to encourage the European sea captains to come to their port.

Once a ship was loaded, the trip, known as "the Middle Passage," usually to Brazil or an island in the Caribbean, was a matter of a few weeks to several months. Between 1500 and the end of the 19th century the time of the voyage diminished considerably. That change was important, because death rates, which ranged from around 10 to more than 20 percent on the Middle Passage, were directly proportional to the length of the voyage. The ship captains had every interest in the health of their cargo, for they were paid only for slaves delivered alive. The death rates among the European captains and crew engaged in the slave trade were at least as high as those among their cargo on the Middle Passage. Of the slave-ship crews that embarked from Liverpool in 1787, less than half returned alive.

Arriving in Brazil or the Caribbean islands, the slaves were sold at auction. The slave auctions were elaborate markets in which the prices of the slaves were determined. The auctions told the captains and their superiors what kind of cargo was in demand, usually adult males. Credit almost always was part of the transaction, and inability to collect was one of the major reasons companies went bankrupt. After the auction the slave was delivered to the new owner, who then put him to work. That also began the period of "seasoning" for the slave, the period of about a year or so when he either succumbed to the disease environment of the New World or survived it. Many slaves landed on the North American mainland before the early 18th century had already survived the seasoning process in the Caribbean.

It can be assumed that the other international slave trades were comparable in many respects to the transatlantic one, but they have not been adequately studied.

Ways of ending slavery. Slavery came to an end in numerous ways. Household slavery ended because of an exhaustion of supplies, because slavery evolved into some other system of dependent labour, because it withered away, or because it was formally abolished. Productive slavery came to an end for the additional reasons that it ceased to be profitable or that it was abolished by warfare or the threat of warfare.

Attitudes toward slavery

Throughout history there have been people who in one way or another believed that slavery was not a good or natural condition. Jean Bodin (1530–96), the French founder of antislavery thought, for example, condemned the institution as immoral and counterproductive and advocated that no group of men should be excluded from the body politic. Nevertheless, remarkably few people found the institution of slavery to be unnatural or immoral until the second half of the 18th century. Until that time Christians commonly thought of sin as a kind of slavery rather than slavery itself as a sin. When concern was expressed for slaves, it was for their good care, not for their unfree status.

Frequently, when slavery passed from the scene, it did so with little fanfare. In most societies, such as ancient Babylonia, Israel, Egypt, or Athens, the institution of slavery had little or no connection with the society's rise or demise. In Rome, on the other hand, slavery began to yield to tenancy and the antecedents of serfdom before the fall of the empire, as the diminishing supply of slaves and the rise of their price coincided with the disintegration of the olive oil- and wine-producing plantations of southern Italy and loss of markets in the face of competition from Spain, Gaul, and North Africa. (This standard interpretation has been challenged, however.) In the Eastern Roman Empire (Byzantium) serfdom was the predominant form of dependent labour, and slavery was definitely secondary. Manumitting slaves became much easier, according to the laws, and the Ecloga and the Procheiron Nomos (see below) prescribed that the slaves of persons who died without testament had to be freed. Throughout most of Europe household slavery persisted well into the late Middle Ages and even later and only gradually died out. Slavic slaves were plentiful, for example, in the Italian city-states as late as the 14th century, and African slaves could be found in Spain and Portugal in the 16th century. Serfdom replaced slavery in medieval Germany. By the end of the Middle Ages slavery no longer existed in England, and the famous Cartwright decision of the reign of Elizabeth I (1569) held that "England was too pure an air for slaves to breathe in."

Enserfment in eastern Europe

Slavery persisted longer in eastern Europe. In Poland it was replaced by the second enserfment; the sale and purchase of slaves were forbidden in the 15th century. A similar process occurred in Lithuania, where slavery was formally abolished in 1588. In Russia it came to an end with the first enserfment: agricultural slaves were formally converted into serfs in 1679, and household slaves were converted into house serfs in 1723. In the Caucasus and in Central Asia slavery persisted until the second half of the 19th century. As the Russian Empire grew and its hegemony spread, it adopted the tendency of 19th-century imperialist powers to enforce abolition when embarking upon colonization. Thus the conquest of the Caucasus led to the abolition of slavery by the 1860s and the conquest in Central Asia of the Islāmic khanates of Bukhara, Samarkand, and Khiva by the 1870s.

Abolition movement

Slavery in England was formally abolished by judicial fiat in 1772, when Chief Justice Mansfield held that the captured fugitive slave James Somersett, from Virginia, could not be claimed by his owner and that furthermore any slave by the act of walking on English soil became free. The fate of slavery in most of the rest of the world depended on the British abolition movement, which was initiated by the English Quakers in 1783 when they presented the first important antislavery petition to Parliament. They were following the Pennsylvania Quakers, who had voiced opposition to slavery in 1688. The Vermont constitution of 1777 was the first document in the United States to abolish slavery. Another sign of the spread of antislavery feeling was the declaration in the U.S. Constitution that the importation of slaves could be forbidden after 20 years (in 1808). An act of March 2, 1807, forbade trading in slaves with Africa. Well before the rise of cotton some people hoped that natural processes combined with a prohibition on infusions would put an end to slavery.

In 1807 the British abolished the slave trade with their colonies. In the Caribbean, slavery was abolished by British Parliamentary fiat, effective July 31, 1834, when 776,000 slaves in the British plantation colonies were freed. The British imperial emancipation can be attributed to the growing power of the philanthropic movement and a double switch in the focus of the British Empire, geographically from west (the Caribbean) to east (India) and economically from protectionism to laissez-faire.

The British move in 1807 to abolish the slave trade had an immediate impact on the juntas struggling for independence in Spanish America. The slave trade was declared illegal in Venezuela and Mexico in 1810, in Chile in 1811, and in Argentina in 1812. In 1817 Spain signed a treaty with Britain agreeing to abolish the slave trade in 1820, but the trade continued to the remaining Spanish colonies until 1880. Chile freed its black slaves in 1823; Mexico abolished slavery in 1829, and Peru in 1854.

The American antislavery movement, linked to the "Second Great Awakening," succeeded in arousing immense hostility between the non-slave North, where most states had voluntarily abolished slavery by 1804, and the slaveholding South, where the "peculiar institution" became even further entrenched because of the spread of cotton cultivation. By the 1850s, however, the old abolition movement had flagged. It took political developments and forces (especially the emergence of the Free-Soil movement and the conflict over the expansion of slavery), the South's secession, the Civil War, and Abraham Lincoln's Emancipation Proclamation on Jan. 1, 1863, to put slavery on the road to extinction in the United States. The proclamation was confirmed by the Thirteenth Amendment to the Constitution, which put an end to slavery.

Abolition of slavery in Brazil

Puerto Rico abolished slavery (with provisions for periods of apprenticeship) in 1873 and Cuba in 1880. Brazil was the last Western Hemisphere nation to abolish slavery. The British antislavery movement of the 1810s had almost put an end to the institution, but a thriving world market for coffee revitalized it in the 1820s. In 1850 Britain declared that a squadron would enter Brazilian territorial waters to seize vessels carrying slaves, and later that year Brazil responded by equating the slave trade with piracy. On May 13, 1888, all Brazilian slaves were manumitted. Initially there was some opposition by the coffee growers, but their resistance crumbled immediately.

The European colonization movement of the second half of the 19th century put an end to slavery in many parts of Africa, East Asia, and Southeast Asia. The abolition of slavery in both Hindu and Muslim India by Act V of 1843 meant only that the British courts would not enforce claims to a slave, but the Penal Code of 1861 made holding a slave a crime. Having seen to the abolition of slavery in most of Latin America and South Asia, the British turned their attention back to Africa. They moved onto the continent, took control of those governments that were thriving on slavery, and attempted to abolish the institution. Lagos was annexed in 1861, and all of Nigeria followed. In the 1870s British missionaries moved into Malaŵi, the place of origin of the Indian Ocean Islāmic slave trade, in an attempt to interdict it at its very source. In 1890 Zanzibar was made a British protectorate after the sultan's authority had been destroyed by the struggle over the slave trade. In Dahomey the French abolition of slavery resulted in the cessation of ceremonial human sacrifice.

The Imperial government formally abolished slavery in China in 1906, and the law became effective on Jan. 31, 1910, when all adult slaves were converted into hired labourers and the young were freed upon reaching age 25. Slavery was legally abolished in Korea in the Gap-o reform of 1894 but remained extant in reality until 1930.

Abolition efforts in the 20th century

Some parts of Africa and much of the Islāmic world retained slavery at the end of World War I. For this reason the League of Nations and later the United Nations took the final extinction of slavery to be one of their obligations. The league had considerable success in Africa, with the assistance of the colonial powers, and by the late 1930s slavery was abolished in Liberia and Ethiopia. After World War II the United Nations Universal Declaration of Human Rights and the European Convention of Human Rights proclaimed the immorality and the illegality of slavery. Slavery was abolished in most Islāmic countries, although it persisted in Saudi Arabia into the 1960s. It finally was made illegal in the Arabian Peninsula in 1962. It is probable that slavery no longer exists as a legal phenomenon recognized by a political authority or government any place in the world.

THE LAW OF SLAVERY

Sources of slavery law. By definition slavery must be sanctioned by the society in which it exists, and such approval is most easily expressed in written norms or laws. Thus it is not accidental that even the briefest code of a relatively uncomplicated slave-owning society was likely to contain at least a few articles on slavery.

Both slave-owning and slave societies that were part of the major cultural traditions borrowed some of their laws about slavery from the religious texts of their respective civilizations. Principles regarding slavery that proved to be either unprofitable or unworkable were among the first to be discarded. An obvious example is provided by the Old Testament law that Hebrew slaves were to be manumitted after six years (Exodus 21:2; Deuteronomy 15:12). A similar general recommendation that slaves be freed after six years in bondage was adhered to by many Islāmic slave-owning societies; it helps to account for the ferocity and frequency of their slave raids, for they had a need for constant replenishment of their slave supplies. In Christian slave societies, on the other hand, the principle that the tenure of slavery should be limited was almost completely ignored.

Practically every society that possessed slaves wrote about them in its laws, and thus only a few codes can be mentioned here. The ancient Mesopotamian laws of Eshnunna (*c.* 1900 BC) and the Code of Hammurabi had a number of articles devoted to slavery, as did the Pentateuch. In ancient India the Laws of Manu of the 1st century BC contained numerous laws on slaves.

Roman slave law

Little is known about the Athenian law of slavery, but the Roman law of slavery was extraordinarily elaborate. Roman law was summed up in the great Pandects of Justinian of AD 533, and some of its slave norms later found their way into the Byzantine Ecloga (which incorporated Syrian norms as well) of AD 726 and, more deliberately, into the Procheiron Nomos of AD 867–879. Romano-Byzantine norms also found their way into the Bulgarian Court Law for the People ("Zakon Sudnyi Liudem") of the end of the 9th century and the 13th-century Ethiopian Fetha Nagast.

The European "barbarian" (Germanic) codes, which first appeared in the 5th century AD and remained in effect for about half a millennium, were derived from customary law influenced by Roman law. The slave statutes of the Russian Russkaya Pravda of the 11th–13th century were all clearly of native East Slavic origin. The same was true of the Muscovite court handbooks (Sudebniki) of 1497, 1550, 1589, and 1606. The Muscovite Russians had a special government office to deal with slavery matters, the Slavery Chancellery (1571–1704), and its practice became the basis of chapter 20 of the great Ulozhenie of 1649, which constituted 119 of the 967 articles of the code; other articles dealt with slavery as well.

Islāmic slave law

The Qur'ān was the fundamental starting point for Islāmic law (Sharīʿah), including the law of slavery. It was supplemented by the *ijmāʿ*, the scholarly legal consensus, and the *qiyās*, juristic reasoning by analogy. Islāmic law regulated in detail every part of the institution of slavery, from the jihad (holy war) and the distribution of booty to the treatment of slaves and emancipation. The last Islāmic slave law was promulgated in 1936 by King Ibn Saʿūd of Saudi Arabia, which restated the teachings of the Qur'ān. It also required owners to register slaves with the government and licensed slave traders.

Some sub-Saharan African societies followed Islāmic law; others had their own. The latter ordinarily were not systematized until the European colonization movement, and so their law of slavery was oral common law.

Slavery was a relatively prominent institution in the Chinese T'ang Code of the 7th century AD. Subsequently it was mentioned in every Chinese law down to the 20th century and was also important in the Korean legal system. The slavery norms of the Mongol Great Yassa of Genghis Khan were locally generated, but subsequent Mongol law reveals considerable influence of the T'ang Code.

The circum-Caribbean world had several basic laws of slavery. The slave law of the Spanish-speaking colonies and then independent countries was based on the Siete Partidas of 1263–65 of Alfonso X of Castile and Léon and the Spanish Slave Code of 1789. Another important code in Latin America was Louis XIV's Code Noir of 1685. The Louisiana Slave Code of 1824 was based on the Siete Partidas and the Code Napoléon.

The Danish Virgin Islands had two largely locally generated codes of 1733 and 1755, although they were approved by the colonial administration of Denmark. The English colonies were completely autonomous, for England had no law of slavery from which to borrow. The first code was that of Barbados of 1688, whose origins are unknown. It was imitated by the South Carolina code of 1740. Beginning with Virginia in 1662, each colony in North America worked out its own ex post facto law of slavery before independence, a process that continued after the creation of the United States and until the Civil War. Slavery is mentioned only three times and referred to at most 10 times (and then only indirectly) in the U.S. Constitution, and, except for a handful of measures on fugitives, there was no federal slave law. The basic protection for the institution of slavery was the Tenth Amendment of 1791, the reserved powers clause, which left the issue of slavery and other matters to the states.

Legal definitions of slavery. Some of the definitions of slavery discussed above were legal, but the majority were not. This section focuses exclusively on legal definitions of slavery. Most groups, whether national or religious, forbade the enslavement of their fellows; thus, the Spanish could not enslave Spaniards, Arabs could not enslave Arabs, and Christians and Muslims could not enslave their coreligionists. Legally the slave ordinarily had to be an outsider. In law the slave was usually defined as property, and the question then was whether he was movable property (chattel) or real property. In most societies he was movable property but in some, real property.

Some societies, such as Muscovy in the 16th and 17th centuries, had different legal categories of slaves. There some slaves were inherited, others were purchased forever, others for a limited time could become perpetual slaves, and still others for specific functions such as estate managers. Different varieties or gradations of slaves were found elsewhere as well, as in China and in certain African societies.

Master–slave legal relationships. The master–slave relationship was the cornerstone of the law of slavery, and yet it was an area about which the law often said very little. In many societies the subordination of the slave to his owner was supposed to be complete; in general, the more complete an owner's control over his slave, the less the law was likely to say about it.

The owner's right to kill his slave

A major touchstone of the nature of a slave society was whether or not the owner had the right to kill his slave. In most Neolithic and Bronze Age societies slaves had no such right, for slaves from ancient Egypt and the Eurasian steppes were buried alive or killed to accompany their deceased owners into the next world. Among the Northwest Coast Tlingit, slave owners killed their slaves in potlatches to demonstrate their contempt for property and wealth; they also killed old or unwanted slaves and threw their bodies into the Pacific Ocean. An owner could kill his slave with impunity in Homeric Greece, ancient India, the Roman Republic, Han China, Islāmic countries, Anglo-Saxon England, medieval Russia, and many parts of the American South before 1830.

The slave's right to life

That was not the case in other societies. The Hebrews, the Athenians, and the Romans under the principate restricted the right of slave owners to kill their human chattel. The Code of Justinian changed the definition of the slave from a thing to a person and prescribed the death penalty for an owner who killed his slave by torture, poison, or fire. Spanish law of the 1260s and 1270s denied owners the right to kill their slaves. Lithuanian and Muscovite law forbade the killing, maiming, or starving of a returned fugitive slave. Ch'ing Chinese law punished a master who killed his slave, and that punishment was more severe if the slave had done no wrong. The Aztecs under some circumstances put to death a slave owner who killed his slave. No society, on the other hand, had the slightest sympathy for the slave who killed his owner. Roman law even prescribed that all other slaves living under the same roof were to be put to death along with the slave who had committed the homicide.

Assault and general brutality were other concerns of the law of slavery. In antiquity slaves often had the right to take refuge in a temple to escape cruel owners, but that sometimes afforded little protection. The ancient Franks and the Germans warned owners against cruelty. The Code of Justinian and the Spanish Siete Partidas deprived cruel owners of their slaves, and that tradition went into the Louisiana Black Code of 1806, which made cruel punishment of slaves a crime. In modern societies brutality and sadistic murder of slaves by their owners were rarely condoned on the grounds that such episodes demoralized other slaves and made them rebellious, but few slave owners were actually punished for maltreating their slaves. In the American South 10 codes prescribed forced sale to another owner or emancipation for maltreated slaves. Nevertheless, cases such as *State* v. *Hoover* (North Carolina, 1839) and *State* v. *Jones* (Alabama, 1843) were considered sensational because slave owners were punished for savagely "correcting" their slaves to death.

Sexual relations between masters and slaves

It was not an axiom of the master–slave relationship that the former automatically had sexual access to the latter. That was indeed the case in most societies, ranging from the ancient Middle East, Athens, and Rome to Africa, all Islāmic countries, and the American South. Places such as Muscovy, however, forbade owners to rape their female slaves, while the Chinese and the Lombards forbade the raping of married slave women. More problematic were sexual relations between mistresses and male slaves. Athens and Rome both put the slave to death, and Byzantine law prescribed that the mistress was to be executed and the slave to be burned alive. The Danish Virgin Islands' laws of 1741, 1755, and 1783, in an attempt to protect northern Europeans from African "contamination," prescribed a fine of 2,000 pounds of sugar for a man who raped a black slave, and a white woman who had sexual relations with a black slave was to be fined, imprisoned, and then deported.

The labour and food regimes were central to almost every slave's life. In societies where the owner's control over his slave was total, such as the Roman Empire or the pre-1830 American South, the law said little or nothing about how long he could work him and whether his slave had a right to food and clothing. In South India the slave owner had an absolute right to whatever labour his slave was capable of rendering. In Muscovy, on the other hand, a slave owner was jailed for forcing his slaves to labour on Sunday. In Judea in 200 BC, in Sicily in 135–32 BC, and on the Nile in AD 46 regulations prescribed the food rations a slave could expect. The Lithuanian Statute of 1588 and the Russians in 1603 and 1649 decreed that slaves had a right to be fed. The Danish Virgin Islands in 1755 prescribed adequate food rations. The Alabama Slave Code of 1852 mandated that the owner had to provide slaves of working age a sufficiency of healthy food, clothing, attention during illness, and necessities in old age.

The slave's right of marriage and offspring

A major issue was whether the master had to allow the slave to marry and what rights the owner had over slave offspring. In general, a slave had far fewer rights to his offspring than to his spouse. Babylonian, Hebrew, Tibetan-speaking Nepalese Nyinba, Siamese, and American Southern slave owners thought nothing of breaking up both the conjugal unit and the nuclear family. Unexpectedly the 1755 Danish Virgin Islands Reglement prohibited separating minors from their parents. In Muscovy and China, slave owners could sell or will children apart from their parents, but marriages were inviolable.

The slave's right of property

In North America, India, Rome, Muscovy, most of the Islāmic world, and among the Tuareg a fundamental principle was that the slave could not own property because the master owned not only his slave's body but everything that body might accumulate. This did not mean, however, that slaves could not possess and accumulate property but only that their owners had legal title to whatever the slaves had. In a host of other societies, such as ancient and Roman Egypt, Babylonia, Assyria, Talmudic Palestine, Gortyn, much of medieval Germany, Thailand, Mongol and Ch'ing China, medieval Spain, and the northern Nigerian emirates, slaves had the right of property ownership. Some places, such as Rome, allowed slaves to accumulate, manage, and use property in a peculium that was legally revocable but could be used to purchase their freedom. This provision gave slaves an incentive to work as well as the hope of eventual manumission.

Considerable research has been done on the treatment of slaves, and the consensus is that, while the law may have spelled out the desired social standards of master–slave relations, it did not necessarily define the reality for any particular situation. Sadists, even psychopaths, who could not cope with their right of total dominance over another human being, might appear anywhere, as might kindly masters. More determining than the law were the conditions of the society itself. At one extreme, among the Tuareg of North Africa, the slave owners themselves often lived badly, and so, of course, did their slaves. At the other extreme, in the American South material conditions were sufficiently favourable to provide comparative comfort for both masters and slaves. Moreover, slaves born of already enslaved parents usually were treated much better than those purchased or captured from foreign groups. The treatment of slaves in expansive, dynamic societies was likely to be worse than in more stable ones.

Legal relationships between slave owners. There was more uniformity across systems regarding legal relationships between slave owners. All societies had provisions for the recovery of runaways, and most imposed sanctions on owners who stole others' slaves (a capital offense in some systems) or helped them to flee. There also were relatively uniform laws about passing slaves from one generation to another.

There was considerable variability among societies in the law of slave transactions. Whereas Roman-law societies had elaborate norms on contracts, Muscovy had essentially none. Whereas legal systems from Babylonia, Athens, Rome, early Germany, China, and Ethiopia to Islāmic societies and Louisiana allowed guarantees by the sellers that slaves would not flee, were free from disease, or had certain skills, no such laws existed in places such as Muscovy.

Legal relationships between slaves and free strangers. Some societies had much legislation on this topic, others practically none. Where the slave was completely dependent on his owner, few laws existed beyond the normal rules governing any form of property; it was the owner's responsibility to recover damages if a third party killed or assaulted either his cow or his slave. The owner, moreover, was held equally or even more responsible for the slave's actions, ranging from homicide to theft, than was the slave himself, for the society desired that the former control his property and there was no assurance that sanctions, especially money fines, could be enforced against slaves.

Attitudes toward homicide of a slave

Homicide of a slave by a stranger was a revealing test of a society's attitude toward the slave. In Mesopotamia and in Islāmic practice the killer of a slave merely had to compensate the owner for the loss of his property. Elsewhere, however, it was different. Roman law introduced the idea in the Lex Cornelia de Sicariis et Veneficis (the dictator Sulla's enactment on murders and poisoners of 81 BC) that a slave was a person and thus that killing a slave could be a crime. That provision found its way into the Code of Justinian. In North America in the period from 1770 to 1830 the killing of a slave was equated in common law with the murder of a white person. Laws were uniformly harsh when a slave killed a stranger who was a freeman.

Some societies did not allow third parties to assault slaves with impunity. In Muscovy, for example, a slave might have honour and could recover from a third party who injured his honour. Societies elsewhere, however, such as the North American Yurok, Tlingit, and other neighbouring Indians, as well as in the American South, explicitly stated that slaves could have no honour, personal status, or prestige. South Carolina law noted that the slave was not "within the peace of the state, and therefore the peace of the state [was] not broken by an assault and battery on him." Conversely, when a slave assaulted a freeman, the latter often recovered from the slave's owner. Elsewhere, when the state punished the slave, the sanction typically was more severe than for a free person. For example, in Ch'ing China a slave was punished one degree more severely than free citizens for offenses against a freeman.

Most societies, such as those in Athens, Rome, Kievan Rus, Thailand, and Louisiana, did not allow slaves to contract independently with third parties, although some allowed the slave to make a contract on his owner's behalf. The brutal deprivation of rights was expressed in the Alabama case *Creswell's Executor* v. *Walter* (1860); the slave, said the court, had "no legal mind, no will which the law can recognize. . . . Because they are slaves, they are incapable of performing civil acts." On the other hand, in a few societies, as in the ancient Middle East, slaves were allowed to contract with third parties. Roman slaves were allowed to make contracts in regard to third peculium.

A few societies, such as late Assyria and Muscovy, allowed slaves to testify in court, but most did not. It was a rare society that permitted a slave to serve as a witness against his owner, but some societies, such as ancient Nuzi and Muscovy, allowed slaves to testify against, even to sue, third parties. That was particularly likely to be the case when slaves played a major role in the society, because disputes could not be resolved by the freemen alone without resort to evidence provided by slaves.

Laws of manumission. Laws of manumission varied widely from society to society and within societies across time. They are often viewed as the litmus test of a particular society's views of the slave, that is, of the capacities the slave was likely to exhibit as a free human being. Many Islāmic societies, broadly interpreting the Hebrew prescription, generally prescribed that slave owners had to free their slaves after the passage of a number of years, essentially the length of time they considered it took for an "outsider" to become an "insider." Most other societies allowed masters to free their slaves whenever they wished, although there were exceptions. Some legal systems prescribed manumission when the slave adopted the religion of his owner. It is hardly surprising that manumission was more frequent in systems of household slavery, for intimate relations between master and slave soon converted the outsider into an insider. With notable exceptions, such as Athens, Rome, Muscovy, and some circum-Caribbean societies, many societies required manumission after three generations.

Manumission upon birth

Birth was occasionally a route to manumission. In thriving slave systems such as those of the New World, in harsh systems such as those among the Northwest Coast Indians and the medieval Germanic peoples, or even in milder systems such as those of the Chinese and the Muscovites, a slave's offspring simply added to the slave population. But that was not universally the case; African slave societies, such as the Dahomeans of West Africa, the Ashanti of Ghana, or the Azande living between the Congo and the Nile, prescribed that the offspring of slaves should be free, as part of the process of incorporation into a new lineage. Although Islāmic law did not require manumission upon birth, the Qur'ān recommended it, and slave owners were often inclined to follow the religious tenet. The Aztecs freed all children born in slavery except the offspring of traitors. In Thailand emancipation was considered a pious act, and at their death many owners freed their slaves.

Rates of manumission

The rate of manumission did not necessarily correspond to the legal ease of manumission. It should be noted, however, that in Rome manumission was relatively easy and was widely practiced, even though there was a 5 percent tax on manumission in the Republic, and the Lex Fufia Caninia of 2 BC forbade manumission by testament of more than a fifth to a half of one's slaves, depending on the number owned. In much of sub-Saharan Africa, manumission was common in most periods, and the freed person typically became a kind of relative in a process of assimilation. In Neo-Babylonia, in Late and Middle Assyria, and in Muscovy manumission was easy but rare; in the American South manumission was comparatively difficult and almost never happened after the prohibition on importing new slaves. The factors of institutional dynamism, expansionism, and profitability, as well as race (see below), may have been the most crucial variants for the South, where manumission was even forbidden in South Carolina in 1820, Mississippi in 1822, Arkansas in 1858, and Maryland and Alabama in 1860; other factors were at work in the ancient Middle East and Muscovy.

There was considerable variation among societies as to whether a slave was allowed to accumulate property that he might keep after manumission. One form of such accumulation was the Roman peculium, which legally belonged to the master. One of its heirs was called *coartación*, the self-purchase system, widely used 1,500 years later in Latin America.

After manumission, most societies prescribed a period of legal transition to freedom. In the Roman Empire, China, and elsewhere, this period took three generations and might mean that the grandchild of a slave owner (the "patron") was legally responsible for the grandchild of a slave (his "client"). Thereafter the descendants of the freedman became full members of society, although perhaps still despised. The reason for the legally mandated period of transition to freedom was clear: the slave initially was not a member of the society but an outsider (see below), and it took time to become integrated into the new society. Equally important, the slave was dependent on his owner, and it took time for the freedman and his heirs to become fully self-reliant members of society. If the slave owner and his heirs were not responsible for the freedmen, the fear was, as expressed in the Louisiana Slave Code of 1824, that the latter might otherwise become public wards.

THE SOCIOLOGY OF SLAVERY

The slave as outsider. The slave generally was an outsider. He ordinarily was of a different race, ethnicity, nationality, and religion from his owner. The general rule, as enunciated by the specialist on classical slavery Moses I. Finley, was that "no society could withstand the tension inherent in enslaving its own members." In most cases, the slave was an outsider because he was enslaved against his will in one society and then taken by force to another.

As with nearly all rules, there were exceptions, however. Korea, for reasons that are not understood, was one. India was another exception, because of ritual requirements that the social origins of intimate associates be known; there slaves were ritually distanced from their owners. Muscovite Russia, which had outsider slaves as well, was yet another exception, perhaps because the boundaries between insiders and outsiders were blurred. A number of scholars have pointed out that, although the status of the slaves was uniformly lower than that of comparable free people in every society, the material and sometimes other conditions of slaves were frequently better than those of free people; thus it is not surprising that free people occasionally volunteered to be slaves. What is somewhat more surprising is that so few societies found that form of social welfare to be acceptable; most took measures to prohibit or inhibit it. Solon in 594 BC, for example, forbade enslavement for debt in Athens, and the Lex Poetelia Papiria did the same for Rome, *c.* 326 BC. Muscovy in 1597 prevented self-sale into slavery from becoming hereditary by mandating manumission of such slaves on their owners' deaths.

Regardless of the slave's origin, he was nearly always a marginal person in the society in which he was enslaved. In Africa slaves were despised, and their low status, which was passed on to freedmen, persists to the present time. In most societies most slaves were at the very bottom of society.

Attitudes toward slavery: the matter of race. Slaves in most societies were despised. This is best seen in the homology for slaves. The favourite homology was the woman or wife, then the minor child or an animal. Other terms for slaves were the apprentice, the pauper, the harlot, the felon, the actor, and the complex image of the Southern "Sambo" or Caribbean "Quashee." Throughout history slaves have often been considered to be stupid, uneducable, childlike, lazy, untruthful, untrustworthy, prone to drunkenness, idle, boorish, lascivious, licentious, and cowardly. In China slaves were considered to be "mean" and "base"; in India they were fed table scraps.

Christianity's tolerance of slavery

The attitudes of the world's great religions toward slavery are of special interest. The Judeo-Christian-Islāmic tradition has been the most tolerant of slavery. Judaic and Islāmic canonical texts refer frequently to slavery and treat it as a natural condition that might befall anyone. But they view it as a condition that should be gotten over quickly. Islāmic practice was based on the assumption that the outsider rapidly became an insider and consequently had to be manumitted after six years. New Testament Christianity, on the other hand, had no prescriptions that slaves be manumitted. Canon law sanctioned slavery. This was attributable at least partially to Christianity's primary focus on spiritual values and salvation after death rather than on temporal conditions and the present life. Under such a regime it mattered little whether someone was a slave or a free person while living on earth.

A major issue in the topic of attitudes toward slavery is that of race. Although slaves were usually outsiders and often despised, there nevertheless were different kinds of outsiders and different degrees of contempt. Studies have shown that race made a difference. In Rome, where most owners and slaves were white, manumission was frequent. In Africa, where most owners and slaves were black, lineage incorporation was the primary purpose of slavery, and in most societies slaves were allowed to participate in many aspects of social life. In the American South, however, where the owners were of northern European stock and the slaves of African stock, the degree of social isolation of and contempt for slaves was extraordinary. Southern slaves were forbidden to engage in occupations that might demonstrate their capacities, intermarriage almost never occurred, and manumission was almost unheard of as the reigning publicists proclaimed ever more loudly that blacks lacked any capacity to maintain themselves as free individuals.

Slave occupations. Throughout history the range of occupations held by slaves has been nearly as broad as that held by free persons, but it varied greatly from society to society. The actual range did not depend upon whether the slave lived in a slave-owning or a slave society, although the greatest restrictions appeared in the latter.

To start at the top, the highest position slaves ever attained was that of slave minister, or *ministerialis. Ministeriales* existed in the Byzantine Empire, Merovingian France, 11th-century Germany during the Salian dynasty, medieval Muscovy, and throughout the Ottoman Empire. A few slaves even rose to be monarchs, such as the slaves who became sultans and founded dynasties in Islām.

At a level lower than that of slave ministers were other slaves, such as those in the Roman Empire, the Central Asian Samanid domains, Ch'ing China, and elsewhere, who worked in government offices and administered provinces. Some of those slaves were government property, whereas others belonged to private individuals who employed them for government work.

On a level similar to that of slaves working in government were the so-called temple slaves. They were employed by religious institutions in Babylonia, Rome, and elsewhere. Unless they were ultimately destined for sacrifice to the gods, temple slaves usually enjoyed a much easier life than other slaves. They served in occupations ranging from priestess to janitor.

The Ottoman janissary

Slaves fought as soldiers and usually were considered of high status. In some societies military slaves belonged to private individuals, in others to the government. In 16th-century Muscovy, for example, cavalrymen purchased slaves who fought alongside them on horseback; in the later 17th century Muscovite slaves were relegated to guarding the baggage train. A special type of slave soldier was the Ottoman janissary. The Islāmic Ottoman Turks confiscated Christian children (called "the tribute children"), took them to Istanbul, and raised them to be professional soldiers, or janissaries. Some janissaries served as members of the palace guard and became involved in the succession struggles of the Ottoman Empire. The Egyptian Mamlūks were also professional soldiers of slave origin who rose to run the entire country. The African Hausa of Zaria and most Sudanic regimes included slaves in all ranks of the soldiery and command. The canoe crews of the West African coast were usually slaves. The British even had detachments of slave soldiers in the Caribbean.

Societies that explicitly refused to employ slaves in combat, such as Athens in its fleet, Rome in its infantry legions, or the American South in the Civil War, were rare. They took such action because fighting was done by freemen, and it was feared that it would be necessary to free the slaves if they could fight. In fact, all of those slave societies occasionally resorted to using slave soldiers when their military situations became desperate.

Slave estate managers

In many societies slaves were employed as estate managers or bailiffs. This was especially likely to be the case when it was deemed unfitting for freemen to take or give orders involving other freemen. Where such cultural taboos existed, managers were almost always either real outsiders (imported foreigners) or fictive outsiders (slaves). In Muscovy estate managers were a special category of slave, and they were the first whose registration with the central authorities was required.

Still other high-status slaves worked as merchants. Before the invention of the corporation, using slaves was one way to expand the family firm. The practice seems to have begun in Babylonia and was perpetuated in Rome, Spain, the Islāmic world, China, and Africa. Slaves were entrusted with large sums of money and were given charge of long-distance caravans. A few slaves in Muscovy were similarly employed in the Siberian fur trade. Other societies, particularly in the American South, forbade slaves to engage in commerce out of fear that they would sell stolen goods.

In nearly all societies possessing slaves, some slaves were found in what might be termed urban occupations ranging from petty shopkeepers to craftsmen. In the Tredegar Iron Works of Richmond, Va., much of the labour force consisted of slaves. In the American South, ancient Rome, Muscovy, and many other societies, slaves worked as carpenters, tailors, and masons. In Bursa, Tur., some of the finest weaving ever done was by slave craftsmen, who often contracted to fulfill a certain amount of work in exchange for emancipation. The stereotype that slaves were careless and could only be trusted to do the crudest forms of manual labour was disproved countless times in societies that had different expectations and proper incentives.

Only a small portion of slaves throughout history were fortunate enough to be employed in elite or prestige occupations. Most were assigned to strictly physical labour, sometimes the most degrading a society had to offer.

Galley slaves

Among the worst forms of slave employment were prostitution and occupations demanding hard physical labour. Mining, often conducted in dangerous conditions causing high death rates, seems to have been the worst. The silver mines at Laurium employed as many as 30,000 slaves, who contributed to the prosperity on which Athenian democracy was based. Slaves were also used in gold mining in Africa and in gold and silver mining in Latin America. Gold and coal mining employed (and killed) millions of state slaves of the Gulag in the Soviet Union between the 1920s and 1956. Slaves have been used on great construction projects such as military fortifications, roads, irrigation projects, and temples from Babylonian to Soviet times. Timber felling for lumber and firewood was another form of hard slave labour, as in the Gulag. Yet another form of brutal slave labour was rowing in the galleys, particularly those that belonged to the Ottoman Empire and sailed the Mediterranean. Tens of thousands of Slavs, victims of Crimean Tatar slave raids, first suffered a hellish existence in the Crimea itself and then ended their days rowing on Ottoman triremes.

Large numbers of slaves were employed in agriculture. As a general rule, slaves were considered suitable for working some crops but not others. Slaves rarely were employed in growing grains such as rye, oats, wheat, millet, and barley, although at one time or another slaves sowed and especially harvested all of these crops. Most favoured by slave owners were commercial crops such as olives, grapes, sugar, cotton, tobacco, coffee, and certain forms of rice that demanded intense labour to plant, considerable tending throughout the growing season, and significant labour for harvesting. The presence or absence of such crops and their relative profitability were among the major determinants of whether or not a slave-owning society became a slave society. In the Roman Empire employment in olive groves and vineyards occupied many slaves. Sugar cultivation made 9th-century Iraq into a slave society. Rice, coconut, coffee, clove, kola nut, peanut, and sesame cultivation were central occupations in some African societies.

The great discovery in Brazil in the second half of the 16th century was the gang labour system, which was so cost-effective that it made Brazilian sugar cheaper in Europe than the sugar produced in the islands off Africa. A plantation using gang labour could produce, on average, 39 percent more output from comparable inputs than could free farms or farms employing non-gang slave labour. The secret of success was that slaves could be driven, whereas free labour could not; this led to the creation of very profitable gangs of slaves supervised by white overseers and black drivers. Tobacco and coffee cultivation also used gang labour, but cultivation of these crops was less physically demanding than that of sugar and cotton and led to much lower mortality rates than did sugar and rice.

Domestic service and concubinage

Throughout history domestic service was probably the major slave occupation. Drawing water, hewing wood, cleaning, cooking, waiting on table, taking out the garbage, shopping, child-tending, and similar domestic occupations were the major functions of slaves in all slave-owning societies. In a major productive slave system, the Roman Empire at the time of Augustus and later, the richest 5 percent of Italy's population owned 1,000,000 house slaves (another 2,000,000 were employed elsewhere, out of a total population of about 7,500,000 people). In yet another productive slave system, the American South, large numbers of slaves also worked in their owners' houses. A related function was concubinage, unquestionably one of the major uses of female slaves since the beginning of the institution and particularly prevalent in China. Some societies prescribed that a concubine who bore her owner children was to be freed; others, ranging from the ancient Middle East to the European Middle Ages, specified that the offspring of free–slave unions were to be freed. Rome and the American South were unusual in believing that all concubines and offspring should remain enslaved. Added to this in Africa was the function of lineage expansion, one of the major purposes of slavery in the sub-Saharan region.

Slave marriages

Slave demography. It is sometimes alleged that slavery and marriage were totally incompatible, for recognition of the husband–wife bond would have limited intolerably the slave owner's authority and his right to dispose of his property. Historically, however, such a view is incorrect. Limitations on the right to dispose of property have been frequent throughout history, and slaves were no exception. Thus, slave marriages were recognized in a number of slave-owning societies, including Carthage, Hellenistic Greece, late Byzantium, most of the Roman Catholic medieval world, Ch'ing China, Hindu India, Thailand, the Tlingit and Kwakiutl, and Oregon coast tribes. Ḥanbalī Muslims stated that a slave could insist that his master provide him with a spouse, and Ming Chinese masters were obliged to choose mates for their female slaves when the latter were in their teens and for males around the age of 20. In Russia marriage between a free person and a slave was recognized legally, but according to one of the oldest Russian laws the free person became enslaved by marrying a slave. In Muscovy if a married slave fled, remarried, and was subsequently apprehended, he was to be rejoined to the first spouse.

In the majority of slave societies (the Danish Virgin Islands excepted), on the other hand, slave marriages were not recognized in law and were not something that slave owners had to think about legally when disposing of slaves. For example, the Louisiana Code of 1824 explicitly stated that a slave had no right to be married. Nevertheless, even in these societies, including Rome, the American South, and West Indian Barbuda, slaves formed what they considered marriages and had children. Southern slave owners often recognized such marriages (even across estate boundaries) and their offspring because to have done otherwise would have interfered with production. In Brazil slave marriages were recognized by the Roman Catholic Church and recognized by law in 1869, but in 1875 only one-sixth of the slaves of marriageable age were recorded as married or widowed.

Slave demography was frequently determined by the occupational employment of the slaves. Consequently, sexual imbalance was not at all unusual. In 9th-century France on the Abbey of Saint Germain des Prés' territory there were nearly three male slaves for every female, presumably because of the demand for agricultural labourers. In late medieval Europe, on the other hand, there was a great demand for female slaves as domestics and concubines. The same was true in China, where by the end of the Ch'ing era the institution of slavery had become primarily a female one. In early modern Russia there were two male slaves for every female because of a market demand for cavalrymen, military body servants, and domestics who could perform heavy labour. Concubinage, moreover, was illegal, and those who sold themselves into slavery practiced female infanticide before selling themselves. In many parts of Africa the demand was primarily for women and children for the purpose of incorporation into and expansion of lineages. Adult males were often killed unless they could be exported abroad. Such export conveniently fit into the circum-Caribbean demand for productive slaves to work in sugar, tobacco, and cotton production. Consequently, twice as many males as females and relatively few children under age 10 were shipped to the New World.

One of the notions about slavery has been that slaves rarely reproduced themselves in bondage. Given the skewed demographic profile of many slave societies, it is not surprising that they failed to do so. The slaves of the Athenian Laurium silver mines or the Cuban sugar plantations, for example, lived in largely male societies. In Islāmic slave-owning societies, castration and infibulation curtailed slave reproduction.

Slave population growth

The major exception to the rule was North America, where slaves began to procreate in significant numbers in the mid-18th century. This fact helped the slave owners survive the cutting off of imports in 1808. Between the censuses of 1790 and 1860 the slave population of the South expanded enormously—from 657,327 to 3,838,765—one of the fastest rates of population growth ever recorded prior to the advent of modern medicine. Paradoxically, although the Southern slave regime was one of the most dehumanizing ever recorded, it was one of the most favourable on record demographically, because the nutritional and general living environments were highly conducive to explosive population growth. Without significant imports the Southern slave population increased fourfold between the early 1800s and 1860.

The ages of slave populations also were determined partially by productive requirements. As mentioned above, in Africa children were preferred for incorporation into lineages, whereas in much of the circum-Caribbean world adults were demanded for production. As a consequence, the age pyramids of both societies were skewed; in Africa children predominated, in much of the New World people over age 15. In Muscovy, to take another example, the age structure was skewed toward young adults, for it was primarily young adult males (aged 15–25) who sold themselves into slavery.

Slave protest. Throughout history human beings have objected to being enslaved and have responded in myriad ways ranging from individual shirking, alcoholism, flight, and suicide to arson, murdering owners, and mass rebellion. Perhaps the most common individual response to enslavement was sluggishness, passivity, and indifference. A nearly universal stereotype of the slave was of a lying, lazy, dull brute who had to be kicked or whipped. There probably were three mutually reinforcing factors at work: an unconscious response to overcontrol and absence of freedom, a conscious effort to sabotage the master's desires, and a conditioned response to the expectation of stereotypical behaviour. Some owners tried to overcome such behaviour by a system of incentives or by strict regimentation, such as the gang system, but historically they were in a minority. Less frequent was suicide. A number of slaves are known to have jumped overboard during the Middle Passage because they feared that the transatlantic voyage was taking them to be eaten by witches or barbarians, a fate that seemed worse than drowning.

Slave flight

Flight, either individually or in groups, was one of the most visible forms of protest against enslavement. The rates of flight, which varied greatly from society to society throughout history, usually depended less on individual slave-owner conduct than on the likelihood of success. Immediate conditions, such as the brutality of an overseer or master or a temporary lapse of supervision, often precipitated slave flight, but willingness to undertake such a form of rebellion against the system was usually determined by such factors as the accessibility of refuge or the ability to blend in with the free population (some societies marked slaves to inhibit such blending). Slave flight was infrequent in societies such as the peacetime American South or in West Africa, where a refuge of freedom was very distant. In East Africa, where flight was curtailed by slave owners united in their desire to prevent it in spite of a high demand for labour, runaways joined neighbouring communities and then raided their former masters. For more than two centuries fugitive slaves in Brazil known as maroons set up independent polities, or *quilombos*, that lasted for years. Maroon communities were found in many other places in Latin America and the Caribbean as well. In Muscovy, where most of the slaves were natives or of similar origin (Poles and Swedes), where there was an open frontier, and where masters had no compunction about taking in other owners' slaves, the rate of flight was very high; and as many as a quarter to a third of the slaves ran away. In China flight by male slaves was also common. During the American Revolution, when the slave owners were occupied with fighting the British, fugitive slaves numbered in the tens of thousands.

Direct, personal attacks on slave owners often were determined by the nature of the slave regime. Where owners believed they enjoyed automatic sexual access to female slaves, both the women and their "husbands" were prone to respond by assaulting the owners or their agents. In Hausaland, killings by concubines instilled great fear in slave owners. Where slaves were driven, assault on the drivers was a not uncommon response. As a result, overseers in the Mississippi Valley feared for their lives and constantly carried arms.

Slave uprisings

The most dramatic form of slave protest was outright rebellion. Slave uprisings varied enormously in frequency, size, intensity, and duration. Perhaps the calmest of all known slave societies were those of West Africa, where the predominance of women and children caused rebellions to be very few. Slave rebellions in North America were also noticeably few and involved only a handful of participants: the New York revolt of 1712, the Stono rebellion of South Carolina (1739), the Gabriel plot in Richmond, Va. (1800), the Denmark Vesey conspiracy in Charleston, S.C. (1822), and Nat Turner's uprising in Jerusalem, Va. (1831) are the best known. Southern slave uprisings were so few and so small because of the absolute certainty that they would be brutally repressed. All the Southern uprisings were savagely repressed, and the Turner rebellion is usually given as the reason for the marked increase in the severity of the slave regime after 1831.

Other slave revolts were on a much grander scale than those of West Africa and North America. One of the most famous slave uprisings was the Gladiatorial War led by Spartacus against Rome in 73–71 BC. The Spartacus rebellion was brutally repressed (the roads leading into Rome were lined with gibbets from which rebel corpses hung). Slaves led the Khlopko and Bolotnikov uprisings in Muscovy in 1603 and 1606, respectively, a time of dynastic crisis. Another great slave rebellion was that of the Zanj (black slaves imported from Zanzibar) in Iraq and Khuzistan in the years 869–883. It was joined by fair-skinned slaves as well and was on a larger scale than the Spartacus revolt. Slave rebellion in China at the end of the 17th and the beginning of the 18th century was so extensive that owners eventually eschewed male slaves and converted the institution into a female-dominated one.

Slave rebellions occurred in every slave society in the Americas from the 16th century onward. Prominent slave revolts occurred in Jamaica in 1760, 1798, and 1831–32, in Barbados in 1816, and in British Guiana in 1823. Perhaps the most famous Caribbean rebellion, in Saint-Domingue, began in 1791 and was subsequently led to victory by the freedman Toussaint-Louverture; it produced the emancipation of its slaves while the French were preoccupied with their own revolution and ultimately led to the independent state of Haiti.

SLAVE CULTURE

The institution of slavery usually tried to deny its victims their native cultural identity. Torn out of their own cultural milieus, they were expected to abandon their heritage and to adopt at least part of their enslavers' culture. Nonetheless, studies have shown that there were aspects of slave culture that differed from the master culture. Some of these have been interpreted as a form of resistance to oppression, while other aspects were clearly survivals of a native culture in the new society. Most of what is known about this topic comes from the circum-Caribbean world, but analogous developments may have occurred wherever alien slaves were concentrated in numbers sufficient to prevent their complete absorption by the host slave-owning or slave society. Thus slave culture was probably very different on large plantations from what it was on small farms or in urban households, where slave culture (and especially Creole slave culture) could hardly have avoided being very similar to the master culture. Slave cultures grew up within the perimeters of the masters' monopoly of power but separate from the masters' institutions.

Religion and slave culture

Religion, which performed the multiple function of explanation, prediction, control, and communion, seems to have been a particularly fruitful area for the creation of slave culture. Africans perceived all misfortunes, including enslavement, as the result of sorcery, and their religious practices and beliefs, which were often millennial, were formulated as a way of coping with it. Myalism was the first religious movement to appeal to all ethnic groups in Jamaica, Voodoo in Haiti was the product of African culture slightly refashioned on that island, and syncretic Afro-Christian religions and rituals appeared nearly everywhere throughout the New World. Slave religions usually had a supreme being and a host of lesser spirits brought from Africa, borrowed from the Amerindians, and created in response to local conditions. There were no firm boundaries between the secular and the sacred, which infused all things and activities. At least initially African slaves universally believed that posthumously they would return to their lands and rejoin their friends.

African elements in New World slave cultures

Black slaves preserved some of their culture in the New World. African medicine was practiced in America by slaves. The poisoning of masters and other hated individuals was a particularly African method of coping with evil. Throughout the circum-Caribbean world slaves and free blacks had electoral procedures, adapted from West African customs, to choose governors, sheriffs, and judges to maintain order among themselves. Objects of material culture, such as rugs, mats, baskets, thatched roofs, and walking canes, were modeled on African examples. Nevertheless, relatively few African social practices or plastic arts survived in the New World. On the other hand, Afro-American music and dance are known to have many African roots, and they differed dramatically from the practices of the European master culture; the use of drum and banjo were especially significant. Songs and spirituals borrowed their strong call-and-response patterns from the West African style. Furthermore, slaves created tales to amuse themselves, and the African element is most evident in animal tales; the tar-baby story is among the best known of the genre. Afro-American stories and songs often featured the devil, who was a demon and a trickster, terrifying, a friend in need, and a source of mirth.

Slave culture also developed beliefs and customs that were at odds with those of the master culture. One such belief was that what the masters called theft was something else; thus stealing from the master was not theft at all but merely a process of channeling his property from one use to another, as in taking his corn and feeding it to his pigs. Polygamous domestic arrangements were a further aspect of slave culture brought from Africa. Yet another aspect of slave culture, especially prevalent in the Caribbean, involved the market. Slaves there were often required to provide their own food, which they raised on provision grounds. If they had any surplus, they were permitted by their owners to sell it in the market. As a result slaves developed an autonomy and an individualism that contrasted starkly with the rigid control of the work gang system and the putative stifling control of slave law.

BIBLIOGRAPHY

General works: A bibliography of more than 6,000 references on slavery has been compiled in JOSEPH C. MILLER, *Slavery: A Comparative Teaching Bibliography* (1977), and continued in the issues of the journal *Slavery & Abolition* (three times a year) in several supplements, most of the references from which have been consolidated in the same author's *Slavery: A Worldwide Bibliography, 1900–1982* (1985). Theoretical works

on slavery include H.J. NIEBOER, *Slavery as an Industrial System: Ethnological Researches,* 2nd rev. ed. (1910, reprinted 1971); and ORLANDO PATTERSON, *Slavery and Social Death: A Comparative Study* (1982). Several cultures are presented in DAVID BRION DAVIS, *The Problem of Slavery in Western Culture* (1966, reissued 1971), *The Problem of Slavery in the Age of Revolution, 1770–1823* (1975), and *Slavery and Human Progress* (1984). Articles of interest are EVSEY D. DOMAR, "The Causes of Slavery or Serfdom: A Hypothesis," *The Journal of Economic History,* 30(1):18–32 (March 1970); MOSES I. FINLEY, "Slavery," in the *International Encyclopedia of the Social Sciences,* ed. by DAVID L. SILLS, vol. 14, pp. 307–313 (1968); and BERNARD J. SIEGEL, "Some Methodological Considerations for a Comparative Study of Slavery," *American Anthropologist,* 47:357–392 (1945).

Slavery in early history: On slavery in the ancient Middle East, see MUHAMMAD A. DANDAMAEV, *Slavery in Babylonia: From Nabopolassar to Alexander the Great (626–331 B.C.),* rev. ed. (1984; originally published in Russian, 1974); and ISAAC MENDELSOHN, *Slavery in the Ancient Near East: A Comparative Study of Slavery in Babylonia, Assyria, Syria, and Palestine, from the Middle of the Third Millennium to the End of the First Millennium* (1949, reprinted 1978).

Central works on slavery in classical antiquity are MOSES I. FINLEY, "Was Greek Civilization Based on Slave Labor?" in his *Slavery in Classical Antiquity: Views and Controversies* (1960); the same author's *Ancient Economy,* 2nd ed. (1985); and *Ancient Slavery and Modern Ideology* (1980). See also MOSES I. FINLEY (ed.), *Classical Slavery* (1987). Other works of major interest include KEITH R. BRADLEY, *Slaves and Masters in the Roman Empire: A Study in Social Control* (1984, reissued 1987); WILLIAM W. BUCKLAND, *The Roman Law of Slavery: The Condition of the Slave in Private Law from Augustus to Justinian* (1908, reprinted 1970); YVON GARLAN, *Slavery in Ancient Greece* (1988; originally published in French, 1982); KEITH HOPKINS, *Conquerors and Slaves* (1978); RAMSAY MacMULLEN, "Late Roman Slavery," *Historia: Zeitschrift für alte Geschichte,* 36(3):359–382 (1987); ALAN WATSON, *Roman Slave Law* (1987); and WILLIAM L. WESTERMANN, *The Slave System of Greek and Roman Antiquity* (1955).

Slavery in Europe: The following works study slavery in Europe, including Russia, after the fall of the Roman Empire: MARC BLOCH, *Slavery and Serfdom in the Middle Ages: Selected Essays* (1975; originally published in French, 1963); PIERRE DOCKÈS, *Medieval Slavery and Liberation* (1982; originally published in French, 1979); PETER FOOTE and DAVID M. WILSON, *The Viking Achievement: The Society and Culture of Early Medieval Scandinavia* (1970, reprinted 1984); ANNA CHATZĒNIKOLAOU-MARAVA, *Recherches sur la vie des esclaves dans le monde byzantyn* (1950); CHARLES VERLINDEN, *L'Esclavage dans l'Europe mědiěvale* (1955); AGNES MATHILDE WERGELAND, *Slavery in Germanic Society During the Middle Ages* (1916); CARL O. WILLIAMS, *Thraldom in Ancient Iceland* (1937); RICHARD HELLIE, *Slavery in Russia, 1450–1725* (1982); RICHARD HELLIE (ed. and trans.), *The Muscovite Law Code (Ulozhenie) of 1649* (1988); and, on the modern period, S. SWIANIEWICZ, *Forced Labour and Economic Development: An Enquiry into the Experience of Soviet Industrialization* (1965, reprinted 1985); and DAVID J. DALLIN and BORIS I. NICOLAEVSKY, *Forced Labor in Soviet Russia* (1947, reprinted 1974).

Slavery in Africa and Asia: JAMES L. WATSON (ed.), *Asian and African Systems of Slavery* (1980), is a collection of informative essays. Slavery in the non-African Islāmic world is explored in DAVID AYALON, *L'Esclavage du mamelouk* (1951); R. BRUNSCHVIG, "ʿAbd," in *The Encyclopedia of Islam,* vol. 1, pp. 24–40 (1960); PATRICIA CRONE, *Slaves on Horses: The Evolution of the Islamic Polity* (1980); HALIL INALCIK, "Servile Labor in the Ottoman Empire," in *The Mutual Effects of the Islamic and Judeo-Christian Worlds: The East European Pattern,* ed. by ABRAHAM ASCHER, TIBOR HALASI-KUN, and BÉLA K. KIRÁLY (1979); DANIEL PIPES, *Slave Soldiers and Islam: The Genesis of a Military System* (1981); and EHUD R. TOLEDANO, *The Ottoman Slave Trade and Its Suppression, 1840–1890* (1982).

Important works on slavery in other parts of Asia are D.R. BANAJI, *Slavery in British India* (1933); BENEDICTE HJEJLE, "Slavery and Agricultural Bondage in South India in the Nineteenth Century," *The Scandinavian Economic History Review,* 15:71–126 (1967); UTSA PATNAIK and MANJARI DINGWANEY (eds.), *Chains of Servitude: Bondage and Slavery in India* (1985); E.G. (R.He.)

Sleep and Dreams

Sleep is a normal, easily reversible, recurrent, and spontaneous state of decreased and less efficient responsiveness to external stimulation. The state contrasts with that of wakefulness, in which there is an enhanced potential for sensitivity and an efficient responsiveness to external stimuli. The sleep–wakefulness alternation is the most striking manifestation in higher vertebrates of the more general phenomenon of periodicity in the activity or responsivity of living tissue (see BEHAVIOUR, ANIMAL). There is no single, perfectly reliable criterion of sleep. Sleep is defined by the convergence of observations satisfying several different motor, sensory, and physiological criteria. Occasionally, one or more of these criteria may be absent during sleep or present during wakefulness, but even in such cases there usually is little difficulty in achieving agreement among observers in the discrimination between the two behavioral states.

Dreaming, a common and distinctive phenomenon of sleep, has since the dawn of human history given rise to myriad beliefs, fears, and conjectures, both imaginative and experimental, regarding its mysterious nature. While any effort toward classification must be subject to inadequacies, beliefs about dreams fall into various classifications depending upon whether dreams are held to be reflections of reality, sources of divination, curative experiences, or evidence of unconscious activity.

This article treats first the psychological and physiological characteristics of the sleeping state. Next, dreaming is examined from both historical-cultural and scientific points of view.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* Part Four, Division II, Section 422 and Division III, Section 433.

The article is divided into the following sections:

Sleep

THE NATURE OF SLEEP

Motor and sensory criteria used in defining sleep

Sleep usually requires the presence of flaccid or relaxed skeletal muscles and the absence of the overt, goal-directed behaviour of which the waking organism is capable. Part of the recurring fascination with sleep talking and sleepwalking stems from their apparent violation of this latter criterion. Were these phenomena continuous, rather than intermittent, during a behavioral state, it is indeed questionable whether the designation "sleep" would continue to be appropriate. The characteristic posture associated with sleep in man and in many but not all animals is that of horizontal repose. The relaxation of the skeletal muscles in this posture and its implication of a more passive role toward the environment are symptomatic of sleep.

Indicative of the decreased sensitivity of the human sleeper to his external environment are the typical closed eyelids (or the functional blindness associated with sleep while the eyes are open) and the presleep activities that include seeking surroundings characterized by reduced or monotonous levels of sensory stimulation. Three additional criteria—reversibility, recurrence, and spontaneity—distinguish the insensitivity of sleep from that of other states. Compared to that of hibernation or coma, the insensitivity of sleep is more easily reversible. Although the occurrence of sleep is not perfectly regular under all conditions, it is at least partially predictable from a knowledge of the duration of prior sleep periods and of the intervals between periods of sleep; and, although the onset of sleep may be facilitated by a variety of environmental or chemical means, sleep states are not thought of as being absolutely dependent upon such manipulations.

In experimental studies, both with subhuman vertebrates and with humans, sleep also has been defined in terms of physiological variables generally associated with recurring periods of inactivity identified behaviorally as sleep. For example, the typical presence of certain electroencephalogram (EEG) patterns (brain patterns of electrical activity as recorded in tracings) with behavioral sleep has led to the designation of such patterns as "signs" of sleep. Conversely, in the absence of such signs (as, for example, in a hypnotic trance) it is felt that true sleep is absent. Such signs as are now employed, however, are not invariably discriminating of the behavioral states of sleep and wakefulness. Advances in the technology of animal experimentation have made it possible to extend the physiological approach from externally measurable manifestations of sleep such as the EEG to the underlying neural (nerve) mechanisms presumably responsible for such manifestations. As a result, it may finally become possible to identify structures or functions that are invariably related to behavioral sleep and to trace the evolution of sleep through comparative anatomic and physiological studies of structures found to be critical in the maintenance of sleep behaviour in the higher vertebrates.

In addition to the behavioral and physiological criteria already mentioned, subjective experience (in the case of the self) and verbal reports of such experience (in the case of others) are used at the human level to define sleep. Upon being alerted, one may feel or say, "I was asleep just then," and such judgments ordinarily are accepted as evidence for identifying a pre-arousal state as sleep, but such subjective evidence can be at variance with behaviouristic classifications of sleep.

Problems in defining sleep

More generally, problems in defining sleep arise when evidence for one or more of the several criteria of sleep is lacking or when the evidence generated by available criteria is inconsistent. Do subhuman species sleep? Other mammalian species whose EEG and other physiological correlates are akin to those observed in human sleep demonstrate recurring, spontaneous, and reversible periods of inactivity and decreased critical reactivity. There is general acceptance of the designation of such states as sleep. As one descends the evolutionary scale below the birds and reptiles, however, and such criteria are successively less well satisfied, the unequivocal identification of sleep becomes more difficult. Bullfrogs (*Rana catesbeiana*), for example, seem not to fulfill sensory threshold criteria of sleep during resting states. Tree frogs (genus *Hyla*), on the other hand, show diminished sensitivity as they move from a state of behavioral activity to one of rest. Yet the EEGs of the alert rest of the bullfrog and the sleeplike rest of the tree frog are the same. There are parallel problems in defining sleep at different stages in the development of a single individual. At full-term birth in the human being, for instance, a convergence of nonsubjective criteria clearly seems to justify the identification of periods of sleep, but it is more difficult to justify the attribution of sleep to the human fetus.

Problems in defining sleep may arise from the effects of artificial manipulation. For example, the EEG patterns commonly used as signs of sleep can be induced in an otherwise waking organism by the administration of certain drugs. Sometimes, also, there is conflicting evidence: a person who is "awakened" from a spontaneously assumed state of immobility with all the EEG criteria of sleep may claim that he had been awake prior to this event. In such troublesome cases and more generally, it is becoming common to qualify attributions of sleep with the criteria upon which such attributions rest—*e.g.*, "behavioral sleep," "physiological sleep," or "self-described sleep." Such terminology accurately reflects both the multiplicity of criteria available for the identification of sleep and the possibility that these criteria may not always agree with one another.

DEVELOPMENTAL PATTERNS OF SLEEP AND WAKEFULNESS

Length of time spent in sleep

How much sleep does a person need? While the physiological bases of the need for sleep remain conjectural, rendering definitive answers to this question impossible, much evidence has been gathered on how much sleep people do in fact obtain. Perhaps the most important conclusion to be drawn from this evidence is that there is great variability among individuals in total sleep time. For adults, anything between six and nine hours of sleep as a nightly average is not unusual, and $7\frac{1}{2}$ hours probably best expresses the norm. Such norms, of course, inevitably vary with the criteria of sleep employed. The most precise and reliable figures on sleep time, including those cited here, come from studies in sleep laboratories, where EEG criteria are employed.

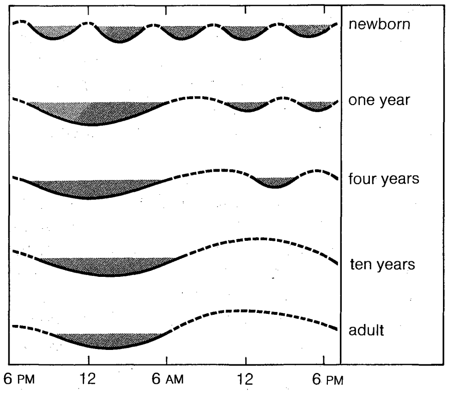
Age consistently has been associated with the varying amount, quality, and patterning of electrophysiologically defined sleep. The newborn infant may spend an average of about 16 hours of each 24-hour period in sleep, although there is wide variability among individual babies. During the first year of life, total sleep time drops sharply; by two years of age, it may range from nine to 12 hours. Decreases to approximately six hours have been observed among the elderly.

As will be elaborated below, EEG sleep studies have indicated that sleep can be considered to consist of several different stages. Developmental changes in the relative proportion of sleep time spent in these sleep stages are as striking as age-related changes in total sleep time. For example, the newborn infant may spend 50 percent of total sleep time in a stage of EEG sleep that is accompanied by intermittent bursts of rapid eye movements (REMs) indicative of a type of sleep that in some respects bears more resemblance to wakefulness than to other forms of sleep (see below *Rapid eye movement sleep*), while the comparable figure for adults is approximately 25 percent, and for the aged is less than 20 percent. There is also a decline with age of EEG stage 4 (deep slumber).

Aspects of sleep patterning

Sleep patterning consists of (1) the temporal spacing of sleep and wakefulness within a 24-hour period and (2) the ordering of different sleep stages within a given sleep period. In both senses, there are major developmental changes in the patterning of sleep. In alternations between sleep and wakefulness, there is a developmental shift from polyphasic sleep to monophasic sleep (*i.e.,* from intermittent to uninterrupted sleep). At birth, there may be five or six periods of sleep per day alternating with a like number of waking periods. With the dropping of nocturnal feedings in infancy and of morning and afternoon naps in childhood, there is an increasing tendency to the concentration of sleep in one long nocturnal period (see the Figure). The trend to monophasic sleep probably reflects some blend of the effects of maturing and of pressures from a culture geared to daytime activity and nocturnal rest. Among the elderly there may be a partial return to the polyphasic sleep pattern of infancy and early childhood, namely, more frequent daytime napping and less extensive periods of nocturnal sleep because of the loss of zeitgebers, time markers that provide cues. These include the need to arise at a set time for work or to get children off to school. Significant developmental effects also have been observed in spacing of stages within sleep. In the adult, REM sleep rarely occurs at sleep onset, while, in newborn infants, sleep-onset REM sleep is typical.

From E.J. Murray, *Sleep, Dreams and Arousal,* p. 297 (1965); Appleton-Century-Crofts



Alternations of sleep and wakefulness at specified ages. The shading indicates periods of sleep.

It would be difficult to overestimate the significance of the various age-related changes in sleep behaviour for a general theory of sleep. In the search for the functional significance of sleep or of particular stages of sleep, the shifts in sleep variables can be linked with variations in waking developmental needs, in the total capacities of the individual, and in environmental demands. It has been suggested, for instance, that the high frequency and priority in the night of REM sleep in the newborn infant may reflect a need for stimulation from within to permit orderly maturation of the central nervous system (CNS). Another interpretation of age-related changes in REM sleep stresses its possible role in processing new information, the rate of acquisition for which is assumed to be relatively high in childhood but reduced in old age. As these views illustrate, developmental changes in the electrophysiology of sleep are germane not only to sleep but also to the role of CNS development in behavioral adaptation.

PSYCHOPHYSIOLOGICAL VARIATIONS IN SLEEP

That there are different kinds of sleep has long been recognized. In everyday discourse there is talk of "good" sleep or "poor" sleep, of "light" sleep and "deep" sleep; yet, only in the second half of the 20th century have scientists paid much attention to qualitative variations within sleep. Sleep was formerly conceptualized by scientists as a unitary state of passive recuperation. Revolutionary changes have occurred in scientific thinking about sleep, the most important of which has been increased sensitivity to its heterogeneity.

This revolution may be traced back to the discovery of sleep characterized by rapid eye movement (REM sleep), first reported by the physiologists Eugene Aserinsky and Nathaniel Kleitman in 1953. REM sleep proved to have characteristics quite at variance with the prevailing model of sleep as recuperative deactivation of the central nervous system. Various central and autonomic nervous system measurements seemed to show that the REM stage of sleep is more nearly like activated wakefulness than it is like other sleep. It now has become conventional to consider REM ("paradoxical") and non-REM (NREM or "orthodox") sleep as qualitatively different. Thus, the earlier assumption that sleep is a unitary and passive state has yielded to the viewpoint that there are two different kinds of sleep, a relatively deactivated NREM phase and an activated REM phase.

Stages of NREM sleep

Non-rapid eye movement sleep. NREM sleep itself is conventionally subdivided into several different stages on the basis of EEG criteria. In the adult, stage 1 is observed at sleep onset or after momentary arousals during the night and is defined as a low-voltage mixed-frequency EEG tracing with a considerable representation of theta-wave (four to seven hertz, or cycles per second) activity. Stage 2 is a relatively low-voltage EEG tracing characterized by intermittent, short sequences of waves of 12–14 hertz ("sleep spindles") and by formations called K-complexes—biphasic wave forms that can be induced by external stimulation, as by a sound, but that also occur spontaneously during sleep. Stages 3 and 4 consist of relatively high-voltage (more than 50-microvolt) EEG tracings with a predominance of delta-wave (one to two hertz) activity; the distinction between the two stages is based on an arbitrary criterion of amount of delta-wave activity, with greater amounts classified as stage 4. Unlike the basic distinction between NREM and REM, differences among NREM sleep stages generally are regarded as quantitative rather than qualitative.

The EEG patterns of NREM sleep, particularly of stages 3 and 4 (tracings of slower frequency and higher amplitude), are those associated in other circumstances with decreased vigilance. Furthermore, after the transition from wakefulness to NREM sleep, most functions of the autonomic nervous system decrease their rate of activity and their moment-to-moment variability. Thus, NREM sleep is the kind of seemingly restful state that appears capable of supporting the recuperative functions assigned to sleep. There are, in fact, several lines of evidence suggesting such functions for NREM stage 4: (1) increases in such sleep, in both man and laboratory animals, have been observed after physical exercise; (2) the concentration of such sleep in the early portion of the sleep period (*i.e.,* immediately after wakeful states of activity) in human beings; and (3) the relatively high priority that such sleep has, among human beings, in "recovery" sleep following abnormally extended periods of wakefulness.

Rapid eye movement sleep. REM sleep is a state of diffuse bodily activation. Its EEG patterns (tracings of faster frequency and lower amplitude than in NREM stages 2–4) are at least superficially similar to those of wakefulness. Most autonomic variables exhibit relatively high rates of activity and variability during REM sleep; for example, there are higher heart and respiration rates and more short-term variability in these rates than in NREM sleep, increased blood pressure, and, in males, full or partial penile erection. In addition, REM sleep is accompanied by a relatively low rate of gross body motility, but with some periodic twitching of the muscles of the face and extremities, relatively high levels of oxygen consumption by the brain, increased cerebral blood flow, and higher brain temperature. An even more impressive demonstration of the activation of REM sleep is to be found in the firing rates of individual cerebral neurons, or nerve cells, in experimental animals: during REM sleep such rates exceed those of NREM sleep and often equal or surpass those of wakefulness. Another distinguishing feature of REM sleep, of course, is the intermittent appearance of bursts of the rapid eye movements, whence the term is derived.

The three events defining REM sleep

For both humans and animals, REM sleep now is defined by the concurrence of three events: low-voltage, mixed-frequency EEG; intermittent REMs; and suppressed tonus of the muscles of the facial region (*i.e.,* suppression of the continuous slight tension otherwise normally present). This decrease in muscle tonus and a similarly observed suppression of spinal reflexes are indicative of heightened motor inhibition during REM sleep. Animal studies have identified the locus ceruleus, in the pons, as the probable source of this inhibition. (The pons is in the brain stem directly above the medulla oblongata; the locus ceruleus borders on the brain cavity known as the fourth ventricle.) When this structure is surgically destroyed in experimental animals, they periodically engage in active, apparently goal-directed behaviour during REM sleep, although they still show the unresponsivity to external stimulation characteristic of the stage. It has been suggested that such behaviour may be the acting out of the hallucinations of a dream.

An important theoretical distinction is that between REM sleep phenomena that are continuous and those that are intermittent. Tonic (continuous) characteristics of REM sleep include the low-voltage EEG and the suppressed muscle tonus; intermittent events in REM sleep include the REMs themselves and, as observed in the cat, spikelike electrical activity in those parts of the brain concerned with vision and in other parts of the cerebral cortex. The various intermittent events of REM sleep tend to occur together, and it seems to be these moments of intermittent activation that are responsible for much of the difference between REM sleep and NREM sleep. The spiking mentioned is observed occasionally in NREM sleep, an occurrence that has been interpreted by some theorists as suggesting that REM sleep is not qualitatively unique in its capacity to support intermittent activation and that between NREM and REM sleep the differences may be less striking than the differences in eye movement and in EEG have indicated.

Sequences of NREM and REM sleep. The usual temporal progression of the two kinds of sleep in the adult human is for a period of approximately 70–90 minutes of NREM sleep (the stages being ordered 1–2–3–4–3–2) to precede the first period of REM sleep, which may last from approximately five to 15 minutes. NREM–REM cycles of roughly equivalent total duration then recur through the night, with the REM portion lengthening somewhat, and the NREM portion shrinking correspondingly, as sleep continues. Approximately 25 percent of total accumulated sleep is spent in REM sleep and 75 percent in NREM sleep. Most of the latter is EEG stage 2. The high proportion of stage 2 NREM sleep is attributable to the loss of stages 3 and 4 in the NREM portion of the NREM–REM cycles after the first two or three.

Light and deep sleep. Which of the various NREM stages is light sleep and which is deep sleep? The criteria used to establish sleep depth are the same as those used to distinguish sleep from wakefulness. In terms of motor behaviour, motility decreases (depth increases) from stages 1 through 4. By criteria of sensory responsivity, thresholds generally increase (sleep deepens) from stages 1 through 4. By most physiological criteria, NREM stages 3 and 4 are particularly deactivated (deep). Thus, gradations within NREM sleep do seem fairly consistent, with a continuum extending from the "lightest" stage 1 to the "deepest" stage 4.

Relative to NREM sleep, is REM sleep light or deep? The answer seems to be that by some criteria REM sleep

Problems of defining depth in REM sleep

is light and by others it is deep. For example, in terms of muscle tone, which is at its lowest point during sleep in REM sleep, it is deep. In terms of its increased rates of intermittent fine body movements, REM sleep would have to be considered light. Arousal thresholds during REM sleep are variable, apparently as a function of the meaningfulness of the stimulus (and of the possibility of its incorporation into an ongoing dream sequence). With a meaningful stimulus (*e.g.,* one that cannot be ignored with impunity), the capacity for responsivity can be demonstrated to be roughly equivalent to that of "light" NREM sleep (stages 1 and 2). With a stimulus having no particular significance to the sleeper, thresholds can be rather high. The discrepancy between these two conditions suggests an active shutting out of irrelevant stimuli during REM sleep. By most physiological criteria related to the autonomic and central nervous systems, REM sleep clearly is more like wakefulness than like NREM sleep, but drugs that cause arousal in wakefulness, such as amphetamine, suppress REM sleep. In terms of subjective response, recently awakened sleepers often describe REM sleep as having been "deep" and NREM sleep as having been "light." The subjectively felt depth of REM sleep may reflect the immersion of the sleeper in the vivid dream experiences of this stage.

Thus, as was true in defining sleep itself, there are difficulties in achieving unequivocal definitions of sleep depth. Several different criteria may be employed, and they are not always in agreement. REM sleep is particularly difficult to classify along any continuum of sleep depth. The current tendency is to consider it a unique state, sharing properties of both light and deep sleep. The fact that selective deprivation of REM sleep (elaborated below) results in a selective increase in such sleep on recovery nights is consistent with this view of REM sleep as unique.

Autonomic variables. Some autonomic physiological variables have a characteristic pattern relating their activity to cumulative sleep time, without respect to whether it is REM or NREM sleep. These variables are viewed by some authorities as incidental rather than essential features of the state of sleep, which is conceived in terms of the central nervous system. Such variables presumably reflect constant or slowly changing features of both kinds of sleep, such as the cumulative effects of immobility and of relaxation of skeletal muscles on metabolic processes. Body temperature, for example, drops during the early hours of sleep, reaching a low point after five or six hours, then rises toward the morning awakening.

Sleep learning, sleep-walking, sleep talking

Behavioral variables. Behaviorally, it has been shown that already established motor responses can be evoked in all stages of sleep, but it has proved much more difficult to demonstrate that new responses can be acquired during sleep. When EEG criteria of sleep are employed, it appears that "sleep learning" of verbal material takes place only to the degree that the person being tested is partially awake during the presentation of the stimuli. Another line of behavioral study is the observation of spontaneously occurring integrated behaviour patterns, such as walking and talking during sleep. In keeping with the idea of a heightened tonic (continuous) motor inhibition during REM sleep, but contrary to the idea that such behaviour is an acting out of especially vivid dream experiences or a substitute for them, sleep talking occurs primarily in NREM sleep and sleepwalking exclusively in NREM sleep. Talking in one's sleep is particularly characteristic of lighter NREM sleep (stage 2), while sleepwalking is initiated from deeper NREM sleep (stage 4). Episodes of NREM sleepwalking generally do not seem to be associated with any remembered dreams, nor is NREM sleep talking consistently associated with reported dreams of appropriate content.

For a discussion of dreaming, see below *Dreams and dreaming.*

EFFECTS OF SLEEP DEPRIVATION

One time-honoured approach to determining the function of an organ or process is to deprive an organism of the organ or process. In the case of sleep, the deprivation approach to function has been applied, both experimentally and naturalistically, to sleep as a unitary state (general sleep deprivation), and, experimentally only, to particular kinds of sleep (selective sleep deprivation). General sleep deprivation may be either total (*e.g.,* a person has had no sleep at all for a period of days) or partial (*e.g.,* over a period a person obtains only three or four hours of sleep per night). The method of general deprivation studies is enforced wakefulness. Selective deprivation has been reported for two stages of sleep: stage 4 of NREM sleep and REM sleep. Both typically occur after the appearance of other sleep stages, REM sleep after all four NREM stages and stage 4 after the lighter NREM stages. The general idea of selective deprivation studies is to allow the sleeper to have natural sleep until the point at which he enters the stage to be deprived and then to prevent the stage, either by experimental awakening or by other manipulations such as application of a mildly noxious stimulus or prior administration of a drug known to suppress it. The hope is that total sleep time will not be altered but that increased occurrence of some other stage will substitute for the loss of the one selectively eliminated.

Types of sleep deprivation

General sleep deprivation. On a three-hour sleep schedule, partial deprivation does not reproduce, in miniaturized form, the same relative distribution of sleep patterns achieved in a seven- or eight-hour sleep period. Some increase is observed in absolute amounts of REM sleep during the three-hour sleep period as compared to the first three hours of normal sleep, and there also is a significant increase in the amount of stage 4 of NREM sleep. Lighter NREM sleep (*e.g.,* stage 2) seems to have a particularly low priority under partial sleep deprivation. Although the REM sleep percentage increases somewhat under partial deprivation, the person is still far from achieving his usual quota in absolute minutes of sleep time. On uninterrupted recovery nights following the termination of the deprivation, there is more REM sleep than there was before the deprivation. This change is viewed as a compensatory "rebound" of REM sleep such that at least some of the quota is made up. Most if not all of the nightly quota of stage 4 of NREM sleep can be achieved on a three-hour nightly schedule. Because partial deprivation on a three-hour nightly regimen also tends to be selective deprivation (the person receives most of his quota of stage 4 NREM sleep but relatively little of his quota of stage REM), the behavioral effects of such deprivation may be relevant to the question of the adaptive functions served by REM sleep. One study has reported no effects from deprivation of REM sleep on the capacity for performance on a perceptual discrimination task but decreased motivation. When a schedule of partial deprivation began to interfere with the routine accumulation of stage 4 (*i.e.,* less than three hours of sleep per night), on the other hand, the capacity for performance seemed to be adversely affected.

Effects of total sleep deprivation

In view of several obvious practical considerations, many general deprivation studies have used animals rather than human beings as experimental subjects. Waking effects routinely observed in these studies have been of deteriorated physiological functioning, sometimes including actual tissue damage. Long-term sleep deprivation in the rat (six to 33 days), accomplished by enforced locomotion of both experimental and control animals but timed to coincide with any sleep of the experimental animals, has been shown to result in severe debilitation and death of the experimental but not the control animals. This supports the view that sleep serves a vital physiological function. There is some suggestion that age is related to sensitivity to the effects of deprivation, younger organisms proving more capable of withstanding the stress than mature ones.

Among human subjects, the champion non-sleeper apparently was a 17-year-old student who voluntarily undertook a 264-hour sleep deprivation experiment. Effects noted during the deprivation period included irritability, blurred vision, slurring of speech, memory lapses, and confusion concerning his identity. No long-term (*i.e.,* post-recovery) effects were observed on either his personality or his intellect. More generally, although brief hallucinations and easily controlled episodes of bizarre behaviour have been observed after five to 10 days of continuous sleep deprivation, these symptoms do not occur in most subjects and thus offer little support to the hypothesis that sleep loss induces psychosis. In any event, these symptoms rarely persist beyond the period of sleep that follows the period of deprivation. When inappropriate behaviour does persist, it generally seems to be in persons known to have a tendency toward such behaviour. Generally, upon investigation, injury to the nervous system has not been discovered in persons who have been deprived of sleep for many days. This negative result must be understood in the context of the limited duration of these studies and should not be interpreted as indicating that sleep loss is either safe or desirable. The short-term effects observed with the student mentioned are typical and are of the sort that, in the absence of the continuous monitoring his vigil received, might well have endangered his health and safety.

Other commonly observed behavioral effects during total sleep deprivation include fatigue, inability to concentrate, and visual or tactile illusions and hallucinations. These effects generally become intensified with increased loss of sleep, but they also wax and wane in a cyclic fashion in line with 24-hour fluctuations in EEG alpha-wave (eight to 12 hertz) phenomena and with body temperature, becoming most acute in the early morning hours. Changes in intellectual performance during moderate sleep loss can, to a certain extent, be compensated for by increased effort and motivation. In general, tasks that are work paced (the subject must respond at a particular instant of time not of his own choice) tend to be affected more adversely than tasks that are self-paced. Errors of omission are common with the former kind of task and are thought to be associated with "microsleep"—momentary lapses into sleep. Changes in body chemistry and in workings of the autonomic nervous system sometimes have been noted during deprivation, but it has proved difficult to establish either consistent patterning in such effects or whether they should be attributed to sleep loss per se or to the stress or other incidental features of the deprivation manipulation. In general, involuntary bodily functions seem relatively more impervious to effects of short-term deprivation than are adaptive, or voluntary, ones. The length of the first recovery sleep session for the student mentioned above, following his 264 hours of wakefulness, was slightly less than 15 hours. His sleep demonstrated increased amounts of both stage 4 NREM and stage REM sleep.

Effects of selective sleep deprivation

Selective sleep deprivation. Studies of selective sleep deprivation have confirmed the attribution of need for both stage 4 NREM and REM sleep, because an increasing number of experimental arousals is required each night to suppress both stage 4 and REM sleep on successive nights of deprivation, and because both show a clear rebound effect following deprivation. Rebound from stage 4 NREM-sleep deprivation occurs only on the night following termination of the deprivation regardless of the length of the deprivation, whereas the duration of the rebound effect following REM-sleep deprivation is related to the length of the prior deprivation. Little is known of the consequences of stage 4 deprivation.

Particular interest has attached to the selective deprivation of REM sleep, partly because of its unique and somewhat puzzling properties as an activated state of sleep and partly because of the association of this stage with vivid dreaming. REM-sleep-deprivation studies once were considered also to be "dream-deprivation" studies. This psychological view of REM sleep deprivation has become less pervasive since the experimental demonstration of the occurrence of dreaming during NREM-sleep stages, and because, contrary to the Freudian position that the dream is an essential safety valve for the release of emotional tensions, it has become evident that REM-sleep deprivation is not psychologically disruptive and may in fact be helpful in treating depression. REM-sleep-deprivation studies have focused more upon the presumed functions of the REM state than upon those of the vivid dreams that accompany it. The evidence from these studies has proved to be partially supportive of a number of different theoretical positions concerning REM sleep. Some animal studies have reported deleterious effects of REM-sleep deprivation on learning or other cognitive tasks (*i.e.,* tasks concerned with thinking, remembering, perceiving, and the like), in line with the view that cognitive processing may be one function of REM sleep. Other animal studies have shown heightened levels of sexuality and aggressiveness after a period of deprivation, suggesting a drive-regulative function for REM sleep. Other observations suggest increased sensitivity of the central nervous system to auditory stimuli and to electroconvulsive shock following deprivation, as might have been predicted from the theory that REM sleep somehow serves to maintain CNS integrity.

Effects of REM-sleep deprivation

Although there is a need for REM sleep, apparently it is not absolute. Animals have been deprived of REM sleep for as long as two months without showing behavioral or physiological evidence of injury. Several problems arise in connection with the methods of most REM-sleep-deprivation studies. Controls for factors such as stress, sleep interruption, and total sleep time are difficult to manage. Thus, it is unclear whether observed effects of REM-sleep deprivation are the result of REM-sleep loss or the result of such factors as stress and general sleep loss. It also is unclear whether it is the loss of continuous REM sleep or of the intermittent events that accompany it that is crucial in REM-sleep deprivation. Preliminary research indicates the latter, suggesting that REM-deprivation studies are more relevant to the function of separate intermittent events occurring in sleep than to the function of the continuous REM sleep.

PATHOLOGICAL ASPECTS

It is important, at the outset, to emphasize that, as dramatic and reliable as the various stages of sleep are, their functions or relations to waking performance, mood, or health are still largely unknown. Thus, association of a sleep abnormality with a certain stage of sleep (either in the sense that an abnormal event occurs during a certain stage or in the sense that an abnormal condition is associated with an increase or decrease in the proportion of total sleep time spent in that stage) is difficult to interpret when the function or necessity of that stage is uncertain. The pathology of sleep includes: (1) primary disturbances of sleep–wakefulness mechanisms, such as seem to characterize encephalitis lethargica ("sleeping sickness"), narcolepsy (irresistible brief episodes of sleep), and hypersomnia (sleep attacks of lesser urgency but greater duration than those of narcolepsy); (2) minor episodes occurring during sleep, such as bed-wetting and nightmares; (3) medical disorders such as sleep apnea whose symptoms occur during sleep; (4) sleep symptoms of the major psychiatric disorders; and (5) disorders of sleep schedule.

Primary disturbances. Epidemic lethargic encephalitis is produced by viral infections of sleep–wakefulness mechanisms in the hypothalamus, a structure at the upper end of the brain stem. The disease often passes through several stages: fever and delirium; hyposomnia (loss of sleep); and hypersomnia (excessive sleep), sometimes bordering on a coma. Inversions of 24-hour sleep–wakefulness patterns also are commonly observed, as are disturbances in eye movements.

Narcolepsy, like encephalitis, is thought to involve specific abnormal functioning of subcortical sleep regulatory centres. Some people who experience attacks of narcolepsy also have one or more of the following auxiliary symptoms: cataplexy, a sudden loss of muscle tone often precipitated by an emotional response such as laughter or startle and sometimes so dramatic as to cause the person to fall down; hypnagogic (sleep onset) and hypnopompic (awakening) visual hallucinations of a dreamlike sort; and hypnagogic or hypnopompic sleep paralysis, in which the person is unable to move voluntary muscles (except respiratory muscles) for a period ranging from several seconds to several minutes. When narcolepsy includes one or more of the accessory symptoms, some of the sleep attacks consist of periods of REM at onset of sleep. This precocious triggering of REM sleep (which occurs in adults generally only after 70–90 minutes of NREM sleep) may indicate that the accessory symptoms are dissociated aspects of REM sleep; *i.e.,* the cataplexy and the paralysis represent the active motor inhibition of REM sleep and the hallucinations represent the dream experience of REM sleep. Thus, narcolepsy involves REM sleep, and it is thought that it probably involves a failure of wakefulness mechanisms to inhibit the REM-sleep mechanisms.

Hypersomnia; hyposomnia

Hypersomnia may involve either excessive daytime sleep and drowsiness or a nocturnal sleep period of greater than normal duration but does not include sleep-onset REM periods. One reported concomitant of hypersomnia, the failure of heart rate to decrease during sleep, suggests that hypersomniac sleep may not be as restful per unit of time as is normal sleep. In its primary form, hypersomnia is probably hereditary in origin (as is also narcolepsy) and is thought to involve some disruption of the functioning of hypothalamic sleep centres. Narcolepsy and hypersomnia are not characterized by grossly abnormal EEG sleep patterns. The abnormality seems to involve a failure in "turn on" and "turn off" mechanisms regulating sleep, rather than in the sleep process itself. Narcoleptic and hypersomniac symptoms can be managed by administration of drugs. Several forms of hypersomnia are periodic rather than chronic. One rare disorder of periodically excessive sleep, the Kleine-Levin syndrome, is characterized by periods of two to four weeks of excessive sleep along with a ravenous appetite and psychotic-like behaviour during the few waking hours. The "Pickwickian syndrome" (in reference to the fat boy, Joe, in Dickens' *Pickwick Papers*), another form of periodically excessive sleep, is associated with obesity and respiratory insufficiency.

Hyposomnia (this word, meaning "too little sleep," is chosen in preference to "insomnia," or "lack of sleep," because some sleep invariably is present) is less clearly understood than the conditions already mentioned. It has been demonstrated that, by physiological criteria, self-described poor sleepers generally sleep much better than they imagine. Their sleep, however, does show signs of disturbance: frequent body movement, enhanced levels of autonomic functioning, reduced levels of stage REM, and in some the intrusion of waking rhythms (alpha waves) throughout the various sleep stages. Although hyposomnia in a particular situation is common and without pathological import, chronic hyposomnia may be related to psychological disturbance. Hyposomnia conventionally is treated by administration of drugs but often with substances that are potentially addictive and otherwise dangerous when used over long periods. Newer treatments involve behavioral programs such as the temporary restriction of sleep time and its gradual reinstatement.

Minor episodes. Among the minor episodes sometimes considered abnormal in sleep are: somniloquy (sleep talking) and somnambulism (sleepwalking), enuresis (bedwetting), bruxism (tooth grinding), snoring, and nightmares. Sleep talking seems more often to consist of inarticulate mumblings than of extended, meaningful utterances. It occurs at least occasionally for many people and at this level cannot be considered pathological. Sleepwalking is not uncommon in children, but its continuation into adulthood is suggestive of persistent immaturity of the central nervous system. Enuresis may be a secondary symptom of a variety of organic conditions or, more frequently, a primary disorder in its own right. In the latter case, it seems to involve some immaturity in neural control of bladder muscles. While mainly a disorder of early childhood, enuresis persists into adulthood for a small number of persons. Treatment generally has been directed either toward sensitizing the sleeper to bladder distention, so that he will awaken and urinate according to appropriate social norms, or toward increasing bladder capacity. Primary enuresis does not seem to be an abnormality of sleep, sleep cycles of bed-wetting and of normal children being roughly the same. Tooth grinding is not consistently associated with any particular stage of sleep, nor does it appreciably affect overall sleep patterning; it, too, seems to be an abnormality in rather than of sleep.

Sleep talking; sleepwalking; bedwetting; tooth grinding

Varieties of nightmare

A variety of frightening experiences associated with sleep, at one time or another, have been called nightmares. Because not all such phenomena have proved to be identical in their associations with sleep stages or with other variables, several distinctions need to be made among them. Incubus, the classic nightmare of adult years, consists of arousal from stage 4 NREM sleep with a sense of heaviness over the chest, with diffuse anxiety, but with little or no dream recall. Night terrors (*pavor nocturnus*) are disorders of early childhood. Delta-wave NREM sleep is suddenly interrupted with a scream; the child may sit up in apparent terror and be incoherent and inconsolable. After a period of minutes, he returns to sleep, often without ever having been fully alert or awake. Dream recall generally is absent, and the entire episode may be forgotten in the morning. Anxiety dreams most often seem associated with spontaneous arousals from REM sleep. There is remembrance of a dream whose content is in keeping with the disturbed awakening. While their persistent recurrence probably indicates waking psychological disturbance or stress caused by a difficult situation, anxiety dreams occur occasionally in many otherwise healthy persons.

Disorders accentuated during sleep. A variety of medical symptoms may be accentuated by the conditions of sleep. Attacks of angina (spasmodic, choking pain), for example, apparently can be augmented by the activation of the autonomic nervous system in REM sleep; the same is true of gastric acid secretions in persons who have duodenal ulcers. NREM sleep, on the other hand, can increase the likelihood of certain kinds of epileptic discharge.

Rhythmic snoring, which can occur throughout sleep, indicates the partial muscular relaxation of sleep, and its occasional occurrence is not abnormal. When snoring is of the loud, laboured, snorting variety, however, and is accompanied by pauses in respiration of more than 10 seconds in duration, broken by gasping sounds, the respiratory disorder called sleep apnea may be present. This disorder can occur at any age but is most common in the elderly. It results in hypoxia and sleep fragmentation, both of which contribute to excessive daytime sleepiness and cognitive deficits. Treatment approaches include behaviour change (reduction of alcohol consumption and body weight), sleep position training, mechanical appliances to keep the airway unobstructed, and surgery.

The resemblance of dream consciousness to waking psychotic experience often has been noted, and the psychotic has been considered a "waking dreamer." Thus, it has been theorized that waking psychotic symptoms may be generated by a spontaneous, or REM-sleep-deprivation-induced, shift of REM phenomena from sleep to the waking state. Symptomatically, schizophrenics have shown neither the exacerbation of psychotic symptoms under experimental REM-sleep deprivation nor the consistent or large deviations from normal EEG sleep patterning that would seem to be required by the hypothesis that sleep mechanisms play some critical role in bringing on psychotic episodes. Depressed people do sleep less and have an earlier first REM period than normal people. The first REM period, occurring 40–60 minutes after sleep onset, is often longer than normal with more eye movement activity. This suggests a disruption in the drive-regulation function, affecting such things as sexuality, appetite, or aggressiveness, all of which are reduced in such persons. REM deprivation by pharmacological agents (tricyclic antidepressants) or by REM-awakening techniques appears to reverse this sleep abnormality and to relieve the waking symptoms.

Disorders of sleep schedule. There are two prominent types of sleep-schedule disorder: phase-advanced sleep and phase-delayed sleep. In the former the sleep onset and offset occur earlier than the social norms, and in the latter sleep onset is delayed and waking is also later in the day than is desirable. These alterations in the sleep–wake cycle may occur in shift workers or following international travel across time zones. They can be treated by gradual readjustment of the timing of sleep.

DRUGS AND SLEEP

Various chemical substances long have been employed to induce or prolong sleep, but there have been few controlled, double-blind studies (neither the physician who evaluates the results nor the patient knows whether the latter has received a drug or placebo—an inert substitute) of alleged hypnotics (sleep-inducing drugs) in which sleep has been assessed by physiological measurement; and the mechanisms of sleep themselves are only now beginning to be isolated. The little research that has been done makes it clear that the manner in which a drug affects sleep can be extremely complex, with different effects sometimes attributable to different dosages of the same substance and with different effects sometimes observed for short-term and long-term administration of the same substance.

Drugs that reduce REM sleep

Many pharmacological agents tend to reduce the absolute amount and relative proportion of sleep spent in REM sleep. In this sense, REM sleep has been called a fragile state. Specifically, most effective hypnotics, particularly the barbiturates (*e.g.,* pentobarbital, secobarbital), decrease both total REM time and the proportion of sleep spent in REM sleep, with enhanced amounts of NREM sleep. Amphetamine, an analeptic (stimulant), decreases REM sleep. Many tranquilizers also slightly reduce REM sleep. There is evidence that the withdrawal symptoms of persons taken off addictive drugs of any variety (*e.g.,* barbiturates, amphetamines, narcotics) are accompanied by relatively high percentages of REM sleep. It has been suggested that the drugs in question are REM-sleep deprivers, that the elevated periods spent in REM sleep on withdrawal represent REM-sleep rebound, that the withdrawal syndrome may be functionally related to high pressure for REM sleep, and that the vivid, unpleasant dreams associated with REM-sleep rebound may be responsible for some patients' return to the use of the REM-sleep-depriving agents. Caffeine seems to have little effect on normal sleep patterning, but the effects of alcohol are variable: the short-term effect is to reduce the time spent in REM sleep, but, with continued use, there may be a REM-sleep rebound. Not all drug effects are on REM sleep; some of the more recently developed tranquilizers and hypnotics have been found to reduce stage 4 of NREM sleep.

Much interest has attached to the search for hypnotic substances that are not REM-sleep deprivers, that is, that induce or prolong sleep without altering natural sleep patterns. While some such hypnotics have been found, they most often either have adverse side effects or have not been fully evaluated. Theoretically, the most interesting substances are those few that have been found to increase REM sleep. In certain dosage ranges and under certain conditions, such an effect has been noted for reserpine, a tranquilizer, and for D-lysergic acid diethylamide (LSD), a hallucinogen. Both substances have important interactions with neurohumours (serotonin and norepinephrine—substances formed in nerve cells), and their effects may offer clues to the mechanisms underlying REM sleep.

THEORIES OF SLEEP

Two kinds of sleep theory of contemporary interest may be distinguished. One begins with the peripheral physiology of sleep and relates it to underlying neural (nervous system) or biochemical mechanisms. Such theories most often rely on experiments with animals by means of drugs or surgery. Alternatively, sleep theories may start with behavioral observations of sleep and may attempt to specify the functions of such a state of lethargy and insensitivity from an evolutionary or adaptive point of view. The question here is not so much how people sleep, or even why they sleep, but what good it does.

Mechanistic theories. Historically, mechanistic theories of sleep have focused on a succession of organs or structures in a manner reflective of the degree of access different civilizations have had to the inner workings of the human body. Thus, the relatively perceptible processes of circulation, digestion, and secretion played large roles in the theories of classical antiquity, and modern theories have been concerned with the central nervous system, particularly the brain, although various peripheral factors in the induction of sleep are not ruled out. Proposals that blood composition, metabolic changes, or internal secretions regulate sleep are necessarily incomplete to the extent that they ignore the contributions of environment and intent to the onset of sleep. It also has been noted that in two-headed human monsters one "twin" may seem asleep while the other is awake, despite their sharing a circulatory system.

Neural theories. Among neural theories of sleep, there are certain issues that each must face. Is the sleep–wakefulness alternation to be considered a property of individual neurons (nerve cells), making unnecessary the postulation of specific regulative centres, or is it to be assumed that there are some aggregations of neurons that play a dominant role in sleep induction and maintenance? The Russian physiologist Ivan Petrovich Pavlov adopted the former position, proposing that sleep is the result of irradiating inhibition among cortical and subcortical neurons (nerve cells in the outer brain layer and in the brain layers beneath the cortex). Microelectrode studies, on the other hand, have revealed high rates of discharge during sleep from many neurons in the motor and visual areas of the cortex, and thus it seems that, as compared with wakefulness, sleep must consist of a different organization of cortical activity rather than some general, overall decline.

Pavlov's theory

Another issue has been whether there is a waking centre, fluctuations in whose level of functioning are responsible for various degrees of wakefulness and sleep, or whether the induction of sleep requires another centre, actively antagonistic to the waking centre. Early speculation favoured the passive view of sleep. A *cerveau isolé* preparation, an animal in which a surgical incision high in the midbrain has separated the cerebral hemispheres from sensory input, demonstrated chronic somnolence. It has been reasoned that a similar cutting off of sensory input, functional rather than structural, must characterize natural states of sleep. Other supporting observations for the stimulus-deficiency theory of sleep included presleep rituals, such as turning out the lights, regulating stimulus input, and the facilitation of sleep induction by muscular relaxation. With the discovery of the ascending reticular activating system (ARAS, a network of nerves in the brain stem), it was found that it is not the sensory nerves themselves that maintain cortical arousal but rather the ARAS, which projects impulses diffusely to the cortex from the brain stem. Presumably sleep would result from interference with the active functioning of the ARAS. Injuries to the ARAS were, in fact, found to produce sleep. Sleep thus seemed passive, in the sense that it was the absence of something (ARAS support of sensory impulses) characteristic of wakefulness.

Theory has tended to depart from this belief and to move toward conceiving of sleep as an actively produced state. Two kinds of observation primarily have been responsible for the shift. First, earlier studies showing that sleep can be induced directly by electrical stimulation of certain areas in the hypothalamus have been confirmed and extended to other areas in the brain. Second, the discovery of REM sleep has been even more significant in leading theorists to consider the possibility of actively produced sleep. REM sleep, by its very active nature, defies description as a passive state. As is noted below, REM sleep can be eliminated in experimental animals by the surgical destruction of a group of nerve cells in the pons, the active function of which appears to be necessary for REM sleep. Thus, it is difficult to imagine that the various manifestations of REM sleep reflect merely the deactivation of wakefulness mechanisms.

One- and two-system theories

The REM–NREM-sleep dichotomy poses a third issue for the theories of sleep mechanisms, or at least for those that accept the idea of sleep as an active phenomenon. Does one hypnogenic (sleep-causing) system serve both kinds of sleep, or are there two antagonistic sleep systems, one for REM sleep and one for NREM sleep? Opinion is sharply divided. One group of theorists states that there must be two sleep systems. It is noted that NREM sleep is not affected, but that REM sleep is abolished, by injuries to the pontine tegmentum (the posterior part of the pons) and that NREM sleep is suppressed in animals whose brain stem has been severed at the midpoint of the pons, suggesting that an NREM-sleep centre behind this section no longer is capable of suppressing the effect of the ARAS. It is further observed that the neurohumour serotonin is localized in the brain-stem regions presumed to be responsible for NREM sleep; that destruction of serotonin-containing nerve cells in the brain stem may produce insomnia; that, in some species, reductions of serotonin by chemical interference with its production produces an amount of sleep loss correlated with the reduction of serotonin; that administration of a serotonin precursor (a substance from which serotonin is formed) after interference with production of serotonin produces a sleeplike state and that artificially induced increases in brain serotonin increase NREM sleep; that the neurohumour norepinephrine is localized in the brain-stem regions presumed to be responsible for REM sleep; and that substances interfering with the synthesis of norepinephrine suppress REM sleep. Other theorists have proposed that REM and NREM sleep are served by a common hypnogenic system. Chemical stimulation of certain brain structures, assumed to constitute a hypnogenic system, has been found capable of inducing both stages of sleep. It also is argued that different varieties of sleep should require different mechanisms no more than do different varieties of wakefulness (*e.g.,* alertness, relaxation).

Functional theories. Functional theories stress the recuperative and adaptive value of sleep. Sleep arises most unequivocally in animals that maintain a constant body temperature and that can be active at a wide range of environmental temperatures. In such forms, increased metabolic requirements may find partial compensation in periodic decreases in body temperature and metabolic rate (*i.e.,* during NREM sleep). Thus, the parallel evolution of temperature regulation and NREM sleep has suggested to some authorities that NREM sleep may best be viewed as a regulatory mechanism conserving energy expenditure in species whose metabolic requirements are otherwise high. As a solution to the problem of susceptibility to predation that comes with the torpor of sleep, it has been suggested that the periodic reactivation of the organism during sleep better prepares it for fight or flight, and that the possibility of enhanced processing of significant environmental stimuli during REM sleep may even reduce the need for sudden confrontation with danger. Other functional theorists agree that NREM sleep may be a state of "bodily repair," while suggesting that REM sleep is one of "brain repair" or restitution, a period, for example, of increased cerebral protein synthesis or of "reprogramming" the brain so that information achieved in wakeful functioning is most efficiently assimilated. In their specification of functions and provision of evidence for such functions, such theories are necessarily vague and incomplete. The function of stage 2 NREM sleep is still unclear, for example. Such sleep is present in only rudimentary form in subprimate species yet consumes approximately half of human sleep time. Comparative, physiological, and experimental evidence is unavailable to suggest why so much human sleep is spent in this stage. In fact, poor sleepers whose laboratory sleep records show high proportions of stage 2 and little or no REM sleep often report feeling they have not slept at all. (D.F./R.D.C.)

Dreams and dreaming

DIVERSE VIEWS ON THE NATURE OF DREAMS

Dreams as reflecting reality. Philosophers continue to argue about the differences between reality and dreams. The English philosopher Bertrand Russell (1872–1970) wrote, "It is obviously possible that what we call waking life may be only an unusual and persistent nightmare," and he further stated that "I do not believe that I am now dreaming but I cannot prove I am not." Philosophers generally try to resolve the question by saying that so-called waking experience seems vivid and coherent. As the French philosopher René Descartes (1596–1650) put it: ". . . memory can never connect our dreams one with the other or with the whole course of our lives as it unites events which happen to us while we are awake"; or, as Russell stated succinctly, "Certain uniformities are observed in waking life, while dreams seem quite erratic."

Dreams in various cultures

Members of many cultures have variously coped with this dilemma; for example, among the Eskimo of Hudson Bay and the Patani Malay people, it is believed that during sleep one's "soul" leaves the body to live in a special dreamworld. Believers often consider it dangerous to wake someone lest his "soul" be lost. On these grounds the Tajal people of Luzon, for example, severely punish for awakening a sleeping person. In other cultures, dream events are held to be identical with reality; thus, a Macusi Indian of Guyana is reported to have become enraged at the European leader of an expedition when he dreamed that the leader had made him haul a canoe up dangerous cataracts. He awoke exhausted and could not be persuaded that the dream was not real. There is a tradition in Borneo that if a man dreams that his wife is an adulteress, her father must take her back. A Zulu man is said to have broken off a friendship after dreaming that the friend meant him harm. A Paraguayan Indian, reportedly having dreamed that a missionary shot at him, attempted to kill the missionary.

In other instances, dream events may be believed to demand fulfillment. Jesuit priests in the 1700s reported that among Iroquois Indians it was obligatory to carry out dreams as soon as possible; one Indian was said to have dreamed that 10 friends dove into a hole in the ice of a lake and came up through another. When told of the dream, the friends duly enacted their roles in it, but unfortunately, only nine of them succeeded. After dreaming of something valuable, Kurdish people were traditionally expected to take it, by force if necessary. Among some natives of Kamchatka a man need only dream of a girl's favour for her to owe him her sexual favours.

Such interpretations in which the dream is given a status of reality need not imply that the two are indistinguishable. In some instances, the dream may be differentiated from reality, but dreams are accorded a superior status to the banal activities of wakefulness.

Dreams in the Bible

Dreams as a source of divination. There is an ancient belief that dreams predict the future; the Chester Beatty Papyrus is a record of Egyptian dream interpretations dating from the 12th dynasty (1991–1786 BC). In the *Iliad,* Agamemnon is visited in dream by a messenger of the god Zeus to prescribe his future actions. From India, a document called the Atharvaveda, attributed to the 5th century BC, contains a chapter on dream omens. A Babylonian dream guide was discovered in the ruins of the city of Nineveh among tablets from the library of the emperor Ashurbanipal (668–627 BC). The Old Testament is rife with prophetic dreams, those of the pharaohs and of Joseph and Jacob being particularly striking. Among pre-Islāmic peoples dream divination so heavily influenced daily life that the practice was formally forbidden by Muḥammad (*c.* 570?–632), founder of the Muslim religion.

Ancient and religious literatures express the most confidence about so-called message dreams. Characteristically, a god or some other respected figure appears to the dreamer (typically a king, a hero, or a priest) in time of crisis and states a message. Such reports are found on ancient Sumerian and Egyptian monuments; frequent examples appear in the Old and New testaments. Joseph Smith (1805–44), the founder of the Mormon religion, said that an angel had directed him to the location of buried golden tablets that described American Indians as descendants of the tribes of Israel.

Not all dream prophecies are so readily accepted. In the *Odyssey,* for example, dreams are classed as false ("passing through the Gate of Ivory") and as true ("passing the Gate of Horn"). Furthermore, prophetic meaning may be attributed to dream symbolism. In the Bible, Joseph interpreted sheaves of grain and the Moon and stars as symbols of himself and of his brethren. In general, the social status of dream interpreters varies; in cultures for which dreams loom important, their interpretation frequently is an occupation of priests, elders, or medicine men.

Perhaps the most famous dream interpretation book is that of the Greek soothsayer Artemidorus Daldianus (*c.* 2nd century AD), the *Oneirocritica* (from the Greek *oneiros,* "a dream"). Dream books remain widely available today. They continue to enjoy profitable sales everywhere among people who follow them in affairs of the heart, in gambling, and in matters of health and work.

Dreams as curative. So-called prophetic dreams in the Middle Eastern cultures of antiquity often were combined with other means of prophecy, such as animal sacrifice, and with efforts to heal the sick. In classical Greece, dreams became directly associated with healing; ailing people came to dream in oracular temples where priests and priestesses advised about the cures dreams were held to provide. Similar practices, known as dream incubation, are recorded for Babylon and Egypt. In a widespread cult, suffering petitioners came to at least 600 temples of the Greek god of medicine to perform rites or sacrifices in efforts to dream appropriately, sleeping in wait of the appearance of the god or his emissary to deliver a cure. Many stone monuments placed at the entrances of the temples survive to record dream cures.

Dreams as extensions of the waking state. Even in early human history dreams also were interpreted as reflections of waking experiences and of emotional needs. Aristotle (384–322 BC), despite his contemporaries who practiced divination and incubation, in his work *Parva Naturalia* (*On the Senses and Their Objects*) attributed dreams to sensory impressions from "external objects . . . pauses within the body . . . eddies . . . of sensory movement often remaining like they were when they first started, but often too broken into other forms by collision with obstacles." In anticipation of psychoanalyst Sigmund Freud (1856–1939), Aristotle wrote that sensory function is reduced in sleep, favouring the susceptibility of dreams to emotional subjective distortions.

In spite of Aristotle's unusually modern views and even after a devastating attack by the Roman statesman Marcus Tullius Cicero (106–43 BC) on dream divination (*De divinatione;* "On Divination"), views that dreams have supernatural attributes persisted vigorously until the 1850s and the classic work of the French physician Alfred Maury, who studied more than 3,000 reported recollections of dreams. Maury concluded that dreams arose from external stimuli, instantaneously accompanying such impressions as they acted upon the sleeping person. He wrote that part of his bed once fell on the back of his neck and woke him, leaving the memory of dreaming that he had been brought before a French revolutionary tribunal, questioned, condemned, led to the scaffold, and bound by the executioner, and that the guillotine blade had fallen.

Creative dreaming

The English poet Samuel Taylor Coleridge reported that he had written "Kubla Khan" as the result of creative thinking in a dream. Having fallen asleep while reading about that Mongol conqueror, he woke to write down a fully developed poem he seemed to have composed while dreaming. Novelist Robert Louis Stevenson said that much of his writing was developed by "little people" in his dreams, and specifically cited the story of Dr. Jekyll and Mr. Hyde in this context. The German chemist F.A. Kekulé von Stradonitz attributed his interpretation of the ring structure of the benzene molecule to his dream of a snake with its tail in its mouth. Otto Loewi, the German physiologist, attributed to a dream inspiration for an experiment with a frog's nerve that helped him win the Nobel Prize. In all of these cases the dreamers reported having thought about the same topics over considerable periods while they were awake.

Psychoanalytic interpretations. Among Freud's earliest writings was *The Interpretation of Dreams* (1899). His insistence that dreams are "the royal road to the unconscious" continued from it down to his last published statement on dreams, printed about a year before he died. Freud held that dreams reflect waking experience; he offered a theoretical explanation for their bizarre nature, invented a system for their interpretation, and elaborated on their curative potential.

Dreamwork

Freud theorized that thinking during sleep tends to be primitive and regressive and that the effects of forgetting (repression) are reduced. Repressed wishes, particularly those associated with sex and hostility, were said to be released in dreams when the inhibitory demands of wakefulness diminished. The content of the dream was said to derive from such stimuli as urinary pressure in the bladder, traces of experiences from the previous day (day residues), and associated infantile memories. The specific dream details were called their manifest content; the presumably repressed wishes being expressed were called the latent content. Freud suggested that the dreamer kept himself from waking and avoided unpleasant awareness of repressed wishes by disguising them as bizarre manifest content in an effort called dreamwork. He held that impulses one fails to satisfy when awake are expressed in dreams as sensory images and scenes. In dreaming, Freud believed:

> All of the linguistic instruments . . . of subtle thought are dropped . . . and abstract terms are taken back to the concrete . . . . The copious employment of symbols . . . for representing certain objects and processes is in harmony (with) the regression of the mental apparatus and the demands of censorship.

Freud theorized that one aspect of manifest content could come to represent a number of latent elements (and vice versa) through a process called condensation. Further displacement of emotional attitudes toward one object or person theoretically could be displaced in dreaming to another object or person or not appear in the dream at all. Freud further observed a process called secondary elaboration, which occurs when people wake and try to remember dreams. They may recall inaccurately in a process of elaboration and rationalization and provide "the dream, a smooth facade, (or by omission) display rents and cracks." This waking activity he called secondary revision.

In seeking the latent meaning of a dream, Freud advised the individual to associate freely about it. From listening to the associations, the analyst was supposed to determine what the dream represented, in part through an understanding of the personal needs of the dreamer.

Carl Jung (1875–1961) disagreed with Freud's view of dreams as being complementary to waking mental life with respect to specific instinctual impulses. Jung felt that dreams are instead compensatory, that they balance whatever elements of character are underrepresented in the way people are living their lives. Dreaming, to Jung, represents a continuous 24-hour flow of mental activity that surfaces in sleep when conditions are right, but which affects waking life when a person's behaviour denies important elements of his true personality.

Thus, dreams are constructed not to conceal or disguise forbidden wishes but to bring the under-attended areas to attention. This function is carried out unconsciously in sleep when people are living well-balanced lives. If this is not the case there may be first bad moods, then symptoms in waking. Then and only then do dreams need to be interpreted. This is best done not with a single dream and multiple free associations but with a series of dreams so that the repetitive elements become apparent.

EFFORTS TO STUDY DREAMING

Dream reports. Though each person seems to know his own private dreams, the manner in which people dream obviously defies direct observation. It has been said that each dream "is a personal document, a letter to oneself" and must be inferred from the observable behaviour of people. Furthermore, observational methods and purposes clearly affect conclusions to be drawn about the inferred dreams. Reports of dreams collected from people after morning awakenings at home tend to exhibit more content of an overt sexual and emotional nature than do those from laboratory subjects. Such experiences as dreaming in colour seldom are spontaneously mentioned but often emerge under careful questioning. Reports of morning dreams are typically richer and more complex than those collected early at night. Immediate recall differs from what is reported after longer periods of wakefulness; psychoanalysts seem to elicit more recollections of overt sexual dreams than do laboratory investigators. In spite of these complications, there have been substantial efforts to describe the general characteristics of what people say they have dreamed.

Length of dream reports

The reported length of dreams varies widely between and within individuals (and by inference, so does the length of the presumed dreams themselves). Spontaneously reported dreams among laboratory subjects are typically short; about 90 percent of these reports are less than 150 words long, although some may exceed 1,000. With additional probing, about a third of such reports are longer than 300 words.

Some investigators have been surprised by repeated findings that suggest dreams may be less fantastic or bizarre than generally supposed. In the language of modern art, one investigator stated that visual dreams are typically faithful to reality (representational) with little, if any, abstractionist or surrealistic dreaming. Any variations from the representational were characterized as impressionistic. Except for those that are very short, dreams are reported to take place in ordinary physical settings, about half of them seeming quite familiar to the dreamer; only rarely is the setting said to be exotic or peculiar.

Apparently dreams are quite egocentric, the dreamer perceiving himself as a participant, though the presence of others is typically recalled. Seldom does the person remember an empty, unpopulated dreamworld, and individuals seem to dream roughly two-thirds of the time about people they know. Usually they are close acquaintances; family members are mentioned in about 20 percent of dream reports. Recollections of notables or weird representations of people are generally rare.

The typical report is of visual imagery; indeed, in its absence, the person may say only that he had been thinking rather than "dreaming" while asleep. Rare statements about dreams dominated by auditory experience commonly are made with claims of actually having been awake. It is unusual, however, to hear of dreams without some auditory characteristics. One typically is told of bland dreams; when there are emotional overtones, they tend to be unpleasant about two-thirds of the time. Fear and anxiety are most commonly mentioned, followed by anger; pleasant feelings are most often those of friendliness. Reports of overtly erotic dreams, particularly among those gathered in laboratories, are infrequent.

Despite their generally representational nature, dreams seem somehow odd or strange. Perhaps this is related to discontinuities in time and purpose. One suddenly may dream of himself in a familiar auditorium viewing a fencing match rather than hearing a lecture and abruptly in the "next scene" walking beside a swimming pool. Or a person may have the experience of lying in a hallway listening to two people standing by an elevator; he may be looking at a bleeding hand and walk across an empty room to a liquor cabinet to find a roll of adhesive tape. These sudden transitions contribute to the dreamer's feeling of strangeness, and this is enhanced by his waking statements that the bulk of his dreams cannot be clearly recalled, giving them a dim, mysterious quality.

Rapid eye movement

Physiological dream research. A new era of dream research began in 1953 with the discovery that rapid eye movements during sleep seem often to signal that a person is dreaming. In that year it was observed that, about an hour or so after falling asleep, laboratory subjects are apt to experience a burst of rapid eye movement (REM) under their closed lids, accompanied by a change in brain waves detected by an electroencephalograph as an electrical pattern resembling that of an alert waking person (see above *Rapid eye movement sleep*). When subjects were awakened during REM, they reported vivid dreams 20 out of 27 times; when roused during non-REM sleep, they recalled dreams in only four of 23 instances. Subsequent systematic study confirmed this relationship between REM, activated brain waves (EEG), and dream recall. Several thousand experimental studies utilizing these observable indexes of dreaming have since been conducted.

A major finding is that the usual report of a vivid, visual dream is primarily associated with REM and activated EEG. On being aroused while exhibiting these signs, people recall dreams with visual imagery about 80 percent of the time. When awakened in the absence of them, however, people still report some kind of dream activity, though only about 30 to 50 percent of the time; in such cases they are apt to remember their sleep experiences as being relatively "thoughtlike" and realistic and as resembling the experiences of wakefulness.

Dreaming in animals

D-state (desynchronized or dreaming) sleep has been reported for all mammals studied; it has been observed, for example, among monkeys, dogs, cats, rats, elephants, shrews, and opossums; these signs also have been reported in some birds and reptiles.

Surgical destruction of selected brain structures among laboratory animals has clearly demonstrated that the D-state depends on an area within the brain stem known as the pontine tegmentum. Evidence indicates that D-state sleep is associated with a mechanism involving a bodily chemical called norepinephrine; other stages of sleep seem to involve another chemical (serotonin) in the brain. Among other physiological changes found intimately related to D-state sleep are increased variability in breathing and heart rate, relaxation of skeletal muscles (in lower animals), and, in humans, reduction of electrical activity in muscles near the base of the tongue and penile erections or increase in vaginal blood flow and uterine contractions.

When people are chronically deprived of the opportunity to manifest D-state activity (by awakening them whenever there is EEG evidence of dreaming), it appears increasingly difficult to prevent them from dreaming. On recovery nights (after such deprivation) when the subject can sleep without interruption, there is a substantial increase in the number of reports of dreaming. This rebound effect continues in some degree on subsequent recovery nights, depending on how badly the person has been deprived.

Dream recall

During D-states in the last 6½ to 7½ hours of sleep people are likely to wake by themselves about 40 percent of the time. This figure is about the same as that for dream recall, people saying they had a dream the previous night about 35 percent of the time (roughly once every three or four nights). Evidence concerning the amount and kind of dreaming also depends on how rapidly one is roused and on the intensity of his effort to recall. Some people recall dreams more often than the average, while others rarely report them. While these two groups of people show little difference in amount of D-state sleep, evidence suggests that non-recall reflects a general tendency on the part of the individual to repress or to deny his experiences.

The psychoanalytic literature is rich with reports indicating that what one dreams about reflects his needs and his immediate and remote past experience. Nevertheless, when someone in D-state sleep is stimulated (*e.g.*, by spoken word or by drops of water on his skin), the chances that he will say he has dreamed about the stimulus, or anything similar, are quite low. Studies in which people have watched vivid movies before falling asleep also indicate some possibilities of influencing dreams but again clearly emphasize the limitations of such influences. Highly suggestible people seem likely to dream as they are told to do while under hypnosis, but the influence of direct suggestion during ordinary wakefulness seems quite limited.

Variations within the usual range of about 18 to 30 percent of D-state sleep apparently are unrelated to differences in the amount or content of dreaming. The amount of D-state further seems generally independent of wide variations in the daily activities or personality characteristics of different people; groups of scientists, athletes, housewives, and artists, for example, cannot be reliably distinguished from one another in terms of D-state activity. Such disorders as schizophrenia and mental retardation appear to have no clearly discernible effect on the amount of time sufferers spend in REM-activated EEG sleep.

DREAMLIKE ACTIVITIES

Related states of awareness may be distinguished from the dream experiences typically reported; these include dreamlike states experienced as a person falls asleep and as he awakens, respectively called hypnagogic and hypnopompic reveries. During sleep itself there are nightmares, observable signs of sexual activity (*e.g.*, nocturnal emissions of sperm), and sleepwalking. Even people who ostensibly are awake may show evidence of such related phenomena as hallucinating, trance behaviour, and reactions to drugs.

Rapid eye movement is not characteristic of sleep onset; nevertheless, as people drift (as inferred from EEG activity) from wakefulness through drowsiness into sleep, they report dreamlike hypnagogic experiences about 90 percent of the time on being awakened. Most of these experiences (about 80 percent) are said to be visual. If dreaming is defined as at least partly hallucinatory and somewhat dramatic, then awakening from drowsiness or at the onset of sleep yields recall of experiences that may be classified as dreams for about 75 percent of the occasions. These "dreamlets" seem to differ from dream-associated REM sleep in being less emotional (neither pleasant nor unpleasant), more transient, and less elaborate. Such hypnagogic experiences apparently tend to incorporate abstract thinking and recall of recent events (day residues) and to be quite typical of falling asleep. Systematic studies remain to be made of the hypnopompic reveries commonly reported mornings before full arousal, but it seems likely that they include recollections of the night's dreams, or represent one's drifting back into transient REM sleep.

Extreme behavioral manifestations during sleep—night terrors, nightmares, sleepwalking, enuresis—all have been found generally unrelated to ordinary dreaming. Night terrors are characterized by abrupt awakening, sometimes with a scream; a sleeping child may sit up in bed, apparently terror-stricken, with wide-open eyes, and often with frozen posturing that may last several minutes. Afterward there typically is no recollection of dreamlike experience. Observed in about 2 or 3 percent of children, roughly half of the attacks of night terror occur between the ages of four and seven; about 10 percent of them are seen among youngsters as old as 12 to 14 years. Nightmares typically seem to be followed by awakening with feelings of suffocation and helplessness and expressions of fearful or threatening thoughts. Evidence of nightmares is observed for 5 to 10 percent of children, primarily about eight to 10 years of age. Studies have suggested that signs of spontaneously generated night terrors and nightmares may be related to abrupt awakening from deep sleep that experimentally appears dreamless. This suggests that the vividly reported fears well may be produced by emotional disturbances that first occur on awakening.

Nightmares

Sleepwalking, observed in about 1 percent of children, predominantly appears between ages 11 and 14. Apparently sleeping individuals rise and walk from their beds, eyes open, usually avoiding obstacles, and expressing no recollection of the episode when they wake. Studies of EEG data indicate that sleepwalking occurs only in deep sleep when dreams seem essentially absent; the behaviour remains to be reported for REM sleep. Enuresis occurs in about one-fourth of children over age four. These episodes seem not to be associated with REM as much as they do with deep sleep in the absence of D-state signs.

Nocturnal emission of sperm remains to be described in terms of any distinguishing EEG pattern; such events are quite rarely observed among sleeping laboratory subjects. Among a large sample of males who were interviewed about their sexual behaviour about 85 percent reported having experienced emissions at some time in their lives, typical frequency during the teens and 20s being about once a month. Of the females interviewed 37 percent reported erotic dreams, sometimes with orgasm, averaging about three to four times a year. Most often, however, openly sexual dreams are said not to be accompanied by orgasm in either sex. Males not infrequently could recall no dreams associated with emission, although most implicated erotic dreaming.

Dreamlike experiences induced as trances, deliriums, or hallucinatory behaviour by drugs seem attributable to lowered efficiency of the central nervous system in processing sensory stimuli from the external environment. The result seems to be that one's physiological activities begin to escape environmental constraint to the point that internalized, uncritical thinking and perceiving prevail.

Since antiquity, dreams have been viewed as a source of divination, as a form of reality, as a curative force, and as an extension or adjunct of the waking state. Psychoanalytic theorists stress the individual meaningfulness of dreams and their relation to personal hopes and fears. Contemporary research focuses on efforts to discover and describe unique, complex biochemical and neurophysiological bases of dreaming. Among the plethora of theories ranging from those that assert dreaming to be awareness of a god's voice to those that reduce the dream to physical activity in the nervous system, no single, encompassing theory seems to be available. (W.B.W./R.D.C.)

Adam Smith

After two centuries, Adam Smith remains a towering figure in the history of economic thought. Known primarily for a single work, *An Inquiry into the nature and causes of the Wealth of Nations* (1776), the first comprehensive system of political economy, Smith is more properly regarded as a social philosopher whose economic writings constitute only the capstone to an overarching view of political and social evolution. If his masterwork is viewed in relation to his earlier lectures on moral philosophy and government, as well as to allusions in *The Theory of Moral Sentiments* (1759) to a work he hoped to write on "the general principles of law and government, and of the different revolutions they have undergone in the different ages and periods of society," then *The Wealth of Nations* may be seen not merely as a treatise on economics but as a partial exposition of a much larger scheme of historical evolution.

Early life. Unfortunately, much more is known about Smith's thought than about his life. Though the exact date of his birth is unknown, he was baptized on June 5, 1723, in Kirkcaldy, a small (population 1,500) but thriving fishing village near Edinburgh, the son by second marriage of Adam Smith, comptroller of customs at Kirkcaldy, and Margaret Douglas, daughter of a substantial landowner. Of Smith's childhood nothing is known other than that he received his elementary schooling in Kirkcaldy and that at the age of four years he was said to have been carried off by gypsies. Pursuit was mounted, and young Adam was abandoned by his captors. "He would have made, I fear, a poor gypsy," commented his principal biographer.

At the age of 14, in 1737, Smith entered the university of Glasgow, already remarkable as a centre of what was to become known as the Scottish Enlightenment. There, he was deeply influenced by Francis Hutcheson, a famous professor of moral philosophy from whose economic and philosophical views he was later to diverge but whose magnetic character seems to have been a main shaping force in Smith's development. Graduating in 1740, Smith won a scholarship (the Snell Exhibition) and traveled on horseback to Oxford, where he stayed at Balliol College.

Influence of Hutcheson

Smith, paste medallion by James Tassie, 1787. In the Scottish National Portrait Gallery, Edinburgh.

Compared to the stimulating atmosphere of Glasgow, Oxford was an educational desert. His years there were spent largely in self-education, from which Smith obtained a firm grasp of both classical and contemporary philosophy.

Returning to his home after an absence of six years, Smith cast about for suitable employment. The connections of his mother's family, together with the support of the jurist and philosopher Lord Henry Kames, resulted in an opportunity to give a series of public lectures in Edinburgh—a form of education then much in vogue in the prevailing spirit of "improvement."

The lectures, which ranged over a wide variety of subjects from rhetoric to history and economics, made a deep impression on some of Smith's notable contemporaries. They also had a marked influence on Smith's own career, for in 1751, at the age of 27, he was appointed professor of logic at Glasgow, from which post he transferred in 1752 to the more remunerative professorship of moral philosophy, a subject that embraced the related fields of natural theology, ethics, jurisprudence, and political economy.

Glasgow. Smith then entered upon a period of extraordinary creativity, combined with a social and intellectual life that he afterward described as "by far the happiest, and most honourable period of my life." During the week he lectured daily from 7:30 to 8:30 AM and again thrice weekly from 11 AM to noon, to classes of up to 90 students, aged 14 to 16. (Although his lectures were presented in English, following the precedent of Hutcheson, rather than in Latin, the level of sophistication for so young an audience today strikes one as extraordinarily demanding.) Afternoons were occupied with university affairs in which Smith played an active role, being elected dean of faculty in 1758; his evenings were spent in the stimulating company of Glasgow society.

His friends and acquaintances

Among his wide circle of acquaintances were not only members of the aristocracy, many connected with the government, but also a range of intellectual and scientific figures that included Joseph Black, a pioneer in the field of chemistry, James Watt, later of steam-engine fame, Robert Foulis, a distinguished printer and publisher and subsequent founder of the first British Academy of Design, and, not least, the philosopher David Hume, a lifelong friend whom Smith had met in Edinburgh. Smith was also introduced during these years to the company of the great merchants who were carrying on the colonial trade that had opened to Scotland following its union with England in 1707. One of them, Andrew Cochrane, had been a provost of Glasgow and had founded the famous Political Economy Club. From Cochrane and his fellow merchants Smith undoubtedly acquired the detailed information concerning trade and business that was to give such a sense of the real world to *The Wealth of Nations.*

The Theory of Moral Sentiments. In 1759 Smith published his first work, *The Theory of Moral Sentiments.* Didactic, exhortative, and analytic by turns, the *Theory* lays the psychological foundation on which *The Wealth of Nations* was later to be built. In it Smith described the principles of "human nature," which, together with Hume and the other leading philosophers of his time, he took as a universal and unchanging datum from which social institutions, as well as social behaviour, could be deduced.

One question in particular interested Smith in *The Theory of Moral Sentiments.* This was a problem that had attracted Smith's teacher Hutcheson and a number of Scottish philosophers before him. The question was the source of the ability to form moral judgments, including judgments on one's own behaviour, in the face of the seemingly overriding passions for self-preservation and self-interest. Smith's answer, at considerable length, is the presence within each of us of an "inner man" who plays the role of the "impartial spectator," approving or condemning our own and others' actions with a voice impossible to disregard. (The theory may sound less naive if the question is reformulated to ask how instinctual drives are socialized through the superego.)

Smith's view of human nature

The thesis of the impartial spectator, however, conceals a more important aspect of the book. Smith saw humans as creatures driven by passions and at the same time self-regulated by their ability to reason and—no less important—by their capacity for sympathy. This duality serves both to pit individuals against one another and to provide them with the rational and moral faculties to create institutions by which the internecine struggle can be mitigated and even turned to the common good. He wrote in his *Moral Sentiments* the famous observation that he was to repeat later in *The Wealth of Nations:* that self-seeking men are often "led by an invisible hand . . . without knowing it, without intending it, [to] advance the interest of the society."

It should be noted that scholars have long debated whether *Moral Sentiments* complemented or was in conflict with *The Wealth of Nations,* which followed it. At one level there is a seeming clash between the theme of social morality contained in the first and the largely amoral explication of the economic system in the second. On the other hand, the first book can also be seen as an explanation of the manner in which individuals are socialized to become the market-oriented and class-bound actors that set the economic system into motion.

Travels on the Continent. The *Theory* quickly brought Smith wide esteem and in particular attracted the attention of Charles Townshend, himself something of an amateur economist, a considerable wit, and somewhat less of a statesman, whose fate it was to be the chancellor of the exchequer responsible for the measures of taxation that ultimately provoked the American Revolution. Townshend had recently married and was searching for a tutor for his stepson and ward, the young Duke of Buccleuch. Influenced by the strong recommendations of Hume and his own admiration for *The Theory of Moral Sentiments,* he approached Smith to take the charge.

The terms of employment were lucrative (an annual salary of £300 plus traveling expenses and a pension of £300 a year thereafter), considerably more than Smith had earned as a professor. Accordingly, Smith resigned his Glasgow post in 1763 and set off for France the next year as the tutor of the young duke. They stayed mainly in Toulouse, where Smith began working on a book (eventually to be *The Wealth of Nations*) as an antidote to the excruciating boredom of the provinces. After 18 months of ennui he was rewarded with a two-month sojourn in Geneva, where he met Voltaire, for whom he had the profoundest respect, thence to Paris, where Hume, then secretary to the British embassy, introduced Smith to the great literary salons of the French Enlightenment. There he met a group of social reformers and theorists headed by François Quesnay, who called themselves *les économistes* but are known in history as the physiocrats. There is some controversy as to the precise degree of influence the physiocrats exerted on Smith, but it is known that he thought sufficiently well of Quesnay to have considered dedicating *The Wealth of Nations* to him, had not the French economist died before publication.

The stay in Paris was cut short by a shocking event. The younger brother of the Duke of Buccleuch, who had joined them in Toulouse, took ill and perished despite Smith's frantic ministrations. Smith and his charge immediately returned to London. Smith worked in London until the spring of 1767 with Lord Townshend, a period during which he was elected a fellow of the Royal Society and broadened still further his intellectual circle to include Edmund Burke, Samuel Johnson, Edward Gibbon, and perhaps Benjamin Franklin. Late that year he returned to Kirkcaldy, where the next six years were spent dictating and reworking *The Wealth of Nations,* followed by another stay of three years in London, where the work was finally completed and published in 1776.

The Wealth of Nations. Despite its renown as the first great work in political economy, *The Wealth of Nations* is in fact a continuation of the philosophical theme begun in *The Theory of Moral Sentiments.* The ultimate problem to which Smith addresses himself is how the inner struggle between the passions and the "impartial spectator"—explicated in *Moral Sentiments* in terms of the single individual—works its effects in the larger arena of history itself, both in the long-run evolution of society and in terms of the immediate characteristics of the stage of history typical of Smith's own day.

Stages of social organization

The answer to this problem enters in Book V, in which Smith outlines the four main stages of organization through which society is impelled, unless blocked by deficiencies of resources, wars, or bad policies of government: the original "rude" state of hunters, a second stage of nomadic agriculture, a third stage of feudal or manorial "farming," and a fourth and final stage of commercial interdependence.

It should be noted that each of these stages is accompanied by institutions suited to its needs. For example, in the age of the huntsman, "there is scarce any property . . . ; so there is seldom any established magistrate or any regular administration of justice." With the advent of flocks there emerges a more complex form of social organization, comprising not only "formidable" armies but the central institution of private property with its indispensable buttress of law and order as well. It is the very essence of Smith's thought that he recognized this institution, whose social usefulness he never doubted, as an instrument for the protection of privilege, rather than one to be justified in terms of natural law: "Civil government," he wrote, "so far as it is instituted for the security of property, is in reality instituted for the defence of the rich against the poor, or of those who have some property against those who have none at all." Finally, Smith describes the evolution through feudalism into a stage of society requiring new institutions, such as market-determined rather than guild-determined wages and free rather than government-constrained enterprise. This later became known as laissez-faire capitalism; Smith called it the system of perfect liberty.

There is an obvious resemblance between this succession of changes in the material basis of production, each bringing its requisite alterations in the superstructure of laws and civil institutions, and the Marxian conception of history. Though the resemblance is indeed remarkable, there is also a crucial difference: in the Marxian scheme the engine of evolution is ultimately the struggle between contending classes, whereas in Smith's philosophical history the primal moving agency is "human nature" driven by the desire for self-betterment and guided (or misguided) by the faculties of reason.

Society and the "invisible hand." The theory of historical evolution, although it is perhaps the binding conception of *The Wealth of Nations,* is subordinated within the work itself to a detailed description of how the "invisible hand" actually operates within the commercial, or final, stage of society. This becomes the focus of Books I and II, in which Smith undertakes to elucidate two questions. The first is how a system of perfect liberty, operating under the drives and constraints of human nature and intelligently designed institutions, will give rise to an orderly society. The question, which had already been considerably elucidated by earlier writers, required both an explanation of the underlying orderliness in the pricing of individual commodities and an explanation of the "laws" that regulated the division of the entire "wealth" of the nation (which Smith saw as its annual production of goods and services) among the three great claimant classes—labourers, landlords, and manufacturers.

This orderliness, as would be expected, was produced by the interaction of the two aspects of human nature, its response to its passions and its susceptibility to reason and sympathy. But whereas *The Theory of Moral Sentiments* had relied mainly on the presence of the "inner man" to provide the necessary restraints to private action, in *The Wealth of Nations* one finds an institutional mechanism that acts to reconcile the disruptive possibilities inherent in a blind obedience to the passions alone. This protective mechanism is competition, an arrangement by which the passionate desire for bettering one's condition—"a desire that comes with us from the womb, and never leaves us until we go into the grave"—is turned into a socially beneficial agency by pitting one person's drive for self-betterment against another's.

The role of competition

It is in the unintended outcome of this competitive struggle for self-betterment that the invisible hand regulating the economy shows itself, for Smith explains how mutual vying forces the prices of commodities down to their "natural" levels, which correspond to their costs of production. Moreover, by inducing labour and capital to move from less to more profitable occupations or areas, the competitive mechanism constantly restores prices to these "natural" levels despite short-run aberrations. Finally, by explaining that wages and rents and profits (the constituent parts of the costs of production) are themselves subject to this same discipline of self-interest and competition, Smith not only provided an ultimate rationale for these "natural" prices but also revealed an underlying orderliness in the distribution of income itself among workers, whose recompense was their wages; landlords, whose income was their rents; and manufacturers, whose reward was their profits.

Economic growth. Smith's analysis of the market as a self-correcting mechanism was impressive. But his purpose was more ambitious than to demonstrate the self-adjusting properties of the system. Rather, it was to show that, under the impetus of the acquisitive drive, the annual flow of national wealth could be seen steadily to grow.

Division of labour

Smith's explanation of economic growth, although not neatly assembled in one part of *The Wealth of Nations,* is quite clear. The core of it lies in his emphasis on the division of labour (itself an outgrowth of the "natural" propensity to trade) as the source of society's capacity to increase its productivity. *The Wealth of Nations* opens with a famous passage describing a pin factory in which 10 persons, by specializing in various tasks, turn out 48,000 pins a day, compared with the few, perhaps only 1, that each could have produced alone. But this all-important division of labour does not take place unaided. It can occur only after the prior accumulation of capital (or stock, as Smith calls it), which is used to pay the additional workers and to buy tools and machines.

The drive for accumulation, however, brings problems. The manufacturer who accumulates stock needs more labourers (since labour-saving technology has no place in Smith's scheme), and in attempting to hire them he bids up their wages above their "natural" price. Consequently his profits begin to fall, and the process of accumulation is in danger of ceasing. But now there enters an ingenious mechanism for continuing the advance. In bidding up the price of labour, the manufacturer inadvertently sets into motion a process that increases the supply of labour, for "the demand for men, like that for any other commodity, necessarily regulates the production of men." Specifically, Smith had in mind the effect of higher wages in lessening child mortality. Under the influence of a larger labour supply, the wage rise is moderated and profits are maintained; the new supply of labourers offers a continuing opportunity for the manufacturer to introduce a further division of labour and thereby add to the system's growth.

Here then was a "machine" for growth—a machine that operated with all the reliability of the Newtonian system with which Smith was quite familiar. Unlike the Newtonian system, however, Smith's growth machine did not depend for its operation on the laws of nature alone. Human nature drove it, and human nature was a complex rather than a simple force. Thus, the wealth of nations would grow only if individuals, through their governments, did not inhibit this growth by catering to the pleas for special privilege that would prevent the competitive system from exerting its benign effect. Consequently, much of *The Wealth of Nations,* especially Book IV, is a polemic against the restrictive measures of the "mercantile system" that favoured monopolies at home and abroad. Smith's system of "natural liberty," he is careful to point out, accords with the best interests of all but will not be put into practice if government is entrusted to, or heeds, "the mean rapacity, the monopolizing spirit of merchants and manufacturers, who neither are, nor ought to be, the rulers of mankind."

The attack on mercantilism

The Wealth of Nations is therefore far from the ideological tract it is often supposed to be. Although Smith preached laissez-faire (with important exceptions), his argument was directed as much against monopoly as government; and although he extolled the social results of the acquisitive process, he almost invariably treated the manners and maneuvers of businessmen with contempt. Nor did he see the commercial system itself as wholly admirable. He wrote with discernment about the intellectual degradation of the worker in a society in which the division of labour has proceeded very far; for by comparison with the alert intelligence of the husbandman, the specialized worker "generally becomes as stupid and ignorant as it is possible for a human being to become."

In all of this, it is notable that Smith was writing in an age of preindustrial capitalism. He seems to have had no real presentiment of the gathering Industrial Revolution, harbingers of which were visible in the great ironworks only a few miles from Edinburgh. He had nothing to say about large-scale industrial enterprise, and the few remarks in *The Wealth of Nations* concerning the future of joint-stock companies (corporations) are disparaging. Finally, one should bear in mind that, if growth is the great theme of *The Wealth of Nations,* it is not unending growth. Here and there in the treatise are glimpses of a secularly declining rate of profit; and Smith mentions as well the prospect that when the system eventually accumulates its "full complement of riches"—all the pin factories, so to speak, whose output could be absorbed—economic decline would begin, ending in an impoverished stagnation.

Later life

The Wealth of Nations was received with admiration by Smith's wide circle of friends and admirers, although it was by no means an immediate popular success. The work finished, Smith went into semiretirement. The year following its publication he was appointed commissioner both of customs and of salt duties for Scotland, posts that brought him £600 a year. He thereupon informed his former charge that he no longer required his pension, to which Buccleuch replied that his sense of honour would never allow him to stop paying it. Smith was therefore quite well off in the final years of his life, which were spent mainly in Edinburgh with occasional trips to London or Glasgow (which appointed him a rector of the university). The years passed quietly, with several revisions of both major books but with no further publications. On July 17, 1790, at the age of 67, full of honours and recognition, Smith died; he was buried in the churchyard at Canongate with a simple monument stating that Adam Smith, author of *The Wealth of Nations,* was buried there.

Beyond the few facts of his life, which can be embroidered only in detail, exasperatingly little is known about the man. Smith never married, and almost nothing is known of his personal side. Moreover, it was the custom of his time to destroy rather than to preserve the private files of illustrious men, with the unhappy result that much of Smith's unfinished work, as well as his personal papers, was destroyed (some as late as 1942). Only one portrait of Smith survives, a profile medallion by Tassie; it gives a glimpse of the older man with his somewhat heavy-lidded eyes, aquiline nose, and a hint of a protrusive lower lip. "I am a beau in nothing but my books," Smith once told a friend to whom he was showing his library of some 3,000 volumes.

Personal qualities

From various accounts, he was also a man of many peculiarities, which included a stumbling manner of speech (until he had warmed to his subject), a gait described as "vermicular," and above all an extraordinary and even comic absence of mind. On the other hand, contemporaries wrote of a smile of "inexpressible benignity," and of his political tact and dispatch in managing the sometimes acerbic business of the Glasgow faculty.

Certainly he enjoyed a high measure of contemporary fame; even in his early days at Glasgow his reputation attracted students from nations as distant as Russia, and his later years were crowned not only with expressions of admiration from many European thinkers but by a growing recognition among British governing circles that his work provided a rationale of inestimable importance for practical economic policy.

Over the years, Smith's lustre as a social philosopher has escaped much of the weathering that has affected the reputations of other first-rate political economists. Although he was writing for his generation, the breadth of his knowledge, the cutting edge of his generalizations, the boldness of his vision, have never ceased to attract the admiration of all social scientists, and in particular economists. Couched in the spacious, cadenced prose of his period, rich in imagery and crowded with life, *The Wealth of Nations* projects a sanguine but never sentimental image of society. Never so finely analytic as David Ricardo nor so stern and profound as Karl Marx, Smith is the very epitome of the Enlightenment: hopeful but realistic, speculative but practical, always respectful of the classical past but ultimately dedicated to the great discovery of his age—progress.

BIBLIOGRAPHY. The complete works have appeared in a definitive edition, "The Glasgow Edition of the Works and Correspondence of Adam Smith," 6 vol. in 7 (1976–83), including vol. 1, *The Theory of Moral Sentiments,* ed. by D.D. RAPHAEL and A.L. MACFIE (1976), vol. 2, *An Inquiry into the Nature and Causes of the Wealth of Nations,* 2 vol., ed. by R.H. CAMPBELL and A.S. SKINNER, vol. 3, *Essays on Philosophical Subjects,* ed. by W.P.D. WIGHTMAN and J.C. BRYCE (1980), which contains the interesting "The History of Astronomy," vol. 4, *Lectures on Rhetoric and Belles Lettres,* ed. by J.C. BRYCE (1983), and vol. 5, *Lectures on Jurisprudence,* ed. by R.L. MEEK, D.D. RAPHAEL, and P.G. STEIN (1978). For the nonspecialist, ROBERT L. HEILBRONER (ed.), *The Essential Adam Smith* (1986), offers fairly extensive readings and short discussions of Smith's main works.

Among biographical works are JOHN RAE, *Life of Adam Smith* (1895, reprinted 1965); WILLIAM R. SCOTT, *Adam Smith as Student and Professor* (1937, reprinted 1965), including "An Early Draft of Part of *The Wealth of Nations,*" various documents, and correspondence; and DUGALD STEWART, *Biographical Memoirs of Adam Smith. . . ,* vol. 10 in *The Collected Works of Dugald Stewart* (1858, reprinted 1966).

DONALD WINCH, *Adam Smith's Politics: An Essay in Historiographic Revision* (1978), reinterprets Smith's place in the history of economic and political thought. ANDREW S. SKINNER and THOMAS WILSON, *Essays on Adam Smith* (1975), contains discussion by well-known scholars of various aspects of Smith's work. KNUD HAAKONSSEN, *The Science of a Legislator: The Natural Jurisprudence of David Hume and Adam Smith* (1981), compares their philosophical systems. Useful articles include ADOLPH LOWE, "The Classical Theory of Economic Growth," *Social Research,* 21(2):127–158 (Summer 1954); NATHAN ROSENBERG, "Adam Smith on the Division of Labour: Two Views or One?" *Economica,* 32(126):127–139 (May 1965), and "Some Institutional Aspects of the *Wealth of Nations,*" *The Journal of Political Economy,* 68(6):557–570 (December 1960); JOSEPH J. SPENGLER, "Adam Smith's Theory of Economic Growth," *Southern Economic Journal,* 25(4):397–415, 26(1):1–12 (April and July 1959); the entry by JACOB VINER, "Adam Smith," in DAVID L. SILLS (ed.), *International Encyclopaedia of the Social Sciences,* vol. 14, pp. 322–329 (1968); and the entry by ANDREW S. SKINNER, "Adam Smith," in *The New Palgrave: A Dictionary of Economics,* ed. by JOHN EATWELL MURRAY MILGATE and PETER NEWMAN, vol. 4 (1987), pp. 357–375, with a bibliography.

Social Differentiation

Social differentiation refers to the recognition and establishment in society of differences between groups or categories of individuals. It is evident that not all differences between individuals give rise to social differentiation. On the one hand there are personal qualities or combinations of qualities that distinguish a particular individual from all others; and on the other hand there are some characteristics that may be possessed in similar degree or kind by a number of individuals—for example, height or weight, colour of hair or eyes, temperament—but which never, or very rarely, lead to social differentiation. Many differences between individuals, however, are invested with social significance (or may be said to be created by society), with the result that the individual is seen as belonging to specific groups and categories that define his position in society. Thus he can be described as male or female, middle class or working class, young or old, married or unmarried, or belonging to a particular ethnic, linguistic, or religious group; and these classifications will refer to typical or expected kinds of behaviour, styles of life, and opportunities.

Another way of describing the same phenomena is to say that each individual occupies or performs "social roles." A society is thus regarded as a system of differentiated roles, and the position of an individual in the society is, in some sense, a product of his various roles.

Whether social differentiation is conceived in terms of roles or in terms of the groups and categories to which an individual belongs or is assigned, it has diverse aspects that must be clearly distinguished. In the first place, differentiation is closely associated with stratification; many social differences are invidiously ranked, so that some categories or groups of individuals have higher status or belong to higher classes than others. Second, the social importance of the various recognized differences may be unequal, and it is generally the case that those differences accompanying social stratification have the greatest prominence. In society as a whole, the distinction between married and unmarried, or between young and old, is usually less significant than the distinction between an aristocrat and a commoner or between an executive of a large corporation and a manual worker. Third, the various positions that an individual occupies may be nonaggregative, incongruous, or conflicting. It does not seem possible, for example, to aggregate the roles of father and corporation executive into an intelligible whole; and from this it follows that differentiation needs to be observed in several distinct spheres of social life and that a distinction has to be made between those roles that fit together in a significant whole and those that do not. Incongruous or conflicting roles appear particularly in connection with stratification; thus, an individual may be highly educated but poor and socially despised, or on the other hand he may be wealthy or powerful but uneducated and lacking the cultural attributes of established members of an upper class. Fourth, it should be noted that social differentiation varies in character from one type of society to another, and even from one society to another within the same type, and that it changes over time. Indeed, one of the principal features to which sociologists have drawn attention is the growth of social differentiation (especially in the form of a more extensive division of labour) in the course of social development.

This article is divided into the following sections:

The criteria of social differentiation

A great many factors enter into the process of differentiation. Initially, a broad distinction may be made between two kinds of factors: those that depend upon biological differences among human beings and those that arise wholly or largely from social or cultural conditions.

BIOLOGICAL FACTORS

Sex differentiation. One of the most obvious differences among human beings is that between the sexes. In all societies men and women are treated differently (often unequally) and have different functions, or roles. Many social scientists from the 19th century onward (among them Karl Marx and Herbert Spencer) have suggested that the economic division of labour began with the division of tasks between the sexes; and this, it is generally held, would arise from biological differences—in particular, men's greater physical strength, which equipped them for the activities of hunting and warfare, and women's reproductive function, which tended to confine them to the area of the home or settlement. Many other social

Social differences between men and women and cultural differences between men and women in early societies, and notably the male dominance in political life, may have followed from this original division of labour; and these differences were perpetuated and developed in later societies. Thus, in spite of considerable variations in the social position of women from one society to another, there has been a general male predominance which has continued up to the present time. In the new industrial societies of the 19th century, women still lacked many of the civil rights (especially property rights) and political rights enjoyed by men, and although they have now gained these rights in most modern societies, considerable differences remain: women workers are concentrated in the less skilled and lower paid occupations; disproportionately few women are in the higher professions; and women usually play little part in politics at the national level. Nevertheless, there have been gradual changes in all these spheres during the present century, and at the same time movements for women's rights—from the woman suffragists to the Women's Liberation Movement—have been a significant element in the more general movements of radicalism and reform.

The social differentiation of the sexes poses an important problem that is relevant to all discussion of the biological factors in social life. Some writers have argued that the physical differences between men and women determine the major psychological differences—of intellect and temperament—that largely account for the differentiation of social roles. Against this view it has been argued that biological elements acquire importance only when they are socially recognized and established; that there are in fact great variations, between societies and between historical periods, in the relative positions of men and women; and that in modern times the differences between the social roles of men and women have tended to diminish. Moreover, the existence of substantial, innate psychological differences between men and women is not securely established, and such differences as do appear can be explained as a consequence of social and cultural influences rather than biological inheritance. In this case, as in many others, the question of the relative importance of nature and nurture is still unsettled. At least, however, it can be said that the differences between men and women need not necessarily lead to economic and social inequality; and it may be claimed further that there is no longer any reason in advanced industrial societies for these differences to produce any large degree of differentiation at all outside the sexual sphere.

Age differentiation. Another biological factor that leads to differentiation is age. In all societies a distinction is made between the young, the mature, and the old; and different roles are assigned to them. A more elaborate classification exists in many societies—for example, according to Hindu doctrine, four stages are to be distinguished in the individual's life (a period of preparation, a period as a householder, a period as a recluse, and a final period of renunciation of the world). In many modern societies it is common to distinguish the periods of childhood, youth (including the transitional stage of adolescence), middle age, and old age. The extent to which these stages are clearly defined or formally recognized, however, varies considerably from one type of society to another, as do the social attitudes toward the members of each category. In some tribal societies there are organized age sets that mark the progress of the individual toward full adult membership of the tribe. On the other hand, in modern industrial societies the points of transition from one age category to another tend to be less well defined, to change over time, and to vary from one sphere of social life to another. Childhood may be regarded as lasting until puberty (or, in social terms, adolescence), and it has corresponded also, to some extent, with the period of formal school education; however, the continuing extension of the period of education has meant that childhood now merges into youth while a condition of financial and social dependency continues, without the sharp break that occurred in earlier societies when the individual moved at an earlier age from school or family to adult work. At the same time, there has developed in modern societies in recent decades a more distinctive "teenage" culture within a broader youth culture. In the legal and political spheres there has been a tendency to recognize earlier maturation by reducing the age of majority and of acquisition of political rights (in Great Britain in 1970, for example, from 21 to 18 years), but there is still not a complete correspondence between the ages at which, in different spheres, individuals assume adult roles.

Inequalities among age groups

The evaluation of different age groups varies widely from one kind of society to another. In many tribal societies and traditional societies, the elders have considerable prestige and power as the possessors of a store of valuable knowledge and experience. In modern industrial societies, on the other hand, they may be regarded as old-fashioned and out-of-date, because of the rapid growth and transformation of knowledge.

Differentiation by age is accompanied by inequalities. In most societies economic resources and political power are in the hands of the middle-aged or old, though there are considerable variations and in periods of social upheaval the young may increase their influence or power. The inequalities arising from age differences, like those arising from the differences between the sexes, are in any case less prominent in most societies than those that emerge from property ownership and other directly social elements in stratification.

Racial differentiation. Race differences have been another important source of social differentiation. In the first place, it may be claimed that the various races of mankind have created widely different civilizations. But this assertion raises difficulties of the kind already encountered in discussing the differences between men and women, namely, that it is not possible to establish a strict relation between the physical characteristics and the psychological and cultural features. In this particular case it seems clear that the diverse forms of nations and civilizations are mainly the product of geographical, social, and historical influences, although the actual creation of nations may have owed something to a sense of racial distinctiveness, among many other factors.

Effects of modern colonialism and imperialism upon race relations

Perhaps the most important observation to be made about differences of race is that they may be either emphasized or treated as unimportant in different times and places, according to the prevailing cultural and political circumstances. Race relations in modern times have undoubtedly been most strongly affected by the colonial situation that followed the overseas expansion of the western European countries. Ideas of racial superiority and inferiority accompanied colonization, and these ideas have persisted up to the present time, sustained by the great discrepancies in wealth and power between the nations of western Europe and North America and the countries of the Third World. Not only were race differences and inequalities emphasized on a world scale during the period of modern imperialism, but they also became prominent within particular societies in which, for one reason or another, different racial groups lived together. Thus, in the Republic of South Africa, a white minority which possesses economic and political power maintains, through the institutions of apartheid, a strict separation between white, black, and coloured members of society in order to perpetuate its own supremacy. In the United States, a black minority originating in the African slave trade of the early period of colonialism has enjoyed formal political rights for a century, but it still occupies in practice a situation of economic, cultural, and political inferiority that is increasingly a source of major political conflict. More recently, in Great Britain, the growth of an immigrant population drawn mainly from the West Indies, India, and Pakistan has resulted in more widespread manifestations of racism and, on the other side, attempts by legislation and by other means to prevent racial discrimination.

The principal aspect of race differences in modern times, therefore, is that such differences have taken the form not merely of differentiation but of gross inequality. It is possible to conceive of a state of affairs in which the differences between races, and the cultural differences that have become associated with them, would be generally regarded as creating a pleasurable diversity of human life;

but this is far from being the case at the present time. The colonial conquests established inequality as a principal element in the relations between races, and the dissolution of the colonial empires is still too recent for their historical consequences to have been eliminated.

Intellectual differentiation. Besides the major biological factors of sex, age, and race, there are other genetic differences between individuals which may lead to social differentiation. One of those most frequently discussed is differences in intelligence. In this case social differentiation is directly linked with stratification; those who are intellectually more able, it is suggested, will attain the leading positions in society. This thesis is clearly most readily applicable to the modern industrial societies, in which social mobility (that is, movement from one level to another in the social hierarchy) is possible and even encouraged and in which, moreover, such mobility occurs to a large extent through the acquisition of educational qualifications. To say this, however, is to recognize that social differentiation and stratification do not by any means correspond with the variations in intellectual ability in all societies. Where there exists a rigid system of stratification (as in a caste system), an individual's position in society is fairly strictly determined by descent, and intellectual or other personal qualities can have little effect upon it. Again, intellectual ability may be more or less highly valued in different types of society; if the principal social activity is hunting or warfare, then physical strength, energy, and courage may be much more important. Even in modern industrial societies, the relation between intelligence and social position is far from straightforward. The inheritance of class position limits the possibility of social differentiation in terms of intelligence; moreover, it is generally acknowledged that there are social, as well as genetic, factors in intelligence itself, so that it may be said that those individuals born into high social positions will display, on average, high intelligence and hence are likely to maintain themselves in these positions, while those born into lower social strata will experience much greater difficulty in developing their intellectual qualities.

This consideration of the biological factors in social differentiation brings to light a question of crucial importance. Although sex, age, race, and individual qualities such as intelligence obviously play some part in social differentiation, they do not have a directly determining influence. Their effect depends upon the way in which they are conceived and treated in each society, and this, in turn, depends upon a great variety of social, cultural, and historical influences.

SOCIAL AND CULTURAL FACTORS

National or societal differentiation

Among the most obvious forms of social differentiation arising from social and cultural factors are (1) the diversity of nations and civilizations, and (2) the distinctions within societies between classes or status groups. The second of these forms will be considered later in discussing stratification. The distinctions between nations, or more generally between the numerous autonomous communities into which mankind has always been divided, are closely associated with differences of language and of culture. Primitive societies, relatively isolated from one another even in the same geographical region, differed in language, in kinship structure, in religious belief and practice, and in economic system—the latter depending partly upon the nature of the physical environment and partly upon the level of technological development in a particular society. Many of these features persist in present-day tribal societies, although they have been greatly modified by the impact of the industrial countries.

It is impossible now to trace the ways in which this differentiation of early human societies came about; and, even in the case of ancient societies that have left historical records, it is not easy to follow in detail the processes by which distinct political communities were created. War and conquest, associated with migrations, played an important part in creating new and larger scale societies, but there were also contrary processes of disintegration and further differentiation. At a later stage, the world religions played a large part in forming distinct areas of civilization. The modern nation-states in Europe were formed largely on the basis of language and historical traditions, while in other parts of the world, more recently, new independent nations have been created on the basis of a religious or cultural identity or have established themselves as the successors to somewhat arbitrarily defined colonial territories (and consequently face difficult problems of social integration).

In considering social differentiation on a world scale, social scientists have been concerned not only with the distinctive features of particular societies and civilizations but also with *types* of society as they have appeared in different historical periods. The French sociologist Émile Durkheim in 1893, for example, distinguished between societies characterized by "mechanical solidarity" and those characterized by "organic solidarity." In the former (primitive and early societies) individuals differ little from each other and are uniformly subjected to the authority of the social group; in the latter (especially modern societies) there is great internal differentiation, individualism flourishes, and individuals are bound to each other by mutual dependence, especially through the extensive division of labour. A distinction that is similar in certain respects is that made by the German sociologist Ferdinand Tönnies in 1887 between *Gemeinschaft* (community) and *Gesellschaft* (society); in the former type of social system, men live in small-scale groups and have direct, face-to-face relations with one another, whereas in the latter type they belong to large-scale groups and are related indirectly and impersonally. This distinction, like Durkheim's, is, at least in part, one between primitive and early societies on the one hand and modern societies on the other.

Other writers have established quite different distinctions between types of society, often making use of economic criteria. One of the best known classifications along these lines is that of Karl Marx, who distinguished several types in terms of their mode of production and the class system arising from it: primitive communism, ancient society, Asiatic society, feudal society, modern capitalist society. More recently, another kind of economic distinction has been made, between industrial societies and nonindustrial or preindustrial societies, the latter being referred to quite frequently as the "developing countries." At the same time, a distinction is now increasingly made between socialist and capitalist economic systems and between the societies that develop upon these different economic bases, even though there are important similarities between all the industrial countries as a social type, on one hand, and the developing countries as a contrasting type, on the other, in spite of differences of economic regime within each type.

Differentiation within societies

The consideration of social and cultural differences between whole societies, or types of society, or civilizations, involves treating these units as if they were themselves relatively homogeneous and undifferentiated. The aspect of social differentiation that has attracted most attention, however, is that which occurs within each society. Some kinds of internal differentiation related to biological characteristics, notably those resulting from sex and age differences, have already been mentioned; but the most prevalent types of social differentiation are those arising directly from social and cultural influences. Many social scientists have regarded the division of labour as the most important factor; one of the most obvious differences between individuals and groups in society is to be found in the kind of work that they perform. In the late 18th century the Scottish economist Adam Smith discussed not only the economic consequences of the extending division of labour but also its effects in determining the characteristics and life-styles of individuals. In the late 19th century the English philosopher Herbert Spencer conceived of the division of labour as a primary element in social differentiation and traced its development in the various parts of society. Similarly, Durkheim considered that the division of labour was the source of the individualism to be found in modern societies and that, although it posed problems of fragmentation and social disintegration, it offered the possibility of a new form of social solidarity based upon the interdependence of individuals and groups.

The great importance of the economic division of labour in producing social differentiation cannot be denied. Moreover, it is closely connected, as will be seen later, with the establishment and modification of social stratification. Nevertheless, it is now generally acknowledged that social differentiation extends beyond the economic division of labour and its effects; as one scholar noted, it "should be thought of as a differentiation of activity of every sort that has significance for the group." Spencer, for example, wrote in terms of the "specialization of functions" which resulted in a clearer distinction between the major parts of society—the governmental, the military, the ecclesiastical, the professional, the industrial—as well as a more intensive division of labour in the productive sphere. But the writer who brought out most plainly the complexity of social differentiation in modern societies was the German sociologist Georg Simmel. In his volume of essays *Über soziale Differenzierung* (1890; "On Social Differentiation") and in other works, he considered the great variety of influences that had contributed to the growth of individualism and the diversification of social groups in the western European countries during the 19th century. The rapid development of a money economy, the growth of cities, the mobility of individuals, the emergence of new social and cultural interests all have tended to produce more varied styles of life. In particular, city life offered the stimulus of diverse and competing intellectual and cultural outlooks, from which new kinds of differentiation could again arise, while the increase in the number of associations of all kinds, concerned with specific interests, permitted the individual to develop particular aspects of his own character and purposes. According to Simmel, in early societies the individual was more or less completely absorbed in the family group, but later he was able to enter into relationships with persons outside his circle on the basis of a similarity in character, tendencies, and activities. Thus new "social circles" arose which intersected the existing "natural groups." In modern societies a vast superstructure of social circles has grown up, and this process has been accompanied by an increase in individual liberty; in Simmel's view, the number of social circles to which the individual belongs is, to some extent, a measure of the development of civilization.

The twin processes of individualism and diversification

Although Simmel attached great significance to social differentiation, he also observed that differentiation was accompanied by a process of integration; and he suggested that human nature shows a fundamental need for both kinds of association—that association which differentiates individuals on the basis of competition and that which brings them together on the basis of cooperation. Thus, he observed that although there is a continual proliferation of more specialized circles because of the appearance of new occupations, new scientific pursuits, and new cultural styles, there is also a continual formation of large circles out of smaller ones—for example, the formation of a working class out of diverse occupational groups. This relationship between differentiation and integration can best be studied by looking at the historical development of social differentiation.

The development of social differentiation

The process of social differentiation has often been taken as one of the principal indexes of social development. Thus, in 1926 the American sociologist Cecil C. North observed that the most significant distinction between a primitive and a highly civilized society was probably the degree to which functional differentiation had taken place. This followed the view of many earlier sociologists. Herbert Spencer for instance, had argued that it is

> a character of social bodies, as of living bodies, that while they increase in size they increase in structure. . . . At first the unlikenesses among [society's] groups of units are inconspicuous in number and degree but as population augments, divisions and subdivisions become numerous and more decided . . . progressive differentiation of structures is accompanied by progressive differentiation of functions.

Spencer's ideas have been revived recently by the American sociologist Talcott Parsons, who has treated social change and development wholly as a process of increasing social differentiation.

It should be recognized, however, that although increasing social differentiation is one important aspect of social development, there are other features that have been regarded by many writers as having equal or greater significance in defining or explaining historical transformations of society. Spencer, for example, saw as one major element in social differentiation the emergence of dominant classes; this, too, was the crucial element in Marx's theory, which—in contrast to the idea of social development through a gradual, progressive differentiation of function—conceived of historical change as proceeding by revolutionary leaps whenever a new ruling class arose as a result of new modes of production. Many recent studies by sociologists and economists have emphasized particularly the distinction between industrial and nonindustrial societies and have considered industrialization, in which social differentiation is only one element, as the major form of social change.

Another important qualification must be applied to the view that social change consists essentially in the process of social differentiation. It is true that in many respects—especially in their occupational structures—modern societies are more differentiated and more heterogeneous than were earlier societies; but forces are also at work making for greater homogeneity. The rise of the European nation-states in the 19th century, the development of national systems of education, the improvement of communications, the increasing size of economic enterprises, and more recently the growth of the mass media have all contributed, in the opinion of many writers, to a greater uniformity of national culture and to the disappearance or attenuation of local and regional diversity. Such developments have been commented upon, from various points of view, in writings on "mass society" and the "consumer society." It has also been argued that increasing social equality in the industrial countries (a diminution of the differences between social strata and greater social mobility) has begun to create a more homogeneous national culture. The factual basis of this argument, however, is disputed, and the most that can be said probably is that the general rise of levels of living, rather than equalization, has had some effect in producing more uniformity in styles of life. The tendencies toward homogeneity are to be seen not only at the national level but also on an international scale, and it has been suggested that all the advanced industrial countries show certain fundamental similarities in their structure and culture—primarily because of industrialism, urbanism, vastly improved communications systems, and the influence of international economic organizations. It would be very difficult, nevertheless, to establish in a precise way the degree to which present-day societies are becoming more or less heterogeneous. What is important is to recognize that the two processes of differentiation and homogenization proceed together, both within and between societies.

Contrasting processes of differentiation and homogenization

THE PROCESSES OF DIFFERENTIATION AND STRATIFICATION

It will be evident from the preceding account that many socially differentiated roles are evaluated as being "higher" or "lower" in some scale of prestige. Social differentiation, that is, overlaps with social stratification, the arrangement of groups and categories of individuals in a hierarchical order. Men and women, different age categories, ethnic groups, religious groups, or occupations may be treated not merely as different but as unequal. Stratification within societies is one of the most important forms of differentiation, but it has been conceived in diverse ways. Most students of the subject would agree that its basis is primarily economic, but economic differentiation itself can be viewed from a variety of aspects. According to Marxist theory, the most important distinction in all societies beyond the most primitive was that between the owners of the means of production and those who supplied their labour power. These two groups constituted the principal classes in every society (though Marx also recognized the existence of intermediate and transitional strata), and the relations between the classes determined

Contrasting processes of differentiation and homogenization the general course of social events in all spheres of life. Depending upon the character of the means of production and, thus, to a large extent, upon the level of technology, different forms of class society have existed. Marx distinguished, in the Western world, ancient society, feudal society, and modern bourgeois (or capitalist) society; and he envisaged the advent of a new form of society, socialism, in the future. In all cases, the rise of new classes and the struggle between classes were the principal causes of major changes in social structure. In the modern capitalist societies, according to Marx, it was the industrial working class, in the various forms of labour movement that are its political expression, that would accomplish such changes and inaugurate a new society.

Marx was not alone in recognizing the importance of social classes; many 19th-century historians, political scientists, and sociologists made similar observations, but they did not all explain the origins and development of classes in the same way, nor did they attach the same political importance to class conflict or envisage the future, as Marx did, in terms of a working class revolution to establish socialism. Spencer drew attention to the role of dominant classes, and Durkheim recognized the pervasiveness of class conflict in the modern European societies, but both considered that classes could coexist harmoniously in the industrial societies, so long as these societies continued to develop their relatively open and democratic character. Other writers, such as the Italian economist Vilfredo Pareto, while adopting the conception of class from Marxist thought, argued that the existence of a governing class or elite was unavoidable and were chiefly concerned, as many later writers have been, with the effectiveness of the dominant class in maintaining a stable social order.

The Marxist scheme has, at various times, been ignored (largely because of its ideological orientation), criticized, and revised. One point of criticism concerns its applicability to all the diverse forms of stratification. It seems most relevant to the 19th-century European societies and to the transition from feudalism to capitalism in western Europe, but much less useful in dealing with such a phenomenon as the Indian caste system. Caste has undoubtedly an economic basis: the major caste categories (the *varṇas*) resemble feudal estates, while the effective caste groups (the *jātis*) are closely related to differences of occupation. Nevertheless, the complexities of the caste system and the sanctions maintaining it can hardly be understood without taking account of the influence of religious ideas; and the historical relations between castes seem far removed from those which characterize the conflict between classes.

Marxist view of class

The interrelations of class, status, and power. A more general criticism of the Marxist theory leads to an alternative conception of social stratification. In writings published posthumously in 1922 the German sociologist Max Weber made a distinction between class, status, and power, arguing that these represented different forms of stratification that coexisted but did not necessarily coincide in modern societies. According to Weber, class situation was mainly determined by the ownership or nonownership of property (more or less along the lines that Marx had described); status situation was determined by the attribution of "social honour" on the basis of consumption or style of life; and the power situation was determined by possession or nonpossession of the means of command. Thus the relative importance of class and status in the stratification system has to be investigated in particular societies and periods; the predominance of one or the other would depend upon economic and cultural conditions that affect the extent to which men become class conscious or status conscious. Moreover, political power is relatively independent of both class and status; it is not regarded, as in Marx's theory, as being merely a consequence or reflection of class position.

The introduction of the notion of social status (which was developed from the feudal idea of legal status) led in due course to the formulation of a distinctive theory of social stratification. In contrast to the Marxist conception—according to which society was divided into major classes engaged in economic, political, and cultural conflict over the basic structure of society itself—the new theory viewed society as a hierarchy of status levels, with each level determined by a social evaluation of the importance or worth of the activities carried on by individuals at that level. The emphasis was upon the placement of individuals in the social hierarchy, not upon the formation of groups and their interrelations. The fact that numbers of individuals occupied the same rank position was considered (if at all) as a secondary phenomenon, and those occupying the same position tended to be treated as forming statistical categories rather than social groups. Thus, in many recent studies of social mobility the various social levels have been defined in terms of occupational prestige, and the scheme of ranking that has been constructed in this way is acknowledged to be a partly arbitrary set of categories, not a system of significant social groups. One researcher in 1954, for instance, distinguished seven occupational prestige categories for the purpose of studying movement between lower and higher social levels in Great Britain, while a pair of researchers in 1967 used a prestige scale of 17 types of occupation for their study of mobility in the United States.

Conceived in this way, stratification is very closely connected with social differentiation in the form of the division of labour, since it is the differentiation of occupations and their evaluation and ranking that are taken to be the source of stratification. It is clear, however, that this does not provide a complete picture of the social hierarchy. Besides the ranking of occupations, and the construction of categories of occupations that are judged to have equal prestige, there is a process of formation of social groups that, through their pursuit of particular interests, play a distinctive part in the system of stratification. Most of what are called the liberal professions, and even the professions as a whole, have generally been regarded as constituting groups of this kind, and it has also been widely recognized that there are various types of elites, not all based upon specific occupations, that have a major influence in shaping the institutions and culture of a society. Furthermore, the various stratified groups and prestige categories are themselves closely connected with social classes, as may be seen from the fact that occupations are thought of, and referred to, as being upper class, middle class, or working class in character. As Simmel observed, the process of occupational specialization is accompanied by an opposite process of incorporation of the occupations into social classes.

There is still another aspect from which the association between status, class, and power should be observed. The prestige of occupations, which is often taken to be the crucial element in establishing a hierarchy of status, at least in modern societies, is determined by social evaluations, but one needs to ask how these evaluations themselves come to be made and accepted. The importance or worth of particular occupations is not something established by nature, and it may be argued that it is those persons who are already wealthy or powerful (that is to say, dominant) in society who decide the scale of prestige. In this sense, therefore, the existence of a status system presupposes the existence of dominant and subordinate classes or of governing elites and subject groups. Nevertheless, other influences upon the prestige of occupations also seem to arise directly from economic and cultural conditions—for example, the changes brought about by the rise of modern science and technology, by the growing secularization of culture, and by the development of mass leisure that has given higher incomes and greater prestige to entertainers of all kinds.

The relations between class, status, and power, as different forms of social stratification, are complex and variable. In some times and places the formation of classes and the struggles between them for political power may be of preeminent importance, as was the case in western Europe during the period of the rise of the bourgeoisie in feudal society, and again in the 19th century when the organized working class movement began to develop. Under other conditions, however, though class divisions exist, they may be less significant than differences of status arising from the diversity of occupations, ethnic origins, and styles of life, influenced by a variety of cultural factors including religious doctrines. It has been argued, for instance, that class differences in the Western industrial societies have begun to lose some of their cultural and political importance in recent decades as a consequence of such changes as the more extensive division of labour leading to a greater variety of status positions, greater social mobility, the expansion of education and of middle class occupations based upon educational qualifications, and higher levels of living. It remains a matter of controversy, however, whether or not social classes have yet ceased to be the principal source of political ideologies and conflicts in these societies.

Definitions of class, status, and power

Social mobility. In the earliest human societies, differences of class and status as one of the principal types of social differentiation may have emerged in various ways—partly as a result of the accumulation of property or the monopolization of leadership positions by particular individuals and families and partly by means of conquest and the enslavement of other social groups. Once established, these differences are maintained by inheritance and strengthened by the elaboration of cultural distinctions in dress, education (initially a distinction between literacy and nonliteracy, and, later, differences in quality and duration of education), and style of life as a whole; they are also consolidated by legal and religious codes. Occupations may become hereditary (either in a formal way, as in the Indian caste system, or on a customary basis); property is transmitted through the family; and political power is inherited by the members of royal and noble families. Of course, the inheritance of social position is never complete in the sense that no new men can attain to wealth, prestige, or power. Pareto exaggerated somewhat when he wrote that "history is a graveyard of aristocracies," but it is certainly true that in all societies there has been some circulation of individuals and families between different social levels. Even in the Indian caste system, which was a particularly closed form of social stratification, it was possible for individuals, and especially for caste groups, to rise in the social hierarchy by various means; and in the European feudal societies there were considerable opportunities for mobility, particularly after commerce and the towns began to develop.

It would seem that modern industrial societies are the ones in which social mobility has generally attained its highest degree and in which inheritance of social position has diminished most. But, in truth, it is difficult, and in many cases impossible, to make rigorous comparisons of the degree of social mobility in one society at different times or in different societies; for the judgments that are made about the relative openness of different types of society tend to be based more upon a consideration of formal opportunities and restrictions than upon an examination of actual movement between social levels. Thus there is controversy about whether or not social mobility in industrial societies has increased during the present century; and, moreover, it is quite clear that there is still a very significant inheritance of class position. The distribution of wealth is obviously highly unequal, and it is primarily through the transmission of property that families in the upper strata maintain their social position and exclude those from lower strata.

Ways in which stratification develops

There are some conditions under which social mobility undoubtedly increases. After a revolution, for example, there is likely to be a general reshuffling of the dominant groups in society; thus, in the U.S.S.R. after November 1917, and in the countries of eastern Europe after 1945, many individuals from subordinate groups in society rose to positions of considerable prestige and power, while others who had previously been dominant fell in the social hierarchy. But at a later stage there may be a new consolidation of status positions. This is particularly noticeable in the sphere of higher education; immediately after the revolutions in eastern Europe, the universities were thrown open to children of working class and peasant families, but as the new upper and middle strata of the population became established they began to acquire privileges for their children, in education as in other spheres, and the recruitment of university students from the working class and peasantry declined again.

Another, more gradual, process affecting social mobility has been the changing structure of occupations in the advanced industrial countries. There has been a steady decline in the numbers employed in agriculture and extractive industries and, more recently, the beginnings of a decline in the numbers of manual workers in manufacturing industry; whereas there has been a continual expansion of clerical, technical, and professional occupations. This process has gone farthest in the United States, where one-half of the employed population is now engaged in middle-class occupations, but it is taking place, also, in the European industrial countries and Japan. Its result is to move a proportion of each new generation from low status manual occupations to higher status white-collar occupations and, at some point, to create, as has been claimed for the United States, a predominantly middle-class society. But this process has further implications for social differentiation; insofar as it establishes, over a large area of society, a middle-class style of life, depending upon similarity of income and occupation, it diminishes differentiation and produces a greater uniformity. This is one aspect of the phenomenon mentioned earlier that sociologists have characterized as mass society. The extent of such uniformity is limited, however, even in the most advanced countries. There is still a clear distinction between the small group of wealthy property owners and the rest of the population; and there are many groups—such as certain ethnic groups, workers in backward or declining industries, and retired workers—who live in conditions of relative poverty far below the standards of middle class society.

THE INDIVIDUAL AND SOCIETY

The phenomenon of social differentiation throws some new light upon the relations between the individual and society. It is not the case that each individual, with his array of personal qualities, confronts the whole society to which he belongs. He is born into particular, differentiated social groups, and his life experiences in these groups do something to form his character and determine his outlook, aims, and achievements. Nevertheless, social differentiation may be regarded as one of the main factors responsible for modern individualism. In broad outline, Durkheim's contrast between early, relatively simple societies, in which the individual is molded to a single pattern of behaviour, and modern complex societies, in which the individual is more differentiated, seems valid if one takes into account not only the increasing division of labour but also the increasing cultural diversity (which arose partly from the criticism of established religious and moral ideas), the development of towns and the consequent opportunities for competition between ideas, and the greater mobility of individuals. Durkheim thought, in fact, that individualism had gone too far in France and was endangering the cohesion of the society. Simmel, on the contrary, writing at about the same time, toward the end of the 19th century in Germany, suggested that modern societies had achieved a better proportion of freedom and restraint than had earlier societies; the individual was freer to choose the social circles to which he would belong, but these numerous and diverse circles were more fully integrated into larger groupings and into the whole society. The proportion between freedom and restraint, between differentiation and individualism, on one side, and the overall regulation of social life, on the other, is clearly not established once and for all in a particular type of society. The industrial societies of the late 20th century seem to many observers to have moved toward greater restraint in many areas of life; the sheer size of organizations, the more powerful means of control in the hands of governments, and the emphasis upon national unity in a century characterized by large-scale international conflicts have all contributed to a loss of individuality and widespread sentiments of individual powerlessness. These tendencies seem to have been countered only in a small degree, in limited areas of life outside the economic and political sphere, by the cultural "permissiveness" that has developed during the past two decades. It remains to be seen how a new balance between individualism and the general regulation of social life (which is needed increasingly on a world scale) will be achieved in the rapidly changing conditions of the late 20th century; but there seems no reason to doubt that it will have to take account of the duality that Simmel observed—the human need, on one side, for differentiation, diversity of life, and individual expression and, on the other side, for cooperation with other men within an ordered social framework in which similarities rather than differences are emphasized. (T.B.B.)

Special categories of social differentiation in modern society

SEX DIFFERENTIATION: WOMEN

There is ample anthropological and historical evidence to indicate that cultures vary widely with respect to the roles that they assign to one sex or the other. Building their homes or shelters, making clothes, planting and cultivating the land, trading, and many other occupations may be regarded as women's jobs in one society, men's in another. With one exception, to be mentioned below, the criteria for the division of labour between the sexes—and consequently the feminine role—seem arbitrary, based on local customs and traditions, rather than on differences between men and women in terms of physical or mental capacities. Women's lesser strength and slighter build than men's, for instance, have not prevented them from being the carriers of burdens or from doing heavy agricultural labour and other strenuous and protracted physical labour. The one constant factor determining the division of labour in all preindustrial societies is the fact that women, because of an almost incessant preoccupation with childbearing and rearing throughout the greater part of their lives, are less mobile than men and are, therefore, allotted tasks nearer their homes. As a consequence, there are some occupations that in most simple societies belong to women's domain: all kinds of housework (such as weaving, basketry, cooking meals, as well as producing the receptacles in which to prepare them and for storing the ingredients), some specific agricultural tasks, and midwifery. Medicine was almost universally a female vocation in prescientific ages and cultures—partly because it has been a domestic craft, handed down from mother to daughter, and partly because in more primitive cultures women have often been believed to possess special magical powers. Healing the sick and wounded accords well with creating new life.

The biological and social roles of women

Popular conceptions of masculinity and femininity. One might be inclined to believe that tenderness toward babies, the love and care for young children, and the desire to help the weak and sick are innate feminine personality traits—predisposing women by nature, as it were, to become the infant-school teachers, nurses, and social workers of today—but it is a fact that there are wide cultural variations in child-care practices, and producing babies in large numbers is not the same as bestowing on each of them the individual loving care that modern pediatricians and child psychologists prescribe. In the headhunting Mundugumor tribe, described by the American anthropologist Margaret Mead, mothers reject their babies and produce a people as aggressive as themselves; in the Samoan villages studied by the same author, mothers hand their babies over, as soon as they are weaned, to an older child, itself often not more than six or seven years of age, who takes charge of its care and basic training—much as the Victorian upper class mother left the upbringing of her offspring to a series of nannies and governesses until they were ready to be sent to boarding school. Abortion and infanticide have been well-known means of population control in many parts of the world and could not have been practiced without the active cooperation of women. In short, it appears to be a fallacy to generalize from the present state of civilization even about as basic and apparently universal a psychological phenomenon as maternal love, because this, too, may take different forms of expression in different cultures and subcultures. Whatever its manifestations, child care is, at any rate, sex-linked in the sense that only women can bear and suckle babies; but fondness for children and tender care for the young are not female monopolies, nor are they characteristic of all women.

In other respects, the connection between the social and biological roles of men and women is much more tenuous and may even be purely coincidental. In some instances, roles have been assigned to one sex rather than another on no more rational a basis than are many social conventions governing the relationship between the sexes. Who greets whom first and whether men walk in front of their wives or vice versa are details of no consequence in themselves. What matters is that conventions exist and are obeyed and regulate even such minutiae of everyday life. That in Western culture one sex fastens their coats on the left and the other on the right side or that baby boys are dressed in blue and girls in pink may seem irrelevant trifles. But all serve the function of underlining, almost from the moment of birth, the contrasts between males and females, rather than their common humanity. The cumulative effect of these practices is by no means negligible. They accentuate the bipolarity of the sexes, and they give a clearer, if more rigid, definition of the roles assigned to either of them. This is particularly important in cultures simple and static enough to base their social organization on status assigned to their members by the accidents of birth, such as the order of seniority, the membership of a kinship group, a caste, or of one rather than the other sex. In that kind of society everybody knows his or her place; but it allows little room for change or adjustment to new situations.

Effects of modernization and democratization

As societies become more complex and technologically advanced, they depend increasingly for their further development on individual talent and initiative. The old system of social stratification, with its rigidly drawn lines between categories of people, is ill adapted to meet the challenges of expansion and social change and unsuited for the best utilization of the available human resources. Hence, it has to be gradually modified and to give way to a new system in which social status is based on personal achievement. The old criteria—age, sex, family membership, and so on—one by one lose their weight in determining a person's place in society.

In political terms, this means that modern societies are becoming more democratic, in the sense that they draw their elites from ever-wider catchment areas. The corresponding sociological process involves the gradual transition from a social organization based on assigned roles to one based on achieved roles. This is of particular interest in the present context; for, although women's growing equality of status, of educational and employment opportunities, and, now, among the younger generation, also of manners and mores may each be traced back to a number of more immediate and specific causes, the overall emancipation of women is a part, and at the same time an example, of the general trend toward the substitution of achievement for assignment as the determinant of social roles. To put it simply, what a person is capable of, has accomplished, or is interested in are becoming matters of greater importance in advanced societies than his or her sex, age, or family connections. Ultimately, this should amount to greater freedom of the individual and his or her assessment on personal merit—or, in the words of the United Nations Charter, "without distinction as to race, sex, language or religion." Why this consequence does not necessarily follow is a question outside the scope of the present article.

Changing fashions regarding masculinity and femininity

The statement that cultures differ from one another in the ways they attribute social roles to men and women implies that in a changing society such differences will occur regardless of local or national traditions. During one period, fashion and a man's status may demand that he adorn himself, wear decorative clothes, shoulder-length hair, or a wig; during another, it would be thought effeminate for him to do so. Similarly, there are fashions in psychological traits: during the Romantic era of the late 1700s and early 1800s, men freely expressed emotions of joy, sorrow, and tenderness; they shed tears without inhibitions and committed suicide for unrequited love. At other times, such demeanour would have been thought unmanly. During the 19th century, European women were regarded as "frail vessels," and, indeed, many suffered from "the vapours" and were liable to faint at the sight of a mouse—an image of femininity that, needless to say, did not apply to the women working in factories and coal mines or as domestic servants. Today, with an eye on population statistics, people are rather inclined to think of women as the tougher sex, because their expectation of life is longer and they show at all ages greater resistance to a variety of serious illnesses. In actual fact, women have become explorers, mountaineers, racing drivers, and pilots and have taken an active part in wars, resistance movements, and revolutions, not only in nurturing roles, as protectors of fugitives, as nurses, and as sutlers, but also as combatants. These activities may not have become part of the accepted feminine role, but neither are they rare enough to be considered unnatural or shocking. Women are actually recruited for compulsory military service, though usually not for combat, in some countries (as in present-day Israel or in Great Britain during World War II), which is a sure enough sign of the widespread acceptance of their changed social role; and the majority of women have lived up to the new image as naturally as their grandmothers did to the 19th-century idea of feminine frailty.

Arbitrary as the definition of male and female roles may appear from a comparative point of view, to the members of a stable society the various facets of a role form an integrated whole that is not only coherent in itself but also closely entwined with complementary roles and supported by a network of social norms that the individual contravenes at his peril. Moreover, they appear to be inevitable and the natural order of things, or they did until anthropological and sociological studies put the absolute nature of that order in doubt.

The concepts of masculinity and femininity, then, exist, above all, in the realm of abstract ideas. At different times, diverse and sharply contrasting qualities were attributed to men and women, thus keeping the idea of bipolarity intact. Rationality, for example, was thought characteristic of men, emotionality of women. Greater practical sense was believed to be typical at times of one, at other times of the other sex. Sometimes the same quality was given a different name according to whether it was manifested in men or women: whereas men's thinking was said to be logical, women were credited with intuition; to have a hunch—presumably a bit of intuition—was not unusual or discreditable for a man but a necessary starting point of scientific discovery and invention.

These and similar convictions, though firmly held by rational men and women, can today be consigned to the sphere of folklore. In reality it has proved impossible to isolate among the wealth of behaviour patterns and personality traits exhibited by women even within one society, let alone in different cultures, those characteristics that could be considered typically feminine in a general sense.

Scientific studies of male–female differences. On a commonsense level, it has always been assumed that psychological differences between the sexes must correspond to their differences in physiological structure and biological function—a view epitomized in Sigmund Freud's famous dictum, "anatomy is destiny." The ordinary layman reflecting on the nature of woman has been joined by psychologists, philosophers, biologists, students of animal behaviour, and other scientific experts in the search for the elusive essence of femininity. The history of scientific investigations into the psychology of women is too long and their findings too diverse and uneven in value to be discussed here at length; instead, some findings obtained by a variety of psychometric tests will be summarized, and then the main current theories of male–female differences briefly considered.

Two important qualifications must be made before any data are reported from the wealth of information collected in numerous, painstaking, and often ingenious studies measuring sex differences in abilities, interests, and personality traits. First, individual differences within any class of people outweigh the mean differences between one class and another. Second, all psychological measuring instruments are culturally relative; that is to say, their findings apply to the status quo in one particular culture (or, possibly, subculture) at a given time. Scales designed for the investigation of one kind of population may not be valid in another. Nor do they, of course, provide explanations as to the origin of the observed traits, although, in combination with other psychological studies, they often are useful indicators of causal connections between certain traits and other psychological phenomena (*e.g.,* motivation, cross-parent identification).

Sex differences in abilities and personality traits

Test surveys have shown significant psychological sex differences in contemporary Western society. As far as measured abilities are concerned, men have been found superior in speed and coordination of gross bodily movements, as opposed to manual dexterity, in which women have a higher mean score. Men are better in spatial orientation, mechanical comprehension, and arithmetical reasoning. Women, on the other hand, excel in speed and accuracy of perception and in memory, numerical computation, verbal fluency, and linguistic abilities generally.

Girls, on the whole, develop faster toward adulthood than do boys, both physically and mentally. This applies at all stages, from infancy, when they are earlier in learning to speak and to count, to adolescence and beyond. This fact is in line with the observation that during their school years girls at first equal if they do not, in fact, excel boys, even in arithmetical reasoning, spatial skill, analytical thinking, and some other predominantly masculine abilities. That is to say, girls reach their peak at an earlier age; boys forge ahead later. Developmental studies, testing in greater detail various intellectual abilities in preschool and school children of different grades, have on the whole supported these findings.

With respect to personality traits, men are characterized by greater aggressiveness, dominance, and achievement motivation; women by greater dependency, a stronger social orientation, and the tendency to be more easily discouraged by failure than men. As the miscellaneous nature of this summary indicates, there is a vast variety of personality traits that might be made the object of comparisons between the sexes. This has, in fact, been done, and the number of studies testing the differential distribution of various traits and types of behaviour between men and women is legion.

Experimental studies have led to the conclusion that masculinity and femininity are not mutually exclusive alternatives but are combinations of traits, unevenly distributed among individuals of either sex. Physically as well as psychologically, each person is a unique balance of characteristics that, if one so wishes, may be placed on a continuum, extending from maleness at one end to femaleness at the other, with a wide area of overlap at the centre, which one might, therefore, with some justification consider sexually neutral.

Masculinity–femininity (M–F) scales

"M–F scales" have been designed on which the degree of "maleness" and "femaleness" of individuals, or of classes of people, such as occupational or age groups, can be measured. Scores on the M–F scale can be and, indeed, have been correlated with other psychological characteristics, such as general intelligence, creativity, self-assertion, dependence, and passivity. These studies have led to further interesting findings; for example, people with a high intelligence quotient and individuals who score high on originality, creativity, and analytical thinking show other traits and interests more typically associated with the sex opposite to their own. In other words, men and boys who excel in these intellectual features are nearer the feminine, and women and girls nearer the masculine, end of the M–F scale than their less gifted peers of the same sex.

This does not mean that intellectual or artistic men are effeminate or that women in high-level professions are masculinized, nor that either type is ill-adapted to their appropriate sex roles. These findings simply confirm in quantitative terms what many a layman has sensed and such writers as Virginia Woolf have expressed when she said, speaking about women and fiction, "for anyone who writes . . . it is fatal to be a man or woman pure and simple; one must be woman-manly or man-womanly" (*A Room of One's Own,* 1929).

The fact that intellectuals, creative artists, original thinkers, and writers of either sex deviate from the norm as measured on the M–F scale, moreover, reflects a bias inherent in the nature of the measuring instrument. Because the scale has been based on a comparison between the mean performances of large numbers of people in a wide variety of tests, such qualities as mechanical ability and interest in engineering or sport have been placed toward the masculine end, whereas aesthetic interests, dependence, and desire for security have been placed toward the feminine end of the scale. What, in fact, are only indices of the relative distribution between men and women of certain qualities and interests have thus become criteria of masculinity and femininity. (The relativity of these standards is highlighted by the fact that engineering, which is practiced as a profession by an infinitesimal number of women in Western countries and has been found in test surveys, mostly administered in the United States, to be one of the most unequivocally masculine interests, is studied by a very high proportion of women in the U.S.S.R.)

The general conclusion from a great variety of investigations into the subject is that masculinity and femininity are matters of degree rather than contrasting concepts at two opposite poles, as they used to be thought of in the past. This view is now supported also by biologists and geneticists, who have found that human beings are ambisexual, in the sense that both men and women possess male and female sex hormones, albeit in different distribution, and the sex organs of either sex contain in rudimentary form those of the other; they consist, so to speak, of the same ingredients, mixed in different proportions.

The effect of sex hormones on human behaviour is not yet fully understood. It is known, however, that sex hormones enter the brain and affect its activity and that, vice versa, the brain exerts a powerful influence over the organs secreting hormones. For details of this process, see the articles REPRODUCTION AND REPRODUCTIVE SYSTEMS: *Human reproduction* and BIOCHEMICAL COMPONENTS OF ORGANISMS: *Hormones*. There is evidence from clinical observation of human beings and from experimental studies of infrahuman mammals that an increase in the amount of male or female sex hormones (as by injections) on members of either sex is followed by behaviour changes. The administration of androgen (a male hormone), for instance, appears to produce more aggression and greater motivation to initiate sexual relations (which in females is, nevertheless, appropriate to their own sex); increased levels of estrogen (a female hormone) appear to lead, among other things, to more passive behaviour and emotional disturbances.

The effect of learning on sex roles

In creatures as dependent on learning as human beings, these hormonal influences produce predispositions to behaviour of one kind or another rather than long-term behavioral changes in the face of many other factors at work, such as existing social norms and past experiences. (For this reason, the developmental stage at which the amount of sex hormones is artificially increased makes a great difference as to their effect.)

To test the relative importance of constitutional and environmental factors in determining the psychosexual orientation of individuals, one group of researchers carried out a series of studies of pseudohermaphrodites—that is, people whose physical sex did not, for a variety of reasons, coincide with the sex assigned to them at birth. With very few exceptions, these persons were, as adults, psychologically fully adjusted to their incongruously assigned sex role. The conclusion of the researchers was that a gender role is entirely the product of learning during the first three years of life and is independent of hormonal, gonadal, or chromosomal sex.

Explanations of how the process of learning a sex role takes place vary and are given by psychologists, according to their own theoretical orientation, in terms of conditioning or imprinting, reinforcement by reward and punishment (which includes subtler forms of social control such as praise, on the one hand, and ridicule, on the other), and the imitation of models. In the latter case, it is usually assumed that a child or adolescent as a rule identifies with the parent of the same sex. Cross-parent identifications, however, do occur and are often thought to be responsible for the development of abilities and personality traits considered more characteristic of the opposite sex. Identification with one rather than the other parent may be due to temperamental affinity between parent and child or to the greater affection, strength of personality, or power of one parent. It has been argued that, in societies in which power is unevenly distributed between the sexes, identifications will more frequently occur with the parent of the more powerful sex. Matters get more complicated—indeed, almost impossible to unravel—however, when, for instance, a daughter identifies with her father, who—himself the son of a widow, or for other reasons lacking a male model during his formative years—had identified with his mother. In such a case (which one might call double-cross-identification), a girl may, in fact, acquire her most feminine qualities through imitation of her father.

In conclusion, no statement can with any certainty be made about the origins of feminine or masculine personality traits beyond saying that psychosexual orientation appears to be the outcome of complex interactions among genetic, hormonal, and environmental factors whose relative importance in the whole process of character formation is impossible to ascertain. This view is now almost universally accepted, by biologically oriented scholars no less than by psychologists and sociologists.

Contemporary roles and status of women. The most decisive and, it would appear, irreversible changes in the status of women were initiated in the 19th century; and the circumstances which got them slowly and falteringly under way were the technical, economic, and social upheavals generally known as the Industrial Revolution. Its impact on the lives of women was profound and manifold and can here only very briefly be indicated. It is important to remember, however, that British Prime Minister Benjamin Disraeli's much-quoted phrase of the "Two Nations" ("the Privileged and the People") applied to women to an even more marked degree than to men.

Effect of the factory system

The transfer of production from home to factory, while sharply increasing the productivity of labour, destroyed the family as an economic unit. Henceforth many thousands of men, women, and even children left their homes to work in factories and mines, living in industrial slums or crowded tenements in big cities. Many women of the new industrial proletariat worked in appalling conditions of near-starvation and unlimited working hours under a system of exploitation that became notorious as "sweated labour"—while they gave birth to one child after another. The conditions of the labouring poor, however, eventually aroused public concern, expressed in social investigations, philanthropic work, and, finally, legislation mitigating bit by bit the worst evils of the factory system through state intervention.

The front of social prejudice was breached by the daughters of wealthy merchants and professional men by way of philanthropic work. The social evils of their day were crying out for remedy and increasingly stirred the public conscience. Helping the poor was both virtuous and unpaid and, therefore, a suitable activity for young ladies—especially in an era that had ceased to trust Providence to put things right and had sufficient self-reliance to take it upon itself to redress the grievances.

Soon there were women of outstanding abilities pioneering in many fields of social service: working for prison reform; joining in hospital administration; organizing nursing as a profession; improving the standards of working class housing; fighting alcoholism, cruelty to children, and prostitution; campaigning for the abolition of slavery; and engaging in social investigations and polemics for law reforms. Their names are too many to bear repeating; they mark milestones in the social history of the 19th century. Some, but by no means all, of them worked for specifically feminine causes, such as a mother's right to the custody of her children, reforms of marriage and divorce laws, more equitable property rights. *The* cause, of course, was votes for women.

Women in the labour market

Somewhere between the upper class social reformer and the female proletariat there was a third category of women, who slowly but in ever-increasing numbers entered the labour market—namely, clerical workers. These were of mixed social origin but came mostly from the classes that hitherto had provided the governesses and the "distressed needlewomen." They did not oust men from their jobs but entered a new type of employment, created by such technical inventions as the telephone, the telegraph, and the typewriter, by the vast expansion of business, and by such new institutions as the general post office, the savings bank, and the like.

The obstacles put up by Victorian prudery against the employment of women in any of these fields seem preposterous in retrospect. Women clerks in the civil service, for instance, had to work behind locked doors that no male—not even the tea-carrying messenger—was allowed to cross. When it was suggested that girls might suitably be employed in the letter-sorting section of the post office, the objection was raised that letters might sometimes have to be opened to discover the sender of nondeliverable mail; in this way, words or phrases might come to the notice of ladies which would offend their sensibilities. These and similar matters were earnestly debated in legislatures and fully reported. Fortunately for the emancipation of women, the argument that usually carried the day was that at the same or lower wages one could engage young women of much superior quality (in every sense of the word) in comparison with men.

The changes that in modern times are taking place in the status and role of women everywhere have been viewed from two angles: as part of a world revolution of family patterns or else as a development toward greater equality of the sexes in political rights, access to education, and employment opportunities—women's emancipation, in short. The difference is one of emphasis: in the former case, the focus is on woman's familial role; in the latter, the perspective includes her position in the social, political, and economic structure of society at large.

The two aspects, women's roles in family and in community, are closely interrelated: changes in one sphere normally produce changes in the other—not surprisingly, since each individual is simultaneously a member of both social systems. Women's status, both in the family and in wider society, has been and is being radically altered by a combination of scientific and technological advances, growing industrialization, ensuing changes in the economic and social structure, and the spread of new ideologies.

Changing family patterns. The revolutions in family patterns and in the social and political position of women are not equally far advanced, just as industrialization and urbanization are not equally developed, in all parts of the world. Even among the industrially highly developed countries, there are some notable variations in the status of women, owing to different historical traditions, social customs, class distinctions, religious affiliations, the "generation gap," and other factors. Bearing all these reservations in mind, it still does not seem unreasonable to assume that Western models of family patterns and of women's roles in and outside the family will gradually spread to other parts of the globe in the wake of economic and technological development.

The example of Japan

Japan is a good, if somewhat extreme, example illustrating this process. Starting from a rigidly patriarchal form of the extended family system in which women occupied completely subordinate positions, changes that in western Europe and the United States took over a century to accomplish were telescoped into less than a quarter of that time. In either case, a world war, with its manpower shortages and the need to recruit women for war work, effected changes of public opinion, which led to constitutional and practical reforms. In the West it was World War I, in Japan World War II that triggered the political and economic emancipation of women. The Constitution of 1946 guaranteed Japanese women equality before the law and abolished political, economic, and social discrimination on the ground of sex. Subsequently, a number of legislative measures were taken to reform the family system and secure for women legal equality in the home, in the sphere of education, and in the labour market. A Women and Minors' Bureau was set up at the Ministry of Labour to help and encourage women to take advantage of their newly won status.

Coeducation was adopted in Japanese high schools in 1950 and later in most universities as a means of furthering the emancipation of women. Although a nine-years course of elementary education is compulsory for both sexes, the proportion of girls advancing to high school level was 63 percent and of those proceeding further to a four-year university course was 17.6 percent, in 1964. As in many other countries, women students outnumber men in literary subjects.

More than 60 percent of Japanese women leaving senior high schools, colleges, and universities hold paid positions, mostly clerical and professional. (Considering that within the lifetime of the present generation some firms would not allow their female employees to answer the telephone lest it be thought impolite for customers to be put in a position of having to discuss business affairs with a woman, this is progress indeed.) More than half the female population aged 15 and over are economically active. Women form 40 percent of Japan's total working population, compared with 36 percent in the United States, Great Britain, or West Germany. The Labour Standards Law (1947) established equal pay for equal work while at the same time providing protective measures, such as permission to take menstruation leave and prohibition against night work in industry and against employment in certain hazardous occupations, such as mining.

It would be a fallacy to deduce that, as far as employment is concerned, the status of women in Japan differs little from that in other highly industrialized countries. Quite apart from the fact that the time span allowed for the adjustment of attitudes to the new situation has been very short, the Japanese economy itself, despite its rapid industrial growth, is so much at variance with the contemporary Western model that it presents an entirely different employment pattern. Only about one-half of all economically active women are wage earners or salaried employees. One-third are unpaid family workers, employed in small family businesses or farmsteads without pay. In agriculture, which not only is a declining industry but also is increasingly becoming feminized (in 1968 53 percent of all persons working on the land were women, compared with 50 percent ten years earlier), more than eight out of ten women work without fixed financial reward.

The rapid expansion of industry and the resulting rising wage levels have attracted men into the industrial sector of the economy, leaving the family small holdings, which are the mainstay of Japanese agriculture, for the women and old men to run. But the flight of young women from the land—at the same time, an escape also from the traditional, patriarchal type of family in which two or three generations, now separated by ideas as well as by age, live under one roof—has become even greater. It is getting more and more difficult for a farmer to find a wife—yet another push in the direction of rural depopulation, a phenomenon that is, of course, not unfamiliar in industrial countries elsewhere.

Political rights. It has now been accepted as axiomatic that equal rights to vote and to be elected to national office are fundamental to women's status. Equality of franchise with men was fought for ardently and for a long time by a dedicated minority against heavy resistance on the part of the "establishment." One of the functions of the United Nations Commission on the Status of Women, set up in June 1946, was to further the cause of women's political rights in all countries. In December 1952 the General Assembly adopted the UN Convention on the Political Rights of Women, which was the first instrument of international law aimed at the granting and protection of women's rights on a worldwide basis.

Rights to vote and hold office

By 1971, of the 129 countries that were members of the UN or the specialized agencies or were parties to the Statute of the International Court of Justice, all but eight allowed women to vote in all elections and to be eligible for election on the same basis with men. In three of these eight (Portugal, Syria, and San Marino), women's suffrage or eligibility for office was subject to certain limitations that were not on a par with men's. In five other countries, women had not by that date been enfranchised; namely, Jordan, Kuwait, Saudi Arabia, Yemen (Ṣanʿāʾ), and Liechtenstein.

The first countries to grant women electoral equality with men were New Zealand (1893), Finland (1906), Norway (1913), and Denmark and Iceland (1915). With the exception of a few individual states of the Australian Federation (1902) and the United States (where Wyoming was the first to grant women the suffrage, in 1869), equality of votes for women came in most leading countries at the end of or soon after World War I: The Netherlands and the Soviet Union in 1917; Germany and Luxembourg in 1919; Austria, Czechoslovakia, Poland, and Sweden in 1918; the United States in 1920; and Great Britain in 1928 (though subject to a number of limitations, age and marital status among others, British women were first enfranchised by the Representation of the People Act of 1918). During the interwar period, electoral equality was extended to women in the Union of South Africa (1930), Spain (1931), Brazil and Siam (now Thailand; 1932), Ceylon, Cuba, Turkey, and Uruguay (1934), Burma and Romania (1935), and the Philippines (1937); in the other states it came in the wake of World War II or else of the replacement of the old colonial empires with new sovereign states.

The extent of women's political power

The right to vote, though an essential means of influencing the distribution of political power in a democracy, does not by itself carry political power. The proportion of women elected to be members of Parliament is in the region of 3–4 percent in the British House of Commons, around 2 percent in the U.S. House of Representatives, and between 7 percent and 9 percent in postwar Federal German parliaments. In the Soviet Union in 1970, women deputies comprised more than 30 percent of the Supreme Soviet, the highest legislative body, but were much less well represented at the centres of real power—that is, the highest levels of the Communist Party. After half a century of women's suffrage, however, the number of women in high positions of political power and influence is still small enough for them to be known by name.

Leaving political power aside, women's vote seems also to bear little relation to their social position in other respects. In France, to give one example, women have always enjoyed high status not only in the family but also socially and culturally. The country has produced a number of eminent women in literature and politics (incidentally, even two ministers of state in the Popular Front Government of 1936, before Frenchwomen had the vote) and includes among its national heroes a woman soldier (Joan of Arc). Frenchwomen, nevertheless, were not enfranchised until 1944.

Switzerland, one of the oldest democracies, did not give women the vote until 1971. This is all the more curious because not only have Swiss women played a considerable part in the economy of their country but Switzerland was among the first to extend university education to women on a basis of complete equality with men. The University of Zürich admitted the first woman student in 1864 and subsequently became the Mecca to which women eager to get a university qualification flocked from all over the world. The University of Zürich set the model for the rest of continental Europe in allowing men and women students to work side by side in the same classrooms and medical schools, to take part in the same lectures and seminars, and to sit examinations on equal terms.

The connection between female suffrage and the general status of women is symbolical rather than real. True, there can be no equality that does not also include political rights. The reverse is, however, not the case. The granting of full citizenship is not necessarily a forerunner, and even less a guarantee, of an improvement in women's status.

Education. Education has a much more direct and powerful bearing on the social position of women (as, indeed, it also has on that of men). Hence, equal educational opportunities are of the greatest importance in raising their status. Equal access to education is one of the basic human rights laid down in the United Nations Charter and has been accepted, at least nominally, by most states.

Rates of women's educational enrollments

Nevertheless, even where equal access to education exists de jure, there is de facto a great difference of opportunity between the sexes. In countries where illiteracy is still widespread, it is at a much higher level among women than among men. (In India, for example, the literacy rate is nearly 34 percent among men, 13 percent among women.)

At the other end, even where university education is financed by public grants, as in Britain, or by public loans, as in the Scandinavian countries, irrespective of sex, parents will, in case of doubt or financial stringency, send their sons to university rather than their daughters. The dropout actually begins at secondary school level. According to an official British report, about one-half of the boys but only one-third of the girls capable of advanced-level work (that is, preparatory to higher education) stay at school after the age of 16. The corresponding watershed in the United States, if less marked, is at the end of high school. To take one scholastic year, 1961–62, as an example, somewhat more girls (51 percent) than boys graduated from high school, but among those enrolling in college the following term, 58 percent were men and 42 percent women. During the same year, slightly more than two out of three bachelor's and first professional degrees, more than two out of three master's degrees, and nearly nine out of ten doctor's degrees were conferred on men. The proportion of women in institutions of higher education is still considerably lower than that of men almost everywhere. (The term higher education includes teachers' colleges, technological institutes, and fine-arts colleges, as well as colleges and universities.)

The prospects of a working class girl getting a higher education are considerably lower than those of a working class boy. In Britain, according to one report, the chances of obtaining full-time higher education are four and a half times better for the son and eight times better for the daughter of a nonmanual worker than of a manual worker. As for full-time courses of degree level, the disproportion between the chances of men and women coming from these two types of family background is much greater still. If the father has a nonmanual occupation, his son's prospects are six times better and his daughter's prospects are 18 times better than the chances of boys and girls, respectively, from manual workers' homes.

Curricular differences between men's and women's education

There are also social pressures—exerted partly by tradition and public opinion, partly by the operation of market forces, and partly by vested interests on the part of older, established professions—to limit the professional and, hence, also the educational choices of women. Where the number of places is limited, as in many medical schools, the chances of women to be admitted are very much lower than men's. There is a tendency for women students to concentrate in large numbers on a limited number of subjects—languages, literature, education, usually social sciences (the list differs somewhat from country to country)—to the near-exclusion of most others. This seems particularly true of the United States, where as many as 40 percent of women students graduating in one year (1960–61) qualified in education, another 24 percent in social sciences, including psychology, and 14 percent in humanities, a substantial proportion of the latter probably also heading for the teaching profession. This leaves very small numbers graduating in medicine, the natural sciences, the fine arts, law, engineering, and agriculture.

In many other countries women have made an impact—to varying extent, and in diverse academic subjects—in traditionally masculine spheres of study. For instance, although law, natural sciences, and medicine together accounted for 13 percent of women students graduating in the U.S. in 1960–61, 40 percent of women students in Italy and 53 percent in France graduated in these three disciplines during the same period. In the Soviet Union at one time well over two-thirds—later reduced to more than one-half—of all medical students and 36 percent of students of engineering in higher educational institutes were women.

The rationale for denying many a gifted girl equal access with men to university education is usually that (1) she is not likely to become the breadwinner of a family; (2) her future socioeconomic status will most probably not depend on her professional occupation or earning capacity; and (3) her career will presumably be only of short duration, thus not warranting the investment of time, money, and energy. Some of these assumptions, as the following section will suggest, have been disproved by the facts. In the present context, under the heading of education, two points deserve mentioning. First, in all countries for which data are at hand (the United States, Great Britain, France,

Values of education in employment and marriage

West Germany, and the Scandinavian countries), there is a strong positive correlation between the educational level and the employment rate of women. Irrespective of their husbands' social status and income (both of which are as a rule higher and make the financial need for a wife's contributory earnings less pressing than among the average population), the more highly educated women are, the more strongly motivated they are to continue in or return to their careers. This development may be fairly recent, but it would seem to go a long way toward disposing of the argument that the higher education of women is wasted.

Second, in contrast to the earlier stages of women's emancipation, when it was feared that a university education might diminish, if not ruin, a girl's marital chances (a fear not entirely without substance at the time), education is today held in such high esteem, in developing as well as in developed countries, that it has gained prestige value. Husbands pride themselves on having a wife with a university qualification or professional training, irrespective of whether or not they are putting it to practical use. A degree is therefore an asset on the marriage market; and, since universities are places where young women are likely to meet congenial young men of the appropriate social class, a daughter's college education may be a better investment than a dowry. This may, in part, explain the rapid increase in the percentage of women among university students in countries as far apart as Argentina, India, Italy, and Japan, among others.

Contrasts between preindustrial and industrial societies

Employment. Before outlining the main features that characterize the employment situation of women in modern industrial societies, it is necessary to comment on the widely held belief that the employment of women, especially of married women, is a recent phenomenon. Women have, on the contrary, at all times and in all types of economy made a substantial contribution to the production and distribution of their communities' resources. In preindustrial societies, as, indeed, in agricultural communities today, the family is an economic unit in which all members do their share of work, as they also share in its proceeds. As far as the employment of women is concerned, the difference between preindustrial societies and highly industrialized modern economies is not that in the latter women represent an increasingly large proportion of the labour force but that most working women are employed outside their homes, as independent individuals, and receive a monetary reward in return for their labour.

In terms of labour statistics, the most highly developed countries do not always show the highest proportion of women among their civilian labour forces; but they have the lowest number of so-called unpaid family workers of either sex. If it is sometimes said that in advanced industrial societies more and more women go out to work, the emphasis is on going out rather than on work; but, even so, the statement is not entirely true. In many countries the sex employment ratio has remained remarkably constant, regardless of temporary fluctuations, ever since the first employment census was taken at roughly one woman to two men. (An exception to this generalization exists in the United States, where women formed only 15 percent of the labour force in 1870 and increased their participation to 36 percent in 1970.)

The present employment situation of women in Western industrial countries may be summarized thus. Because manpower—particularly skilled and highly qualified manpower—has become one of the scarce resources of modern times and because the reserves of rural populations that could be recruited into industry have been shrinking, modern societies increasingly depend on the work of women. Contemporary industries, highly mechanized, provide a large variety of skilled, semiskilled, and unskilled work that no longer requires physical force but depends on manual dexterity and speed—abilities in which many women excel.

Modern economies have developed a large apparatus of distribution and administration, and both the clerical and sales sectors employ vast armies of women. Moreover, the steady growth of the so-called tertiary, or service, sector is characteristic of all modern economies: from the expansion of the communications system to beauty parlours, from tourism and catering to the manifold government services, there are growing fields of employment largely depending on female labour. To these newer fields may be added those that are traditionally considered more largely women's domain: schoolteaching, librarianship, nursing, physiotherapy, social work, and so on.

The increase of married women in the labour force

Another striking characteristic of the present employment situation is the ever-increasing number of married women who go out to work. In industrialized countries, well over one-half of all working women (nearer 60 percent in the U.S., Great Britain, Canada, Japan, and Sweden) are married. In part, this is due to demographic factors. The extended life span, increased marriage rates, lower average age of marriage, relatively smaller families, and generally improved standards of health have led to a situation in which women no longer spend the greater part of their adult lives bearing children and looking after infants. Another result of some of the demographic trends is that well over one-third of the people in most industrial countries are either under the age of 15 or over the age of 65; that is, a growing percentage are below or above the working ages. In addition, rapid technological change and other complexities of modern societies seem to necessitate a steady extension of the period of education for a growing section of the population—thus further reducing the proportion of those available for work. It thus becomes clear why economic incentives as well as social and moral pressures operate to induce those of working age who are capable of doing so to join the labour force. Since virtually all men and single women, if they are not still under training, are gainfully employed, the only groups to which the choice is still open are married women, especially those who either have not yet had or no longer have young children.

The early marriages that have become popular today would in most instances not be possible without both partners contributing to the capital outlay needed for setting up a home and to the cost of running it. This is one of the reasons why it is now customary among young women of all social classes to carry on in employment after marriage until soon before the birth of the first child.

The increase in the number of married women working (more than one-third of the married women in Great Britain, France, West Germany, and the U.S.) is only partly due to the practice of continuing employment during the early years of marriage. It is due to a larger extent to the growing number of women who return to paid employment in their mid-30s and 40s; that is, after bringing up their families. The growth in the female labour force has primarily been the result of the increasing employment of married women between the ages of 35 and 55. A graph showing the employment rates of women by age groups in all industrial countries typically consists of a two-humped curve: one high peak at the ages of 18–20, then a steep decline until roughly the age of 35, after which there is a second, lower, and flatter peak (whose level has in recent years been progressively rising) for the age group 35–55.

The reasons for this development are manifold and can here be summarized only briefly. First, there is the reduction of the amount and physical strain of housework, resulting both from the smaller size of families and from the increasing mechanization of modern households. Second, in addition to simplifying the tasks that inevitably have to be carried out at home, industry has altogether taken over many processes that previously were part of the housewife's job. By modern research and mass-production methods, it has become possible to reduce the cost and improve the quality of a large variety of household products. While doing this, industry has at the same time created innumerable new jobs for women to fill.

In contrast to earlier stages of industrialization, which concentrated primarily on the production of industrial equipment, the latest phase of economic development in all advanced countries is marked by mass production of consumer goods—goods that ordinary men and women wish to possess and that may substantially alter the quality of their lives. In order to create a large enough market, industry relies heavily on advertising. The growth of the economy thus exerts a constant pressure on the public to buy more and more, and purchases on the installment plan make it possible to widen the circle of people to whom these goods become accessible. The inducement for married women to make an extra effort in order to increase the family income by going out to work is, therefore, considerable.

Among various other motives for married women to take up employment outside their homes, the most frequent are the need for personal contacts, resulting from the social isolation of housewives in dormitory suburbs and new housing estates, and the desire to exercise their abilities and put their previous training to good use.

The question of equal rates of pay for women

Despite the dependence of the economy on women's work and in spite of a growing egalitarian philosophy, women are almost universally either paid at a lower rate than men or employed in the lower grades or both. Equal-pay conventions have been passed by such organizations as the International Labour Organization, and many countries have enacted equal-rights legislation. Even though the United States is one of these countries (having passed its equal-pay act in 1963), the median earnings of year-round, full-time working American women was 58 percent that of American men in 1966. Although it is argued that the principle of "equal pay for work of equal value" is very difficult to establish in industry (By what standards are the respective values of particular processes to be assessed? Do men and women ever do the same kind of work?), professions that have traditionally been staffed by women—such as teaching, nursing, and social work—have a low pay structure that is only beginning to be improved by the growing infiltration of men into their ranks. It is true that in most of the high professions—including the executives, administrators, and scientific experts in industry and government, journalists and editors, physicians, lawyers, university teachers, legislators, and government officials—remuneration is related to the post, irrespective of sex. But it is much more difficult for women than for men to reach high-level positions, and it is a moot point whether this disparity of achievement between the sexes is primarily due to the entrenched male prejudice (as is often asserted), to the discontinuity of most women's careers, or to the reluctance of many women to assume positions of responsibility because their families come first in their order of priorities. The new employment patterns, outlined earlier, in which women's main career period coincides with their years of maturity, when they may well be able to give another 30 years' continued service, is too recent a development to have yet changed employers' attitudes. In the present climate of opinion it seems reasonable to assume that, as the number of women acquitting themselves with distinction in high office goes on increasing as it has done in recent years, the prospects of promotion will improve for all women of ability.

Marriage and sexual behaviour. The ideal of marriage generally accepted in contemporary Western societies and among the westernized strata of developing countries is that of partnership—that is, a sharing of interests and responsibilities between husband and wife on as nearly equal a basis as possible. As with so many other ideals, practice often falls short of precept, especially if, as in this instance, social class and family traditions sometimes combine with personal temperaments to put up an emotional resistance against the implementation of principles to which one is intellectually committed. There are, however, many factors, both material and ideological, which support a trend toward an increasing approach to the model, quite apart from the fact that it largely emanates from and is actually put into practice by the younger generation, especially the more highly educated among them, and is therefore likely to spread as more adolescents grow up to marriage age.

The ideal of marriage as a partnership is in line with the prevailing ideology of equality between the sexes. It is backed up by similar educational levels between husband and wife, by women's experience of personal independence and occupational as well as other extradomestic interests before marriage. Sharing of interests is, together with sexual attraction, a major factor in mate selection; and since joint interests—be they at work or at leisure—usually provide the focal points for people to meet, it is not surprising that they assume a central place in their relationship.

Roles of men and women in the home

If women's interests have increasingly stretched out beyond the home, men, in return, have become more home centred, partly under the influence of television and partly as a result of suburbanization. The mechanization of modern homes has made many domestic chores less dependent on traditional skills and less feminine in character. With many married women employed away from home and sharing in the breadwinning activities that previously were the husband's responsibility alone, a sense of fair play has perforce induced many men to share in some, at least, of the household tasks. Increased leisure hours allow this male participation in the home, and the do-it-yourself type of hobby in fashion encourages it. Psychologists, moreover, increasingly emphasize the importance of the paternal role in child rearing; in the present age of the mass media, these and similar theories and their practical implications are brought home to the widest possible public.

All these factors combine to make family life, in and out of the home, a more cooperative venture. Who, in these circumstances, is the dominant partner of a couple is a matter of personality characteristics rather than of social conventions. The times have passed when the father was the generally recognized authority in the family. Many of the more important family decisions, as well as the assertion of parental authority, have to be taken by the mother. Apart from the fact that a family, as a rule, moves wherever a husband's work takes him for any length of time, there are hardly any generally accepted conventions about male or female dominance, either in general or in any particular sphere.

This is one of the factors that have made compatibility between marriage partners an issue of crucial importance and that have made the choice—now left entirely to the couple concerned, without parental intervention—so difficult. In these circumstances, it would seem reasonable that a certain amount of experimentation in human relations goes on among young men and women before they make what, for all intents and purposes, is a permanent decision. This experimentation increasingly also includes premarital sexual relations.

The Kinsey female

When the Alfred Kinsey report *Sexual Behavior in the Human Female* (1953) brought to light the fact that 50 percent of the women in his sample had had premarital sex experience, the American public seemed surprised. Yet it is difficult to see how the peer-group culture that discourages any kind of chaperonage or control by adults and that accepts as natural facts such practices as mixed holiday camps, weekend trips, travel abroad, and so on could have had any other effect. The double standard of morality between men and women was repugnant to younger people long before the equality of the sexes in other respects had been widely accepted and long before safe contraceptives made equal standards a practical proposition.

Since the data were collected by Kinsey's group, further changes in the direction of greater permissiveness have no doubt taken place. Sex mores are in a state of flux. This does not mean to say that there is a trend toward more promiscuity. It may well be that new norms are evolving that have been called "permissiveness with affection" and that are not only more in line with the egalitarian standards accepted in other fields of activity but also less hypocritical than the bourgeois morality they seem to be replacing. Among the working classes and rural populations, premarital intercourse has previously been an accepted part of their mores. If, for whatever reason and in whatever guise, a similar pattern is spreading among the middle classes, this seems to be a sociologically unusual case of a social practice moving upward on the social scale. (V.K./Ed.)

AGE DIFFERENTIATION: YOUTH

Until comparatively recent years, attention was focussed primarily on the biological and physical aspects of youth, or adolescence. Physiological changes were visibly so striking that other, more subtle social factors were either ignored or undervalued. It was thought that the onset of puberty set up strong emotional states of mind characterized by periods of moodiness and storm and stress. This was a view that greatly appealed to romantic novelists and poets, but one that studies of different cultures later discredited.

The physical changes that characterize the postpubertal stage are indeed striking, but it has to be remembered that growth and change have already become familiar to children and of themselves need not seem threatening. It is the social attitudes that are built up around these body changes that determine young people's own attitudes and subsequent behaviour in relation to them. Physical growth, although subject to much variation among individuals, tends to accelerate at this stage. There are changes in glandular balance, and the development of secondary sexual characteristics is conspicuous. For girls, the onset of menstruation seems to have a critical significance, while the less clearly marked signs of puberty in boys, including seminal emissions, proceed, it seems, at only a slightly slower rate.

Physical maturation. A strong body of professional opinion suggests that during the last 50 to 100 years children have been maturing in the physiological sense at progressively earlier ages. It is not certain that this is a worldwide phenomenon, but it is agreed that potentially it is likely to become one as the more technically backward and underdeveloped nations become more prosperous. In some societies it seems that puberty is reached by as much as five years earlier than a century ago, and evidence derived from records kept over a number of years in schools and clinics suggests that children since about 1900 have on average increased in height, at age five to seven, by one to two centimetres (0.4 to 0.8 inch) each decade and, at 10 to 14, by two to three centimetres (0.8 to 1.2 inches) each decade. Body weight has also gone up proportionately. Only temporary disruptions of normal life caused by war, famine, or economic crisis seem to have halted this trend.

As far as earlier sexual maturing is concerned, the records largely rely on statistics that have been sporadically kept during the last century relating to the age of menarche (first menstrual period). Information for boys, concerned, for example, with the appearance of pubic hair, seems much less reliable.

National comparisons of the onset of puberty

Comparative data deriving from different sources over a long period of time are not entirely satisfactory, but there is a degree of consistency that suggests that the age of menarche in Europe has been getting progressively lower. Data from Norway, Germany, Finland, Sweden, Denmark, Great Britain, and the United States follow an almost identical pattern. At the present time Cuban girls have the earliest recorded menarche age, with a mean of 12.3 years for Negroes and 12.4 for whites. Chinese girls in Hong Kong are almost as early and well in advance of the European mean of 13.3. East Europeans appear to lead the west in physiological maturity, while the more prosperous American girls are also a step or two ahead. In Africa, the less well-off, such as the South African Bantu, lag seriously behind, with a mean age of 15.4. Only the Bundi of New Guinea, with an average menarche age of 18.8, are comparable to the Europeans of a century ago. Some experts consider that this trend toward earlier maturity will continue and that the mean age throughout the world will drop even lower. The reasons are probably both genetic and environmental. A better diet and higher standard of nutrition are clearly the most important, and this is supported by the finding that there is a significant relationship between the age of menarche and the number of children in the family—the larger the sibling group, the later the menarche. The same seems to hold true for children's height and weight. By implication, social-class differences and parental means seem to be important, since diet and medical care depend upon them to a considerable extent. There is some evidence that the onset of menarche and the development of secondary sexual characteristics do occur earlier in the more privileged and better off social groups, but the relationship between social class and maturation is not a simple one.

Earlier physical maturity has obvious social implications. Clearly, the lowering of the mean age for marriage in some societies is closely connected with it. Together with the later age of menopause, it has expanded the period of the individual's potential fertility at a time when world population is seen to be approaching a crisis point. Earlier maturity also has important consequences in the educational sphere, especially in more advanced societies, in which the years of formal training are necessarily becoming longer. Pedagogical practice is beginning to alter, sometimes radically, to meet the new levels of maturity of pupils. Parents, too, are finding that older disciplinary sanctions are becoming less and less effective, that simple veto or moral exhortation no longer go unchallenged.

Psychological maturation. Freudian theory tended to direct attention to the first few years of life as being the most crucial. It posited a latency period that seemed to operate until around the age of 11, followed by the necessary resolution of the Oedipal conflict (libidinal attraction of a child to the parent of the opposite sex) in the early teens that had to take place amid the rising tide of overt sexuality. Such a thesis tended to confirm the storm and stress notion of adolescence and to a very large extent depended on the idea of basic instinctual drives impelling the individual in more or less predetermined directions. Latter-day Freudians imply that it is always necessary to accept adolescents on their own terms because they can behave in no other way. Not to do so would produce frustration and be likely to result in various kinds of deviance, delinquency, and psychic sickness. Adolescence, in this view, is itself almost a kind of temporary mental illness that the young person simply has to endure, a disturbing but inevitable feature of the growing-up process that must be tolerated and cannot be either cured or altered. But both psychoanalytical and physiological theories have been considerably modified during recent years. Increasingly there has been a deeper realization of the social and cultural influences on the psychic development of the individual and a concomitant exploration of the sociocultural determinants of behaviour.

The growing-up process has come to be seen as a search for identity. Identity implies self-realization within a particular social environment and period. The individual, innermost self may be unique, but it must always be realized within specific and, historically speaking, widely different social milieus. There is a dynamic interplay between the inner self and the surrounding culture, and it is out of this tension that individual self-identity finally emerges.

Identities may be partly given or ascribed by the community in which the young person finds himself. They may also be achieved to some extent by hard work and competitive success. In some milieus the pressures to conform to a particular behaviour pattern are severe indeed. Some youngsters react by choosing a deviant identity, as this seems the only way open to them to become themselves and to actualize their inner potentialities.

In most cultures the acceptance and realization of a sexual identity is a fundamental social necessity. Male and female roles, even in "primitive" societies, are very different. Boys and girls during the developmental period are hence called on to solve different problems and to learn to behave in dissimilar ways. Boys early become conscious of their future tasks as breadwinner, father, and citizen and tend to focus their identity around work, vocation, and earning a living. Girls, by contrast, are less oriented to the working world and more concerned with the search for their future mate. They see themselves more as wives and mothers than as employees or professionals.

But the key orientation for all adolescents is the future. They know that they are passing through a transitional, preparatory stage for a fuller and longer period of adult life that is not far away. Boys, because of their vocational and breadwinning role, need to develop greater independence of thought and action than their sisters so that they can challenge the environment successfully. Girls, by contrast, become more involved in interpersonal relationships and are much less group minded. Boys, too, may be called on to defend the state with their lives or at least to protect their family and kin group. They need therefore to develop an external stance of greater courage and toughness than girls and are much more susceptible to accusations of cowardice. By the same token, they are under considerable social pressure to prove their masculinity in purely sexual terms—not to have had sexual experience at a time when their coevals claim to have had it is felt to be denigrating. Feelings of sexual incompetence, fears of impotence, and doubts about homosexual tendencies in boys are matched in girls by anxieties about attractiveness and lesbianism.

Varying physiological and psychological maturity and the demands of society

Socialization. The physiological and psychological development of the individual during adolescence is always closely associated with social influences and societal demands. These demands can at times pull in conflicting directions, thus imperilling the individual's inner harmony and self-image. Society requires the growing boy and girl to develop socially, as well as physically and psychologically, through a series of stages that are more closely associated with chronological age than general maturity. Differences between individuals composing the same status group can thus be considerable. Variations in the age of puberty, of physical growth and emotional stability, of family background, and of innate intelligence lead to further confusion and uncertainty. At this stage young people are acutely conscious of themselves and of differences between themselves and their contemporaries. They are inclined to be highly introspective, self-critical, hypersensitive to criticism, anxious to be accepted, yet impelled to assert their own individuality. Clashes with parents and teachers are common, largely because most of the adults with whom they come into contact are in a superior position and tend to misread every kind of youthful nonconformity as rebellion or conceit.

The fact that society expects its young people to develop along certain lines and to remain involved in either full-time or further education long after physiological maturity has been reached and passed has been called social adolescence. There is so much factual information and technical know-how to be transmitted that the span of formal education must necessarily be lengthened every generation. For the most highly specialized and theoretically demanding work, the period of continuous training could well last into the mid-20s. This means that more and more young people remain in economic dependence either on their parents or on society during their prolonged educational phase. It is not surprising that at times this lack of financial independence proves irksome and that some students react by excessive sensitivity to what they feel is authoritarianism and overregimentation by those who are in control of their studies and their destinies.

While individuals are arriving at their various maturational stages at differing times, the principal social and personal developmental tasks, as they have been called, must be tackled and, if possible, accomplished before final maturity and individuality are attained. A developmental task is one that arises at a particular stage of life, successful achievement of which leads to happiness and success with later tasks, while failure leads to personal unhappiness, social disapproval, and subsequent difficulty with the other tasks that lie ahead. Such tasks are closely interrelated, and failure at one level will almost inevitably produce stress and strain at another level. The young person who succeeds in mastering the earlier problems is more likely to be successful with the later ones.

The goal of these developmental tasks may be termed adult competence. In conventional social groups this implies doing well at work, succeeding in sexual activity and family life, and becoming a law-abiding, responsible citizen sharing the economic and political burdens of the community as a whole. Less orthodox groups might well scorn the notion of good citizenship. Others might regard economic success and material rewards as distasteful and even perhaps positively evil, while others, yet again, might prize sexuality for its own sake apart from either marriage or family life. But the norms that may be said to characterize society as a whole are those that the respectable middle class uphold. Almost by definition, the values of stable family life, conscientious work, and responsible citizenship comprise the normative order in most modern industrial urban societies.

The main developmental tasks that each young person in modern society is obliged to tackle may be summarized under three chief heads: (1) coming to terms with society, (2) coming to terms with self, and (3) coming to terms with life as a whole. Coming to terms with society consists of being educated, getting a job, participating in political affairs, and bringing up a family. Coming to terms with self involves attaining a valid sexual self-image and the realization of individual talents, especially artistic and creative, of every kind. Coming to terms with life as a whole is a more synthetic experience and refers to the acquisition of a general moral code, a set of values, and, in some cases, the acceptance and internalization of religious beliefs and attitudes.

The three main obligatory developmental tasks

These three are, of course, related aspects of a general process of self-realization and the acquisition of a valid identity. They comprise in fact the basic issues that face all people in all epochs. But adolescence is the stage when they confront individuals with the greatest urgency and emotional force. This is precisely why adolescence is traditionally regarded as a preeminent time of artistic and spiritual flowering. It is the reason why it is thought of as a time when the intensity of individual loneliness is most keenly suffered, when there is leisure to contemplate the great issues of life and death, love and rejection, faith and despair, before the commitments and responsibilities of adult existence force the mind to operate on a lower and more pragmatic level. The loneliness and at times the despair of modern life are tragically demonstrated by the fact that the suicide rate for this younger age group in Great Britain has nearly doubled since the end of World War II.

Functions and roles of youth. In primitive and stable cultures the function of youth is to continue the traditional way of life even when at the same time there is a tension between youths and adults for status and power. Adults maintain a jealous social distance between themselves and the young, who aspire to their prestige.

Thus, the Nuer of the south Sudan maintain social distance between the age grades by careful segregation at sacrificial feasts and by a formal deference to elders that precludes open contest. Relations between peers are accordingly all the more affective and friendly, and adolescents regard one another as brothers who can offer each other mutual support and comradeship.

In traditional peasant societies, delayed maturity is institutionalized. Rural Irish society, for example, was characterized by late marriage, a low fertility rate, and long-withheld status, since the basis of economic life was the family farm, which a son inherited only when his father was too old to work it himself. Peer groups consisting of middle-aged men as well as younger men existed to cope with the problem of delayed status and intergenerational tension. Similar peasant societies in Wales, traditional China, French Canada, and central Europe presented a comparable social structure.

In modern advanced industrial societies, the adolescent period reveals parallels with peasant and traditional cultures. But the function of youth is much more dynamic and creative. Duty to parents and submission to authority have to be learned and maintained, and once again the peer group acts as a cushion against excessive reaction to frustration and provides a realistic social world of equals in which the adolescent learns how to cooperate with contemporaries in a completely egalitarian way. In the adolescent period, peer groups are at the height of their influence. Young people with weak parental attachments seem at this stage to regard the valuations and approval of their peers as much more important than the judgments of parents, teachers, and the adult world in general.

Adolescent reactions to looming demands of adulthood

Young people react to their experiences at this developmental stage in two very different ways. They tend to be defensive and overreactive to the adult world, which they perceive as both frustrating and threatening. At the same time, rising anxieties about their own competence may drive them to regress to childhood for temporary comfort and security. Both reactions can bring them into conflict with the representatives of authority and the adult world. Boisterous high spirits, rough playfulness, and the flouting of prohibitions are all in evidence during this stage, and thumbing a nose at older people seems to be something of a psychological necessity. At such times and, more especially, during skirmishes with authority figures, the very fact of being an adolescent provides a symbol of collective identification, enabling youth to see itself as good in and for itself over and against other age groups in the community. The organizers of Fascist youth in Italy and of Nazi youth in Germany before World War II exploited this aspect of adolescence and endeavoured to alienate children from parents—with devastating success.

Youth groups, whether formal or spontaneous in origin, whether officially sponsored or made up of groups of friends and street mates, tend to die away and lose their appeal after the transitional phase has passed. Youth cultures with their own style of clothing, behavioral standards, and characteristic drugs and music are obviously only temporary substitutes for maturer and delayed satisfactions.

The creative and dynamic aspects of the role of youth in modern industrial societies—and, indeed, in almost all societies that are in a state of conscious transition from older to more westernized patterns and life-styles—are becoming more and more apparent during the closing decades of the 20th century. In broad terms this relates to ways in which, during the teenage period, growth is deliberately encouraged, experimentation fostered, and criticism stimulated. The role of the university is here of paramount importance, especially new universities that have been founded on modern liberal ideas and that encourage the study of politics and sociology.

Political impact of youth activists

At a time of accelerated social and technological change this creative aspect of the adolescent role is of great social significance. It was, for example, the zeal and enthusiasm of the young Red Guards in China, in which country youths probably outnumber adults, that made Mao Tse-tung's cultural revolution possible. Further, the rebellion of left-wing students in Ceylon during 1971, although put down, seems to have forced the government into more obviously Socialist policies than they had hitherto been pursuing. In the early 1970s it was estimated that half the population of Africa was below the age of 20. Thus, it is clear that in such developing countries as the new African states political influence and power to shape the future destiny of their country will, by sheer weight of numbers, lie mainly with the young.

Student demonstrations and campus rebellions that have erupted in the United States, France, Germany, Great Britain, and other countries reveal that even in very affluent societies young people still possess revolutionary and reformist zeal and are prepared to insist on the right to have a say in the organization of their own societies. At the same time, however, it is necessary to point out that such politically active young people are probably still in a minority, certainly in the Western world, in which the pressures for social and economic conformity are very persuasive.

Youth and the family. The family is clearly a most powerful socializing institution, and, because of its primacy, it probably has a greater long-term influence on a child's personality and future life than any other group. The quality of emotional relationships within the family and the values and attitudes that are either encouraged or discouraged by parents seem to differ according to social class and status. In Western societies, the children of middle class parents are expected to behave in a way that is appropriate to the family's status and their own future roles. They are required to work hard at school, to control their aggressiveness, to organize their lives in terms of long-term goals and deferred rewards, to be cooperative with authority, and to work and play harmoniously with their contemporaries—without, however, sacrificing individual achievement or ultimate competitiveness.

Working class youngsters, on the other hand, are more likely, except for the socially ambitious, to be brought up in a much less controlled manner. Discipline will be more erratic and less consistent. Future ambitions do not go much beyond the desire to obtain a steady job with good pay, following, if possible, an apprenticeship. Spontaneity and aggressiveness of a physical nature are widely permitted and expected. All this is in contrast to the more rationally ordered, emotionally inhibited, and occupationally oriented upbringing of middle class culture. This is one reason why casual delinquency is a common feature of lower working class life and why the destructiveness and aggression of middle class pupils and students is frequently channelled into organized pranks.

Girls in lower class social strata are more home centred and less free ranging than their brothers. Domesticity comes to them at an early age, and there is seldom any idea of a lifetime's occupation outside the combined role of wife and mother. Middle class girls, however, who have usually enjoyed as good an education as their brothers, are more likely to think in terms of a job or a profession in which even during marriage they may retain an interest and to which they may return when their children are no longer dependent.

Working class children leave school much earlier than middle class children, although the gap is being narrowed in more affluent societies, which can afford a longer period of formal education and dependency than can poorer countries. It has further been noted that access to higher education is easier for middle class than for working class young people. In Great Britain, of the 10 or 11 percent of the school population who go on to university education, rather less than 30 percent are working class in origin, out of a total population that probably contains about 70 percent who are working class in socioeconomic terms. West Germany appears to do much worse, with only about 5 percent of its graduates coming from other than middle class backgrounds. In the United States, there is a much greater degree of equality of opportunity for members of all social classes to obtain admission to higher education than is generally the case in most European countries.

Contrasting parental roles in the socialization process

Parental involvement in the training of children varies widely. In more simple communities the association is often very close, the child self-consciously accompanying the appropriate parent as he goes about his daily business so as to be able to make a complete identification with his own future role. A deeply traditional society such as India contrasts with modern American culture in the degree of emphasis given to parental significance. In the United States a child is taught to relate to contemporaries and peers from quite an early age and to base behaviour as much upon their views and attitudes as upon what parents say and advise. In India, on the contrary, children seem to be brought up to be highly receptive to parental sway, the father particularly serving as a pious model for filial emulation and as a symbol of traditional authority. Such a family structure makes for great social stability and for continuity of behaviour between the generations. It looks backward as much as forward and is highly resistant to social change.

A wide variety of relationships between parents and children exists throughout the world. The link, however, is obviously still of enormous importance, even in communities where peer groups are most vital. Postwar Japan is a good example of the tenacious way in which family life, although shaken, is not completely disrupted even by national catastrophe. In spite of the gigantic emotional and social upheaval following military defeat, national humiliation, and the drastic diminution of the authority of the semi-divine emperor, the stability of family life seems to have remained unbroken at the personal and emotional level, even though growing political and ideological differences have weakened the traditional cultural continuity of the generations.

Youth and education. It is the function of the school and of organized education to carry on and extend the socialization process begun in the family. In advanced Western societies, education is concerned mainly with maintaining the existing culture, supporting the status quo, and promoting a limited amount of social change and social mobility for its more successful participants. In younger countries, however, the role of education is often to stimulate creative dissatisfaction among more intelligent youth, thus making the emergence of a new elite possible. Such new elites are usually urban rather than rural in origin and, as in Latin America, tend to be recruited from the offspring of already existing bureaucratic and governmental elites.

It is clearly understood in all societies that education holds the key to individual future success, and in societies that are already stratified along social class lines it is inevitable that schools will reflect existing differentials. In the United States, for example, professional employees have on average twice as long a formal education as farm labourers and considerably more years at school than factory workers. By and large, although the middle class is permeable and capable of increasing its numbers by recruitment upward from lower status groups, it retains its elitist position by its strategic grasp on educational institutions.

The elites thus fostered by the educational system and the competitive strains experienced in school make a substantial contribution to the creation of many and varied youthful maladjustments. The failure of traditional educational institutions to care for the whole child, the inability to educate for emotional as well as for intellectual growth, the emphasis on self-interest and paper qualifications, all have contributed to the emergence of many of the antisocial types of behaviour to be discussed later in this article.

Youth and work. Work is obviously one of the most important formative elements in the developing self-image of the adolescent. The occupational role links the individual closely to people of other ages and ranks and, at the same time, anchors him firmly in the economic life of the community. It gives him deeper social roots, enhances future prospects and opportunities, and, in theory at least, should nourish feelings of dignity and usefulness. It is through employment, moreover, that the young person achieves financial independence and is thereby enabled to marry and set up his own home. As already indicated, male and female attitudes to employment are different in most cultures because of the differential roles males and females are called on to play in regard to homemaking and child rearing. But in all societies a failure at the work level for a young man means a failure at the economic level, too, and this in turn almost inevitably produces feelings of inadequacy and insecurity that impede the individual's growth to full maturity and satisfactory citizenship. Many kinds of psychological problems derive from a boy's inability to achieve his occupational and work role, and many social problems, such as vandalism, stealing, and gang warfare, are directly attributable to youths' feelings of worthlessness and resentment at being excluded from the material achievements and rewards of ordinary life. Much juvenile crime in modern industrial societies has been traced to economic frustration and consequent status frustration among socially disadvantaged youngsters who have been obliged to live all their lives in substandard conditions and attend low-grade schools.

Consequences of failure in the world of work

Since work is so important for the economic health of both society and individual, it is remarkable how little thought and care has been given to this stage of a youth's life. Even in the most advanced industrial societies there has often been a serious lack of continuity between school and work. Vocational education as compared with bookish learning has often been despised by teachers. There has also been considerable disdain for manual work. Communist countries have done their best to redress this adverse bias and have deliberately extolled the virtues of physical work. Students in Communist states have often been obliged, for example, to do a stint of manual work as a necessary part of their preparation for citizenship, and in modern China pupils spend part of their time in workshops making serviceable articles. Leisure time, also, is partly devoted to "socially useful labour" of various kinds. In this way every child is made community minded and encouraged to see the virtue of manual work.

In the non-Communist Western countries much more is left to chance, to market demand, and to personal and family choice. Middle class children are on the whole very carefully trained and initiated into white-collar jobs and the professions. But the majority of children are still obliged to leave school at a time when their physical, mental, and emotional growth is unfinished, and they are plunged headfirst into adult-dominated working life with little or no skilled help to enable them to adjust to the new and sometimes disturbing experience. The divorce between school and work is much too complete. Attempts to provide vocational guidance undoubtedly help, as does the allocation of certain teachers to careers advice at the school level.

No amount of personal counselling, however, can overcome the major problem, which, in the advanced industrial capitalist societies, is primarily one of a growing lack of employment. Periods of economic difficulty and policies of deflation make the young unskilled worker, especially school leavers, exposed to the humiliation of unemployment and reliance on public welfare. Even those lucky enough to have secured apprenticeships cannot be guaranteed continuing employment during times of economic stress. As with other elements in the labour force, moreover, the young are increasingly exposed to the risk of redundancy—in spite of their training and skill—as technological changes cause the labour force in particular industries to shrink. In Great Britain in 1971, with the total of unemployed running near the 1,000,000 mark, thousands of school leavers and even hundreds of university graduates found themselves unable to get work. The government was forced to contemplate taking the unprecedented step of recruiting as many of them as possible for community projects designed to improve the environment. Such measures, however, can be regarded only as temporary palliatives to a widespread problem that has hit even the richest of all industrial societies, the United States. Despite many millions of dollars being invested in various urban aid programs and ameliorative schemes designed to promote better attitudes to education and to prevent juvenile delinquency, teenagers, black teenagers most especially, seem to be chronically exposed to long-term unemployment. The community simply has no use for their services, and serious social commentators have suggested that as many as a third of all young blacks leaving schools in American cities are facing a hopeless future.

The burgeoning problem of youth unemployment

Yet, while the most disadvantaged youngsters face the prospect of long-term uselessness, other working class youths have in recent years, in some manufacturing trades especially, been enjoying a higher wage increase than any other section of the working population. Such contrasts are hard to reconcile with the ideology of the welfare state and the caring community.

Youth and the economy. Most modern industrial societies have enjoyed increasing affluence as scientific, technological, and organizational skills have been further developed and exploited. In advanced societies the young, whether as workers or dependents, have received a generous share of the general prosperity. Their economic importance, however, as contrasted with the 19th century, has been probably as much as consumers as producers of goods and services. The United States economy since the 1960s has been able for the first time to sustain a large leisure class of youngsters not in the labour force but yet consumers on a considerable scale or, if employed, free to spend their earnings as they please. In western Europe, too, a similarly rising tide of affluence has swept teenagers into prominence as a group well worth the serious attention of manufacturers. There are now a whole variety of goods and articles that are especially designed for the teenage market and for that age group alone. The clothing trade, the soft-drink industry, and much of the entertainment industry rely very heavily on the patronage of the young. Teenagers also spend a fair proportion of their cash on food, alcohol and tobacco, cosmetics, holidays, and gasoline.

Growth of the youth market

The rise of the teenage market was originally a direct result of the better job and pay prospects of young workers in the period following the end of World War II. It had a clear proletarian base and was firmly linked to the 15-to-25 age group. Middle class youth, for the most part still held back in full-time education, had to rely on parental generosity, but figures for Great Britain show that middle class boys tended in the event to have almost as much spending power as their working class counterparts. Most of the money was spent in similar ways; boys and girls from middle class backgrounds attending selective and privileged schools tended to buy the same records, wear the same style clothes in their leisure hours, and enjoy the same amusements. A growing classlessness among youth arising from sharing a common teenage culture has been observed and commented on. At college and university level, students seem to want to look like young workers, and the almost universal popularity of jeans among all kinds of young people, male and female, is a sociological phenomenon of great interest, witnessing not only to egalitarianism but also to the unisexual trends in contemporary youth culture. The old distinctions between the behaviour and attitudes of the sexes have almost everywhere become blurred, and girls, perhaps for the first time in history, have openly become pacesetters in certain consumption spheres.

Teenage culture, with its emphasis on youthfulness, novelty, daring inventiveness, sexuality, tolerance, and gregariousness, does not exist either at its more commercial level or in its psychological depths apart from the wider society. It satisfies the young who subscribe to its values, and in so doing it feeds the adult economy with profits. Some social commentators see youth as typifying a postulated future leisure-orientated culture—the culture of a time when working hours will be drastically reduced and when more and more people will have to find deep satisfactions in leisure-time activities.

Youth and sexual behaviour. The growth of permissiveness and the rejection of older, more puritanical attitudes toward work and sexual behaviour is an aspect of a supposed widespread movement toward the creation of a much freer and more creative way of life that certain self-conscious sections of the youth believe themselves to be pioneering. The growth of student power on campuses and the movement toward "pupil power" at secondary schools, as well as the advent of what has been described as "playpower"—a general philosophy of pleasure-seeking and self-indulgence which seeks to overthrow established authorities—are now almost worldwide phenomena.

In the years following the conclusion of World War II great changes have affected sexual behaviour. What has characterized Western societies is an increasing permissiveness among the young, especially among girls. More widely available and improved contraceptive techniques have combined to reinforce the pleasure ethic, which defines chastity as unnatural and regards full sexual experience outside marriage as the norm. Many young people clearly accept such a norm and openly practice what in an earlier generation would have been condemned as promiscuity. But there are great variations between individuals and social groups, and in this respect, although the general approach to sexuality is much franker and more guilt-free, it is still possible to observe differences related to social class, religious affiliation, and educational level. Young people from strong religious backgrounds, for example, are still more likely to value virginity very highly. It is very clear, however, that in the sphere of intersexual relations there is widespread acceptance of equality and that it is no longer solely the male prerogative to initiate activity nor is it a question of the girl tamely submitting to the masculine urge. Both the pleasure and the affection of sexual relationships tend more to be based on complete mutuality and partnership.

Findings of sex surveys

It is exceptionally difficult to obtain reliable information in so sensitive an area as sexual behaviour. It is necessary to rely to a large extent on research findings that may be out of date or, as was the case in the Kinsey inquiry conducted in the United States in the early 1950s, based on a statistically imperfect sample. The Kinsey report indicated that sexual activity during adolescence was at its height among American boys between the ages of 17 and 20 and that lower class boys were much more active than their college-going contemporaries. Girls, by contrast, showed much less activity up to the age of 15, when almost all the boys had achieved orgasm with or without a partner. Masturbation was widely practiced and homosexual experience by no means rare.

A later English study, based on evidence provided by 1,873 young people between the ages of 15 and 19, presents a more balanced picture, which, while confirming that the momentous years for sexual growth are indeed the middle and late teens, tends to undermine the view that teenagers' sexual ethics and behaviour have radically changed in recent years. The study estimated that 34 percent of the boys in the sample and 17 percent of the girls had had sexual experiences by the age of 18, although this in many cases fell short of full intercourse. The girls in this study seemed to start their sexually active lives before their brothers but at a later date were overtaken and passed by them. The boys appeared to be rather more promiscuous and sexually adventurous than the girls. The great majority of both sexes, however, seemed to have survived the difficulties of adolescence without serious sexual problems or breakdowns arising. On the other hand, the casualties, although in a minority, cannot be lightly dismissed. Illegitimate birth rates for girls between the ages of 11 and 16 have risen during recent years. So, too, has the incidence of youthful abortion in those countries that have legalized it and that keep statistical records. Growing permissiveness is also reflected in the rising incidence of venereal disease among the teenage population of Europe and other areas. In spite of widespread sex education—in Sweden, for example—an increasing number of youngsters contract diseases that seem to have increasing resistance to antibiotic treatment.

There is, however, no reason to think that the adolescent age group is behaving in any society very differently from older sections of the population. Marriage and family life, furthermore, are still regarded by most youngsters with extreme favour. But there is a shift of emphasis, and a new pattern of relationships has emerged. This may be summarized as an acceptance of individuality, greater tolerance for other people's behaviour, and genuine desire for equality and mutuality in all things. Tolerance and unwillingness to condemn those who are different in colour, race, or culture forms the foundation for a new ethic among young people almost everywhere. As allegiance to formal religion and acceptance of established dogmas weaken, ethical sensitivity and commitment reappear in the rejection of militarism, the campaign against all kinds of discrimination, and a repudiation of the grosser manifestations of modern materialism.

Factors behind changing attitudes to sexual relations

Such changes as have been outlined above arise from a variety of causes. One is the growing numerical and economic strength of youth in modern society generally. Much, too, must be attributed to new patterns of child rearing and new ideas in the child-care field that have encouraged the more child-centred home and school. Emphasis in modern education is increasingly on the emotional and creative aspects of the curriculum and less and less on the hard slog of rote learning and reliance upon discipline imposed in an arbitrary fashion by adults from above. Principles of participation, discussion, and rational explanation and individual decision making, which formerly were only to be found operating in experimental schools, are becoming much more widely accepted in general education at both state and private levels.

Varieties of youth. Much of what has been said above can now be summarized in a tentative typology of modern youth. The foregoing analysis seems to lead to four principal illustrative profiles that highlight the trends and regularities in youthful behaviour in many different countries.

The upper class conformist. The apparently well-adjusted, mainly conformist, upper and middle class youth may be said to typify success within a specific cultural system. They have been pupils at leading schools. They have had the support of parents throughout the growing-up process. On the whole they have identified with their parents' outlook and way of life, obeyed the codes of their teachers, passed the necessary examinations, acquired the diplomas and certificates that will admit them into the business and commercial world at a reasonably well-paid level or that will give them access to high-status professions. Some have come from lower class families and have risen in the socioeconomic hierarchy by their hard work and natural ability, but the great majority have been born into the middle and upper classes and have been socialized in the appropriate norms. Their political views are more likely than not to be conservative or mildly liberal, since these are the values they have been brought up to respect. Their future prosperity, moreover, depends very largely upon the stability and perpetuation of the existing system. In some countries, this class of youth will have been educated in elitist institutions such as the French *lycées,* which set out to inculcate qualities of leadership in the professions, in the military sphere, or in political and public life. As a group, these young people are a blend of established privilege with meritocratic achievement. They tend to deprecate excessive emotions of any kind and to be against histrionic gestures. The males are inclined to treat women as idealized inferiors and on the whole are well-content with a social, economic, and political world that gives them a monopoly of opportunity, authority, and autonomy. The psychological stresses to which they will be exposed will arise from anxiety about living up to family expectations and doing at least as well in life as their parents. Some of the more sensitive ones may also feel themselves constantly challenged by the ideals of political democracy to defend themselves against the accusation of elitism and class privilege.

Emotional attitudes of the upper class conformist

The working class conformist. The second group is lower in social status than the group delineated above. It comprises the well-adjusted, conformist, lower middle class and upper working class youth who constitute a very large proportion of the age group in modern industrial societies. They will have been brought up with a comparatively good health service and in a bland social climate that stresses the community's responsibility for its children. At school they will have enjoyed a fair general standard of education but will probably have been particularly interested in practical and technical subjects with a strong vocational usefulness. When they leave school they are likely to seek employment in skilled manual work so that, financially at least, they will receive high wages at an early age and so come to have a considerable stake in the political stability of modern industrial society. They work hard and expect good pay. They see money as a means to enjoy their immediate leisure in the form of stylish clothes, cars, drink, music, sex, and all the sensuous good things of life. When they get a little older and consider it time to settle down, they will want a modern house or flat in a new town or in a suburb. They enjoy and in the future will expect to go on enjoying a high standard of physical comfort, and their lives will become increasingly home centred. They are often politically inert and, in Great Britain, unlike their Socialist grandparents, do not see any need to go on fighting the old class war. Their links with the old working class culture and traditions are hence growing weaker. They are the new, almost classless, self-confident young people of an affluent age, who are unlikely to show radical political attitudes. On the contrary, they are as likely as not to regard those members of the same social class who are unemployed or in much lower status and less skilled work as constituting, in time of economic depression, a threat to their own recently won high standard of living.

Political uninterest of affluent working class youth

Nonconformists. Most societies other than primitive cultures have a quota of nonconformists, some of whom may be regarded as moral deviants but others of whom simply refuse or are unable to accept the norms of the majority of the community. Modern European and North American societies have been producing an abundance of such types since World War II. Even the Soviet Union, during the 1950s, produced its own version of rebellious unconventional youth, the *stilyagi,* who, like the British Teddy boys and the German leather-jacketed *Halbstarken,* were in their day conspicuous for both their clothing and behaviour.

It is useful to distinguish lower class anti-authority delinquents from their more morally committed and more intellectually oriented contemporaries. Underprivileged minority groups of working class youth are in the main merely reactive against their lower status and depressed opportunities. In a sense, they are hitting back at those who have denigrated them and, by limiting their opportunity for development and mobility, have condemned them to second-class citizenship. Dropouts from the school system are the victims of chronic underprivilege, grinding cultural poverty, and social disadvantage. In former days they would have perhaps submitted to the dead-end jobs that were all that would have been left for them. But amid surrounding affluence they have reacted more aggressively. In a study of American youth made in the late 1950s, the American sociologist Robert Havighurst and his colleagues estimated that something like 29 percent of the rising generation was composed of drifters and socially alienated youngsters coming from all social classes, although predominantly from the lower middle and working class group. The actual proportion of such disaffected youth in contemporary Western society is difficult to estimate. All that is certain is that the number is large and perhaps increasing. The violence of such groups as the Hell's Angels, who are to be found in many Western countries, is deeply disturbing. Whether in Copenhagen or California, their deportment is that of aggressive dropouts from conventional society. Their groups, or chapters, are growing, and in England they appear to be the natural descendants of the motor-cycling Rockers who in the mid-1960s fought the Mods (fashionably dressed teenagers) in various public places. Their gang warfare, remotely suggestive of classical Chicago and New York models, with female followers emotionally identifying with them, presents a strangely melodramatic image of confused adolescents in a society that has no place for them and in which they presumably feel psychologically obliged to hate and to fight back against everyone who is not a member of their own group. (J.B.M./Ed.)

AGE DIFFERENTIATION: THE AGED

The position of older people in modern industrial society must be interpreted in light of the fact that many of them survive beyond the age at which they would perform or be rewarded in major social roles: worker, parent of dependent child, or spouse. By contrast, in most primitive and agrarian societies, old age (at least up to senility) has been associated with some special characteristic regarded as an asset in the respective culture, such as usefulness in the performance of chores, skill in dancing or storytelling, control of property rights, power in the family, seasoned experience, or (especially in preliterate societies) extensive knowledge.

The status of the aged in the economically advanced nations today derives from broad changes over the past century in the entire society and its culture. Demographic change has altered the age composition of the overall population, and for the individual, the expectation of life has been increasing as mortality rates decline. Economic development has been accompanied by decreasing proportions of older men in the labour force, posing problems of income maintenance for those no longer economically active. Levels of educational attainment have been rising. Urbanization has transformed the residential setting. The structure of the family has altered. Thus the social context of the aged today differs markedly from the earlier situation when today's older people were reared and almost certainly from the projected future when today's younger people will have grown old.

The social context. *The demographic base.* In Western nations generally, there has been a marked rise in the number of older people, paralleling the expansion of the population as a whole. Over the first half of the 20th century the annual rate of increase in the age category of 65 and over has ranged from about 1 percent in France or Sweden to nearly 3 percent in Canada or the United States.

Numbers of older people have been increasing even faster than the total population. Thus, in Sweden and France the proportion of the total population aged 65 and over had already reached 8 percent by the turn of the century; in the United States between 1850 and 1960, this proportion rose from 3 percent to 9 percent. This long-term tendency for the older age groups not only to grow larger but to grow faster than the younger segments of the population is characteristic of industrialized societies generally; by contrast, in most of the less developed countries of Asia, Africa, and Latin America, the proportions of persons 65 and over still fall below 5 percent. These changing proportions of old people within the population have resulted primarily from declines in fertility rates, which have reduced the accretions to the younger age categories, and not, as commonly supposed, from the declines in mortality. The improvements in reducing mortality have, in the past, had their effect most directly on infants and small children (though any future benefits in Western countries are likely to accrue at the later ages). Although the increasing proportions of survivors may eventually swell the ranks of old people, they have in the meantime added to the numbers at the young ages, not only initially when they were young themselves but later on when they became parents.

Increases in females

Not only have the number and proportion of older people been changing in the West but among older people the proportion of females has been rising. Except in some underdeveloped areas, male mortality rates are generally higher at all ages than corresponding rates for females (even for some animal species). Hence there is typically an excess of females over males among the aged. In the category of people age 75 and over in the United States, there are only about 73 men for every 100 women, a discrepancy that has been widening.

For individuals within a society, the secular declines in mortality (and the consequent increase in the expectation of life) have greatly improved the chances of surviving into old age. The change is not in the *span* of human life (the ultimate length of life attainable by a member of the human species) but in the proportion of people enduring into the higher ages of this span. Thus the average lifetime in ancient Rome or medieval Europe is estimated at some 20 to 30 years. In several Western countries, a man born in the middle of the last century could look forward to four decades of life; today a man can look forward to living well into his 60s, a woman to living into her 70s. Such demographic changes characterizing Western civilization appear to be unparalleled in human history. They have profound societal implications—for example, for government involvement in programs for older people, for the increasing supply of mature individuals available for the labour force, or for the structure of the family because all the family members, but particularly the females, tend to live longer.

Economic status. The age structure of society is closely linked to the economy. In this realm older people tend, on the average, to be comparatively disadvantaged, although individual variations are great. Their low status is indexed by their comparatively low rates of participation in the labour force and by their low average incomes.

Decline in employment

There has been a steady decline (apart from short-term fluctuations attendant upon mobilization for war) over several decades in the proportion of men 65 and over who are in the labour force in most industrialized countries (in contrast to agricultural countries).

No firm explanations for the long-term decline in the employment of older men have been satisfactorily demonstrated. Extensive research on past trends and on age patterns today point, however, to a variety of associated factors and facilitating mechanisms, such as the possibility that technology may have advanced to the point of a sufficiency of manpower to meet existing demands for goods and services without the participation of older workers; the decline of agriculture and of self-employment, in which the aged are free to continue work or to taper off from it gradually; the steady rise in the educational level of the labour force, which appears to favour the better educated and the more recently trained younger workers; and the extension of public and private pension plans, which afford alternative sources of income to increasing proportions of older workers and which often specify the age for mandatory retirement.

The striking discrepancy in rates of labour-force participation between older and younger men (most younger men are in the labour force) has differential consequences for the age strata, affecting not only their respective involvement in the goal-directed activities of the society but also their financial status and the time available for their leisure pursuits.

Decline in income

In regard to financial status, people over 60, and even those in their 50s, have markedly lower median incomes than people in their middle years, even after various adjustments are made (for example, for family size). The substantial data available for the United States, for instance, show that, over time, there have been absolute increases in the income and the purchasing power of older people, with a declining share from earnings and a rising share from social security and other retirement benefits (often paid in fixed dollars); however, older people continue to lag behind the young.

To be sure, older people on the average, with their years of asset accumulation mainly behind them, own more and owe less than younger people. Among elderly married couples, substantial proportions (the majority in the United States) own their homes. But assets, which are very unequally distributed, tend to be correlated with income, so that those families with the lowest incomes are also the least likely to have any assets.

What kind of life does the older person's income support? Here again data available for the United States show that he tends to live closely within the limits of his income, spending less than younger age groups for most budgetary items, including leisure items, but spending a larger share for health expenditures when his government has no comprehensive program of medical insurance. His spending is restricted both by age-associated factors (such as reductions in family size after the children leave home) and by his comparatively low income; the income of many older people, when judged by arbitrary standards set by economists, is not adequate to meet their needs.

Education. The age strata of the society are distinguished from one another not only in labour-force participation and in income but also in educational background. Older people have less formal education and less recent education than younger people. Among persons 75 and over in the United States, where the century-long spread of formal schooling accentuates the age differences, more than 70 percent have had only eight years of schooling or less, compared with less than 20 percent of those aged 25 to 29. Moreover, although the average educational attainment of older people is rising, the lag of old behind young persists.

Lower levels of education

These striking age differences in education have widespread ramifications throughout society. Since comparatively few older people are well educated, few of them possess those characteristics, typically valued in Western culture, that are associated with high education. Thus, the less educated majority of older people are less likely than the few who are well educated to remain active; they are more likely to retire. They are also less likely to belong to voluntary associations or to read or to want to learn more. They have lower incomes. They are often less happy and generally less optimistic about the future, but at the same time, they are less introspective and less ready to doubt their own adequacy as spouses or parents. They are more negative in their view of death and think about it more, although fewer of them are disposed to plan for it.

Age categories in the population differ not only in level but also in recency of education. Thus, the content of knowledge and attitudes acquired vary by cohort. The information imparted to doctors or engineers during their training, for instance, differentiates sharply between the backgrounds of old and young. Yet within each cohort, there is a certain age homogeneity in values and beliefs (about what is good, beautiful, or true) among individuals who were educated at the same point in history.

It is interesting to note that one reason education can make such enormous differences among the age strata in modern society is that formal schooling, rather than being spread over the life course, is almost completely concentrated in the early years of life. A person enters adulthood with a fixed educational background that functions sociologically in almost the same way as such inborn characteristics as skin colour or sex. Adult education (a channel that might close part of the age gap) is developing, but it still reaches only small proportions of people in their middle or later years.

Residential setting. Historic changes in population distribution, in community planning, and in the designing and marketing of houses affect the physical and social environment of the older person; influencing the range of his human contacts, his day-to-day activities, and the community services and facilities available to him. In the modernized nations persons who are now old have, to a great extent, been swept along in the massive movements of the population from agricultural to industrial areas, from farms to cities or suburbs. Many of the elderly, however, have been left behind, as age-mates die off and younger generations move away. Moreover, the houses in which most older people live were built in an earlier era. As their houses have aged, the inhabitants themselves have moved along the life course toward increased leisure in retirement, diminished families, and reduced incomes.

In general, however, most older people do not avail themselves of the freedom from occupational and family commitments to move away from their former homes, a fact that gives some indication of the meaning of the older person's home and the factors mediating his relation to his environment. Rates of moving are generally highest among people in the youngest age groups. Moreover, when older people do move they are more likely to move within the confines of their immediate locale than to change their community setting. It thus appears that, basically, the individual's ties to his place of residence become stronger as he grows older. And older people who own their homes, or those who have strong social connections with the neighbourhood, are the least willing to move.

Family status. The social position of the aged is importantly tied to the structure of the family, which has been gradually changing in Western society over the past century. Although this change is usually described as the isolation of the nuclear family (*i.e.,* parents and their children), perhaps it may be more accurately described as the subdivision into two or even three generations of distinct nuclear families: the young couple with their dependent children, the middle-aged parents, and the aged generation of grandparents.

Independence of the aged

As life expectancy has risen, husbands and wives have become increasingly likely to survive together into old age; and widowhood, even if not curtailed in length, has been postponed. Today, in such countries as the United States, Great Britain, or Denmark, in the 65-and-over age range, most men (about two-thirds), but a minority of women (about one-third), are living with their spouses. Moreover, most of those 65 and over, the married and even the widowed, maintain independent households. In the United States this way of living has been increasing, as decreasing proportions of older people live in the same household with their children. Even when households are shared today, the older person is, more often than not, himself the head of the house or the host, not a guest or subordinate in the home of his child. Living entirely alone is a frequent pattern among older people. This is especially true among women, more than one-fourth of whom (mainly widows) live alone. Moreover, the norms appear to favour separate households for older people, except for those who are ill.

Thus a new type of nuclear family, the independent, older family (often a single-person "family") is developing, with little-explored consequences for the older person or for the society as a whole.

The aged individual. The social aspects of old age cannot be understood without reference to the physiological processes that distinguish old people from the young. The age structure of the society is fundamentally affected by biology, not only because there is the succession of births and deaths but also because individuals at different stages of life show important differences in both physical structure and function.

With age, there are declines in the number and quality of vital cells and a decreased ability of the organism to adapt to changes in the environment. Associated with such age-related differences is the fact that the health of older people is generally poorer than that of the young. While older people have fewer acute illnesses, they are more subject to chronic conditions: such impairments as failing vision or hearing or such ailments as rheumatism and arthritis, heart disease, and high blood pressure. In the United States, for example, some four out of five persons 65 and over have at least one chronic condition. Thus there are increases by age in physician visits, in the number and duration of hospital stays, and in the number of days spent in restricted activity or in bed. Nevertheless, only a small proportion of old people are so severely handicapped that they cannot carry on their major activity, whether it be a job outside the home or housework.

Behavioral changes

Physical changes associated with age are related not only to health but also to behaviour, though the causal linkages seem far from clear. When compared with younger people, older people are more likely to show deficits in sensory and perceptual skills; in muscular strength; in the ability to react quickly; in complex sensorimotor coordination (such as that required in driving a car); and, most important of all, in certain forms of memory, in learning and in various aspects of intellectual functioning. There are also age-related decrements for both men and women in sexual activity, though sexual capacity persists at least into the 70s or 80s.

Of course, not all the differences between old and young are necessarily reflective of a biological, or even a social, process of aging. It would be fallacious, for example, to attribute entirely to old age the comparatively poor performance of older people on intelligence tests. In cross-section studies (conducted among several age groups at a single time), intelligence appears to reach a peak among people in their late teens or early 20s and then to decline with age in the older strata. But to infer that intelligence falls off so early in the life course of particular individuals because of age-associated changes (as in general health) is open to serious question, as a few longitudinal studies (which trace individuals over the life course) have begun to suggest. In this instance, the interpretative difficulty seems associated with social change, with the long-term upward trend in education. Intelligence test performance is highly correlated with educational level, and education sets older cohorts sharply below younger cohorts.

Unfortunately, there is little information about trends over time in health, physical functioning, or the associated changes in behaviour. For the population as a whole, to be sure, the rising proportions of older people point to the likelihood of increasing prevalence of the chronic conditions associated with senescence; indeed, there have been increases over the past century in death rates resulting from such illnesses of later life as heart disease or cancer. But it is uncertain whether older individuals today are healthier than older individuals in the past. Medical advance may have improved their physical condition, or it may, by interfering with the principle of survival of the fittest, have yielded a larger but less hardy population.

Whatever the trends may be, the inferior physical state of the older segments of society, in contrast to the younger segments, has both societal antecedents and societal consequences. Health is conditioned by such social factors as standard of living, education, and advances in medicine and public health. In turn, the physical state of older people sets limits to their social adjustment and to the contributions that they can make to society.

How, then, does the older individual respond to a life situation in which he tends to be comparatively disadvantaged both in health and physical fitness and as a member of society? Does he in fact conform to the tragic stereotype of the old person as destitute, ill, facing irreparable losses, no longer integrated into society, and no longer subject to society's controls and sanctions? Is it true, as often supposed, that his feelings are fully reflective of the relatively deprived status of the aged within the society and that he is characterized by a loss of self-esteem, a deprecatory view of his low education, a sense of dejection and despair over his losses, and anxiety about his health, finances, and death? A glance at the available clues shows a picture that is, at least in certain respects, at sharp variance with such a stereotype.

Personality. Old people resemble the rest of the population in many of their personality characteristics, despite certain distinctive types of emotional expressions and modes of adaptation. Thus the aged, in comparison with the young, appear to be more rigid, passive, and introverted, more restrained and cautious, and less oriented to achievement. Age differences in personality and the individual's disposition to organize his behaviour in particular ways cannot be separated, however, from his biological condition and the social roles that he plays. And there is little evidence to indicate how many of the unique aspects of the personality of the older individual are a result of accumulated experience, relative lack of education, inexperience with personality tests, weakened sensory and motor skills, or limited opportunities to test out his ideas on other people.

Degree of neurosis, psychosis, and deviance

Disturbances of thought, affect, or behaviour afflict, in varying degrees, somewhat fewer than 10 percent of the people 65 and over in several localities studied in Europe and the United States. The milder mental disorders (neuroses) do not appear to increase by age. But psychoses (and various psychiatric symptoms experienced as bodily illness) are apparently more prevalent among older than among younger people, both because in later life there are certain conditions connected with the degeneration of the central nervous system and because the older the individual is, the greater his chances are of having any chronic or irreversible disease that does not result in early mortality. Although the burden of mentally ill older people upon families and treatment facilities has undoubtedly been rising over time, the rise is due partly, perhaps entirely, to changes in longevity—to the increasing numbers of people who survive into old age.

There are differences by age in various types of deviant behaviour. For example, crime rates, as observed in disparate times and places, show a consistent decline as age advances beyond adolescence. Moreover, life-course analyses demonstrate a curtailment in criminal behaviour with age even among those who have previously engaged in such behaviour. Thus, in the comparatively rare instances when older people commit criminal acts, these are ordinarily relatively harmless offenses rather than aggressive outbursts against society or acts of violence against other persons. In contrast, suicide is most pronounced in the older age categories, a pattern observed in many countries in both the 19th and the 20th centuries.

Social roles. The older the individual is (beyond the middle years), the fewer social roles he plays on the average (as he retires from work, his children leave home, and his age peers die off) and the fewer and less varied are his contacts with other people and with the environment generally. Individuals are not all alike, however, and social activity is greatest among those aged who are in good health or who come from higher rather than lower socioeconomic backgrounds. Moreover, much depends upon the particular exigencies that permit some older individuals, but not others, to retain their major familial and occupational roles.

Work and retirement

The aging individual faces the culmination of his occupational role and a final period of retirement. For older men today, the modal role is retirement, not work. If they grew up in an era when retirement was not widely institutionalized, they now confront a world increasingly populated by age peers who are no longer full-time members of the labour force.

Those men and women who do remain in the labour force during their later years are not making generally inferior contributions, despite their frequently poorer performance under laboratory conditions. Studies under actual working conditions show older workers performing as well as younger workers, if not better, by most, though not all, measures. (Of course, such age patterns of actual performance are traceable in part to labour-market conditions and to selective processes that allow the retention of the more competent older workers in their jobs.) That there is no necessary decline in creative productivity with aging is evidenced through analyses of the published biographies of contributors to numerous scholarly, scientific, and artistic fields (though widely quoted earlier studies had propounded somewhat misleading contrary findings).

In addition to maintaining their productivity, many older people also take a generally positive view of their occupational role. As compared with the young, older people still in the labour force tend to be more strongly committed to the kind of work they do, to adapt better to the job, and to express greater satisfaction with it. Moreover, despite their inferior education and the lowered aspirations attendant upon age, older workers do not fall very far short of the young in their sense of occupational adequacy or in the emphasis they place on the intrinsic satisfactions of the work itself.

Once older people have retired, they seem on the whole to accept the new role of retired person, although many say that they regret losing their work associates, the feeling of usefulness, the work itself, and the associated earnings. Retirement per se does not appear to have a deleterious effect on health nor does it affect social participation in the other roles of the retired person. To be sure, adjustment to life is generally poorer among retired old people than among age peers who are still working, but this results in part from the selective process whereby the healthier and more advantaged oldsters tend to continue working.

Political roles

Older people, even those with little education, are significantly involved in the political system. They are, for example, at least as likely as younger people to vote. They are better represented among the political elite and in leadership positions in many types of decision making. They are more disposed to keep up with the news and with public affairs through the mass media.

In general, today's generation of older people are more conservative than younger people in their political attitudes. There are important exceptions, however, as on issues affecting their own economic self-interest. In the United States, for example, the old have often tended to support extensions of social security or government health insurance but have frequently voted against school bonds. Yet there is little indication whether future generations of old people, subjected to shifting political climates and to rising levels of education, will perhaps adopt a less conservative stance and a generally greater flexibility of attitude.

Religious and other associations

Religion assumes greater importance among older than younger segments of the society, although research (which is less complete than research on the polity) does not show whether religious values become intensified with aging or whether the older cohorts reflect a stronger religious emphasis in their early training. The aged are more caught up than the young in such personal observances as prayer and reading scriptures, and elderly members of religious organizations benefit from a variety of special programs, such as home visits and nursing homes. Church attendance, however, declines in the oldest years.

In addition to religious and political affiliations, modern pluralistic societies offer a variety of voluntary associations as potential links between older people and the larger community—associations such as clubs, lodges, auxiliaries, and the many other formal organizations to which people belong part-time and without pay. To be sure, membership in such associations is less widespread among older people generally than membership in a church or voting in a national election; and average membership rates show a drop in later life after a rise in the middle years, though individuals vary greatly around this average—depending upon their education and income. The special clubs (such as Golden Age Clubs or Senior Centres) established in many Western countries to provide older people with recreational, educational, health, or welfare services seem to attract comparatively few participants.

Family roles

Old people play a variety of family roles, and they seem no less likely than younger people to feel satisfied and adequate both as spouse and as parent. For those older people who have a living spouse, the marital relationship is of central importance, and older couples share many joint activities; but many of the aged, especially women, must adjust to widowhood.

Most old people play the enduring role of parent. While their children in turn form families of their own, new linkages develop with children-in-law; and grandchildren, even great-grandchildren, proliferate. Living separately from children does not mean complete isolation from them. More than 80 percent of older people who have living children live less than an hour away from the nearest child, and a similar proportion see one of their children at least every week. Bonds with siblings or other relatives are often maintained, and a few old people continue in the role of offspring to parents who have survived into very old age.

The ties of the elderly to their relatives and to their children in particular are by no means limited to visiting. There are also widespread exchanges of material support of various amounts and kinds, ranging from financial contributions and care in illness to baby-sitting and help with housework and home repairs. Contrary to the often-held theory of a one-way flow of contributions to older people, the flow of support between aged parents and their adult offspring appears to be two-directional, from parent to child or from child to parent as need and opportunity dictate.

Although close parent–child ties seem important to both older people and their offspring, the offspring feel closer to their new family of procreation than to their family of orientation. Thus the norms of intergenerational independence seem to operate to reduce the emotional dependence of the elderly upon their adult children.

Leisure

Friends and neighbours play an important part in the lives of many older people, often providing help and services as well as informal contact with the world outside the home. They are, however, generally less important to the aged individual than children and other relatives, serving more as a complement than as a substitute for kinship association. Friendships and neighbourly relations, which tend to be maintained well into later life, are most widespread among older people of comparatively high socioeconomic status and among those who have resided for a long time in the same neighbourhood. Older people tend, though by no means exclusively, to have friends who are similar to themselves in status characteristics (notably age) that reflect common experiences or values.

Maturity yields new increments of leisure time, as commitments relax to parental and later to occupational roles. Many and varied pursuits fill these hours of leisure. Visiting with friends and relatives is an important activity. Much time is devoted, for purposes of information as well as entertainment, to watching television and reading the newspaper. Only small minorities, however, spend their leisure in crafts, hobbies, or intellectual and artistic activities; and vacations and outings beyond the home, particularly foreign travel, are restricted to the few. Indeed, some older people, especially the very old and the disadvantaged, often have difficulty finding anything at all to do.

When the leisure of old and young is compared, varied age patterns emerge for different sets of activities. In the United States, for example, certain types of activities (gardening or walking) seem characteristic of older people. Other kinds of activities (swimming, museum attendance, or playing a musical instrument) are widespread among the young but largely unfamiliar to today's older generation—a possible portent of social changes to come. Thus a "mass" culture may exist at the younger age levels that will permeate society only as these cohorts (generations) reach maturity.

Attitudes and satisfactions. Age is related not only to psychological characteristics and to performance in roles but also to the individual's estimate of himself, his attitudes toward the environment, and his feelings of gratification or deprivation.

Relatively positive self-evaluations

Underlying the several dimensions of his personality, a clear sense of his own identity is experienced by the typical older person. Although conceptions of old age are often assumed to be largely pejorative, the modal older person appears to evaluate quite positively such aspects of the self as his moral virtues or the adequacy of his role performances. At the same time, he minimizes in his self-image many of those aspects that are negative, such as his failing health, his personal appearance, his relative lack of education, or the fact that he is old.

If many older people, even though objectively disadvantaged, fail to take deprecatory views of themselves, the reasons are not entirely clear. By virtue of their long years of life, these people have acquired experience, possible wisdom, and the opportunity to come to terms with themselves. Perhaps they judge themselves less with reference to younger people or to themselves at an earlier age than with reference to others who are at least as old as they.

Older people differ sharply from the young in many of their opinions, feelings, and dispositions toward such central aspects of life as health, personal problems, or death. To a greater degree than younger people, they take aches and pains for granted, put relatively little faith in medical science, and feel they understand their own health best—though the frequency of thinking about health, visiting doctors, and taking medicines rises with age. Certain elements in their conception of physical illness appear also in their outlook on mental illness: the sense of inevitability and incurability and the stricture that the individual should look after himself. They are likely to define their personal problems generally as unchangeable and to stress the individual's responsibility, although they seem ready enough to seek assistance in those instances when assistance is deemed appropriate. Death is typically confronted openly as an inexorable fact. Most older people report that they think about death, are willing to discuss it, and have made preparation for it. Few stress otherworldly aspects, either hope of heaven or fear of a last judgment. Indeed, few show marked fear of any sort, expressing the view rather that death is more tragic for the survivor.

Fatalism combined with stress on individual responsibility

Certain recurrent themes are discernible beneath the myriad specific differences, as old and young define and assess their life situations differently and hence are inclined toward differing courses of action. First, older people tend to have less "sense of mastery" over the conditions of their lives than do younger people, considering the world potentially less changeable. Second, older people tend (paradoxically) to stress the "responsibility of the individual" for his own destiny; whereas younger people are more likely to stress environmental influences. Third, in line with such differences in definitions of the situation, old and young tend to favour different "types of approaches" to life situations. Thus older people, defining many of life's ills as inevitable, may be more disposed to seek palliative rather than corrective or preventive treatment. Or again, if older people attribute to the individual the responsibility for cause and cure of his problems, they may be more disposed to lay exhortation or blame upon him than to attack his social or his somatic conditions. Fourth, when older people do become committed to a particular approach, they may be typically as willing and able as the young to *implement* it. Thus much of the often noted lower activity levels of the aged may perhaps be explained through their differing definitions and evaluations of the situation rather than through any age-related tendency toward generalized passivity.

Such differences in the life attitudes of old and young are probably traceable in part to the differences in educational level and to the impact of the aging process itself. In addition, the differences are undoubtedly reflective of the long-term social and cultural change in which each new cohort (generation) has been socialized to new understandings, norms, and habit patterns.

In some general sense, satisfaction with life (happiness, morale, adjustment) seems to diminish with age. This decline, already apparent in early adulthood, is not peculiar to senescence; but it becomes intensified (as both longitudinal and cross-section studies suggest) with age-related deterioration in health, loss of key roles, or reduction of activity. Thus age appears to be associated with a general diminution of the opportunities for happiness.

Nevertheless, when research is focussed, not upon overall satisfaction but upon more specific reactions to particular areas of life, older people appear to differ from younger people in the kinds of gratifications and anxieties experienced and regarded as salient. The typical older person is as likely as the younger person to seem content with his occupational and familial roles and to encounter no greater problems in them. And despite the objective difficulties confronting him, he appears even less likely to worry about his health, for example, or his finances. Thus, the older a person is, the more nearly he seems to have come to terms with many of the specific conditions of his life.

Many studies of life satisfaction have challenged the provocative notion of "disengagement," conceived by some researchers as a mutually satisfying process of withdrawal between the individual and society in preparation for the incapacitating diseases of old age and eventual death. In the main, the evidence lends little support to the theory, although continuing activity is clearly not a *necessary* condition of satisfaction for all older people. For the majority, however, the sense of well-being is associated with high rates of interaction and contact with the environment—just as adjustment is associated also with good health, with favourable occupational and familial circumstances, and with a high sense of self-esteem.

Programs and policies. The modern stereotypical view of old age as a situation of utter and inevitable disadvantage has often overemphasized the problems and weaknesses of the elderly without paying proper attention to their strengths and their potential contributions to society. In fact, there are many areas of independence and an absence of serious physical disability among the majority of today's aged. Moreover, the relative deprivations of the older population as a whole are offset by numerous exceptions, since there are segments of this population who enjoy adequate education or income or who exhibit high levels of adjustment and interaction with their fellows. Such exceptions serve both to deny the intractability of the current problems of the elderly and to suggest areas in which ameliorative effort is likely to produce needed solutions.

Nevertheless, the deprivations remain. The central fact is that a great many older people nowadays are not filling socially valued roles in the economically developed countries. This fact can be punishing to the individual, and for the society it can be a costly waste of human resources. Concern for this fact—a concern that has become intensified with the multiplying proportions of old people in the population and with the recently emerging power of the medical profession to prolong the lives of many dying patients—has led to the formulation of various policies and programs.

Types of programs. The problems of the aged, like those of the poor or the disabled, have been handled through a wide variety of institutions and arrangements at different times and in different places. In most agrarian societies, the aged have found security in a familistic social organization in which food is shared, oldsters often marry younger mates, or progenitors hold sway over descendants. The family has been bulwarked by such other structures as the church or the guilds in medieval Europe, by private philanthropy and the giving of alms as broadly established in many cultures, or by the building of institutions to house the aged (which existed in Europe as early as the 3rd and 4th centuries).

Comparisons between agrarian and industrial societies

Modern industrial societies, with their complex structures and their large proportions of older people, have developed many special forms of adaptation.

The family is still of central importance to the older person's security (statutory responsibility of adult children for their needy parents continues to exist in a number of countries); today's aged couple, however, with their increased years of joint survival and their tendency to live apart from their children, are likely to depend primarily upon each other, turning to children or relatives only under conditions of special need.

Following the breakup of medieval institutions in Europe, the aged are variously assisted by state intervention, private and corporate philanthropy, religious and fraternal organizations, or labour unions; and private enterprise is often engaged in building housing and residential communities for the aged or in arranging for the delivery of health care or other services to older people. In the United States, for instance, many older people have secured financial protection above the government-supported minimum through private pensions, voluntary health insurance, or life insurance benefits to the bereaved spouse. Only small fractions of those 65 and over (less than 5 percent in the United States and less than 4 percent in England and Wales) are residents of old age homes and other institutions.

Public programs and governmental acts to meet the needs of the aged, from the bread and circuses of ancient Rome to the modern welfare state, have had varying histories in different countries throughout the world—depending upon particular social philosophies; upon the crises created by war, plague, or famine; or upon the maladjustments and dislocations created by basic changes in economic, religious, military, and other social institutions. In England, for example, a series of 16th-century enactments, culminating in the Poor Law of 1601, recognized a degree of public responsibility for the aged, along with the sick and the poor, although the administration was left to the local parish. In subsequent years, various legislative and administrative modifications were made in the law, including the reversion (under the Poor Law Amendment Act of 1834) to an austere system of workhouses in which a uniform, stringent discipline was imposed upon the aged, the sick, and the able-bodied poor. Not until 1925 did England introduce social insurance for the aged (followed in the 1940s by the legislation underpinning the full welfare state system), in which contributions are regulated by law and benefits disbursed without a means test. Meanwhile in Germany Bismarck instituted as early as the 1880s a full program of social legislation, including old-age pensions. Austria, the Scandinavian countries, the Low Countries, France, and Italy followed the German model; and by the mid-1960s, well over 100 countries had social security programs. The United States, slow to yield its philosophy of individualism, long clung to vestiges of Elizabethan-type poor laws, not enacting an old-age pension program until 1935, when, as a consequence of the Depression, the Social Security Act was signed. The basic plan has been supplemented by other federal, state, and municipal programs, including Medicare, Medicaid, the Older Americans Act, income-tax exemptions, subsidized housing and liberal financing of mortgages, and old-age assistance as the last line of income defense. These and many other aids and services to older people have alleviated some of the difficulties and set a floor to older people's income, but they have not brought this income up to the level of younger people.

Poor laws and social insurance

Development of the professions. The extension of programs to ameliorate the condition of older people has enlarged the demands upon the practicing professions. The long-term intrusion of old age and its concomitants into the established professions, though often unnoticed, has increased the likelihood that the physician or nurse must treat the chronic ailments and disabilities associated with senescence, that the architect must provide housing for older couples or widows living alone, that the social worker or minister must deal with persons no longer absorbed in occupations or parenthood, and that the lawyer must advise on the estates of persons who can expect to live well beyond the age of retirement.

Professional aid to the aged

In addition to increasing in numbers within the clientele of the professions, older people have created demands that often require new kinds of services or shifts in professional emphasis. Thus educators may be expected to provide continued education or retraining to adults, mass communicators to forge links between old people and society, or public-health experts to expand the delivery of health care to this segment of the community. Architects and city planners must arrange for nearby facilities (such as stores, buses, medical services, churches, or recreational activities) on which older people in failing health and vigour are especially dependent; and, since the elderly seem loath to move away from familiar surroundings, homes may be designed to allow expansion and contraction, for example, or ranges of housing suitable for all stages of the life course may be planned within a single neighbourhood.

Furthermore, certain developing needs of older individuals, notably their need for help in planning for retirement and for income maintenance, point to gaps in the structures of existing professions. To be sure, advice is proffered by a number of specialists on selected aspects of the older worker's participation in the labour force or on financial management, and thousands of recreation workers offer leisure-time programs for the aged. Yet there is typically no single source of unified advice for the person who is considering retirement, who is seeking to optimize his use of leisure in retirement, or who is attempting to understand the intricacies of social security, pension benefits, insurance annuities, real property, and other assets. This gap becomes increasingly apparent as the mass of today's workers confront the necessity of planning for retirement, suggesting possible future changes in the structure of existing professions to meet developing needs.

The basis in research. The planning of programs and policies and the training of professionals to implement them rests increasingly upon research on old age and on the related processes of individual aging and social change. Early forerunners of research leading to social policy include the monographs of Frédéric Le Play (*Les Ouvriers européens,* 1855), which were used in propaganda for state reform in France entailing patriarchal control in the family; or the detailed house-to-house surveys of Charles Booth (*Labour and Life of the People,* 1889), which led eventually to the Old Age Pensions Act of 1908 in Britain. More general studies of age as an explanatory factor in social behaviour were conducted as early as the mid-19th century, when Adolphe Quetelet made quantitative analyses by age categories of crime rates and suicide rates (*Du système social et des lois qui le régissent,* 1848).

Recent social research on old age has benefitted from the advances of the social sciences generally, from the compilation of basic demographic data for many countries, and from the proliferation of empirical studies in the Western world, particularly in the United States. Research has been stimulated by interdisciplinary groups formed to develop gerontology as a special field (in particular, the International Association of Gerontology and its branches in many countries). The focus of such groups, initially centred on biology and clinical medicine, was extended in the 1950s to include psychology and the social sciences as well. The accumulation of knowledge has been fostered by universities, by foundations, and by governmental and international agencies and has begun to yield not only more rational solutions to practical problems but also a more complete understanding of old age in terms of the dynamic processes of aging and the flow of cohorts through a changing society. (M.W.R./A.F./Ed.)

RACE DIFFERENTIATION

Social relevance of physical traits

Race, in the sense relevant to racism, refers to a human group that defines itself or is defined by others as culturally different by virtue of innate and immutable physical characteristics. Thus, under racism a race is defined *socially* but on the basis of *physical* characteristics. Such physical characteristics have no inherent significance, but only such significance as is socially attributed to them in a given society. If a group in a given society is defined in terms of its skin colour, its hair texture, its facial features, its body build, and so on, then it is a "race," in racist terms. Presumably, if a group were socially defined in terms of sharing a common language, a common set of religious beliefs, or some other cultural characteristic—*without* physical considerations—then it would be an "ethnic group." In the case of both race and ethnic group, the defining criterion is relative to a given society, and the same person or group may be differently defined in different societies. Thus a black North American may be a "Negro" in his own country but a "Yankee" in Mexico. The first label is racial, the second ethnic or cultural.

In practice, the distinction between a "race" and an "ethnic group" is not always clear-cut, and many groups are socially defined in terms of both physical and cultural criteria. Jews, for instance, have frequently been regarded as both a racial and a cultural group. In such equivocal cases, it is necessary to try to determine which criterion is paramount. In Nazi Germany, Jews were primarily regarded as a race, whereas in the Middle East they are more an ethnic group. In any case, the phenomena of prejudice and discrimination that are commonly linked with differences between human groups are not markedly different whether one deals with a race or with an ethnic group. The one essential distinction is that culturally based groups generally tend to be more open and flexible in composition than physically based ones. One can convert to another faith or learn another language, whereas what one can do to one's physical appearance is decidedly limited. It should be remembered, however, that ancestry can mark a person in racist terms even though he may outwardly have no distinguishing physical trait. "Aryans" in Nazi Germany, for instance, were summarily reclassified as "Jews" when search into their ancestry discovered a Jewish forebear, and "whites" in South Africa have been similarly reclassified as "coloureds" after investigation had revealed a non-European ancestor.

Parallel to the problem of distinguishing between race and ethnic group is the problem of distinguishing between racism and ethnocentrism. Presumably, the distinction is that in ethnocentrism the alleged inferiority, disabilities, and negative traits of the outgroup are thought to be culturally determined (and *only* culturally determined), whereas in racism there is a belief that the disabilities are inborn. In practice, however, the cause of the alleged disability is not always made explicit, and it is not always easy to distinguish between racism and ethnocentrism. This is the case, for example, with anti-Semitism, which sometimes takes a cultural emphasis and sometimes a racial one. Ethnocentrism is in reality a much more widespread phenomenon than racism. Indeed, it may be said to be almost universal. Members of nearly all the world's cultures regard their own way of life as superior to that of even closely related neighbours. The exceptions to the universality of ethnocentrism are some of the societies, often small nonliterate ones, that have been conquered by more powerful ones and reduced to the status of a subject people. In some cases, after many years of oppression, some peoples have accepted their conqueror's derogatory views of themselves and flattering view of their masters. Under slavery, great numbers of American blacks, for instance, were psychologically conditioned to consider themselves inherently inferior. Unlike ethnocentrism, racism is far from universal. In fact, as a fully explicit theory of the biological causation of cultural behaviour, it is the exception rather than the rule. Ethnocentrism and racism are not mutually exclusive, of course: racist societies are almost invariably ethnocentric as well; people often feel superior to others on both racial and cultural grounds. Nevertheless, many highly ethnocentric societies are not racist.

Ethnocentric and racial aspects of anti-Semitism

The term racial discrimination denotes all forms of differential behaviour based on race. The most notable form of racial discrimination is, of course, physical *segregation* by race, but there are many others, such as rules of *etiquette* defining forms of address between racial "superiors" and "inferiors," or choice of friends or spouses. *Racial endogamy* (that is, marrying within one's own racial group) is frequently required and almost always preferred in racially stratified societies. *Commensality* rules (rules determining with whom one may or may not eat) are also a very common manifestation of racial discrimination. The term racial discrimination, then, always refers to behaviour and indeed to social behaviour.

A second aspect of racism is *racial prejudice.* Prejudice is a psychological phenomenon; it is defined as an attitude, usually emotional, acquired without, or prior to, adequate evidence or experience. It can be favourable or unfavourable and can develop in a person through suggestion, belief, or emulation. Racial prejudice consists of negative attitudes directed in blanket fashion against socially defined races (not necessarily coincident with biologically defined races).

Although it is important to distinguish between the psychological and social aspects of racism—that is, between discrimination and prejudice—it is equally essential to understand that the two are inextricably related. Prejudice against a certain category of persons could not develop in the minds of individuals unless their society had already set groups apart and subjected some of them to discrimination. Conversely, it is difficult to conceive of a society in which a system of discrimination could exist in the absence of widespread prejudice among members of the discriminating group. Discrimination and prejudice are mutually reinforcing. Prejudice is a rationalization for discrimination, and discrimination often brings forth in the victims those behaviour patterns that seem to validate the prejudice. A white bigot, for example, can easily rationalize the existence of inferior schools for blacks if he believes that blacks are not capable of benefitting from equal schooling. The same bigot, when he compares the competence of graduates of the inferior black schools and

Reinforcing roles of discrimination and prejudice white schools, will find confirmation for his belief that blacks are intellectually inferior.

If there were always a one-to-one relationship between discrimination and prejudice, the distinction would serve no useful purpose. However, this is not the case. There are wide differences in individual prejudice, tolerance, and open-mindedness within a given society. One finds relatively open-minded or unprejudiced persons who live in virulently racist societies and pathological bigots who live in nonracist societies. It is in such cases that one can expect to find discrepancies between the level of prejudice and discrimination. The open-minded white person who lives in South Africa, for example, finds it practically impossible not to be racially discriminatory in his behaviour. The law compels him to be so; and even if he chooses to go to jail in protest, he will be sent to a superior white jail. The reciprocal is also true. The bigot who lives in a nonracist society will often hide his prejudice and refrain from open acts of discrimination. In both cases, the person conforms to social norms in his outward behaviour; that is, he behaves in a manner consistent with the behaviour of the majority but inconsistent with his own attitudes.

A number of studies have demonstrated, however, that such situations are transitory for most people because they are so difficult to live with. Open-minded persons tend to become prejudiced after moving to a racist environment, or at least to become more prejudiced than they would otherwise have been; conversely, prejudiced persons become more tolerant in a nonracist society. These changes in attitudes can be quite rapid, taking no more than a few days or weeks, and changes in behaviour can be nearly instantaneous. Generally, however, there is an appreciable time lag between change in behaviour and change in attitudes, and it is this lag that makes the imperfect correspondence between discrimination and prejudice.

The history of racism. In nearly all the world's societies, men have apparently developed pride in the cultural accomplishments of their own groups and a corresponding derogation of those of their neighbours. Notably, however, the idea that certain groups of people are superior to others because of their genetic makeup does not appear to have been widespread. Where it now exists, it is mostly an outgrowth of the rationalizations of slavery and colonial expansion in the vast territories dominated by European settlers.

Hindu racism. Some scholars have argued that the Hindu caste system originated in a physical difference between the conquering Aryans and the conquered Dravidians. The top three caste levels, or *varṇa*—Brahmin, Kṣatriya, and Vaiśya—were in all probability recruited from the ranks of the Aryans, whereas the fourth *varṇa,* the Śūdra—as well as the "untouchables" who fall outside the scope of the four *varṇa*—were perhaps originally composed mostly of Dravidians. The word *varṇa* means "colour," even though the colours traditionally associated with the *varṇa*s show no relation to skin pigmentation. It is true that in Hindu culture, the colour dualism of white and black has associations with good and evil as it does in the Judeo-Christian tradition, but the link with skin pigmentation is not established. In modern India, there is a weak association between light skin and high caste, and perhaps a slight overrepresentation of lower castes among the darker skinned southern Indians, but skin colour in India is anything but a reliable index of social status. Krishna, the most cherished character in the Hindu mythology, is often represented as a darkly handsome young man frolicking with a bevy of fair girls. Many Indians express a marked aesthetic preference for light skin, especially in women, but, on balance, the evidence that the Indian caste system is racial in origin and that India is or was a racist society is unconvincing. The basic caste dichotomy between "once-born" and "twice-born" was probably related to the *cultural* distinction between Aryan conquerors and Dravidian conquered. The latter were probably darker skinned than the former, but it is not established that this physical distinction was the socially significant one.

Skin colour and Hindu caste

Middle Eastern racial attitudes. The Bible, one of the oldest sets of written documents in the Judeo-Christian tradition, contains no positive suggestion that the ancient Semites were racists. The ambiguous reference in the Song of Solomon ("I am dark, but comely, O daughters of Jerusalem, like the tents of Kedar, like the curtains of Solomon. Do not gaze at me because I am swarthy, because the sun has scorched me. My mother's sons were angry with me, they made me keeper of the vineyard;") might be interpreted as expressing a prejudice against blackness. Several other passages in the Bible, notably the curse of Noah on Canaan in Gen. 9:22–27, have been interpreted by later racists in a racial light, but in themselves they do not necessarily suggest anything of the kind, and, on balance, the evidence is negative.

The same is true of the Qur'ān and the Islāmic tradition in which religious conversion has always been the test of membership in the ingroup. Although it is true that black Africa was the source of many of the slaves in Muslim countries and that, to this day, in some Arab countries a dark skin is a presumptive sign of slave descent and hence of low social status, none of the Muslim countries ever developed a racial caste system. Since the spread of Islām across the Sahara in the early 11th century, it has become by far the most important religion in black as well as in white Africa, and by now approximately one-fifth of the world's and one-half of Africa's Muslims are black. From medieval times, black African kings went on pilgrimage to Mecca with thousands of their subjects and were well received, and Arab writers on black Africa reveal no racism in their writings. They often express admiration for the black Muslim kingdoms that they encountered, and whatever negative value judgments they make are religious or moralistic in nature (such as the disapproval of the nakedness of women). Even the devastation brought about by the Arab slave trade in East Africa in the middle of the 19th century does not appear to have been rationalized on racial terms as European slavery was.

East Asian racial attitudes. Chinese and Japanese cultures have traditionally been conscious of physical differences, especially from an aesthetic point of view, but neither society ever developed a racial caste structure. Even in pre-Tokugawa Japan, where there existed a fairly rigid "estate" system similar to that of medieval Europe, the distinctions were apparently not racial, and the Burakumin caste—an outcast, "untouchable" group that still exists today—is not physically distinguishable (even though one theory, popular in Japan, holds that the ancestors of the Burakumin were anciently Korean war prisoners and slaves). In any event, both Chinese and Japanese express a sometimes marked aesthetic dislike for physical types that are at variance with their own well-established canons of beauty. A 16th-century Chinese mandarin, for example, likened the hairiness of Portuguese sailors to that of monkeys and pronounced the Portuguese totally lacking in the social graces of civilized life, though surprisingly clever and capable of learning. Many Japanese find black skin and other Negroid characteristics unattractive and, since the recent wave of American influence, appear to have adopted some Western canons of beauty, as witnessed by the eyelid operations undergone by some women. The generally inferior status of Koreans in Japan seems to be based more on socioeconomic and cultural than on racial criteria; and the distinctive-looking Ainu minority on Hokkaido Island do not appear to be the target of racial prejudice. Thus, despite narcissistic canons of physical beauty and highly ethnocentric judgments of other cultures, East Asian civilizations do not exhibit what might properly be called racism.

Japanese outcasts

Racism in nonliterate societies. The evidence from the world's many nonliterate societies is fragmentary on the topic of interethnic and interracial relations. There are, however, a few documented cases of indigenous systems of racism not attributable to contact with Western societies. One of the most notable cases is that of the traditional kingdoms of Rwanda and Burundi in the interlacustrine area of central Africa. Until the overthrow of the *ancien régime* shortly after independence in 1961, the population was stratified into three racial castes. The tall, semitic looking Tutsi constituted some 15 percent of the population and, as pastoralist conquerors, ruled over the Hutu horticulturalists. The Hutu, of average stature and distinctly Negroid in physical appearance, constituted a servile peasantry of approximately 80 to 85 percent of the population. At the bottom of the hierarchy was a small group (approximately 1 percent of the total) of pygmoid Twa. The close relation between physical stature and social status made for a truly racist system. The Tutsi claim to superiority was based to a considerable extent on their physical characteristics.

European racism. Far and away the most widespread, enduring, and virulent form of racism and the costliest in terms of human suffering has been that which developed in western Europe and its colonial extensions in Africa, Asia, Australia, and the Western Hemisphere. Western racism is of relatively recent origin. None of the main waves of influence on European civilization seems to have brought racism with it. In ancient Greece and Rome, the status criteria were cultural and not racial. The barbarian was the person who spoke another language. Slavery was a juridical and economic condition unrelated to racial or ethnic origin. The statuses of patrician or plebeian, patron or client, slave or freeman, citizen or noncitizen were all based on strictly nonracial criteria. Although Roman literature is often quite ethnocentric in its judgment of barbarians, differences in physical appearance are generally mentioned neutrally as interesting *exotica.* A number of black Africans must have reached Rome in the last centuries of the empire, and blacks appear on frescoes in a number of Roman sites in Europe and North Africa, but there is no evidence that they were regarded as inherently inferior.

In the Middle Ages, the religious criterion of membership in the ingroup became paramount. Anti-Semitism was clearly religious and not racial in nature and continued so through the Renaissance, the Reformation, and the Wars of Religion of the 16th and 17th centuries. The important thing was whether one was Christian, Moor, or Jew, Catholic or Protestant. Even at the height of religious persecution during the Spanish Inquisition and the Thirty Years' War, acceptance was typically granted in return for a simple public profession of faith. "Race," in any case, was irrelevant.

The anti-Semitic wave that swept Germany in the 1930s and ended in the crematoria of the death camps in the 1940s will hopefully remain the most heinous manifestation of racism in human history. Although Nazi anti-Semitism grew out of a long tradition of religious intolerance in Europe and more especially of victimization of Jews in eastern and central Europe, Hitler's theory of the master race gave it a hitherto unknown genocidal virulence.

Even when Europeans first came into more extensive and direct contact with large numbers of dark-skinned peoples, as a result of their colonial expansion starting in the late 15th century, racism took some time to develop.

The Spanish

The Spanish conquest of the New World was more than averagely brutal, and the economic exploitation of the Indians was thorough; but the Spanish crown quickly settled the issue of the Indians' humanity by declaring that they did have souls worthy of salvation and that they should not be enslaved. It is true that in the Spanish colonies of the Americas, there developed a caste system that was at least partly racial: a fundamental distinction was made between an Indian, a *mestizo* (or mixed-blood), and a Spaniard; but an equally important difference was made between a Spaniard born in Spain and a criollo, a Spaniard born in the colonies. Initially, the Spaniards expressed wonder and admiration for the accomplishments of the Indian civilizations that they destroyed. This did not prevent them from condemning what they regarded as barbarism and idolatry, but there is no suggestion that the Spaniards regarded the Indians as genetically inferior when they first met them. Only after the Indians had been reduced by epidemics, wars, tribute exactions, and countless acts of brutality to the status of an impoverished servile peasantry did negative stereotypes about them develop. The Spanish colonial caste system established in the 16th century was continuously undermined by a dual process of hispanization and miscegenation, which blurred both cultural and racial distinctions between groups. By the time that the criollos gained their independence from Spain in the second decade of the 19th century, the caste system had lost its social significance except in the countries that, like Guatemala, Peru, and Bolivia, were still predominantly Indian.

Muted racism in Spanish America

Today, racism, though not totally absent in Spanish America, is certainly much less prevalent than in other parts of the continent. Cultural criteria are far more important than physical ones in most of Spanish America, even in the heavily Indian countries. In some Latin American countries, the term *mestizo* no longer generally denotes a person of mixed Spanish-Indian descent but instead often designates a person who speaks Spanish as his mother tongue even though he may be of pure Indian ancestry. Many derogatory stereotypes about Indians do continue to exist, and in the heavily Indian countries, Indians continue to be subjected to various forms of social discrimination; but, by and large, an Indian ceases to be regarded as such when he becomes hispanicized in his language, customs, and religion. Racism, as such, is minimal.

The Portuguese

The Portuguese case is somewhat different from the Spanish one. In Africa the initial contacts between Portuguese and Africans were relatively free of racism and relatively peaceful and friendly, except in east Africa, where Portugal came in conflict with Arabs and Persians. There is, for example, a record of a friendly correspondence between the kings of Portugal and Kongo and of an exchange of ambassadors. Starting in the middle of the 16th century, these auspicious beginnings were increasingly compromised by Portuguese military incursions, the sacking of cities, and incessant demands for slaves for the Brazilian plantations. Brazil soon became, with the West Indies and the Southern English colonies of North America, one of the world's three major consumers of black slave labour, and it remained so until the middle of the 19th century. Generally, the Portuguese claim that its colonialism in Africa has been nonracial is correct, at least by comparison with the British, Belgian, and Dutch. This is not to say that the Portuguese regime in Africa has been any less oppressive and exploitative than the regimes of the other colonial powers, but whereas the latter have frequently applied racial tests of discrimination, the Portuguese have been ethnocentric rather than racist.

Complex race relations in Brazil

In Brazil, race relations are quite complex and vary greatly from one region to another. Brazil's reputation as a "racial paradise" appears to most observers to be undeserved; on the whole there is considerably more racism in Brazil than in Spanish America, though much less than in the United States. Consciousness of physical differences is highly developed, and Brazilians use a complex racial nomenclature to describe a score or more of combinations of facial features, hair texture, and skin pigmentation resulting from the intermixture of Afro-, Euro-, and Indo-Brazilians. Certain stereotypes are attached to these physical types as well as an order of aesthetic preference, but the very complexity of the nomenclature itself has made impossible the establishment of any system of racial castes, and members of the same family may frequently fall into different "racial" categories. Thus, Brazil might be described as a highly racially conscious country but without a rigid system of racial castes and without well-defined forms of racial discrimination. Such discrimination as exists is usually a subtle combination of racial, ethnic, and social-class factors, with race frequently not the most important one.

The French

The French, like the Portuguese and Spaniards, tended to be more ethnocentric than racist in their colonial policy of "assimilation," but in practice, like the Portuguese, they failed to assimilate more than a tiny minority of their African subjects. Consequently, except for a few black professionals and intellectuals who were totally integrated in French society, French colonial policy was not all that different in practice from that of more avowedly racist powers. It should also be noted that in Algeria, where there was a European settler population of more than 1,000,000, the French exhibited considerable racism vis-à-vis the Arabs.

The Netherlands and Great Britain were responsible for the growth of the most racist colonial societies that the

The Dutch and English

world has ever known—namely, South Africa, the United States, and Australia. In Australia, racism has taken the form of discrimination against the aboriginal population and the exclusion of immigrants of non-European stock. In the United States, virtual genocide against the Indian groups was accompanied by the institutionalization of a slave plantation system and, after 1865, of racial segregation and discrimination against the "emancipated" Afro-Americans. In addition, a number of states adopted racially discriminatory laws against other nonwhite groups, notably Asians, in the field of immigration, marriage, and political rights. As late as World War II, tens of thousands of American citizens were interned for several years in camps, solely on the basis of their Japanese ancestry.

The South African policy of apartheid has become a byword for racial discrimination and, next to the Nazi policy of genocide against Jews, represents the most extreme and systematic form of racism practiced in a modern society. The white government of South Africa is attempting to create four rigid colour-castes (Europeans, Asians, Africans, and Coloureds), to segregate them physically, and to perpetuate the economic and political privileges of the white minority at the expense of 82 percent of the population. In theory, apartheid aims to establish a "separate but equal" system, but in practice the indefinite maintenance of white supremacy is clearly the objective. Countless laws limit the nonwhite South Africans' rights to travel, own and occupy land, hold meetings, seek work, attend universities, enter public places, marry, vote, and indeed be present almost any place without the consent of the white authorities.

Causes of racial prejudice and discrimination. As a well-developed theory, racism is a fairly recent phenomenon, even in Western history. The 18th century was predominantly environmentalist in its outlook; the science of that day tended to attribute social behaviour either to climatic and geographical environment or to sociocultural factors. Racism as a widely accepted "scientific" theory of behaviour did not appear until the 19th century, which was the age of racism *par excellence.* Although Charles Darwin himself was not a racist, his theory of biological evolution was extended to social evolution, giving birth to the theory of social Darwinism. Mankind was regarded as having achieved various levels of evolution, culminating in the white-European civilization. These stages of evolution were thought to be related to the innate genetic capabilities of the various peoples of the world. By the second half of the 19th century, racism was accepted as fact by the vast majority of Western scientists, and various forms of it were popularized through the writings of Joseph-Arthur, comte de Gobineau, Houston Stuart Chamberlain, Rudyard Kipling, Alfred Rosenberg, and Adolf Hitler.

"Scientific" support in 19th century

By the 1930s the intellectual climate had swung clearly away from racism, and racism had lost its apparent scientific respectability. The social sciences began to adhere to a strict theory of the social determination of human behaviour, to the nearly complete exclusion of biological or physical-environmental factors. Man was held to be almost entirely a product of his culture, and each culture was to be evaluated in its own terms. This cultural relativism was popularized by such anthropologists as Ruth Benedict and Margaret Mead, and the study of race relations became distinctly antiracist in orientation. Gordon Allport, Otto Klineberg, Roger Bastide, Gunnar Myrdal, and E. Franklin Frazier, to name but a few of the prominent scholars active in the 1930s and 1940s, all took the position that such "racial" differences as are found between human groups are attributable to the differential social environments in which they find themselves and not to any intrinsic physical properties.

Most recently the pendulum is once more swinging away from the extreme social environmentalism and cultural relativism that dominated the social sciences until the 1950s. Genetic and biological factors in human behaviour and aptitudes are once again becoming accepted as having at least some importance, although the crude racism, evolutionism, and social Darwinism of the 19th century seem to be permanently discredited.

As a rule, complex social phenomena like racism cannot be explained in terms of a single causal factor. Causation is not only multiple but also often reciprocal, in the sense that A generally is a cause of B and B in turn frequently is a cause of A. This is clearly what happens in the relation between discrimination and prejudice. Each is a cause of the other, and this vicious circle is often difficult to break. The reciprocal causation between discrimination and prejudice illustrates the interplay between psychological and sociocultural variables, and both approaches are essential to a comprehensive understanding of race relations.

Specious popular theories. Numerous theories on the causes of racism have been advanced, some patently false, others partly true; at the present stage of knowledge, only an eclectic but selective acceptance of several of the theories can give a comprehensive view of the phenomenon. Perhaps one of the commonest popular theories to account for prejudice and discrimination (both racial and ethnic) is that it is "their own fault." The theory advanced by most dominant groups in racially or ethnically stratified societies is that the allegedly reprehensible behaviour and qualities of the outgroup causes discrimination and prejudice in the ingroup. This theory, even when it is not made explicit, is often implied in the very definition of the situation as the "Negro problem," the "Jewish problem," the "Asian problem," and so on. It should be clear that such an approach is a *symptom* of racism or ethnocentrism and not an explanation thereof.

"Their own fault" theory

Another unviable theory of the cause of racism is that there is an innate or instinctive repulsion between groups of people who look different. Experiments on young infants have shown that infants could easily be conditioned to scream with fear when a white rabbit entered a room and, conversely, to pet snakes. There seem to be no innate dislikes of any animals in man, much less of relatively minor differences in appearance between members of the same species. If this is true, then there is no intrinsic relation between racism and the sheer presence of physical differences. Physical differences are one of the important conditions facilitating the development of racism once it is there, but they are not a cause of racism. Differences in physical appearance are simply visual stimuli to which prejudices may or may not become attached.

Psychological theories. Several psychological theories about the causes of racial and ethnic prejudice have linked the phenomenon with certain personality traits or with certain responses to social situations. The "frustration-aggression" theory holds that frustration frequently leads to aggression and that this aggression becomes "displaced" onto scapegoats that are quite unrelated to the source of the frustration. Outgroups are frequently blamed for one's frustrations and failures, and this displacement of aggression is often accompanied by "projection"—that is, by the attribution to others of one's own undesirable or unavowed traits. Although a number of experiments have shown that experimentally induced frustration can lead to displaced hostility against outgroups, the theory does little to explain why certain persons are more apt to displace their hostility than others and why certain groups are chosen as scapegoats. It also fails to account for the fact that highly privileged groups can be as strongly prejudiced as groups that have suffered much frustration.

The "authoritarian personality" approach holds that persons who exhibit certain attitudes and personality traits such as respect for power, submission toward superiors, aggression toward subordinates, lack of self-insight, superstitiousness, and contempt for weakness are predisposed to be generally prejudiced against all ethnic and racial outgroups. Numerous studies have shown some relation between these factors, at least in Protestant, Anglo-Saxon cultures, but the theory does not easily account for great differences in levels of prejudice between groups of people who show substantially the same amount of "authoritarianism." Two matched groups of American whites, one Southern, one Northern, for example, showed nearly identical levels of authoritarianism, but widely discrepant levels of anti-Negro prejudice.

Authoritarian personality theory

The relation between personality traits and prejudice seems to vary considerably depending on the social climate. Thus, in societies in which racial discrimination is the norm, as in South Africa, even persons who show little authoritarianism will typically be prejudiced. (This has been referred to as "conformity prejudice" to distinguish such attitudes from the more psychopathological forms of bigotry.) It may also be that, in societies that do not openly condone discrimination, the authoritarian personality is more apt than other personalities to be a bigot. Thus, although attempts to apply this psychological theory at the societal level—as, for example, by explaining the rise of Nazism through the authoritarian structure of the German family—are at best unconvincing, the theory seems able to account for individual differences in levels of prejudice within the same cultural group.

Economic influences. Social scientists have stressed a number of social variables that may be causally linked with prejudice and discrimination. Economic factors are of unquestioned importance. Marxian writers have interpreted racism as a rationalization for slavery and colonialism and also as a means of splitting the working class along colour lines and of deflecting attention from the central reality of class conflict to the ancillary problem of "race." It is certainly no accident that racism flourished at the time of the second great wave of European colonial expansion and the scramble for Africa, and the ideology of colonialism and the white man's burden was often expressed in racist terms. It is also true that racism provided ideological justification for slavery. But slavery antedates the development of racism in Western societies, and some slave societies, notably those of Latin America, have been much less racist than those of English or Dutch origin in North America, the Caribbean, and South Africa.

Non-Marxian writers have stressed the importance of other economic factors, such as competition for jobs, as problems aggravating interethnic or interracial conflicts. Racial segregation in urban ghettos and its resultant conflicts have been linked with the pattern of absentee landlordism in slums and the control of the housing market by realtors and investors. In blatantly discriminatory societies like South Africa the link between racist legislation and the economic interests and privileges of the white minority is obvious. A common form of economic determinism in racial and ethnic relations is the "middleman syndrome." A number of scattered minorities, often of alien origin, are subjected to much the same syndrome of prejudice. Indians in east and South Africa, Lebanese in west Africa, Chinese in Southeast Asia, and Jews in various countries, insofar as they have concentrated in retail trade and middle-level white-collar occupations, have often been the victims of an "anti-Semitic" type of prejudice, being accused of clannishness, rapaciousness, underhandedness, dishonesty, stinginess, and exploitation of the indigenous majority. These stereotypes are due in part to the envy felt toward an alien minority whose living standard is often above the average in the host country.

Minority middleman as bias target

Relations of production—that is, the economic and class position of the constituent racial or ethnic groups within a society—are always of crucial importance in determining the type of relations that exist between these groups. Equally important and closely related to the relations of production are the relations of power between groups. For example, a multiracial society in which a minority exerts a clear domination over a majority, such as is characteristic of colonial regimes, makes for a type of race relations different from that of an ostensibly democratic society such as the United States, where a majority discriminates against a minority. An agrarian, patriarchal state such as characterized the slave regimes of the Western Hemisphere or the Boer republics in the 19th century makes for a type of race relations different from that of a highly urbanized and industrialized country like modern South Africa. The techniques of racial domination, for example, are radically different in a slave plantation and in an urban ghetto. Relations of power determine the legal structure of the society, and many studies have demonstrated the importance of legislation in changing a society either in a more egalitarian direction, as in the United States since the 1940s, or in a more racist one as in South Africa under apartheid.

Religion's role. Religion has also been shown to be related to the amount of prejudice and discrimination. There is an undeniable difference between the more racially tolerant Catholic countries of Europe and their colonial extensions and the more racist Protestant countries. The Catholic Church has frequently taken a more universalistic position and rejected racism, whereas many Protestant denominations, especially the more fundamentalistic and puritanical ones, have often interpreted the Scriptures in a racist fashion. The role of the Dutch Reformed churches in South Africa in supporting apartheid as the will of God is well known, and Protestant Fundamentalism in the United States has sometimes also been deeply racist.

Demographic influences. Numerous racial studies have stressed the importance of demographic and ecological factors in intergroup relations. The demographic ratios between groups, the number of distinguishable groups, and the geographical concentration of these groups within a country all affect the system of intergroup relations. Thus situations in which the dominant group is a majority are different from those in which it is a small minority, and different again from those in which two groups of nearly equal size maintain a competitive balance of power. It also matters whether groups are evenly spread throughout a country or heavily concentrated in a given province or packed in urban ghettos. And the balance of power of course varies according to whether there are two, three, four, or many groups.

Social and cultural factors. The degree of cultural differences between groups is also a relevant factor. Ethnic or racial prejudice is often exacerbated by barriers of language or customs. Acute racial conflicts, however, can also exist between groups that are culturally nearly identical—as between white and black Americans.

Situations of rapid change are often marked by an intensification of racial and ethnic conflicts because one aspect of change is frequently an alteration in the traditional relations between groups. Such changes are commonly perceived as a collective threat, and this makes for outbursts of conflict. The rapid immigration of racially distinctive groups, as in post-World War II Britain, is a case in point. The rapid influx of a hitherto rural group into urban areas can have the same effect, as shown in the urbanization of Afro-Americans in the last few decades.

Conflict from sudden social change

International conflict can have domestic repercussions in intergroup relations, as witnessed by the wave of anti-Japanese racism in the United States during World War II or by the wave of anti-Algerian feelings in France during the Algerian war of independence.

The complex interplay of these numerous social and psychological factors on racial and ethnic relations makes predictions and generalizations hazardous. No single factor ever accounts for more than a fraction of the phenomenon to be explained, and the relative importance of various factors is often difficult to establish.

Effects of racial discrimination. The consequences of racial discrimination are as diverse as its causes. It is useful to distinguish here between psychological and social effects and between those effects on the group that discriminates, on the group that is discriminated against, and on the society at large.

Effects on victims. There is little doubt that psychologically racism is harmful to its victims. The most profound effect of racism associated with situations of extreme degradation (such as is found under slavery or in concentration camps or in racist states like South Africa) is the acceptance by the oppressed group of the dominant group's definition of the situation. This is the phenomenon of self-hatred found, for example, in cases of Jewish anti-Semitism or in the acceptance by blacks of white aesthetic criteria such as the desirability of having straight hair or a light skin. Self-hatred is often accompanied by neurotic symptoms of apathy, anxiety, and depression or by forms of self-destructive escapist reactions such as alcoholism or drug-addiction or, in extreme cases, by paranoid, schizophrenic, or manic-depressive psychoses. In such situations of extreme degradation then, the oppressed group frequently reacts in an "intropunitive" fashion; that is, it turns its frustrations inwardly against the self or the ingroup at large. At the social level, this intropunitiveness takes the form of predatory crimes by an organized underground against the oppressed group. Racial ghettos in the U.S. and South Africa, for example, have very high rates of crimes committed by blacks against other blacks, a phenomenon that is encouraged by the disinterest of the police in providing adequate protection.

When victimized groups do not accept their inferior status or when conditions improve to such a degree that they regain self-respect and conceive of the possibility of changing the status quo, frustration turns outward as hostility and aggression against the dominant group. Paradoxical as it seems, situations of open racial conflict, like other forms of revolution, are generally associated with periods of both relative and absolute improvement in the position of the subjugated groups. Hostility toward the dominant group may take many forms, ranging from nonviolent passive resistance to apolitical crime and politically inspired guerrilla warfare. The search for an identity independent of the dominant group's definition of the situation is often only a preliminary step to concerted political action, frequently violent, to try to overthrow the existing racial order. Group cohesiveness and political militancy replace apathy and self-hatred.

Turning against the dominant group

Effects on the dominant group. From the perspective of the dominant group, the effects of racism are more mixed. Psychologically, racism warps the personality of the oppressor as it does that of the oppressed, though probably in a less devastating way. Racially prejudiced persons living in highly racist societies can behave "normally" in situations not involving race; yet racism, by erecting an irrelevant and artificial barrier between people, strains relations and distorts social perception in the dominant group. Social consequences of racism for the dominant group can vary widely. Generally, in colonial-type situations in which the dominant group is a minority and has entrenched itself in an economically and politically privileged position, the benefits it derives from racism can be considerable. Thus the artificially high standard of living of the white South African population probably can only be maintained by the elaborate apparatus of racial laws limiting the freedom of movement, organization, and employment of the nonwhite majority. Some of those material benefits for the whites are diverted to the maintenance of the repressive apparatus; however, the economic balance remains positive for the whites, even though the total economic cost of segregation for the society as a whole is quite high.

In situations in which the dominant group is in large majority, as in the United States and Australia, the economic benefits of racial discrimination to the dominant group as a whole tend to be much more marginal and are often overshadowed by the costs in conflict, violence, and lost productivity. There are also situations in which the economic effects of racism may be opposite for different segments of the racially dominant group; in the antebellum South, for example, slavery benefitted the slave- and land-owning aristocracy but not the white yeomen and workers.

If one attempts to assess the overall effects of racism on an entire society, one must conclude that they are negative insofar as racism erects an artificial barrier to the full use of talents and often generates destructive conflicts.

Three modes of relations

The reduction of racial discrimination. In practical terms, situations of racial discrimination and conflict may be reduced to three broad types:

Segregationist or apartheid societies. In societies like South Africa, it is clearly in the collective interests of the racially dominant group (typically a minority) to maintain the status quo. The reduction of racial discrimination in such cases can come about through a drastic change in the power structure (as it did in the U.S. South as a result of the Civil War) or it can come about in evolutionary fashion (as it did in colonies ruled by Great Britain); but, in any case, the new ruling group no longer feels the need to defend its interests by maintaining a racial caste system.

Pluralistic societies. Those societies in which several racial groups, none of them clearly dominant, compete for power and economic resources (as in some parts of Africa and Asia) probably offer the widest range of alternatives for the reduction of racial tensions. Racial and cultural assimilation may reduce differences and blur old lines of cleavage. Or a more amicable modus vivendi may develop from changes in government policy, the spread of a broader nationalist ideology, or changes in the economic and political structure making for a more democratic society. When conflicts escalate to chronic violence and civil war, political partition and emigration are other possibilities for reducing tensions.

Societies publicly committed to ending racial discrimination. In some societies, as in Australia and the United States, official government policy is often against racial discrimination and has to contend both with the inertia of conservative opinion from the dominant group and the "revolution of rising expectations" from the hitherto subordinated group.

There seem to be two basic approaches to the alleviation of racial tensions in this third type of society, assuming an official desire to do so. One is to attack racial prejudice by educating the public. There is abundant evidence that people's attitudes can be changed by propaganda and that behavioral changes follow changes in attitudes; but there is also evidence that as a method to bring about rapid social change in a conservative population, this approach is relatively expensive and ineffective. In terms of practical consequences, it may be more important to reduce racial discrimination than racial prejudice, and, hence, it follows that the strategy of attacking discrimination is frequently more directly effective.

Dilemma of means and ends

Legislation is undoubtedly one of the main ways of destroying racial discrimination, provided it is followed by forceful implementation. This often entails a dilemma of means and ends: the achievement of a more democratic society may imply the use of force against a majority—a policy that democratically elected governments are naturally loath to adopt. Consequently, attempts to outlaw various aspects of racial discrimination (for example, in housing and employment) have frequently failed to bring about the rapid change that was intended because of a lack of determined implementation. The delays in school integration in the United States can be considered a case in point. By contrast, integration in the U.S. armed services has been more rapid and thorough, largely because it was done autocratically.

At the economic level, it is clear that the profit system of production helps to perpetuate disabilities for racial minorities. High returns on slum property, for example, are one of the factors making for the persistence of racial ghettos in the United States. Racial discrimination in housing creates an artificial scarcity of housing for blacks, who are thus forced to pay higher rents than their white counterparts. This makes for high returns on investments in the black areas that, because of high population density and municipal neglect, quickly become slums. Other economic systems, such as the "consumer credit," are also known to discriminate against the poor and thus to affect racial minorities disproportionately. Reforms in the economy might be effective in reducing racial discrimination, but the realistic prospect of such reforms in the United States is limited.

In the last analysis, the most effective way of reducing racial discrimination may be militancy on the part of the groups that are discriminated against. When such groups are large enough to affect the outcome of elections and when the political system is democratic enough to give the voters some real alternatives, political action can be effective within the constitutional framework. When such conditions are lacking, political action ranging from civil disobedience to guerrilla warfare has been known to bring about important changes. (P.L.v.d.B./Ed.)

SOCIAL STRATIFICATION: CLASS

Although the economic basis of classes has been generally recognized, many disagreements have arisen as a result of attempts to define social class. First, there has been confusion about how widely the concept should be employed. It was used initially to denote the social groups that emerged in postfeudal societies, but it was then applied to the divisions in a wide range of societies. James Madison, for example, said in *The Federalist:*

> Those who hold property and those who are without property have ever formed distinct interests in society. Those who are creditors, and those who are debtors, fall under a like discrimination. A landed interest, a manufacturing interest, grow up of necessity in civilized nations, and divide them into different classes, actuated by different sentiments and views.

Similarly, Marx and Engels in *The Communist Manifesto* spoke of "freeman and slave, patrician and plebeian, lord and serf, guild master and journeyman" as being engaged in class struggles and regarded the distinctive feature of modern societies as being merely that the class antagonisms have been simplified, so that society is more and more splitting up into "two great classes directly facing each other: bourgeoisie and proletariat." In an unfinished chapter on social classes in *Das Kapital,* it seems to have been Marx's intention to confine the use of the term class to the "three great classes of modern society": wage labourers, capitalists, and landowners.

A major problem is that of choosing between a definition of class that would make it possible to apply the concept to all forms of society—ancient city-states, early empires, caste society, and feudal society, as well as to modern capitalist societies—while taking into account the specific characteristics of each of these forms; and a definition that would confine the concept to the social divisions in modern societies, treating other forms of society as having quite different kinds of stratification, arising from other factors besides the ownership of property. It is difficult, for example, to apply the concept of class to the traditional Indian caste system, which seems to depend, to a large extent, upon occupational differentiation and religious distinctions and which also seems to result in a fragmentation of society that is an obstacle to the formation of broad social classes (see below *Social stratification: caste*).

Even when the term class is applied to modern societies differences of view arise about its scope and meaning. Some of these differences result from disagreements concerning the relations between classes and the influence of classes in political life, and they will be more fully considered below. There are also problems, however, in distinguishing classes in a precise way from elites, status groups, or interest groups. The concept of elite, for example, was elaborated by the Italian sociologists Vilfredo Pareto and Gaetano Mosca as an alternative to the Marxist concept of the ruling class, and, although it has not been used consistently in this way, it does still overlap, to some extent, with the notion of class. Among recent writers, an American, C. Wright Mills, used the term power elite instead of ruling class (1956), in order to avoid the assumption that political power is always based upon property ownership; others have made a careful distinction between elites and classes and have been concerned to examine the nature of the connection between them.

Classes and elites

The distinction between classes and status groups was made most clearly by the German sociologist Max Weber, who regarded the former as being based upon economic interests, while the latter were constituted by evaluations of the honour or prestige of an occupation, cultural position, or family descent. But this distinction also has not always been observed, with the result that individuals having roughly the same social prestige, such as those in a particular category of occupations, have sometimes been regarded as forming a class.

It is also necessary to differentiate between social classes and interest groups, even though classes themselves may be regarded as being, in a very broad sense, interest groups. In modern societies, particularly, interest groups are numerous. They include many occupational associations, as well as cultural, recreational, regional, and other groups that pursue their special interests by a variety of means. The number of social classes is, in the view of all writers on the subject, much more limited, and classes may be seen as pursuing the more general economic and political interests of their members and as being involved, to some extent, in shaping and changing the character of society as a whole.

Another major disagreement in the definition of social class exists between those who regard classes as real social groups, possessing a class consciousness and exhibiting a distinctive culture and style of life, and those who treat "class" as an analytical construct, useful for some purposes in distinguishing categories of individuals on the basis of their income, education, or occupation. The first kind of definition is to be found in Marxist theory, which is concerned particularly with the historical development of classes as social groups having a determining influence upon the course of social events. Marx himself sketched a historical account of the rise of the bourgeoisie and, subsequently, of the proletariat (see especially, *The Poverty of Philosophy,* 1847) and made a distinction between the "class in itself" (that is, a collection of individuals who were placed in similar economic conditions) and the "class for itself" (that is, a more or less organized group, pursuing in a conscious fashion definite economic and political ends). Among later Marxist writers, the Hungarian philosopher and critic György Lukács, in several essays collected in *History and Class Consciousness* (1923), emphasized the importance of class consciousness, while introducing a new element in his account of the role of revolutionary intellectuals in the formation of such a consciousness. It is, however, not only in Marxist theory that the idea of class, in Marx's latter sense, has prevailed, since non-Marxist sociologists have made studies of working class, middle class, and upper class as distinct communities; and Weber regarded class as one of the most important bases for communal action.

Marx's two concepts of class

The concept of class as a collection of individuals sharing similar economic circumstances has been used widely in censuses and in studies of social mobility. Thus, the Office of Population Censuses and Surveys in Britain makes use of five broad categories of social class, based on an occupational classification; and studies of social mobility, examined below, have generally employed categories formed in a similar way by grouping together occupations that are regarded as being at approximately the same level in the social hierarchy. Some other sociological studies have made distinctions between categories of individuals in terms of prestige, without paying much attention to questions concerning the formation and development of classes.

Theories of social class. Many disagreements over the definition of class are bound up with differences in theoretical approach, involving divergent conceptions of the importance of classes in the social structure and of the nature of the relationship between classes. Theories of social class were only fully elaborated in the 19th century as the modern social sciences, especially sociology, developed. Earlier writers, although they could not fail to observe the existence of great economic inequalities in their societies, did not attempt to formulate a general theory of the causes and consequences of such inequalities. At the most, they reflected, as did Plato and Aristotle, upon some of the more prominent features of social stratification and proposed ideal systems that would be conducive to political stability and rational government. Plato thus advocated a society divided into three classes—guardians, auxiliaries, and workers—in which the guardians would form a disinterested ruling elite, while Aristotle recognized in society three elements—the very rich, the very poor, and those in the middle—and considered the best political system to be that in which the middle strata had a preponderant influence.

Class relations in the political theory of Plato and Aristotle

Pre-Marxist views. In the 17th and 18th centuries a new discussion of social inequality and stratification began, provoked largely by the challenge to aristocratic rule from the bourgeoisie. In the writings of the English political philosophers Thomas Hobbes and John Locke there was developed an individualistic theory of property, corresponding with the growth of a market economy, which either assumed, in Hobbes' case, an equality among men, a struggle between individuals needing to be regulated by a powerful state, and the absence of cohesive classes; or, in the case of Locke, accepted the existence of a division between property owners and a labouring class. The French political philosopher Jean-Jacques Rousseau, in an essay on the origin of inequality (1755), made a distinction between natural inequalities and those that resulted from social conventions, but he conceived society in terms of the relations between individuals rather than between classes. Madison, writing in a society which had declared the principle of human equality and in which few aristocratic privileges existed, was more aware of the social divisions that might arise from divergent economic interests, and his emphasis upon the distinction between the owners of property and those without property foreshadows one of the important elements in Marx's theory. Madison, however, went on to distinguish a considerable number of interest groups as the basis of political factions, and he was far from conceiving society as a class system in which one class must necessarily dominate others.

Other writers in the later 18th and early 19th century who contributed elements of a theory of social classes include the Scottish philosophers Adam Ferguson and John Millar, in whose works a distinction was established between civil society (*i.e.,* the nonpolitical elements in society, such as the economic system and the family) and the state. The conditions of civil society, especially the property system, were seen as determining, to a large extent, the form of political life. This idea was expounded by the French social theorist Saint-Simon (1817), who argued that government was only a form that corresponded with the character of the underlying system of production and who analyzed the changes in production that led to the decline of the feudal ruling class and the rise of the new class of industrialists. In the writings of Saint-Simon's Socialist followers, a theory of the proletariat was first adumbrated (1824). A later work, by the sociologist and legal theorist Lorenz von Stein (1842), developed a conception of the proletariat as a major political force in modern society. This directly influenced the development of Marx's theory.

Another contribution to the theory of class came from political economy. In Adam Smith's *Wealth of Nations* (1776) the principal emphasis was upon social differentiation and stratification resulting from the division of labour, but the English economist David Ricardo (1817) treated the main factors of production—land, labour, and capital—as constituting economic interest groups or classes, between which there was a profound clash of interests.

Marx's analysis. These diverse elements were brought together in Marx's theory of class, which has dominated all later discussion. In the passage quoted earlier, Marx disclaimed any credit for having discovered the existence of classes or the conflict between them; what he had accomplished, he claimed, was to show: "(1) that the *existence of classes* is only bound up with *particular historical phases in the development of production,* (2) that the class struggle necessarily leads to the *dictatorship of the proletariat,* (3) that this dictatorship itself constitutes only the transition to the *abolition of all classes* and to a *classless* society." The starting point of his theory was an elaboration of the distinction between civil society and the state. The anatomy of civil society, according to Marx, was to be found in political economy. What distinguishes one type of society from another is its mode of production (that is to say, the nature of its technology and division of labour), and each mode of production engenders a distinctive class system in which one class controls and directs the process of production while another class is, or other classes are, the direct producers and the providers of services to the dominant class. The relations between the classes are antagonistic since the classes are in conflict over the appropriation of what is produced; and, in certain periods, when the mode of production itself is changing as a result of developments in technology and in the utilization of labour, such conflict becomes extreme and a new class challenges the dominance of the existing rulers of society. The dominant class at any time controls not only material production but also the production of ideas; it thus establishes a particular cultural style and a dominant political doctrine, and its control over society is consolidated in a particular type of political system. The subject classes and especially a class that is growing in strength and influence as a consequence of changes in the mode of production generate political doctrines and movements in opposition to the ruling class.

Marx's view of the inevitability of class antagonism

The theory of class is at the centre of Marx's whole social theory, for it is the social classes formed within a particular mode of production that are regarded as establishing a specific form of state, animating political conflicts, and bringing about major changes in the structure of society.

Marx distinguished several historical types of society: "In broad outline we can designate the Asiatic, the ancient, the feudal, and the modern bourgeois modes of production as progressive epochs in the economic formation of society" (1859). But Marx and the Marxists who followed him did not undertake any detailed historical studies of earlier forms of society, and he was not able to set out a convincing empirical account of the development of social classes over the whole span of human history. He restricted his analysis of class structure mainly to modern capitalist society, and he was concerned above all with the rise of the proletariat, the progress of its struggles against the bourgeoisie, and the conditions arising out of the capitalist system of production that would make possible a successful working class revolution and the inauguration of a new type of society that would be without classes.

Views of Max Weber

Post-Marxist analyses. Later theories of class have been concerned in the main to revise, refute, or provide an alternative to the Marxist theory and, in a similar way, have been concentrated upon the development of classes in modern capitalist societies. In recent years, however, a growing amount of attention has been given to the formation of new classes in the Socialist societies of eastern Europe and in the developing countries. The German sociologist Max Weber was one of the first to undertake a critical revision of the Marxist theory, mainly in his essay on class, status, and party (1922), but, in more general terms, in many of his writings. Weber, in the first place, questioned the importance attributed to social classes in the political development of modern societies and in the causation of major social changes. In his view, capitalism had been brought into existence by the influence of certain ideas and especially by the influence of Protestantism on economic behaviour, as well as by the economic interests of the bourgeoisie. He also argued that the development of the European countries in the late 19th century had been affected by nationalism as much as it had by class ideologies and movements. There was another factor, too, that limited the significance of class as a basis of political action, namely, the existence of social stratification in terms of social honour or prestige, which cut across class divisions and tended to produce a condition of social harmony in which peaceful competition and emulation prevailed, rather than an increasingly intense class struggle. More generally, Weber contested Marx's view of the future development of capitalist society, for, whereas Marx envisaged the successful outcome of the working class struggle as the creation of a liberated classless society, Weber foresaw a continuation of the increasing organization of social life and a monstrous growth of bureaucratic regulation, which would attain its greatest extent in a Socialist society.

From a different aspect, Pareto and, in a more qualified way, Mosca also rejected Marx's division of society into contending classes and propounded instead a theory based upon a distinction between the "governing elite" and the masses. Pareto praised Marx's conception of the class struggle as a major contribution to social theory but then transformed it into the idea of a conflict for the possession of political power between an established elite and a rising elite. This conflict resulted, throughout history, in the substitution of one ruling elite for another, while domination and exploitation of the masses continued; in Pareto's view there is no progressive movement toward a classless society as Marx thought. This notion of the rise and fall of ruling elites is to be found in much modern writing on the class structure; it appears, for example, in the U.S. economist Thorstein Veblen's account (1921) of the rise of the engineers (though, in other respects, Veblen remained closer to the Marxist theory) and in recent discussions of technocracy.

The extent and significance of class conflict

One of the most important issues that has divided social theorists in their analysis of class structure has been, in fact, the assessment of the extent and significance of class conflict. Those who have opposed the Marxist theory most strongly have focussed attention on the functional interdependence of classes and their harmonious collaboration. The sociological theory known as functionalism, which attained its greatest influence in the United States, has developed this theme. Functionalism stands quite clearly in a general opposition to Marxism by virtue of its unhistorical approach, by its emphasis upon the regulation of social life by values that are more or less universally accepted in a given society, and by the importance that it assigns to social integration as against social conflict. Functionalism does not offer, in the strict sense, a theory of class. Its concern is with stratification as it arises from social differentiation and the evaluation and ranking of mainly occupational roles. The functionalist writers, therefore, take up the problem of social status, in the sense in which Max Weber distinguished this from the problem of social class, and they deal with the placement of individuals in the social hierarchy rather than with the formation of distinctive social groups.

Although the attention given to social status grew considerably in the two decades after 1945, partly under the influence of functionalist ideas, problems of class were far from neglected. Indeed, renewed reflection upon the nature and significance of social classes was stimulated by changes in class structure that seemed to be taking place, especially in Western industrial societies.

The theme of the relation between class and politics has figured prominently in most recent discussions. It is argued that in the new "postindustrial" society, which many believe is now emerging, the ruling class is no longer the property-owning bourgeoisie but the technocrats and bureaucrats who direct the process of technological innovation and economic growth; and the opposition to their rule is led not by the working class but by those groups that feel most keenly their dependent position and their exclusion from genuine political participation. Social conflict has therefore assumed a directly political character, instead of arising from economic antagonism.

The Marxist theory of class has thus been questioned in several respects. First, it has been claimed that classes in capitalist societies have tended to lose their distinctive character, while the antagonism between them has declined to such an extent that it no longer produces serious political conflict. From this point of view it may be argued that the class system has lost much of its social significance and that gradations of social status are now more important in determining the actions of individuals and groups. On the other side, however, it is suggested that although the major social classes of 19th-century capitalism have declined, new social classes are being formed in the advanced industrial societies (both capitalist and Socialist) that are beginning to engage in social struggles of a new kind. Furthermore, there are Marxists who would contend that, despite the uncertainties produced by the economic and social changes of the past few decades, the division between bourgeoisie and proletariat remains the fundamental source of conflict in society and continues to be expressed in the ideologies of vigorous social movements. These theoretical disagreements are far from being resolved, but further light may be shed on the problems that they pose by considering some of the ways in which differences between social classes have been characterized.

Characteristics of different social classes. In spite of controversies over the theory of class, there is a large measure of agreement among social scientists on the characteristics of the principal social classes, especially in modern societies. A distinction is habitually made between the upper class, the middle class, and the working class, but this needs to be refined and supplemented in various ways. Some writers have used the term lower class to refer to the working class, but others have distinguished a lower class, or lumpenproletariat, from the main body of the working class. This lower class may comprise particular ethnic groups, such as black and Mexican workers in the United States, and immigrant workers, such as those recruited from former colonial territories and from southern Europe by the industrially advanced European countries, as well as casual and unskilled workers in backward regions and declining industries, all of whom are characterized by exceptionally low levels of living, economic insecurity, and lack of social rights.

Conventional class divisions

It is also necessary to take account of the peasantry as a distinct social class, though it was neglected for a considerable time by Western social scientists. In many European societies there are still a substantial number of peasant cultivators; and in the Socialist countries of eastern Europe, in particular, a description of social classes cannot ignore the development of the peasantry and its relations with other groups in society. The importance of the peasantry has also been more fully recognized in recent years because of the role of political movements based largely upon peasant support in the developing countries. Marx's view of the peasantry as a predominantly conservative element in society and as a group that was unlikely to evolve an independent political consciousness or organization has been modified or abandoned by later Marxists. Radical social thinkers are now more inclined to attribute a major revolutionary role to the peasantry, or to large sections of it, in the countries of the Third World.

The delineation of the principal social classes does not imply that these classes have exactly the same character in all modern societies nor that they are entirely homogeneous groups. Nevertheless, there are broad differences between classes and common characteristics within them that make the distinction valid and useful.

The upper class. The upper class in Western capitalist societies is distinguished above all by the possession of largely inherited wealth. In Great Britain, for example, some 40 percent of all personal wealth is concentrated in the hands of the top 1 percent of property owners; in the United States, where the distribution of property is rather less unequal than in most European countries, the top 1 percent still owns about 30 percent of all personal property. Since the beginning of the 20th century, this concentration of wealth has tended to diminish in most countries, but the wider diffusion of property ownership is still mainly confined to the upper 5 percent of the population. The ownership of large amounts of property and the income derived from it confer many advantages upon the members of the upper class. They are able to develop a distinctive style of life based upon expensive cultural pursuits and leisure activities, from which the great majority of the population is excluded, to exert a considerable influence upon economic policy and political decisions, and to procure for their children a superior education and economic opportunities that help to perpetuate family wealth.

Whether these characteristics make the upper class a ruling class in the Marxist sense is still vigorously debated. The question involves considering how far major political and economic decisions are influenced by the general interests of the upper class and how far this class is preeminent as a source of recruitment of top decision makers. On one side, it is argued that the upper class of large property owners provides the elites—economic, political, military, and intellectual—that determine the main course of a society's development, while, on the other side, it is claimed by the pluralist political thinkers that decision making results from the activities, often conflicting, of many different groups in society, none of which is clearly or permanently predominant.

The "new class" of Socialist societies

In the Socialist societies of eastern Europe, personal wealth obviously has little significance in the formation of a class, but it has been argued by the Yugoslav writer Milovan Djilas that a new upper class, indeed, a ruling class, has emerged in these societies on the basis of the possession of political and administrative power. The members of this class are not able to accumulate personal property on a large scale but can acquire in other ways all kinds of privileges—in housing, education, travel, and consumption—that enable them to develop an exclusive style of life. One difference from Western capitalist societies is that such advantages are less easy to transmit by inheritance than is private property, and for this reason an upper class in the Socialist societies is likely to be less stable in its membership over time. Nevertheless, some advantages may well be transmitted as a result of the privileged access to higher education and to important jobs that the children of upper class families enjoy.

Although the upper class in most societies shows a considerable degree of continuity in its membership from generation to generation, changes do occur through the rise and fall of individuals and groups as a result of changes in the social structure, the occurrence of exceptional ability or lack of ability in particular individuals, or by sheer chance. Such changes are particularly evident in many developing countries, and there may be considerable variations in the composition of the upper class. In some countries (as, for example, in Latin America or in the Middle East) large landowners may still form an important element in the upper class, though their preeminence is being challenged by the rise of a business class. Elsewhere, in Asia and Africa, nationalist political leaders who rose to prominence in the course of struggles against colonial rule and high officials or military leaders may form the nucleus of a new upper class, while in those countries in which revolutions have occurred, as in China, the new elites may be largely recruited from the working class and peasantry. They may tend, as in the countries of eastern Europe, to draw together in the formation of a new upper class, although some aspects of the Chinese cultural revolution seem to have been directed against such a development.

The working class. The principal contrast with the upper class in the industrial societies is provided by the working class, constituted essentially by manual workers in extractive and manufacturing industry. What characterizes the working class as a whole is lack of property and dependence upon wages. With this condition are associated relatively low levels of living and of education, restricted access to secondary and higher education, limited opportunities for leisure and cultural activities, and exclusion, to a large extent, from the spheres of important decision making. There are, of course, considerable differences within the working class, and a distinction has commonly been made between skilled, semiskilled, and unskilled workers, corresponding broadly with differences in income level. More recently, social scientists have emphasized the difference between the relatively prosperous workers in modern expanding industries and the less prosperous workers in some of the older industries.

There have been significant changes in the condition of the working class over the past few decades. Levels of living have risen, although as a consequence of general economic growth rather than any major redistribution of wealth and income; and access to education has improved, though it is still the case, in most countries, that a very small proportion of working class children enter higher education and hence make their way into the occupational and social elites. At the same time, the economic security of most workers has been increased by policies of full employment and by more extensive welfare services. These changes were widely interpreted during the 1950s as the *embourgeoisement* of the working class—that is, as an erosion of its distinctive characteristics and its gradual assimilation into the middle class. Such accounts have, however, been examined more critically in recent years, and the extent to which the working class remains socially, culturally, and politically distinct from other groups in society has been emphasized. The idea that the advanced industrial societies were becoming "middle class societies" and that this condition had already been more or less attained in the United States, which developed from the *embourgeoisement* thesis, was also sustained by the general shift in the economy from manufacturing to service industries, which involved a relative contraction in the numbers of manual workers and an increase in the numbers of clerical, technical, and professional workers. Thus, although there are still disagreements among social scientists about the size of the working class and the general features of its development, it can scarcely be denied that some important changes have occurred that require, at the least, a reconsideration of the Marxist theory of its political role.

The *embourgeoisement* thesis

It is evident that the position of the working class varies quite widely from one country to another. In some European countries, notably in France and Italy, a large part of the working class is strongly influenced by Marxist ideas and supports political parties that aim to bring about revolutionary changes in society, whereas in other countries—in Great Britain, West Germany, and Sweden, for example—the main working class parties are reformist in their policies. In the United States, on the other hand, there has been no major independent political movement of the working class since World War I, and class consciousness has had much less influence in political life than has been the case in Europe. These differences cannot easily be explained in general terms, but it has been observed that working class consciousness was more intense and took a more revolutionary form in those European societies in which the development of capitalism was slower and more backward than elsewhere; and this observation would apply also to Russia before 1917. In the case of the United States, the failure of a political movement of the working class to develop on anything like the European scale has been accounted for in various ways: by the exceptional opportunities for mobility (or at least the strong and pervasive belief that such opportunities existed), by the fragmentation and disruption resulting from massive immigration, by the existence of a large black lumpenproletariat, and by the divisions in the working class movement that were produced by World War I and the Russian Revolution. At all events, it is clear that the working class in different countries has assumed different characteristics and has espoused very diverse ideologies.

The middle class. While the upper class and the working class can be viewed as relatively homogeneous groups quite sharply differentiated from each other, the middle class often has been treated as a more varied, residual category, comprising those groups, mainly defined in terms of occupation, that do not clearly belong to one of the other classes. Marx, for example, referred to the "intermediate and transitional strata" that obscured the boundaries of the principal classes. Generally speaking, the middle class has been taken to include the various levels of clerical workers, those engaged in technical and professional occupations, supervisors and managers, and self-employed workers, such as small shopkeepers, farmers, and (in some societies) the wealthier peasants. At the top—in the case of wealthy professional men or managers in large corporations, for example—the middle class merges into the upper class, while at the bottom—where routine and poorly paid jobs in sales, distribution, and transport are concerned—it merges into the working class. When a contrast is drawn between middle-class and working class styles of life it is often based implicitly upon "ideal types": the middle-class individual is conceived as a professional or senior clerical worker, the working class individual as a factory worker.

Middle-class divergencies in social and political outlook

To some extent, these distinctions within the middle class are recognized by references to the upper middle class and lower middle class, but there are other differences that do not coincide exactly with this division. There is, for example, considerable diversity of social and political outlook in the middle class: in Western societies the predominant political attitudes may range between liberal and conservative, but in some conditions a part of the middle class, at least, may adopt extreme right-wing views (as in its support for National Socialism in Germany); and, on the other hand, there is a well-known phenomenon of middle-class radicalism, which became more prominent during the 1960s with the development of the largely middle-class student movement. Other distinctions arise from longer term historical changes in the composition and social situation of the middle class. The "old" middle class, with which Marx and other 19th-century writers were largely concerned, consisted chiefly of small independent producers and independent professional men; the "new" middle class of the late 20th century is made up primarily of employees in public services and in large business enterprises at various levels of clerical, technical, and professional work. This transformation seems to have produced a greater diversity, fluidity, and uncertainty in the cultural and political character of the middle class, so that to speak of the advent of middle-class societies, as the numbers of the new middle class increase, may not provide any clear indication of the form that such societies will eventually take.

The industrial countries resemble each other in their occupational structure, and the development of occupations under the influence of technological innovation and economic growth is also similar, but this does not prevent considerable differences in the class structure. There is, as has been noted, an important distinction to be made between the Western capitalist countries and the Socialist countries of eastern Europe in respect to the character of the upper class or elites, and other classes in these two types of society may also show important differences, especially in their social outlook and political involvement.

International comparisons. It is difficult to make rigorous comparisons of the character of different classes in different countries, since comprehensive studies of the class system are lacking, especially in the Socialist countries, though a major study in Czechoslovakia (1969) provides much valuable information. Even within Western societies there is much diversity, and the degree of class consciousness and class conflict, in particular, varies widely from one country to another, as well as fluctuating over time. One observer, for example, wrote in 1914 of the first decade of the 20th century that it was a turning point in American society, when deep class feeling found expression in both political parties and brought to public attention the existence of a profound conflict between great wealth and the lower middle and working classes; but the feeling, and the conflict, subsided again, and in spite of a limited revival of class consciousness in the 1930s the general character of American society has been one of ideological classlessness. In most of the European countries, though, class consciousness has found expression in distinctive parties, and class conflict has been overt.

Classes in the developing countries

In the developing countries, modern social classes exist, for the most part, only in embryonic form. It has been observed already that the upper class in these societies may be far from homogeneous or stable and may include such disparate elements as feudal landowners, capitalist entrepreneurs, nationalist or revolutionary leaders, higher castes, and military chiefs. In those countries in which industrialization is not far advanced, the urban working class will be small, and, if the workers have only recently migrated to the towns, as is the case in many African and Asian countries, there may be little development of class consciousness. Similarly, the middle class is likely to be small, although some sections of it may be particularly privileged and influential by virtue of the educational level of their members, who may form part of a Western educated elite. Numerically, the most important class in African and Asian societies is the peasantry, and, even in the more urban and industrial societies of Latin America, this class is still relatively large. Consequently, peasant organizations and movements are of great political significance, and major social conflicts are likely to occur over issues of landholdings, land reform, and agricultural prices, rather than over industrial conditions. As industrialization proceeds, the occupational structure of the developing countries will come to resemble more closely that of the industrial countries, but the class structure may take various forms, depending upon historical traditions and political changes. Many developing countries aim deliberately to bring about a condition of much greater economic and social equality, and it has still to be seen what kind of class system, or classlessness, will emerge from the profound changes that are occurring in such societies as India, China, Tanzania, and Chile.

Social mobility. The term social mobility, in its widest sense, refers to any movement of individuals, families, or groups between different sectors of society. Thus movement from one occupation to another, or from one region of a country to another, is a kind of mobility. On an international scale, migration is a very important type of mobility.

Types of mobility. A distinction is usually made between "horizontal" and "vertical" social mobility, the former involving no change in the position of the individual or group in the social hierarchy, while the latter does involve a change of social level. When an industrial worker moves from one factory to another or a manager takes a position in another company, there is no significant change in his social status or class membership. But, if an industrial worker or the child of an industrial worker becomes a wealthy businessman or lawyer, he has changed quite radically his position in the class system. Vertical mobility may, of course, involve either upward or downward movement. A ruined aristocrat, or a member of an upper class dispossessed of his wealth in a revolution and obliged to enter a manual occupation, has experienced a change of social level that may affect his whole life or particular aspects of it. Modern sociologists have concentrated their attention mainly on upward social mobility, because they have been preoccupied with the question of equality of opportunity in the relatively open and democratic industrial societies; but it has been suggested more recently that the degree of downward mobility might be a better indicator of the "openness" of a society, since it would show the extent to which it is relatively easy or difficult for privileged individuals and groups to maintain and transmit to their descendants the advantages that they enjoy.

There has also been a marked preoccupation with the mobility of individuals, although it is evident that whole families, groups, and even classes may at certain times change their position in the social structure. One of the few writers to bring out the diverse aspects of vertical mobility was the economist Joseph Schumpeter (1927), who analyzed and illustrated what he termed the "rise and fall" of individuals, families, and whole classes within the class system. But Pareto, too, in his examination of the "circulation of elites" (1915–19), paid attention both to the movement of individuals into and out of the elites, and to the rise and fall of whole elite groups.

Intragenerational and intergenerational mobility

In studying the movement of individuals, sociologists have distinguished between intragenerational and intergenerational mobility; that is to say, between the mobility of an individual within his own adult lifetime and the mobility represented by a change in social level from the parental to the filial generation (almost always from father to son). Comprehensive national studies of mobility that have been undertaken in recent years have dealt almost entirely with intergenerational mobility, examining changes in occupation between father and son in terms of a scale of occupational prestige. At the same time, such studies have concentrated heavily upon educational opportunity as a major factor influencing upward mobility.

The rise and fall of families, groups, and classes is less easy to study in a quantitative manner, but such changes can be documented in other ways. The emergence of new ruling dynasties is one example of the upward mobility of families, and other examples can be found in the rise and fall of family businesses, of politically influential families, or of intellectual families. The mobility of particular social groups may occur as a result of economic, political, or cultural influences.

There have been important changes in the position of various groups in the modern industrial societies: the prestige and influence of scientists has increased, while that of clergymen has diminished; bureaucrats have become a much more important group, as have the officials of a dominant political party in some societies. Finally, the rise and fall of whole classes is a phenomenon that occurs when there are substantial changes in the whole structure of society. In the Marxist theory, such changes take the form of a social revolution, in which the established ruling class is overthrown by a new class, as in the rise to power of the bourgeoisie with the development of modern capitalism. But a change in the relative position of classes may also occur in a more gradual way, and an example may perhaps be found in the growth of the new middle class in present-day industrial societies.

Vertical social mobility is a feature of all societies, except perhaps the most simple and primitive. In European feudal societies, there were opportunities for upward mobility, one avenue being through the church, and these opportunities increased with the revival of the towns and the growth of trade. One study of the circulation of elites in France between the 11th and 18th centuries gives examples of the rise and fall of particular individuals and families, as well as tracing the fortunes of such groups as lawyers, financiers, and traders.

Inadequacy of historical studies of mobility

The problem posed by such historical studies is that they largely provide illustrations and, for lack of data, do not show the degree of mobility; that is to say, the numbers of individuals or families who actually changed their position in the social hierarchy over a given period. Historical comparisons of mobility are thus difficult and largely speculative, and there are many problems even in examining the trends of mobility in the industrial societies in recent times. It is nevertheless generally considered that vertical social mobility (especially of individuals) is greater in modern industrial societies than in earlier societies. Modern studies suggest, however, that, even in industrial societies, mobility is limited and that there are no substantial differences between industrial societies in the amount of mobility, even though, for example, it has been generally believed that social mobility is greater in the United States than in European countries. In particular, the movement of individuals from the working class into the upper class is rare in all societies. Sociologists have, therefore, introduced another distinction between short-range and long-range vertical mobility; and comparisons between industrial societies show that the greater part of mobility is short-range.

These modern studies suggest a cautious interpretation of historical accounts of social mobility, which may give undue prominence to exceptional cases of upward or downward movement. It is likely that in all societies, at most times, there is a considerable stability of class membership that, even when not maintained by any formal sanctions, is ensured by the inheritance of property, educational advantages, or political influences.

The process of mobility. The nature and degree of vertical mobility in a society is affected by a variety of influences. One universal factor is the occurrence, in any population, of individuals who are exceptionally endowed—with intelligence, physical strength, beauty, skill in warfare or business, or the quality of charisma that enables them to become religious or political leaders. Beautiful women have risen to social eminence as the mistresses of kings and nobles and as film stars, just as men (and to a much lesser extent women) have risen by the accumulation of wealth, the attainment of political or military power, and intellectual or artistic achievement. But the manifestation of such personal qualities and the advantages that they bring are limited and controlled by many social factors.

In the first place, the open or closed nature of the class system has a powerful influence. It is not only that the individual in a closed system will encounter great practical obstacles if he seeks to escape from his situation as a slave, serf, or member of a lower caste; the ideology that upholds such a system and emphasizes the importance of everyone "knowing his place" tends to inhibit the development of personal talent and ambition at the lower levels of society. In the more open class systems of modern societies, on the contrary, there are no formal restrictions upon vertical mobility, and the ideas of equality and reward for merit, which have gradually entered the general social consciousness since they were formulated in the 18th-century revolutions, encourage an individualistic striving for success throughout large sections of society. Even in these societies, however, talented individuals in a lower social class have to surmount many obstacles, arising mainly from poverty and the difficulties of access to education. On the other side, less talented individuals are able to maintain their position in the upper class because of their inherited social advantages.

The extent to which individual talent will result in upward mobility is also limited by the general orientation of a society's activities. A tribal society that lives by hunting or is engaged in continual warfare will place a high value on physical strength and agility; a nation engaged in imperial expansion is likely to rate military qualities highly; and one that is chiefly concerned with industrial development may attach the greatest importance to business ability. The role of science and technology in present-day industrial societies makes certain kinds of intellectual ability (and the selection and training of such ability) particularly important, so that some writers have referred to the rise of a "meritocracy" or a "scientific and educational estate" or a "technocratic elite."

Mobility and changes in social structure

One of the most profound influences upon mobility comes from the general changes in social structure. A revolution that dispossesses an existing upper class or a national liberation movement that overthrows foreign rule creates opportunities for other individuals, groups, and whole classes to establish themselves in a dominant position. In the early years of the Socialist regimes in eastern Europe, for example, the universities were opened to young people from working class and peasant families, while restrictions were placed upon the entry of those from the middle class. More gradual changes, especially in the occupational structure, also affect mobility. The expansion of clerical, technical, and professional employment involves a continuing movement out of manual work and accounts for a large part of the upward mobility in Western industrial societies. In earlier periods economic changes had similar effects; the revival of trade and the growth of towns in European feudal societies made it possible for serfs to embark upon new occupations and to escape the constraints of the feudal system. A similar movement from country to town is occurring in the present-day developing countries and involves, in most cases, upward mobility in terms of rewards, opportunities, and social status. There are also movements from poorer to wealthier regions in a particular country. The postwar movement in Italy from the relatively poor agrarian south to the more prosperous industrial north and the movement of black Americans from the South to industrial areas provide examples.

After a revolution a new system of stratification may emerge, and the rate of social mobility may decline again. Similarly, if there is little economic development or the rate of growth slows down, opportunities for mobility will be diminished. In such conditions, the possibilities of upward mobility will depend largely upon the extent of downward mobility. One other factor, however, may influence this situation. If the upper and middle classes practice family limitation to such an extent that they do not reproduce themselves from generation to generation, the vacant places may be filled by individuals who rise from lower classes. Such differential fertility, however, has rarely, if ever, been a major influence, and most analysts believe that it has been declining in the developed industrial societies during the past few decades.

Mobility and migration

International movements of population have been important at various times in promoting upward mobility. The colonial expansion of the western European countries from the 16th century on provided opportunities for individuals to enrich themselves as traders or settlers, at the same time as they subjugated and enslaved other peoples in Asia, Africa, and America. Later, with the creation by European settlers of new societies, especially in North America, fresh opportunities for mobility were provided by large-scale immigration. The expansion of U.S. society across the continent during the 19th century brought millions of working class and peasant immigrants from Europe who were leaving conditions of poverty and subordination that seemed unalterable in their own societies.

Consequences of mobility. The determinants of mobility outlined above are difficult to isolate and measure, as are the social consequences of mobility. On one side, it may be said that the movement of large numbers of people up and down the social hierarchy tends to break down the exclusiveness of social classes and to create a more uniform national culture. Presumably, this would also lead to a diminution of class prejudices and class conflicts. It has often been claimed, in fact, that the allegedly lesser degree of class consciousness in U.S. society, as compared with European societies, is due to a higher rate of mobility in the former. Although this may be doubtful in the light of recent studies that show no great differences in overall mobility in the industrial societies, the widespread belief that opportunities for upward mobility are actually greater than in other societies may itself have had an important influence. From another aspect, however, it can be argued that the preoccupation with vertical mobility reinforces the class system; the individual who is concerned to rise or avoid falling in the social hierarchy accepts and indeed emphasizes the importance of class and status distinctions. It has been suggested that these distinctions might be diminished much more by the attainment of greater economic and social equality than by any amount of individual mobility.

Another consequence of mobility that is seen as beneficial from the point of view of society as a whole is the more effective use of ability. If individuals are confined to the social sphere in which they are born, many useful talents will remain undiscovered and unused. The expansion of education in modern industrial societies has been stimulated by the desire to provide opportunities for the development of all the abilities available in the population, though this is still very imperfectly achieved.

Possible undesirable consequences of mobility

On the other hand, vertical mobility may have some undesirable consequences. Such mobility, whether upward or downward, imposes strains upon the individual striving for success and adapting to new social milieus and may be disruptive of families and local communities. More generally, a high rate of mobility may be regarded as producing in society the condition that the French sociologist Émile Durkheim called "anomie" (normlessness and resultant disorientation and anxiety), in which there is insufficient regulation of behaviour and the individual suffers from the "malady of infinite aspiration." The existence of such strains may lead to a higher incidence of mental illness among highly mobile individuals, but it seems doubtful that mobility is a major factor in mental illness, given that such illness has been increasing rapidly in the industrial societies, while there has been no correspondingly marked increase in mobility. It seems likely that it is the pace of economic and cultural change in general and the conditions of urban-industrial life that impose the greatest strain upon individuals. (T.B.B.)

SOCIAL STRATIFICATION: CASTE

Caste systems are moral systems that differentiate and rank the whole population of a society in corporate units (castes) generally defined by descent, marriage, and occupation. Elaborately differentiated and ranked caste systems have developed especially in the regional societies of India and among adjacent Hindu and related populations in the territories of modern Pakistan, Bangladesh, Nepal, and Sri Lanka (Ceylon) over the past 2,000 years. Simpler caste systems have developed elsewhere. The nature, history, and variety of these systems, their significance for general understanding of human society and for particular understanding of South Asian society and religion are the subjects of this section.

So intricate are the connections of caste systems in South Asia with regional systems of ideas regarding such matters as genetics, physiology, kinship, ethics, and cosmogony that they have been equated by some scholars with the whole culture of Hinduism and declared to be unique phenomena inseparable from it. Caste systems are found, however, in combination with other religions and cultures in South Asia and elsewhere. Their features as a general type may be compared with other systems of social class or stratification.

Caste systems compared to other systems of social stratification

Caste systems resemble racial stratification in their biological concern with differences of birth and marriage; they resemble stratified plural societies in their presumption of profound differences in group behaviour; they depart from both in conceiving of themselves simultaneously as unitary societies that are culturally integrated. Unlike racially or culturally plural societies, where prior intractable difference among groups is taken as a moral reason for the divided constitution of the society, established caste systems may differentiate into further, new units or they may reassemble their units into one.

Caste systems resemble the much more widespread systems of social and economic classes in containing ranks that tend to be culturally marked, occupationally linked, hereditary, and endogamous (marrying within a group). They differ from such systems in having as their ranked units not only individual persons and families but also larger corporate groups. Corporate caste units differ from social classes in being necessarily defined—rather than incidentally distinguished—by occupation, descent, and marriage. Castes have no other necessary cultural markings, although classes, being assemblages of persons on the basis of their attributes, necessarily do. The ranking of corporate units in caste systems creates an illusion of individual immobility (a feature sometimes taken as typical of caste systems); yet rates of individual rise and fall are not known to differ between class systems and caste systems, as the types are here defined.

Caste systems are comparatively rare among large-scale moral systems in making the differentiation and interrelations of corporate groups into major concerns; but in this they are at one with a large and diverse category of small-scale societies. The sharings and exchanges by which caste systems reckon the boundaries, alliances, and ranks of their corporate units have much in common with widespread forms of marriage and parent–child relationships, gift giving and tribute, ritual, sports competitions, communication networks, and dominance in animal as well as human societies. But caste systems are unique in their ways of combining these features—in having biological and behavioral schemes for differentiating and ranking occupational and ethnic units according to the determined way they relate to each other in sharings and exchanges. They have proven uniquely capable, in each of the regional societies of South Asia, of relating hundreds of units in dozens of higher and lower ranks and of generating new societal forms through combinations and transformations of existing schemes.

Theories of caste. For about two centuries, the explanation and analysis of South Asian caste systems have been matters of interest and controversy among foreign observers, who have brought with them assumptions and sensitivities peculiar to their own respective societies and times.

No visitor of ancient or medieval times seems to have felt that rank, corporateness, heredity, and endogamy among the occupational and ethnic groups of India were worthy of special mention. The Portuguese seafarers who traded mainly on the west coast of India in the 16th and 17th centuries described groups they called *castas* (from which derive the English and French words *caste*), meaning "species" or "breeds" of animals or plants and "tribes," "races," "clans," or "lineages" among men. Only in the 18th century did the distinction that is now made between unranked tribes and ranked castes begin to be drawn clearly in the usage of the French and English.

Attempts by Western observers to explain castes

Consideration of the thoroughgoing inequality and exclusiveness of the castes, as well as the peculiar occupational division of labour prescribed for them, generally produced a sense of shock in Western missionaries and officials of the turbulent 19th and 20th centuries. Attempts were made to explain the castes as an imagined rational legislation by some unknown past authority, as a self-serving invention by the system's top-ranking priestly castes, or (after Charles Darwin) as the unplanned evolution of successively higher castes through the growth of superior technological specialization.

The insufficiency of these—or, indeed, of any—simple conjectures for explaining the origins of these apparently irrational systems strengthened a trend toward more complex historical speculation. Castes were seen as heirs of the Indo-European language family's common traditions of private kin-group ritual by Émile Senart, a late-19th-century Sanskrit scholar. In 1891 H.H. Risley, a British anthropologist, reported that proportionally wider noses correlate with lower caste rank and also with a geographic gradation from northern to southern India; this suggested a hypothesis of repeated invasion from Central Asia and from the north to the south by longer nosed racial elements. Other official British Indian research stressed separate surveys of the physical traits and customs of each of the thousands of castes and tribes. Compendious reports of such surveys reinforced a conception of Indian society as a geographical accident and a political composite. Many authors speculated on historical factors favouring the development of the Indian caste systems—such factors as diffusions of primitive customs, ancient movements of peoples, and the mutually distancing adaptations of allegedly alien peoples to each other—and these speculations were compiled in a list of 15 factors by J.H. Hutton, census commissioner and ethnologist, at the end of the British regime in 1946.

What was missing from these atomistic historical analyses was any conception of a caste system as an integrated whole. Such conceptions were provided in nationalistic political contexts in the late 19th and early 20th centuries. Max Weber, a German sociologist, emphasized the connections of caste with Hindu religion as part of his larger effort to reveal why the West had progressed more rapidly than Asia. Skeptical toward Hindu religious explanations, the French sociologist Célestin Bouglé in 1908 postulated, from descriptions of the relations of the castes, an underlying set of social structural "ideas"—hereditary specialization, rank, and mutual repulsion concerned with purity and impurity—governing the whole system. Hutton held that social differentiation in caste systems requires an assumption of a once widespread preliterate philosophy concerning the powers of bodily and other substances and the dangers of magical contagion. The British social anthropologist A.M. Hocart, combining observations in Sri Lanka (Ceylon) and Polynesia with Vedic (early Indian-language) texts, saw caste systems as organizations for royal rituals of worship. In 1952 M.N. Srinivas, an Indian anthropologist working in southern India, attempted to derive both the unity and the ranks of Indian caste systems from the imitation by diverse groups of the customs of the highest Hindu castes, a process that he called "sanskritization."

Western social values reflected in explanations

Western comparative social theorists have generally placed caste systems not in a unique religious ideological or structural category by themselves but at the end of a theoretical series of types beyond medieval and ancient Europe and furthest from the equalitarian, competitive tendencies of the modern West in matters of social differentiation and social stratification. The enclosure of individuals in culturally diverse ranked ethnic groups (castes) was seen as poles away from a culturally homogenizing and individualizing modern society. The multiplicity of the castes and their apparent social distance and segregation from each other through endogamy and restrictions on contact seemed to exceed in stringency any but the most extreme differentiations (*e.g.,* Black and white in the U.S.) among ethnic groups of a single society in the West. Castes were also commonly regarded in Western comparative perspective simultaneously as social-status groups and as economic classes. They were considered rigidly closed classes, permitting recruitment of individuals into caste membership only by birth, not by achievement. Caste systems were further mistakenly thought to allow vertical mobility only through movement by the whole corporate unit, not through individual or familial movement. They were seen as guaranteeing the virtual immobility of groups, as well, owing either to the preponderant power of the conservative high-caste elite or to the strength of cultural consensus and traditional sacred sanctions or to both.

Although comparative sociology thus attempted to look at South Asian caste systems as extreme instances of presumed universal features of human society and implied a view of them as social systems rather than as accidental collections of ideas and peoples, its typifications of these systems remained sociocentric, reflecting modern Western society's assumptions about essential elements and processes, while reversing some cherished Western values. It did not attempt to base its understanding closely upon the cognitive assumptions actually prevalent in South Asia. For understanding of this sort, one must examine certain Indian social concepts that are known first from Vedic texts from 1000 BC. These are maintained to the present by the predominant Hindu population and are widely shared among persons of all religions residing in South Asia.

Jāti

Indian social concepts. The organization of South Asian society is premised on the ancient and continuing cultural assumption that all living beings are differentiated into genera, or classes, each of which is thought to possess a defining coded substance. One of the commonest words for genus in most Indian languages, *jāti,* is derived from an Indo-European verbal root meaning "genesis," "origin," or "birth." It is applied to any species of living things, including gods and humans. Among humans, *jāti* can designate a distinct sex, a race, a caste, or a tribe; a family, a lineage, or a clan; an ethnic group, a regional population, the followers of an occupation or a religion, or a nation.

Every human genus (and therefore every caste) is thought to have as the shared or corporate property of its members a particular substance (*e.g., śarīra,* "body," *rakta,* "blood") embodying its code for conduct (*dharma*). Each caste's inborn code enjoins it to maintain its substance and morality, its particular occupation, and its correct exchanges with other castes. Indian thought does not separate "nature" and "morality" or "law," so that castes are, in Western terms, at once "natural" and "moral" units of society. These units make up a single order, one that is profoundly particularized.

The persons of each caste are believed to transmit the particles of substance that are peculiar to their caste from one generation to the next through a series of natural and moral acts extending from birth to marriage. The male and female sexes, like castes, are thought to be composed of nonequivalent, complementarily coded bodily substances; the reproductive essence of each, variously conceptualized but often identified with semen and uterine blood, is required to make the child complete from birth in his caste's particular nature. Acts that wrongly mix bodily substances, such as improper procreation, are thought to alter the embodied morality of the caste and its offspring. Each caste must therefore be concerned with regulating marriage.

Castes are related to each other externally not by hereditarily shared substance but by exchange of nonhereditary substances. Each caste is involved through its existence and its means of subsistence in transformations and exchanges of transformed natural substances. Of these substances, a caste's own bodily substances (*e.g.,* hair, blood, semen, and feces) and food (which is seen as becoming transformed into human bodily substance) are considered capable of creating, expressing, or altering relationships of rank and solidarity between it and other castes. The substances derived from each caste's pursuit of its occupation are also major media, along with services, of intercaste exchange. Each caste is thought to maintain or alter its moral standing (that is, its rank with respect to other castes), its hereditary substance, and its natural code according to the way that it receives or refuses to receive bodily substances, consumes or refuses to consume food, and gives or refuses to give services in exchanges with particular other castes.

The Vedic heritage. A conception of Indian society in terms of genus (*varṇa,* here synonymous with *jāti*) appeared first in the Rigveda (Ṛgveda), the oldest collection of Vedic priestly hymns, composed in Punjab about 1200–1000 BC. The Vedic people of that time saw themselves as members of a single "genus of respectable men" (*ārya-varṇa*), "the humans" (*manuṣa*). Their code enjoined them to offer sacrifice (*yajña*) to members of another genus of beings, the Vedic gods (*devas*); it also enjoined them to smite and enslave their enemies, "the nonhumans" (*dasyu-varṇa*), who were naturally and morally fit for service.

The conception of society as containing more than two *varṇa*s appeared only after 1000 BC, when descendants of these early Aryans began to settle in the upper Ganges region and built a more complex society containing towns and the beginnings of states. It appeared then in the increasingly elaborate body of Vedic sacred texts and ultimately reached its culmination in the classical moral code book (*Dharma-śāstra*) of the Manu school (*c.* 200 BC–AD 200).

Division of Puruṣa into specialized *varṇa*s

The whole later Vedic society continued to think of itself as sharing one original natural substance, conceived as the body of Puruṣa, the original code man. The division of Puruṣa by the gods into distinct specialized *varṇa*s mythically inaugurated the Vedic sacrifice. Henceforth, only those who had the substance of Puruṣa in their bodies were to follow the code of exchanges required by the sacrifice.

Sacrifice was seen as fundamental for upholding the natural and moral order of the cosmos. It required exchanges between the two specialized genera, gods and men. Gods, the beings who wield divine power (*brahman*), were seen as the ultimate source of bodily existence and well-being; men were the givers of the food that the gods needed to sustain themselves. Mutual exchange of food through the sacrifice thus created solidarity between gods and men.

Exchange in the sacrifice also created a ranked relationship between gods and men. Only pure food was fed to gods by men, while gods, after they had eaten, returned only their leavings for men to eat. These same asymmetrical events that created rank—that elevated the gods and lowered men—were conversely interpreted as expressions of rank previously established. Thus, men regarded their own food leavings as contaminated by saliva and therefore as impure and valueless to others but considered the leavings of the gods as transvalued—pure and incomparably valuable precisely because they were filled with the divine natural substance that brought human well-being.

Rank in this ancient South Asian moral order was thought of as being based less upon established possessions than upon generosity. Gods were of higher rank than men not so much because they possessed the attribute of divine power as because they were incomparably generous in bestowing that power on men. Men were of lower rank because they could not return this gift. They could give the gods the most valued foods, but they could not equal the value of the divine power contained in the gods' gift to men.

The same relationship existed among the specialized natural genera within the society of men—between the "once-born" and the genera of the "twice-born" (*dvi-jāti*), those who became divinized humans through a second, ritual birth. The once-born, called Śūdra (Servant), was not to hear the sacred Vedic words or to sacrifice directly or to receive the gods' leavings. He was instead to exchange with the twice-born in the same way that the twice-born, to whom the term *ārya* was exclusively applied, exchanged with the gods. Born of the lowest part of Puruṣa, the feet, the Śūdra followed a code enjoining him to serve the twice-born in exchange for maintenance. He could symbolize his ranked relationship, as was done in the sacrifice, by feeding pure food to his human superiors and eating their leavings in return. His service was a form of worship but an inferior one that properly brought only the divine gift of maintenance in return. Because the Śūdra was defined as being unable to return even this gift of maintenance, his moral rank was considered to be lower than the rank of the twice-born.

The twice-born was the divine human genus of Aryans, whose males came to share the divine sounds of the Veda through a second, divine birth and initiation into Vedic study and sacrifice. Their code also required married male householders to exchange gifts among themselves. The wife and children of a twice-born householder were forbidden, as was the Śūdra, from hearing Vedic sounds and from carrying on the sacrifice. But women and children were conceived as sharing the effects of those duties through having bodily substance in common with their household head.

The three types of twice-born persons

The code book enjoining sacrifice and exchange also defined three specialized genera of people within the twice-born genus. The substance of each of these had its distinctive ranked origin and inherent ranked powers, and the code for conduct of each was specialized. The Brāhmaṇa, born from the highest part of Puruṣa, his mouth, possessed godly power (*brahman*): he was to teach the Vedas, perform sacrifices for the Kṣatriya and Vaiśya, and accept gifts from them in exchange. The Kṣatriya, born from the arms of Puruṣa, possessed royal power (*kṣatra*): he was to fight enemies, give gifts and food to the Brāhmaṇa, and protect the Vaiśya; in exchange, he received a share in the leavings of the sacrifice from the Brāhmaṇa and wealth from the Vaiśya. The Vaiśya, born from the thighs of Puruṣa, possessed productive power (*viś*): he was to produce wealth for the Brāhmaṇa and the Kṣatriya through agriculture, commerce, and animal herding, and was to give a share of it as taxes to the Kṣatriya in exchange for protection.

Each superior genus is considered divine in relation to each inferior genus. The moral ranks of the genera were gauged in *varṇa* theory also by the values assigned to the different things they gave each other. Since the wealth given by the Vaiśya to the Kṣatriya was considered less valuable than the divine protection received in exchange, the Vaiśya ranked below the Kṣatriya. The Brāhmaṇa, acting as representative of the whole society, fed the gods through the sacrifice and was first to eat their leavings, to take their power. In comparison to the Kṣatriya and the Vaiśya, he was therefore a "god on earth." Because the gifts and food given by the Kṣatriya and the Vaiśya to the Brāhmaṇa were considered to be less in value than the remainder of the sacrificial leavings that he gave to them, he was thought to have a higher rank than they. Beneath all three was the Śūdra, with his offering of mere labour, benefitting by the activities of all.

The four *varṇa*s of Vedic theory may have had a waning existence in parts of northern India when the theory was first being formulated, between 1000 and 300 BC. But the authors of the classical moral code books in the centuries following (*c.* 200 BC–AD 200) were concerned with reconciling this theory with the multitude of specialized *jāti*s of uncertain *varṇa* that they actually saw about them. They explained the existence of non-Vedic *jāti*s by a theory of miscegenation: The *jāti*s were offspring of improper mixing and remixing among descendants of the four pure Vedic *varṇa*s. The numerous *jāti* units, their varied codes for conduct, and many ranks were all seen in the Vedic scheme itself as responses to the requirements of particular places, times, and genera of persons. The four *varṇa*s together with the sacrifice from which they were thought to spring were seen as the universal, eternal, and logically complete scheme for upholding nature and morality.

Hindu worship and the castes. The Vedic scheme continues to the present as a template, generating systematic conceptions of the local, everchanging castes (*jāti*s) and their exchanges in the closely connected scheme of Hindu image worship, called *pūjā* (literally, "respect"). Evidences of the proliferous systems of castes connected with image worship appeared gradually after AD 500.

Complex systems of castes required by Hindu image worship

The Hindu gods to be worshipped are related among themselves, like men, by shared and exchanged natural substance. They have not merely abstract qualities and representations like the Vedic gods, but also particular life-like images, biographies, bodily functions, and specialized relations to men. They are attached by particular codes of worship to particular occasions, communities, and genera of persons. The occasions for their worship are times of bodily events in their own or their worshippers' lives—births, weddings, deaths, and the routines of such things as the daily bath or meals—and in the natural cycles of the Sun, Moon, Earth, and other planets, whose heat and cold, dark and light, wet and dry, etc., are seen as bodily states affecting human beings.

The codes of Hindu worship require the existence of complex local communities of castes. Worship cannot proceed without a priest to bring the living substance of the god into the image, made by an image maker. The priest must utter formulas (*mantras*) that activate this divine life substance and other formulas that have the power to transform the ordinary materials of worship into sublime offerings. The priest must be a male of the highest, most godlike caste available—ideally a Brahmin skilled by heredity in the maintenance of ritual boundaries between substances, and empowered to transform them.

To sponsor the worship there must be a local worshipper of means, typically a ruler or man of wealth, who can by gifts entreat a priest to mediate with the god. There must be specialists of appropriate castes—*e.g.,* temple keeper, garland maker, cook, sweet maker, singer, musician, dancer—to feed, attend, and entertain the god. Before the worshipper can approach the god, he must prepare himself and his caste to be as godlike as possible and must remove as much as possible from his person and his caste any insulting, transmissible bodily substance. He does so through bathing and through engaging the services practiced by other castes, such as those who do the work of barber, washerman, midwife, funeral priest, leatherworker, scavenger, or sweeper. These castes are by their intimate receivings of bodily substance rendered subordinate to the worshipper, as a child's receiving of bodily substance renders him subordinate to his parents. Each caste contributes in its particular way to the worship, directly or indirectly, and each then receives in return and in order of rank a share, either in the transvalued leavings of the god's food (called *prasāda,* "favour") or in the leavings of those who do receive a share.

Hindu worship thus greatly ramifies the specialities assigned to the four *varṇa*s and invites specialization by caste. One effect of such worship is a ranking of all participating castes by a pattern of exchanges in which natural substances and services go up and divinely transvalued substances containing divine benefits go down. Another effect is the establishment of a solidarity of substance among all the castes.

Varieties of caste systems. Caste groups range in size from hundreds up to millions, with their estimated median population lying between 5,000 and 15,000. Such populations are likely to be spread over dozens or hundreds of villages and cities and over hundreds of miles of territory. Thus, few castes ever meet as wholes in one place. Nevertheless, the universality of concern for a caste's substance and code and for its rank (which can be altered for all by the conduct of a single member) guarantees at least an informal, diffuse organization of authority within each caste. Recruitment of allies or a shift to a larger context of competition may lead a caste to fuse with groups otherwise treated as separate categories.

In the eyes of others, a caste is most often categorized in an occupational role. Each caste in fact owns a set of related occupations among which its members may choose according to their particular economic situation. Thus, for example, each of the "royal," traditionally warrior, castes (called Rājput) includes landlords, cultivating tenants, and landless labourers, as well as princes and soldiers. Least specialized are some of the tribal *jāti*s in the hills and forests of central India, who traditionally do for themselves all work except metal-working and the literate professions. About one-third of all the South Asian population is in castes for whom some aspect of agriculture is the main traditional occupation. Another third, traditionally specialized by caste in nonagricultural work, in fact earns most of its living in agriculture.

Local communities and class

Settlements of fewer than 1,000 persons have contained most of the predominantly rural population of South Asia up to the 20th century. These settlements have commonly comprised members of from five to 20 castes—the number varying according to the density of the particular region and the wealth of the local population. Contact among persons of different castes is typically close and frequent in villages, being required by economic division of labour and by the forms of ceremony. Persons are readily identified by one another as members of known castes and the import of their actions accurately assessed. On the average, villagers agree with each other by majorities of 90 percent or more concerning the ranks of eight out of any 12 local castes.

Apart from their belonging to castes, the households of most villages are organized in economic and political systems that concentrate power in the hands of a landed or commercial minority. Membership in the local ruling class rarely corresponds closely with the membership of any local caste group: individuals, households, and families may rise or fall in their economic resources and influence, apart from the ranks of their castes. Local caste groups often differ greatly in their members' aggregate or average wealth and influence. Castes that have no other economic resources must serve and defer in ritual ways to those with power in order to subsist. Rank is traded in order to eat. Thus, the actual distribution of politico-economic power within a community can effect a rearrangement of the order of ranks among the castes.

The rankings of castes in villages are alterable but are not quickly altered, locally supported as they usually are by politico-economic interests, restrained by complex multilateral exchanges, and remembered by minds accustomed to a hereditary order. The mild but ubiquitous inclination of castes to improve their ranks can be estimated from the finding that the average villager believes the correct rank of his own caste to be about half a rank higher than what nonmembers of his caste are willing to concede. Efforts by rural caste groups to depart from the locally accepted line of precedence are numerous, even if moderate and slow to take effect. That castes' local ranks do change is known from case histories and from the differences in the same castes' ranks that occur from place to place.

The caste systems of rural people, as they are believed to have existed at the beginning of British rule in 1858 and as they continue to some degree into the present, can be divided into five major regions of South Asia.

Caste systems in southern India and Sri Lanka. The southern, Dravidian-speaking portion of India is characterized by a proliferation of castes, consistent with regional concern for female bodily substance. Except in the matrilineal castes (in which membership is gained through the mother) of Kerala, both parents are thought of as contributing caste code to their offspring. Marriages outside Kerala are uniformly made within the caste. Endogamous castes here tend to become very small and close, to divide into numerous smaller circles by the preferred repetition of reciprocal, protective marriages among cousins and other known kin. Distinctions between castes are more often marked by visible attributes. Only whole, uncooked foods, such as betel leaf and nut, are much exchanged beyond the caste and household.

The relatively small spread of each caste leaves it available to be ranked consistently by its members' exchanges with other castes in just a few nearby localities; there is little danger of conflict over precedence through comparisons with possibly inconsistent rankings of the same castes in any remote villages or kingdoms. At the same time, local communities are the largest and most complex in South Asia, averaging 10 to 15 local caste groups in the southeast and 15 to 20 in the southwest.

The stability of rice agriculture and government in the lowlands of southern India have also favoured a formal administration of land tenure from the state down to the cultivator (*raiyatvāri* tenure), operating either through hereditary local officials whose castes (*e.g.,* the Nāyar) have been or become regarded as the high castes or through land-endowed temples administered by Brahmins. Dynasties have had long durations, and conquests by other than neighbouring kingdoms have been few. One result has been a frequently close identification of land-tenure positions with certain castes and a closer correlation than elsewhere between castes' ranks and their powers. Brāhmaṇa caste groups have in some areas taken the positions of rulers. Another result of these conditions has been the formal social organization of the whole village community on caste lines for the several purposes of legal administration, occupation, and ritual.

Rankings of local castes in 20 or more grades are encountered in Kerala. An extreme etiquette of formal speech, clothing, gesture, and distancing among the castes is required there. On the other hand, repetition of the sets of priestly and pollution-removing (*e.g.,* barber, washerman) castes for patrons at three or four ranks and marriage of women above their caste (intercaste hypergamy) integrate the many castes into single, ranked schemes. The central role of Hindu temples in focussing the services and ranks of castes continues from Kerala up the western coast of Mysore and also down to Sri Lanka (Ceylon), especially in its Kandyan highland region. In much of Sri Lanka, however, the small village settlements have few castes, favouring their Buddhist caste system.

The caste systems of villages in Tamilnadu and Andhra Pradesh are less centrally structured and somewhat less elaborately ranked than in Kerala. Local communities contain fewer castes, castes whose wealth and power are less closely correlated with their ranks and whose residences are divided into hamlets with separate caste-linked temples. In some districts castes are organized in competing sets—*e.g.,* castes of the "right hand" versus those of the "left hand"—reflecting rivalries between ruling castes, between indigenous and immigrant castes, or between agriculturalists on the one hand and traders and artisans on the other.

Castes in the northern plains

Caste systems in the northern plains of India. The region of the later Aryan settlement in eastern Punjab and in the upper Ganges Valley (in Uttar Pradesh) and of the plains in the north Indian area where Indo-Aryan languages continue to be spoken today (Bihār, West Bengal, and Gujarāt) are generally densely populated with moderately sized villages having caste systems somewhat less elaborate than those in southeastern India. Each settlement averages about 500 persons belonging to ten castes, nine of which are Hindu and one is Muslim.

Centralization and formal organization are slight. Villages in the northern parts generally have no temple at all; those of Gujarāt generally have many private temples but none that can bring all the castes of a locality together in a ranked order of worship; those of Bihār and West Bengal that have centralized worship, organized by a local landlord, are few. The intercaste organization in the villages of the northern plains, both for worship and for control of land and conflict, tends to be based upon a plurality of landed households, mostly of the higher castes. Each household conducts its separate worship, and each separately employs specialist members of five to 15 castes. Such specialists serve by heredity on fixed rates of annual payment either in land or crop shares.

The main occasions for proving the ranks of the castes, beyond the regularly rendered services and payments, are household-sponsored feasts. Intercaste feasts in this region use a class of perfected (*pakkā*) cooked foods that are based on clarified butter, need not be served hot, and are therefore thought to be not so open to combination with bodily substance. Such feasts are offered to representatives of every caste in the village, and the resulting acceptances and rejections of food make public show of each caste's relative standing.

Local rankings of the castes in most of the northern plains are less isolated and more subject to contravention by rankings occurring elsewhere, primarily as a result of the very wide range of marriage. Except in Bengal, clan terms of kinship are used locally among persons of all castes, and locally born women must marry outside their localities. Caste by caste, linear rankings of local castes become impossible. Nevertheless, high local agreement occurs on blocks of castes; about three-quarters of the possible ranks are distinguishable.

Some castes of the northernmost plains, with some higher castes of the central region and all castes of the western region, hold that their natural code is transmitted by the father alone. Many of these marry hypergamously, linking higher with lower clans and castes. Castes here tend to have larger spreads and the largest regional populations.

The small kingdoms and pockets of Hindu and Buddhist settlement on the Himalayan slopes of northern South Asia differ greatly from the plains and among themselves in their environments. Many villages here are composed of only one, two, or three castes or tribes and thus have a very simple division of labour. These villages may be quite isolated settlements, practicing close reciprocal marriages.

The more densely populated Himalayan areas, such as the valley of Nepal, were strongly Hinduized by Rājput and Brāhmaṇa immigrants, increasingly so after the Muslim conquests of the plains. Nepal contains dozens of Buddhist and Hindu castes that are elaborately graded and linked, both by position in the state and sometimes by intercaste hypergamous marriages. Both parents are believed to transmit caste-coded substance, and offspring of mixed marriages are assigned to third castes having ranks between those of their two parents' castes.

Caste systems in central India

Caste systems in central India. The central Hindu region extending from Rājasthān in the north through Madhya Pradesh to Mahārāshtra on the south and Orissa on the east is characterized by relatively sparse rural population that tends to be concentrated in villages of moderately large size—500 to 700. The average number of castes present in these villages is less than in the northern plains, for in each state and locality two or three out of a few very large clusters of castes preponderate.

Within the central zone, the regions of Rājasthān, Kutch, Kāthiāwār, and much of Madhya Pradesh contain large desert or hilly areas that can be exploited fully only by herders and semimigratory farmers. Where permanent villages exist, they organize hereditary intercaste services by household. But wide and flexible networks of organization are advantageous within the castes of these mobile farmers. They are essential for the controlling castes of Rājput and other warriors and among the numerous small Hindu and Jaina (a religion founded in India in the 6th century BC) trading castes of the region. Such networks are structured for these higher castes not by close caste councils such as those that prevail in southern India but rather by the rulers' deep and widespread corporate lineages and clans (recorded for them by genealogist castes), by belief in exclusively male transmission of caste code, and by broad rules of marriage like those found in the northern plains. Within such rules, alliances may be sought and broken. Equipped with such effective structures for mutual aid in an otherwise famine-prone environment, cultivating (Rājput), herding (Gūjar, Ahīr), and merchant (Mārwāri) castes of the dry lands have spread into the neighbouring plains, often as predatory forces in politics and commerce. At the same time, the nondominant castes of Rājasthān, although widely dispersed, follow an opposite strategy of reciprocating, caste-endogamous marriage (inside the caste) that tends to consolidate rather than expand their scarce resources.

South of Rājasthān and north of Mahārāshtra is the fertile plateau of Mālwa, a crossroads of trade, migrations, and routes of conquest in all directions. Villages here, like villages in parts of southeastern India, are often divided between two sets of castes: on the one hand, those who eat meat, worship the Hindu goddesses, and follow the Rājput and local Brāhmaṇa codes and, on the other hand, those who are vegetarian, worship the Hindu god Vishnu (Viṣṇu), follow the Vaiśya code, and are often immigrant castes.

Farther south in the central zone is Mahārāshtra. The Mahārāshtrian village makes public feasting an important focus of intercaste relationships, although restricting feasting to the feeding of kinsmen and traditional servants; it also separates its lowest castes (*e.g.,* Mahār) from the others in a distinct residential hamlet, regards its specialist castes as serving the village as a whole, and organizes all its castes around one or more temples. What distinguishes and moderates intercaste relations in the Mahārāshtrian village is the strongly communitarian nature of village institutions: the village runs its affairs by decision of a village council that includes representatives of all castes and typically makes its main temple into a community centre. It shares some of these features with villages in adjacent sections of western Andhra Pradesh (Telingana or Telengana) and northwestern Mysore.

On the wide eastern and southern margins of the central zone and through its heart in the hills of the west and on both sides of the Narmada River Valley are forested areas inhabited largely by hundreds of tribal peoples—endogamous ethnic groups that have distinct moral systems, that trade their products in peasant markets, but that engage little if at all in the exchanges related to worship that would make them part of any neighbouring Hindu moral system of ranked groups. Non-Hindu tribes are also numerous in Assam and in the North East Frontier Agency (*e.g.,* Nāga). Many Hindu castes derive from such tribes.

Caste systems in Bangladesh and Pakistan

Caste systems in Bangladesh. The densely populated floodplain of the Ganges and Brahmaputra rivers differs radically from northern India in the ecology of its human settlement. A conception of the stable village of locally exchanging castes does not exist. Instead, the scattered households, loosely linked in shifting affiliation with the stronger leaders among them, seek to fill their needs for caste-specialized products through resort to cash exchanges at rotating markets. What specialized services and goods are not traded at markets are brought door-to-door by waterborne artisans and merchants. Even agricultural labourers are often itinerant and indistinguishable from mobile fishermen; only domestic service is generally rendered on long-term local contracts.

The rural population of this socially fluid region is also for the most part relatively undifferentiated by caste and even by kinship groupings of any considerable depth. Localities for miles may be inhabited by a single genus of Muslim cultivators: specialized Hindu castes concentrate themselves apart or cluster at the rare permanent markets and centres of land administration. Thus, neither the human materials nor the institutions of domestic or community worship are present to encourage any elaborate rankings of castes. Indeed, the region is not known to have been Hindu in any large degree or for any appreciable time. Its older past was Buddhist in regime; it came at last under the rule of a Hindu dynasty only a century before its conversion to Islām began in the 13th century. Both Buddhist and Islāmic treatments of caste are congenial to the peculiarities of the region.

Caste systems in Pakistan. Like Bangladesh, the provinces of Pakistan—the desert of Baluchistan, the hills of the North-West Frontier Province and Kashmir, and the plains of Sind and West Punjab—passed from a Buddhist to an Islāmic regime without elaborate development of caste ranking in the Hindu style. Here, again, the ecology of much of the region does not permit the co-residence of many ethnic groups. Neither the mobile herdsmen of the desert and hills nor the cultivators in tiny hamlets on the Indus Plain can assemble many castes to construct complex local systems. Exchanges among the castes of these areas take place more often in towns and for cash at market rates.

Where villages are larger and richer, as in West Punjab, they have attracted members of numerous castelike lineages, or clans, and have become more than equal in ethnic complexity to villages of Hindu eastern Punjab. But here conditions of instability—like those noted for Rājasthān and Mālwa in the central region of India—play a part, for both West Punjab and the North-West Frontier Province have been shattered socially by repeated tribal incursions. Parts of the same tribes and lineages have taken widely varying ranks, according to their political fortunes in different localities. Although marriage is spatially closer than in south India, tribal and lineal names are spread over great distances and tend to confound ranks based on local exchanges. Fewer than one-third of the possible ranks are therefore found to be distinguished among castes in villages and towns of this region.

Caste systems outside South Asia

South Asian caste systems overseas. Caste systems have been carried by South Asians to other continents but are found there only in drastically reduced versions.

Traders and settlers from India established elite cultures of Vedic, then Buddhist religion in many parts of Southeast Asia during the early centuries of the Christian Era, but only on the small Hindu island of Bali are traces of a caste society known to have survived beyond the advent of Islām. In Bali, the four Vedic *varṇa*s are employed as a ranked classification of patrilineal titles (those handed down through the father's line of descent) held by generally endogamous (sometimes hypergamously related) lineages. Higher titleholders are more likely to marry nonlocally. They often receive elaborate verbal deference from lowers. They may refuse cooked food from lowers to assert superiority without believing that food transfers alone can alter rank. Apart from some specialization in worship, Balinese caste titles in practice designate claims to rank, rather than major occupational groupings.

The millions of South Asians who went as labourers to Africa, Malaya, Fiji, Trinidad, Suriname, and Guyana in the 19th and 20th centuries proved unable to carry complex caste systems with them. The regional heterogeneity of those who migrated permanently made their caste identities and their codes of exchange mutually unintelligible. Original caste names have been changed, and identities of code and substance are everywhere merged by marriage into composite regional or linguistic and religious castes. Such a composite Hindu caste is commonly further divided by a single distinction into a priestly and nonpriestly caste. Only those overseas traders (in Burma, Malaya, or East Africa) who return periodically to their home regions are able to adhere to their original codes of marriage and caste identity. Nowhere abroad have modern South Asians set up local communities having a caste division of labour in work or worship, again excepting the Brāhmaṇa role among Hindus.

Caste systems in cities. Caste systems are also modified by the conditions of city life. Like overseas migrants, urban residents in South Asian cities of all regions and since ancient times have had to cope with the difficulty of identifying and ordering great numbers of regionally heterogeneous castes. They have attracted and supported specialized groups little known in rural areas. They have also had to cope with largeness of scale, with recognizing the castes of thousands of mobile individuals. Their larger populations within each caste have furthermore tended to segregate themselves in self-sufficient enclaves, each with its own internal division of labour and its separate cult or sect. Finally, their intercaste exchanges have always tended to be mediated more by shifting power and prices in the marketplace than by corporate group codes.

Specialized mercantile, administrative, and military camp cities of the northern and western regions have seen these tendencies carried furthest, also suffering frequent depopulation and relocation with changes in their specific functions. Certain more permanent royal and religious cities, especially in the south, have seen these tendencies counteracted most fully by centralized exchanges at palace or temple among formal representatives of the various castes. Royal regulation of service, payment, residence, and consumption according to caste rank and unilateral arbitration of disputes over rank also reduced the urban potentialities of anonymity and disorder.

Caste and the religions related to Hinduism. Belonging to a caste is thought by South Asians of the indigenous religions to raise difficulties for the perfection of a person's "soul," his unique natural code (*ātman*). Yet a person cannot exist embodied in the natural order without belonging by birth to one of that order's natural genera and without being subject to its inborn generic code.

Religious attempts to find liberation from caste

Vedic liberation and caste. In the Vedic view, the soul is contained in two kinds of body: a gross body that is abandoned at death and a subtle body that clings to the soul. The gross body belongs to a natural genus, while the subtle body does not; yet, being still a unit in the natural order, the subtle body must go on to be reborn sooner or later within a gross body belonging to some natural genus. The moral actions (*karman*) of a person in following the code of his genus affect the quality of his natural substance; and this determines where in the ranked order of natural genera his soul will be reborn—among plants, animals, demons, gods, or in the same or some other caste of humans.

Further Vedic views stress not the unknowable ultimate rebirth of the soul but its long continuity in its original birth as a heaven-dwelling spiritual ancestor, fed by offerings from corporeal descendants, or as a dissatisfied terrestrial ghost, troubling living persons. These and still other Vedic views continue in the beliefs of some Hindu castes, along with popular theories of this-worldly punishment and reward for moral actions.

Liberation (*mokṣa*) from the endless flux (*saṃsāra*) of birth and rebirth—often called transmigration—is the highest goal of the Vedic religion. Liberation means absorption of the individual code or soul into Brahman, the divine, perfect substance that is the ultimate source of the natural and moral order. This goal is attainable only by a male of twice-born genus who has followed the sacrificial code through the three life stages of student, householder, and forest dweller. Only he is to enter the fourth, or ascetic (*sannyāsi*), stage by abandoning the sacrifice and performing his own funeral. As an ascetic, he is morally dead and thus need have no more concern for his caste nor it for him. He is to own nothing and give nothing to others but is to beg from others of any caste a minimum of food. Thus abasing himself, the ascetic reverses his former high rank. Through knowledge and meditation and aided by such austerities, he strives to obtain control over the relationship of his soul and body in order to effect their complete separation. At his second, natural death, if he has achieved control, his soul is thought to attain perfect liberation from the caste-bound natural order.

Hindu sects and caste. Later, in Hinduism, liberation is thought to be attained through the individual's participation in one of the numerous Śaiva, Vaiṣṇava, or Śākta "sects." Each sect is both a divine and a human moral order thought to have a code above and beyond the natural and moral codes that are inborn in the ranked human genera. Each sectarian order consists of three kinds of persons—gods, preceptors (gurus), and devotees. Persons of any caste or sex are thought eligible to participate. They are related within the sect not by their previous particular natures but by manipulations of divinely coded substance.

In some sects, liberation is attained by assembling these persons more closely. By means of direct personal devotion (*bhakti*) to a chosen supreme deity, devotees are believed to attain a permanent relationship of superior love (*parā-bhakti*) equivalent or superior to liberation. By accepting or eating substances, especially food leavings transvalued by preceptor and deity, the devotees bind themselves to the god and to each other as members of his divine family, overriding the ranks of their castes as they are ordinarily maintained through image worship.

In other sects, those called Tantric, liberation is attained by reversal. By means of secret words and prescribed collective ritual acts directly contrary to ordinary moral codes—*e.g.*, eating meat, drinking wine, having promiscuous sexual intercourse—a person is thought to destroy the bonds that normally link him to the lower human order. He is thereby thought to attain a superior liberated state (*parā-mukti*) while still in human form.

Liṅgāyats and Sikhs. The Liṅgāyat community of Mysore arose within Hinduism in opposition to Jaina and Brāhmaṇa domination during the 12th century; the Sikh community of the Punjab arose as a synthesis of Islām and Hinduism during the 16th century. Both religious communities make radical revisions by manipulating together the mutually immanent, nondual constituents of the Hindu systems that are seen either as encoded substances or embodied codes. Liṅgāyats and Sikhs both believe that they become a divine human genus when they are given initiation (*dīkṣā*) into the making of natural sacred sounds by their teachers (gurus). The Liṅgāyats believe that they become human incarnations of their supreme god, Śiva. Being divine, they reason that their bodily substances at birth, death, or menstruation no longer pollute, as do those of ordinary Hindus. The Sikhs believe that through initiation they incorporate their teachers, who are believed to be perfect and divine, even though human. Both Sikhs and Liṅgāyats believe that they attain liberation while still belonging to their many original castes. These castes are thought to continue as a simply human, therefore lower, order. Ranks of castes in these orders, as among Muslims, are expressed in upward transfer of daughters in marriage.

The higher divine order within both of these communities consists of the categories of teachers, priests, and disciples. These categories are also conceived to be both moral and natural. Any person of any caste or sex who comes to possess the sacred natural sounds of the Liṅgāyats or Sikhs may become a Liṅgāyat or Sikh disciple; and any Liṅgāyat or Sikh may in theory become a priest or teacher. In fact, it tends to happen that members of the higher castes are more likely to become teachers or priests, and members of the lowest castes are liable to be regarded as inferior disciples and therefore excluded in some ways. What distinguishes these communities from their Hindu neighbours, despite such discrimination, is their members' mutual sharing and exchange of transvalued substances. Thus, Liṅgāyat disciples and gurus mutually regard each other as gods, drinking the dirt of each other's feet, while Sikhs of all castes drink nectar from a common bowl and take food reciprocally.

Caste among non-Hindus in South Asia. Other major religious communities in South Asia share with Vedic and Hindu peoples some basic assumptions regarding the particularity of human genera, the unity of substance and code, and most of the meanings of exchanges. Unlike Hinduism, however, both indigenous Buddhism and the foreign religions are at pains to distinguish human from divine substance and the inferior order of castes from another order of superior morality.

Buddhism and caste. The Buddha and his followers advocated a universal moral code transcending all particular codes. By this code, each person should honour the Buddha and his followers with gifts and should be personally nonviolent, moderate, generous, and self-denying in emulation of the Buddha. Living by this code, any person eventually escapes both from the social order and from the world of nature. He attains a superior nonnatural state called Nirvāṇa.

Buddhist conception of a universal moral code

Buddhism relegates the natural Vedic *varṇa*s to a lower moral order and distinguishes from it a higher moral order conceived as containing three new categories—householders, king, and monks. Householders of all castes, rather than only Vaiśyas and Śūdras, are seen as the providers of food, wealth, and service. The king and his officials are to be chosen from among the most qualified persons rather than from among Kṣatriyas only. The highest teachers of morality, the Buddhist monks, are to be chosen by personal qualifications, rather than being hereditary Brāhmaṇas.

Ranks among these social categories are conceived in Buddhist thought as emerging from exchanges like the Vedic exchanges. The Buddhist exchanges differ, however, in being conceived as contractual or voluntary in origin, rather than inherent in any genus. Householders owe taxes to the king as a reward for his godlike gifts of protection and charity. Both king and householders make gifts to the propertyless monks; monks should accept these regardless of the nature of the gift or the donor's sex or caste but should return no food substance, not even leavings, to their benefactors. Instead, monks are to return only the supreme gift—instruction in the words of the Buddha regarding knowledge of nature and regarding the code leading to liberation of the soul from the natural order.

The Buddhist conception of society prevailed among peoples on the trade-oriented peripheries of South Asia (the Himalayan borderland, the present Bengal-Bihār, Pakistan, and Sri Lanka [Ceylon]) and in scattered urban areas until the 8th to 13th century, when it was supplanted in most areas by Hinduism or Islām. Only in Sri Lanka did a Buddhist society survive along with castes until the British period. There, many gods and ranked systems of 20 or more natural castes are found, much as in Hindu South Asia. Above is the distinctive higher moral order of Buddhism, consisting of the Buddha and several orders of monks, the state, and householders, all concerned with the goal of personal spiritual liberation. In the modern Buddhist democracy of Sri Lanka, natural castes tend to lose their moral significance as units of exchange and rank, while the state's legislation is seen as "returning" the society more and more to the remade social order conceived by the Buddha.

Jainism and caste. Jainism arose at the same time and in the same region (Bihār) as Buddhism, and, like Buddhism, it conceives of certain householders and ascetics—not castes—as the social units of a transcendent moral order. It differs from Buddhism in that it does not present an alternative conception capable of embracing the whole of society. The Jaina code for conduct is more extreme than that of Buddhism, requiring adherence to a rule of thoroughgoing nonviolence. In theory, persons of any *varna* or *jāti* may become Jainas; but virtually all occupations, with exceptions such as banking and commerce, are considered to be violent. Hence, most adherents have been members of castes of merchants. Hundreds of small Jaina castes are now found in western India (Gujarāt, Mahārāshtra, Rājasthān).

Islām and caste. Islām was introduced into South Asia by merchants, conquering armies, and missionary Ṣūfīs (Muslim mystics). It became established by the 13th and 14th centuries and became the predominant religion in Pakistan and Bangladesh, where the Buddhist pattern of social organization had predominated. Like the Buddhists, Muslims of South Asia conceive of society as containing a lower and a higher moral order. The lower moral order consists of ranked genera—caste brotherhoods (*berādarīs*) thought to be related by the shared natural substance of blood.

Muslim conception of a lower and a higher moral order

The moral ranks of these rural blood brotherhoods in Pakistan are often based on a reputation for past violence and on the local, hypergamous exchange of women. A brotherhood should take care of its own women; hence, the brotherhood that gives women to another is thought to be morally deficient and to rank lower. In the northern plains of India, where Muslim castes live among Hindu majorities, their moral ranks are more likely to be based on food exchanges. In Muslim-majority communities, however, the public donation of cooked food shows a brotherhood's piety and raises its rank, although the receiving of such donations is not considered to lower its rank.

The moral order of blood brotherhoods, or castes, is felt by Muslims to be transcended by a number of purely social, contractual brotherhoods whose members are supposed to behave toward each other as if they were related by blood even though they are not. The largest purely social brotherhood in the higher moral order is a religious one and consists of those persons who worship Allāh and submit to the Islāmic code for conduct enshrined in the Qur'ān. The single Islāmic deity is said to be the source of the natural and moral order but to transcend it himself. Men depend on him for their bodily existence and salvation, but he does not depend on them, not even for food. Muslims offer up their total submission, but no material goods. However, exchanges of food are made among Muslims on ritual occasions to express the equality and solidarity of the members of a social brotherhood, and also to express the differences of rank in the higher social order. By reciting the sounds of the Qur'ān, eating substances animated by the words of saints, and venerating the remains of dead saints and of the Prophet (Muḥammad) himself, the worshipper becomes more like the saint or the Prophet. Servants of a landholder or followers of a village headman—also brotherhoods in the Muslim moral order—express their subordination by taking ordinary cooked food from him.

The relative ranks of these purely religious and social roles in the higher moral order usually coincide with the relative caste ranks of their occupants in the lower moral order. Persons who occupy the higher roles of saint, pious Muslim, and landholder are usually members of the higher castes, and persons who occupy the lower roles of casual Muslim and servant are usually members of the lower castes. Yet Muslims are quite clear that, when there is a discrepancy between the two, the role occupied by a person in the higher moral order takes precedence. As a result, there is a persistent strain in Muslim communities to bring the caste membership of a person into accord with the role he occupies in the higher Islāmic moral order.

Judaism and Christianity and caste. Other religions accommodate what are seen in South Asia as natural castes. Thus, in Bombay there are Jews of white, black, and recent immigrant descent; in Cochin, besides white and black, there are Jews of slave-mixed descent. Christian converts of many centuries marry and eat within their respective original castes or adopted sects, especially in south India. Adaptations in the higher moral spheres of these religions are much like those made within Buddhism and Islām.

Legal and political roles of caste. *During the pre-British period.* By Hindu conception, castes are categories essential to defining morality (*dharma,* sometimes translated "law"), but not to the calculations of political or economic advantage (*artha*) that all men make as individuals. Morality is conceived to be as highly particularized as nature. Its stratified principles are partly compiled in the moral code books, but its full contents include the varied and innumerable unwritten moral codes (*ācāra*) that are thought to inhere in particular corporate units of each specified kind—lineages (*kula*), castes, or localized communities (*deśa*). If individuals or groups of different castes compete for the same advantages or ends, their competition is not necessarily a matter of moral concern. However, one point of contact between self-interested behaviour and morality is elaborately considered by Hindu legalists: the office of the king. It is the moral duty of the ruler (properly a Kṣatriya) to use force (*daṇḍa*) so as to establish the moral order, especially in order to maintain the rank and separation of the castes, so that their internal self-government and their proper exchanges may continue.

Content of Hindu moral law

All rules, rewards, and punishments among the castes are systematically unequal. Lower castes are customarily prohibited not only from participating in higher worship but also from such acts as touching the higher castes' water, wells, utensils, clothing, persons, or food and from trespassing on their furniture, buildings, roadways, light, sight, and air. Such acts of trespass, along with many more crimes, are scaled from more to less consequential, as the castes involved are ranged from high to low. Done at the command of a person of higher caste to a person of lower caste, such acts are thought to be privileged or acceptable, but, done on the lower's initiative, they cause insult or "pollution" to the higher and deserve graded retaliation or punishment.

During the British period. British administration took an interest in the Vedic moral code books as statements of abstract principle but followed their own views of law as essentially above nature and as unconnected with particular categories of men. As part of a policy of nonintervention in religious and social matters, they declined to play explicitly either the Hindu ruler's role of enforcing caste distinctions or the reformer's role of abolishing them. Local officials were generally as unsympathetic to reform as were local communities, so that, in effect, local caste codes of exchange tended to be supported. At the same time, other governmental measures and widened communications unintentionally encouraged an intensification of internal caste organization. Military units were recruited on a caste basis. The caste membership of individuals was registered in censuses and published in composite totals, and competitive claims by about one-fifth of the castes to affiliation with Vedic *varṇa*s were stimulated by court applications of Hindu personal law.

Limited reforms of the political relationships among castes were undertaken after 1919 in connection with the widening of political franchise. These reforms included reserved legislative seats and benefits in education and employment favouring the lowest ("Scheduled"; *i.e.,* officially listed) and very low ("Backward") castes and tribes. Such reforms underlined the separateness of caste groups and rewarded political allegiance to them and to the imperial government awarding the new advantages. Certain larger castes or merged clusters of similar castes also became politicized, forming associations to press for advantages in the widened arena of governmental competition. In all regions, effective organization for gaining power required less narrowly based political alliances, factions, and parties that could incorporate members of many castes.

Effects of the Indian independence movement

Such political changes during the later British era, along with the British exclusion of religion from governmental concern, stimulated leaders of the independence movement to try to reshape the Hindu social system, seen as a whole made up of particular natural genera, into a structure suited to the winning and the running of a nation of united citizens. B.G. Tilak in Mahārāshtra in the 1890s mobilized urban ceremonies of communal worship in which representatives of all Hindu castes and neighbourhoods offered prayers for political salvation to the Vedic and regional god Gaṇapati. Mahatma Gandhi, Tilak's pupil and the architect of India's freedom, in the 1930s urged a return from the multiplicity of *jāti*s and secular individualism to a neo-Vedic system of four *varṇa*s and stages of personal life (*varṇāśrama-dharma*). This was to be a system emphasizing the mutual responsibility of each to all, one in which men would affiliate themselves with *varṇa*s (interpreted as organically related socioeconomic classes) according to the way they reshaped their bodily natures by following codes of vegetarian and nonalcoholic diet, fasting, sexual abstinence, and public service. Gandhi's hope was to abolish the category of the lowest, sub-Śūdra castes—whose members he labelled Harijans (Offspring of God)—by reversing their former position in the code of exchanges. Harijans were made to serve cooked food to workers of the higher castes, while these in turn swept the garbage from the Harijans' streets. Harijans entered previously forbidden temples of southern India under Gandhi's leadership. Ultimately, as the reformers hoped, the many previous grades in worship tended to become reduced for all persons to the minimal two grades of priest and worshipper, if not to a single grade. The wide popular appeal of these and similar programs of revival and reform must be ascribed to their speaking initially in the caste idiom of substance and code. Their successes led to the strengthening and activation of still larger regional and religious castes, such as Hindus, Muslims, and Dravidian nationalists, which sometimes clashed with others in subsequent competition for power.

A still more innovative and prominent change in caste thinking, devised first in 19th-century Bengal, declares the land substance of India to be the nourishing mother of all her people, Hindu and Muslim, high caste and low. Mother India's code for conduct enjoins unity on all residents in her service and defense. This universalizing scheme spread officially through the nationalist movement to the new nations of India and Bangladesh.

Modernizing tendencies in caste thinking

Since 1947. The independent governments of South Asia have moved vigorously to modify caste conduct through legislative action. Most consistent with earlier Buddhist and Islāmic roles was Pakistan's declaration to be an Islāmic state having transcendent law and therefore having no need to recognize the natural castes.

A secular legislative Indian approach to conduct is seen in the Hindu code laws of the 1950s. These replace the particularistic Vedic moral code books by a uniform code taking no account of *varṇa.* They also abolish caste endogamy as a requisite for valid marriage. The legislative approach is seen fully in the Indian constitution of 1950, authored chiefly by B.R. Ambedkar, leader of a party of the lowest castes. The constitution rests on the notion that government must regulate individuals directly and not through autonomous corporate castes. It abolishes caste "untouchability" (now to be legally defined by courts) and forbids any other restriction on public facilities arising out of caste membership. Subsequent legislation against caste restrictions has proven generally influential at the urban temple or the crossroad coffeeshop but not at the village well. Ambedkar advised his followers to renounce Hinduism in favour of Buddhism, which he saw as providing a casteless social system.

Many modern South Asians consider caste-reform actions by government as necessary and desirable but regard the distribution of economic resources among castes as the most crucial problem. South Asian Marxists go further in their economic program, yet less far in their social program, holding that castes are secondary and need not be a subject of policy; Marxists expect that castes will disappear by general intermarriage once the only real forces—the antagonisms of the economic classes—are resolved by revolution. The overall official Indian position on caste systems by the 1970s was a compromise: natural ethnic groups are relegated to a lower order that is devoid of legality, and provision of comprehensive moral, economic, and political codes is a function reserved to the processes of the transcendent national state.

Persistence and evolution of caste

The ideas of South Asian citizens as to what caste systems are and should be vary widely among the positions sketched. Practice also differs. Thus, norms of caste endogamy appear generally to have stiffened, while marriages outside of certain small urban groups of high caste nevertheless may exceed 20 percent. Traditional caste occupations are followed by an overall minority that grows less each year, but these occupations are often replaced by similar substitutes. The forms of Hindu worship are subject to constant innovation, but worship itself—ranked exchange between the genera of men and gods—is not abandoned. Where prevailing opinion is conservative, as in most rural localities, caste codes of exchange may continue to be observed publicly although individuals violate them privately; where opinion follows the official position, as it often does in cities, ranked exchanges among the castes may be confused or transcended publicly but maintained by conservative families in the domestic sphere. Most individuals move among social compartments that differently organize the enduring linkage between substance and code.

Caste systems in societies outside South Asia. Caste systems need not be thought of as unique to South Asia or to its emigrants. Rudimentary caste systems have appeared elsewhere to the extent that similar situations, structures, and cultural concepts were present.

Situations of encroachment between alien ethnic groups have generally been productive of simple, short-lived caste systems like that of Aryans and Dasyus in northern India in early Vedic times. Many a society has opposed itself as a superior whole to a despised immigrant population of traders, artisans, or Gypsies but usually without developing systematic conceptions or mutual consensus regarding ranks. Many a society has incorporated but ranked separately, then in time assimilated, a caste of foreign conquerors (*e.g.,* Peru), slaves (*e.g.,* Brazil), or noncitizens (*e.g.,* imperial Rome). Occasionally, a society such as Mexico, with its duality of European and Indian cultures, has preserved contrasting ethnic styles of life long after rank, descent, and marriage have ceased to insulate the onetime castes from each other socially.

A relatively small number of ethnically heterogeneous, expanding societies—certain medieval African tribal kingdoms and some recent European colonial states such as the United States, Rhodesia (now Zimbabwe), and the Republic of South Africa—have used political means to perpetuate the ranks, occupations, and biological relationships of two to four ethnic categories. The legality of the black and white caste systems in the United States did not endure two centuries, and the moral future of other recently legislated colour-caste systems is in question, but there is no doubt that ritualized composite tribal kingdoms such as Mali and Rwanda in Africa did maintain simple caste systems with moral authority for some five centuries.

Castes have rarely developed out of a single society's classes. In East Asia, several homogeneous societies sharing Buddhist ideas regarding the bodily pollution of death (Tibet, Korea, Japan) have generated internally their own local fractions of morally abhorred specialists, originally leatherworkers. These occupationally outcaste persons constitute small, scattered populations, separated in marriage and descent from the local majorities, although not thought of as ethnic or corporate units. In the lower Mississippi Valley of North America, the Natchez and Chitimacha tribes developed internal caste systems tied to hereditary offices in village war and temple cults while absorbing alien ethnic groups as the lowest of four ranks. The relative success of the Natchez in developing an internal caste system may be attributed to their facing, like the later Aryans, sharply defined alien ethnic units with an internal moral system of sharing and exchange.

(Mc.M./R.B.I.)

MINORITY GROUPS

The most common general description of a minority group used is of an aggregate of people who are distinct in religion, language, or nationality from other members of the society in which they live and who think of themselves, and are thought of by others, as being separate and distinct. Separation, too, often implies that the members of such a minority are excluded from taking a full share in the life of the society because they differ in certain ways from the dominant group—a situation that tends to develop attitudes of discrimination and prejudice toward the minority in question, attitudes that may also be assumed by other groups or minorities in the society. The minority itself is likely to respond with strong attitudes of group loyalty and to develop forms of behaviour that, by design or not, help to segregate its members still further from the rest of society.

"Minority" and "minority group"

The sociological employment of the word minority, then, largely agrees with common usage in denoting a distinct, separate group of people who are different in certain easily recognized aspects from the majority. But the term minority group implies rather more; for to a sociologist a social group of any kind is an aggregate of people with defined aims and rules of membership and with its own obligatory rules of behaviour and a subculture that publicly mark it off from the rest of society. It is the use of particular forms of cultural behaviour, used as criteria or emblems, that marks off a minority group from other types of group.

The word minority denotes by implication a part of a larger whole, but a minority group in the sociological sense is not always a numerical minority of the population. In parts of the southern states of the U.S., blacks form a clear majority of the population, but they are nonetheless a minority group in relation to the numerically smaller dominant group of whites. A similar situation existed in East African towns under the former colonial rule of the British. Under British rule immigrants from India had settled in East Africa as traders and skilled artisans. Most of them lived and worked in the towns, where they formed the overwhelming majority of the population, although, in East Africa as a whole, the Indians numbered less than 1 percent of the total African population. Despite appearances in the towns, the Indians were clearly a "minority group." In South Africa, to take another example, the Bantu population, although many times more numerous than the dominant white group, are nevertheless a "minority group."

A minority group is generally but not always politically less influential than other sections of the population, but its political position is only one factor in distinguishing a minority from other types of grouping that may also occupy subordinate positions. What marks off a minority group in the eyes of members of a society are a number of other distinctive features: race (as, for example, in South Africa or the U.S.), culture, language, religion, or economic function. To ordinary citizens it is characteristics of this kind that matter when they think of minority groups. A few examples of different kinds of minority groups should make these various points clearer.

After the Norman conquest of England in AD 1066, the native Anglo-Saxon inhabitants still constituted the majority of the population, but their culture and the social forms sustaining it were subordinated to Norman-French political, social, and cultural institutions. Like Africans, many Asians, and American Indians under the former European colonial empires, they lived as a linguistic and cultural minority group.

Religious minorities

The demarcation of minorities by religion is possibly more familiar from historical sources than from contemporary situations, where, especially in the Western world, the adherents of separate religious persuasions are more commonly regarded as categories of the population than as coherent groups of people with distinctive religious, cultural, economic, and political aims, which they pursue in their own interests. But even today such situations are not uncommon. In the northern parts of western Malaysia, for example, Thai-speaking Buddhists form an important religious and cultural minority group, whereas a few miles across the border in southern Thailand it is the Muslim Malays who are a religious and cultural minority. In India and Pakistan the confrontation of Hinduism by Islām led to the emergence of minority groups whose differences, though expressed primarily in a religious idiom, had important political and economic aspects. When the English consolidated their conquest of Ireland in the 16th and 17th centuries, a small number of English-speaking Protestants gradually spread out through a much larger Irish-speaking population of Roman Catholics and subordinated them religiously, culturally, economically, and politically. But only in some contexts were the Irish regarded as a purely religious minority group: in most situations they were seen, and felt themselves, to be primarily political and economic subordinates.

Economic minorities

Any social group formed for particular aims is likely to develop distinctive cultural features, but a group whose ends are primarily economic seems to do so less frequently, unless its organization is also intimately associated with other principles, such as race or kinship. Shopkeepers in any society are people with a number of shared interests. They are usually united in common associations, such as chambers of commerce, but it is unusual for them to constitute a minority group in the strict sense. In certain circumstances, however, they may do so. During the 19th and 20th centuries large numbers of Chinese people emigrated to Southeast Asia. Their motives in leaving China were almost exclusively economic: it was hard for them to earn a living at home. In Southeast Asia most of them eventually became traders, forming closely knit economic groups. The indigenous inhabitants of Southeast Asia, however, as much as the Chinese themselves and their colonial rulers, always saw these groups as Chinese first and only secondly as economic. In other words, the immigrants lived as Chinese ethnic groups with economic functions rather than as economic groups, most of whose members happened to be foreigners.

During the same period there was also a large emigration from the subcontinent of India to places as far apart as the Caribbean, Fiji, East and South Africa, Mauritius, and Great Britain. Like the Chinese, these Indian emigrants left their homes for economic reasons and settled abroad as trading or labouring minorities, but, as in Southeast Asia, the people among whom they settled regarded them primarily as cultural and ethnic groups.

The form of a minority group and its position in a particular society depend on many variable factors. Its members, as has been seen, may be bound to one another by common religious ideals or by similar political, cultural, or economic interests, or the tie may be one of race. In East Africa the Indian immigrant settlers distinguished themselves from the Africans and the Europeans first by the differences of their Indian languages and their Indian culture, but they also used the criterion of race to separate themselves, especially from the Africans. In Great Britain the dominant English group uses race as the main criterion to segregate ethnic minorities such as immigrants from the Caribbean, India, Pakistan, or East Africa. But however a minority group may be demarcated, for it to maintain itself as a group its organization normally must include political, economic, and cultural aspects. The emphasis placed on these various factors determines the form that the minority group takes and the place that it is assigned in society. Further, the emphasis itself varies with factors such as the group's size, its ideology, and, to some extent the outcome of these two, its wealth and political power.

The nature of ethnic groups and other types of minority groups. A social group, as noted earlier, may be founded on almost any kind of common interest, but, as also noted, strict reference to minority groups should be made only when the interests that bind the members also serve to separate them from the rest of society in ways that are felt to be significant by everybody. In most Western countries Freemasons are an organized minority of the male population, but to most people their characteristics do not mark them off as a minority group in quite the same way as do the distinctions of race for blacks in the U.S., for example.

"Race" and ethnic groups

Physically men vary widely, and in some societies selected bodily characteristics, lumped together under the broad heading of "race," are used as marks of social differentiation and for the formation of minority groups. If race is thought to be important, then it is likely to be used in forming groups that today are more usually called ethnic groups than minorities. (Some writers, especially in the U.S., have applied the term ethnic group also to immigrant groups who are distinguished by cultural differences in language and national origin but who have no distinguishing physical characteristics. They can, if they wish, sometimes shed their particular cultural characteristics and disappear into the wider population in ways not open to the members of ethnic or racial groups who carry the marks of difference on their persons.)

Not every society whose population is racially diverse elects to make use of race for social purposes. In much of the Greco-Roman world, in many parts of past and modern Islām, and in some areas of Latin America a man's racial attributes may have as little significance as does the possession in northern Europe of dark or fair hair. The variations in the use of physical characteristics for social purposes can be placed illuminatingly on a scale. At one end are those societies in which racial attributes, if they are noticed at all, merely place people in ethnic categories, in much the same way as the males and females of a population are often separated for social purposes. Among the ruling classes of Mexico, for instance, the physical differences between people of predominantly Caucasian and Amerindian descent are very apparent, but in many situations of social life they are unimportant compared with the possession of a common pattern of social positions in society and a shared culture based on the Spanish language. Such a society is at the opposite end of the scale contrasted to one like South Africa, which makes extensive use of racial criteria in the allocation of group membership.

An important characteristic of a social category is that it can easily become a group if its members are led to hold values in common and to follow rules binding on all members. In the same way a social group, whose members lose their common purpose and sense of corporate identity, can become no more than a social category or even disappear altogether. Indian immigrants in South Africa, for example, were heterogeneous in origin and social composition, and in the earlier stages of their settlement they were loosely united only by some common, but vague, qualities of "Indianness." Nevertheless, they did constitute a distinct and recognizable element in the population, thus making them a social grouping more cohesive than a mere category but less cohesive than a fully organized group. Later changes in South African law compelled the Indians to assume more and more common, obligatory rules of behaviour that were different from those of other sections of the population, thus consolidating them into an increasingly corporate and separate ethnic group.

Characteristics of cultural diversity. It is clear that any society may include (and that most have and do include) a large number of subgroups, or constituent groups. The manner in which the constituent groups are arranged and related to one another determines the social form or structure of the society. Minority and ethnic groups do not in principle differ from other social subgroups; however, their aims, the rules by which they recruit members, and their internal organization may well be different and impose special forms of behaviour on their members. Just how a minority group is related to the other sections of a society depends in part on the structure of the society itself and in part on the structure of the minority group.

An integral aspect of the structure of any social group is the set of ideas and beliefs held by its members, which largely determines their aims and, to a greater or lesser degree, guides their actions. The ideology of a minority group is an important element in the place that it is allowed to occupy in a society, but as important, and often more significant, is the ideology of the dominant group in the society. Its members and those of the other constituent groups exercise all kinds of political, economic, and other pressures to produce a situation that as far as possible satisfies them. But it is rare for any group, whether dominant or not, to have the power to impose a situation that is wholly of its own choosing: the process is almost always a two-way, reciprocal one.

There are, roughly speaking, two ways in which the members of a society may try to solve the problems posed by the presence of a minority group. They may either attempt to eliminate it altogether or decide to tolerate it. Both methods, separately or combined, with good grace or bad grace, have been used many times in the past. They are still being used today.

Elimination of minorities: assimilation, suppression, ejection. When the physical features, aims, or behaviour of the members of a minority group are unacceptable to the rest of society, there may be attempts to get rid of the minority altogether—either by forcing or encouraging its members to adopt the dominant group's culture and so be assimilated or by completely ejecting the minority from the society.

Assimilation

Assimilation (sometimes called acculturation) has been defined as those phenomena that result when groups of individuals having different cultures come into continuous first-hand contact, with subsequent changes in the original culture patterns of either or both groups. The process is a familiar one in the modern world. During the 19th and 20th centuries very large groups of immigrants, many of them speaking foreign languages, were encouraged to settle in the United States, but the possibility that they might develop into permanent, compact minority groups was felt to be a threat by the largely Protestant, English-speaking dominant group of American society. Prolonged and successful efforts were therefore made by means of school education and ideological indoctrination to assimilate the immigrants and their children as rapidly as possible. A similar policy of directed acculturation has also been successfully followed in Thailand, where the governing elite felt that the large and economically powerful minority of immigrant Chinese traders presented a political and cultural danger to the Thai people. The government, therefore, by means of legal inducements and restrictions on business and family life, combined with compulsory Thai education, have, without physical force and in a relatively short time, almost completely eliminated the Chinese minority as an ethnic group.

Ejection and suppression

The contrasting method of ejecting an unacceptable minority (and coercing those who chance to remain) is perhaps only a little less common than peaceful assimilation. A combination of ejection and suppression has been used many times in many parts of the world. In the 17th century Protestants in France were banished or driven into concealment if they refused to change their religion. In the same century the small minority of Christians in Japan was proscribed and eradicated. In modern Indonesia the Chinese trading minority, as in Thailand, was seen as a threat to national interests; the traders were therefore violently driven out of the country or forced rapidly to adopt most aspects of Indonesian culture. In the newly independent countries of East Africa the dominant African group, considering the long-settled Indian traders to be a threat to their interests, physically ejected as many as they could and severely limited all spheres of activity open to those who remained. Perhaps the most dramatic example of extermination or attempted extermination was the fate of the Jews under Nazi rule.

Assimilation necessarily takes time. It is usually a reciprocal process, and it is not always the culture of the dominant group that survives. The Greek invaders who followed Alexander III's armies and set up independent kingdoms in northwestern India disappeared almost without trace. For 200 years after the Norman conquest of England, the French language and culture were supreme, but English, a modification of Anglo-Saxon, was the language finally spoken in the country. The dominant culture evolved into a combination of French, Norman, and Saxon institutions; the same eclectic process can be seen at work in any postcolonial country in the world today.

Toleration of minorities: pluralism. A minority may be tolerated either because its aims and organization are not felt to be sufficiently objectionable to be eradicated or because the dominant group in the society, even if it dislikes the minority, may think that it is unable for political or ideological reasons or that it is morally wrong to assimilate, eject, or suppress it.

The rulers of several countries in western Europe in the 12th and 13th centuries found it hard to tolerate Jews, but so many of the rulers relied on Jewish trade and finance that they could not afford to destroy them. The rulers were consequently forced to allow Jews to live partly on their own terms, difficult though it was in that particular feudal society to accommodate non-Christian aliens or persons without feudal status. In England this was done by segregating them in ghettos; in Spain and Portugal, where the feudal system was less rigidly organized, their freedom was greater.

During the 20 years after 1950, immigrants from the Caribbean, Pakistan, and India settled in Britain. The British did not welcome their arrival, even though their services were essential for running the economic and social system, nor did the British like certain aspects of the immigrants' culture, which combined with their physical appearance made the new minority grops socially very visible. But the ideology of the British people made it equally difficult for them seriously to consider eliminating these new groups either by ejection or by assimilation, and so they were reluctantly compelled to accept forms of cultural, social, and ethnic heterogeneity that had not before existed in their society.

The toleration of ethnic and cultural minority groups can produce a wide range of different types of social organization, most of which involve some form of separation. A minority may be completely segregated (as in medieval Jewish ghettos) even when separatism may not otherwise be a major structural principle in the society. Alternatively, separatism may run right through the system, as it does, for example, in Switzerland. In that country separate linguistic and cultural groups are effectively segregated by living in different districts, although all are united by a central administrative system, which, unlike that in most multiracial and multicultural societies, is not controlled by one dominant group. Other less extreme forms of separatism are produced by discrimination of varying degrees of intensity and by excluding a minority group from goods valued by members of the society. A society divided into minorities resolves the problems of pluralism by balancing the factors that make either for the complete elimination of the minorities on the one hand, or for complete separatism, short of fragmentation of the whole society, on the other hand.

The pluralist model

Types of societies with cultural divisions. Pluralistic situations are common in all parts of the world and have given rise to much discussion. The term pluralism is used by political scientists for the view that political, cultural, and social systems are most usefully considered as being made up of separate but interdependent groups whose qualities together produce a characteristic and valuable moral order or unity. After World War II, pluralism was used and developed to describe and interpret societies divided into cultural and ethnic minorities and held together by the political power of one dominant group. J.S. Furnivall, who first began to limit the term in this way, wrote in 1948:

> In Burma, as in Java, probably the first thing that strikes the visitor is the medley of peoples—European, Chinese, Indian and native. It is in the strictest sense a medley, for they mix but do not combine. Each group holds by its own religion, its own culture and language, its own ideas and ways. As individuals they meet, but only in the market-place, in buying and selling. There is a plural society, with different sections of the community living side by side, but separately, within the same political unit. Even in the economic sphere there is a division of labour along racial lines.

The stratification model

Whether or not such "plural societies" are usefully considered as a special type is a matter that has provoked much argument. For one thing, critics would contend that all complex societies are more or less culturally heterogeneous and that to list alternative values and institutions within individual societies does not often help to distinguish one type of complex society from another. For reasons of this kind most social scientists have preferred to use the traditional models of stratification in analyzing social diversity. A society in which technology and the economy are able to support a large population is usually divided into broad divisions or strata—classes, castes, or estates—that form a hierarchy of wealth, power, and prestige. Such strata are marked off from one another by special rules of behaviour or forms of subculture, which are to a greater or lesser extent obligatory on all the members of each stratum, and which give them a graded access to goods (such as wealth, power, and prestige) that are valued by everybody in the society. Even though these broad divisions may not always correspond with the sections of a plural society or with ethnic or minority groupings, they do correspond often enough to merit further consideration of stratified and unstratified forms of society in reference to minorities and ethnic groups.

Relatively stratified societies. In any system of stratification the forms of behaviour and the rights of graded access to valued goods, which mark off one stratum from another, must be both objectively observable and subjectively accepted by most of the members of the society, all of whom must also occupy only one place in the system at one time. These criteria are sufficient to distinguish a system of ranked social groups, as, for example, that of the upper, middle, and lower classes in England during the 19th century, from an ordering of ranked statuses or positions, such as was also found in England in the same period in the rules of precedence that placed the queen's subjects in descending order below her, from the degrees of peerage to the degrees of commoner status. These criteria alone are, however, insufficient for distinguishing different types of stratification, any of which may be found in a society where ethnic or other forms of minority group are component elements of the system.

A system of social stratification may be closed or open. If an individual's place, once assigned, can in theory or practice never or rarely be altered, the system is closed. If, in contrast, social mobility from one stratum to another is permitted, then the system is open, and the relation of one stratum to another is necessarily competitive. In a closed system not only is place assigned but shares in scarce and valued resources are also differentially assigned to the separate strata. As places and resources are graded and fixed, it follows that if a closed system is to work the relations between the strata must be cooperative to a considerable degree.

Caste systems

A traditional Hindu caste system was a small self-contained hierarchy of endogamous groups in which an individual was given a permanent position at birth. Relations between the groups were governed by religious rules, the breach of which was believed to produce a state of dangerous impurity that carried ritual, legal, and other penalties.

The English word caste refers to two separate systems of social relations. In the one, the traditional fourfold division of Hindu society into four *varṇa* or castes (priests, soldiers and administrators, businessmen, and labourers) is sometimes described in Sanskrit literature in terms of what appear to be ethnic differences, but at least in historical times the *varṇa* have not constituted a system of stratification. Sociologically speaking they are categories of value, which refer to all parts of the Hindu world and which people use, among other things, for placing themselves and the subcaste group to which they belong in the hierarchy of districts outside their own local caste system.

The word caste also refers to the several thousand small, self-contained, local hierarchies of endogamous subcaste groups, or *jāti,* of which Hindu society was made up and of which a Hindu state might include a great many. Each *jāti* was named and ranked, though the ranking might not be the same even in adjacent local hierarchies. Traditionally each subcaste had a particular service assigned to it, so that the sons of goldsmiths or priests, for example, though not bound to follow these occupations, could prevent others from practicing them. In India neither castes nor subcastes were usually ethnic or cultural minority groups in the usual sense of the word, but in Iran and other parts of the Near East, cultural minorities are sometimes components in small-scale caste systems. It is possible, too, that in some areas of the southern states of the United States society could be most usefully described and interpreted by using a similar model of a local caste system.

Estate systems

If one is content to say, as are many, that in both South Africa and India social stratification is based on caste, then the concept of closed stratification need be examined no further. But writers on India do not usually agree that "colour-bar" societies are necessarily caste systems, and certainly in South Africa, although individuals are assigned positions in ranked strata at birth, the society is large scale and is not made up of many small, local hierarchies. Most important, as in most industrial societies, the ties between individuals are not multiple: the fact that a man employs another does not usually mean that he is also his landlord, his creditor, his lawyer, a member of the same church congregation, and attached to the same political party. Thus in many of its aspects the South African system of closed stratified ethnic groups is nearer to the model of a feudal estate system than to that of a caste system.

In Europe feudal estates were defined and ranked by law, and penalties for a breach of the rules of rank were legal, not ritual as in a caste system. Admission to the estates was regulated by birth and a few other carefully stated criteria, so that a man's social standing as a noble, a cleric, or a commoner was legally defined and carried with it rights and duties shared by all members of his estate and not by others. Estates were also political in nature in that representatives for assemblies such as Parliament in England and France were recruited according to their rank. An estate was a closed group whose members could not in theory move out of it into another.

The population included in an estate system might, unlike that in a local caste system, be so large that the people in it did not have the multiple ties and close knowledge of one another, characteristic of a caste system and perhaps necessary for the working of the intricate and close-knit network of ties and regulations that held it together.

In writing of ethnic minorities in contemporary societies or of slaves in older societies, authors often speak of "caste"; and though they are generally aware of the fact that they are using an analogy, nevertheless misleading implications are frequently carried by the metaphor and are not always discounted. In analyzing the place of highly segregated minority groups in a large-scale society, a model based on a caste system is seldom as useful as one based on an estate system.

Open stratification

In some situations and places, as in parts of the Caribbean, ethnic or culturally distinct groups are often treated as, and in fact may be, social classes. Sociologists generally consider a social class to be an aggregate of people in roughly the same social position, which is different from that of other social classes, and which, unlike position in a caste or an estate system, allows movement from one stratum to another. Because mobility is permitted it is not always easy to draw a boundary between one class and the next, nor is it always easy to decide how far the members of a class are bound to one another by ties that make the whole aggregate an institutionalized group. Furthermore, in an open system of stratification the scarce resources valued by the society are not overtly and explicitly allocated to each ranked stratum, and relations between classes are therefore necessarily primarily competitive, not cooperative as they often are in a closed system, where, within limits, an individual's share of resources is prescribed by his rank.

When some of the qualifications for belonging to a social class are also those for belonging to a minority group the difficulties of analysis may become very great indeed. In the later stages of the Spanish Empire in Mexico the qualities of being Indian—qualities such as physical appearance, the use of an Indian language, and a peasant or servile status—were also the marks of low class position. At a later period, with the acquisition of wealth, Spanish culture, and political influence, individuals from the lower classes could and did move in relatively large numbers from one social class to another. In the process the boundaries both between the social classes and between the ethnic groups often became blurred.

When social mobility in a system of stratification becomes very general and rapid, the system may sometimes change quite quickly into one of ranked individuals and not of ranked groups. In the opinion of some students of society, this condition has already been reached in the United States and may be a contributory factor in the difficulty that is sometimes met in absorbing certain minority groups. For instance, other members of American society are more likely to regard Negroes as stereotyped representatives of a minority group with prescribed social roles to play than they are to regard them as individuals making their own social roles outside fixed social groups. To the degree that Negroes are seen in this way they are encouraged to conform with the general view and assume stereotyped roles. Because they lack the greater freedom that other citizens have in choosing roles and in moving from one position to another, they often become even more effectively segregated.

The traditional models of stratified societies, which have been discussed here, are of course merely "ideal types" that have been constructed for studying social processes, which in different combinations produce different types of society. Any real-life society may in fact never quite match any of the ideal types, whose functions are simply to isolate the social processes that, acting together, produce particular situations. The models are useful in helping to think about such situations and in allowing a minority group to be placed in the structure of the society of which it forms a part. Much of the thought about minority groups in the past has been confused by focussing attention on inessential attributes. It is not the blackness of the Bantu in South Africa that is socially significant: it is their position in the formal structure of the society.

Relatively unstratified societies. In all societies there is a division of social labour and some diversification, but not all are stratified. Most of the discussion of pluralism has been of racially and culturally diverse populations within the jurisdiction of a central government—in such countries as Switzerland, Malaysia, and Canada. But there are other types of plural situations in which separate ethnic or cultural groups live within a common and accepted system of relationships that does not amount to either an effective central administration or a system of ranked groups. Systems of independent but allied groups of this kind were not uncommon, especially in tribal areas, before the expansion of European colonial regimes. In the eastern woodlands of North America, for instance, a group of Indian tribes known as the Iroquois had confederated for purposes of making decisions in common, even though central administrative control was lacking.

The Swiss model

In Switzerland, as has been noted, cultural and linguistic groupings are sharply differentiated and maintained. Within itself each group may be separately and differently stratified, but access to power in the wider society does not seem to be limited by local or cultural origins, nor does it seem to be limited by any ranking of the separate cultural groupings.

In western Malaysia the population is evenly divided between Malays and Chinese. There is also a small minority of Indians and even smaller ones of aboriginals, Thai-speaking Buddhists, and a few other small groups. The aboriginal population is almost wholly separated from the rest, and the majority of the Malays live in rural districts, whereas the Chinese are mostly urban dwellers. The ethnic groups are not segregated by law. The political constitution provides that the men who direct the machinery of government and hold legislative powers shall be impartially selected by voting. In practice electoral procedures and the staffing of the army and the civil service have put most political power in the hands of Malays. The greatest economic strength is in the hands of the Chinese. This distribution makes a permanent balance of power difficult. The fortunes of the Chinese could be threatened by political action, and they might use their wealth to upset the political balance and so threaten the Malays. Under the colonial rule of the British, the Malays, the Chinese, and the Indians were unorganized ethnic categories; but since independence the categories have for political purposes become more and more organized as corporate ethnic groups. Neither the Malay nor Chinese group is completely dominant, and in the strict sense neither is a minority group.

The situation in Malaysia, where no ethnic group is completely able to dominate the central government, is exceptional. The situation in Kenya, Tanzania, or Uganda is more usual. Since independence the Africans have been the dominant group in all those countries, which also contain Arab, European, and Indian minorities. Like the Chinese in Malaysia, the Indians in East Africa are economically strong, but their numbers have always been far too few for them ever to think of making a bid to take over the central administration and run the country in their own interest. Indians, for various reasons, are now regarded by the Africans as an objectionable minority group, and for ideological reasons they are being driven out of Kenya and Uganda.

The effects of the rise of the nation-state

Toleration of minority groups depends in part, as noted earlier, on such factors as size, wealth, access to power, and ideology. In modern nation-states wide differences of ideology are not as a rule very willingly permitted, possibly because the idea of a nation implies that if the nation and the dominant group controlling it are to survive, its citizens ought to hold strong, common, national values. The difficulties in deciding how far divergent minorities and ideas can be tolerated is not new, nor are they confined to new nation-states with ethnic and cultural minority groups held together only by the political power of a dominant group. In the 16th century France was divided between Roman Catholic and Protestant Christians, and each group, for its own safety, felt that it had to capture the central government. The victorious Roman Catholics, for their own sake and the safety of the French nation, as they saw it, did not cease their war until the Protestant minority was virtually eliminated.

The idea of a nation-state and the idea of tolerating a minority are to some extent in opposition to one another. The very long-standing solution to the problem reached by a country like Switzerland is unusual. The balance reached in such countries as Malaysia or Canada sometimes gives the impression of a temporary solution, which may at any time give way to a unitary state dominated by one group or to the secession of the minority to form a new nation. The dilemma is important in many parts of the world, especially in such areas as the Caribbean, the United States, and southern and southeastern Asia, where cultural distinctions have often fused with political hostility. It is this widespread fusion of ethnic and cultural hostilities as one of the main elements of political programs that has undoubtedly drawn many to the concept of a plural society. The concept does not give a satisfactory account of the structural characteristics of pluralistic societies, but what its advocates may be attempting to describe and analyze is a political situation in which ethnic and cultural loyalties are felt to be more important than the interests of class or party or any other group in society. This transformation of ethnic and cultural hostilities into political programs is closely related to the problems of minority groups and their place in society.

In the past, pluralism has usually been discussed as if it were a feature only of societies with a central administration. It is, however, not uncommon to find ethnic and cultural groups, whether adjacent or intermingled, that live within a common system of relations constituting an alliance of some kind but not an effective central administration.

"Tribal pluralism"

In northern Thailand, Burma, Borneo, New Guinea, and other parts of the world small independent groups of ethnically and culturally distinct peoples were dispersed and mingled over wide areas without being subject in any effective sense to a central government. Among the Kachin of highland Burma, peoples of different languages and cultures, sometimes resident in the same villages, were united in a common network of marital, political, and trading alliances. On the Baram and Rajang rivers of Sarawak in Borneo, villages having different cultures and speaking different languages were interspersed along the banks. Each village was politically independent with its own characteristic social structure. In most villages the inhabitants were rigidly ranked: those of the lower ranks married and lived, for the most part, within their native villages; but those of the upper ranks, both men and women, married and often moved into other villages and other cultures for political and economic advantage. In most of these societies ranking was a fundamental principle of organization, but the different villages and cultures were not ranked against one another. Each was different from and none was considered better than the other. The system of alliances that held together a considerable population, culturally and linguistically divided, had certain similarities to the system by which modern nation-states maintain their independence and diversity.

The functions of minorities and ethnic groups. Minority groups have performed almost every type of function in almost all known types of social system. Minorities have played economic roles as specialist bankers, traders, or craftsmen; more often they have been manual labourers, whether slave, serf, or free. As revolutionary groups they have acted as ideological leaders in political life; sometimes their function has been to hold the political balance; more often they have been the subject of exploitation. Some, because they have special skills, may be valued for their artistic contributions to social life and yet not be altogether socially acceptable to the rest of society. Earlier it was noted that the role played by a minority group within a society varies with such factors as its size, its skills, and its ideology and also with the roles of the dominant and other groups in the society. The amounts of wealth that the members of the group can accumulate and the political influence that they can exercise vary with the ways in which these factors arrange themselves. Factors such as these obviously work differently in different types of society, and even in the same type the balance is never likely to be identical in any two societies.

Their economic roles. A division of labour is a feature of all societies, even the simplest, but unless the population is large enough to free specialists from the task of finding sufficient food and shelter for themselves and their dependents, the society is unlikely to be able to support wholly specialized groups. Without a sufficiently large population, too, a system of social stratification cannot develop; for a graded distribution of resources among the social strata is possible only if there is a sufficiency of basic goods for everybody.

In a system of closed stratification, in which movement from one stratum to another is forbidden, and in which resources are differentially allocated to the strata, functional specialization is likely to be a feature of the system. Specialized groups, handling resources that are the property, so to speak, of their members and of their stratum, are likely to resist change and defend their specialization and the resources that are needed for it. In an open system of stratification, on the other hand, where social mobility is the reward for talent of various kinds, the temptation to form perpetual, specialized minority groups is probably not so great.

In caste and estate systems

In a Hindu caste system the allocation of economic, political, and ritual roles is probably more formally and rigidly arranged than in almost any other kind of society; but it is not usual to consider the specialized subcastes, which make up the system, as minority groups. On the other hand, the outcaste groups, who were said by the Hindu to be altogether outside the system and whose menial occupations and servile structural position separated them, often physically, from the rest of society, are probably best understood when regarded as minority groups. Similarly, in a feudal system the roles of the estates were strictly prescribed: the nobles fought for all, the clergy prayed for all, and the commoners worked for all. Insofar as the nobles dominated society, both the clergy and the commoners could be considered minority groups, though it is not usual to call them so, for medieval European society had in it a number of smaller groups that were unambiguously minorities in the usual sense. The structure of a feudal system allows little place in it for trade, which indeed was not an approved activity in medieval Europe, though of course it was necessary and was carried on by specialized minority groups such as the Jews or by anomalous minorities such as the merchants in semi-independent towns.

In the colonial and postcolonial societies of the modern world, the population is more often than not ethnically and culturally diverse and is often also rigidly stratified. In these societies specialized minority groups are common. When the British established a colonial regime in East Africa at the end of the last century, the African population lacked most of the technical and trading skills that were needed to develop the area and produce a revenue for the administration. Immigrants from the west coast of India were therefore encouraged to move into the interior regions and set themselves up as a trading minority. They differed from the Africans and the Europeans in physique, language, religion, and culture. They were absorbed into the hierarchy of colonial society as a specialized minority group, with a virtual monopoly of retail trade and a position of wealth, influence, and prestige greater than that of the Africans but lower than that of the Europeans.

After independence the hierarchies in the East African countries were rearranged. The position of a non-African minority group with a major share of the country's retail trade was ideologically unacceptable to the new African rulers. The countries they ruled were ethnically and culturally highly diversified, and their main concern was to encourage the growth of a unified nation, whose citizens shared common, patriotic values, even, if need be, at the expense of equality of opportunity. The rulers therefore adopted policies designed to eliminate non-African minorities such as the Indians. With local variations the same situation can be found in all parts of Southeast Asia, where rulers of dominant groups have attempted either to absorb or to drive away Chinese and Indian minority groups that have specialized in trade or crafts.

Minority groups have occupied servile or labouring positions in every type of society. The San (Bushmen) of Botswana in southern Africa are a minority group loosely attached as herdsmen and servants to Tswana society. Pagan tribes, immigrants, and conquered groups have on many occasions been brought into Hindu society as servile minorities, usually as outcasts outside the caste system, but sometimes (though more rarely) they have been incorporated as subcastes on the lower rungs of the hierarchy. In England after the Norman conquest the servile roles of the feudal system were mostly occupied by the previously free Saxons, the Welsh, and other native minority groups. Ethnic and cultural minority groups of African slaves and Amerindians filled the lower strata of the rigidly organized class systems of the 18th century in the Caribbean area. In the less rigid class system of modern Britain immigrant minorities from the Caribbean, Pakistan, and India for the most part are labourers.

The labour of ethnic groups

Because the distinguishing marks of an ethnic group are physically carried by its members, it is harder for them to be assimilated. And if racial attributes are important in the ideology of the dominant group of the society, it may be easier for a cultural minority to improve its status than it is for an ethnic group. The Irish who settled in the United States as labourers and various eastern Europeans who followed them have found it possible (at least in the second or third generation) to be socially mobile by changing their cultural identities in a way that has not yet been really open to blacks. It is not entirely accidental that ethnic groups tend to be more segregated and restricted and therefore regularly found among the poorer classes of a society. As long as the ethnic groups reside in the lower ranks of the social system, the privileged classes—unthreatened—can talk easily and abstractly of the desirability of equality of opportunity and the undesirability of segregation and restriction of opportunity. If an ethnic minority does acquire wealth or influence, however, either through its own efforts within society or through circumstances outside it, then the dominant group is usually compelled to make the necessary changes in its practices as well as ideology to accommodate if not assimilate the minority. But the process is never easy and is seldom willingly undertaken.

Their political roles. The political roles open to a minority depend on many of the same factors as limit its economic opportunities. Its numbers may be too small, as were those of the Indian immigrants in East Africa, for it ever to contemplate making a bid for control of the central political machinery, whereas in Malaysia the Chinese were sufficiently numerous to threaten a takeover of the government and thus could protect themselves. In fact, they accomplished the takeover in Singapore. Many minorities, however—as, for instance, merchants whose main interest in a political system is the preservation of law and order needed for peaceful trading—do not possess an active political ideology. It is only if circumstances force them and the structure of the society permits it that they think of protecting themselves by direct action. A minority group by definition is subordinate, and its usual position is near the bottom of the power structure, especially if its values diverge markedly from those of the main body politic.

Minorities acquiring power and leadership

The opportunities for acquiring power depend not only on a minority's own characteristics but also on the nature of the larger society. In a Hindu caste system the hierarchy is one of ritual prestige. The priestly groups are endowed with the greatest sanctity and honour. But ideally secular power ought not to be in their hands. It is the prerogative of the administrative or warrior castes. In practice, political power under Hinduism has often been held by dominant priestly or merchant castes, and even by labouring castes, without wrecking the system. In theory, too, a society of feudal estates ought to be ruled only by nobles; but if, as happened at the Norman invasion of England, the conquerors were of mixed origins, they were soon attributed noble status and the system survived.

In an open class system, if a minority group achieves power in a modern society and displaces a dominant group, the distribution of roles among most of the ruled classes is unlikely to be fundamentally altered, whatever the fate of individuals. This situation can be documented from many parts of the Communist and the postcolonial worlds. In Ghana under the British colonial regime, the African elite was a minority group that was drawn from several indigenous linguistic and cultural groups and whose members were often foreign educated and English speaking. When this group took over the colonial administration from the British as the dominant group, the society in its broad essentials altered little, except that the Ghanian elite ceased to be a minority group.

A favourably placed minority may occupy a strategically important position in a political system without being the dominant group. After their defeat in the Boer War at the beginning of this century, the Afrikaners were sociologically speaking a minority group though numerically a majority of the white population of South Africa. Their ideology differed from that of the dominant English group, though both had much in common concerning ideas of race, stratification, and the political superiority of whites. These ideas were directly opposed to the idea of equality of opportunity, which was paradoxically held concurrently by the English. The ideology of the Afrikaners was less ambiguous, and in a real sense they were the ideological leaders of the whites in South Africa. When they eventually gained control of the central administrative system and, as the dominant group, began to put their ideas on race and minorities into practice, there was little real resistance.

In South Africa a linguistic and cultural minority was able, as in other parts of the postcolonial world, to become dominant without a military conquest or revolution. In the Soviet Union, in Mainland China, and in other Communist countries, the Communist Party has usually gained power by force. In all countries the party began as a minority group based on a political philosophy in which differences of race, language, and culture were not considered to be relevant criteria of membership. In the period before it gained control of the central administrative machinery, the party was undoubtedly, especially in many of the undeveloped tropical areas, a minority group that acted as an ideological leader and an instrument of social change.

A minority group may be in an important political position in a society and yet not be able to take over the administration and rule it in its own interests. In parts of the European colonial empires, for example, trading immigrants were disenfranchised minorities; but because their economic power was great in the countries in which they had settled, they could frequently persuade, and sometimes force, colonial rulers to modify policies unfavourable to trade, though possibly advantageous to the rulers or other groups in the society. In Hawaii in the 1890s the white men who dominated the economy even persuaded the United States to annex the islands after a new U.S. tariff had threatened their sugar exports.

In the latter part of the 19th century the Irish formed a minority group in Great Britain, and their parliamentary representatives in London were sufficiently numerous to hold the balance for a time in the political struggles of the rest of the United Kingdom. A not dissimilar position was held for a few years by the Cape Coloureds of the Cape Province of South Africa before their vote was removed.

The risks of arbitration

The role of arbiter, of choosing whether to give or refuse support, can be a dangerous one for a minority group. Even that of a "go-between" who mediates between the rulers and the ruled members of society may bring hatred and disaster in its train, as the Anglo-Indian community discovered when British rule ended in India; and as Chinese and Indian groups who had specialized in working with colonial civil services also discovered when former colonial territories gained independence. In situations where a minority holds a balance of power, it may feel obliged for the protection of its own interests, as were the Afrikaners, to become dominant in the society. On the other hand, it may be safer for the minority, if it can, to secede altogether and become independent before it is stripped, as was the Cape Coloured population of South Africa, of all political power. The Irish solved the dilemma by secession from the United Kingdom, and the Chinese of Singapore by secession from Malaysia.

In the discussion of the economic functions of minority groups it was noted that most often they were servile or exploited and that both the form and function of the group largely depended on the form and ideology of the society of which they were a part. It was also seen that the degree of subordination or exploitation and the type of relation that a minority can have with a dominant group is variable. Thus, for instance, Brāhmaṇ priests in a caste system are the ritual servants of the other subcaste groups and may be exploited politically and economically by a lower ranked but dominant group, and yet the ritual relationship is not a servile one. Similarly in feudal Europe the nobles and the clergy exploited and segregated minorities such as the Jewish trading community, but the relationship differed in its degree of subordination and exploitation from the relationship of the nobles to serfs and slaves. Nor was the relationship of the Indian trading community in East Africa with the British rulers a wholly subordinate one, although the British exploited and used the Indians' commercial skills and political weakness. In British Guiana or Fiji the situation was different. There Indian coolies were imported as indentured plantation labourers when the suppression of the slave trade put an end to that source of cheap African labour, and as a result both the freed African and the indentured Indians, though not technically slaves, occupied an almost servile status. (H.S.M.)

BIBLIOGRAPHY. The principal general studies of social differentiation are GEORG SIMMEL, *Über soziale Differenzierung: Soziologische und psychologische Untersuchungen* (1890); and C.C. NORTH, *Social Differentiation* (1926). Differentiation in terms of social roles is discussed in R. LINTON, *The Study of Man* (1936); H.H. GERTH and C. WRIGHT MILLS, *Character and Social Structure* (1953); and M.P. BANTON, *Roles* (1965).

Age differentiation is discussed in KARL MANNHEIM, "The Problem of Generations," in *Essays on the Sociology of Knowledge,* 2nd ed. (1952); S.N. EISENSTADT, *From Generation to Generation* (1956); and MARGARET MEAD, *Culture and Commitment: A Study of the Generation Gap* (1970). The division of labour is treated at length in EMILE DURKHEIM, *De la division du travail social* (1893; Eng. trans., *The Division of Labour in Society,* 1933), which also deals with the differentiation of societies into types. Other classifications of the types of society include FERDINAND TONNIES, *Gemeinschaft und Gesellschaft* (1887; Eng. trans., *Community and Association,* 1955), KARL MARX and FRIEDRICH ENGELS, *Die deutsche Ideologie* (1846; Eng. trans. of pt. 1 and 3, *The German Ideology,* 1938), *Manifest der kommunistischen Partei* (1848; Eng. trans., *The Communist Manifesto,* 1933); RAYMOND ARON, *The Industrial Society* (1967). The literature on stratification is extensive, but the following works provide a view of the major aspects: S. OSSOWSKI, *Class Structure in the Social Consciousness* (Eng. trans., 1963); MAX WEBER, "Class, Status, Party," in *Wirtschaft und Gesellschaft* (1922), Eng. trans. in H.H. GERTH and C. WRIGHT MILLS (eds.), *From Max Weber* (1946); J.A. SCHUMPETER, "Social Classes in an Ethnically Homogeneous Environment," *Imperialism and Social Classes* (1951); KINGSLEY DAVIS and WILBERT MOORE, "Some Principles of Stratification," in R. BENDIX and S.M. LIPSET (eds.), *Class, Status and Power,* 2nd rev. ed. (1966). On elite groups, see C. WRIGHT MILLS, *The Power Elite* (1956); and T.B. BOTTOMORE, *Elites and Society* (1964). There have been many studies of social mobility; two national inquiries which also deal with wider issues are D.V. GLASS (ed.), *Social Mobility in Britain* (1954); and PETER BLAU and OTIS D. DUNCAN, *The American Occupational Structure* (1967). See also ABNER COHEN, *The Politics of Elite Culture* (1981); and ARTHUR MARWICK, *Class: Image and Reality in Britain, France and the USA since 1930* (1980).

Women and sex differentiation: F. BEACH (ed.), *Sex and Behaviour* (1965); and E.E. MACCOBY (ed.), *The Development of Sex Differences* (1967), symposia by well-known experts discussing sex differences in temperament and abilities and their possible origin and explanation; SIGMUND FREUD, "The Psychology of Women," in *Neue Folge der Vorlesungen zur Einführung in die Psychoanalyse* (1933; Eng. trans., *New Introductory Lectures on Psychoanalysis,* ch. 33, 1942); and "Some Psychological Consequences of the Anatomical Distinction Between the Sexes," *Int. J. Psychoanal.,* 8:133–142 (1927), two classical formulations by the founder of psychoanalysis on his interpretation of feminine psychology; VIOLA KLEIN, *The Feminine Character: History of an Ideology* (1946, 1971), a comparative analysis of various theories about the psychology of women; MARGARET MEAD, *Sex and Temperament in Three Primitive Societies* (1935) and *Male and Female* (1949), anthropological studies of temperamental sex differences, based on field work in primitive societies; L.M. TERMAN and C.C. MILES, *Sex and Personality* (1936, reprinted 1968); and L.M. TERMAN and L.E. TYLER, "Psychological Sex Differences," in L. CARMICHAEL (ed.), *Manual of Child Psychology* (1954; 3rd ed., 1970), psychometric studies of personality differences between men and women; ELIZABETH BOTT, *Family and Social Network* (1957), a small-scale, intensive investigation of the connection between the distribution of roles between husbands and wives and their wider network of family and other social relationships; W.J. GOODE, *World Revolution and Family Patterns* (1963), a study by the well-known American sociologist on current changes in the structure and form of the family and their connection with technical and industrial developments; A.C. KINSEY *et al., Sexual Behavior in the Human Female* (1953); A. MYRDAL and VIOLA KLEIN, *Women's Two Roles: Home and Work,* 2nd rev. ed. (1968), a comparative study of the changing role of women in four highly industrialized countries (United States, Britain, France, and Sweden), its causes and consequences; F.I. NYE and L.W. HOFFMAN (eds.), *The Employed Mother in America* (1963), an anthology of detailed and statistically substantiated studies of the manifold aspects of maternal employment in the U.S.: the reason why so many married women go out to work, what effect this employment has on different types of children and in different situations, on the relationships between husbands and wives and on the women themselves; RAPHAEL PATAI (ed.), *Women in the Modern World* (1967), a symposium of essays by 24 social scientists, mostly women, from different parts of the world, describing recent changes in the status of women in their respective countries, including Asian, American, African, and European nations. See also LISA LEGHORN and KATHERINE PARKER, *Woman's Worth: Sexual Economics and the World of Women* (1981).

Youth: E.A.M. DOUVAN and J. ADELSON, *The Adolescent Experience* (1966), is an authoritative description of normal as opposed to deviant youth, and is particularly perceptive on differential sex roles. S.N. EISENSTADT, *From Generation to Generation* (1956), remains perhaps the most complete sociological analysis of the status, function, and role of youth in modern societies and is valuable for understanding peer groups. J.S. COLEMAN, *The Adolescent Society* (1961); PAUL GOODMAN, *Growing Up Absurd* (1960); J.B. MAYS, *The Young Pretenders* (1965); E.A. SMITH, *American Youth Culture* (1962), examine a variety of aspects of teenage culture in several different societies. D. GOTTLIEB, J. REEVES, and W.D. TENHOUTEN, *The Emergence of Youth Societies* (1966), provides a bibliography for cross-cultural analysis that attempts to include the whole world; and MARGARET MEAD, *Coming of Age in Samoa* (1943, reprinted 1961), and *Growing Up in New Guinea* (1942, reprinted 1962), are interesting studies of more primitive cultures that have a bearing on modern industrial urban life. Psychological works that complement and expand the sociological approach to adolescence are among the most valuable texts on the subject. P. BLOS, *On Adolescence* (1962), is a well-known essay; and C.M. FLEMING, *Adolescence: Its Social Psychology,* 2nd rev. ed. (1963), synthesizes the psychological, social, and physiological aspects. ERIK ERIKSON, *Childhood and Society,* 2nd rev. ed. (1963), and *Identity, Youth and Crisis* (1968), are classic statements of the psychoanalytical approach to adolescent personality structure in relation to cultural influences. M. ROSENBERG, *Society and the Adolescent Self-Image* (1965), gives the results of large-scale study of American children and young people. R.J. HAVIGHURST, *Human Development and Education* (1953), examines at length the important idea of the various developmental tasks facing the adolescent in general, while R.F. PECK *et al., The Psychology of Character Development* (1960), offers research evidence to show that, in spite of widespread views to the contrary, the influence of parents on their children's moral values is more often than not still paramount. PATRICIA M. SPACKS, *Adolescent Idea: Myths of Youth and the Adult Imagination* (1981), explores the conceptions adults maintain about adolescents.

The aged: Extensive empirical and theoretical work has been collected in the following three handbooks, comprising essays on varied aspects of gerontology: J.E. BIRREN (ed.), *Handbook of Aging and the Individual: Psychological and Biological Aspects* (1959); C. TIBBITTS (ed.), *Handbook of Social Gerontology: Societal Aspects of Aging* (1960); and E.W. BURGESS (ed.), *Aging in Western Societies* (1960). More recent information on several of these topics may be found in a special issue of the *International Social Science Journal,* entitled "Old Age," vol. 15, no. 3 (1963). Findings from some 3,000 social science studies concerning people in their middle and later years have been condensed and organized for ready reference in M.W. RILEY and A. FONER *et al., Aging and Society,* vol. 1, *An Inventory of Research Findings* (1968). The findings from this inventory are interpreted for use in those professions concerned with older people in M.W. RILEY, J.W. RILEY, JR., and M.E. JOHNSON (eds.), *Aging and Society,* vol. 2, *Aging and the Professions* (1969). Systematic research findings for selected times and places appear in the analysis of ethnographic reports in L.W. SIMMONS, *The Role of the Aged in Primitive Society* (1945); H.D. SHELDON, *Older Population of the United States* (1958); and in the parallel surveys reported for Great Britain, Denmark, and the U.S. in E. SHANAS *et al.*, *Old People in Three Industrial Societies* (1968).

Race differentiation: T.W. ADORNO *et al.*, *The Authoritarian Personality* (1950), an influential study of the psychodynamics of prejudice from a psychoanalytical perspective; G.W. ALLPORT, *The Nature of Prejudice* (1954), a standard text by a social psychologist; B.N. COLBY and P.L. VAN DEN BERGHE, "Ethnic Relations in Southeastern Mexico," *American Anthropologist*, 63:772–792 (Aug. 1961), a description of a system of ethnic relations between Maya Indian groups and Spanish-speaking ladinos; O.C. COX, *Caste, Class and Race* (1948), a detailed critique of the field of race and ethnic relations by a Marxian sociologist; A.W. LIND (ed.), *Race Relations in World Perspective* (1956), a collection of essays dealing with racial situations in various parts of the world; A. MARCHANT, *From Barter to Slavery* (1942), the early history of racial and cultural contacts in Brazil; L. MARQUARD, *The Peoples and Policies of South Africa* (1952), the most concise introduction to racial problems in South Africa; GUNNAR MYRDAL, *An American Dilemma* (1944), a monumental study of black America in the 1940s; R.E. PARK, *Race and Culture* (1950), a collection of sociological essays on race and culture; T.F. PETTIGREW, *A Profile of the Negro American* (1964), a useful summary of studies on black Americans; D. PIERSON, *Negroes in Brazil: A Study of Race Contact at Bahia* (1942), a pioneer study of Afro-Brazilians in the North East; T. SHIBUTANI and K.M. KWAN, *Ethnic Stratification: A Comparative Approach* (1965), a text on comparative race and ethnic relations; G.E. SIMPSON and J.M. YINGER, *Racial and Cultural Minorities*, 3rd ed. (1965), a standard text stressing North America; K.M. STAMPP, *The Peculiar Institution: Slavery in the Ante-Bellum South* (1964), a good account of antebellum slavery in the U.S.; F. TANNENBAUM, *Slave and Citizen: The Negro in the Americas* (1947), a comparative study of slavery in the Americas; P.L. VAN DEN BERGHE, *Race and Racism* (1967), a text on comparative race relations in Mexico, Brazil, the U.S., and South Africa, and *South Africa: A Study in Conflict* (1965), a comprehensive sociological analysis of South Africa; C. WAGLEY, *Amazon Town: A Study of Man in the Tropics* (1964), a community study of a multiracial town in the Amazon basin, and (ed.), *Race and Class in Rural Brazil* (1952), a series of studies of race relations in various regions of Brazil; and R.M. WILLIAMS *et. al.*, *Strangers Next Door: Ethnic Relations in American Communities* (1964), a compilation of research findings on race and ethnic relations in the U.S.; STEPHEN STEINBERG, *The Ethnic Myth: Race, Ethnicity, and Class in America* (1981), depreciates cultural values and emphasizes class to explain differential race mobility.

Social class: Two short introductions to the study of social class are KURT B. MAYER and WALTER BUCKLEY, *Class and Society*, 3rd ed. rev. (1969); and T.B. BOTTOMORE, *Classes in Modern Society*, 2nd ed. (1966). The historical development of ideas and theories of class has not been very fully discussed, but some treatment is given in STANISLAW OSSOWSKI, *Struktura klasowa w społecznej świadomości* (1957; Eng. trans., *Class Structure in the Social Consciousness*, 1963), which also contains a good account of the Marxist theory. Another exposition and critical examination of Marx's theory is provided by RALF DAHRENDORF, *Soziale Klassen und Klassenkonflikt in der industriellen Gesellschaft* (1957; Eng. trans., *Class and Class Conflict in Industrial Society*, 1959). The ideas of the early American sociologists are discussed in CHARLES H. PAGE, *Class and American Sociology*, new ed. (1969), which contains a long introduction surveying much of the research on social class and mobility over the past 30 years. MAX WEBER'S writings on social class and status are to be found mainly in his work *Wirtschaft und Gesellschaft*, 4th ed., 2 vol. (1922; Eng. trans., *Economy and Society*, ed. by GUENTHER ROTH and CLAUS WITTICH, 3 vol., 1968). The theory of elites is expounded by VILFREDO PARETO in *Trattato di sociologia generale*, 2nd ed., 3 vol. (1923; Eng. trans., *The Mind and Society*, 4 vol., 1935); more recent studies include C. WRIGHT MILLS, *The Power Elite* (1956); and T.B. BOTTOMORE, *Elites and Society* (1964). Among the general studies of class are REINHARD BENDIX and S.M. LIPSET (eds.), *Class, Status and Power*, 2nd ed. (1966); and GERHARD E. LENSKI, *Power and Privilege* (1966). Particular social classes are discussed in C. WRIGHT MILLS, *White Collar* (1951); G.A. BRIEFS, *The Proletariat* (1937); J.H. GOLDTHORPE *et al.*, *The Affluent Worker*, 3 vol. (1968–69); and ERIC R. WOLF, *Peasants* (1966).

Social mobility: A pioneer survey of social mobility is P.A. SOROKIN, *Social Mobility* (1927, reprinted with an additional chapter on cultural mobility, 1959). Two major national studies are D.V. GLASS (ed.), *Social Mobility in Britain* (1954); and PETER M. BLAU and OTIS D. DUNCAN, *The American Occupational Structure* (1967). Comparisons between societies are discussed in S.M. LIPSET and REINHARD BENDIX, *Social Mobility in Industrial Society* (1959); and S.M. MILLER, "Comparative Social Mobility," *Current Sociology*, 9:1–89 (1960). Some aspects of the social context in which mobility occurs are examined, with reference to the United States, in ANSELM L. STRAUSS, *The Contexts of Social Mobility* (1971).

Caste: L. DUMONT, *Homo Hierarchicus* (1966; Eng. trans. 1970), description, history, and theories of the Hindu caste system in contrast to Western philosophies, with comprehensive bibliography up to 1962; J. SILVERBERG (ed.), *Social Mobility in the Caste System in India* (1968), corrects Western stereotypes. Important classical analyses are those of C. BOUGLE, *Essais sur le régime des castes* (1908; Eng. trans., *Essays on the Caste System*, 1971); A.M. HOCART, *Les Castes* (1938; Eng. trans., *Caste: A Comparative Study*, 1950); J.H. HUTTON, *Caste in India*, 4th ed. (1963); and MAX WEBER, *Hinduismus und Buddhismus* in vol. 2 of *Gesammelte Aufsätze zur Religionssoziologie* (1921; Eng. trans., *The Religion of India: The Sociology of Hinduism and Buddhism*, 1958). D.M. SCHNEIDER, *American Kinship* (1968), provides the theoretical approach used here; it was first applied to an Indian caste by S. Barnett. P.V. KANE, *History of Dharmáśāstra*, 5 vol. (1930–62), an encyclopaedic digest of Vedic codes; G.S. GHURYE, *Caste and Race in India*, 5th ed. rev. (1969), historical interpretation of social developments; the *Census of India* (1881–1971), statistics and descriptions; D.G. MANDELBAUM, *Society in India*, 2 vol. (1970), summary of recent field studies with bibliography; M. MARRIOTT, *Caste Ranking and Community Structure in Five Regions of India and Pakistan* (1960), ecological comparisons and bibliography of older descriptive works.

Minority groups: H. KOHN, *The Idea of Nationalism* (1944); L. WIRTH, "The Problem of Minority Groups" in R. LINTON (ed.), *The Science of Man in the World Crisis* (1945); and A.M. and C.B. ROSE (eds.), *Minority Problems* (1965), give a good background to the problems implicit in the ideas of nationalism and minorities, especially with reference to the West. L. KUPER and M.G. SMITH (eds.), *Pluralism in Africa* (1969), and H.S. MORRIS, *Indians in Uganda* (1968), examine the problem of ethnic and minority groups in non-Western societies and consider the subject of social and cultural pluralism in terms first raised by J.S. FURNIVALL in *Colonial Policy and Practice: A Comparative Study of Burma and Netherlands India* (1948). G.A. DE VOS and H. WAGATSUMA (eds.), *Japan's Invisible Race* (1966), discuss the same problems in a psychological rather than a sociological idiom. P. MASON, *Patterns of Dominance* (1970), treats a selected number of societies in different parts of the world and at different historical periods and evaluates various solutions for the problems of ethnic and cultural minorities. Of special interest for minority problems in the Western world are M. FREEDMAN (ed.), *A Minority in Britain: Social Studies of the Anglo-Jewish Community* (1955); E.J.B. ROSE *et al.*, *Colour and Citizenship* (1969); and C. WAGLEY and M. HARRIS, *Minorities in the New World* (1958). B. BENEDICT, *Indians in a Plural Society* (1961); F. and L.O. DOTSON, *The Indian Minority Zambia, Rhodesia and Malawi* (1968); S. PATTERSON, *Colour and Culture in South Africa* (1953); and D.E. WILLMOTT, *The Chinese of Semarang* (1960), give useful and illuminating descriptive accounts of ethnic groups and minorities outside Europe and America. The essays in F. BARTH (ed.), *Ethnic Groups and Boundaries: The Social Organization of Culture Difference* (1969), re-examine the traditional problems of maintaining ethnic or minority identities. STANLEY LIEBERSON, *A Piece of the Pie: Blacks and White Immigrants Since 1880* (1980), examines the different economic progress made by blacks and other minority groups; THOMAS SOWELL, *Markets and Minorities* (1981), studies the effect of discrimination on the economic progress of various minority groups.

The Social Sciences

The social sciences, which deal with human behaviour in its social and cultural aspects, include the following disciplines: cultural (or social) anthropology, sociology, social psychology, political science, and economics. Also frequently included are social and economic geography (see GEOGRAPHY) and those areas of education that deal with the social contexts of learning and the relation of the school to the social order (see TEACHING). History is regarded by many as a social science, and certain areas of historical study are almost indistinguishable from work done in the social sciences. Most historians, however, still consider history as one of the humanities. It is generally best, in any case, to consider history as marginal to the humanities and social sciences, since its insights and techniques pervade both (see HISTORY).

The study of comparative law may also be regarded as a part of the social sciences, although it is ordinarily pursued in schools of law rather than in departments or schools containing most of the other social sciences.

During the past quarter of a century, the term behavioral sciences has become more and more commonly used for the disciplines cited as social sciences. Those who favour this term do so in part because these disciplines are thus brought closer to some of the sciences, such as physical anthropology, linguistics, and physiological psychology, which also deal with human behaviour. Whether the term behavioral sciences will in time supplant "social sciences" or whether it will, as neologisms so often have before, disappear without trace in a few years is impossible to say. For the purposes of this article, the two terms may be considered synonymous.

The concern in this article is much less with the conclusions and results of the individual social sciences than with their disciplinary identity in modern society. The concern is with the social sciences as vital elements in the aftermath of the two great revolutions, the political and industrial, which opened the 19th century, with the pattern the social sciences assumed in that century, and their extraordinary development in the 20th century.

The article is divided into the following sections:

History of the social sciences

Although, strictly speaking, the social sciences do not precede the 19th century—that is, as distinct and recognized disciplines of thought—one must go back farther in time for the origins of some of their fundamental ideas and objectives. In the largest sense, the origins go all the way back to the ancient Greeks and their rationalist inquiries into the nature of man, state, and morality. The heritage of both Greece and Rome is a powerful one in the history of social thought as it is in so many other areas of Western society. Very probably, apart from the initial Greek determination to study all things in the spirit of dispassionate and rational inquiry, there would be no social sciences today. True, there have been long periods of time, as during the Western Middle Ages, when the Greek rationalist temper was lacking. But the recovery of this temper, through texts of the great classical philosophers, is the very essence of the Renaissance and the Age of Reason in modern European history. With the Age of Reason, in the 17th and 18th centuries, one may begin.

HERITAGE OF THE MIDDLE AGES AND THE RENAISSANCE

The same impulses that led men in that age to explore the earth, the stellar regions, and the nature of matter led them also to explore the institutions around them: state, economy, religion, morality; above all, the nature of man himself. It was the fragmentation of medieval philosophy and theory, and, with this, the shattering of the medieval world view that had lain deep in thought until about the 16th century, that was the immediate basis of the rise of the several strands of specialized thought that were to become in time the social sciences.

Adverse effects of medieval theology

Medieval theology, especially as it appears in St. Thomas Aquinas' *Summa theologiae,* contained and fashioned syntheses from ideas about man and society—ideas indeed that may be seen to be political, social, economic, anthropological, and geographical in their substance. But it was partly this close relation between medieval theology and ideas of the social sciences that accounts for the longer time it took these ideas—by comparison with the ideas of the physical sciences—to achieve what one would today call scientific character. From the time of the great Roger Bacon in the 13th century, there were at least some rudiments of physical science that were largely independent of medieval theology and philosophy. Historians of physical science have no difficulty in tracing the continuation of this experimental tradition, primitive and irregular though it was by later standards, throughout the Middle Ages. Side by side with the kinds of experiment made notable by Roger Bacon were impressive changes in technology through the medieval period and then, in striking degree, in the Renaissance. Efforts to improve agricultural productivity; the rising utilization of gunpowder, with consequent development of guns and the problems that they presented in ballistics; growing trade, leading to increased use of ships and improvements in the arts of navigation, including use of telescopes; and the whole range of such mechanical arts in the Middle Ages and Renaissance as architecture, engineering, optics, and the construction of watches and clocks—all of this put a high premium on a pragmatic and operational understanding of at least the simpler principles of mechanics, physics, astronomy, and, in time, chemistry.

In short, by the time of Copernicus and Galileo in the 16th century, a fairly broad substratum of physical science existed, largely empirical but not without theoretical implications on which the edifice of modern physical science could be built. It is notable that the empirical foundations of physiology were being established in the studies of the human body being conducted in medieval schools of medicine and, as the career of Leonardo da Vinci so resplendently illustrates, among artists of the Renaissance, whose interest in accuracy and detail of painting and sculpture led to their careful studies of human anatomy.

Very different was the beginning of the social sciences. In the first place, the church, throughout the Middle Ages and even into the Renaissance and Reformation, was much more attentive to what scholars wrote and thought about man's mind and his behaviour in society than it was toward what was being studied and written in the physical sciences. From the church's point of view, while it might be important to see to it that thought on the physical world corresponded as far as possible to what Scripture said—witnessed, for example, in the famous questioning of Galileo—it was far more important that such correspondence exist in matters affecting the nature of man, his mind, spirit, and soul. Nearly all the subjects and questions that would form the bases of the social sciences in later centuries were tightly woven into the fabric of medieval scholasticism, and it was not easy for even the boldest minds to break this fabric.

Adverse effects of reverence for classics and Cartesianism

Then, when the hold of scholasticism did begin to wane, two fresh influences, equally powerful, came on the scene to prevent anything comparable to the pragmatic and empirical foundations of the physical sciences from forming in the study of man and society. The first was the immense appeal of the Greek classics during the Renaissance, especially those of the philosophers Plato and Aristotle. A great deal of social thought during the Renaissance was little more than gloss or commentary on the Greek classics. One sees this throughout the 15th and 16th centuries.

Second, in the 17th century appeared the powerful influence of the philosopher René Descartes. Cartesianism, as his philosophy was called, declared that the proper approach to understanding of the world, including man and society, was through a few simple, fundamental ideas of reality and, then, rigorous, almost geometrical deduction of more complex ideas and eventually of large, encompassing theories, from these simple ideas, all of which, Descartes insisted, were the stock of common sense—the mind that is common to all human beings at birth. It would be hard to exaggerate the impact of Cartesianism on social and political and moral thought during the century and a half following publication of his *Discourse on Method* and his *Meditations.* Through the Age of Reason and down through the Enlightenment in the later 18th century, the spell of Cartesianism was cast on nearly all those who were concerned with the problems of the nature of man and society.

Both of these great influences, reverence for the classics and fascination with the geometrical-deductive procedures advocated by Descartes must be seen from today's vantage point as among the major influences retarding the development of a science of society comparable to the science of the physical world. It is not as though data were not available in the 17th and 18th centuries. The emergence of the national state carried with it evergrowing bureaucracies concerned with gathering information, chiefly for taxation, census, and trade purposes, which might have been employed in much the same way that physical scientists employed their data. The voluminous and widely published accounts of the great voyages that had begun in the 15th century, the records of soldiers, explorers, and missionaries who perforce had been brought into often long and close contact with primitive and other non-Western peoples, provided still another great reservoir of data, all of which might have been utilized in scientific ways as such data were to be utilized a century or two later in the social sciences. Such, however, was the continuing spell cast by the texts of the classics and by the strictly rationalistic, overwhelmingly deductive procedures of the Cartesians that, down until the beginning of the 19th century, these and other empirical materials were used, if at all, solely for illustrative purposes in the writings of the social philosophers.

HERITAGE OF THE ENLIGHTENMENT

There is also the fact that, especially in the 18th century, reform and even revolution were often in the air. The purpose of a great many social philosophers was by no means restricted to philosophic, much less scientific, understanding of man and society. The dead hand of the Middle Ages seemed to many vigorous minds in western Europe the principal force to be combatted, through critical reason, enlightenment, and, where necessary, major reform or revolution. One may properly account a great deal of this new spirit to the rise of humanitarianism in modern Europe and in other parts of the world and to the spread of literacy, the rise in the standard of living, and the recognition that poverty and oppression need not be the fate of the masses. The fact remains, however, that social reform and social science have different organizing principles, and the very fact that for a long time, down indeed through a good part of the 19th century, social reform and social science were regarded as pretty much the same thing could not have helped but retard the development of the latter.

Nevertheless, it would be wrong to discount the significant contributions to the social sciences that were made during the 17th and 18th centuries. The first and greatest of these was the spreading ideal of a science of society, an ideal fully as widespread by the 18th century as the ideal of a physical science. Second was the rising awareness of the multiplicity and variety of human experience in the world. Ethnocentrism and parochialism, as states of mind, were more and more difficult for educated people to maintain given the immense amount of information about—or, more important, interest in—non-Western peoples, the results of trade and exploration. Third was the spreading sense of the social or cultural character of human behaviour in society—that is, its purely historical or conventional, rather than biological, basis. A science of society, in short, was no mere appendage of biology but was instead a distinct discipline, or set of disciplines, with its own distinctive subject matter.

Ideas of structure and developmental change

To these may be added two other very important contributions of the 17th and 18th centuries, each of great theoretical importance. The first was the idea of structure. First seen in the writings of such philosophers as Hobbes, Locke, and Rousseau with reference to the political structure of the state, it had spread by the mid-18th century to highlight the economic writings of the Physiocrats and Adam Smith. The idea of structure can also be seen in certain works relating to man's psychology and, at opposite reach, to the whole of civil society. The ideas of structure that were borrowed from both the physical and biological sciences were fundamental to the conceptions of political, economic, and social structure that took shape in the 17th and 18th centuries. And these conceptions of structure have in many instances, subject only to minor changes, come down to 20th-century social science.

The second major theoretical idea was that of developmental change. Its ultimate roots in Western thought, like those indeed of the whole idea of structure, go back to the Greeks, if not earlier. But it is in the 18th century, above all others, that the philosophy of developmentalism took shape, forming a preview, so to speak, of the social evolutionism of the next century. What was said by such writers as Condorcet, Rousseau, and Adam Smith was that the present is an outgrowth of the past, the result of a long line of development in time, and, furthermore, a line of development that has been caused, not by God or fortuitous factors, but by conditions and causes immanent in human society. Despite a fairly widespread belief that the idea of social development is a product of prior discovery of biological evolution, the facts are the reverse. Well before any clear idea of genetic speciation existed in European biology, there was a very clear idea of what might be called social speciation—that is, the emergence of one institution from another in time and of the whole differentiation of function and structure that goes with this emergence.

As has been suggested, these and other seminal ideas were contained for the most part in writings, the primary function of which was attack on the existing order of government and society in western Europe. Another way of putting the matter is to say that they were clear and acknowledged parts of political and social idealism—using that word in its largest sense. Hobbes, Locke, Rousseau, Montesquieu, Adam Smith, and other major philosophers had as vivid and energizing sense of the ideal—ideal state, ideal economy, ideal civil society—as any earlier utopian writer. These men were, without exception, committed to visions of the good or ideal society. Their interest in the "natural"—that is, natural morality, religion, economy, or education, in contrast to the merely conventional and historically derived—sprang as much from the desire to hold a glass up to a surrounding society that they disliked as from any dispassionate urge simply to find out what man and society are made of. The fact remains, however, that the ideas that were to prove decisive in the 19th century, so far as the social sciences were concerned, arose during the two centuries preceding.

THE 19TH CENTURY

Effects of the democratic and industrial revolutions

The fundamental ideas, themes, and problems of the social sciences in the 19th century are best understood as responses to the problem of order that was created in men's minds by the weakening of the old order, or European society, under the twin blows of the French Revolution and the Industrial Revolution. The breakup of the old order—an order that had rested on kinship, land, social class, religion, local community, and monarchy—set free, as it were, the complex elements of status, authority, and wealth that had been for so long consolidated. In the same way that the history of 19th-century politics, industry, and trade is basically about the practical efforts of human beings to reconsolidate these elements, so the history of 19th-century social thought is about theoretical efforts to reconsolidate them—that is, to give them new contexts of meaning.

In terms of the immediacy and sheer massiveness of impact on human thought and values, it would be difficult to find revolutions of comparable magnitude in human history. The political, social, and cultural changes that began in France and England at the very end of the 18th century spread almost immediately through Europe and the Americas in the 19th century and then on to Asia, Africa, and Oceania in the 20th. The effects of the two revolutions, the one overwhelmingly democratic in thrust, the other industrial-capitalist, have been to undermine, shake, or topple institutions that had endured for centuries, even millennia, and with them systems of authority, status, belief, and community.

It is easy today to deprecate the suddenness, the cataclysmic nature, the overall revolutionary effect of these two changes and to seek to subordinate results to longer, deeper tendencies of more gradual change in western Europe. But as many recent historians have pointed out, there was to be seen, and seen by a great many sensitive minds of that day, a dramatic and convulsive quality to the changes that cannot properly be subsumed to the slower processes of continuous evolutionary change. What is crucial, in any event, from the point of view of the history of the social thought of the period, is how the changes were actually envisaged at the time. By a large number of social philosophers and social scientists, in all spheres, those changes were regarded as nothing less than of earthquake intensity.

The coining or redefining of words is an excellent indication of men's perceptions of change in a given historical period. A large number of words taken for granted today came into being in the period marked by the final decade or two of the 18th century and the first quarter of the 19th. Among these are: industry, industrialist, democracy, class, middle class, ideology, intellectual, rationalism, humanitarian, atomistic, masses, commercialism, proletariat, collectivism, equalitarian, liberal, conservative, scientist, utilitarian, bureaucracy, capitalism, and crisis. Some of these words were invented; others reflect new and very different meanings given to old ones. All alike bear witness to the transformed character of the European social landscape as this landscape loomed up to the leading minds of the age. And all these words bear witness too to the emergence of new social philosophies and, most pertinent to the subject of this article, the social sciences as they are known today.

Major themes resulting from democratic and industrial change. It is illuminating to mention a few of the major themes in social thought in the 19th century that were almost the direct results of the democratic and industrial revolutions. It should be borne in mind that these themes are to be seen in the philosophical and literary writing of the age as well as in social thought.

First, there was the great increase in population. Between

Effects of population growth

1750 and 1850 the population of Europe went from 140,000,000 to 266,000,000; in the world from 728,000,000 to well over 1,000,000,000. It was an English clergyman-economist, Thomas Malthus, who, in his famous *Essay on Population,* first marked the enormous significance to human welfare of this increase. With the diminution of historic checks on population growth, chiefly those of high mortality rates—a diminution that was, as Malthus realized, one of the rewards of technical progress—there were no easily foreseeable limits to growth of population. And such growth, he stressed, could only upset the traditional balance between population, which Malthus described as growing at geometrical rate, and food supply, which he declared could grow only at arithmetical rate. Not all social scientists in the century took the pessimistic view of the matter that Malthus did but few if any were indifferent to the impact of explosive increase in population on economy, government, and society.

Second, there was the condition of labour. It may be possible to see this condition in the early 19th century as in fact better than the condition of the rural masses at earlier times. But the important point is that to a large number of writers in the 19th century it seemed worse and was defined as worse. The wrenching of large numbers of people from the older and protective contexts of village, guild, parish, and family, and their massing in the new centres of industry, forming slums, living in common squalor and wretchedness, their wages generally behind cost of living, their families growing larger, their standard of living becoming lower, as it seemed—all of this is a frequent theme in the social thought of the century. Economics indeed became known as the "dismal science," because economists, from David Ricardo to Karl Marx, could see little likelihood of the condition of labour improving under capitalism.

Third, there was the transformation of property. Not only was more and more property to be seen as industrial—manifest in the factories, business houses, and workshops of the period—but also the very nature of property was changing. Whereas for most of the history of mankind property had been "hard," visible only in concrete possessions—land and money—now the more intangible kinds of property such as shares of stock, negotiable equities of all kinds, and bonds were assuming ever greater influence in the economy. This led, as was early realized, to the dominance of financial interests, to speculation, and to a general widening of the gulf between the propertied and the masses. The change in the character of property made easier the concentration of property, the accumulation of immense wealth in the hands of a relative few, and, not least, the possibility of economic domination of politics and culture. It should not be thought that only socialists saw property in this light. From Edmund Burke through Auguste Comte, Frédéric Le Play, and John Stuart Mill down to Karl Marx, Max Weber, and Émile Durkheim, one finds conservatives and liberals looking at the impact of this change in analogous ways.

Effects of urbanization and technological change

Fourth, there was urbanization—the sudden increase in the number of towns and cities in western Europe and the increase in number of persons living in the historic towns and cities. Whereas in earlier centuries, the city had been regarded almost uniformly as a setting of civilization, culture, and freedom of mind, now one found more and more writers aware of the other side of cities: the atomization of human relationships, broken families, the sense of the mass, of anonymity, alienation, and disrupted values. Sociology particularly among the social sciences turned its attention to the problems of urbanization. The contrast between the more organic type of community found in rural areas and the more mechanical and individualistic society of the cities is a basic contrast in sociology, one that was given much attention by such pioneers in Europe as the French sociologists Frédéric Le Play and Émile Durkheim; the German sociologists Ferdinand Tönnies, Georg Simmel, and Max Weber; the Belgian statistician Adolphe Quetelet; and, in America, by the sociologists Charles H. Cooley and Robert E. Park.

Fifth, there was technology. With the spread of mechanization, first in the factories, then in agriculture, social thinkers could see possibilities of a rupture of the historic relation between man and nature, between man and man, even between man and God. To thinkers as politically different as Thomas Carlyle and Karl Marx, technology seemed to lead to dehumanization of the worker and to exercise of a new kind of tyranny over human life. Marx, though, far from despising technology, thought the advent of socialism would counteract all this. Alexis de Tocqueville declared that technology, and especially technical specialization of work, was more degrading to man's mind and spirit than even political tyranny. It was thus in the 19th century that the opposition to technology on moral, psychological, and aesthetic grounds first made its appearance in Western thought.

Sixth, there was the factory system. The importance of this to 19th-century thought has been intimated above. Suffice it to add that along with urbanization and spreading mechanization, the system of work whereby masses of workers left home and family to work long hours in the factories became a major theme of social thought as well as of social reform.

Effects of the rise of the masses

Seventh, and finally, mention is to be made of the development of political masses—that is, the slow but inexorable widening of franchise and electorate through which ever larger numbers of persons became aware of themselves as voters and participants in the political process. This too is a major theme in social thought, to be seen most luminously perhaps in Tocqueville's *Democracy in America,* a classic written in the 1830s that took not merely America but democracy everywhere as its subject. Tocqueville saw the rise of the political masses, more especially the immense power that could be wielded by the masses, as the single greatest threat to individual freedom and cultural diversity in the ages ahead.

These, then, are the principal themes in the 19th-century writing that may be seen as direct results of the two great revolutions. As themes, they are to be found not only in the social sciences but, as noted above, in a great deal of the philosophical and literary writing of the century. In their respective ways, the philosophers Hegel, Coleridge, and Emerson were as struck by the consequences of the revolutions as were any social scientists. So too were such novelists as Balzac and Dickens.

New ideologies. One other point must be emphasized about these themes. They became, almost immediately in the 19th century, the bases of new ideologies. How men reacted to the currents of democracy and industrialism stamped them conservative, liberal, or radical. On the whole, with rarest exceptions, liberals welcomed the two revolutions, seeing in their forces opportunity for freedom and welfare never before known to mankind. The liberal view of society was overwhelmingly democratic, capitalist, industrial, and, of course, individualistic. The case is somewhat different with conservatism and radicalism in the century. Conservatives, beginning with Edmund Burke, continuing through Hegel and Matthew Arnold down to such minds as John Ruskin later in the century, disliked both democracy and industrialism, preferring the kind of tradition, authority, and civility that had been, in their minds, displaced by the two revolutions. Theirs was a retrospective view, but it was a nonetheless influential one, affecting a number of the central social scientists of the century, among them Auguste Comte and Tocqueville and later Max Weber and Émile Durkheim. The radicals accepted democracy but only in terms of its extension to all areas of society and its eventual annihilation of any form of authority that did not spring directly from the people as a whole. And although the radicals, for the most part, accepted the phenomenon of industrialism, especially technology, they were uniformly antagonistic to capitalism.

These ideological consequences of the two revolutions proved extremely important to the social sciences, for it would be difficult to identify a social scientist in the century—as it would a philosopher or a humanist—who was not, in some degree at least, caught up in ideological currents. In referring to such minds as Saint-Simon, Comte, Le Play among sociologists, to Ricardo, the Frenchman Jean-Baptiste Say, and Marx among economists, to Jeremy

Bentham and John Austin among political scientists, even to anthropologists like the Englishman Edward B. Tylor and the American Lewis Henry Morgan, one has before one men who were engaged not merely in the study of society but also in often strongly partisan ideology. Some were liberals, some conservatives, others radicals. All drew from the currents of ideology that had been generated by the two great revolutions.

New intellectual and philosophical tendencies. It is important also to identify three other powerful tendencies of thought that influenced all of the social sciences. The first is a positivism that was not merely an appeal to science but almost reverence for science; the second, humanitarianism; the third, the philosophy of evolution.

Effects of Positivism

The Positivist appeal of science was to be seen everywhere. The rise of the ideal of science in the Age of Reason was noted above. The 19th century saw the virtual institutionalization of this ideal—possibly even canonization. The great aim was that of dealing with moral values, institutions, and all social phenomena through the same fundamental methods that could be seen so luminously in such areas as physics and biology. Prior to the 19th century, no very clear distinction had been made between philosophy and science, and the term philosophy was even preferred by those working directly with physical materials, seeking laws and principles in the fashion of a Newton or Harvey—that is, by persons whom one would now call scientists.

In the 19th century, in contrast, the distinction between philosophy and science became an overwhelming one. Virtually every area of man's thought and behaviour was thought by a rising number of persons to be amenable to scientific investigation in precisely the same degree that physical data were. More than anyone else, it was Comte who heralded the idea of the scientific treatment of social behaviour. His *Cours de philosophie positive,* published in six volumes between 1830 and 1842, sought to demonstrate irrefutably not merely the possibility but the inevitability of a science of man, one for which Comte coined the word "sociology" and that would do for man the social being exactly what biology had already done for man the biological animal. But Comte was far from alone. There were many in the century to join in his celebration of science for the study of society.

Humanitarianism, though a very distinguishable current of thought in the century, was closely related to the idea of a science of society. For the ultimate purpose of social science was thought by almost everyone to be the welfare of society, the improvement of its moral and social condition. Humanitarianism, strictly defined, is the institutionalization of compassion; it is the extension of welfare and succour from the limited areas in which these had historically been found, chiefly family and village, to society at large. One of the most notable and also distinctive aspects of the 19th century was the constantly rising number of persons, almost wholly from the middle class, who worked directly for the betterment of society. In the many projects and proposals for relief of the destitute, improvement of slums, amelioration of the plight of the insane, the indigent, and imprisoned, and other afflicted minorities could be seen the spirit of humanitarianism at work. All kinds of associations were formed, including temperance associations, groups and societies for the abolition of slavery and of poverty and for the improvement of literacy, among other objectives. Nothing like the 19th-century spirit of humanitarianism had ever been seen before in western Europe—not even in France during the Enlightenment, where interest in mankind's salvation tended to be more intellectual than humanitarian in the strict sense. Humanitarianism and social science were reciprocally related in their purposes. All that helped the cause of the one could be seen as helpful to the other.

Effects of evolutionary theory

The third of the intellectual influences is that of evolution. It affected every one of the social sciences, each of which was as much concerned with the development of things as with their structures. An interest in development was to be found in the 18th century, as noted earlier. But this interest was small and specialized compared with 19th-century theories of social evolution. The impact of Charles Darwin's *Origin of Species,* published in 1859, was of course great and further enhanced the appeal of the evolutionary view of things. But it is very important to recognize that ideas of social evolution had their own origins and contexts. The evolutionary works of such social scientists as Comte, Herbert Spencer, and Marx had been completed, or well begun, before publication of Darwin's work. The important point, in any event, is that the idea or the philosophy of evolution was in the air throughout the century, as profoundly contributory to the establishment of sociology as a systematic discipline in the 1830s as to such fields as geology, astronomy, and biology. Evolution was as permeative an idea as the Trinity had been in medieval Europe.

Development of the separate disciplines. Among the disciplines that formed the social sciences, two contrary, for a time equally powerful, tendencies at first dominated them. The first was the drive toward unification, toward a single, master social science, whatever it might be called. The second tendency was toward specialization of the individual social sciences. If, clearly, it is the second that has triumphed, with the results to be seen in the disparate, sometimes jealous, highly specialized disciplines seen today, the first was not without great importance and must also be examined.

Unification versus specialization

What emerges from the critical rationalism of the 18th century is not, in the first instance, a conception of need for a plurality of social sciences, but rather for a single science of society that would take its place in the hierarchy of the sciences that included the fields of astronomy, physics, chemistry, and biology. When, in the 1820s, Comte wrote calling for a new science, one with man the social animal as the subject, he assuredly had but a single, encompassing science of society in mind—not a congeries of disciplines, each concerned with some single aspect of man's behaviour in society. The same was true of Bentham, Marx, and Spencer. All these minds, and there were many others to join them, saw the study of society as a unified enterprise. They would have scoffed, and on occasion did, at any notion of a separate economics, political science, sociology, and so on. Society is an indivisible thing, they would have argued; so, too, must be the study of society.

It was, however, the opposite tendency of specialization or differentiation that won out. No matter how the century began, or what were the dreams of a Comte, Spencer, or Marx, when the 19th century ended, not one but several distinct, competitive social sciences were to be found. Aiding this process was the development of the colleges and universities. With hindsight it might be said that the cause of universities in the future would have been strengthened, as would the cause of the social sciences, had there come into existence, successfully, a single curriculum, undifferentiated by field, for the study of society. What in fact happened, however, was the opposite. The growing desire for an elective system, for a substantial number of academic specializations, and for differentiation of academic degrees, contributed strongly to the differentiation of the social sciences. This was first and most strongly to be seen in Germany, where, from about 1815 on, all scholarship and science were based in the universities and where competition for status among the several disciplines was keen. But by the end of the century the same phenomenon of specialization was to be found in the United States (where admiration for the German system was very great in academic circles) and, in somewhat less degree, in France and England. Admittedly, the differentiation of the social sciences in the 19th century was but one aspect of a larger process that was to be seen as vividly in the physical sciences and the humanities. No major field escaped the lure of specialization of investigation, and clearly, a great deal of the sheer bulk of learning that passed from the 19th to the 20th century was the direct consequence of this specialization.

Classical economists and socialists

Economics. It was economics that first attained the status of a single and separate science, in ideal at least, among the social sciences. That autonomy and self-regulation that the Physiocrats and Adam Smith had found, or thought they had found, in the processes of wealth, in the operation of prices, rents, interest, and wages during the 18th century became the basis of a separate and distinctive economics—or, as it was often called, "political economy"—in the 19th. Hence the emphasis upon what came to be widely called laissez-faire. If, as it was argued, the processes of wealth operate naturally in terms of their own built-in mechanisms, then not only should these be studied separately but they should, in any wise polity, be left alone by government and society. This was, in general, the overriding emphasis of such thinkers as David Ricardo, John Stuart Mill, and Nassau William Senior in England, of Frédéric Bastiat and Jean-Baptiste Say in France, and, somewhat later, the Austrian school of Carl Menger. This emphasis is today called "classical" in economics, and it is even now, though with substantial modifications, a strong position in the field.

There were almost from the beginning, however, economists who diverged sharply from this laissez-faire, classical view. In Germany especially there were the so-called historical economists. They proceeded less from the discipline of historiography than from the presuppositions of social evolution, referred to above. Such men as Wilhelm Roscher and Karl Knies in Germany tended to dismiss the assumptions of timelessness and universality regarding economic behaviour that were almost axiomatic among the followers of Adam Smith, and they strongly insisted upon the developmental character of capitalism, evolving in a long series of stages from other types of economy.

Also prominent throughout the century were those who came to be called the Socialists. They too repudiated any notion of timelessness and universality in capitalism and its elements of private property, competition, and profit. Not only was this system but a passing stage of economic developments; it could be—and, as Marx was to emphasize, would be—shortly supplanted by a more humane and also realistic economic system based upon cooperation, the people's ownership of the means of production, and planning that would eradicate the vices of competition and conflict.

Political science. Rivalling economics as a discipline during the century was political science. The line of systematic interest in the state that had begun in modern Europe with Machiavelli, Hobbes, Locke, and Rousseau, among others, widened and lengthened in the 19th century, the consequence of the two revolutions. If the Industrial Revolution seemed to supply all the problems frustrating the existence of a stable and humane society, the political-democratic revolution could be seen as containing many of the answers to these problems. It was the democratic revolution, especially in France, that created the vision of a political government responsible for all aspects of human society and, most important, possessed the power to wield this responsibility. This power, known as sovereignty, could be seen as holding the same relation to political science in the 19th century that capital held to economics. To a very large number of political scientists, the aim of the discipline was essentially that of analyzing the varied properties of sovereignty. There was a strong tendency on the part of such political scientists as Bentham, Austin, and Mill in England and Francis Lieber and Woodrow Wilson in the United States to see the state and its claimed sovereignty over human lives in much the same terms in which classical economists saw capitalism.

Concern with sovereignty

Among political scientists there was the same historical-evolutionary dissent from this view, however, that existed in economics. Such writers as Sir Henry Maine in England, Numa Fustel de Coulanges in France, and Otto von Gierke in Germany declared that state and sovereignty were not timeless and universal nor the results of some "social contract" envisaged by such philosophers as Locke and Rousseau but, rather, structures formed slowly through developmental or historical processes. Hence the strong interest, especially in the late 19th century, in the origins of political institutions in kinship, village, and caste, and in the successive stages of development that have characterized these institutions. In political science, as in economics, in short, the classical analytical approach was strongly rivalled by the evolutionary. Both approaches go back to the 18th century in their fundamental elements, but what is seen in the 19th century is the greater systematization and the much wider range of data employed.

Cultural anthropology. In the 19th century, anthropology also attained clear identity as a discipline. Strictly defined as "the science of man," it could be seen as superseding other specialized disciplines such as economics and political science. In practice and from the beginning, however, anthropology concerned itself overwhelmingly with primitive man. On the one hand was physical anthropology, concerned chiefly with the evolution of man as a biological species, with the successive forms and protoforms of the species, and with genetic systems such as stocks and races in the world. On the other hand was social and cultural anthropology: here the interest was in the full range of man's institutions but confined to those found in fact among existing preliterate or "primitive" peoples in Africa, Oceania, Asia, and the Americas. Above all other concepts, "culture" was the central element of this great area of anthropology, or ethnology, as it was often called to distinguish it from physical anthropology. Culture, as a concept, called attention to the nonbiological, nonracial, noninstinctual basis of the greater part of what one calls civilization: its values, techniques, ideas in all spheres. Culture, as defined in Tylor's landmark work of 1871, *Primitive Culture,* is the part of man's behaviour that is learned. From cultural anthropology more than from any other single social science has come the emphasis on the cultural foundations of man's behaviour and thought in society.

Anthropological focus on primitive man and evolutionism

Scarcely less than political science or economics, cultural anthropology shared in the themes of the two revolutions and their impact on the world. If the data that cultural anthropologists actually worked with were generally in the remote areas of the world, it was the effects of the two revolutions that, in a sense, kept opening up these parts of the world to more and more systematic inquiry. And, as was true of the other social sciences, the cultural anthropologists were immersed in problems of economics, polity, social class, and community, albeit among preliterate rather than "modern" peoples.

Overwhelmingly, without major exception indeed, the science of cultural anthropology was evolutionary in thrust in the 19th century. Edward B. Tylor and Sir John Lubbock in England, Lewis Henry Morgan in the United States, Adolf Bastian and Theodor Waitz in Germany, and all others in the main line of the study of primitive culture saw existing native societies in the world as prototypes of their own "primitive ancestors," fossilized remains, so to speak, of stages of development that western Europe had once gone through. Despite the vast array of data compiled on non-Western cultures, the same basic European-centred objectives are to be found among cultural anthropologists as among other social scientists in the century. Almost universally, then, the modern West was regarded as the latest point in a line of progress that was single and unilinear and on which all other peoples in the world could be fitted as illustrations, as it were, of Western man's own past.

Sociology. Sociology came into being in precisely these terms, and during much of the century it was not easy to distinguish between a great deal of so-called sociology and social or cultural anthropology. Even if almost no sociologists in the century made empirical studies of primitive peoples, as did the anthropologists, their interest in the origin, development, and probable future of mankind was not less great than what could be found in the writings of the anthropologists. It was Auguste Comte who coined the word sociology, and he used it to refer to what he imagined would be a single, all-encompassing, science of society that would take its place at the top of the hierarchy of sciences—a hierarchy that Comte saw as including astronomy (the oldest of the sciences historically) at the bottom and with physics, chemistry, and biology rising in that order to sociology, the latest and grandest of the sciences. There was no thought in Comte's mind—nor was there in the mind of Herbert Spencer, whose general view of sociology was very much like Comte's—of there being other, competing social sciences. Sociology would be to

The "grand" view of sociology

the whole of the social world what each of the other great sciences was to its appropriate sphere of reality.

Both Comte and Spencer believed that civilization as a whole was the proper subject of sociology. Their works were concerned, for the most part, with describing the origins and development of civilization and also of each of its major institutions. Both declared sociology's main divisions to be "statics" and "dynamics," the former concerned with processes of order in society, the latter with processes of evolutionary change in society. Both men also saw all existing societies in the world as reflective of the successive stages through which Western society had advanced in time over a period of tens of thousands of years.

The "problems" view of sociology

Not all sociologists in the 19th century conceived their discipline in this light, however. Side by side with the "grand" view represented by Comte and Spencer were those in the century who were primarily interested in the social problems that they saw around them—consequences, as they interpreted them, of the two revolutions, the industrial and democratic. Thus in France just after midcentury, Frédéric Le Play published a monumental study of the social aspects of the working classes in Europe, *Les Ouvriers européens,* which compared families and communities in all parts of Europe and even other parts of the world. Alexis de Tocqueville, especially in the second volume of his *Democracy in America* (1835), provided an account of the customs, social structures, and institutions in America, dealing with these—and also with the social and psychological problems of Americans in that day—as aspects of the impact of the democratic and industrial revolutions upon traditional society.

At the very end of the 19th century, in both France and Germany, there appeared some of the works in sociology that were to prove most lasting in their effects upon 20th-century sociology. Ferdinand Tönnies, in his *Gemeinschaft und Gesellschaft* (1887; translated as *Community and Society*), sought to explain all major social problems in the West as the consequence of the West's historical transition from the communal, status-based, concentric society of the Middle Ages to the more individualistic, impersonal, and large-scale society of the democratic-industrial period. In general terms, allowing for individual variations of theme, these were the views of Max Weber, Georg Simmel, and Émile Durkheim (all of whom also wrote in the late 19th and early 20th century). These were the men who, starting from the problems of Western society that could be traced to the effects of the two revolutions, did the most to establish the discipline of sociology as it is found for the most part in the 20th century.

Social psychology. Social psychology as a distinct discipline also originated in the 19th century, although its outlines were perhaps somewhat less clear than was true of the other social sciences. The close relation of the human mind to the social order, its dependence upon education and other forms of socialization, was well known in the 18th century. In the 19th century, however, an ever more systematic discipline came into being to uncover the social and cultural roots of human psychology and also the several types of "collective mind" that analysis of different cultures and societies in the world might reveal. In Germany, Moritz Lazarus and Wilhelm Wundt sought to fuse the study of psychological phenomena with analyses of whole cultures. Folk psychology, as it was called, did not, however, last very long in scientific esteem.

Early group studies

Much more esteemed, and closer to 20th-century conceptions of social psychology, were the works of such men as Gabriel Tarde, Gustave Le Bon, Lucien Lévy-Bruhl, and Émile Durkheim in France and Georg Simmel in Germany (all of whom also wrote in the early 20th century). Here, in concrete, often highly empirical studies of small groups, associations, crowds, and other aggregates (rather than in the main line of psychology during the century, which tended to be sheer philosophy at one extreme and a variant of physiology at the other) are to be found the real beginnings of social psychology. Although the point of departure in each of the studies was the nature of association, they dealt, in one degree or other, with the internal processes of psychosocial interaction, the operation of attitudes and judgments, and the social basis of personality and thought—in short, with those phenomena that would, in the 20th century, be the substance of social psychology as a formal discipline.

Social statistics and social geography. Two final manifestations of the social sciences in the 19th century are social statistics and social (or human) geography. At that time, neither achieved the notability and acceptance in colleges and universities that such fields as political science and economics did. Both, however, were as clearly visible by the latter part of the century as any of the other social sciences. And both were to exert a great deal of influence on the other social sciences by the beginning of the 20th century: social statistics on sociology and social psychology pre-eminently; social geography on political science, economics, history, and certain areas of anthropology, especially those areas dealing with the dispersion of races and the diffusion of cultural elements. In social statistics the key figure of the century was a Belgian, Adolphe Quetelet, who was the first, on any systematic basis, to call attention to the kinds of structured behaviour that could be observed and identified only through statistical means. It was Quetelet who brought into prominence the momentous concept of "the average man" and his behaviour. The two major figures in social or human geography in the century were Friedrich Ratzel in Germany and Paul Vidal de la Blache in France. Both broke completely with the crude environmentalism of earlier centuries, which had sought to show how topography and climate actually determine human behaviour, and they substituted the more subtle and sophisticated insights into the relationships of land, sea, and climate on the one hand and, on the other, the varied types of culture and human association that are to be found on earth.

In summary, by the end of the 19th century all the major social sciences had achieved a distinctiveness, an importance widely recognized, and were, especially in the cases of economics and political science, fully accepted as disciplines in the universities. Most important, they were generally accepted as sciences in their own right rather than as minions of philosophy.

THE 20TH CENTURY

What is seen in the 20th century is not only an intensification and spread of earlier tendencies in the social sciences but also the development of many new tendencies that, in the aggregate, make the 19th century seem by comparison one of quiet unity and simplicity in the social sciences.

In the 20th century, the processes first generated by the democratic and industrial revolutions have gone on virtually unchecked in Western society, penetrating more and more spheres of once traditional morality and culture, leaving their impress on more and more nations, regions, and localities. Equally important, perhaps in the long run far more so, is the spread of these revolutionary processes to the non-Western areas of the world. The impact of industrialism, technology, secularism, and individualism upon peoples long accustomed to the ancient unities of tribe, local community, agriculture, and religion was first to be seen in the context of colonialism, an outgrowth of nationalism and capitalism in the West. The relations of the West to non-Western parts of the world, the whole phenomenon of the "new nations," are vital aspects of the social sciences.

So too are certain other consequences, or lineal episodes, of the two revolutions. The 20th century is the century of nationalism, mass democracy, and large-scale industrialism beyond reach of any 19th-century imagination so far as magnitude is concerned. It is the century of mass warfare, of two world wars with toll in lives and property greater perhaps than the sum total of all preceding wars in history. It is the century too of totalitarianism: Communist, Fascist, and Nazi; and of techniques of terrorism that, if not novel, are to be seen on a scale and with an intensity of scientific application that could scarcely have been predicted by those who considered science and technology as unqualifiedly humane in possibility. It is a century of affluence in the West, without precedent for the masses of people, to be seen in a constantly rising standard of living and a constantly rising level of expectations.

The last is important. A great deal of the turbulence in the 20th century—political, economic, and social—is the result of desires and aspirations that have been constantly escalating and that have been passing from the white people in the West to ethnic and racial minorities among them and, then, to whole continents elsewhere. Of all manifestations of revolution, the revolution of rising expectations is perhaps the most powerful in its consequences. For, once this revolution gets under way, each fresh victory in the struggle for rights, freedom, and security tends to magnify the importance of what has not been won.

Once it was thought that by solving the fundamental problems of production and large-scale organization, man could ameliorate other problems, those of a social, moral, and psychological nature. What in fact occurred, on the testimony of a great deal of the most notable thought and writing, was a heightening of such problems. It would appear that as man satisfies, relatively at least, the lower order needs of food and shelter, his higher order needs for purpose and meaning in life become ever more imperious. Thus such philosophers of history as Arnold Toynbee, Pitirim Sorokin, and Oswald Spengler have dealt with problems of purpose and meaning in history with a degree of learning and intensity of spirit not seen since perhaps St. Augustine wrote his monumental *The City of God* in the early 5th century when signs of the disintegration of Roman civilization were becoming overwhelming in their message to so many of that day. In the 20th century, though the idea of progress has certainly not disappeared, it has been rivalled by ideas of cyclical change and of degeneration of society. It is hard to miss the currency of ideas in modern times—status, community, purpose, moral integration, on the one hand, and alienation, anomie, disintegration, breakdown on the other—that reveal only too clearly the divided nature of man's spirit, the unease of his mind.

Effects of alienation and social isolation

There is to be seen too, especially during later decades of the century, a questioning of the role of reason in human affairs—a questioning that stands in stark contrast with the ascendancy of rationalism in the two or three centuries preceding. Doctrines and philosophies stressing the inadequacy of reason, the subjective character of human commitment, and the primacy of faith have rivalled—some would say conquered—doctrines and philosophies descended from the Age of Reason. Existentialism, with its emphasis on the basic loneliness of the individual, on the impossibility of finding truth through intellectual decision, and on the irredeemably personal, subjective character of man's life, has proved to be a very influential philosophy in the writings of the 20th century. Freedom, far from being the essence of hope and joy, is the source of man's dread of the universe and of his anxiety for himself. Søren Kierkegaard's 19th-century intimations of anguished isolation as the perennial lot of the individual have had rich expression in the philosophy and literature of the 20th century.

It might be thought that such intimations and presentiments as these have little to do with the social sciences. This is true in the direct sense perhaps but not true when one examines the matter in terms of contexts and ambiences. The "lost individual" has been of as much concern to the social sciences as to philosophy and literature. Ideas of alienation, anomie, identity crisis, and estrangement from norms are rife among the social sciences, particularly, of course, those most directly concerned with the nature of the social bond, such as sociology, social psychology, and political science. In countless ways, interest in the loss of community, in the search for community, and in the individual's relation to society and morality have had expression in the work of the social sciences. Between the larger interests of a culture and the social sciences there is never a wide gulf—only different ways of defining and approaching these interests.

Marxist influences. The influence of Marxism in the 20th century must not be missed. Currently the works of Lenin have outstripped the Bible in distribution in the world. For hundreds of millions of persons today the ideas of Marx, as communicated by Lenin, have profound moral, even religious significance. But even in those parts of the world, the West foremost, where Communism has exerted little direct political impact, Marxism remains a potent source of ideas. Not a few of the central concepts of social stratification and the location and diffusion of power in the social sciences come straight from Marx's insights. Far more is this the case in the Communist countries—the Soviet Union, other eastern European countries, China, and even Asian countries in which no Communist domination exists. In all these countries, Marx's name is virtually sacrosanct. There is not the same degree of differentiation of social sciences in these countries that is found in the West. As an example, sociology hardly exists as a recognized discipline in these countries, and by the standards of the West, the other social sciences have little more than a rather rudimentary existence. Economics alone tends to be favoured, and this is, of course, largely Marxian economics—the economics of Marx's *Das Kapital.*

But even though Marxism has had relatively little direct impact on the social sciences as disciplines in the West, it has had enormous influence on states of mind that are closely associated with the social sciences. Especially was this true during the 1930s, the decade of the Great Depression. Today signs are not lacking of a strong revival of interest in Marx that could very well, through sheer numbers of its adherents, affect the nature of the social sciences in the years ahead. Socialism remains for a great many persons an evocative symbol and creed. Marx remains a formidable name among intellectuals and is still, without any question, the principal intellectual source of radical movements in politics. Such a position cannot help but influence the contexts of even the most abstract of the social sciences.

Triumph of social planning and Keynesianism

What Marx's ideas have suggested above all else in a positive way is the possibility of a society directed, not by blind forces of competition and struggle among economic elements, but instead by directed planning. This hope, this image, has proved a dominant one in the 20th century even where the influence of Marx and of Socialism has been at best small and indirect. It is this profound interest in central planning and governance that has given almost historic significance to the ideas of the English economist J.M. Keynes. What is called Keynesianism has as its intellectual base a very complex modification of the classical doctrines of economics—one set forth in Keynes's famous *The General Theory of Employment, Interest and Money,* published in 1935–36. Of greater influence today, however, than the strictly theoretical content of this general theory is the political impact that Keynesian ideas have had on Western democracies. For out of these ideas came the clear policy of governments dealing directly with the business cycle, of pumping money and credit into an economic system when the cycle threatens to turn downward, and of then lessening this infusion when the cycle moves upward. Above all other names in the West, that of Keynes has become identified with such policy in the democracies and with the general movement of central governments toward ever more active and constant regulation of processes once thought best left to what the classical economists thought of as natural laws. True, the root ideas of the classical economists are found in modified form even today in the works of such economists as the American Milton Friedman. But it would not be unfair to say that Keynes's name has become associated with democratic economic planning and direction in much the way that Marx's name is associated with Communist economic policies.

Freudian influences. In the general area of personality, mind, and character, the writings of Sigmund Freud have had influence on 20th-century culture and thought scarcely less than Marx's. His basic theories of the role of the unconscious mind, of the lasting effects of infantile sexuality, and of the Oedipus complex have gone beyond the discipline of psychoanalysis and even the larger area of psychiatry to areas of several of the social sciences. Anthropologists have applied Freudian concepts to their studies of primitive cultures, seeking to assess comparatively the universality of states of the unconscious that Freud and his followers held to lie in the whole human race. Some political scientists have used Freudian ideas to

Freudian emphases on the unconscious and the unrational illuminate the nature of authority generally, and political power specifically, seeing in totalitarianism, for example, the thrust of a craving for the security that total power can give. Sociology and social psychology have been influenced by Freudian ideas in their studies of social interaction and motivation. From Freud came the fruitful perspective that sees social behaviour and attitudes as generated not merely by the external situation but also by internal emotional needs springing from childhood—needs for recognition, authority, self-expression. Whatever may be the place directly occupied by Freud's ideas in the social sciences today, his influence upon 20th-century thought and culture generally, not excluding the social sciences, has been hardly less than Marx's.

Diffusion of the social sciences

Specialization and cross-disciplinary approaches. A major point to make about the social sciences of the 20th century is the vast increase in the number of social scientists involved, in the number of academic and other centres of teaching and research in the social sciences, and in their degree of both comprehensiveness and specialization. The explosion of the sciences generally in the 20th century—an explosion responsible for the fact that a majority of all scientists who have ever lived in human history are now alive—has had, as one of its signal elements, the explosion of the social sciences. Not only has there been development and proliferation but there has also been a spectacular diffusion of the social sciences. Beginning in a few places in western Europe and the United States in the 19th century, the social sciences, as bodies of ongoing research and centres of teaching, are today to be found almost everywhere in the world. In considerable part this has followed the spread of universities from the West to other parts of the world and, within universities, the very definite shift away from the hegemony once held by humanities alone to the near-hegemony held today by the sciences, physical and social.

Specialization has been as notable a tendency in the social sciences as in the biological and physical sciences. This is reflected not only in varieties of research but also in course offerings in academic departments. Whereas not very many years ago, a couple of dozen advanced courses in a social science reflected the specialization and diversity of the discipline even in major universities with graduate schools, today a hundred such courses are found to be not enough.

Side by side with this strong trend toward specialization, however, is another, countering trend: that of cross-fertilization and interdisciplinary cooperation. At the beginning of the century, down in fact until World War II, the several disciplines existed each in a kind of splendid isolation from the others. That historians and sociologists, for example, might ever work together in curricula and research projects would have been scarcely conceivable prior to about 1945. Each social science tended to follow the course that emerged in the 19th century: to be confined to a single, distinguishable, if artificial, area of social reality. Today, evidences are all around of cross-disciplinary work and of fusion within a single social science of elements drawn from other social sciences. Thus there are such vital areas of work as political sociology, economic anthropology, psychology of voting, and industrial sociology. Single concepts such as "structure," "function," "alienation," and "motivation" can be seen employed variously to useful effect in several social sciences. The techniques of one social science can be seen consciously incorporated into another or into several social sciences. If history has provided much in the way of perspective to sociology or anthropology, each of these two has provided perspective, and also whole techniques, such as statistics and survey, to history. In short, specialization is by no means without some degree at least of countertendencies such as fusion and synthesis.

Professionalization

Another outstanding characteristic of each of the social sciences in the 20th century is its professionalization. Without exception, the social sciences have become bodies of not merely research and teaching but also practice, in the sense that this word has in medicine or engineering. Down until about World War II, it was a rare sociologist or political scientist or anthropologist who was not a holder of academic position. There were economists and psychologists to be found in banks, industries, government, even in private consultantship, but the numbers were relatively tiny. Overwhelmingly the social sciences had visibility alone as academic disciplines, concerned essentially with teaching and with more or less basic, individual research. All this has changed profoundly, and on a vast scale, during the past three decades. Today there are as many economists and psychologists outside academic departments as within, if not more. The number of sociologists, political scientists, and demographers to be found in government, industry, and private practice rises constantly. Equally important is the changed conception or image of the social sciences. Today, to a degree unknown before World War II, the social sciences are conceived as policy-making disciplines, concerned with matters of national welfare in their professional capacities in just as sure a sense as any of the physical sciences. Inevitably, tensions have arisen within the social sciences as the result of processes of professionalization. Those persons who are primarily academic can all too easily feel that those who are primarily professional have different and competing identifications of themselves and their disciplines.

Nature of the research. The emphasis upon research in the social sciences has become almost transcending within recent decades. This situation is not at all different from that which prevails in the physical sciences and the professions in this age. Prior to about 1945, the functions of teaching and research had approximately equal value in many universities and colleges. The idea of a social (or physical) scientist appointed to an academic institution for research alone, or with research preponderant, was scarcely known. Research bureaus and institutes in the social sciences were very few and did not rival traditional academic departments and colleges as prestige-bearing entities. All of that was changed decisively beginning with the period just after World War II. From governments and foundations, large sums of money passed into the universities—usually not to the universities as such, but rather to individuals or small groups of individuals, each eminent for research. Research became the uppermost value in the social sciences (as in the physical) and hence, of course, in the universities themselves.

Use of mathematics and computers

Probably the greatest single change in the social sciences during the past generation has been the widespread introduction of mathematical and other quantitative methods. Without question, economics is the discipline in which the most spectacular changes of this kind have taken place. So great is the dominance of mathematical techniques here—resulting in the eruption of what is called econometrics to a commanding position in the discipline—that, to the outsider, economics today almost appears to be a branch of mathematics. But in sociology, political science, social psychology, and anthropology, the impact of quantitative methods, above all, of statistics, has also been notable. No longer does statistics stand alone, a separate discipline, as it did in effect during the 19th century. This area today is inseparable from each of the social sciences, though, in the field of mathematics, statistics still remains eminently distinguishable, the focus of highly specialized research and theory.

Within the past decade or two, the use of computers and of all the complex techniques associated with computers has become a staple of social-science research and teaching. Through the data storage and data retrieval of electronic computers, working with amounts and diversity of data that would call for the combined efforts of hundreds, even thousands of technicians, the social sciences have been able to deal with both the extensive and intensive aspects of human behaviour in ways that would once have been inconceivable. The so-called computer revolution in modern thought has been, in short, as vivid a phase of the social as the physical sciences, not to mention other areas of modern life. The problem as it is stated by mature social scientists is to use computers in ways in which they are best fitted but without falling into the fallacy that they can alone guide, direct, and supply vital perspective in the study of man.

Closely related to mathematical, computer, and other

Emphasis on empirical evidence and data gathering

quantitative aspects of the social sciences is the vast increase in the empiricism of modern social science. Never in history has so much in the way of data been collected, examined, classified, and brought to the uses of social theory and social policy alike. What has been called the triumph of the fact is nowhere more visible than in the social sciences. Without question, this massive empiricism has been valuable, indispensable indeed, to those seeking explanations of social structures and processes. Empiricism, however, like quantitative method, is not enough in itself. Unless related to hypothesis, theory, or conclusion, it is sterile, and most of the leading social scientists of today reflect this view in their works. Too many, however, deal with the gathering and classifying of data as though these were themselves sufficient.

It is the quest for data, for detailed, factual knowledge of human beliefs, opinions, and attitudes, as well as patterns and styles of life—familial, occupational, political, religious, and so on—that has made the use of surveys and polls another of the major tendencies in the social sciences of this century. The poll data one sees in his newspaper are hardly more than the exposed portion of an iceberg. Literally thousands of polls, questionnaires, and surveys are going on at any given moment today in the social sciences. The survey or polling method ranks with the quantitative indeed in popularity in the social sciences, both being, obviously, indispensable tools of the empiricism just mentioned.

Specific versus grand theory

Theoretical modes. It is not the case, however, that interest in theory is a casualty of the 20th-century fascination with method and fact. Though there is a great deal less of that grand or comprehensive theory that was a hallmark of 19th-century social philosophy and social science, there are still those persons occasionally to be found today who are engrossed in search for master principles, for general and unified theory that will assimilate all the lesser and more specialized types of theory. But their efforts and results are not regarded as successful by the vast majority of social scientists. Theory, at its best, today tends to be specific theory—related to one or other of the major divisions of research within each of the social sciences. The theory of the firm in economics, of deviance in sociology, of communication in political science, of attitude formation in social psychology, of divergent development in cultural anthropology are all examples of theory in every proper sense of the word. But each is, clearly, specific. If there is a single social science in which a more or less unified theory exists, with reference to the whole of the discipline, it is economics. Even here, however, unified, general theory does not have the sovereign sweep it had in the classical tradition of Ricardo and his followers before the true complexities of economic behaviour had become revealed.

Developmentalism. Developmentalism is another overall influence upon the work of the social sciences, especially within the past three decades. As noted above, an interest in social evolution was one of the major aspects of the social sciences throughout the 19th century in western Europe. In the early 20th century, however, this interest, in its larger and more visible manifestations, seemed to terminate. There was a widespread reaction against the idea of unilinear sequences of stages, deemed by the 19th-century social evolutionists to be universal for all mankind in all places. Criticism of social evolution in this broad sense was a marked element of all the social sciences, preeminently in anthropology but in the others as well. There were numerous demonstrations of the inadequacy of unilinear descriptions of change when it came to accounting for what actually happened, so far as records and other evidences suggested, in the different areas and cultures of the world.

Influences of national growth and development

Beginning in the late 1940s and the 1950s, however, there was a resurgence of developmental ideas in all the social sciences—particularly with respect to studies of the new nations and cultures that were coming into existence in considerable numbers. Studies of economic growth and of political and social development have become more and more numerous. Although it would be erroneous to see these developmental studies as simple repetitions of those of the 19th-century social evolutionists, there are, nevertheless, common elements of thought, including the idea of stages of growth and of change conceived as continuous and cumulative and even as moving toward some more or less common end. At their best, these studies of growth and development in the new nations, by their counterposing of traditional and modern ways, tell a good deal about specific mechanisms of change, the result of the impact of the West upon outlying parts of the world. But as more and more social scientists have recently become aware, efforts to place these concrete mechanisms of change into larger, more systematic models of development all too commonly succumb to the same faults of unilinearity and specious universalism that early-20th-century critics found in 19th-century social evolution.

Social-systems approach. Still another major tendency in all of the social sciences since World War II has been the interest in "social systems." The behaviour of individuals and groups is seen as falling into multiple interdependencies, and these interdependencies are considered sufficiently unified to warrant use of the word "system." Although there are clear uses of biological models and concepts in social-systems work, it may be fair to say that the greatest single impetus to development of this area was widening interest after World War II in cybernetics—the study of human control functions and of the electrical and mechanical systems that could be devised to replace or reinforce them. Concepts drawn from mechanical and electrical engineering have been rather widespread in the study of social systems.

In social-systems studies, the actions and reactions of individuals, or even of groups as large as nations, are seen as falling within certain definable, more or less universal patterns of equilibrium and disequilibrium. The interdependence of roles, norms, and functions is regarded as fundamental in all types of group behaviour, large and small. Each social system, as encountered in social-science studies, is a kind of "ideal type," not identical to any specific "real" condition but sufficiently universal in terms of its central elements to permit useful generalization.

Emphasis on pattern and interdependence

Structuralism and functionalism. Structuralism in the social sciences is closely related to the theory of the social system. Although there is nothing new about the root concepts of structuralism—they may be seen in one form or other throughout Western thought—there is no question but that in the present century this view of behaviour has become a dominant one in many fields. At bottom it is a reaction against all tendencies to deal with human thought and behaviour atomistically—that is, in terms of simple, discrete units of either thought, perception, or overt behaviour. In psychology, structuralism in its oldest sense simply declares that perception occurs, with learning following, in terms of experiences or sensations in various combinations, in discernible patterns or gestalten. In sociology, political science, and anthropology, the idea of structure similarly refers to the repetitive patternings that are found in the study of social, economic, political, and cultural existence. The structuralist contends that no element can be examined or explained outside its context or the pattern or structure of which it is a part. Indeed, it is the patterns, not the elements, that are the only valid objects of study.

What is called functionalism in the social sciences today is closely related to structuralism, with the term structural-functional a common one, especially in sociology and anthropology. Function refers to the way in which behaviour takes on significance, not as a discrete act but as the dynamic aspect of some structure. Biological analogies are common in theories of structure and function in the social sciences. Very common is the image of the biological organ, with its close interdependence to other organs (as the heart to the lung) and the interdependence of activities (as circulation to respiration).

Interactionism. Interaction is still another concept that has had wide currency in the social sciences of the 20th century. Social interaction—or, as it is sometimes called, symbolic interaction—refers to the fact that the relationships among two or more groups or human beings are never one-sided, purely physical, or direct. Always there is reciprocal influence, a mutual sense of "otherness." And always the presence of the "other" has crucial effect in one's definition of not merely what is external but what is internal. One acquires one's individual sense of identity from interactions with others beginning in infancy. It is the initial sense of the other person—mother, for example—that in time gives the child its sense of self, a sense that requires continuous development through later interactions with others. From the point of view of interactionist theory, all one's perceptions of and reactions to the external world are mediated or influenced by prior ideas, valuations, and assessments. Always one is engaged in socialization or the modification of one's mind, role, and behaviour through contact with others.

FUTURE OF THE SOCIAL SCIENCES

What has been covered in the preceding paragraphs may be the most that can be said within restricted compass about the social sciences of the 20th century without turning to the individual social sciences themselves and related disciplines (see below). The concern here has been with only those major contextual influences, tendencies of overall character, and dominant ideas or theories that the social sciences taken as a whole manifest in one degree or other.

Relation of social sciences to society

There is one final aspect of the subject that must be considered briefly, for how it is resolved will have much effect upon the future of the social sciences in the West. This is the relation of the social sciences to organized society, to government and industry, and other institutional centres of authority. At the present time, there is a significant and undoubtedly growing feeling among social scientists, especially younger ones, that the relationship has become altogether too close. The social sciences, it is said, must maintain their distance, their freedom, from bureaucratized government and industry. Otherwise they will lose their inherent powers of honest and dispassionate criticism of the ineffective or evil in society. Although there may be a certain amount of feeling ranging from the naïve to the politically revolutionary in such sentiments, they cannot be taken lightly, as is apparent from the serious consideration that is being given on a steadily rising scale to the whole problem of the relationship between social science and social policy.

Since the inception of the social sciences—since, indeed, the time when the universities in the West came into being for the express purpose of training professional men in law, theology, and medicine—man has properly sought, through knowledge, to influence social policy, taking this latter term in the widest sense to include not merely the policies of national government but of local government, business, professions, and so on. What else, it may be asked, are the social sciences all about if it is not to use knowledge to improve social life; and how else but through influencing of the major institutions can such improvement take place?

So much is true, comes the answering response. But in the process of seeking to influence the great agencies of modern power and function—of what is loosely called the Establishment—the social sciences may themselves become influenced adversely by the values of power and affluence to be found in these great agencies. They themselves may become identified with the status quo. What the social sciences should give, say the partisans of this view, is a continuation of the revolutionary or at least profoundly reformist tradition that was begun in the 18th century by the philosophers of reason who, detesting the official establishment of their day, sought on their own to transform it. What is today called objectivity or methodological rigour turns out to be, say these same partisans, acceptance of the basic values of reigning government and industry.

It is this essential conflict regarding the purposes of the social sciences, the relation of the social sciences to government and society, and the role of the individual social scientist in the society of the 20th century that bids fair at this moment to be the major conflict of the years ahead. How it is resolved may very well determine the fate of the social sciences, now less than two centuries old.

(R.A.N./Ed.)

Cultural anthropology

Etymologically, anthropology is the science of man. In fact, however, it is only one of the sciences of man, bringing together those disciplines the common aims of which are to describe man and explain him on the basis of the biological and cultural characteristics of the populations among which he is distributed and to emphasize, through time, the differences and variations of these populations. The concept of race, on the one hand, and that of culture, on the other, have received special attention; and although their meaning is still subject to debate, these terms are doubtless the most common of those in the anthropologist's vocabulary.

Early emphasis on "primitive" man

Anthropology, which is concerned with the study of human differences, was born after the Age of Discovery had opened up societies that had remained outside the technological civilization of the modern West. In fact, the field of research was at first restricted to those societies that had been given one unsatisfactory label after another: "savage," "primitive," "tribal," "traditional," or even "preliterate," "prehistorical," and so on. What such societies had in common, above all, was being the most "different" or the most foreign to the anthropologist; and in the early phases of anthropology, the anthropologists were always European or North American. The distance between the researcher and the object of his study has been a characteristic of anthropological research; it has been said of the anthropologist that he was the "astronomer of the sciences of man."

Anthropologists today study more than just primitive societies. Their research extends not only to village communities within modern societies but also to cities, even to industrial enterprises. Nevertheless, anthropology's first field of research, and the one that perhaps remains the most important, shaped its specific point of view with regard to the other sciences of man and defined its theme. If, in particular, it is concerned with generalizing about patterns of human behaviour seen in all their dimensions and with achieving a total description of social and cultural phenomena, this is because anthropology has observed small-scale societies, which are simpler or at least more homogeneous than modern societies and which change at a slower pace. Thus they are easier to see whole.

What has just been said refers especially to the branch of anthropology concerned with the cultural characteristics of man. Anthropology has, in fact, gradually divided itself into two major spheres: the study of man's biological characteristics and the study of his cultural characteristics. The reasons for this split are manifold, one being the rejection of the initial mistakes regarding correlations between race and culture. More generally speaking, the vast field of 19th-century anthropology was subdivided into a series of increasingly specialized disciplines, using their own methods and techniques, that were given different labels according to national traditions. The Table shows the terminology current in North America and in continental Europe.

Cultural and physical anthropology

Thus two large disciplines—physical anthropology and cultural anthropology—and such related disciplines as prehistory and linguistics now cover the program that originally was set up for a single study of anthropology. The two fields are largely autonomous, having their own relations with disciplines outside anthropology; and it is unlikely that any researchers today work simultaneously in the fields of physical and cultural anthropology. The generalist has become rare. On the other hand, the fields have not been cut off from one another. Specialists in the two fields still cooperate in specific genetic or demographic problems and other matters.

Prehistoric archaeology and linguistics also have notable links with cultural anthropology. In posing the problem of the evolution of mankind in an inductive way, archaeology contributed to the creation of the first concepts of anthropology, and archaeology is still indispensable in uncovering the past of societies under observation. In many areas, when it is a question of interpreting the use of rudimentary tools or of certain elementary religious phenomena, prehistory and cultural anthropology are mutually helpful. "Primitive" societies that have not yet reached the metal age are still in existence.

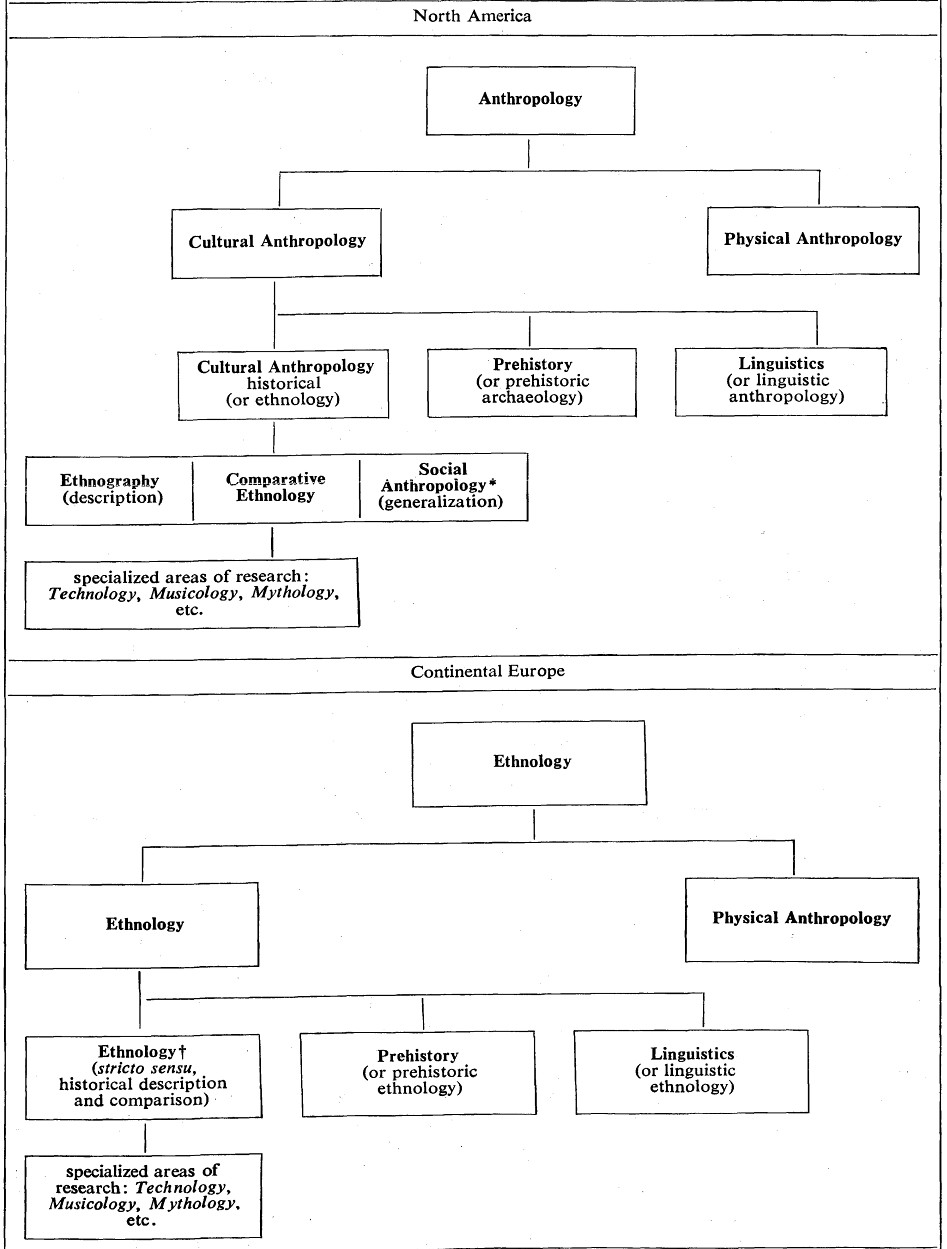
Relations between linguistics and cultural anthropology are numerous. On a purely practical level the cultural anthropologist has to serve a linguistic apprenticeship. He cannot do without a knowledge of the language of the people he is studying, and often he has had to make the first survey of it. One of his essential tasks, moreover, has been to collect the various forms of oral expression, including myths, folk tales, proverbs, and so forth. On the theoretical level, cultural anthropology has often used concepts developed in the field of linguistics: in studying society as a system of communication, in defining the notion of structure, and in analyzing the way in which man organizes and classifies his whole experience of the world.

Cultural anthropology maintains relations with a great number of other sciences. It has been said of sociology, for instance, that it was almost the twin sister of anthropology. The two are presumably differentiated by their field of study (modern societies versus traditional societies). But the contrast is forced. These two social sciences often meet. Thus, the study of colonial societies borrows as much from sociology as from cultural anthropology. And it has already been remarked how cultural anthropology intervenes more and more frequently in urban and industrial fields classically the domain of sociology.

Exchanges with other disciplines

There have also been fruitful exchanges with other disciplines quite distinct from cultural anthropology. In political science the discussion of the concept of the state and of its origin has been nourished by cultural anthropology. Economists, too, have depended on cultural anthropology to see concepts in a more comparative light and even to challenge the very notion of an "economic man" (suspiciously similar to the 19th-century capitalist revered by the classical economists). Cultural anthropology has brought to psychology new bases on which to reflect on concepts

Terminology of Anthropological Disciplines in North America and Continental Europe



North America
Anthropology
Cultural Anthropology
Physical Anthropology
Cultural Anthropology historical (or ethnology)
Prehistory (or prehistoric archaeology)
Linguistics (or linguistic anthropology)
Ethnography (description)
Comparative Ethnology
Social Anthropology* (generalization)
specialized areas of research: Technology, Musicology, Mythology, etc.
Continental Europe
Ethnology
Ethnology
Physical Anthropology
Ethnology† (stricto sensu, historical description and comparison)
Prehistory (or prehistoric ethnology)
Linguistics (or linguistic ethnology)
specialized areas of research: Technology, Musicology, Mythology, etc.

*The term social anthropology is used in Great Britain, either instead of ethnology or instead of cultural anthropology. †There is a tendency at the moment—in France, for example—to use the three terms describing the levels of research which are gradually establishing themselves in North American usage—*i.e.*, ethnography, etc. In eastern and central Europe the term ethnography is often used in the inclusive sense of ethnology.

of personality and the formation of personality. It has permitted psychology to develop a system of cross-cultural psychiatry, or so-called ethnopsychiatry. Conversely, the psychological sciences, particularly psychoanalysis, have offered cultural anthropology new hypotheses for an interpretation of the concept of culture.

The link with history has long been a vital one because cultural anthropology was originally based on an evolutionist point of view and because it has striven to reconstruct the cultural history of societies about which, for lack of written documents, no historical record could be determined. Cultural anthropology has more recently suggested to historians new techniques of research based on the analysis and criticism of oral tradition. And so "ethnohistory" is beginning to emerge. Finally, cultural anthropology has close links with human geography. Both of them place great importance on man either as he uses space or acts to transform the natural environment. It is not without significance that some early anthropologists were originally geographers.

HISTORICAL DEVELOPMENT OF CULTURAL ANTHROPOLOGY

All human societies have been curious about how their customs originated and what the differences between their own culture and that of neighbouring societies might mean. Thus, in a sense they have all constructed their own anthropologies. But the interpretations put forward, even when they were founded partly on accurate observation, most often remained on the level of myth. Embryonic scientific thought began to appear in only a limited number of centres of civilization: in the classical Mediterranean world, in China, in the medieval Arab world, and in the modern Western world. Only in the West, however, did various ideas converge to bring about the birth of scientific anthropology in the 19th century.

A characteristic common to all these centres of civilization was the control that they exercised over vast areas and the opportunity that they enjoyed—through their soldiers, merchants, pilgrims, and missionaries—to gather observations on a wide variety of populations. Such a gathering of data was necessary in order even to begin to understand how men adapted to their environments, how they used their various economic, social, and political institutions, and how mankind evolved from simple to complex societies. Historians and philosophers among the ancient Greeks, Arabs, and Chinese all asked such questions. To take only the example of western Europe, many pertinent questions were posed by the French philosophers Jean Bodin and Michel de Montaigne as early as the 16th century, by the English philosophers Thomas Hobbes and John Locke in the 17th, and by the French philosophers Montesquieu, Rousseau, and Voltaire in the 18th, to mention only those who are often placed among the precursors of modern anthropology.

Historical changes affecting the birth of anthropology

19th-century beginnings. Modern anthropology began to take shape before the middle of the 19th century because of a series of innovations in the Western world. The last great phase of the discovery of the world had begun at the end of the 18th century. At the same time, political and intellectual revolutions had facilitated the questioning of certain religious dogmas, thus opening the way to the discussion of hitherto half-forbidden subjects. The 19th century, therefore, soon saw a revival of interest in and study of the origin of man, the unity or plurality of the human species, and the fixity or mutability of animal species.

Thus, the science of anthropology developed as an outgrowth of contemporary studies of the classification of human races; of the comparative characteristics of human anatomy; of the history of human settlements; of the classification of languages and the comparison of grammars; of the comparison between primitive and ancient societies; and of the historical development of man's economy and industry. Finally, about 1840, a principle for the study of human facts was proposed: the concept of evolution. This was even before Charles Darwin had published his celebrated *Origin of Species* (1859). This concept, arising in strong debates, provided the starting point for anthropology.

Evolutionism. Almost to the end of the 19th century, evolutionism determined the complexion of the new science. A major task of cultural anthropology was thought to be that of classifying different societies and cultures and defining the phases and states through which all human groups pass—the linear interpretation of history. Some groups progress more slowly, some faster, as they advance from the simple to the complex, from the homogeneous to the heterogeneous, from the irrational to the rational. It suffices to quote an American anthropologist, Lewis Henry Morgan:

> As it is undeniable that portions of the human family have existed in a state of savagery, other portions in a state of barbarism, and still other portions in a state of civilization, it seems equally so that these three distinct conditions are connected with each other in a natural as well as necessary sequence of progress (*Ancient Society,* 1877).

Other quotations from a Scotsman, John F. MacLennan, or an Englishman, Edward B. Tylor, would take the same position.

Cultural anthropology, then, set out to analyze the totality of human culture in time and space. But by assuming a linear conception of history, it too often neglected the discontinuities and interferences of concrete history. Morgan, and particularly Tylor, however, sometimes felt the necessity of introducing the concept of the "diffusion," or spread, of cultural characteristics from one people to another—thus suggesting that characteristics could develop independently and converge and that a people could leap over "stages" of evolution by borrowing knowledge from others. Moreover, because it based itself on a theory that all mankind had a similar psychic outlook or that something called "human nature" was universal, anthropology also failed to take into account the fact that the same cultural trait can mean different things depending on the society in which it is found.

Impact of Marxist evolutionism

Marxism and the collectors. At the same time, in the second half of the 19th century another kind of evolutionism developed, that of Karl Marx and Friedrich Engels. Partly independent of anthropological evolutionism (Marx's *Critique of Political Economy* dates from 1859), partly linked to it (Engels' most important work appeared after Morgan's *Ancient Society* and made use of it), the Marxist theory laid stress on the causes of human evolution. A society was defined by its mode of production, on which its political, juridical, and ideological superstructures were allegedly based. These superstructures continued to exist after the mode of production had changed; and in the conflict that followed, this contradiction opened the way to a new type of society. Numerous anthropologists have taken the Marxist analysis into account, even if only to retain its historical view and to reject its economic determinism.

During this same period, especially toward the end of the 19th century, the tales of missionaries, traders, and travelling adventurers included an abundance of miscellaneous information that was collected in such works as Sir James Frazer's *Golden Bough* (1890) and Ernest Crawley's *Mystic Rose* (1902). These rather encyclopaedic collections of customs, religious and magical practices, and other curious data were read with relish by the intellectual community; the theories that accompanied the collections were equally appreciated by evolutionary-minded anthropologists, as the theories were meant to establish an evolutionary sequence of magical, religious, and scientific thought, using the data as evidence.

20th-century trends. By the beginning of the 20th century, many cultural anthropologists had already begun to turn toward what might be called a more pluralistic viewpoint. To account for the variety of societies and cultures and the broadening of the differences that separated them, they suggested taking the total circumstances of each human group into account by considering the whole of its history, the contacts that it had had with other groups, and the favourable or unfavourable circumstances that had weighed on its development. Such a view was distinguished by a marked relativism: each culture represented an original development, conditioned as much by its social as by its geographical environment and by the manner in which it used and enriched the cultural materials that came to it from neighbours or others (through "diffusion") or from its own creativity (through "invention" and "adaptation").

Boas and the culture history school. Cultural anthropology was also diversifying its concepts and its areas of research without losing its unity. Franz Boas, a German-born American, for example, was one of the first to scorn the evolutionist's search for selected facts to grace abstract evolutionary theories; and he inspired a number of students—Ruth Benedict, Alfred L. Kroeber, Margaret Mead, and Edward Sapir—to go out and seek evidence of man's behaviour among people in their natural environs, to go into the field to gather facts and artifacts and record observable cultural processes. He thus is known as the founder of the so-called culture history school, which for much of the 20th century dominated American cultural anthropology.

Emphasis on field work and observation

Beyond this emphasis on field work and first-hand observation, it may also be said that Boas inclined toward what was called functionalism or the functional approach—an approach based on sociological theories of the late 19th and early 20th centuries that tended to liken societies to living organisms or machines, with interdependent parts. In the words of Melville J. Herskovits, one of Boas' students,

> the *functional* view, attempts to study the interrelation between the various elements, small and large, in a culture. Its object is essentially to achieve some expression of the unities in culture by indicating how trait and complex and pattern, however separable they may be, intermesh, as the gears of some machine, to constitute a smoothly running, effectively functioning whole (from *Man and His Works,* 1948).

Boas insisted upon this method of considering any single culture as a whole. Finally, by emphasizing the importance of collecting life histories, he drew attention to the problems posed by connections between culture and personality.

Mauss and the "sociological" school. In a similar way, Marcel Mauss, in France, influenced the characteristic tendencies of a whole generation of European sociologists and cultural anthropologists, including Alfred Métraux and Claude Lévi-Strauss, and founded the Institute of Ethnology of the University of Paris; he also influenced such men as the noted British cultural (or social) anthropologists Bronislaw Malinowski and Arnold R. Radcliffe-Brown. In general it may be said that Mauss, like Boas, was insistent upon studying social phenomena as a system—but in a slightly different fashion. Like many others of his time he conceived of systems as self-regulating or equilibrium-seeking, composed of elements that operate to maintain the integration or adaptation of the system. Mauss gave impetus, in fact, to what was called structuralism or the structural approach, which focussed more on society as an indivisible social organism than on society as an interrelation of individuals (the functionalist's emphasis). Like Boas, Mauss also tried to twin culture and personality—that is, cultural anthropology and psychology.

The "grand diffusionists." The large and influential American school of "culture history" anthropologists led by Boas should not be confused with a distinct and smaller group of Austro-German diffusionists, led by Fritz Graebner and Wilhelm Schmidt, who constituted what has been called the "culture-historical" school in Europe. These latter, too, had rejected classical 19th-century evolutionism, but they were nevertheless inclined toward painting grand theories—principally the theory that out of a few ancient cultural centres or civilizations, born quite separately, there had developed all the array of cultures existing today. Diffusion, or the spreading of culture traits, in their view, was the prime force of human development, and all cultural development could be traced to a few inventive centres. Because they termed these original centres Kulturkreise, (or "cultural clusters"), they were also known as the Kulturkreise school of cultural anthropology. This kind of pseudo-history was carried to even greater lengths by a British group of diffusionists, led by Grafton Elliot Smith and William J. Perry, who even named a single fountainhead of all cultural development—Egypt.

The Kulturkreise school

Functionalism and structuralism. Some schools of research that began to develop between the two world wars more or less vigorously rejected the historical approaches, sometimes denying any interest in them whatever. According to the cultural functionalists, including the followers of Malinowski, the only way to explain facts was to define the function that they performed currently in a given culture. The aim of all cultural anthropological research, they held, should be to perceive the totality of a culture and the organic connection of all its parts. Consequently, comparison did not make sense: each culture was a unique reality. History, moreover, made no more sense; a culture was to be interpreted at one point in time, as if the age and the origin of the elements composing it were without importance. The only thing that counted was the function the elements performed *now.* Earlier cultural anthropologists had talked of "survivals," customs or other cultural traits that survived from out of the past though no longer with any real function or meaning. But Malinowski would say, "There are no survivals"; everything current, according to the functionalists, has *some* function.

Whereas the name of Malinowski is supremely associated with the school of functionalism, the name of Radcliffe-Brown is known as one of the most important proponents of present-day structuralism. Relying on the concepts of formal mathematics and linguistics, Radcliffe-Brown and other structuralists tried to determine whether in cultural anthropology it was possible to reveal that which "suggests the character of a system" beyond empirical reality and which "alone is the true object of science" (Lévi-Strauss). A structure is not a sum of social relations, which are only the primary material from which the observer extracts "structural models." A structure is a system of which the members of the society being studied are not aware or only partly so. The model that the cultural anthropologist constructs from the system is valid when the model's operation can account for all the observed facts. This exacting approach has proved particularly useful in studying kinship and marriage relations as well as myths. The difficulties of using this approach in other fields, as well as the fact that historical changes are difficult to include in this sort of static analysis, strengthen the objections that many workers in the field have raised against it.

Structure unperceived by society's members

Cultural psychology. One development of the interwar period led certain cultural anthropologists to speak of a new subdiscipline, cultural psychology, or ethnopsychology, which is based on the idea that culture conditions the very psychological makeup of individuals (as opposed to the older notion of a universal psyche or human nature). In the 1930s, for instance, in her studies of the American Southwest, Ruth Benedict found that the ways in which the Pueblo Indians thought and reasoned were strikingly different from the ways in which their immediate neighbours thought and reasoned, even though their geographical environment was virtually identical. Her conclusion was that each culture over the ages had evolved and given to its members a unique "psychological set" or orientation toward reality and that this set actually determined how the members saw and processed information from the environment. Culture, in effect, affects the ways in which the mind works.

Studies in culture and personality have developed in many directions. Research into forms of child rearing, for instance, have called in question the universality of Freudian propositions concerning parent–child relationships. There have been many studies of value systems, which give a culture what has been called its "configuration," or of the personality types prized or rejected by each culture, or of the "national characteristics" of certain modern societies. The results of these studies have, however, been uneven in quality.

Neo-Marxism and neo-evolutionism. Finally, certain theoretical tendencies of the 19th century came back into favour. For political reasons Soviet cultural anthropologists have conducted their research in the tradition both of Marxist analysis and of a fairly rigid evolutionism. Even their choice of subjects is sometimes linked to official ideology—as, for example, a program of religious anthropology aimed expressly at the "elimination of religious prejudice in the Russian population." Elsewhere, in France, for example, a brand of neo-Marxism has influenced a new generation of cultural anthropologists to concentrate on analyses of primitive economies. Classical evolutionism, meanwhile, has been revived in the United States by some cultural anthropologists who speak of "multilinear evolutionism" or many paths to modernization.

STATUS OF CONTEMPORARY CULTURAL ANTHROPOLOGY

The problem of making cultural anthropology "scientific"

It is true that cultural anthropology has not reached a state of complete coherence. This is clear from the persistence of divergent national traditions and from the way in which research can be impregnated with explicit or implicit ideologies. It is also true that different schools of thought coexist in the same country and that cultural anthropology is not therefore based on a unified body of concepts, whereas a science is defined above all as a homogeneous language for interpreting a specific level of reality. A "science" of culture would seem possible only if anthropologists could free themselves of ethnocentrism and produce concepts and other elements that were universal, objective, and theoretically significant. The functionalists think they have fulfilled these conditions. The structuralists challenge this and, in their turn, try to fulfill the conditions. Thus cultural anthropology—as opposed, for example, to linguistics—has developed only very partially a terminology independent of a national or private language. These limitations are still encountered by most of the social sciences. But cultural anthropology's primary aim—to permit cross-cultural comparability—makes the problem even more serious.

The new research and fieldwork. Cultural anthropology is undergoing a crucial test of another kind. Its traditional objects of study—"primitive" or "traditional" cultures—seem to be disappearing. Either they are dying out because they find it impossible to adapt themselves to a modern world or they are transforming under the direct or indirect influence of modern industrial societies. Moreover, those that do remain at a folk level often take exception to being placed among societies that are the subject of anthropological study, seeing this as a manifestation of condescension and a vestige of domination.

Much cultural anthropological research and study has entered the library or laboratory. One of the criticisms of Boas and others engaged in pure fieldwork was that they were collectors rather than systematizers. There is thus a considerable wealth of ethnographic data to be analyzed, collated, classified, and interpreted in order to be made useful. Files of information are being arranged in what are called Human Relations Area Files. More and more typologies are being constructed, typologies based on political systems or technology, or systems of kinship. In addition, new readings of the material are being attempted in the hope that mathematical formulations or models might be obtained. Also emerging is the study of insufficiently known societies by techniques of simulation.

Many cultural anthropologists refuse to turn to the laboratory and continue to do fieldwork, either among Western populations or among modernizing, formerly colonial populations. They are joined in this task by researchers native to those populations. For some anthropologists these field studies provide an opportunity for a true anthropological experiment, determining how people respond to modernizing influences and how elements of the old culture evolve into those of the new. Such anthropologists tend to reject the concept that social systems seek integration and "equilibrium." Instead they propose a more "dynamic" interpretation of traditional societies and emphasize the role played therein by tensions and conflicts.

Economic development and anthropology

In any case, at a time when the problems of development are among the primary cares of the world, a growing number of anthropologists are devoting themselves to research the results of which can be used in political policy and decision making—whether they are employed directly by interested governments, or lent by foreign governments or international organizations, or recruited by foundations for study and development.

Non-Western cultural anthropologists. A significant development in the latter half of the 20th century has been the emergence of more and more non-Western cultural anthropologists. Originally, cultural anthropology was a Western interest and endeavour, and it has continued to be dominated by Westerners. Even in non-Western countries where anthropology institutes and university departments have begun to multiply somewhat—as in Japan, India, and some Latin-American nations—cultural anthropologists have remained rather constricted. Japan is a good example. Cultural anthropology as an independent science there is still young, having arisen largely only since World War II; and most Japanese cultural anthropologists in the schools have had to be hybrid teachers, attaching themselves to sociology or social science departments and teaching sociology or some other related discipline in addition to cultural anthropology. Not only have cultural anthropology courses been few but also funds for field studies have been limited, so that there have been few lengthy and intensive studies; what research there has been has focussed largely on Japanese or other East or Southeast Asian communities. Furthermore, Japanese cultural anthropologists have shared a problem faced by many non-Western researchers, in that the native language in which they write has not been as readily accessible to foreigners as have been western European languages. "International communication," the Japanese cultural anthropologist Takao Sofue has noted, "has [thus] been seriously restricted with the result that Japanese scientists have been isolated from effective criticism from abroad" ("Social Anthropology in Japan," *American Behavioral Scientist,* 12:15–17, Jan.–Feb. 1969). It has also meant, of course, that they have not been sufficiently widely read abroad to make their influence felt. This problem, though, is not so serious in non-Western countries like India, where a European language constitutes a major language of scholarly communication.

Applied studies. From the cultural anthropologist's point of view, applied studies—that is, research meant to give practical aid and guidance to governments and other organizations—have in many ways been an undoubted gain. Concerned as they so often were with the effects of social change, applied studies offered the nearest approach to the controlled experiment in the social sciences. The specialized inquiries greatly deepened the knowledge of particular aspects of primitive society and culture, especially of economic and political organization, land tenure, and law. The scientific value of such research apart, work in the applied field also offered to many anthropologists the purely human satisfaction of aiding backward peoples in their struggle to meet and master the forces of Western civilization.

The concrete gains derived by colonial governments were more difficult to assess, partly because the officials were not bound to act upon the cultural anthropological findings and partly because the value of the findings was not always wholeheartedly accepted. Sometimes, it is true, the cultural anthropologist found himself embarrassed by the excessive confidence of his employers that he had the key to all problems. More often, the employers were inclined to question whether cultural anthropology was in fact as helpful and the information it provided as indispensable as enthusiasts would make it out to be. Some impatience was felt with the "academic" cultural anthropologist who would insist on comprehensive studies when only some specific information was asked for, or who seemed to deal in a complicated fashion, using complicated language, with issues that to the practical man appeared straightforward. To all this cultural anthropologists could reply that, though the knowledge they sought was not indispensable to government, it facilitated informed and smooth government.

But cultural anthropologists also had to face another, more disturbing criticism—that they overemphasized the importance of tradition and were hostile to modern development. Nor was this view limited to colonial administrators; educated Africans and Indonesians openly expressed their distrust of a science the primary interest of which was in "primitive" peoples and which might play into the hands of reactionaries and upholders of "colonialism."

If these objections did not promise too well for the future of applied cultural anthropology, cultural anthropologists themselves had grown more cautious. They came to fear that the applied work might entice too many of the younger cultural anthropologists away from general and theoretical research, so that the very progress of the discipline might be endangered. Conversely, the man fully committed to applied work, like the permanent government cultural anthropologist, would be in danger of losing touch with universities and academic centres, and hence with the advances achieved in his discipline. He would turn into a mere technician, perhaps still useful to his employers but no longer truly representing anthropological knowledge.

The theoretical researcher versus the technician

There were graver problems of an ethical nature. A change of roles is forced upon the cultural anthropologist when he is consulted on the best way to implement government policies. To be sure, he might see no cause for disagreeing with the policy, and the best way of imposing it might well be understood to be the one best serving the interests of the native peoples. Even so, the cultural anthropologist, in abandoning the point of view of the scientist, must pronounce upon the merits and demerits of particular courses of action and thus introduce value judgments. Nor will the issues always be clear-cut and uncontroversial; in that case the cultural anthropologist might have to take sides and argue from his own political and moral convictions. And if his recommendations had little chance against administrative considerations or the dictates of "higher policy," personal frustrations would be added to the dubiousness of his position.

On the other hand, if the cultural anthropologist presented his facts without adding recommendations or warnings, he would be furnishing information that might be put to uses with which he could not in good conscience agree. Or again, he might be tempted to restrict his advice to the most efficient means for achieving certain ends, dismissing the ends themselves, the policy to be implemented as not of his concern—which would hardly diminish his ethical commitment.

All these issues were widely and on occasion heatedly debated among cultural anthropologists. In an attempt to clear the air the Society for Applied Anthropology published in 1951 a carefully worded code of ethics. It appealed to the social conscience of the individual research worker and to his responsibility at all times to uphold the moral tenets of civilization—respect for the individual and for human rights and the promotion of human and social well-being. Not all cultural anthropologists were prepared to endorse this assumption of a moral mission on the part of the "disinterested" scientist. The dilemma, then, though vital for the future of applied cultural anthropology, remained unresolved. (Pa.M./Ed.)

Sociology

Sociology is a branch of the science of human behaviour that seeks to discover the causes and effects that arise in social relations among persons and in the intercommunication and interaction among persons and groups. It includes the study of the customs, structures, and institutions that emerge from interaction, of the forces that hold together and weaken them, and of the effects that participation in groups and organizations have on the behaviour and character of persons. Sociology is also concerned with the basic nature of human society, locally and universally, and with the various processes that preserve continuity and produce change.

It is social life that is distinctive in the regulation of behaviour in human beings; the human animal does not have such instincts as serve to guide the behaviour of lower animals, and he is therefore more dependent on social organization than is any other species. Institutionalized social forms therefore are assumed to play the major part in influencing human actions, and it is the task of sociology to discover how these forms operate on the person, as well as how they are established, develop, elaborate, interact with one another, and decay and disappear. Among the most important of such structures is the family, the subject of an important field of sociology. The peer group, the community, the economic and political orders, various voluntary associations, and special organizations such as the church and the military are of particular importance in this inquiry.

Relation of sociology to other disciplines

Though sociology can be considered as a part of the Western tradition of rational inquiry inaugurated by the ancient Greeks, it is specifically the offspring of 18th- and 19th-century philosophy and has been viewed as a reaction against the frequently nonscientific approaches of classical philosophy and folklore to social phenomena. It was for a time presented as a part of moral philosophy, which covered the subject matter that eventually also became the concern of the various social sciences that are now separate from moral philosophy. Some aspects of other fields remain of interest to the sociologist. Although psychology has traditionally centred its interest on the individual and his internal mental mechanisms, and although sociology has given its major attention to collective aspects of human behaviour, the two disciplines share the subfield of social psychology. The relation of sociology to social anthropology is even closer, and until about the first quarter of the 20th century the two subjects were usually combined in one department, differentiated mainly by the emphasis of the anthropologists on the sociology of preliterate peoples. Recently even this distinction has been fading, as social anthropologists have increasingly added studies of various aspects of modern society to their field of interest. Political science and economics had much of their early development in the practical interests of nations and for a time evolved separately from basic sociology; but recently in both fields an awareness of the potential utility of some infusion of sociological concepts and methods has brought relations closer. A somewhat similar situation has also been developing in respect to law, education, and religion and to a lesser extent in such contrasting fields as engineering and architecture.

Nineteenth-century sociology, influenced by the successes of biology and evolutionary theory, took an interest in resemblances between men and lower animals—in their having, for example, similar instincts—and also in the parallels between biological and social evolution. These interests have declined, but sociology continues to share with the other sciences some interest in ecology, behavioral genetics, and questions of fertility and mortality as they relate to population studies. There is also a conviction among sociologists that contact between physiology and sociology is necessary to avoid errors of ignorance in both fields.

HISTORICAL DEVELOPMENT OF SOCIOLOGY

Early major schools of thought. The founders of sociology spent decades almost exclusively in the process of finding a direction for their new discipline. In the course of this groping effort they tried several highly divergent pathways, some suggested by methods and contents of other sciences, others invented outright by the imagination of the scholar.

Social Darwinism and evolutionism. Darwinian evolutionary theory doubtlessly suggested a way in which a science of human behaviour could become academically respectable, and a line of creative thinkers, including Herbert Spencer, Benjamin Kidd, Lewis H. Morgan, E.B. Tylor, L.T. Hobhouse, and others, developed analogies between human society and the biological organism and introduced into sociological theory such biological concepts as variation, natural selection, and inheritance—evolutionary factors resulting in the progress of societies through stages of savagery and barbarism to civilization, by virtue of the survival of the fittest. Some writers also perceived in the growth stages of each individual a recapitulation of these stages of society. Strange customs were thus accounted for on the assumption that they were throwbacks to an earlier useful practice; an example offered was the make-believe struggle sometimes enacted at marriage ceremonies between the bridegroom and the relatives of the bride, reflecting an earlier bride-capture custom.

The notion of stages of evolution

Social Darwinism waned in the 20th century, but in its popular period it was used to justify unrestricted competition and a laissez-faire doctrine in order that the "fittest" would survive and that civilization would continue to advance.

Determinism: economic, environmental, biological. Except in the philosophy of Karl Marx (whose writings ranged over all the social science fields rather than specifically in sociology), the doctrine of economic determinism never gained a strong foothold in sociology. This was not a consequence of scholarly ignorance; sociologists of all periods have read Marx and have usually read such writers as the historian Charles A. Beard, who emphasized economic self-interest, and Werner Sombart, the German sociologist who had been a convinced Marxist in his early career. But there have been only some adapted reflections of these economic views in the writings of such sociologists as Franklin H. Giddings or Frank H. Hankins who viewed some political and religious doctrines as rationalizations of economic and social interests.

The human geographers—Ellsworth Huntington, Ellen Semple, Friedrich Ratzel, Paul Vidal de La Blache, Jean Brunhes, and others—were also read critically by sociologists but did not make a lasting major contribution to the mainstream of sociological thought, even though there are some who believe that the social morphology of Émile Durkheim, Maurice Halbwachs, and others—that is, their theories about the roles of individuals interacting in a social system—grew in part from this interest.

Aside from the interest in evolution, organismic analogies, and the instinct concept, sociologists have not found biological determination of value to them and have spent more energy in refuting it than in making use of it.

Early functionalism. Following the achievement of a consensus that there should be a place for a science of sociology, there emerged an international effort to define the distinctive character of the subject and especially to clarify its differences from psychology and biology, fields that had also begun to generalize about human behaviour. A Frenchman, Émile Durkheim (1858–1917), was prominent among scholars who considered this question; he argued that there can arise from various kinds of interaction among individuals certain new properties (*sui generis*) not found in separate individuals. These "social facts" as he called them—collective sentiments, customs, institutions, nations—call for study and explanation on a distinctly sociological level rather than on the level of individual psychology. Furthermore, the interrelations of the parts of a society were perceived as cohering into a unity, an integrated system with a life character of its own, exterior to the individual, and exercising constraint over his behaviour. This direction of causation, from group to individual (rather than the reverse as conceived by most biologists of the time) gave encouragement to the scholar of the new science. Some writers have designated such a view "functionalism," although the term has in recent years acquired some broader variations of meaning.

Durkeim's "social facts"

Durkheim also pointed out that groups could be held together on two contrasting bases: the sentimental attraction of similarities (mechanical solidarity), such as occurs in friendship groups and among relatives and neighbours, and the organization of complementary differences (organic solidarity), such as occurs in industrial, military, governmental, and other organizations that exist because they have tasks to perform. Other theorists of Durkheim's period, notably Henry Maine and Ferdinand Tönnies, made similar distinctions in different terms—*status* and *contract* (Maine) and *Gemeinschaft* and *Gesellschaft* (Tönnies)—and conceived of the major trend of civilization as an expansion of the latter and a relative decline of the former.

Some later anthropologists, especially Bronisław Malinowski and A.R. Radcliffe-Brown, developed a doctrine also called functionalism, based on the recognition of the interrelatedness of the parts of a society, in bonds so thoroughly interpenetrating that a change in any single element would tend to produce a general disturbance in the whole. This concept gained a following for a time among many social anthropologists, leading some to advocate a policy of complete noninterference with even the most objectionable practices in a preliterate society (such as headhunting) for fear that control might produce far-reaching disorganization.

William G. Sumner, in his *Folkways,* defined an institution as a "concept and a structure," meaning a purpose or function that is carried out by some systematic organization of persons. Much of the sociology of Max Weber consists of the analysis of societies in such terms. Georg Simmel, sometimes called the founder of the "formal school" of sociology, viewed society as a process ("something functional") that is real and not merely an abstraction, and he built on this idea a statement of sociology consisting of a systematic analysis of social forms.

Modern major directions of interest. The early schools of thought—each presenting a systematic formulation of sociology that implied possession of exclusive truth and that involved a conviction of the need to destroy rival systems—in time gave way to distinguishable directions of interest and emphasis that did not have to be considered inharmonious. These new directions have no dominant leaders and no clearly defined borderlines.

Functionalism and structuralism. Following the main contributions in the earlier theoretical formulations of Charles H. Cooley, such later authors as Pitirim A. Sorokin, Talcott Parsons, Robert Merton, Everett C. Hughes, and others have elaborated on the nature of organizations and their relation to the behaviour of persons and have attempted to build workable conceptualizations of very large social systems, nations, and societies. Sorokin designated his viewpoint as "integralist" and wrote at length about the civilization-cultures that in their balance of values and conditions could be viewed as entities that had distinguishable life cycles, with "ideational," "idealistic," and "sensate" stages marking their growth and decline, thus following a philosophy-of-history tradition shared by Edward Gibbon, Oswald Spengler, and Arnold Toynbee.

Cultural life cycles

Talcott Parsons has given attention to social systems in a more analytical way, inquiring into the conditions that each system must meet in order to survive (the "functional prerequisites"), the character of the standardized and stable interpersonal arrangements (structures) needed to make each system work, the relations to environmental conditions, problems of boundaries, the recruitment and control of members, and the like. Along with Robert Merton and others, he also worked on the classifications of such structures and on distinctions of function.

The subject matter and methods involved in such structural-functional analysis have indeed become so broad that some authors (such as Marion Levy) have held that it becomes synonymous with scientific analysis in general, or at least with scientific study of the nature of organization.

On a smaller scale, Kurt Lewin and his co-workers pursued somewhat parallel questions, investigating the nature of small groups, families, professional and military units, looking for arrangements and relationships of the parts of each person's "psychological life space" and of the interrelations of these to a "social space" or society's total range of action. The choice of such relatively small units for research made fruitful experimentation possible, and from Lewin's leadership grew the influential research movement that became known as group dynamics. Some writers have also applied the descriptive term *microfunctionalist* to this tradition.

Symbolic interactionism. Sociologists did not for long find the 19th-century instinctivist psychology congenial, and most of them also failed to appreciate the doctrines of classical or Watsonian behaviourism, which sought to be totally objective and experimental. One influential movement in social psychology, however, did take early root and eventually became the largest and most influential field in modern American sociology. In recent years it has become known as "symbolic interactionism," but it was under development for decades before it acquired a name.

Out of early ideas expressed by J. Mark Baldwin and William James, a group of three scholars, John Dewey, George H. Mead, and Charles H. Cooley, built the foundations of a psychology that was to become most useful to sociology. In brief, their contribution was to advance the theory that mind and self are not part of the innate

The concept of self

equipment of the human organism but arise in experience and are constructed in a social process—that is, in a process of interaction among persons in intimate, personal communication with one another. The self, or self-concept, as developed by Mead and others, is thus essentially an internalization of aspects of an interpersonal or social process. It exists in imagery and symbolization and is internalized and organized for each person out of his perception of how other persons conceive him. This self-concept, however inexact, fluctuating, and uncertain, nevertheless functions as a guide in social behaviour—that is, persons tend to act in order to preserve the existing or desired image of their self.

William I. Thomas, a sociologist and colleague of the philosopher Mead at the University of Chicago in the early years of the 20th century, regularly taught a course in social psychology based on Mead's conceptions. Thomas was succeeded in 1919 by Ellsworth Faris, himself a psychologist but later a member of the department of sociology, and through his work the tradition was further developed and brought into closer relation to the sociological tradition of Robert E. Park and Ernest W. Burgess, also at Chicago. In this tradition an interest in an appropriate methodology accompanied the growth of substantive knowledge; Thomas particularly emphasized the value of extensive use of personal documents, life histories, and autobiographies. In recent years interest in research on the self and self-conscious behaviour has spread widely, and is now participated in by psychologists, philosophers, and essayists, as well as by a movement within sociology called "ethnomethodology," which investigates areas of symbolic interaction by informal observation, reflection, and skilled interpretation, methods sometimes called *Verstehen* (understanding).

Modern determinism. Economic determinism reflects the interest that a few early sociologists took in views of Karl Marx, such as the idea that differentiation into social classes and conflict between these classes derive from economic factors and the belief that the political system is in large part a product of such social stratification. A residue of this kind of determinism is found among the self-proclaimed "Marxian sociologists." Perhaps the most widely read of these was C. Wright Mills, whose concept of a "power elite" has been extensively and critically examined, with varying resulting judgments on its utility. As Mills saw it, this elite constitutes an integrated ruling group of a capitalistic economic and military system, sometimes called the military-industrial complex, exercising arbitrary power in its own interests. This particular determinism is not supported by most existing objective research, which generally finds a far more pluralistic distribution of political power.

A contrasting view of class conflicts was advocated by Karl Mannheim, who saw the cleavages as ideologically produced, as divergences in modes of thought rather than as rational perception of economic interests. Since Mannheim hoped that such conflicts could be resolved, his doctrine should not be considered fully deterministic, but it did stimulate an effort to interpret the relations between ideas and actions that came to be known as the "sociology of knowledge."

Mathematical modelism. A variety of efforts has been made to describe and investigate behaviour mathematically, through measurement and counting and the use of mathematical models. This approach in part characterized the early "sociometry" of J.L. Moreno (although its meaning has greatly drifted and broadened in recent years), the "field theory" of Kurt Lewin, and the investigations by George K. Zipf, John Q. Stewart, and others into the relations of rank and size of political units, the frequency of word use in language, and other simple arithmetic relations. Some of the concepts of game theory, first introduced into economics by its inventors, John von Neumann and Oskar Morgenstern, have also penetrated into sociology. Also the rapidly expanding use of computers has in recent times encouraged the development of various kinds of simulation of behaviour. Some investigations of complex interaction patterns have been carried out by devising games with rules to fit the problem and persons to execute the roles. When specified rules become highly detailed and complex, the outcome may be sought through the use of a computer; thus the game is converted into a simulation. Sociologists have participated, along with other social scientists, in the creation of such simulations of various political and military processes. Extension of these techniques into a variety of interaction processes is to be expected.

METHODOLOGICAL CONSIDERATIONS IN CONTEMPORARY SOCIOLOGY

Much of 19th-century sociology was devoid of systematic method, but late in the period the proliferation of schools of thought, based on speculative sociologies, made evident the need for ways of obtaining verifiable knowledge. Early attempts were crude and unfruitful; such broad surveyors as Charles Booth, who produced a monumental series on London, relied mainly on the gathering of masses of facts. Frédéric Le Play in France made extensive studies of family budgets. Herbert Spencer and others assembled vast stores of observations made by other persons, using these to illustrate and support generalizations already formulated.

Early exploitation of statistical materials, such as officially recorded rates of births, deaths, crimes, and suicides, provided only a moderate advance in knowledge, because this approach was too capable of supporting preconceived ideas. Among the most successful of this type of study was research on suicide by Émile Durkheim, whose successors in France and elsewhere developed the methodology a considerable way toward scientific adequacy.

After the turn of the century, interest in, and the determination to achieve, a sociological methodology grew steadily. The *Methodological Note,* constituting the greater part of a volume in W.I. Thomas and Florian Znaniecki's *Polish Peasant in Europe and America* (5 vol., 1918–20), has been recognized as an important advance, not so much in methodology as in committing sociologists to the task of achieving it.

Inductive research

Significant advances toward scientific effectiveness occurred at the University of Chicago in the 1920s. Under the stimulation of Robert E. Park, Burgess, and their colleagues a series of studies of the metropolis was conducted. The spirit was inductive, and hypotheses were discovered in rather than imposed on gathered information. Large numbers of students took part in the effort and contributed to both methods and findings. A conspicuous part of the effort consisted of mapping locations of various phenomena: land uses, residences of population categories (racial, ethnic, and occupational), residences of persons who commit various types of crimes or suicide, families becoming divorced or broken through desertion, and so forth. But along with such information on spatial distributions, data were sought by other means, including participant observation in groups and communities, gathering of life histories and case studies, assembly of relevant historical information, study of the life cycles of social movements and sects, and the like. Attention was explicitly given to the improvement of methodology in all of these efforts, to an extent approximately equal to the attention given to substantive findings. Here for the first time was developed a large-scale cooperative effort in which theory, methodology, and findings evolved together in an inductive process. The influence of this development at Chicago spread rapidly about the United States and in time influenced sociology almost everywhere it was studied in the world.

Statistics. Statistical methods were introduced into sociology from other sciences, and virtually from the start, sociologists have found statistical measures of relationship of great value. Karl Pearson's "coefficient of correlation," for example, has been a popular as well as important statistical concept for the measurement of cause-and-effect relationships among continuous variables. This method reveals the *degree* of causal connection between two variables, though not necessarily the *nature* of the connection. In sociology there are types of data that are relevant to causal inquiry but do not have the characteristics that qualify for the Pearsonian coefficient. Thus, much development work has been done to provide other measures of association involving, for example, rankings of groups or individuals or qualitative comparisons (such as whether males and females differ systematically in specified qualities).

Factor analysis, also based on an elaboration of Pearsonian correlation, performs another valuable service to sociology. If there are a large number of variables causally intertwined in a complex way, it is possible that these variables can be reduced to a small number of factors. Fifty different tests of mental ability, for instance, may be in fact 50 different mixtures of only seven or eight dimensions of mental ability. Factor analysis involves reducing such variables to a more limited number of common factors and determining the relative importance of each factor in the original variables. The process has its imperfections and the computations are laborious, but the availability of computers has overcome the latter disadvantage, and in recent years the technique has increased in use.

These statistical methods and many others are applicable to all branches of sociology and are increasingly fruitful in transforming sociology into science (see also STATISTICS). In general, the growth of statistical methods has been so rapid that the invention of new techniques has outstripped the ability of scholars to find data worthy of the devices. Thus the rate of progress in the near future may depend to a large extent on improvement in satisfactory data gathering and measurement. Methodologies of data gathering are in fact of major interest in sociology. Techniques of observation—of persons, groups, organizations, communities—have been extensively developed. Important for the same purpose are the various means of quantifying these observations, including scales of various kinds, sociometric techniques that make interrelations subject to statistical analysis, content analysis of written materials, and classification of cross-cultural information.

Experiments. Experimental methods, once believed to be inapplicable to sociological research, were extensively applied by psychologists, first on individuals and later on groups. By the 1930s some psychologists—notably Kurt Lewin and his colleagues and also Muzafer Sherif—found means of conducting experiments on social interaction. Sociologists soon followed their example and in time a number of laboratories for such research were established; Robert F. Bales, at Harvard, has made systematic observations on interaction in small, artificial groups and has produced clear and useful results, confirmed in other laboratories. Experiments are also conducted in classrooms, in summer camps, in formal organizations, and elsewhere. In general the success of experimentation has been greatest in simple situations in which the number of variables is limited. Complex experiments, however, are possible in some circumstances, and the design of complex formal experiments is becoming a developed art in a variety of fields, including sociology.

Harvard interaction studies

Data collection. Within the main categories of research methods there are many special problems for which techniques have been devised. Data collection, for example, is effected in many different ways, from unstructured observation, essentially methodless, to sophisticated measurement through special instruments. Some of the basic problems of data collection concern such matters as the most efficient use of terminology, the definitions of units to be measured, and the classifications to be used. In general it is necessary to consider the nature of a specific problem in order to choose the most appropriate unit. For example, in a study of the relation of the size of a city to the cost of operating its local government, the proper unit might well be the population residing within its political boundaries. If the research question, however, is the relation of city size to any of a number of forms of social disorganization, it may be more fruitful to recognize that sociologically the significant unit would include much or all of the settled areas outside the city limits.

In the fields of social differentiation and occupational mobility the matter of definition of specific occupations is critical. If persons are asked in a questionnaire to state their occupation, the usual response is to give only one occupation, and this one is sometimes vaguely defined and made obscure by the tendency to give a euphemistic answer. Persons change occupations; some have more than one; some might claim an occupation that they merely aspire to. The art of obtaining useful answers to such important questions involves carefully designed questions adapted to the specific purposes of the study. General classifications, intended for a variety of studies, have limited utility.

In the process of gathering research data for sociology there are occasional obstacles to direct observation. In such cases indirect indicators may provide crude but useful substitutes. For example, alcoholic consumption in a small village in which the beverage is supposed to be prohibited may be estimated by a count of empty bottles in trash receptacles, or perhaps in the town dump. Library book circulation has been used to estimate the use of television in a community in which withdrawals of books of fiction declined, while nonfiction withdrawals remained as before.

Questionnaires

Questionnaires are convenient for obtaining information from large numbers of respondents but involve many methodological problems. Wording of questions must of course be intelligible to uneducated and uninterested persons, must have standard meanings to persons of varying backgrounds, must avoid topics that arouse resistance and refusal to complete the questionnaire, and must avoid being too complex or difficult so that returns are insufficient or constitute a biased sample. Since it is known that slight alterations in the wording of questionnaire items may produce considerable variations in the pattern of responses, the precise wording becomes a matter of some art as well as science. A similar effect occurs in the order of items, since some may suggest or influence responses on later ones.

Interviewing

Similar issues are involved in data gathering through interviewing. It is necessary to control such variables as the appearance, manner, and approach of the interviewer, the specific manner in which questions are asked, ways of avoiding interviewer influence on the responses, and the tendency of some respondents to refuse to answer questions or to discontinue the interview. To meet the problems of resistance on sensitive subjects and inarticulateness about some feelings, various indirect or projective devices may be employed so that a respondent in answering one question provides information he may not realize he is giving about other questions.

Questionnaires and interviews may be so arranged that the patterns of responses form a scale, converting qualitative variations into measures available for statistical treatment. An early scaling method, devised in the late 1920s by a psychologist, L.L. Thurstone, is still widely used in sociology. It is formed in the following way: a list of questionnaire items is presented to a number of judges who independently relist the items in the order in which they consider them important or of interest. From their decisions are selected items on which there is satisfactory agreement of scale value.

Scaling may also be provided by statements to which a respondent is asked whether he "strongly approves," "approves," is "undecided," "disapproves," or "strongly disapproves." Or the quantitative differences may be introduced through a logical sequence of preference answers—for example, whether the respondent would admit a particular category of person (a) to close kinship by marriage, (b) to his club as a personal chum, (c) to employment in his occupation, (d) to citizenship in his country. Here it is assumed that the later answers imply more desired social distance.

Sociometry

A method or class of methods called sociometry has been under development since its introduction in the middle 1930s by J.L. Moreno. The essence of the method is the collection and tabulation of information about various types of interaction among members of groups of small or moderate size. The interaction may be either actual behaviour or merely anticipated or desired behaviour, and it may consist of preferences for various kinds of association with other persons, such as having them as friends, sitting with them, working with them, and the like. The information may be collected by observation of real behaviour or by interviews or questionnaires with specific items regarding personal choices. After the information is gathered, it is sometimes put in the form of a sociogram, consisting of names of persons enclosed in circles or squares distributed over an area and connected with lines and arrows that indicate both detail of choices and general patterns of relationships. A person receiving many choices is readily seen as the target end of many lines and is sometimes referred to as a "star." A person completely unchosen has no lines pointing toward his name and is called an isolate. Further investigation of persons typed in this fashion may be made by statistical methods, case studies, or otherwise. Overall, it can be said that various improvements and elaborations of the basic sociometric approach have been made, and the method is now less distinctively separate from other social psychology research than it was originally.

Ecological patterning. Ecological methods in sociology were first developed in connection with research on the characteristics of the metropolis, especially in regard to features of a nonsocial character, such as the patterns resulting from the distribution and movements of populations and institutions in the general process of struggling for advantage. A conspicuous part of most early urban studies consisted of mapping such distributions. The patterns of land values, of locations of various types of businesses and industries, of ethnic categories of the population, and of types of behaviour (delinquency and crime, vice, family disorganization, mental disorders, etc.) were all shown to be interrelated in a general urban ecology. This fact was then shown to be related to many aspects of behaviour of city people, and valuable contributions were made to such general sociological topics as social differentiation, migration and vertical mobility, and social disorganization.

In recent years sociological ecology has broadened in meaning and in the elaboration of methods. One modern approach, known as ecosystem theory, consists of tracing general patterns of flow of materials, energy, and information into a system and their transformation during the flow through the system, among other things.

Problems of bias. Since most sociological knowledge is based on the study of samples from some larger universe of items, the possibilities of major errors from sampling bias constitute a methodological issue. Where biases cannot be controlled, the direction and extent may sometimes be estimated, but elimination of biases through use of quotas—or, when possible, random methods—yields the best results. This can be done, for example, by first randomly selecting a number of definable regions and metropolitan areas, then selecting randomly from each such area certain urban blocks and rural segments, then further selecting from these segments certain dwelling units, and finally selecting from the dwelling units the specific persons to constitute the sample.

Search for error

In every stage of the process of discovery in sociology there are possibilities of error, and recognition of these is a part of the progress of sociological methodology. There is continuous creation of technical devices to reduce such errors and to estimate the amount of error that has not been eliminated.

National methodological preferences. All the methods described above are widely used, but their relative popularity in various nations is somewhat related to both the nature of the financial support of research and the field of national interest. Where agricultural problems are of major interest, rural sociology and community studies that can be conducted inexpensively by one or a few investigators are popular. In France, Italy, and several other European nations, industrial sociology is understandably important, much of it based on case studies of industries and the experiences of workers. Sociology in Great Britain, the Scandinavian countries, and Japan covers most of the fields mentioned above.

The broad methodological concepts have varied somewhat according to the country and according to the subfield of sociology. Early in the century there was presumed to be a general difference between the sociologies of European countries and the sociologies of the United States—the former appearing to prefer broad sociological theory based on philosophical methods and the latter showing more inclination toward induction and empiricism. Such differences have declined steadily in recent times, and what differences remain may be in part a result of the differential financing of expensive research.

In the U.S.S.R. and nations under its influence there is much emphasis on the concepts and methods of Marxist sociology, which has only a small following elsewhere. A more important methodological issue divides basic scientific sociology from applied sociology; scholars interested in applied sociology tend to deprecate the methods and findings of the scientific sociologists as being either irrelevant or supportive of an objectionable status quo. Issues of ethics have also in recent years been raised, particularly in regard to observations and experiments in which the privacy of subjects may be felt to be invaded.

STATUS OF CONTEMPORARY SOCIOLOGY

Professional status. The Greek philosophers and the line of European philosophers in the succeeding centuries throughout Western civilization discussed much of the subject matter of sociology without thinking of it as a distinct subject. In the early 19th century all the subject matter of the social sciences was discussed under the heading of moral philosophy. Even after Auguste Comte introduced the word *sociologie* in 1838, the matter was combined with other subjects for some sixty years. Not until the universities undertook a commitment to the subject could a person make a living as a full-time sociologist. This commitment had first to be made by scholars of other fields, of which history was a principal early sponsor.

As early as 1876, at the new Johns Hopkins University, some of the content of sociology was taught in the department of history and politics. In 1889 at the University of Kansas, the word appeared in the title of the department of history and sociology. In 1890 at Colby College, a historian, Albion Small, taught a course called sociology, as did Franklin H. Giddings in the same year at Bryn Mawr College. But the first real commitment to the creation of a field of sociology took place in 1892 at the new University of Chicago, where newly arrived Albion Small asked for and received permission to create a department called sociology—the first such in the world. In the following year or two, departments in the subject were founded at Columbia, Kansas, and Michigan and very soon afterward at Yale, Brown, and many other universities. By the late 1890s nearly all of the educational institutions in the United States either had departments of sociology or offered courses in the subject.

First university department of sociology

In 1895 the *American Journal of Sociology* began publication at the University of Chicago, in time to be followed by a large number of journals in many other countries. Ten years later the *American Sociological Society* was organized, also to be followed in time by a large number of national, regional, international, and special sociological organizations. These quickly institutionalized the subject and have continuously served to guide its directions and to establish, very roughly, its boundaries. Eventually in 1949 the International Sociological Association was established under the sponsorship of UNESCO, and Louis Wirth (1897–1952) of the University of Chicago was elected its first president.

The rapid growth in numbers of full-time sociologists, along with growth of publications, allowed the content of the discipline to expand rapidly. By 1970 there were more than a dozen important sociological journals and an indefinite number of minor journals in the U.S., as well as a considerable number in other nations. Research grew throughout the 20th century at an accelerated pace, especially since the 1920s, partly as a consequence of strong financial support from foundations, government, commercial sources, and private gifts. Along with this there came a flourishing of research institutes, some affiliated with university departments and some independent. A small but increasing number of full-time sociologists gain their livelihood through full-time research independent of universities.

Similar developments have occurred in various other parts of the world, with variations resulting from special conditions in each case. In France, where Auguste Comte and later Émile Durkheim gave early impetus to sociology, there was early development in many fields of the subject. The two World Wars slowed the development, but after 1945 a strong revival of interest in sociology took place, during which the French government established a number of institutes in the social sciences at the level of institutes in the natural sciences, including several in Paris for sociological research—notably the Centre d'Études Sociologiques, the Institut National d'Études Démographiques, and the Maison des Sciences de l'Homme. These institutes receive government funds and employ many full-time sociologists, some of them among the prominent scholars in the nation. French universities have been somewhat more conservative; the Sorbonne, for example, had in 1970 only one chair officially assigned to sociology. The new University of Nanterre, however, established a department with four professorships. A rich amount of research publication has been produced in France since World War II, particularly in general sociology, theory, methodology, social psychology, industrial sociology, and the sociology of work.

German sociology had a strong base in the late 19th century and afterward, and the writings of Ferdinand Tönnies, Max Weber, Georg Simmel, and others were influential in all parts of the world. By the early 1930s, however, official Nazi hostility had impeded its development and by the time of the Second World War had destroyed it as an academic subject in Germany. Immediately after the war a new generation of scholars, aided by visiting sociologists, imported the new empirical research methods and began the development of a style of German sociology much different from the earlier theoretical and philosophical traditions. At the University of Frankfurt the Institut für Sozialforschung (social research), established by private financing before the war, was revived and has stimulated much research production. West German universities remained conservative for a time, but two newly created universities—the Free University of Berlin and the University of Constance—made sociology one of their major subjects. By 1970 most West German universities had at least one chair in sociology. National needs received special emphasis, including administrative research of use to planning, studies of unemployment, youth problems, and delinquency. A significant amount of research is also published in such fields as rural sociology, political sociology, and the family.

Sociology in Great Britain

In Great Britain, despite the early prominence of Herbert Spencer and L.T. Hobhouse, sociology was little regarded by leading universities until recent years. Before World War II Britain excelled in anthropology, especially in the study of nonwhite societies of the empire. Sociology concentrated on studies of the poor, and much of it was undertaken by persons whose affiliation was similar to that of social workers in the U.S. The major prewar sociology department, at the London School of Economics, had the objective more of social reform than scientific objective research. In the postwar period, however, a considerable revival of sociology took place; Oxford and Cambridge recognized the subject by creating positions for sociologists, and various new universities established chairs and departments. Significant work in Britain has been done in such fields as population and demography, sociology of organization, and general sociology. The Tavistock Institute of Human Relations in London has become world famous and concentrates on human relations in the family, the work group, and organizations.

A parallel growth took place in Canada, Australia, and New Zealand. Canada, with some apparent reluctance, allowed itself to be much influenced by American sociology and has recently built many new departments with sociologists trained in the U.S.

The Scandinavian countries have also to a considerable extent adopted the methods and some of the content of American sociology, and the subject has had rapid development in many of the universities and in research institutes, some of which are connected with universities. There is also a considerable amount of interchange between sociologists in these countries.

Japan has a record of much sociological activity dating back to the 1870s. The Japanese Sociological Society (Nippon Shakai Gakkai), headquartered at the University of Tokyo, was founded in 1923; and by 1960 there were about 150 universities and colleges with courses in the subject. In the early period sociology was nearly all imported; Comte and Spencer, and later Giddings and Gabriel Tarde, were their important theorists. After the Second World War there were rapid changes in sociology in Japan, with empirical research methods largely replacing the earlier philosophical style. Importations from American sociology became abundant. Popular among these were industrial sociology, educational sociology, public opinion research, and the study of mass communications.

Sociology in the Soviet Union was long held back by the perceived incompatibility of the subject with Marxist theory. In recent years, however, it has been permitted to develop, and sociological institutes and chairs of sociology are increasing. By 1970 the Soviet Sociological Association had more than a thousand members. Leading research interests have been such subjects as labour productivity, education, crime, and alcoholism. There remains an apparent tendency to avoid issues that might imply conflict with Marxist thought.

Nations under the influence of the Soviet Union have also from time to time been inhospitable to sociology, but the strong interest of younger scholars has made possible some relaxation of this opposition, and in recent years there has been considerable progress of sociology in Yugoslavia, Czechoslovakia, Hungary, and Poland, with occasional setbacks in some areas, such as Czechoslovakia.

In Israel the dominant department of sociology is at the Hebrew University in Jerusalem, where there are also several research institutes. Israeli sociology maintains continuous close contacts with American sociology, and many of the leading Israeli sociologists have had training or teaching experience in the U.S. Among the specialties in Israel are research in methodology, communication, criminology, and the collective settlements (*kibbutzim*) in which new forms of custom and social organization are observed while under development.

The passing of the Fascist regime in Italy and the relative liberalization in Spain have opened the door to sociology, and academic chairs and research institutes are gradually increasing in these countries. Of particular interest are studies of industrial efficiency and social mobility. The general conservatism of universities, however, may constitute a retarding influence for some time to come.

In Latin America objective sociology has been much resisted, partly because it has been viewed as a threat to the political and social order, but also because of meagre financial support of research and the low salary level of professors, many of whom must supplement their earnings in the practice of law, in civil service, and other occupations. In the 1960s, however, the number of full-time chairs increased and a number of research institutes, some financed by U.S. funds, were established. Political instability in some countries remains a major hindrance, and in such countries able scholars continue to be forced from their university positions from time to time.

Little by little sociology is penetrating into some of the developing nations. A number of African universities have formed departments, and the subject is gaining in importance in the Philippines, India, Indonesia, and Pakistan.

Scientific status. It is evident that sociology has not achieved triumphs comparable to those of the several older and more heavily supported sciences. A variety of interpretations have been offered to explain the difference—most frequently, that the growth of knowledge in the science of sociology is more random than cumulative. The true situation appears to be that in some parts of the discipline—such as methodology, ecology, demography, the study of social differentiation and mobility, attitude research, and the study of small-group interaction processes, public opinion, and mass communication—there has in fact taken place a slow but accelerating accumulation of organized and tested knowledge. In some other fields the expansion of the volume of literature has not appeared to have had this property. Critics have attributed the slow pace to a variety of factors—the appetite of sociologists for neologisms and jargon, a disposition for pseudo-

Criticisms of sociology

quantification, and excessive concern with imitation of the methods of natural sciences, overdependence on data from interviews, questionnaires, and informal observations. All these shortcomings can be found in contemporary sociology, but none is characteristic of all areas. In general there has been progress toward efficient terminology and methods and toward more satisfactory data, and conclusions are increasingly based on the harmonious mixture of research methods applied to varied and repeated studies, and therefore are less dependent on the strength of one particular methodological device.

Bias, in more than one direction, is sometimes presumed to be a chronic affliction of sociology. This may arise in part from the fact that the subject matter of sociology is familiar and important in the daily life of everyone, so that there exist many opportunities for the abundant variations in philosophical outlook and individual preferences to appear as irrational bias. Thus critics have expressed disapproval of the sociologists' skepticism on various matters of faith, of their amoral relativism concerning customs, of their apparent oversimplifications of some principles, and of their particular fashions in categorization and abstraction. But skepticism toward much of the content of folk knowledge is a characteristic of all science, and relativism can be interpreted as merely an avoidance of antiscientific ethnocentrism. Furthermore, abstraction, categorization, and simplification are necessary to the advancement of knowledge, and no one system satisfies everyone.

The dispute about the main purpose of sociology, whether it works to understand behaviour, or to cause social change, is a dispute found in every pursuit of scientific knowledge, and such polarization is far from absolute. Persons differ in the degree to which they regard the value of science as an intellectual understanding of the cosmos or as an instrument for immediate improvement of the human lot. Since even the "purest" scientist conceives of his work as benefiting mankind, the issue narrows to a difference in preference between an *ad hoc* attack on immediate human problems and a long-run trust that basic knowledge, gathered without reference to present urgencies, is even more valuable. Sociologists differ on this issue; in some countries there is much pressure toward early practicality of results; in others, including the United States, the larger number of scholars and the principal sociological associations have shown preference for "basic science." In very recent times, however, there has emerged a radical movement among students in various countries involving advocacy of complete commitment to action on current political and social problems.

A degree of polarization has also arisen over the proper strategy for research—whether research should take its directions from the needs of society and mankind or from the evolving theoretical corpus of sociology. In nations that allow academic freedom such disputes are usually of low intensity, because each scholar selects his research interests on any basis he prefers, including that of personal taste. In this way presumably the motivation of the investigator is maximized.

Objectivity and value-neutrality

Sociologists most interested in action express impatience at the claims of others who prefer to separate their research from personal values. Much of the dispute prevails only because the two sides argue past each other. There can be wide agreement that no human being is without personal values, that research forced to confirm a particular set of values is not good science, and that there can be scientific issues toward which a particular investigator is value-neutral. In research that is susceptible to contamination by the values of the worker, it is generally possible to minimize the damage by employing methodological devices that help to insulate the scientist from his wishes for a particular outcome—such devices as objective observational techniques and measurement methods, independent and blind analysis of results, and so forth.

Current trends. It would appear that the growth of sociology will accelerate in the visible future. Among present trends suggesting this likelihood are the increase in public appreciation of the subject, the expansion of available funds for both teaching and research, the steady reduction of sectarian opposition to inquiry into social institutions, the improvement in research methods and methods for gathering data that qualify for modern statistical treatment, and the growth of acceptance and support from scientists in other fields. There are possible factors that could inhibit such growth, such as some forms of extreme nationalism and internal conflict, but such conditions so far have impeded development only locally and temporarily.

Furthermore, it appears likely that public interest in the development of sociological knowledge will increase as a consequence of rising awareness of its promise for human safety and welfare. As the expansion of civilization, with its advanced science and technology, progressively conquers the natural hazards that afflict preliterate and preindustrial peoples and diminishes such threats as natural catastrophes, famine, and disease, a wide range of new problems emerges. These are not the menaces of an impersonal nature, but dangers that arise from imperfection in human behaviour, particularly in organized human relations. Wars have shown a tendency to become larger and ever more destructive, and the causes, though far from being understood, clearly lie, in large measure, in the complexities of social organization, in the interaction of great corporate national bodies. There appears to be little hope that politics, unaided by social science among other disciplines, could reverse this trend.

Domestic problems within nations, regions, cities, and towns appear also to become increasing sources of human troubles. There is a general rise in the severity of ethnic hostilities, and of internal conflicts between generations, political factions, and other divisions of the populations. There are also threats to human welfare from various forms of general social disorganization, reflected in the spread of pockets of poverty, crime, vice, political corruption, and family disorganization. In recent times the threats of overpopulation and potential destruction of the ecological environment have added a further reason for public alarm. Contemporary sociology obviously does not yet provide the solutions, but what prospects of human survival there are depend a great deal on the increase of the applicable knowledge of various social sciences, including sociology.

Emerging subfields. Because human behaviour observes no limits in its directions, it is possible for sociologists to extend their inquiries accordingly. The expansion of sociological interests thus has involved some penetration of adjacent traditional academic fields, such as political science, economics, anthropology, psychology, communications, speech, and to some extent even physiology and zoology. Fields within traditional sociology have also broadened their content, producing such expanded subjects as ecology and comparative sociology. Not all this extension is new, however, since much of the 19th century sociology was also very broad, especially the cosmic sociology of one worker, Lester F. Ward, who conceived sociology as the science of sciences, properly covering and organizing all knowledge.

Applications of sociology

Applications of sociology also appear to be spreading in a variety of directions, and here the possibilities seem unlimited. Sociologists aid industries in obtaining more efficient production; they help unions to increase their power; they organize rebellions of young persons, reform disorganized villages, counsel persons and families, and give or sell services to a wide variety of consumers. To what extent these applied activities will continue to spread will doubtless depend on their effectiveness relative to other means of gaining the same effects.

There is also an expansion of sociology into other than practical applications; for example, there is mathematical sociology, in which mathematical models of social behaviour are developed without systematic observations of behaviour. These efforts are not directed toward immediate human use, but may have value as bases for comparison with real behaviour and thus aid explanation of behavioral causes. A mathematical model of a completely just theoretical process of social mobility, for example, could be useful as a standard for comparing actual mobility at different times and in different nations.

Emerging methodologies. After the easiest sociological questions have been answered, the further progress of research requires ever greater effort and cost, and the proportion of discoveries by individual investigators declines as the necessity for larger teamwork research expands. This foreshadows increasing complexity of the organization of research, as has already taken place in older sciences. Large-scale research in sociology is made possible, and perhaps inevitable, by the availability of expensive computers, elaborate techniques of multivariate analysis, and the storage of information in the form of data banks and the like.

The strongest methodological emphasis in the near future is likely to be on the processes of rigorous testing of generalizations that now appear to be of strategic value in the general structure of sociological knowledge. Complete surprises in the field of human behaviour are less likely than in other sciences, since most of the possible human situations have been familiar in folk knowledge as well as in academic sociology. But the subject contains many inconsistent principles, and few of these have been put to a definitive test, partly from lack of adequate methodology and to some extent from shortage of funds and scientific manpower.

Emerging roles for sociologists. In general the principal employment of sociologists has been in educational institutions, but recently, in various countries, there has been an increasing penetration into other fields of activity. Sociologists, particularly in earlier decades, have been involved in various organized agencies devoted to social work. They have also participated in government work at various levels, from the lower bureaucratic ranks all the way to high administrative responsibility, and in the case of Thomáš Masaryk, former president of Czechoslovakia, to the highest office of a nation. In the United States sociologists have been extensively employed in the Bureau of the Census; the Bureau of the Budget; the Institutes of Health; various other sections of the Department of Health, Education, and Welfare; and the office of the president, where they have made contributions to policy.

Other directions of sociological activity include the roles of consultant, social critic, and social activists and even revolutionaries. When the activity diverges far enough from traditional academic sociology, it may cease to be regarded as sociological, but it appears likely that sociologists will continue to spread their activities over the ever-widening region of national or global concern, in the name of their science or otherwise. (R.E.L.F.)

RELATED FIELDS

Social psychology. Social psychology is the scientific study of the behaviour of individuals in their social and cultural setting. Though the term may be taken to include the social activity of laboratory animals or those in the wild, the emphasis here is on human social behaviour.

Once a relatively speculative, intuitive enterprise, social psychology has become an active form of empirical investigation, the volume of research literature having risen rapidly after about 1925. Social psychologists now have a substantial volume of observation data covering a range of topics; the evidence remains loosely coordinated, however, and the field is beset by many different theories and conceptual schemes.

Early impetus in research came from the United States, and much work in other countries has followed U.S. tradition, though independent research efforts are being made elsewhere in the world. Social psychology is being actively pursued in the United Kingdom, Canada, Australia, Germany, The Netherlands, France, Belgium, Scandinavia, Japan, and the Soviet Union. Most social psychologists are members of university departments of psychology; others are in departments of sociology or work in such applied settings as industry and government.

Scope of social psychology

Much research in social psychology has consisted of laboratory experiments on social behaviour, but this approach has been criticized in recent years as being too stultifying, artificial, and unrealistic. Much of the conceptual background of research in social psychology derives from other fields of psychology. While learning theory and psychoanalysis were once most influential, cognitive and linguistic approaches to research have become more popular; sociological contributions have also been influential.

Social psychologists are employed, or used as consultants, in setting up the social organization of businesses and psychiatric communities; some work to reduce racial conflict, to design mass communications (*e.g.,* advertising), and to advise on child rearing. They have helped in the treatment of mental patients and in the rehabilitation of convicts. Fundamental research in social psychology has been brought to the attention of the public through popular books and in the periodical press.

Research methods. Laboratory experiments, often using volunteer students as subjects, omit many features of daily social life. Such experiments also have been criticized as being subject to bias, since the experimenters themselves may influence the results. Research workers who are concerned with more realistic settings than with rigour tend to leave the laboratory to perform field studies, as do those who come from sociological traditions. Field research, however, also can be experimental, and the effectiveness of each approach may be enhanced by the use of the methods of the other.

Many colleges and universities have a social-psychology laboratory equipped with observation rooms permitting one-way vision of subjects. Sound and video recorders and other devices record ongoing social interaction; computing equipment and other paraphernalia may be employed for specific studies.

Social behaviour is understood to be the product of innate biological factors resulting from evolution and of cultural factors that have emerged in the course of history. Early writers (*e.g.,* William McDougall, a psychologist) emphasized instinctive roots of social behaviour. Later research and writing that tended to stress learning theory emphasized the influence of environmental factors in social behaviour. In the 1960s and 1970s field studies of nonhuman primates (such as baboons) drew attention to a number of similarities with human social behaviour, while research in cultural anthropology has shown that many features of human social behaviour are the same regardless of the culture studied. It is coming to be a widely accepted view that human social behaviour seems to have a biological basis and to reflect the operation of evolution as in the case of patterns of emotional expression and other nonverbal communication, the structure of language, and aspects of group behaviour.

Much research has been done on socialization (the process of learning from a culture), and learning has been found to interact with innate factors. An innate capacity for language, for example, makes it possible to learn a local language. Culture consists of patterns of behaviour and ways of organizing experience; it develops over the course of history as leaders and innovators introduce new elements, only some of which are retained. Many aspects of social behaviour can be partly accounted for in terms of their history.

Social perception. In some laboratory experiments, subjects watch stills or moving pictures, listen to tape recordings, or directly observe or interact with another person. Subjects may be asked to reveal their social perception of such persons on rating scales, to give free descriptions of them, or to respond evaluatively in other ways. Although such studies can produce results that do not correspond to those in real-life settings, they can provide useful information on the perception of personality, social role, emotions, and interpersonal attitudes or responses during ongoing social interaction.

The effect of cultural stereotypes

Research has been directed to how social perception is affected by cultural stereotypes (*e.g.,* racial prejudice), by inferences from different verbal and nonverbal cues, by the pattern of perceptual activity during social interaction, and by the general personality structure of the perceiver. The work has found practical application in the assessment of employees and of candidates for positions.

There has also been research on the ways in which perception of objects and people is affected by social factors such as culture and group membership. It has been shown, for example, how coins, colours, and other physical cues are categorized differently by people as a result of their group membership and of the categories provided by language. Other studies have shown the effect of group pressures on perception.

Interaction processes. The different verbal and nonverbal signals used in conversation have been studied, and the functions of such factors as gaze, gesture, and tone of voice are analyzed in social-interaction studies. Social interaction is thus seen to consist of closely related sequences of nonverbal signals and verbal utterances. Gaze has been found to perform several important functions. Laboratory and field studies have examined helping behaviour, imitation, friendship formation, and social interaction in psychotherapy.

Among the theoretical models developed to describe the nature of social behaviour, the stimulus–response model (in which every social act is seen as a response to the preceding act of another individual) has been generally found helpful but incomplete. Linguistic models that view social behaviour as being governed by principles analogous to the rules of a game or specifically to the grammar of a language have also attracted adherents. Others see social behaviour as a kind of motor skill that is goal-directed and modified by feedback (or learning), while other models have been based on the theory of games, which emphasizes the pursuit and exchange of rewards and has led to experiments based on laboratory games.

Small social groups. All small social groups do not function according to the same principles, and, indeed, modes of social activity vary for particular kinds of groups; *e.g.,* for families, groups of friends, work groups, and committees.

Early research on social groups

Earlier research was concerned with whether small groups did better than individuals at various tasks (*e.g.,* factory work), while later research has been directed more toward the study of interaction patterns among members of such groups. In the method known as sociometry, members nominate others (*e.g.,* as best friends) to yield measures of preference and rejection in groups. Others have studied the effects of democratic and authoritarian leadership in groups and have greatly extended this work in industrial settings. In research on how people respond to group norms (*e.g.,* of morality or of behaviour), most conformity has been found to the norms of reference groups; *i.e.,* to such groups as families or close friends that are most important for people. The emergence and functioning of informal group hierarchies, the playing of social roles (*e.g.,* leader, follower, scapegoat), and cohesiveness (the level of attraction of members to the group) have all been extensively studied. Experiments have been done on processes of group problem solving and decision making, the social conditions that produce the best results, and the tendency for groups to make risky decisions. Statistical field studies of industrial work groups have sought the conditions for greatest production effectiveness and job satisfaction.

Social organizations. Such organizations as businesses and armies have been studied by social surveys, statistical field studies, field experiments, and laboratory experiments on replicas of their social hierarchies and communication networks. Although they yield the most direct evidence, field experiments present difficulties, since the leaders and members of such organizations may effectively resist the intervention of experimenters. Clearly, efforts to try out democratic methods in a dictatorship are likely to be severely punished. Investigators can study the effects of role conflict resulting from conflicting demands (*e.g.,* those from above and below) and topics such as communication patterns in social organizations. Researchers also have studied the sources of power and how it can be used and resisted. They consider the effectiveness of different organizational structures, studying variations in size, span of control, and the amount of power delegation and consultation. In factories, social psychologists study the effects of technology and the design of alternative work-flow systems. They investigate methods of bringing about organizational change; *e.g.,* in the direction of improving the social skills of people and introducing industrial democracy.

Changes in approach since 1900

Ways of looking at working organizations have changed considerably since 1900. Classical organization theory was criticized for its emphasis on social hierarchy, economic motivation, division of labour, and rigid and impersonal social relations. Later investigators emphasized the importance of flexibly organized groups, leadership skills, and job satisfaction based on less tangible rewards than salary alone. There has been a rather uneasy balance in the industrial social psychologist's concern with production and concern with people.

Personality. It is evident that there are individual differences in social behaviour; thus, people traditionally have been distinguished in terms of such personality traits as extroversion or dominance (see PERSONALITY). Some personality tests are used to predict how an individual is likely to behave in laboratory discussion groups, but usually the predictive efficiency is very small. Whether or not an individual becomes a leader of a group, for example, is found to depend very little on what such personality tests measure and more on his skills in handling the group task compared with the skills of others. Indeed, the same person may be a leader in some groups and a follower in others. Similar considerations apply to other aspects of social behaviour, such as conformity, persuasibility, and dependency. Although people usually perceive others as being consistent in exhibiting personality traits, the evidence indicates that each individual may behave very differently, depending on the social circumstances.

Socialization. The process by which personality is formed as the result of social influences is called socialization. Early research methods employed case studies of individuals and of individual societies (*e.g.,* primitive tribes). Later research has made statistical comparisons of numbers of persons or of different societies; differences in child-rearing methods from one society to another, for example, have been shown to be related to the subsequent behaviour of the infants when they become adults. Such statistical approaches are limited, since they fail to discern whether both the personality of the child and the child-rearing methods used by the parents are the result of inherited factors or whether the parents are affected by the behaviour of their children.

Problems in the process of socialization that have been studied by experimental methods include the analysis of mother–child interaction in infancy; the effects of parental patterns of behaviour on the development of intelligence, moral behaviour, mental health, delinquency, self-image, and other aspects of the personality of the child; the effects of birth order (*e.g.,* being the first-born or second-born child) on the individual; and changes of personality during adolescence. Investigators have also studied the origins and functioning of achievement motivation and other social drives (*e.g.,* as measured with personality tests).

Several theories have stimulated research into socialization; Freudian theory led to some of the earliest studies on such activities as oral and anal behaviour (*e.g.,* the effect of the toilet training of children on obsessional and other "anal" behaviour). Learning theory led to the study of the effects of rewards and punishments on simple social behaviour and was extended to more complex processes such as imitation and morality (*e.g.,* the analysis of conscience).

The self. Such concepts as self-esteem, self-image, and ego-involvement have been regarded by some social psychologists as useful, while others have regarded them as superfluous. There is a considerable amount of research on such topics as embarrassment and behaviour in front of audiences, in which self-image and self-esteem have been assessed by various self-rating methods. The origin of awareness of self has been studied in relation to the reactions of others and to the child's comparisons of himself with other children. Particular attention has been paid to the so-called identity crisis that is observed at various stages of life (*e.g.,* in adolescence) as the person struggles to discern the social role that best fits his self-concept.

Factors in the origin of predispositions of individuals

Attitudes and beliefs. Research into the origins, dynamics, and changes of attitudes and beliefs has been carried out by laboratory experiments (studying relatively minor effects), by social surveys and other statistical field studies, by psychometric studies, and occasionally by field experiments. The origins of these socially important predispositions have been sought in the study of parental attitudes, group norms, social influence and propaganda, and in various aspects of personality. The influence of personality has been studied by correlating measured attitudes with individual personality traits and by clinical studies of cognitive and motivational processes; so-called authoritarian behaviour, for example, has been found to be deeply embedded in the personality of the individual. Early research based on statistical analyses of social attitudes revealed correlations with such factors as radicalism–conservatism. Later research on consistency provided extensive laboratory evidence of consistency but little evidence of it in actual political behaviour (*e.g.,* in attitudes on different political issues).

Research on attitude change has studied the effects of the mass media, the optimum design of persuasive messages, the effects of motivational arousal, and the role of opinion leaders (*e.g.,* teachers and ministers). Research has been carried out into the origins, functioning, and change of particular attitudes (*e.g.,* racial, international, political, and religious), each of which is affected by special factors. Attitudes toward racial minority groups, for example, are affected by social conditions, such as the local housing, employment, and the political situation; political attitudes are affected by social class and age; and religious attitudes and beliefs strongly reflect such factors as inner personality conflict.

Various specialties in social psychology. Many social psychologists are concerned with such aspects of public opinion (social survey) research as the design of standardized interviews and questionnaires. Forms of questions have been devised to compensate for errors that arise from the efforts to respond in a socially approved manner; some are designed to detect lying. Mass communications have been devised on the basis of research into persuasion. Use is also still made of Freudian symbolism and theory.

Research into the causes of mental disorders has shown the importance of social factors in the family and elsewhere. Mental patients often show deficiencies in social performance that may be the cause of other symptoms. Many social psychologists hold that social factors may also apply to such disorders as schizophrenia, which also seem to have hereditary and chemical bases. There has been a corresponding growth in the use of various kinds of social therapy in psychiatry (*e.g.,* group therapy, therapeutic communities, and social-skills training).

Considerable research has been devoted to industrial productivity, absenteeism, labour turnover, accidents, and job satisfaction. Factors that have been found to be important include the style of supervision and management, the size and composition of working groups, the technology and the work-flow systems, the span of control, and other features of the organizational structure. Research results point strongly toward the advantages of a less rigid hierarchical structure of authority, with more delegation of authority and consultation, training in supervisory skills, small and cooperative work teams, and interesting and varied work.

A major application of research in social interaction and group behaviour is in training in social skills, as in the T-groups, or sensitivity training, noted above. Role playing with video-tape playback and training in the imitation of other persons who serve as behavioral models are used in teaching people new skills. Actual training on the job has the advantage that there is no gap between the training and the work itself. All of these methods have been shown to be effective, depending on the job and the teacher. Social-skills training has been given successfully to industrial managers and supervisors, social workers and clergymen, interviewers, public speakers, mental patients, and juvenile delinquents.

A great deal of research has been done on factors underlying racial prejudice, but the understanding thus obtained has not had much effect upon the social problems involved. Similarly, the causes of delinquency and crime have been extensively studied, but it is not feasible to manipulate the factors influencing crime, such as genetic factors, methods of upbringing, and inequalities of opportunity. Social psychology has made some contribution to education; sociometry is quite widely practiced as a means of grouping children, and evidence is growing about the optimum styles of teacher behaviour. (M.Ar./Ed.)

Criminology. Criminology is the scientific study of the nonlegal aspects of crime (including juvenile delinquency). In its wider sense, embracing penology, it is thus the study of the causation, correction, and prevention of crime—seen from the viewpoints of such diverse disciplines as ethics, anthropology, biology, ethology (the study of character), psychology and psychiatry, sociology, and statistics. Whereas the traditional legal approach to crime focusses on the action of crime and the protection of society, criminology focusses on the person of the criminal and the essential interests of the individuals of whom society consists. Whereas criminal law has been a relatively conservative force, often slow to change even where change has seemed imperative, criminology as a part of the developing social sciences of the past hundred years has been a revolutionary force—its object being not to replace the legal system in dealing with crime and punishment but to supplement it, making it less rigid and more sympathetic to approaches wider than strictly legal ones.

Criminology and criminal law compared

Without denying the value of "pure research," one must point to criminology and particularly penology as primarily practical subjects or "applied" disciplines. This practical value of criminological research can make itself felt in several ways. Its accumulated findings can give judges, prosecutors, lawyers, probation officers, and prison officials better understanding of crime and criminals, leading hopefully to more effective and humane sentencing and methods of treatment. Criminological research and knowledge can be equally at the disposal of legislators and administrators to assist in their task of reforming the law and improving penal and reformatory institutions. Essentially this purveyance of information represents a neutral role for criminologists; they garner the facts, and the various governmental officials decide for themselves what kind of practical conclusions to draw from the facts. Increasingly, however, some criminologists—like their counterparts in such fields as the atomic sciences—are demanding that scientists fully shoulder the moral and political responsibilities for their discoveries and for the use made of them instead of leaving vital decisions entirely to their governments. Thus some criminologists, for instance, insist upon actively campaigning against capital punishment, given the facts as they see them. Opponents of this activist role, on the other hand, contend that penological arguments are not sufficient but must be weighed along with political, social, religious, and moral arguments and that this all-round consideration should be left to responsible political bodies. The view does not deny the right of criminologists to express their opinions as ordinary citizens and voters; it does contend, nevertheless, that a government of officials responsive to the popular will, however fallible it may be, is less dangerous than a "government by experts."

Another question involving the scope and functions of criminology is whether or not it should extend to the study of crime detection, involving such measures as photography, toxicology, fingerprint study, and the like. In several countries, notably Austria and Belgium, and at the school of criminology of the University of California at Berkeley, this so-called criminalistics has long been an important branch of criminological teaching and research, and the distinguished *Journal of Criminal Law, Criminology, and Police Science* (U.S.) devotes much of its space to criminal investigation. Actually, the only reason for excluding it from criminology is perhaps the expense of staff and equipment, which can be better borne by police colleges and similar specialized institutions. On the other hand, in recent decades criminology has undergone an important and perfectly legitimate extension of its territory by devoting much attention to so-called victimology—the study of the victim of crime, his relations to the criminal, and his role as a potential causal factor in crime.

The role of criminalistics and victimology

Although the exclusion of criminalistics makes it easier to locate criminology on the map of scientific studies, its origin in, its close relations to, and its partial dependence on so many other disciplines result in considerable diversity and confusion regarding its proper place in the academic curriculum. Universities in continental Europe, when they do not ignore criminology altogether, tend to treat it as part of legal education; even where its principal teachers are not lawyers. In Great Britain the only existing Institute of Criminology is part of the law faculty of Cambridge University; in other schools criminological research and teaching are usually divided between departments of sociology or social administration, law faculties, and institutes of psychiatry. In South America the anthropological and medical elements predominate, and in the United States, criminology, with a few notable exceptions, forms an established section of departments of sociology.

Given this situation in which criminology is submerged in other fields, it is not surprising that most teachers and researchers in criminology regard themselves first as sociologists, psychologists, lawyers, or whatever and only secondarily as criminologists. Their education contributes to this status; although a number may have pursued some criminological studies in their undergraduate years, criminology is largely a postgraduate discipline, at least in terms of major concentration for students.

This floating character of criminology weakens its position and tends to lend doubt to its claim to scientific status. Nevertheless, other disciplines—such as psychology, psychiatry, history, sociology, and social anthropology—have gone through similar birth pangs and, even after having achieved more or less assured positions, still face challenges to their claim to being scientific disciplines. The answer lies perhaps in historian H.R. Trevor-Roper's remark, "there are sciences and sciences." If the results of research can be viewed relatively, it is possible to perceive science in the criminologist's systematic application of sound research methods and his development of a body of facts from which he interprets general trends on a subject of real importance to mankind.

Historical development. The origins of criminology are generally dated from the late 18th century, when those imbued with a spirit of humanitarianism began questioning the cruelty, arbitrariness, and inefficiency of criminal justice and prison systems. From this period arose the so-called classical school of criminology, composed of such reformers as the Italian Marchese di Beccaria and the Englishmen Sir Samuel Romilly, John Howard, and Jeremy Bentham, all of whom may be said to have sought penological and legal reform rather than criminological knowledge per se—that is, knowledge about crime and criminals. Their principal aims were to mitigate legal penalties and subject judges to the principle of *nulla poena sine lege* or "due process of law" and also to reduce the application of capital punishment and humanize penal institutions. In all this they were moderately successful, but in their desire to make criminal justice "just," they tried to construct rather abstract and artificial equations between crimes and penalties, thereby forgetting the personal characteristics and needs of the individual criminal. Moreover, the object of punishment was seen as being primarily retribution, with deterrence occupying second place, and reformation lagging far behind.

Positivist school

By the second half of the 19th century these deficiencies, together with the influential teachings of the French sociologist Auguste Comte, had prepared the ground for the positivist school, which sought to bring a scientific neutrality into criminological studies. Instead of assuming a moral stance that focussed on measuring the criminal's "guilt" and "responsibility," the positivists attempted a morally neutral and social interpretation of crime and its treatment. Their leading figure, Cesare Lombroso (1836–1909), professor of psychiatry and anthropology at the University of Turin, sought through firsthand observation and measurement of prison inmates to determine the characteristics of criminal types. Some of his investigations led him into anthropometric interpretations—for example, his oft-criticized deduction of the "born criminal" with cranial, skeletal, and neurological malformations—but largely he and other positivists helped to introduce the ideas that crime has multiple causes and that most criminals are not born criminal but are shaped by their environmental upbringing and associations. With the positivists, therefore, the emphases in criminology had turned to experimental case studies and to preventive and rehabilitative measures. Without the upheaval caused by the positivists not only criminological research in the modern sense but also the present-day alternatives to capital punishment and old-fashioned imprisonment such as probation, suspended sentence, fines, and parole, inadequate as some of them are, would have been unthinkable.

Today, nevertheless, the feeling is widespread that the battle of ideas fought by the classical and positivist schools has not yet produced the secure foundations on which the criminology and the penal systems of the future can be built. Thus a third school, the postwar movement of "social defense," also originating in Italy, has tried to combine their best features and eliminate their excesses. This school disapproves of any rigid typology of criminals and stresses the uniqueness of human personality; it refuses the "scientism" of the positivists in favour of a strong belief in moral values—most importantly in balancing the rights of criminals and the rights of society. The school still speaks with too many voices, however, to be conclusively labelled.

Independent of these debates between schools, however, are the advances accomplished by such great figures as the statisticians Adolphe Quetelet (1796–1874) and André Michel Guerry (1802–66), the sociologists Gabriel Tarde (1843–1904) and Émile Durkheim (1858–1917), and of course Sigmund Freud, all of whom introduced a wealth of new ideas into the old problems of the social and individual characteristics of human, including criminal, behaviour.

Forming and testing a hypothesis

Modern trends. The objectives of criminological research are sometimes said to be threefold: descriptive, causal, and normative. The descriptive aspect consists of the collection of relevant and reliable facts, together with their interpretation. The collection does not begin as a random and meaningless running after whatever phenomena happen to rouse the researcher's interest. Rather it is preceded by some hypothesis or "hunch," an assumption about what the researcher expects to find. The hypothesis "organizes" his inquiry. As the collection of facts proceeds, he may find either that his hypothesis is correct or that it requires revision or abandonment and thus the development of a new hypothesis to guide further research. The history of criminology reflects this perennial revision and renewal of inquiry, this continuous process of abandoning seemingly well-established theories in favour of new ones. Lombroso's theory of the "born criminal," the theory that all crime (or at least all economic crime) is due to poverty, and the theory that all juvenile delinquents come from broken homes had all to be drastically revised.

The causal aspect involves relating the effects of one body of facts on another. Although regarded nowadays with some suspicion or indifference (even in the natural sciences), the search for causes is not being dispensed with altogether. So long as one does not jump to causal conclusions when arriving at statistical correlations or does not pressure "facts" into some proof of a popular theory, theories of causation can be useful in planning for the alleviation of crime and criminality.

The normative aspect, however, is more decidedly suspect. Research aimed at formulating so-called laws governing criminological phenomena has been thus far futile and does not look promising. What is sometimes regarded as a "law" has in reality been a mere trend. To diagnose statistical trends may be useful so long as their possible ephemeral nature is recognized, but trends are not laws, and there is thus but little scope for the normative approach in criminology.

Cross-disciplinary and cross-cultural approaches

Criminology, as suggested earlier, is cross-disciplinary and indeed draws methods or techniques from both the natural and the social sciences and must continually take heed of developments in other fields. It also depends increasingly on cross-cultural approaches; there have been recent statistical (though admittedly controversial) comparisons of "delinquent generations" in England, New Zealand, Denmark, and Poland; various studies of the sociological and statistical aspects of homicide; and studies of the ecological significance of "criminal areas" and of the possibility of predicting criminality.

In common with other disciplines, criminology must face such distinctions as between pure and applied research and between statistical and intuitive ways of thinking, but what is almost unique to criminological research is its intense involvement with society and its difficulty in achieving "detachment." Not only do society's biases toward crime and punishment influence a criminologist's choice and execution of research but also he is dependent on the willing cooperation of governmental departments and other public authorities to secure essential raw material or data. There are only a few limited areas—such as adolescent delinquency and gang activities—in which research can be pursued privately without resort to official help.

Seen in the light of the previous remarks on the history of criminology, the development of criminological research can be divided into three stages: the prescientific, lacking any theoretical basis and largely identifiable with the work of the classical school; the semiscientific, possessing theories and hypotheses but without scientifically sound techniques and largely characteristic of the efforts of the positivist school; and the scientific, hopefully trying to repair earlier deficiencies and developing or improving the techniques described below.

Statistics. Often serving as the initial step in any research and regarded by some researchers, perhaps incorrectly, as the one and only reliable technique, the collection and interpretation of statistics for social and criminological purposes began in Europe early in the 19th century. The reputed "father" of this criminological method is the Belgian astronomer Adolphe Quetelet, who is perhaps best remembered for his famous "law," developed from the French and Belgian statistics, which showed that crime in any given country remains fairly constant over the long term (short-term fluctuations being insignificant). When he qualified himself, however, by saying that the volume and kind of crime were constant only so long as society's social, economic, and political conditions remained unchanged, he deprived the "law" of much of its significance for a rapidly changing modern world.

The manner and extent of data collection today differ considerably from country to country or, in federal unions like the United States, even from state to state or province to province. They differ in how often data are collected and published, in what items are given importance, in the choice between complete listings and sample surveys, in the ratio between governmental and private research, and so forth. Such far-reaching differences, together with the differences in law and its administration and in popular views and habits, have made it so far impossible to devise a meaningful system of international criminal statistics. Generally, however, there is increasingly less tendency to collect any and all data, regardless of reliability or practical value, and to concentrate on limited, reliable data involving matters of agreed upon importance.

Comparison of police and court statistics

A noteworthy distinction to be made is between police statistics and court statistics. Police data are nearer to the event but perhaps less reliable, and they usually describe the crimes only, not the criminals. The data from the courts, being based on convictions, do deal with the persons involved but include only the material brought forward by the prosecution and the defense. All criminal statistics indeed depend entirely on human factors such as the willingness of private individuals and officials to prosecute, on the popularity or unpopularity of the criminal laws at issue, and so forth. The figures also usually fail to rate very clearly the gravity of individual cases; except for such broad categories as "petty" and "grand," theft is theft regardless of the value of the objects stolen. Only recently have more detailed categories been attempted for criminological research.

Case studies. Also called the individual "case history," the case study concentrates on the career or life of one individual or group of individuals and is the method used primarily, though not exclusively, by psychologists, psychiatrists, and psychoanalysts. If well done, such histories can give deep insights into the personalities and motives of criminals, but the method does have shortcomings. Although the volume of case histories has grown large, their reliability is sometimes suspect—partly because of a criminal's natural reluctance to expose himself completely and partly because of the nature of the publication of case histories. Their publication is comparatively rare; professional ethics often forbid the exposure of details given confidentially, and those studies actually published may be too few to be typical and may even on occasion be designedly selective because of an investigator's wish to prove a theory.

Closely related to case studies are autobiographies and other books written by ex-prisoners, but in spite of their considerable human and scientific interest, they do suffer from even greater disadvantages, chiefly questionable objectivity. Sociologists have also contributed important studies of individuals in their social environments.

Typologies. The typological method involves classifying offenses, criminals, criminal associations, criminal areas, or whatever according to some criteria of relatedness or similarity. Thus there have been attempts to dichotomize criminals as either "normal" or "abnormal," "habitual" or "professional," or to form a continuum of criminals from the "insane" at one extreme through various career criminals, petty offenders, and white-collar criminals to "organized" or "professional" criminals at the other extreme. The typological method is less impersonal and heterogeneous than the statistical method and less individual or specific than the case study. Developed mainly in Germany and Austria and more recently in the United States, the method has been disputed; psychiatrists and psychoanalysts have especially questioned its value, primarily because it attempts to reduce complex phenomena to simple terms and tends to ignore important individual differences. Nevertheless, employed with restraint, the method is indispensable as a bridge between the two extremes, and it is in fact often used unknowingly by both statisticians and case students.

Experimental methods. A controlled experiment involves taking two closely related situations or groups, subjecting one of them to a specific change and comparing the subsequent characteristics of both. In the past, so-called experiments by judicial, penal, and reformatory institutions were not really controlled or even experimental in the scientific sense, for public agencies, at least in theory, are bound by the idea of justice to give equal treatment to equals, not one kind of treatment to one group and another kind to another group. Thus, generally speaking, most controlled experiments must be left to universities and other private bodies, and indeed the need for strict control and variable treatment has been recently accepted in such researches as Harvard University's Cambridge-Somerville Youth Study, which sought the effects of counselling on "pre-delinquent" boys.

Problems of crime prediction

Prediction studies. Criminological prediction—not unlike actuarial prediction used by insurance companies—is intended to forecast, usually in percentages, the future conduct of persons under certain conditions. Based on statistics or case histories or both, the predictions attempt to indicate probabilities—how any specific individuals or groups are likely to be affected by certain conditions or treatments. Thus, for example, various categories of criminals are listed as likely to be recidivistic.

The techniques involved in constructing prediction tables are too complicated to be discussed in brief; they have been developed and refined in the past 40 years mainly by Sheldon and Eleanor Glueck of Harvard University and also by several other authors in various countries. Statistical prediction by itself can never be conclusive; it must be subjected to rigorous validation for any individual or group, and even then it can merely show certain probabilities, which should be used in penal decisions only with the greatest caution and along with the lessons of experience derived from other sources. Nevertheless, the method can be valuable in supplementing the inevitably limited personal experience of judges and administrators, and indeed in recent decades prediction research has probably nowhere in the social sciences been more popular and urgent than in criminology.

Action research. Action research, which is often contrasted with experimental research, consists of drawing upon the observations of field workers and other persons directly involved with delinquents, potential delinquents, or prisoners. Thus, for example, have social workers attempted to help slum children and adolescents with their problems and at the same time studied their delinquent behaviour, related it to their environment, and evaluated the results of the youth clubs or other services offered. The chief values of action research are that it aims at practical results through collaboration with fieldworkers, tries to build a bridge between theoretical and practical work, and may well dispense with formal hypotheses and simply aim at preventive tactics. Its best known and perhaps most successful example has so far been Clifford Shaw's Chicago Area Project, which, in close cooperation with the famous ecological studies of the University of Chicago, has tried to enlist suitable local people to deal with the social problems of their area.

Sociological research. Sociological research involves various methods—general surveys and personal interviews, as well as statistical, case-study, typological, experimental, and predictive techniques—and thus the purpose of classifying sociological research separately is chiefly to signal its focus or fields of interest. Mainly, criminology derives benefits from three fields of sociological study: (1) social institutions, involving such things as different conceptions of, or attitudes toward, property held by various societies or groups or the different effects of mass media on crime; (2) social groups, involving such things as the influence of juvenile gangs or criminal subcultures on individual criminal behaviour or the influence of prejudice on certain racial, national, or religious minorities; and (3) ecology, involving the study of different geographical areas and their rates and kinds of crime. Clifford Shaw's ecological studies of Chicago have been especially revealing in analyzing urban areas that either "breed" crime or "attract" crime. (H.M./Ed.)

Economics

No one has ever succeeded in neatly defining the scope of economics. Economists used to say, with Alfred Marshall, the great English economist, that economics is "a study of mankind in the ordinary business of life; it examines that part of individual and social action which is most closely connected with the attainment and with the use of the material requisites of wellbeing"—ignoring the fact that sociologists, psychologists, and anthropologists frequently study exactly the same phenomena. Another English economist, Lionel Robbins, has more recently defined economics as "the science which studies human behaviour as a relationship between (given) ends and scarce means which have alternative uses." This definition—that economics is the science of economizing—captures one of the striking characteristics of the economist's way of thinking but leaves out the macroeconomic approach to the subject, which is concerned with the economy as a whole.

What economists do

Difficult as it may be to define economics, it is not difficult to indicate the sort of questions that economists are concerned with. Among other things, they seek to analyze the forces determining prices—not only the prices of goods and services but the prices of the resources used to produce them. This means discovering what it is that governs the way in which men, machines, and land are combined in production and that determines how buyers and sellers are brought together in a functioning market. Prices of various things must be interrelated; how does such a "price system" or "market mechanism" hang together, and what are the conditions necessary for its survival?

These are questions in what is called "microeconomics," the part of economics that deals with the behaviour of such individuals as consumers, business firms, traders, and farmers. The other major branch of economics is "macroeconomics," in which the focus of attention is on aggregates: the level of income in the whole economy, the volume of total employment, the flow of total investment, and so forth. Here the economist is concerned with the forces determining the income of a nation or the level of total investment; he seeks to learn why full employment is so rarely attained and what public policies should be followed to achieve higher employment or more stability.

But these still do not exhaust the range of problems that economists consider. There is also the important field of "development economics," which examines the attitudes and institutions supporting economic activity as well as the process of development itself. The economist is concerned with the factors responsible for self-sustaining economic growth and with the extent to which these factors can be manipulated by public policy.

Cutting across these three major divisions in economics are the specialized fields of public finance, money and banking, international trade, labour economics, agricultural economics, industrial organization, and others. Economists may be asked to assess the effects of governmental measures such as taxes, minimum-wage laws, rent controls, tariffs, changes in interest rates, changes in the government budget, and so on.

The size of the profession

In the 19th century, economics was the hobby of gentlemen of leisure and the vocation of a few academicians; economists wrote about economic policy but were rarely consulted by legislatures before decisions were made. Today, there is hardly a government, international agency, or large corporation that does not have its resident economist. According to an estimate of the National Science Foundation (U.S.), for instance, there were 11,000 economists in the United States in 1966. Clearly, much depends on how one defines the job of an economist: the list of the National Science Foundation is confined to persons whose chief competence is in any one of the recognized economic specialities. Of the 11,000 professional economists, about 4,500 were employed as teachers of economics; the rest worked in various research or advisory capacities, either for themselves, for industry, or for government. This leaves out of account many others employed in accounting, commerce, marketing, and business administration; they may think of themselves as economists, but their professional expertise falls within other fields. There are perhaps another 10,000 economists in the rest of the world—their numbers have never been counted. It would be reasonable to estimate the total number of professional economists in the world in 1970 at 20,000, a number that was apparently growing at about 5 percent per year. There were about 75 English-language journals in economics and another 25 in various foreign languages, with new ones appearing every year. This implies the publication of about 1,500 scientific papers per year, not to mention the 700 new books on economics published every year. This is indeed "the age of economists," and the demand for their services seems insatiable.

HISTORICAL DEVELOPMENT OF ECONOMICS

The work of Adam Smith

The effective birth of economics as a separate discipline may be traced to the year 1776, when the Scottish philosopher Adam Smith published *An Inquiry into the Nature and Causes of the Wealth of Nations.* There was, of course, economics before Adam Smith: the Greeks made significant contributions and so did the medieval scholastics; from the 15th to the 18th century, an enormous pamphlet literature appeared that developed the implications of economic nationalism, a body of thought now known as "mercantilism"; for a brief period in the 18th century the French "physiocrats" developed a fairly sophisticated economic model; and several other 18th-century figures can compete with Smith for the title of "first economist." Nevertheless, Adam Smith wrote the first full-scale treatise on economics and, by his magisterial influence, founded what later generations were to call the "English School of Classical Political Economy."

Analysis of the market. The *Wealth of Nations,* as its title suggests, is essentially a book about economic development and about policies that promote or hinder development. In its practical aspects it is an attack on the protectionist doctrines of the mercantilists and a brief for free trade. But in the course of attacking "false doctrines of political economy," Adam Smith was led to analyze the workings of a free-enterprise system as a governor of human activity. In a competitive market each individual, being one among many, can exert only a negligible influence on prices; each must take prices as they come and is free only to vary the quantities bought and sold at given prices; yet the sum of all individuals' separate actions determines prices. The "invisible hand" of the market, as Adam Smith was fond of saying, assures a social result that is independent of individual intentions and thus creates the possibility of an objective science of economic behaviour. Adam Smith believed that he had found, in the competitive market, an instrument capable of converting "private vices" (like selfishness) into "public virtues" (like maximum production). But this is only true if the competitive system is embedded in an appropriate legal and institutional framework, an insight that Adam Smith developed at length but that was largely forgotten by later generations. Within this great tome on the theme of rich and poor nations was contained a simple theory of value (or prices), a crude theory of distribution, an even cruder theory of international trade, and a primitive theory of money; but with all their imperfections, these were the building blocks of classical and modern economics. The book's very fecundity gave it strength because it left so much for disciples to tidy up.

The later classical economists

Construction of a system. David Ricardo's *Principles of Political Economy and Taxation* (1817) was, in one sense, simply a critical commentary on the *Wealth of Nations;* in another sense, it gave an entirely new twist to the developing science of political economy. Ricardo invented the concept of the "economic model," a tightly knit logical apparatus consisting of a few strategic variables, an apparatus that was capable of yielding, after a bit of manipulation, results of enormous practical import. At the heart of the Ricardian system is the notion that economic growth must sooner or later be arrested, owing to the rising cost of growing food on a limited land area. An essential ingredient of this argument is the Malthusian principle—enunciated in Thomas Malthus' *Essay on Population* (1798)—that population tends to increase up to the limits set by the existing supply of food, thus holding down wages. As the labour force increases, extra food to feed the extra mouths can be produced only by extending cultivation to less fertile soil or by applying capital and labour to land already under cultivation (with diminishing results because of the so-called law of diminishing returns). Although wages are held down, profits do not rise proportionately because tenant farmers outbid each other for superior land. The chief beneficiaries of economic progress, therefore, are the landowners.

Since the root of the trouble, according to Ricardo, is the declining yield of wheat per unit of land, one obvious solution is to import cheap wheat from other countries. Eager to show that Britain would benefit from specializing in manufactured goods and exporting them in return for food, Ricardo hit upon the "law of comparative costs" as proof. He assumed that, within countries, labour and capital are free to move in search of the highest returns; between countries, however, they are not. In these circumstances, Ricardo showed, the benefits of trade are determined by a comparison of costs *within* each country, rather than by a comparison of costs *between* countries. It pays a country to specialize in the production of those goods that it can produce *relatively* more efficiently and to import everything else; although India may be able to produce everything more efficiently than England, India is nevertheless well advised to concentrate its resources on textiles, in which its efficiency is relatively greater, and to import British capital goods. The beauty of the argument is that if all countries take full advantage of the territorial division of labour, total world output is certain to be larger than it will be if some or all countries try to become self-sufficient. Ricardo's law became the fountainhead of 19th-century free-trade doctrine, which would have been enough, if he had said nothing else, to give him a place in the economists' pantheon.

Ricardo's influence

The influence of Ricardo's treatise was felt almost as soon as it was published, and for over half a century the Ricardian system dominated economic thinking in Britain. In 1848 John Stuart Mill's restatement of Ricardo's thought in his *Principles of Political Economy* brought it new authority. After 1870, however, most economists turned their backs on the range of problems that had concerned Ricardo and began to re-examine the foundations of the theory of value; that is, they became interested in the theory of why goods exchange at particular prices, so that for a while they devoted almost all of their efforts to the problem of resource allocation under conditions of perfect competition.

The three generalizations of Marxism

Marxism. A few words must first be said, however, about the last of the classical economists, Karl Marx. The first volume of *Das Kapital* appeared in 1867; the second and third after his death, in 1883 and 1894. For a generation, therefore, the competitive market theorists jostled with the followers of Marx. By 1900 the intellectual battle was over, and thereafter professional economists largely lost interest in Marx. Despite the Russian Revolution, despite what amounts to official endorsement of Marxism in one-third of the world, and despite the lingering influence of Marx's ideas, Marxian economics has been moribund ever since Marx's death in 1881. If Marx may be called "the last of the classical economists," it is because to a large extent he found his economics not in the real world but in the teachings of Smith and Ricardo. They had espoused a "labour theory of value," which holds that products exchange roughly in proportion to the labour costs incurred in producing them. Marx worked out all the logical implications of this theory and added to it "the theory of surplus value," which rests on the axiom that human labour alone creates all value and hence constitutes the sole source of profits. It is an axiom in the sense that it cannot be established in terms of the theory itself: it must be imported from without. To say that an economist is a Marxian economist is in effect to say that he shares the value judgment that it is socially undesirable for some people in the community to derive their income merely from the ownership of property. Since few professional economists in the 19th century accepted this ethical postulate and most were indeed inclined to find some social justification for the existence of private property and the income derived from it, Marxian economics fell on deaf ears. The Marxian system, moreover, culminated in three great generalizations: the tendency of the rate of profit to fall, the growing impoverishment of the working class, and the increasing severity of business cycles, of which the first is the linchpin of all the others. Marx's exposition of the "law of the declining rate of profit" is invalid; with it all of Marx's other predictions fall to the ground. In addition, Marxian economics had little to say on some of the practical problems that are the bread and butter of economists in any society. This is enough to suggest why Marxian economics failed to make many converts among academic economists. Marxists will reply that the reason is simply that academic economists have always been "lackeys of the capitalist class." Perhaps so, but the fact remains that Marx has had virtually no effect on modern economic thought.

The marginalists. The marginal revolution was essentially the work of three men: Stanley Jevons, an Englishman; Carl Menger, an Austrian; and Léon Walras, a Frenchman. Their contribution was the replacement of the labour theory of value by the marginal utility theory of value; their explanation of prices began with the behaviour of consumers in choosing among increments of goods and services (see ECONOMIC THEORY). The idea of emphasizing the marginal or last unit proved in the long run to be more significant than the introduction of utility. It was the consistent application of marginalism that marks the true dividing line between classical theory and modern economics. The classical political economists saw the economic problem as that of predicting the effects of changes in the quantity of capital and labour on the rate of growth of national output. The marginal approach, however, focussed on the conditions under which these factors tend to be allocated with optimal results among competing uses—optimal in the sense of maximizing consumers' satisfactions.

Throughout the last three decades of the 19th century, the English, Austrian, and French contributors to the marginal revolution largely went their own way. The Austrian school dwelt on the importance of utility as the determinant of value and vehemently attacked the classical economists as completely outmoded. A brilliant second-generation Austrian economist, Eugen von Böhm-Bawerk, applied the new ideas to the determination of the rate of interest, putting his stamp for all time on capital theory (see ECONOMIC THEORY). The English school, led by Alfred Marshall, sought a reconciliation with the doctrines of the classical writers. The classical authors, Marshall argued, concentrated their efforts on the supply side in the market; marginal utility theory was concerned with the demand side, but prices are determined by both supply and demand, just as a pair of scissors cuts with both blades. Marshall, seeking to be practical, applied his "partial equilibrium analysis" to particular markets and industries.

The leading French marginalist was Léon Walras, who carried the approach furthest by describing the economic system in general mathematical terms. For each product there is a "demand function" that expresses the quantities of the product that consumers demand as depending on its price, the prices of other related goods, the consumers' incomes, and their tastes. For each product there is also a "supply function" that expresses the quantities producers will supply as depending on their costs of production, the prices of productive services, and the level of technical knowledge. In the market, for each product there is a point of "equilibrium"—analogous to the equilibrium of forces in classical mechanics—at which a single price will satisfy both consumers and producers. It is not difficult to analyze the conditions under which equilibrium is possible for a single product. But equilibrium in one market depends on what happens in other markets (a "market" in this sense being not a place or location but a complex of transactions involving a single good), and this is true of every market. There are literally millions of markets in a modern economy, and therefore "general equilibrium" involves the simultaneous determination of partial equilibria in all markets. Walras' efforts to describe the economy in this way led the historian of economic thought Joseph Schumpeter to call his work "the Magna Carta of economics." Walrasian economics is undeniably abstract, but it provides an analytical framework for incorporating all of the elements of a complete theory of the economic system. It is not too much to say that nearly the whole of modern economics is Walrasian economics. Certainly, modern theories of money, of employment, of international trade, and of economic growth are all Walrasian general equilibrium theories in a simplified form.

The neoclassical era

The years between the publication of Marshall's *Principles of Economics* (1890) and the Great Crash in 1929 may be described as years of reconciliation, consolidation, and refinement. The three national schools gradually coalesced into a single mainstream. The theory of utility was reduced to an axiomatic system that could be applied to the analysis of consumer behaviour under various circumstances, such as a change in income or price. The concept of marginalism in consumption led eventually to the idea of marginal productivity in production, and with it came a new theory of distribution in which wages, profits, interest, and rent were all shown to depend on the "marginal value product" of a factor. Marshall's concept of "external economies and diseconomies" was developed by his leading pupil, Arthur Pigou, into a far-reaching distinction between private costs and social costs, thus laying the basis of welfare theory as a separate branch of economic inquiry. There was a gradual development of monetary theory, which explains how the level of all prices is determined as distinct from the determination of individual prices, notably by the Swedish economist Knut Wicksell. In the 1930s the growing harmony and unity of economics was rudely shattered, first by the simultaneous publication of Edward Chamberlin's *Theory of Monopolistic Competition* and Joan Robinson's *Economics of Imperfect Competition* in 1933 and then by the appearance of John Maynard Keynes's *General Theory of Employment, Interest and Money* in 1936.

The critics. Before going on, it is necessary to take note of the rise and fall of the German Historical school and the American Institutionalist school, which levelled a steady barrage of critical attacks on the orthodox mainstream. The German historical economists, who had many different views, basically rejected the idea of an abstract economics with its supposedly universal laws; they urged the necessity of studying concrete facts in national contexts. While they gave impetus to the study of economic history, they failed to persuade their colleagues that their method was invariably superior. The institutionalists are more difficult to categorize. "Institutional economics," as the term is narrowly understood, refers to a movement in American economic thought associated with such names as Thorstein Veblen, Wesley Clair Mitchell, and John R. Commons. These writers had little in common aside from their dissatisfaction with the abstract theorizing of orthodox economics, its tendency to cut itself off from the other social sciences, and its preoccupation with the automatic market mechanism. They failed to develop a theoretical apparatus that would replace or supplement the orthodox theory. This may explain why the phrase "institutional economics" has become little more than a synonym for "descriptive economics." The hope that institutional economics would furnish a new interdisciplinary social science proved stillborn. (This is perhaps not surprising, because it was by abstracting purely economic forces from the totality of social interactions that economics got so far ahead of the other social sciences in theoretical rigour.) Although there is no longer an institutionalist movement in economics, the spirit of institutionalism is alive in such works as the Harvard economist John Kenneth Galbraith's *The Affluent Society* (2nd ed., 1969) and *The New Industrial State* (1967).

Forms of imperfect competition

Returning to the innovations of the 1930s, the theory of monopolistic or imperfect competition remains somewhat controversial to this day. The older economists had devoted all their attention to two extreme types of market structure, that of "pure monopoly," in which a single seller controlled the entire market for one product, and that of "pure competition," characterized by many sellers, highly informed buyers, and a single, standard product. The theory of monopolistic competition gave recognition to the range of market structures that lie between these extremes, including (1) markets having many sellers with "differentiated products," employing brand names, guarantees, and special packaging that cause consumers to regard the product of each seller as unique; (2) "oligopoly," markets dominated by a few large firms; and (3) "monopsony," markets with a single monopolistic buyer and many sellers (see ECONOMIC THEORY). The theory produced the powerful conclusion that competitive industries in which each seller has a partial monopoly because of product differentiation will tend to have an excessive number of firms, all charging a higher price than they would if the industry were perfectly competitive. Since product differentiation—and the associated phenomenon of advertising—seems to be characteristic of most industries in developed capitalist economies, the new theory was immediately hailed as injecting a healthy dose of realism into orthodox price theory. Unfortunately, its scope was not great enough. It failed to provide a satisfactory theory of price determination under conditions of oligopoly. In advanced economies many of the manufacturing industries are oligopolistic. The result has been to leave a somewhat undigested lump at the centre of modern price theory, a constant reminder of the fact that economists still lack an adequate explanation of the conditions under which the giant firms of rich countries conduct their affairs.

Keynesian economics. The second major breakthrough of the 1930s, the theory of income determination, was primarily the work of one man—John Maynard Keynes. Keynes asked questions that in some sense had never been asked before; he was interested in the level of national income and the volume of employment rather than in the equilibrium of the firm or the allocation of resources. It was still a problem of demand and supply, but "demand" here means the total level of effective demand in the economy, and "supply" means the nation's capacity to produce. When effective demand falls short of productive capacity, the result is unemployment and depression; when it exceeds the capacity to produce, the result is inflation. The heart of Keynesian economics consists of an analysis of the determinants of effective demand. If one ignores foreign trade, effective demand consists essentially of three spending streams: consumption expenditures, investment expenditures, and government expenditures, each of which is independently determined. Keynes attempted to show that the level of effective demand so determined may well exceed or fall short of the physical capacity to produce goods and services: that there is no automatic tendency to produce at a level that results in the full employment of all available men and machines. This fundamental implication of the theory came as something of a shock to exponents of the traditional economics who had been inclined to take refuge in the assumption that economic systems tend automatically to full employment. By keeping his attention focussed on macroeconomic aggregates, like total consumption and total investment, and by a deliberate simplification of the relations between these economic variables, Keynes achieved a powerful model that could be applied to a wide range of practical problems. His system subsequently underwent considerable refinement—some have said that Keynes himself would hardly have recognized it—and became thoroughly assimilated into the body of received doctrine (see ECONOMIC THEORY). Still, it is not too much to say that Keynes is perhaps the only economist to have added something really new to economics since Walras and perhaps since Ricardo.

Keynesian economics as conceived by Keynes was entirely "static"; that is, it did not involve time as an important variable. But a disciple of Keynes, Roy Harrod, soon developed a simple macroeconomic model of a growing economy; in 1948 he published *Towards a Dynamic Economics,* launching an entirely new speciality, "growth theory," which absorbed the attention of an increasing number of economists.

Postwar developments. In the 25-year period following World War II, economics was so totally transformed that those who studied it before the war might as well have lived in another world. First of all, there was an enormous increase in the use of mathematics, which came to permeate virtually every branch of economics. Previously, few economists had made use of mathematics other than differential and integral calculus. Matrix algebra became important with the advent of "input–output analysis," an empirical method of reducing the technical relations between industries to a manageable system of simultaneous equations; it was an attempt to put quantitative flesh on the bones of a general equilibrium model of the economy. A closely related phenomenon was the development of "linear programming" and "activity analysis," which opened up a whole host of industrial problems to numerical solution and introduced economists for the first time to the mathematics of "inequalities" rather than exact equations. Likewise, the emergence of "growth economics" promoted the use of difference and differential equations.

New mathematical tools

Hand in hand with the spread of mathematical economics went an increasing sophistication of empirical work under the rubric of "econometrics," comprising a combination of economic theory, mathematical model building, and statistical testing of economic predictions. The development of econometrics had an impact on economics in general, since those who formulated new theories began to cast them in terms that allowed them to be empirically tested.

The postwar years also saw a renewal of interest in the underdeveloped countries. Economists became aware that they had too long neglected "an inquiry into the causes of the wealth of nations." There was also a conviction that economic planning of one variety or another was needed to close the gap between the rich and poor countries. Out of these concerns came the field of development economics. Regional economics, urban economics, health economics, and the economics of education are other offshoots of the mainstream since 1945.

The postwar tendencies in economic thought were best exemplified, not by the emergence of new techniques or by the addition of new parts to the economics curriculum but by the disappearance of divisive "schools," by the increasingly standardized professional training of economists all over the world, and by the transformation of the science from a rarefied academic exercise to an operational discipline geared to practical advice. This transformation brought prestige to the profession but also a new responsibility: now that economics really mattered, economics had to reckon with the conflict that so often exists between analytical precision and economic relevance.

The question of relevance was at the centre of a "radical critique" of economics that developed along with the campus revolts of the late 1960s. The radical critics declared that economics had become a defense of the status quo and that its practitioners had joined the power elite. The marginal techniques of the economists, ran the argument, were profoundly conservative in their bias, and encouraged a piecemeal rather than a revolutionary approach to social problems; likewise, the tendency in theoretical work to ignore the everyday context of economic activity amounted in practice to the tacit acceptance of prevailing institutions. The critics said that economics should abandon its claim of being a value-free social science and address itself to the great questions of the day—those of civil rights, poverty, imperialism, and nuclear war—even at the cost of analytical rigour and theoretical elegance.

It is true that the study of economics encourages a belief in reform rather than revolution; economics as a science does not provide enough certitude for any thoroughgoing reconstruction of the social order. It is also true that most economists tend to be deeply suspicious of monopoly in all forms, including state monopolies, and to favour competition between independent producers as a way of diffusing economic power. Finally, most economists prefer to be silent on large questions if they have nothing to offer beyond the expression of personal preferences: most economists as economists are fundamentally concerned with the professional standards of their discipline, and this may mean in some cases frankly conceding that economics has as yet nothing very interesting to say about these questions. (It does not mean, however, that they desire to justify the status quo.) Yet the radical critique of modern economics was not to be lightly dismissed. The radical economists were posing issues that were important. At the very least it could do the economic researcher no harm to think about the social and political relevance of his work.

METHODOLOGICAL CONSIDERATIONS IN CONTEMPORARY ECONOMICS

The role of value judgments

Economists are sometimes confronted with the charge that their discipline is not a science. Human behaviour, it is said, cannot be analyzed with the same objectivity as the behaviour of atoms and molecules. Value judgments, philosophical preconceptions, and ideological biases must interfere with the attempt to derive conclusions that are independent of the particular economist espousing them. Moreover, there is no laboratory in which economists can test their hypotheses.

This argument raises issues for all of the social sciences. Only a very general reply can be given here. Economists are wont to distinguish between "positive economics" and "normative economics." Positive economics seeks to establish facts: Will a subsidy to butter producers lower the price of butter? Will a rise in wages in the automobile industry reduce the employment of automobile workers? Will devaluation improve the balance of payments? Does monopoly foster technical progress? Normative economics, on the other hand, is not concerned with matters of fact but with questions of policy, of "good" or "bad": Should the goal of price stability be sacrificed to that of full employment? Should income be taxed at a progressive rate? Should there be legislation in favour of competition?

Positive economics in principle involves no judgments of value; its findings may be as impersonal as those of astronomy and meteorology, two natural sciences that are also denied the advantage of conducting laboratory experiments. As the British philosopher David Hume argued 200 years ago, there is no logical way to deduce "ought" from "is" or prescriptions from descriptions; all statements of fact are ethically neutral. In that sense a value-free economics is possible (at least in principle): if economics is about the application of means to achieve given ends, there would seem to be no reason why one cannot analyze the allocation of means to achieve *any* end. This is not to deny that most of the interesting economic propositions involve the addition of definite value judgments to a body of established facts, that ideological bias creeps into the very selection of the questions that economists investigate, that what is a means from one point of view may be an end from another, nor even that much practical economic advice is loaded with concealed value judgments, the better to persuade rather than merely to advise. This is only to say that economists are human. The commitment of economists the world over to the ideal of value-free positive economics (or to the candid declaration of personal values in normative economics) serves as a defense against the attempts of special interests to bend the science to their own purposes. The best assurance against bias on the part of any particular economist is the criticism of other economists. The best protection against special pleading in the name of science is the professional standards of scientists.

Importance of statistics

Methods of inference. But how, one may ask, are facts established in a science that cannot conduct experiments? In essence, the answer is: by means of statistical inference. Economists typically begin by describing the area under study according to what they feel to be important. Then they construct a "model" of the real world, deliberately repressing some of its features and emphasizing others; they abstract, isolate, and simplify, thus imposing order on a world that at first glance appeared disorderly. Having evolved an admittedly unrealistic representation of the real world, they then manipulate the model by a process of logical deduction, arriving eventually at some prediction or implication that is of general significance. At this point, they return to the real world to see whether or not the prediction is borne out by observed events.

But the observable events that are available to test a theory never exhaust the population of all such events: they are merely a sample of it. This raises the problem of statistical inference; namely, what can be inferred about a population from a sample of the population? The theory of statistical inference is simply an agreed-upon procedure for making such inferences, but in the nature of the case it never succeeds in removing all elements of judgment from an inference. Thus the empirical truths of economics are invariably surrounded by a band of doubt, and economists speak of them as "probable" or "likely"; they are propositions in which economists have "a certain degree of confidence" because it is unlikely that they could have come about by chance.

It follows that judgments are at the heart of both positive and normative economics. It is easy to see, however, that judgments about "degrees of confidence" and "statistical levels of significance" are of a totally different order from those that crop up in normative economics. When men say that every individual should be allowed to spend his income as he likes, that people should not be free to control material resources and to employ others, or that governments must offer relief for the victims of inexorable economic forces, they are making the kind of value judgments that laymen have in mind when they accuse economists of producing personal preferences in the guise of scientific conclusions. There is no room for such value judgments in positive economics.

Testing theories. In the past some economists tended to claim too much for their propositions. Economic models were said to be based on fundamental axioms and premises about economic behaviour that were absolutely true a priori because they were derived from an examination of one's own economic behaviour. Since the theorems of the model were deduced from these axioms by the laws of logic, the theorems also were held to be true a priori. Economic models did not need to be confronted with empirical evidence.

The problem of validity

This extreme apriorist position may be contrasted with the ultraempiricist view, which holds that one must begin and end with observable facts; the latter approach, however, has never appealed to more than a small minority of economists. In the middle ground between these two sharply opposing views is the methodological position that has found increasing acceptance among modern economists. It argues that one must test the predictions or conclusions of a model but without worrying too much about the realism of its premises, axioms, or assumptions. Most assumptions in economic theory cannot be tested directly. For example, there is the famous assumption of price theory that businessmen strive to maximize profits. Attempts to find out whether they do, by asking them, usually fail; after all, businessmen are no more fully conscious of their own motives than other people are. A logical approach would be to observe businessmen in action. But that would require knowing what sort of action is associated with profit maximizing, which is to say that one would have drawn out all the implications of a profit maximizing model. Thus one would be testing an assumption about business behaviour by comparing the predictions of a theory of the firm with observations from the real world.

This is not as easy as it sounds. Since the predictions of economics partake of the nature of probability statements, there can be no such thing as a conclusive, once-and-for-all test of an economic hypothesis. The science of statistics cannot prove any hypothesis, it can only fail to disprove it. A theory that survives a statistical test is not true as such; it is only provisionally true because it has so far resisted all attempts to falsify it. Attempts to falsify economic hypotheses never yield unambiguous results, and hence economic theories tend to survive until they are falsified repeatedly with new or better data. This is not because they are *economic* theories but because the attempt to compare predictions with outcomes in the social sciences is always limited by the rules of statistical inference.

It is not remarkable that competing theories exist to explain the same phenomena, with economists disagreeing as to which theory is to be preferred. While virtually all economists today agree that theories should be submitted to empirical testing and that the theory is to be preferred that allows predictions that conform, in a probabilistic sense, most closely to observable events, this precept can be very difficult to apply in practice. There have been periods in the history of economics when there was overwhelming agreement in the profession as to which models or theories were "true." But a period of consensus may be followed by a generation of doubt until a new departure is made that succeeds in producing a new consensus. In this, economics is not very different from physics.

Much has been written about the doubtful accuracy of economists' predictions. Of course, economists cannot foretell the future as such; only soothsayers do that. Economists can foretell the effects of specific changes in the economy, but they are better at predicting the direction than the actual magnitude of events. When economists predict that a tax cut will raise national income, one may be confident that the prediction is accurate; when they predict that it will raise national income by a certain amount in three years, however, the forecast is likely to miss the mark. The reason is that most economic models do not contain any explicit reference to the passage of time and hence have little to say about how long it takes for a certain effect to make itself felt. Short-period predictions generally fare better than long-period ones, in part because most economic models rely on propositions about the plans and intentions of economic agents, whereas the data on which the theories are tested are derived from past events. This is disappointing, but it does not mean that economics is not a science.

The firm and the household

Microeconomics. Since Keynes, economic theory has been of two kinds: macroeconomics—or the study of the determinants of national income—and the traditional microeconomics. The latter approaches the economy as if it were made up only of business firms and households (ignoring governments, banks, charities, trade unions, and all other economic institutions) interacting in two kinds of markets—product markets and markets for productive services, or factor markets. Households appear as buyers in product markets and as sellers in factor markets, where they offer men, machines, and land for sale or hire. Firms appear as sellers in product markets and as buyers in factor markets. In each type of market, price is determined by the interaction of demand and supply, and the problem of microeconomic theory is to say something meaningful about the forces that make up demand and supply.

Theory of choice. At first it appears that all one can say is that everything depends on everything else. But firms and households do not behave in a vacuum. Firms face certain technical constraints in producing goods and services, and households have definite preferences for some products over others. It is possible to express the technical constraints facing business firms by writing down a series of "production functions," one for each firm. A production function is simply a kind of equation that expresses the fact that the output of a firm depends on the quantity of inputs it employs and, in particular, that inputs can be technically combined in different proportions to produce a given level of output. A production engineer could calculate, on the basis of existing technical knowledge, the largest possible output that could be produced with every possible combination of inputs and in this way could define a boundary to the range of production possibilities open to a firm. By itself this does not tell how much the firm will produce or what mixture of products it will make or what combination of inputs it will adopt: these depend on the prices of products and the prices of inputs (or "factors of production"), which have yet to be determined. One may assume that the firm is motivated in a particular way: it wants to maximize profits, which are defined as the difference between the sales value of its output and the money outlays required to obtain its inputs. It will, therefore, select that combination of inputs that minimizes the costs of producing any given quantity of output and will select from the range of possible combinations of products that combination that maximizes its revenues. This is to say that it always tries to move along its production function, along the edge of the boundary of technical possibilities. But where it ends depends, in part, on the demand for its products. This leads to the part played by households in the system.

Households are endowed with definite "tastes" that can be expressed in a series of "utility functions," one for each household. A utility function is an equation like a production function, expressing the fact that the pleasure or satisfaction that households derive from consumption depends on the products that they purchase and on the various ways in which they combine these products in consumption to yield a given level of satisfaction. The utility function need not be specified in the same detail as a production function. One may think of it as a general description of the household's preferences between all the paired alternatives with which it will be confronted. Here, too, it is necessary to assume something about motivation to make any progress: the assumption is that households seek to maximize satisfaction, distributing their given incomes among available consumer goods in such a way as to derive the largest possible "utility" from consumption. Their incomes, however, remain to be determined.

Supply and demand curves

The purpose of production functions in economic theory is to provide an anchor in the bedrock of technology from which to derive the "supply curves" of firms in product markets and the "demand curves" of firms in factor markets. Similarly, the purpose of utility functions is to provide an anchor in subjective "tastes" from which to derive the "demand curves" of households in product markets and the "supply curves" of households in factor markets. All of these demand and supply curves express the quantities demanded and supplied as a function of prices, not because price is the only determinant of economic behaviour but because the purpose is to have a theory of price determination. Much of economic theory is devoted to showing how various production and utility functions, coupled with certain assumptions about behaviour, lead to demand and supply curves in which the quantity demanded is inversely related and the quantity supplied positively related to price. The figure depicts these relationships (curves would be just as suitable as straight lines).

Not all demand and supply curves look alike. The essential point is that most demand curves are negatively inclined, while most supply curves are positively inclined. This may seem a modest result for a great deal of effort, but the argument has powerful implications. The participants in a market will be driven automatically to the price at which the two curves intersect; this price p is called the "equilibrium" price or "market-clearing" price because it is the only price at which supply and demand are equal. If it is a market for butter, any change in the production function of dairy farmers or in the utility function of butter consumers or in the prices of cows, grassland, and milking equipment or in the incomes of butter consumers or in the prices of nondairy products that consumers buy can be shown to lead to definite changes in the equilibrium prices of butter and in the equilibrium quantity of butter produced. Better still, the effects of a government ceiling on the price of butter or of a tax on butter producers or of a price-support program for dairy farmers can be predicted with almost perfect certainty. As a rule, the prediction will refer only to the direction of change (the price will go up or down); but if the demand and supply curves of butter can be defined in quantitative terms on the basis of past data, one may be able to predict the actual magnitude of the change.

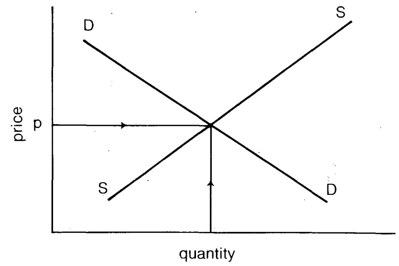


Illustration of the relationship of price to supply (S) and demand (D).

Theory of allocation. This analysis of the behaviour of firms and households is to some extent symmetrical: all economic agents are conceived of as ordering a series of attainable positions in terms of an entity they are trying to maximize. For a firm these attainable positions are essentially input combinations; for a household they are product combinations. From the maximizing point of view, some combinations are better than others; the best combination is called the "optimal" or "efficient" combination. The rule for efficient, optimum allocation may now be stated baldly: an optimum allocation is one that equalizes the returns of the marginal or last unit to be transferred between all the possible uses. In the theory of the firm, an optimum allocation of outlays among the factors of production implies that the "marginal physical product" of an additional dollar devoted to hiring the services of any one of the factors is the same for all factors; the so-called law of eventually diminishing marginal productivity, a property of a wide range of production functions, ensures that such an optimum exists. In the theory of consumer behaviour an optimum situation obtains when the consumer has distributed his given income in such a way that the "marginal utility" of each additional dollar spent on any of the products purchased is equal for all products; the "law of eventually diminishing marginal utility," a property of a wide range of utility functions, ensures that such an optimum exists. These are merely particular examples of the "equimarginal principle," which is not only at the core of the theory of the firm and the theory of consumer behaviour but also underlies the theory of money, of capital, and of international trade. In fact, the whole of microeconomics is nothing more than the spelling out of this principle in ever wider contexts.

Law of diminishing marginal productivity

The equimarginal principle is, of course, applicable to any decision that involves alternative courses of action. Economics furnishes a technique for thinking about decisions, whatever their character and whosoever makes them. Military planners may, for example, consider a variety of weapons in the light of a single objective, that of damaging an enemy; some of the weapons are effective against the enemy's army, some against the enemy's navy, and some against his air force; the problem is to find an optimal allocation of the defense budget, one that equalizes the marginal contribution of each type of weapon. But defense departments rarely have single objectives; along with maximizing damage to an enemy there may be another objective, such as minimizing losses from attacks. In that case, more than the equimarginal principle is needed for a decision; it is necessary to know how the department ranks the two objectives in order of importance, since different rankings will imply different optima. But a ranking of objectives is simply a utility function or a preference function.

In other words, when an institution pursues multiple ends, decisions about how to achieve them require a weighting of the ends. Every decision involves a "production function"—a statement of what is technically feasible—and a "utility function"; the equimarginal principle is then invoked to provide an efficient, optimal strategy. This applies just as well to the running of hospitals, churches, and schools as to the conduct of a business enterprise, to the location of an international airport as well as to the design of a development plan for an underdeveloped country. This is why economists crop up in what seem to be the most unlikely places, advising on activities that are obviously not being conducted for economic reasons.

The different approach of macroeconomics

Macroeconomics. There is, however, an approach to economics in which the foregoing considerations do not apply. That is the field known as macroeconomics. In macroeconomics one is concerned with the aggregate outcome of individual actions. Keynes's "consumption function," for example, which relates aggregate consumption to national income, is not built up from individual consumer behaviour; it is simply an empirical generalization. The focus is on income and expenditure flows rather than on markets. Purchasing power flows through the system from business investment to consumption, but it leaks out at two places in the form of personal and business savings. Counterbalancing the savings are investment expenditures in the form of new capital goods, houses, and so forth, which constitute a source of new injections of purchasing power in every period. Since savings and investments are carried out by different people for different motives, there is no reason why "leakages" and "injections" should be equal in every period. If they are not equal, national income, the sum of all income payments to the factors of production, will rise or fall in the next period. When planned savings equal planned investment, income will be at an equilibrium level, that is, a level at which it can sustain itself; when the plans of savers do not match those of investors, the level of income will go on changing until the two do match. One can complicate this simple model by making investment a function of the interest rate; by introducing the government budget, the money market, labour markets, imports and exports, foreign investment; and so forth. But all this is far removed from the problem of resource allocation and from the maximizing behaviour of individual economic agents.

The result is a kind of intellectual schizophrenia in which the techniques of microeconomics do not carry over fully into macroeconomics and vice versa. This is widely held to be an unsatisfactory state of affairs; economists have in recent years sought to build a bridge between the individual consumer and the overall consumption function and between the individual investor and the behaviour of aggregate investment. Nevertheless, the bridge remains incomplete, and the student of economics must be prepared to work with two boxes of tools.

FIELDS OF CONTEMPORARY ECONOMICS

The following is a bird's-eye view of the main fields of contemporary economics.

Public finance. Since the time of Ricardo economists have been concerned with the incidence of taxes, that is, with determining who it is that really pays a tax. If a corporation faced with a profits tax reacts by raising its prices, it may succeed in making the consumer pay the tax; on the other hand, if sales decline as a result of the rise in price the firm may have to lay off some of its workers, and the burden of the tax will be shared by consumers, wage earners, and shareholders. This simple example shows how complex may be the actual incidence of a tax. A large part of the literature of public finance in the 19th century was devoted to such problems.

Taxes and government expenditures

Keynesian economics brought new dimensions to public finance: the older preoccupation with tax incidence gave way to the analysis of the impact of government expenditures on the level of income and employment (see GOVERNMENT FINANCE). It was some time, however, before economists realized that they lacked a theory of government expenditures, that is, a set of criteria for determining what activities should be supported by governments and what should be the relative expenditure on each. One of the most exciting recent developments in the field of public finance is the attempt to devise such criteria. Decisions on public expenditures have proved to be susceptible to much of the traditional analysis of microeconomics. In the 1960s there developed a technique known as "cost–benefit analysis," which tries to appraise all of the economic costs and benefits, direct and indirect, of a particular activity so as to decide how to distribute a given public budget most effectively between different activities. This technique has been applied to everything from the construction of hydroelectric dams to the control of tuberculosis. Its exponents hope that the same type of analysis that has proved so fruitful in the past in analyzing individual choice may also succeed with problems of social choice.

Money. One of the oldest, widely accepted functions of government is control over the supply of money. The dramatic effects of changes in the quantity of money on the level of prices and the volume of economic activity were recognized and thoroughly analyzed in the 18th century, and monetary economics has ever since constituted one of the principal branches of economics. In the 19th century a complex and somewhat crudely formulated tradition grew up known as the "quantity theory of money," which held that any change in the supply of money can only be absorbed by variations in the general level of prices (the purchasing power of money). In consequence, prices will tend to change proportionately with the quantity of money in circulation. As the growth of fiat paper money gave governments increasingly effective control over the stock of circulating media, the quantity theory of money supplied an apparently simple rationale for the management of the economy: all that was needed to prevent inflation or deflation was to vary the quantity of money in circulation inversely with the level of prices.

Keynes's attack on monetary policy

One of the targets of Keynes's attack on traditional thinking in his *General Theory of Employment, Interest and Money* was this quantity theory of money. Keynes produced a different theory of the demand for money that implied that the impact of a change in the stock of money on the level of national income is weak and at best indirect; the effect on prices is virtually nil, he maintained, at least in economies with heavy unemployment such as prevailed in the 1930s. He put his emphasis instead on government budgetary and tax policy and direct control of investment. As a consequence, economists lost faith in monetary management and came to regard monetary policy as more or less ineffective in controlling the volume of economic activity.

In the 1960s there was a remarkable revival of the older view, at least among a small but growing school of American monetary economists. They accepted much of Keynesian economics but argued that the effects of fiscal policy are unreliable unless the quantity of money is regulated at the same time. They refurbished the quantity theory of money and tested the new version on a variety of data for different countries and for different time periods, leading to the broad conclusion that the quantity of money does matter (see MONEY).

In the late 20th century the controversy was still raging. It is notable that this debate, unlike previous debates in the history of monetary economics, was characterized by disputes over empirical findings—that is, it was focussed on the testable character of different monetary theories rather than on the manner of their formulation. Progress was made slower by the political overtones of the controversy: in some countries, belief in the efficacy of monetary policy had become a kind of litmus test of political conservatism. Nevertheless, a reconciliation between Keynesians and quantity theorists needed only some agreement as to the magnitude of monetary forces and the degree of stability of the demand for money. Monetary economics seemed at last to be coming of age as an empirical discipline.

International economics. The foundations of international economics were firmly established in the 19th century. The subject has consisted ever since of two distinct but connected parts: (1) the "pure theory of international trade," which seeks to account for the gains obtained from trade and to explain how these gains are distributed among countries, and (2) the "theory of balance-of-payments adjustments," which analyzes the workings of the foreign exchange market, the effects of alterations in the exchange rate of a currency, and the relations between the balance of payments and the level of economic activity.

In modern times, the Ricardian pure theory of international trade has been reformulated by the American Paul Samuelson, improving on the earlier work of two Swedish economists, Eli Heckscher and Bertil Ohlin. The so-called Heckscher-Ohlin theory explains the pattern of international trade as determined by the relative land, labour, and capital endowments of countries: a country will tend to have a relative cost advantage in goods requiring the intensive use of the country's relatively abundant factor of production (thus land-rich Canada exports wheat) and to import goods requiring the intensive use of the country's relatively scarce factor (thus capital-poor Canada imports American automobiles). This theory absorbs Ricardo's law of comparative costs but goes beyond it in linking the pattern of trade to the economic structure of trading nations. It implies that foreign trade is a substitute for international movements of labour and capital—which raises the intriguing question of whether or not foreign trade may work to equalize the prices of all factors of production in all trading countries. Whatever the answer, the Heckscher-Ohlin theory provides a model for analyzing the effects of a change in trade on the industrial structures of economies and, in particular, on the distribution of income between factors of production. Much of the recent effort of specialists in international economics has gone toward refining the Heckscher-Ohlin model and testing it on an ever wider range of empirical evidence.

The economics of labour and industry

Labour. Like monetary and international economics, labour economics is an old economic speciality. It gets its raison d'être from the peculiarities of labour as a commodity. Labour itself is not bought and sold; rather, its services are hired and rented out. But since people cannot be disassociated from their services, various nonmonetary considerations play a role in the sale of labour services as contrasted with the sale of machine time or the rental of land. Yet, the bulk of the literature in labour economics was until recently concerned solely with the demand side of the labour market. Wages, the textbooks all said, were determined by the "marginal productivity of labour," that is, by the relationships of production and by consumer demand. If the supply of labour came into the picture at all, it was merely to allow for the presence of trade unions; unions could only raise wages by limiting the supply of labour.

After a long period of neglect, the supply side of the labour market began, in the 20th century, to attract the attention of economists. First, attention shifted from the individual worker to the household as a supplier of labour services; the increasing tendency of married women to enter the labour force and the wide disparities and fluctuations observed in the rate that females participate in a labour force drew attention to the fact that an individual's decision to supply labour is not independent of the size, age structure, and asset holdings of the household to which he or she belongs. Second, the new concept of "human capital"—that people make capital investments in their children and in themselves by incurring the costs of education and training, the costs of searching for better job opportunities, and the costs of migration to other labour markets—has served as a unifying explanation of the diverse activities of households in labour markets. In this way, capital theory (see ECONOMIC THEORY) has become the dominant analytical tool of the labour economists, replacing or supplementing the traditional theory of consumer behaviour. The economics of training and education, the economics of information, the economics of migration, the economics of health, and the economics of poverty are some of the by-products of this new perspective. A field that was at one time regarded as rather cut-and-dried has taken on new vitality.

Labour economics, old or new, has always regarded the explanation of wages as its principal task, including the factors determining the general level of wages in an economy and the reasons for wage differentials between industries and occupations. Wages are influenced by trade unions; the impact of their activities is of increased importance at a time when most governments manage the economy with one eye on the unemployment statistics. The prewar fears of chronic unemployment gave way to the postwar fears of chronic inflation at or near levels of full employment. In response to this a vast literature sprang up after 1945 analyzing the inflationary pressures stemming from both the supply side and the demand side of labour markets. Whether prices were being pushed up by the labour unions ("cost push") or pulled up by excess purchasing power ("demand pull") became the issues in this long debate on inflation, a controversy that is, of course, intimately related to the quarrels in monetary economics mentioned earlier.

Industrial organization. The principal concerns of this field are the structure of markets, public policy toward monopoly, the regulation of public utilities, and, of late, the economics of technical change.

The monopoly problem, or, more precisely, the problem of the maintenance of competition, does not fit well into the received body of economic thought. Economics started out, after all, as the theory of competitive enterprise, and even today its most impressive theorems require the assumption of numerous small firms, each having a negligible influence on price. Yet the typical market structure of manufacturing today is that of oligopoly—competition among the few—and some industries are dominated by firms so large that their annual sales volume exceeds the national income of the smaller countries of western Europe. It is tempting to leap to the conclusion that oligopoly is deleterious to economic welfare, on the ground that it leads to the misallocation of resources. But some economists, notably Joseph Schumpeter, have argued that economic growth and technical progress are brought about not through free competition but through large firms and the destruction of competition. According to this view, monopoly has its origin in the need of business firms to protect themselves from the risks associated with the introduction of new products, new techniques, and new methods of marketing. The giants, therefore, compete not in price but in successful innovation, and this kind of competition has proved more effective for economic progress than the more traditional price competition described in orthodox textbooks of economic theory.

Merits of monopoly and competition

Although this thesis smacks of *post hoc ergo propter hoc* ("after this, therefore because of this")—giant firms have prospered in rapidly growing economies; therefore, growth is due to giant firms—it makes the merits of "trust busting" and cartel dissolution somewhat less compelling. The question is what sort of competition is socially most desirable. If each of four or five large firms in an oligopolistic industry finds it necessary to compete in terms of the quality of its products and its research or by means of better technology and superior merchandising, the performance of the industry may well be more satisfactory than if it were reorganized into a price-competitive industry. But if the four or five giants settle down to a quiet life and concentrate their rivalry on sales promotion techniques, the verdict must be less favourable. One cannot, it seems, draw facile conclusions about the competitive results of different market structures; it is necessary to approach the monopoly problem with a generous dose of pragmatism.

The reason why there is so much uncertainty in the economic discussion of policies toward big business is the lack of a general theory of oligopoly. There are dozens of special theories applying to special cases, but there is no single, organizing framework with testable implications about the behaviour of oligopolists in general.

Agriculture. Farming has long provided economists with their favourite example of a perfectly competitive industry. But with increasing government regulation of agriculture, it also provides striking examples of the effects of price controls, income supports, output ceilings, and marketing cartels. Agricultural economics commands attention wherever governments wish to stimulate farming or to protect farmers—which is to say, everywhere.

Agricultural economists generally have been closer to their subject matter than other economists. In consequence, more is known about the technology of agriculture, the nature of farming costs, and the demand for agricultural goods than is known about any other industry. The student of economics who wants to learn how to estimate a production function or a demand curve is well advised to go to the literature on agricultural economics.

The underdeveloped countries have furnished a new laboratory for agricultural economics. Many such countries have a "subsistence agriculture," in which the farmer produces mainly for his own family consumption and brings to market only what is left over. Subsistence farmers are only tenuously linked to the money economy. They are more reluctant than commercial farmers to take the risks entailed in experimenting with new seeds, fertilizers, and farming methods: given the vagaries of the weather, they prefer to operate on the basis of the worst weather that can be expected rather than the best or even the average. While the pessimism of subsistence farmers is perfectly rational, it makes the task of predicting their response to new prices or new methods doubly difficult. The economist must also recognize that every agricultural area presents its own production, processing, and marketing problems. To suggest changes that will raise agricultural productivity in these circumstances is no easy task, and agricultural economists often find themselves warning governments not to intervene too vigorously, since much intervention in the past has been shown to be wrong or inappropriate.

The problem of economic development in Africa, Asia, and Latin America centres on the agricultural sector; one of the abiding questions is how far industrialization can proceed without there first being an agricultural revolution. For this reason, if for no other, agricultural economics has a large future.

Growth and development. The study of economic growth and development is not a single branch of economics but falls, in fact, into two quite different fields. The two fields—"growth" and "development"—employ different methods of analysis and are indeed addressed to two distinct types of inquiry.

Development economics is easy to describe. It is one of the three major subfields of economics, the other two being microeconomics and macroeconomics. Development economics resembles economic history in that it seeks to explain the changes that take place in economic systems with the passage of time.

The subject of economic growth is not so easy to characterize. It is the most technically demanding field in the whole of modern economics, impossible to grasp for anyone who lacks differential calculus. Its focus is the properties of equilibrium paths, rather than equilibrium states. One makes a model of the economy and puts it into motion, requiring that the time paths described by the variables be self-sustaining in the sense that they continue to be related to each other in certain characteristic ways. Then one can investigate the way economics might approach and reach these steady-state growth paths from given starting points. Beautiful and frequently surprising theorems have emerged from this experience, but as yet there are no really testable implications nor even definite insights into how economies grow.

Harrod–Domar growth model

Growth theory began with the work of Roy Harrod in England and Evsey Domar in the United States. Their joint product has been known ever since as the Harrod–Domar model. Keynes had shown that new investment has a multiplicative effect on income and that the increased income generates extra savings to match the extra investment, without which the higher income level could not be sustained. One may think of this as being repeated from period to period, remembering that investment, apart from raising income disproportionately, also generates the capacity to produce more output that cannot be sold unless there is more demand, that is, more consumption and more investment. That is all there is to the model. It contains one behavioral condition—that people tend to save a certain proportion of extra income, a tendency that can be measured. It contains one technical condition—that investment generates additional output, a fact that can be established. And it contains one equilibrium condition—that planned saving must equal planned investment in every period if the income level of the period is to be sustained. Given these three conditions, the model generates a time path of income and even indicates what will happen if income falls off the path.

More complex models have since been built, incorporating different saving ratios for different groups in the population, technical conditions for each industry, definite assumptions about the character of technical progress in the economy, monetary and financial equations, and much more.

Mathematical economics. Differential calculus has long been the traditional tool of mathematical economics. Many economic problems, particularly in microeconomics, take the form of maximizing some variable (such as profits) subject to a constraint (such as the production function), for which calculus supplies the simplest technique. Traditionally it was applied to problems in comparative statics. These problems include so-called endogenous variables, the values of which are determined within the model, as well as constants that originate outside the model and are called "exogenous variables" or "parameters." The object is to discover the effects of changes in one or more of the parameters upon the equilibrium situation. The latter is a situation in which all of the endogenous variables are simultaneously in a state of rest. If the value of some of the parameters is changed, the result is a new equilibrium state.

The application of mathematical methods

Much economic analysis, even when it is expressed in words, is simply the method of comparative statics. But comparative statics has its limitations: it tells the investigator *where* the system will arrive, but it does not tell him *when* it will arrive or what will happen along the way; and it cannot tell him whether, once driven out of the way, it will ever get back to its destination. In other words, comparative statics ignores the process of adjustment from the old equilibrium state to the new one, and it entirely neglects the time element in that adjustment process. The study of this process of adjustment over time is called "economic dynamics," and one may think of it as the economics of disequilibria.

Just as differential calculus is the mathematics of comparative statics, difference and differential equations are the ideal tools for handling dynamic problems. Difference equations deal with time as a discrete variable—changing only from period to period—whereas differential equations treat time as a continuous variable; the choice between them is simply one of convenience. They enable one to ask such questions as: if the system is pushed out of equilibrium, perhaps because one of the parameters of the model has changed, will economic forces drive it toward a new equilibrium position or away from one, will the time path described by the endogenous variables be steady or fluctuating, and if fluctuating, will the movements be damped down or will they increase and become explosive?

Economic dynamics is one of the newer developments of mathematical economics, and often it falls short of the ambitious demands made on it. Dynamic models, for example, are typically formulated in terms of linear equations, not because the world is linear but because nonlinear equations can be very difficult to solve. Likewise, the coefficients of difference and differential equations are usually taken to be constants, again for the sake of making the mathematics of the analysis manageable. This means that if the economic environment changes as the model runs its course, its predictions will be false. An abiding danger in all mathematical economics is the tendency to adopt economic assumptions for the sake of mathematical convenience. The way to meet this danger is for economists to acquire enough mathematical sophistication so that they will not be dazzled by displays of mathematical technique.

Econometrics. Like mathematical economics, econometrics is something economists do rather than a special area of interest. Econometrics refers to the study of empirical data by statistical methods, the purpose of which is the testing of hypotheses and the estimation of relationships suggested by economic theory. Whereas mathematical economics considers the purely theoretical aspects of economic analysis, econometrics attempts to falsify theories that are expressed in explicit mathematical terms. But frequently the two go together.

The classic technique for estimating an economic relationship is that of "least squares," which is a method of fitting a trend line to a scatter of observations that minimizes the square of the deviations of the observed points from the line. To take a simple example: the Keynesian theory assumes that consumers' expenditures depend principally on income; one may interpret this to mean that consumption depends *only* on income and then test the hypothesis by trying to fit a trend line to a series of observations of income and consumption over a period of time. In so doing, one is really saying that the observations that fall to either side of the line are due either to errors in measuring the variables or to errors in specifying the relationship between consumption and income. It is essential to the method of least squares that these "errors" be randomly distributed or at any rate distributed in known ways. When this condition is violated, least squares estimates are unreliable. It is sometimes difficult to tell with economic data just how the errors are randomly distributed, and it is precisely for this reason that an econometrician is needed rather than an ordinary statistician.

Problem of error distribution

A still more significant trend in recent econometrics is the tendency to move from single-equation estimates (such as the relationship between consumption and income) to systems of simultaneous equations. While consumption depends on income, income also depends on consumption; this kind of interdependence requires two equations rather than one. More generally, most economic variables are the result of demand and supply forces that simultaneously determine quantities and prices. To estimate a demand curve for butter from a single-equation regression (by relating the price of butter to the quantities of butter consumed, the incomes of consumers, and the prices of near substitutes for butter) is likely to produce a biassed answer because the price of butter is also influenced by supply conditions in the dairy industry. This creates the so-called identification problem, namely, the question of whether it is possible to identify a demand curve or a supply curve from observed price–quantity data. The use of simultaneous equation models to estimate economic relationships is by now perhaps the best way of distinguishing econometrics from economic statistics.

The foregoing discussion covers only nine major branches of economics. There are many other fields in economics, including economic history, comparative economic systems, business cycles, economic forecasting, national income accounting, managerial economics, business finance, marketing, the economics of natural resources, economic geography, consumer economics, and regional economics.

(M.Bg.)

Political science

Political science is most generally understood to mean the systematic study of government processes by the application of scientific methods of analysis. More narrowly and more traditionally, it has been thought of as the study of the state and of the organs and institutions through which the state functions. In most countries, political science is thought to be a single discipline, but the plural form has been used in France, as in the name of the École Libre des Sciences Politiques (now Institut d'Études Politiques de l'Université de Paris), founded in 1871—although there is also an Association Française de Science Politique. Speculation about political subjects is not unknown in ancient non-Western cultures, but most students agree that the roots of political science are to be found in the earliest sources of Western thought, especially in the works of Aristotle, who is recognized by many as the founder of political science.

Political science and political philosophy

Although political science may be distinguished from political philosophy, the distinctions are unsatisfactory inasmuch as they lack categorical rigour. In the most usual distinction, political philosophy is thought to be concerned primarily with the study of political ideas, often within the context of their times. It is strongly normative in its thrust and disposition and rationalistic in its method. Political science, however, concerns itself with institutions and behaviour, eschews normative judgments as much as possible, and attempts to derive principles from objective facts with as much quantification as the evidence will allow. Political philosophy thus speculates about the place and order of values, the principles of political obligation (why men should or should not obey political authority), and the nature of such terms as right, justice, and freedom. Political science, on the other hand, seeks to establish by observation (and, if possible, by measurement) the existence of uniformities in political behaviour and to draw correct inferences from these data. The stated differences between political philosophy and political science are less than is sometimes supposed, for the most empirical scholar in both the social and natural sciences makes use of unproved postulates, hunches, and intuitions; and the most rationalistic philosopher employs conceptions that embody empirical statements.

Some theorists, however, who believe it possible to develop a completely value-free science of politics insist that the distinction between political philosophy and political science is not faint but vivid. It is their opinion that only a few hundred philosophers and political theorists have ever contributed to systematic speculation about and study of politics. It was said in 1966 by one of the exponents of this view that "probably two out of every three political scientists who have ever lived are alive and practicing today." In this view, political philosophy is believed to be addicted to obscurity and opacity of statement—an effort to bespeak the unspeakable—and it is thought that its task should be a more modest one, namely, to grope with the grammar of philosophical statements. This would require political philosophers to put their intelligence to the elucidation of the language of politics and to expose the difficulties placed by language in the consideration of matters of fact. One of those interested in this approach was the English political philosopher T.D. Weldon in *The Vocabulary of Politics* (1953), but few have followed his initiative.

Scientific status of the subject

The question as to whether political science is a science is largely inconsequential, because the problem is primarily one of definition. If the term science is to be applied to any body of systematically organized knowledge based on facts ascertained by empirical methods and described by as much measurement as the material allows, then political science is a science, just as are the other social disciplines. If, on the other hand, the term science is to be limited to those disciplines in which the scholar can control the materials to be studied and can perform experiments that others can reproduce under the same conditions and in which predictability is possible, then the label is less appropriate, although not entirely misapplied. The American political economist Thorstein Veblen denied that political science was anything more than a "taxonomy of credenda," and, more recently, a British writer, Bernard Crick, has said that the hope of creating an artificial science of politics on natural principles, although not originally and uniquely American, has been largely generated and sustained by two aspects of the American culture—an agreement on liberal doctrine that has made politics less a matter of serious doctrinal splits than of mere disagreement among partisans of the same creed, and a general national preoccupation with technology.

HISTORICAL DEVELOPMENT OF POLITICAL SCIENCE

Early trends. The origins of contemporary political science are to be found in the enthusiasm for the creation of social science that was widespread in the 19th century, an enthusiasm stimulated by the rapid growth of the natural sciences. It might be said that one starting point for the development of modern political science is the work of the Comte Henri de Saint-Simon, a notable Utopian Socialist, who in 1813 suggested that morals and politics could become "positive" sciences; that is, disciplines whose authority to command belief would rest not upon subjective preconceptions but upon objective evidence. With him worked the mathematician and philosopher Auguste Comte, the two collaborating in the publication in 1822 of the *Plan of the Scientific Operations Necessary for the*

Reorganization of Society, which argued, among much else, that politics would become social physics and that the purpose of social physics was to discover unchanging laws of progress. Out of this collaboration emerged the law of the three stages through which knowledge had to pass—the theological, the metaphysical, and the positive—that Comte was to establish as the theme of the science of social physics, a study he came to name sociology. An intellectual connection between political science and sociology was thus early established in schemes of political and social regeneration and reform, although political science was thought to be limited to only one form of association in society, namely, the state. Comte thought that the principal methods for the study of social phenomena were observation, experiment, and abstraction. Although one might have thought that politics could not be an experimental science, Comte was of the view that political experimentation did take place whenever there was a change in the life of the state, intended or not. It must be said, however, that even on this account there is no close similarity to experimentation in chemistry and physics, in which all the variables can be controlled.

In the search for more objective methods of inquiry into political and other social phenomena in the 19th century, contributions to the explanation of the state were supplied by several new intellectual disciplines. Because political science deals with some aspects of human behaviour, for example, it is closely allied to other social sciences that also deal with human behaviour. Long before the development of scientific inquiries in the 19th century, numerous theories of the state had drawn inspiration from the human being as model, as in the *Policraticus* of John of Salisbury (1159), in which the physiology of the body and that of the state are compared; or in *The Republic* of Plato, in which the elements of the human personality prefigure the class structure of the state; and in Rousseau's *Contrat Social,* in which the political order is animated by a general will (will being a human attribute). The positivism of the 19th century, however, brought new approaches to the study of the state, although the older ones continued to coexist with them. Among those following Comte was the Polish-born sociologist Ludwig Gumplowicz, who built a sociology on Comtean foundations but who owed much also to Darwin, to the social Darwinist Herbert Spencer, and to contemporary anthropology. In Gumplowicz' view, the earliest forms of group life were small hordes bound by consanguinity, which developed into matriarchies and patriarchies. He supposed the existence of a social-evolutionary process characterized by conflicts between autonomous groups and by conflicts of interest within those groups. The product of this process was the state, founded on force and maintained by power.

Sociological analyses of the state

Gumplowicz and several other 19th-century political sociologists anticipated 20th-century concerns in political science with the significance of groups, the nature of interests, the role of parties as interest groups, and the social context within which political events occur.

Still another 19th-century writer with some precedental connection to the political science of the 20th was the Italian Vilfredo Pareto. Although he lived and wrote in both the 19th and 20th centuries, he may be counted in the earlier period because of his advocacy of the "logicoexperimental" approach to sociology, which involved observation and logical inference. Pareto had no direct influence on the development of political science, but in two respects his sociology had implications for the developing discipline. First, his was a psychological sociology, and much of his concern was with the influence of beliefs, attitudes, opinions, and sentiments in shaping social life. This anticipates the 20th-century approach of many political scientists who regard psychology as the most important adjunct of the scientific study of politics. Second, Pareto thought of society as a system always tending toward equilibrium, and the conception of politics as a system was to mark much of academic political science after World War II (see below). Also to be mentioned in the context of important 19th-century sociological theories is the work of a Swedish political scientist, Rudolf Kjellen, whose systematic treatment of the state as a fusion of organic and intellectual moral elements in an ambience of geographical determinism led to a theory of politics that he termed geopolitics.

Juristic influences. In addition to sociology, another discipline with which the development of political science has been historically related is law. A close connection between the state and law was made in the 16th century in the French political philosopher Jean Bodin's theory of sovereignty, which supposed the necessary existence in each state of an authority to make the law. This theory gave rise to numerous juristic theories of the state, especially among German publicists of the 19th century who sought to define the nature of federation and empire. Although the doctrine of sovereignty made most sense as a statement of the power of monarchs to make the law in simple unitary (nonfederal) systems, earnest writers forced the facts of federation and empire to fit the theory and often ignored facts that did not. The Bodinian view invested sovereignty with attributes of singularity and omnipotence—that is, sovereignty was viewed as being indivisible and absolute—but theoretical efforts were made in Germany before 1871, notably by Georg Waitz, to establish federal theory on a division of sovereignty between the centre and the member states. After 1871, the theory of Max von Seydel, namely, that since sovereignty is indivisible, it cannot be divided and must rest in a single location—either in the constituent members of a federal system or in the centre—supplanted that of Waitz. Georg Jellinek, an Austrian, attempted to resolve the paradox that so-called sovereign states are in fact limited by constitutions and laws and by membership in the family of nations by arguing that the restrictions are autolimitations. That is to say, since by definition there is no power above the state, if in fact there are limitations it must be the state that created them. The state therefore continues to be omnipotent. In France, juristic theories of the state also persisted strongly because the teaching of political science was conducted in the law schools as "constitutional law." Efforts were made by some professors, however, to broaden the legal approach, notably by Léon Duguit, who attempted a sociological positivistic treatment of juridical rules for the limitation of the state, and Maurice Hauriou, who contributed a theory of institutions. In England the emergence of political science as a subject was recognized in the establishment of the London School of Economics and Political Science in 1895 and by the founding of a separate chair of politics at Oxford in 1912.

The doctrine of sovereignty

Developments in the United States. The enthusiastic development of social sciences in the 19th century, stimulated as it had been by the rapid growth of the natural sciences, reinforced an existing interest in politics in the United States and created a generation of distinguished American political scientists. There had, in fact, been much interest in the teaching of political subjects in American colleges and universities well before the 19th century. Political science in the United States, however, free of any connection with moral philosophy, fusion with history, or submergence in political economy, may be said to date from 1880, when John W. Burgess, after studying at the École Libre des Sciences Politiques, succeeded in establishing a separate school of political science at Columbia University. Although political-science faculties increased in numbers after 1900, the growth was uneven, and in some major institutions separate departments were not created until after World War I.

The development of American political science in the last quarter of the 19th century was influenced by the experience of numerous scholars who had done graduate work at German universities in which political science was taught as *Staatswissenschaft* ("science of the state") in an ordered, structured, and analytical organization of concepts, definitions, comparisons, and inferences. To modern readers the work of these men often seems somewhat formalistic and institutional in tone and focus. It did represent, however, an effort to establish an autonomous discipline, separate from history, moral philosophy, and political economy. Some of the new American political scientists, such as Woodrow Wilson and Frank Goodnow, also showed in their writing an awareness of such new intellectual currents as theories of evolution and turned their attention to an examination of American institutions that, in the United States Constitution, had originally been based on the admiration of much of the 18th-century world for the harmonious perfections of mechanics. For Wilson, it was to be Darwin, not Newton, who would provide the inspiration for a transformation in American political science from the study of static institutions to the study of social facts, more truly in the positivist temper, less in the analytic tradition, and more oriented toward factual realism.

Bentley's early work on group processes

Little-noticed at the time he wrote *The Process of Government* (1908), Arthur F. Bentley was to have a celebrated influence on the development of American political science in the 1930s and the 1950s. Although his influence was not immediately felt, he sounded certain themes that became the orthodoxy of the new science of politics after World War II. First, he rejected all metaphysics and normative formulations as "spooks" and "mind-stuff" and insisted that the proper study of politics was observable fact, in imitation of the natural sciences. Second, his basic concept was the "group," rejecting thereby all previous formulations of the subject matter of political science that centred on the "state." Third, the "raw material of government," he thought, was the activity of men and the processes through which this activity flowed in legislation, administration, and adjudication. Behaviour and process were to become the focus of much of the interest in political science in the 1950s, after Bentley's single work on politics was given new currency just before the outbreak of World War II. He was considerably before his time in presaging the end of preoccupation with institutional and descriptive analysis. He acknowledged the leadership of Gumplowicz, who, in his view, had "taken the most important step toward bringing out clearly the nature of the group process," discarding the "individual as a causal factor in society," and insisting "that all social movements are brought about by group interaction."

Although the effort of Bentley to develop an objective, value-free analysis of politics had no initial consequence, other movements toward this goal were more immediately successful. The principal impetus was provided by what became known as the Chicago school in the mid-1920s and thereafter. The leading figure in this movement was Charles E. Merriam, who in 1925 published *New Aspects of Politics,* a book that argued for a reconstruction of method in political analysis, urged the greater use of statistics in the aid of empirical observation and measurement, and postulated that out of the converging interests of politics, medicine, psychiatry, and psychology might come "intelligent social control." The basic political datum for Merriam at this stage of his thinking was "attitude"; hence his reliance upon the insights of psychology for a better understanding of politics. These ideas were not entirely new, since Graham Wallas, an Englishman, had said in *Human Nature in Politics* (1908) that a new political science should be based upon quantitative methods and that serious attention should be given to the psychological elements ("human nature") in political activity, including nonrational acts and the exploitation in political life of subconscious nonrational inferences. The American political scientist and journalist Walter Lippmann had expressed much the same view in *Public Opinion* (1922). One of those in the Chicago group who carried the connection between politics and psychology quite far was Harold Lasswell, in his *Psychopathology and Politics* (1930). In *Power and Personality* (1948) he fused the Freudian categories of the earlier work with subsequent writings on power.

Influential works of Merriam and Lasswell

These two leading expositors of the Chicago school, Merriam and Lasswell, both published books at about the same time that gave a central place to the phenomenon of power in the empirical study of politics. Merriam published *Political Power* in 1934 and Lasswell *Politics: Who Gets What, When, How* in 1936. Merriam undertook to show how power came into being, to describe what he called the credenda, miranda, and agenda of authority (which he tended to equate with power), the techniques of power holders, the defense available to those over whom power is wielded, and the dissipation of power. Lasswell's 1936 work was a naturalistic description of "influence and the influential." Although both were cast in the empirical mode, the second was more successful in this regard than the first, which tended to be abstract and rhetorical. A truly empirical work of the Chicago school that had considerable significance in the development of academic political science was Charles E. Merriam and Harold F. Gosnell's work, published in 1924, on *Non-Voting, Causes and Methods of Control,* which used sampling methods and survey data. Since then, certainly one of the most successful achievements in empirical political science has been the study of voter behaviour and election results. Although members of the Chicago school insistently professed an interest in value-free political science, they were characterized by two normative predilections—their acceptance of the values of the democratic system and their earnest attempts to improve it through their writings.

By 1945 political science in the United States was much more than the concern for institutions, law, formal structures of public government, procedures, and rules that it had earlier been. There was by then also a considerable body of writing on processes—on the dynamics as well as the statics of public governance. There were works on pressure groups and lobbies, on the "invisible government" operating behind public authority, on actual bureaucratic processes as distinguished from the rules of administrative procedure, on bosses and political parties, and on ethnic influences in the behaviour of the electorate. All of these works signified a turning away from formality and the development of a growing interest in the factual realities of political behaviour.

Developments in Europe. Outside the United States the development of political science was less quantitative and behavioral. In France the main tradition in the study of political institutions was still legal rather than sociological. Constitutional law and history were abundant, and politics in the main was viewed from legal perspectives, though not entirely so. As early as 1913 one writer, André Siegfried, had introduced the geographical and historical study of elections in *Tableau politique de la France de l'Ouest sous la troisième République,* and the development of French sociology in the works of Émile Durkheim and others had applications in political science.

In England, although there was little development of a quantitative science of politics, a substantial contribution was made toward the formulation of political philosophies that centred attention upon the group basis of politics. Particularly notable were the works of J.N. Figgis, G.D.H. Cole, Ernest Barker, and Harold Laski. In Sweden, Herbert Tingsten in his work *Political Behaviour: Studies in Election Statistics* (1937) gave currency in the title to what was to be the main development in political science after World War II.

METHODOLOGICAL CONSIDERATIONS IN CONTEMPORARY POLITICAL SCIENCE

Behavioralism. In American political science since the end of World War II, the behavioral persuasion has been the dominant one. A former president of the American Political Science Association has attributed the rapid development of the behavioral approach to six causes: the inspiration of the Chicago school; the immigration to the United States in the 1930s of large numbers of European scholars (particularly Germans) with backgrounds in European sociology, who stressed the relevance of sociology to politics; the movement of many political scientists into administrative and political positions during World War II; the influence of foundation support in the encouragement of research in political behaviour; the increasing development of the survey method in certain political studies, such as voter behaviour; and the missionary work of the Social Science Research Council under leadership sympathetic to behavioralism.

Etiology of the behavioral approach

Although the term behavioralism has been freely used in political-science writings, there is in fact confusion as to whether it is a field of study, a method, or an approach. One American political scientist, Heinz Eulau, in *The Behavioral Persuasion in Politics* (1963), has said that the behavioral persuasion "is concerned with what man does politically and the meanings he attaches to his behavior," and he has suggested that researchers cannot afford to get tangled up in problems of definition. Another American, Robert Dahl, has said that it is a mood or even "the scientific outlook." The term behavioral, then, may be merely a term having distinctiveness, weight, and value for a certain time only, since it seems primarily to signify that phase in the quarter century after World War II during which there was a significant revival of interest in empirical studies in politics, a movement strong enough to establish at least a partnership with the traditional approaches, although some of its advocates have gone so far as to say that their science has made traditional approaches outdated.

Systems analysis. Contemporary political science does not display as much coherence as earlier modes of inquiry (coherence was one of their principal virtues), but it does exhibit a refreshing complexity, of both concept and method. Although much effort has been spent on the production of empirically derived evidence in a scatter of fields and a diffusion of subjects and although critics have scoffed at studies that they have said only prove the obvious, the product of 25 years of behavioralism has been voluminous and often stimulating in quality. Common in this output is the assumption that politics is process, the ceaseless interaction of individuals and groups on each other in a flow of activities in and around public governance. The most commanding concept devised to fit this flow with form has been the concept of the system. In this view the focus of political science is not the individual in solitude nor the multitude nor even the group. The American political scientist David Easton's *The Political System* (1953), a seminal work in empirical political theory, conceived of the political system as part of the total social system. For Easton the political system comprised all those activities having to do with the formulation and execution of social policy; that is, "policy-making process." The identifying criterion of political behaviour for Easton was the "authoritative allocation of values" for the society, by which he distinguished his sense of the subject matter of political science from that of Lasswell, who had argued that political science was concerned with the distribution and contet of patterns of value throughout the society. In this conception of system, which is not unrelated to the conception of system in physics and biology, linkages are found between the system and its environment. Inputs (demands) flow into the system and are converted into the outputs (decisions and actions) that constitute the authoritative allocation of values for the society; that is, the distribution of rewards in wealth, power, and status that the system may provide.

Variants of systems theory

There are various versions of systems theory, although all suppose the existence of the system and more or less consciously pattern it after systems models in other disciplines. There has thus been developed a view of systems, based upon engineering models and ideas, that rejects the view of Easton that there can be a general theory of political systems. Another theorist, drawing on cybernetics, has viewed the political system as a communications net. Although expositors of systems concepts generally suppose they are working with scientific theory, critics have said that they are merely creating new taxonomies. What is certain is that systems theory has introduced new and—to more traditional scholars in the field—unusual terms into the vocabulary of politics. Thus, instead of such terms as the state and sovereignty, the new idiom speaks of systems, inputs and outputs, feedbacks, circular loops, netwoks, legitimacy symbols, information storage and retrieval, political socialization, interest articulation and aggregation, cluster blocs, zero-sum games, macropolitics and micropolitics, and much else drawn from the concepts and languages of other sciences and from statistics, with hopeful assertions about the possibility of making politics predictable.

Although decision making as a research field in political science may be analytically regarded as part of the process by which inputs are converted into outputs in systems theory, it also has an origin independent of systems theory. Interest in game theory provided a stimulant to studies of decision making, which already had an established place in the lore and lexicon of politics and administration. In decision theory the paradigm is the rational actor, and the research problem is the ascertainment of the most efficient means to effect given goals, which may or may not be rational. Investigators into decision making are generally less concerned with the system as a whole than with the activity that they regard as the most important part of it, namely, the way in which decisions are or should be made according to rational calculation. A body of writing on decision making by judges has earned a sub-classification as "jurimetrics."

Interest groups, elites, and political parties. Studies of interest groups, elites, and political parties also have their own independent origins, although they, too, have been brought within the framework of systems analysis. Interest groups and political parties, for example, have been described as agencies for the articulation and aggregation of interests, which in turn provide inputs (demands) for the political system to convert into outputs (decisions and actions). But interest-group analysis antedates the advent of behavioralism. The modern concern for the subject starts perhaps with studies of prohibition and other pressure groups during the 1920s. More generalized and theoretical treatments of interest groups and political parties resulted in part from a revived interest in the work of Bentley in the 1930s and 1950s. The study of elites was begun at least as early as 1936 (Lasswell's "influentials"), and it came to the forefront in the 1950s in community studies made by political scientists in Atlanta, Chicago, New York, New Haven, and elsewhere. Such studies had long been familiar in sociology, but they acquired special significance in political science, because democratic values seemed threatened by the possible existence of elites. Despite declarations of their concern to establish a value-free science, American political scientists have thus tended to cleave to the traditional democratic ethic, in which elites are presumed to have no place.

Analysis of political attitudes and voting behaviour. What some have called the behavioral revolution had its greatest successes in the analysis of public opinion, political attitudes, and electoral behaviour. Especially in the period after World War II, the refinement of statistical techniques in public-opinion polling, the analysis of voter behaviour, and the development of new research concepts have brought the study of opinions and attitudes closest to the goal of the scientific outlook and some considerable distance from the mark made by Merriam in the 1920s. The Survey Research Center at the University of Michigan has become an important national centre for the collection of data on elections and voter behaviour.

CURRENT TRENDS

Reactions against "scientism"

The effort to establish a value-free, objective political science in the United States in the two decades after World War II has won what is doubtless a permanent place for the scientific study of politics, but it has also bred a critical reaction. In the late 1960s opponents of "scientism" rejected what they felt was the increasing subjection of spontaneity and human values to determinisms in every aspect of life and argued that political science was an example of the pervasiveness of technology and of a search for rationality in a social complex that might be irrational and out of control. Although political science had developed skillful and sensitive techniques for the quantification of data termed political, there is no orthodoxy on the scope of political science nor on the delimitation of separate areas of research. Quite different outcomes emerge from the basic assumptions as to the focus of the discipline, whether it be power, government, system, process, decision making, or policy formulation. The failure of the discipline to settle the question of identity has made for a creative and inventive exploration of many avenues of research, but the achievement of a unified general theory of political behaviour on which there is common consent still lies ahead.

Even outside the United States, non-normative political science is not extensive, although it is not unknown. England has made many creative contributions to political theory and law throughout its history, as have other European countries, but it has also produced substantial works that can be classified as positive (*i.e.,* non-normative) political science. Among these are the studies of R.T. McKenzie and D.E. Butler in the field of political parties, voter behaviour, and pressure groups, S.E. Finer on interest groups, and U.W. Kitzinger on German elections. Notable work has been done in France in the field of political parties by Maurice Duverger and François Goguel. Work has also been done on the political socialization of children in French schools by Charles Roig and François Billon-Grand. In Denmark, beginnings were made in the systematic study of political science in 1959 with the founding of the Institute of Governmental Studies at the University of Århus. In Finland the first extensive studies on voting behaviour appeared in 1956.

In Japan there was a flowering of social sciences after World War II, but political science at first did not grow at the same pace as other social sciences because of lack of agreement about both subject matter and method, a difficulty felt from the beginning by the man recognized to be the founder of Japanese academic political science, Onozuka Kiheiji, who published *Principles of Political Science* in 1903. With the opening of the behaviour of public officials and institutions to scientific scrutiny, however, there has been much political inquiry that would qualify as political science, including, for example, systems analysis and works on political culture, political development, and process and behaviour.

Political science in Communist countries

Although in the past the objective study of political subjects by researchers in Communist regimes has been difficult, if not impossible, a somewhat more permissive policy in some countries has led to what may be the beginnings of scholarly political science. The most advanced political science is to be found in Poland and Yugoslavia, and Romania and Czechoslovakia have come to recognize political science as a discipline. The Soviet Union does not yet sanction political science, but scholars do conduct empirical research, which was endorsed in 1962 by the U.S.S.R. Academy of Sciences under the term "concrete sociological investigations." The greatest movement has been in the conduct of public-opinion polls using advanced Western techniques. Interest in the development of political science was evidenced in the publication in 1969 of *Politicheskaya nauka v SShA: Kritika burzhuaznykh Kontseptsy vlasti* ("Political Science in the U.S.A.: A Critique of Bourgeois Conceptions of Power"), by V.G. Kalensky. Although there is no officially sanctioned political science, there is a Soviet Association of Political Sciences, which has sent delegates to the meeting of the International Political Science Association. Despite its title, the Soviet Association of Political Sciences is most heavily oriented toward the state and the law, and its members have been critical of what they regard as the anti-Marxist bias of bourgeois political science. One of its members, however, F.M. Burlatsky, published a major article in *Pravda* in 1965 calling for the establishment of a genuine political science in which the findings would emerge from the data.

In Yugoslavia a political-science association was established in 1951, and in 1962 a faculty of the political sciences was established at the University of Zagreb. In Czechoslovakia a political-science association was formed in 1965 and became a member of the International Political Science Association; and in 1968 a political-science association was formed in Romania. Political science in Yugoslavia has tended to centre on traditional divisions of the discipline, such as political theory, comparative government, and international relations. In Poland, political science has centred on the study of political behaviour, on community power structures, on voter behaviour, and on public opinion. Techniques of considerable sophistication have been employed.

Political science is one of the means by which people seek to understand the human condition and man's fate. Or, as Aristotle believed, politics is the most important of human activities, and the sovereign science. For 24 centuries, at least, the greatest intellects and scholars have striven to state the universal elements of just order in human affairs. None has succeeded in this, so far, hopeless ambition, although most have contributed some special insight and added to the common wisdom. The effort to achieve magisterial comprehension will doubtless continue; and the search will change direction as experience requires, with the aid that new perceptions, concepts, and methods will provide. Progress toward establishing general laws, however, may never be as steady or as swift in political science as it has been in laboratory sciences like physics; for, as Albert Einstein once said, politics is more difficult than physics. (Ea.L.)

Study of international relations

HISTORICAL DEVELOPMENT OF THE STUDY OF INTERNATIONAL RELATIONS

Three contemporary forces go far to account for the impressive growth of scholarly studies of international relations and foreign policy in the 20th century. An autonomous academic discipline has emerged, related to geography, history, law, sociology, psychology, general political science, philosophy, and other fields, yet belonging to no one of these. The first impelling force was noted above: the growing demand to find better, less dangerous, more effective means of guiding relations among peoples, societies, governments, and economies. A second force is the result of the monumental upwelling of intellectual activity in modern times based on the belief that systematic observation and inquiry will dispel ignorance and serve the betterment of mankind. One sentence by Diderot characterizes this force as well today as when it was written in the 18th century: "Everything must be examined, everything must be shaken up, without exception and without circumspection." The third force is the consequence of the popularization of political affairs, including one of its most important sectors, foreign affairs. Only late in the 19th century did the traditional view that foreign and military matters should remain an exclusive preserve of rulers and special elites yield to the opposite belief that such matters constitute an important concern and responsibility of all the people. This popularization of international relations made logical the idea that education should include instruction in foreign affairs and that knowledge in the field should be advanced in the interests of public control over international political and military matters. The experience of World War I, the war to make the world safe for democracy, strengthened the conviction that not enough was known about international relations and that the universities should reduce ignorance in the field through more research and teaching.

The popularization of foreign and military affairs

Between the two world wars. A strong impulse toward the development of international studies in universities came in the 1920s. New centres, institutes, and schools devoted to teaching and research in international relations were founded. Courses were organized and general textbooks on the subject began to appear. Private organizations were formed, and large grants of philanthropic funds were channelled to the support of scholarly journals, to the advancement of citizenship in world affairs through special training institutes, conferences, and seminars, and to the stimulation of university research.

Initially, three subject areas commanded the most attention. All three had roots in the period of World War I. In the revolutionary upheavals at the end of the war, great portions of the government archives of imperial Russia and imperial Germany were opened and made public in a series of documentary publications. Very exciting scholarly work began to appear that pieced together the hitherto-unknown history of prewar alliances, secret diplomacy, and military planning. These materials were integrated to provide explanations of the origins of World War I. The two decades between the two great wars were the heyday of diplomatic history, and the most famous of the students of international affairs were historians. With great ingenuity and industry, they presented the world with superb examples of the art and science of diplomatic history.

The second subject that captured attention was bound up with the hope and expectation of a new world order in the making through the League of Nations. Some of the schools of international relations that were founded in the

1920s had the explicit purpose of preparing civil servants for what was expected to be the dawning age of international government. Thus the genesis and organization of the League, the history of earlier plans for international federations, and the analysis of the problems and procedures of international organization and international law were investigated with enthusiasm.

The third study of consequence during the early part of the interwar period was an offshoot of the peace movement and was concerned with scholarly investigations of international warfare: its cause, its costs, and its sociological and psychological aspects. In addition to the data and the interpretations dredged up in the study of war, the interest in the question "why war?" brought a host of new social scientists—economists, sociologists, and psychologists—into active participation in international studies for the first time. They were pioneers in what later came to be known as the "behavioral approach" to international relations.

Realpolitik in the 1930s

The breakdown of the League, the rise of the aggressive dictatorships, and the coming of World War II in the 1930s caused a reaction against the international government and peace-inspired themes in the study of international relations. Idealism and moralism were criticized, and "realism" became the new thought in the field. The image was built at that time that the first stage of academic development of international studies was the handiwork of starry-eyed idealists and peace visionaries who ignored the hard facts of international politics. This characterization is untrue, the fact being that the scholarship on world affairs of the '20s and the '30s was extensive and sound in the organization of data and in the development of some fundamental concepts.

In the European tradition since early modern times, the knowledge of international relations had been loosely ordered in two branches of learning. The first is diplomatic history, which has been considered to reflect the variety of political experience, the particularity of events, and the contingencies in the actual practices of diplomacy and war. The second is international law, which has been viewed as registering the "residue of history"—the fundamental principles of conduct, the uniformities in international phenomena, and the permanent aspects of practice. The effect of the new field of international relations was to broaden the traditional organization almost beyond recognition.

New areas of inquiry during the interwar period

Some of the topics that today are considered novel and of recent origin were being explored vigorously in the two interwar decades; by the time of World War II, they already had acquired large bibliographies. It is instructive to recall a few of those topics in order to correct the stereotype that moralist teachings were then entirely dominant: the relationship of problems of racial and ethnic minorities to international affairs, the effects of the population explosion on foreign policies, the linkage between raw materials and other of the "life-support systems" of the planet with the actions of nations, the effects of imperialism and colonialism, the strategic aspects of international relations including the effects of geographical location and space on military power and the influence on governments of what has come to be called the "military-industrial complex," the economic inequalities of nations, and the role of public opinion, national differences, and cultural orientations in world affairs. If these studies tended to be short on theory and long on description, nevertheless the topics investigated remain relevant.

Certain individual scholarly contributions of the 1930s deserve particular notice because they were forerunners of what was to be developed after World War II. Harold D. Lasswell was making explorations of the relationships between world politics and the psychological realm of symbols, perceptions, and images. Abram Kardiner and his associates were laying the groundwork for a psychoanthropological approach to the analysis of national behaviour and culture, which later became a popular but short-lived theory of international relations. Frederick L. Schuman was producing foreign policy analyses that synthesized analytic comment with accounts of current international events. Schuman thus set the style that is still followed by government interpreters of foreign policy developments and by the news analysts of world affairs.

Quincy Wright was leading one of the first team research projects in the field and was investigating numerous aspects of international behaviour in a very broad approach to the study of war. Carl J. Friedrich, Frederick L. Schuman, Harold Sprout, Nicholas Spykman, E.H. Carr, Brooks Emeny, and others were developing the main lines of analysis of what became the power-politics explanation of international relations.

Some 30 years later, one begins to appreciate that the definition of the study of international relations and the widening of its scope were the fundamental contributions of the scholars of the interwar period. Many of the innovators of the 1930s found their services enlisted by governments during World War II for work in intelligence, propaganda, and political analysis. In this respect, the war stimulated systematic social-science investigations of international phenomena. On the other hand, World War II became a divide for academic international relations. The war made a drastic change in the agenda of world politics. The postwar intellectual climate shifted away from many of the earlier interests, emphases, and problems. There was a readiness in the early postwar years for an analysis that would cut through the details of studies of myriads of international topics and that would provide a focussed view of the fundamental nature of international politics. An intellectual hunger for theory existed.

The postwar ascendancy of political realism. Hans Morgenthau's *Politics Among Nations,* first published in 1948, met this need for theory. Writing in 1959, Stanley Hoffmann expressed what was, in all likelihood, the opinion of most students of international relations:

Hans Morgenthau and the "realist" theory of power politics

> The theory which has occupied the center of the scene in this country [the United States] during the last ten years is Professor Morgenthau's "realist" theory of power politics.

At the time of this writing, the influence of the Morgenthau text continues to be strong in most countries outside the Communist world. The realist theory still requires the attention of new students of international relations. A reader is best advised to explore the theory at its source. *Politics Among Nations* remains an impressive study; it is clearly conceived and well argued.

At the heart of the realist theory is the concept of interests. Politics is defined as the struggle for power, whether in domestic or international settings. The struggle for power is part of human nature and takes form in society according either to the competition or to the alignment of interests. Collaboration occurs when parties find their interests are coinciding. Rivalry, competition, and conflict result from the clash of interests. Accommodations are possible through the application of political skill.

In an international system composed of sovereign nation-states, the survival of both the states and the system depends on the intelligent pursuit of national interests and on the realistic calculations of national power. As long as the state system persists, the only truly constructive way to participate in international politics is through skilled diplomacy. Religious and ideological crusades threaten the ruin of both the individual states and the system, and disasters follow from attempts to reform nations toward the ideal of universal trust and cooperation.

Thus the realist theory of power politics was brought forward in the late 1940s to stand guard against idealists: those who would think and act in the visionary ways of moralism and legalism in world affairs. No impressive new formulation of political idealism appeared to carry the challenge to the realist position, and the "great debate" of realism versus idealism gradually faded from the scene.

Many scholars of international relations neither opposed nor accepted the power-politics theory. Some simply were engrossed in other aspects of international-relations teaching and research. Large sums of money were made available in the 1950s for the development of foreign-area studies, and general theoretical concerns played little part in the growth of area specialization. Other scholars agreed with Morgenthau's statement that theory and research should have a "concern with human nature as it actually is, and with the historic processes as they actually take place," but they did not believe that the realist conceptualization provided a sufficient explanation of observed international behaviour.

The behavioral decade: mid-1950s to mid-1960s. An important new influence was the arrival in the field of a number of fresh ideas, conceptualizations, models, and paradigms that were loosely identified in ensemble as behavioral theory. The new movement distracted attention from the realist–idealist question. The unanticipated appearance in the mid-1950s of a large number of possible alternative ways to organize international data and to orient inquiries in international relations soon appeared to threaten the very foundations of scholarly communication. Simply to list a number of the conceptual innovations suggests the reason for the anxiety that the discipline might lapse into complete incoherence. In addition to power theory, there appeared a welter of theories, each with its distinctive label: decision making, system, conflict, deterrence, capabilities, field, communication, integration, development, environmental, cognitive, and, finally, game theory. Much of the intellectual effort of the "behavioral decade" went into the task of attempting to understand, compare, interpret, and integrate all these ideas. The scholarly goal of the period became to build an integrated framework of theories—to carry out conceptual mapping.

The behavioral aim to integrate the mass of ideas

To describe the efforts at theoretical integration that were made and the problems that were encountered would require book-length treatment. Suffice it to say that the comparing and integrating of the elements of theory turned out to be difficult. The more the matter was investigated, the more the specialists in theory questioned the necessity of arriving at one comprehensive structure of theory. The international realities that theory is supposed to reference and explain are varied and diverse, so why should one not expect that a number of separate theories would be needed to account for different parts and aspects of international relations?

Increasingly, explanations that trace the forces of international relations to any single source have been seen to be unsatisfactory. The struggle for power among nations, for example, can be accepted as a fact in past and current international politics, but to theorize that all other factors are subordinate to or dependent upon this one is to exclude too much that is important and interesting in international phenomena. Similarly, the formulation that asserts that the character of nations and, hence, the character of their participation in international relations are determined by child-rearing practices is simple, appealing; at the same time, however, it is unacceptable because it theorizes a single cause where multiple causation prevails. The Communist theory that international relations are the historical expression of the class struggle also falls into the single-source classification of theory.

The attitude nurtured in the behavioral decade emphasized the necessity of recognizing social multidimensionality and, therefore, multiple causation and the multiple forms of explanation and theory. Under this perspective, one might well conclude that the concept of the struggle for power among nations and the idea that international relations is really a manifestation of a global struggle between social classes both relate to human conflict and that a theory of conflict should encompass these as well as other conflict interpretations. Indeed, the anticipated integrating effect on theory and research in international relations was a main motive in advancing general conflict theory in the '60s, but it is important to add that conflict theory came to coexist with integration theory and game theory, both of which approach some conflict phenomena from different conceptual angles.

Development of the theory of conflict

By the end of the behavioral decade, the multiple-theory perspective had come into the ascendancy in North America and western Europe. International-relations scholars in the Soviet Union who were following closely the Western literature in the field reported with some satisfaction that Western theory had become eclectic and was in disarray in contrast to their own, which they declared to be based on the unified theory of the science of Marxism. At the same time, they gave indications that some of the Western trends in international-relations thinking were being introduced in socialist countries and that a muted contest between traditional and behavioral approaches was underway.

By the 1970s only the realist theory of power politics survived as a relatively simple and comprehensive explanation of international politics in a conceptual environment that otherwise had become pluralistic and complex to the extent that "theory" could no longer be outlined quickly or conveniently in a classroom or before an audience. A situation had begun to develop that put the question of a single theory of international relations in about the same class with that of a single theory of biology.

Contemporary perspectives in international relations. *Foreign-policy and international-systems perspectives.* One important clarification developed from the effort of the behavioral decade to bring the various theories together in a unified structure. It was the consensus that the academic organization of the discipline has two principal parts. It is convenient to call each part a perspective on the subject. The parts are called the foreign-policy and the international-system-analysis perspectives.

The foreign-policy perspective covers many theory and research interests. Fully generalized, it embraces all the inquiries that look into the domestic sources of external or international phenomena. Thus, a study of any set of traits, structures, or processes arising within a national society or polity that can be demonstrated to determine or influence importantly how that society or polity participates in international relations belongs to the foreign-policy perspective. The decision-making approach to international politics meets the requirement, for example. The analysis of the information that decision makers use, of their perceptions and motives, of the influences on them exerted by public opinion, and of the organizational settings in which they operate is a manifestation of the foreign-policy perspective. Studies that seek to relate the facts of wealth and power of a nation to its international status and role provide other illustrations.

Comparative foreign-policy analysis is an area of theory and research effort that first appeared in the mid-1960s. Its objectives are, first, to examine the data of domestic sources of external conduct country by country using standard criteria of data selection and analysis, and, then, to compare across countries for generalized findings on foreign-policy performances. When the details of the domestic sources and the external performances have been compared, theories about the domestic–external linkages and about the groupings of countries according to the types of linkage are expected to develop. The comparative foreign-policy approach, so described, develops theory through inductive research procedures.

The second perspective is that of international system analysis. Whereas foreign-policy analysis concentrates on the actors, international system analysis is preoccupied by the interaction. The term "interaction" suggests challenge and response, give and take, or move and countermove. Diplomatic histories feature the narratives of action and response in international situations and interpret the meanings in the exchanges. The theory of the balance of power is an example of an international-system conception. Explanations and descriptions of bargaining in international negotiations fit the perspective and so also do studies of arms races and other escalating processes. A model of the international trading system would be an example of a structural approach to international system studies, while an examination of how and why a coalition of states disintegrates would represent a process approach to international system analysis.

The theorist of international systems may gain a general outlook on the phenomena he studies through a system perspective, but he must bring in a certain amount of empirical detail when he identifies the components, relationships, and environments of the system that is the object of his theoretical inquiry. System theory does not turn out to be any single formulation; it is more in the nature of a conceptual anchoring point for a variety of specific formulations. Thus one system theorist may define the components of his system as geographical nation-states related according to rules and political structures, whereas another theorist may define the components of his system as nonterritorial, nonstate transactional units only partly related by the influences wielded by national governments.

The general system perspective. Although the theoretical development of the system idea may lead to very diverse outcomes, another more general concept—that of open, adaptive systems—may provide the most promising approach to a comprehensive understanding of the dynamics of relations among nations. Without imposing any single school of thought or any single interpretation of world affairs, it has a loosely unifying effect on the outlook of students of the field. The so-called general system perspective on international relations may be compared to the map of a little-explored continent. Outlines, broad features, and a continental delineation are not in question, but everything else remains in doubt, is subject to controversy, and awaits exploration. One commentator has remarked that general system theory is not really a theory but instead is "a program or a direction in the contemporary philosophy of science." (From Anatol Rapoport, "Systems Analysis," in *International Encyclopedia of the Social Sciences,* vol. 15, p. 452, 1968.)

General concept of open, adaptive systems

As noted above, the quest for theoretical unification during the behavioral decade resulted in the widespread acceptance of two perspectives—a foreign-policy approach and an international-system approach. The general concept of open, adaptive systems provides a conceptual bridge connecting the two perspectives and creates a loose bond joining many of the diverse theoretical formulations prevailing in the field. An examination of the line of general thinking that builds the bridge and provides the bond is, therefore, well worth attention.

One begins to think about almost any open, adaptive system that involves human beings as a living system. If the system is living, its pervading characteristic is activity. Acting units, however they are recognized and defined, are doing things, participating in events, carrying forward processes, and creating effects. The effects created by activity include progressive influences on the actors. That is to say, the acting unit is immune neither to the effects of its own participation nor to the participatory influences generated by other acting units. It is this situation that establishes the condition of the openness of a system. Streams of influencing activity contain two kinds of processing: the first kind is regular, which is to say, governed by rules and repetitive in form, and the second kind is unexpected, irregular, and variant.

It is the second type that stimulates change and that initiates the special processing called adaptation. A living system is open and is able to adapt, however, only if it in some way has gained access to information on the state of affairs that joins it with its environment and, further, in some way has achieved means to direct and to change its stream of activity. Thus in addition to the fundamental concept terms of openness and adaptation, the general system perspective incorporates the ideas of communication and corrective action or, more generally, of communication and control.

Another view adds the observation that there is a systematic deception afflicting human understanding when the unit of action—the actor or the initiator—is seen as an entity. For social phenomena, the system perspective advises us that we make a grievous error when we identify individual persons, groups, organizations, nations, and so on as separate, uniquely named things. Recognized correctly, all these are nothing other than organized and interlocking activity flows, proceeding across historical time in somewhat regularized fashion. John Doe is to be described, literally, as an organized packet of active processes in exchange with an environment and utilizing communication and control to survive and adapt. The same description fits Japan: an incredibly complex network of related action much more than a place, a people, or a name.

Not only does the general system perspective urge that the "actor" be considered as a configuration of activity but it also prompts a recognition that, most often, the configuration itself has a hierarchical organization. In fact, the use of the term "system" is ordinarily an effort to convey the meaning that smaller organized activity flows serve larger activity flows and that the functional linking of subordinate parts to the operating whole is the process that defines what an actor really is. Thus the conventional explanation is that any recognizable living system is made up of related "components" and that each component, when examined at its own level, is found to be a functioning system in its own right. It also may be called a "subsystem." Enough of the system conceptualization has been suggested here to show next how these fundamentals have been translated for the purposes of international-relations theory.

In world history, the Earth has been populated by hundreds of separate and relatively isolated social systems. Each system, as a somewhat ordered stream of interrelated activities, has had exchanges with its particular environment in its own time and in its own way and has employed communication and control capabilities either to succeed at adaptation or to fail at it and, therefore, perish. What today is called international relations is that sector of exchange of a social system with its particular environment that has to do with interlinked action flows to and from other separate social systems. The knowledge problem of international relations is to understand, describe, and explain such flows to and from social systems from their source to their termination. Social systems thus consist of complexes of "internal" interacting subsystems or components, only some of which connect their processes with the action flows between that social system and another.

Internal processes and interactive processes of nations

The next logical thought then is that there can be only two sources of international conduct. One originates in the activity complexes within each participating social system and the other arises from the effects of the interlinked action flows to and from the participating social systems that together make up the membership of an international system. Hence, two basic perspectives of theory and research on international relations are distinguished by the primary attention given either to the origins of conduct arising from internal processes or to origins of conduct arising from the effects of the processes of exchange between social systems—or, to put it more succinctly, from the effects of interaction.

Obviously, the two perspectives are related because each casts its beam on a sector of a whole phenomenon of action and interaction. If he expects to be understood, the theorist must specify not only the basic perspective he wishes to emphasize but also particular identifications of the "units" of action, the kinds of action flows, and the linkages of processes and effects in this particular conception of the system that concerns him. In a multidimensional social world, the theorist can exercise his choice of a focus of inquiry in many different ways. Multiple theories are the outcome that may be expected from the introduction of the concept of general systems into the study of international relations.

The rise of quantitative research and computers. The emphasis on theory building and theory integrating after World War II was perhaps a reaction against the emphasis on methodology inherent in the historical and institutional studies of the 1930s. In turn, the renewed interest in empirical research after the behavioral decade probably was a reaction against the excessively intensive theorizing. Only part of the renewal of interest in data gathering and data analysis can be accounted for in this way, however. The marked increase in quantitative data studies after the mid-1960s has resulted from the direct influence of the computer. Computerization came late to the field of international relations; how to use the machines to good advantage was not apparent at first because most observations on the conditions of international relations are recorded in narrative or literary form.

Uses of computers in international relations

The first big discovery about computers in the study of international relations was that they could be made to serve the function of marvelously efficient librarians. By placing data collections under computer management, researchers could improve their investigations by incorporating vastly larger collections of facts in their work. Facts that had a narrative, nonquantitative form could be included in storage and retrieval systems almost as readily as numerical data. The second revelation was that by systematic coding and counting, many kinds of nonquantitative data could be transformed into quantitative indicator information and then be condensed and evaluated by mathematical and statistical procedures. Vistas on new research possibilities were opened and exploratory studies were made in a number of directions. Through quantitative, computer-assisted research detailed, painstaking examination of historical records has again become important. The new research also gives promise of bringing the interests of academic theory and research into closer accord with the interests of government analysts and the practitioners of diplomacy.

RELATIONS BETWEEN SCHOLARSHIP AND ACTION IN FOREIGN AFFAIRS

The differences between the interests of scholars and practitioners of international affairs have appeared to be more prominent than the similarities. A steady concern of scholars has been to avoid both the fact and the reputation of serving as apologists for official foreign policies. One of the first teachings of the idealism of the discipline's founding period at the time of World War I was to maintain an attitude of future-oriented reform of the international order. Existing systems had lesser importance according to the early objectives of the field. The principle of scientific detachment in social-science research also has contributed to the scholarly effort to evaluate international events and developments from a global standpoint rather than from the perspective of any one country's foreign-policy position. On the other side, practitioners have been inclined more to indifference than to hostility in their attitudes toward academics in international relations. They frequently have professed that for their day-to-day work they have found little of value in the theory and research contributions of the field. One looks in vain, therefore, for many signs of direct influence in either direction. An indirect and subtle exchange has occurred, nevertheless, and it has had importance in the direction of foreign affairs.

Mutual influences of government and academia

New international programs or new foreign-policy directions undertaken by governments often have attracted so much interest in the universities that research programs have been initiated and special subfields of international studies have resulted. Examples of such subfields include: (1) "national development" stimulated by the foreign-assistance programs to aid underdeveloped countries; (2) the "area studies" that emerged from World War II because of the problems that Western governments had in finding knowledgeable personnel who understood the languages, histories, cultures, geography, and politics of Asian, African, and Latin-American regions; and (3) "national security," resulting from the heavy influence of military factors on foreign policy and especially from the nuclear-control problem in the post-World War II period.

The indirect influence flowing in the other direction from university studies into governmental thinking may be traced in a number of noteworthy examples during the past two decades: first, the realist formulation of the power-politics theory has filtered into the foreign-policy thinking of the U.S. government to such an extent that most foreign-policy decisions have been defended by arguments of national interest and power calculation and opposing views have been discounted for reflecting insufficient "hard-nosed" realism. Another interesting example was the preoccupation of Pres. John F. Kennedy's administration with the details of the process of foreign-policy decision making in crisis periods. This orientation can be traced to the popularity of decision-making theory advanced in the academic field in the preceding decade. One other example has been identified in the Soviet Union's revision of foreign-affairs doctrine to accommodate the deterrence theory of nuclear defense. Concepts drawn from the literature of American "defense intellectuals" can be readily seen in Soviet works on military doctrine.

Although the past relations of scholars and practitioners of international relations have been relatively mild and indirect, the future may change this customary relationship. The implications of system theory can be expected to percolate slowly but deeply into the understanding of both officials and the public. As this occurs, there will be greater appreciation of how truly complex and far-reaching the flows of international events are. The problems of survival and adaptation will be seen in a new light and the realization of how interdependent modern nation-states are—how much they are bound to a common fate—should lead to more careful, better researched, and more deliberate formulations of foreign policy. The search for more accurate appraisals of the state of the world in its international aspect, which is the vocation of theory and research in academic international relations, should bring officials and researchers together.

Demand for data

On the other side of the relationship, the surge of growth in quantitative, computer-assisted studies in the universities is creating an increasing appetite for more frequent and more exact reports on the state of the world and in more and more of its aspects. The academic community in whatever country one might name lacks the resources and trained manpower to satisfy this growing appetite for data. The demand could well lead to increased responsiveness of the data-gathering services of national governments and to large reductions both in secrecy and in governmental interference with free public communication among nations. The current practice of withholding large amounts of information about developments in the flows of international events is an atavism left over from the era of aristocratic diplomacy. Today it has become a threat to the survival of mankind.

If the data on the conditions and relationships of the world's social systems (now made more manageable and more available for immediate use through computer systems) are brought into full and untrammeled circulation, the academic field of international relations and the governmental analysis and planning agencies will have much more in common than they have had. The end result should be the development of entirely new, more competent, and more realistic approaches to the formulation and execution of foreign policies. (C.A.McC./Ed.)

Comparative law

HISTORICAL DEVELOPMENT OF COMPARATIVE LAW

The expression comparative law is a modern one, first used in the 19th century when it became clear that the comparison of legal institutions deserved a systematic approach, in order to increase understanding of foreign cultures and to further legal progress. From early times, however, certain scholars and researchers have made use of the comparative technique, conscious of the advantages to be gained.

Ancient roots of law. In the 6th century BC according to legend, the Greek lawgiver Solon, faced with the task of compiling the laws of Athens, gathered together the laws of various city-states. Similarly, in the 5th century BC, a Roman commission was reported to have consulted the statutes of the Greek communities in Sicily before giving Rome the famous *Laws of the Twelve Tables.* Aristotle, in the 4th century, is said to have collated the constitutions of no less than 158 city-states in his effort to devise a model constitution. Thus, from ancient times it would seem that those wishing to set up a just system have sought inspiration and example from abroad. The true expansion of comparative law, however, was hindered by a number of obstacles—such as the parochialism of social groups, contempt for foreigners, or "barbarians," and belief in the sacredness or everlasting inviolability of inherited legal rules.

Although certain practices and institutions that crept into Roman law undoubtedly originated in the imperial provinces, Roman legal science took no cognizance of comparative law. Nor can the medieval universities in Europe be said to have displayed great concern for comparative law. Over the centuries, their interest was limited to Roman law, supplemented in certain areas or modified to some extent by canon law. While members of the first school of thought (called glossators) confined themselves to the task of elucidating the meaning of the Roman codes of law, their successors (the postglossators) undertook the systematic arrangement and adaptation of that law to prevailing social conditions. At no time was there an effort to compare laws. The customary laws that one found here and there could hardly hold any interest for scholars labouring to give society a model of ideal justice and to discover or elucidate a higher law above man's making. Indeed, in their opinion, local laws were no more than rubbish and evidently doomed to decay. To compare these local practices would have been a waste of time; to compare them with Roman laws would have been almost indecent.

The ancient search for "higher" or ideal law

Role of judges. Such contempt was not characteristic of the attitude of the judges and lawyers whose duty it was to administer justice, mainly by applying the customary law. Their material contained areas of uncertainty and required adaptation to social needs. In the work of ascertaining the content of a custom, and in the task of filling the gaps of customs, judge or lawyer had to consider which customs to allow to prevail. In so doing, he had to decide whether one custom was more just than another and how far he should go in introducing concepts of ideal justice (based on Roman law) that were being promoted by the universities. Two processes were thus at work: the elimination of conflicting local customs and the acceptance and rejection of elements of Roman law. With regard to the first process, the comparative aspects of the work took place behind the scenes, and consequently the results of melding the different local or municipal laws are known, but the reasoning leading to the result is not. With regard to the second process, by contrast, certain publications place the act of comparison in full view. This was particularly noticeable in England, where some writers—such as Sir John Fortescue in the 15th century and Saint-Germain in the 16th—took upon themselves the comparison of common law and Roman law, and in 1623 Sir Francis Bacon suggested to James I that a work be drafted comparing English and Scots law, as a preliminary step toward the unification of the two systems.

19th-century beginnings. Despite the occasional use of the comparative technique, nevertheless, comparative law itself was not recognized as a separate branch or as a fundamental technique of legal science until the 19th century. In particular, it played no part in legal education. It was quite unthinkable that the pursuit of justice should be taught by reference to a host of customary rules that were incomplete, sometimes archaic, and generally regarded as barbaric. A foundation of ethical and political principles rather than sociological considerations, an appeal to reason rather than a study of human behaviour or judicial precedent—these were deemed the true criteria of progress.

End of dualism between ideal law and everyday practice

With the coming of the 19th century, codification of the law put an end to the dualism existing in many countries between an ideal system, as taught in the universities, and the laws that were applied in everyday practice. Codification of those everyday laws gave them the status of a national law, thoroughly purged of anachronisms and arranged in a systematic manner. That codified law became the cornerstone of legal education. This promotion of local customs, regarded henceforth as being fully consonant with natural justice, may be considered as the underlying cause of the appearance and rise of comparative law.

In short, the attitude toward comparative law tends to change when a country makes its national law the object of legal study and law students begin contrasting it with foreign counterparts. In Europe this dawning change was evident early in the 19th century. Legal periodicals were founded in Germany in 1829 and in France in 1834 to further a systematic study of foreign law. In France, the civil and mercantile laws of modern states were translated with "concordances" referring to the corresponding provisions of the French codes; and in England in 1850–52, Leone Levi published a work entitled *Commercial Law, Its Principles and Administration; The Mercantile Law of Great Britain Compared with Roman Law and the Codes or Laws of 59 Other Countries.*

A chair of comparative legislation was set up in 1831 in the Collège de France; and this was followed, in 1846, by a chair of comparative criminal law in the University of Paris. In 1869 the Société de Législation Comparée was founded in France, followed in 1873 by the Institut de Droit International and the International Law Association. In England, the Society of Comparative Legislation was founded in 1895, and the Quain Professorship of Comparative Law was created at London University in 1894. Similarly, chairs in comparative law were founded and projects in foreign law undertaken all over the continent of Europe, but with particular vigour in France.

First International Congress of Comparative Law

International efforts. The 19th century drew to a close with an important event—the meeting of the First International Congress of Comparative Law in Paris in 1900. Experts from every part of Europe delivered papers and discussed the nature, aims, and general interest of comparative law. Particular emphasis was laid on its role in the preparation of a "common law for the civilized world," the contents of which would be laid down by international legislation. The stress, however, was on comparative legislation and codification because (with the exception of one English jurist) the congress had attracted only jurists from continental European nations, all of which had coded law, in contrast to English customary, or common, law. Consequently, the idea of an enacted world law was the natural outcome of its proceedings.

The upheavals resulting from World War I (1914–18) prompted a change in direction. From then on, European interest began to extend beyond the continental systems themselves, first, to those of the common-law countries (chiefly England and the United States), then still further afield to the Socialist systems, and finally, after 1945, to the laws of the newly independent states of Asia and Africa. The new territory for legal study that has thus been opened up has resulted in references to comparative law, rather than to comparative legislation.

METHODOLOGICAL CONSIDERATIONS IN CONTEMPORARY COMPARATIVE LAW

The world contains a vast number of national legal systems. The United Nations brings together representatives of some 127 states, but these states are far outnumbered by legal networks, since not all states—notably federal ones—have accomplished unification within their own frontiers. It is thus an enormous task to try to compare the laws of all the different jurisdictions. This problem, however, should not be overly magnified. Differences between the diverse systems are not always of the same order; some are sharp; others are so closely similar that a specialist in one branch of a legal "family" often may easily extend his studies to another branch of that family. For this reason, one can distinguish two types of research in comparative law. The exponent of "microcomparison" analyzes the laws belonging to the same legal family. By observing their differences, he will decide whether they are justified and whether an innovation made in one country would have value if introduced elsewhere. The researcher pledged to "macrocomparison," on the other hand, investigates those systems differing most widely from each other in order to gain insight into institutions and thought processes that are foreign to him. For the "pure jurist," concerned mainly with legal technicalities, microcomparison holds the greater attraction; whereas macrocomparison is the realm of the political scientist or legal philosopher, who sees law as a social science and is interested in its role in government and the organization of the community.

Two types of research in comparative law

Microcomparison. Microcomparison demands no particular preparation. The specialist in one national system is usually qualified to study those of various other countries of the same general family. His chief need is access to bibliographical material. In the United States, each state has its own statutes and, to some purposes, its own common law. Thus, the American lawyer must be a microcomparatist as he takes the 50 state systems and the federal law into daily account in his practice of the law. The same is true, to a large extent, of the Australian, or Indian, or Kenyan lawyer, who must take into account not only his own national system but also the laws of England and of other common-law jurisdictions in the Commonwealth. Whatever can be said of the common-law systems holds largely true for the Roman-law and Socialist families. French comparative law students encounter little difficulty in contrasting the laws of certain countries, so long as they confine their study to French, German, Italian, and Dutch law, which are related in tradition and structure and serve a similar type of society.

Macrocomparison. The situation differs greatly in consideration of macrocomparison. Here no comparison is possible without previously identifying and thoroughly mastering the fundamentals of the law systems as they differ from place to place. The jurist must, as it were, forget his training and begin to reason according to new criteria. If he is French, English, or American, he must recognize that in some folk societies of the Far East, the upright citizen never crosses the threshold of a courtroom and acknowledges no subjective rights; instead, the citizen's behaviour is governed by rites handed down from his ancestors, ensuring him the approval of the community. Likewise, if the Western jurist is to understand the law of the Muslim or Hindu, he must realize that the law is contained in rules of conduct laid down by a religion for its followers, and for its followers only. These rules, creating obligations and not rights, rank above all worldly matters and, in particular, are not to be confused with the regulations that a national government may, at a given time, enact and ratify. Further, in comparing his system of law with that of a Communist nation, the Westerner must remember that on no account does the citizen of a Marxist-Leninist state regard the rule of law as an ideal for society. Far from it, for his dream is to see law—which to him is synonymous with injustice and coercion—wither away in an affluent society founded on human solidarity and fellowship. A considerable shifting of legal gears is necessary before a French or German jurist can grasp the vital importance that the English or American lawyer traditionally attaches to the concept of due process and the rules of evidence; in continental eyes, procedural rules take second place to substantive law.

Mastering fundamentals of a foreign system

The specialist of macrocomparison also picks out the structural differences existing between certain systems. Accordingly, the Anglo-American lawyer must be aware of the importance of the distinction between public and private law—between law involving the state and law involving only individuals. The jurist in a Roman-law country must, conversely, appreciate the significance of the concepts of common law (unwritten customary law of various kinds) and equity (the use of injunctions and other equitable remedies), neither of which have counterparts in his own system. The lawyer from a centralized country must familiarize himself with the distinction between federal law and the laws of secondary jurisdictions (states, provinces, cantons, and so forth)—a distinction that is of fundamental importance in many countries. If he is from a nation like England or France that acknowledges the sovereignty of the national parliament, he must give due weight to the prominence of constitutional law in countries that permit courts to review the constitutional validity of legislative acts—especially in countries such as the United States and the Federal Republic of Germany. The jurist in a "bourgeois" country must appreciate the policy of collective ownership of means of production in Socialist states.

Parliamentary versus constitutional law

Classification of families of law. The terms microcomparison and macrocomparison, reflecting the language of economics, are in keeping with the idea that legal systems can be grouped into families, such as common-law, Roman, and Socialist. But it must be acknowledged that the number of identifiable families and the appropriate classification of a given system are questions always open to argument. The legal system of a given country, for instance, may exhibit some features that relate it to a particular family and others that may escape that classification. Such blurring of distinctions is particularly true of law in countries of Africa and the Middle East, where certain sectors of the law have been transformed by Western ideas (as in criminal and mercantile law and procedure) leaving other sectors (such as personal status, family law, and land law) faithful to traditional principles of the region. The phenomenon is not peculiar to those countries, however.

Wide differences also may be detected between legal systems that are commonly regarded as belonging to the same family. American law, for instance, without hesitation is ranked as a member of the common-law family; yet countless differences set it apart from English law, in large part because the United States has a federal and England a unitary system of government.

PURPOSES OF COMPARATIVE LAW

Historical and cultural comparisons. First of all, there has been a tendency to view comparative law from the standpoint of its value to the historical study of legal decision making—a consideration that was responsible for establishing the first chairs of comparative law in 19th-century Europe. Ideas regarding the place of law in society and the nature of the law itself—whether divine or secular, whether dealing with substantive or procedural rules—obviously become appreciably clearer when comparative law is joined to historical research. Indeed, to some extent historical background may aid in forecasting the future of certain national systems

A closely related consideration prompts many Western jurists, political scientists, and sociologists to acquaint themselves with non-Western methods of reasoning. Comparative studies reveal that the citizen of some countries of Asia and Africa looks upon the concept of a just social order with thoughts and feelings far removed from those of Western man. The notions of a rule of law and of rights of the individual—fundamental to Western civilization—are not wholly recognized by those societies that, faithful to the principle of conciliation and concerned primarily with harmony within the group, do not favour excessive Western-style individualism or the modern Western ideal of legal supremacy. Thus comparative law may enable statesmen, diplomats, and jurists to understand foreign points of view, and it may frequently help to create better international understanding.

Understanding another culture's reasoning

Commercial uses. Comparative law may be used for essentially practical ends. The businessman, for instance, needs to know what benefits he may expect, what risks he may run, and generally how he should act if he intends to invest capital or make contracts abroad. It was with this purpose in mind that the first French institute of comparative law was set up in Lyon in 1920; its mission was to instruct French legal advisers on foreign trade. It was this practical aspect that also encouraged the growth of comparative law in the United States, where the essential aim of the law school has been usually to turn out practitioners; and one need hardly mention the strong link in Germany between big industry and the various institutes of comparative law. Sometimes it is said that studies with such a focus should not be considered a part of comparative law, but practical considerations certainly have helped to finance and promote the development of comparative legal studies in general.

Aid to national law. The improvement of national legislation was the prime consideration during the 19th century in countries that were codifying or recodifying their legal systems. Numerous later additions to the Code Napoléon, drawn up in 1804, for instance, were of foreign origin. Many other nations, of course, followed France's lead and introduced into their own systems elements of the French Napoleonic codes and institutions of French public law. It is well worth noticing that a book on French administrative laws was published in German by Otto Mayer before Mayer felt himself able to write a textbook on German administrative law.

The foreign inspiration of a number of legal rules or institutions is a well-known phenomenon, sometimes so all-embracing that one speaks of "reception"—reception, for instance, of the English common law in the United States, Canada, Australia, India, and Nigeria; reception of French law in French-speaking Africa, Madagascar, Egypt, and Indochina; reception of Swiss law in Turkey; and reception of both German and French law in Japan, along with even some reception of American common law. The study of comparative law has found a special place in countries where such a reception has occurred.

Use in international law. In modern times the spirit of nationalism has often tended to frustrate the development of an international law that would overcome individual national differences. One task facing statesmen and jurists is to inject new life into this effort, adapting it to the exigencies of the modern world. Those engaging in international trade, for instance, do not know with certainty which national law will regulate their agreements, since the answer depends to a large extent on a generally undecided factor—namely, which national court will be called upon to decide the questions of competence. Thus, the sole lasting remedy would seem to be the development of an international law capable of governing all legal questions outside the jurisdiction of a single state. Such a project can succeed only through the medium of comparative law.

(R.Da./Ed.)

BIBLIOGRAPHY. The most comprehensive and detailed bibliographical background for the history of the social sciences is to be found in the *Encyclopaedia of the Social Sciences,* 15 vol. (1930–35), still valuable, especially in its historical sections, despite its age; and in the *International Encyclopedia of the Social Sciences,* 17 vol. (1968). The best individual work, by now a classic in the history of ideas, on the period leading up to the emergence of the individual social sciences, is PRESERVED SMITH, *A History of Modern Culture,* 2 vol. (1930–34, reprinted 1962). JAMES WESTFALL THOMPSON, *A History of Historical Writing,* 2 vol. (1942), is useful in this respect also. On the age immediately preceding the rise of the social sciences, the best study by far is LESTER G. CROCKER, *Nature and Culture: Ethical Thought in the French Enlightenment* (1963), and *An Age of Crisis: Man and World in Eighteenth Century French Thought* (1959), recommended to be read or consulted in that order. The best general work on the history of the social sciences and the history of social philosophy in the West is HARRY ELMER BARNES and HOWARD BECKER, *Social Thought from Lore to Science,* 2nd ed., 2 vol. (1952). The first volume deals with the issues and problems of all the social sciences, with major emphasis on the period following the breakup of the Middle Ages; the second volume is primarily concerned with sociology in the 20th century.

ERIC J. HOBSBAWM, *The Age of Revolution: 1789–1848* (1962), is an important and fascinating treatment of the social, cultural, and intellectual aspects of the age in which the individual social sciences emerged in western Europe. ROBERT A. NISBET, *The Sociological Tradition* (1966), although concerned primarily with sociology, deals with the specific ways in which the ideologies and themes of the democratic and industrial revolutions became translated into social theory. The same author's *Social Change and History* (1969) deals in detail with the incorporation of the theory of social evolution into the social sciences of the 19th century. For the rise and development of the individual social sciences in the 19th and 20th centuries, the following works are recommended. (*Anthropology*): ROBERT H. LOWIE, *The History of Ethnological Theory* (1937); and MARVIN HARRIS, *The Rise of Anthropological Theory: A History of Theories of Culture* (1968). (*Economics*): ERICH ROLL, *A History of Economic Thought,* 3rd ed. rev. (1954); and the extremely readable ROBERT HEILBRONER, *The Worldly Philosophers: The Lives, Times, and Ideas of the Great Economic Thinkers,* 3rd ed. (1967). (*Political science*): GEORGE SABINE, *A History of Political Theory,* 3rd ed. (1959), best on the three centuries preceding the 20th; FRANCIS W. COKER, *Recent Political Thought* (1934), excellent for the early 20th century; and LEO STRAUSS and JOSEPH CROPSEY (eds.), *History of Political Philosophy* (1963). (*Sociology*): Barnes and Becker, referred to above, for detailed information on the history of sociology in the 19th and early 20th centuries; Nisbet, also referred to above, dealing with the relation between political ideologies and the currents of sociological thought in the late 19th century; and LEWIS A. COSER, *Masters of Sociological Thought* (1971), a very good general history of sociology in 19th- and 20th-century Europe and America. (*Social psychology*): FAY BERGER KARPF, *American Social Psychology: Its Origins, Development and European Background* (1932), the best account of social psychology in the 19th and early 20th centuries, and THOMAS C. WIEGELE, *Biology and the Social Sciences* (1982), on the effect biological research is having on the social science disciplines.

For authoritative and easily available accounts of very recent developments in the social sciences, the reader is advised to turn to the articles in this encyclopaedia on the individual social sciences both for content and for bibliographical sources. The *International Encyclopedia of the Social Sciences,* already referred to above, is indispensable in this respect.

Anthropology: Histories of anthropological science include T.K. PENNIMAN, *A Hundred Years of Anthropology,* 3rd ed. rev. (1965), which covers all of anthropology; and P. MERCIER, *Histoire de l'anthropologie* (1966), which covers only cultural anthropology. The principal textbooks are M.J. HERSKOVITS, *Man and His Works* (1948); F.M. KEESING, *Cultural Anthropology: The Science of Custom* (1958); and J. POIRIER (ed.), *Ethnologie générale* (1968). In cultural anthropology—aside from two works by the "fathers" of the discipline, L.H. MORGAN, *Ancient Society* (1877); and E.B. TYLOR, *Anthropology: An Introduction to the Study of Man and Civilisation* (1881)—some of the classic general works are FRANZ BOAS, *The Mind of Primitive Man* (1911), and *Race, Language and Culture* (1940); BRONISLAW MALINOWSKI, *A Scientific Theory of Culture, and Other Essays* (1944); A.R. RADCLIFFE-BROWN, *Structure and Function in Primitive Society* (1952); A.L. KROEBER (ed.), *Anthropology Today* (1953); CLAUDE LEVI-STRAUSS, *Anthropologie structurale* (1958; Eng. trans. 1963); G. BALANDIER, *Anthropologie politique* (1967; Eng. trans. 1971); and M. MAUSS, *Oeuvres* (1968). Studies of individual peoples that have become classics include W.H.R. RIVERS, *The Todas* (1906); M. GRANET, *Fêtes et chansons anciennes de la Chine* (1919; Eng. trans., *Festivals and Songs of Ancient China,* 1932); BRONISLAW MALINOWSKI, *The Argonauts of the Western Pacific* (1922), and *Coral Gardens and Their Magic* (1935); A.R. RADCLIFFE-BROWN, *The Andaman Islanders* (1922); MARGARET MEAD, *Coming of Age in Samoa* (1928); P. SCHEBESTA, *Bambuti, die Zwerge vom Kongo* (1932); FRANZ BOAS, *The Religion of the Kwakiutl Indians* (1930); R.F. FORTUNE, *Sorcerers of Dobu: The Social Anthropology of the Dobu Islanders of the Western Pacific* (1932); R.W. FIRTH, *We, the Tikopia: A Sociological Study of Kinship in Primitive Polynesia* (1936); M. GRIAULE, *Masques Dogons* (1938); M.J. HERSKOVITS, *Dahomey: An Ancient West African Kingdom* (1938); M. LEENHARDT, *Gens de la grande terre* (1937); E.E. EVANS-PRITCHARD, *The Nuer* (1940); and E.R. LEACH, *Political Systems of Highland Burma: A Study of Kachin Social Structure* (1954).

Sociology: Among older titles of major significance, generally considered classics, are W.G. SUMNER, *The Folkways* (1907, reissued 1940); C.H. COOLEY, *Human Nature and the Social Order* (1902, reissued 1967); G.H. MEAD, *Mind, Self, and Society,* ed. by C.W. MORRIS (1934); E. FARIS, *The Nature of Human Nature* (1937); R.E. PARK and E.W. BURGESS, *Introduction to the Science of Sociology* (1921, reissued 1969); and W.F. OGBURN, *Social Change with Respect to Culture and Original Nature,* new ed. (1950; suppl. ch., 1964). A comprehensive summary of early sociological theory is available in H.E. BARNES (ed.), *An Introduction to the History of Sociology* (1948). The following titles provide excellent coverage of the main directions and subfields of recent and contemporary sociology: R.E.L. FARIS (ed.), *Handbook of Modern Sociology* (1964); R.K. MERTON, L. BROOM, and L.S. COTTRELL (eds.), *Sociology Today,* 2 vol. (1959, reissued 1965); G.D. GURVITCH and W.E. MOORE (eds.), *Twentieth Century Sociology* (1945); J.G. MARCH (ed.), *Handbook of Organizations* (1965); and N.J. SMELSER and J.A. DAVIS (eds.), *Sociology* (1969). Two influential general texts are L. BROOM and P. SELZNICK, *Sociology,* 4th ed. (1968); and G.A. LUNDBERG *et al., Sociology,* 4th ed. (1968). Leading books treating communities and societies as wholes are TALCOTT PARSONS, *Societies: Evolutionary and Comparative Perspectives* (1966); I.T. SANDERS, *The Community,* 2nd ed. (1966); R.K. MERTON, *Social Theory and Social Structure,* rev. ed. (1957); G.C. HOMANS, *Social Behaviour: Its Elementary Forms* (1961); G.E. LENSKI, *Human Societies: A Macrolevel Introduction to Sociology* (1970); and A.L. STINCHCOMBE, *Constructing Social Theories* (1968). The technical and statistical methods used in sociology are presented in E.F. BORGATTA (ed.), *Sociological Methodology* (1968); and J.H. MUELLER, K.F. SCHUESSLER, and H.L. COSTNER, *Statistical Reasoning in Sociology,* 2nd ed. (1970). ERNEST GELLNER, *Soviet and Western Anthropology* (1980), illustrates differing approaches to anthropological study.

Social psychology: Excellent general textbooks include EDWIN P. HOLLANDER, *Principles and Methods of Social Psychology,* 2nd ed. (1971); and ROGER W. BROWN, *Social Psychology* (1965). A comprehensive account of research is G. LINDZEY and E. ARONSON (eds.), *Handbook of Social Psychology,* 2nd ed., 5 vol. (1968–69). A useful account of theories is MARVIN E. SHAW and PHILIP R. CONSTANZA, *Theories of Social Psychology* (1970). Social psychology approached through detailed analysis of social interaction is described in MICHAEL ARGYLE, *Social Interaction* (1969). A. PAUL HARE, EDGAR F. BORGATTA, and ROBERT F. BALES (eds.), *Small Groups* (1965), is a most useful collection of papers. Research on social psychology in industry is described in BERNARD M. BASS, *Organizational Psychology* (1965). Social behaviour in relation to personality is dealt with in EDGAR F. BORGATTA and WILLIAM W. LAMBERT (eds.), *Handbook of Personality Theory and Research* (1968). A so-called symbolic interactionist approach is represented by GREGORY P. STONE and HARVEY A. FARBERMAN, *Social Psychology Through Symbolic Interaction* (1970); and by ERVING GOFFMAN, *Relations in Public* (1971).

Criminology: Important titles include H. MANNHEIM, *Comparative Criminology,* 2 vol. (1965); M.E. WOLFGANG and F. FERRACUTI, *Il comportamento violento* (1966; Eng. trans., *The Subculture of Violence,* 1967); H. MANNHEIM (ed.), *Pioneers in Criminology,* 2nd ed. (1972); L. RADZINOWICZ, *Ideology and*

Crime (1966), a survey containing much historical material; J.T. SELLIN and M.E. WOLFGANG, *The Measurement of Delinquency* (1964), an attempt to find an operational definition of serious offenses and to construct a "crime index"; H. MANNHEIM, *Social Aspects of Crime in England Between the Wars* (1940); F.H. MCCLINTOCK and N.H. AVISON, *Crime in England and Wales* (1968), partly an updating of the preceding work; L.T. WILKINS, *Social Deviance* (1964), an attempt to bridge the gap between social research and social action from the viewpoint of the statistician; H. MANNHEIM and L.T. WILKINS, *Prediction Methods in Relation to Borstal Training* (1955); S. and E. GLUECK, *Predicting Delinquency and Crime* (1959), and *Ventures in Criminology* (1964); and A.K. BOTTOMLEY, *Criminology in Focus: Past Trends and Future Prospects* (1979).

Economics: The best introduction to methodological issues in economics is still L. ROBBINS, *The Nature and Significance of Economic Science,* 2nd ed. (1935). A more modern position on empirical testing is well conveyed by M. FRIEDMAN in *Essays in Positive Economics* (1953). The best way to learn about economics is to browse through an introductory textbook such as P.A. SAMUELSON, *Economics: An Introductory Analysis,* 8th ed. (1970); R.G. LIPSEY and P.O. STEINER, *Economics,* 2nd ed. (1969); or A.A. ALCHIAN and W.R. ALLEN, *University Economics* (1964). Good histories of economic thought include H.L. HEILBRONER, *The Worldly Philosophers,* rev. ed. (1953), a pleasure to read; O.H. TAYLOR, *A History of Economic Thought* (1960), arranged chronologically; and E. WHITTAKER, *A History of Economic Ideas* (1940), arranged topically. J.A. SCHUMPETER, *History of Economic Analysis* (1954); and M. BLAUG, *Economic Theory in Retrospect,* 2nd ed. (1968), are advanced references. Excellent articles on the great economists, as well as superb but sometimes quite difficult essays on the leading branches of modern economics may be found in the *International Encyclopedia of the Social Sciences,* 16 vol. (1968). Further readings for advanced students are those published by the American Economic Association, *Survey of Contemporary Economics, I,* ed. by H.S. ELLIS (1948); *A Survey of Contemporary Economics, II,* ed. by B.F. HALEY (1952); and *Surveys of Economic Theory,* 3 vol. (1965). Each branch of economics has its own text. (*Microeconomics*): C.E. FERGUSON, *Microeconomic Theory,* 2nd ed. (1969); K.J. COHEN and R.M. CYERT, *Theory of the Firm: Resource Allocation in a Market Economy* (1965). (*Macroeconomics*): G. ACKLEY, *Macroeconomic Theory* (1961); T.F. DERNBURG and D.M. MCDOUGALL, *Macroeconomics,* 3rd ed. (1968). (*Development economics*): C.P. KINDLEBERGER, *Economic Development,* 2nd ed. (1965); B.H. HIGGINS, *Economic Development,* 2nd ed. (1968). (*Public finance*): R.A. MUSGRAVE, *The Theory of Public Finance* (1959). (*Monetary economics*): A.G. HART and P.B. KENEN, *Money, Debt and Economic Activity,* 3rd ed. (1961); L.V. CHANDLER, *The Economics of Money and Banking,* 5th ed. (1969). (*International economics*): C.P. KINDLEBERGER, *International Economics,* 4th ed. (1968). (*Labour economics*): A.M. CARTTER and F.R. MARSHALL, *Labour Economics: Wages, Employment, and Trade Unionism* (1966); L.C. HUNTER and D.J. ROBERTSON, *Economics of Wages and Labour* (1969). (*Industrial organization*): E.H. CHAMBERLAIN (ed.), *Monopoly and Competition and Their Regulation* (1954); J.S. BAIN, *Industrial Organization* (1959). (*Agricultural economics*): T.W. SCHULTZ. *The Economic Organization of Agriculture* (1953), and *Transforming Traditional Agriculture* (1964). (*Growth economics*): R.G.D. ALLEN, *Macro-Economic Theory: A Mathematical Treatment* (1967), a fairly difficult book; most texts on macroeconomics and economic development devote a chapter or two to growth theory. (*Mathematical economics*): A.C. CHIANG, *Fundamental Methods of Mathematical Economics* (1967). (*Econometrics*): A.A. WALTERS, *An Introduction to Econometrics* (1968); C. CHRIST, *Econometric Models and Methods* (1966). T.W. HUTCHISON, *The Politics and Philosophy of Economics: Marxians, Keynesians and Austrians* (1981), a history of economic thought; and DANIEL BELL and IRVING KRISTOL (eds.), *The Crisis in Economic Theory* (1981).

Political science: Although works of classical political philosophy are both venerable and extensive, few of them qualify as modern political science because they are neither quantitative nor, in most respects, even empirical in tone and temper. ARISTOTLE'S *Politics* and MACHIAVELLI'S *The Prince* come closest to meeting empirical standards. AUGUSTE COMTE, *Cours de philosophie positive,* 6 vol. (1830–42; Eng. trans., *The Positive Philosophy of Auguste Comte,* 2 vol., 1853), and *Système de politique positive,* 4 vol. (1851–54; Eng. trans., *System of Positive Polity,* 4 vol., 1875–77), are seminal statements in the 19th century on a science of society. LUDWIG GUMPLOWICZ, *Grundriss der Sociologie* (1885; Eng. trans., *The Outlines of Sociology,* 1899; 2nd ed., 1963); and GUSTAV RATZENHOFER in *Wesen und Zweck der Politik,* 3 vol. (1893), argue the case for the primacy of groups in studies of the state. A useful summary statement of the sociologies of the 19th century is NICHOLAS S. TIMASHEFF, *Sociological Theory: Its Nature and Growth,* 3rd ed. (1967). A good general work on the efforts of German jurists in the 19th century to cope with the facts of federalism is RUPERT EMERSON, *State and Sovereignty in Modern Germany* (1928). Among Americans who either studied in Germany in the 19th century or showed the influence of new European thought in their work were THEODORE D. WOOLSEY, *Political Science; or, The State Theoretically and Practically Considered,* 2 vol. (1877); JOHN W. BURGESS, *Political Science and Comparative Constitutional Law* (1891); WOODROW WILSON, *The State: Elements of Historical and Practical Politics* (1889), and *Congressional Government* (1885, reprinted 1961); and FRANK J. GOODNOW, *Politics and Administration: A Study in Government* (1900, reprinted 1967). An Englishman who studied American institutions was JAMES BRYCE, *The American Commonwealth,* 3 vol. (1888; abridged ed., 1959).

An excellent statement of the content of political-science teaching in America is ANNA HADDOW, *Political Science in American Colleges and Universities, 1636–1900* (1939, reprinted 1969). The most notable precursor of the behavioral approach in the 20th century was ARTHUR F. BENTLEY, *The Process of Government: A Study of Social Pressures* (1908, reprinted 1949). Others were GRAHAM WALLAS, *Human Nature in Politics,* 4th ed. (1962); and WALTER LIPPMANN, *Public Opinion* (1922; paperback ed., 1965). Besides works of the Chicago School mentioned in the article, the following may be noted: CHARLES E. MERRIAM, *Chicago: A More Intimate View of Urban Politics* (1929, reprinted 1970); LEONARD D. WHITE, *The Prestige Value of Public Employment in Chicago* (1929); and HAROLD D. LASSWELL and DANIEL LERNER (eds.), *The Policy Sciences: Recent Developments in Scope and Method* (1951), an effort to bring scientific method to the study of choices in public policy. Support for the establishment of a value-free science of politics was also provided by STUART A. RICE, *Quantitative Methods in Politics* (1928, reprinted 1969), who wrote the first general work on the application of statistical methods to the study of politics; GEORGE E.G. CATLIN, *The Science and Method of Politics* (1927); and WILLIAM BENNETT MUNRO, *Invisible Government* (1928). A useful summary survey of political science around the world after the end of World War II is *Contemporary Political Science,* published in 1950 by the UNITED NATIONS EDUCATIONAL, SCIENTIFIC AND CULTURAL ORGANIZATION.

International relations: ADDA B. BOZEMAN, *Politics and Culture in International History* (1960), is the best guide to histories and concepts of past international systems. Other useful references that survey premodern international relations are COLEMAN PHILLIPSON, *The International Law and Custom of Ancient Greece and Rome,* 2 vol. (1911); RICHARD L. WALKER, *The Multi-State System of Ancient China* (1953); GEOFFREY F. HUDSON, *Europe and China: A Survey of Their Relations from the Earliest Times to 1800* (1931); FRANK M. RUSSELL, *Theories of International Relations* (1936); and SHMUEL N. EISENSTADT, *Political Systems of Empires* (1963). Accounts of the earlier development of the academic study of international relations may be found in EDITH E. WARE, *A Study of International Relations in the United States: A Survey for 1937* (1938); SIR ALFRED ZIMMERN, *The Study of International Relations* (1931); and GRAYSON L. KIRK, *The Study of International Relations in American Colleges and Universities* (1947). Representative of the work of the 1930s that widened the scope of the field are HAROLD D. LASSWELL, *World Politics and Personal Insecurity* (1935; paperback ed., 1965); FREDERICK L. SCHUMAN, *International Politics: An Introduction to the Western State System and the World Community,* 6th ed. (1958); C.K. LEITH, *World Minerals and World Politics* (1931, reprinted 1970); W.S. THOMPSON, *Danger Spots in World Population* (1929); PAUL RADIN, *The Racial Myth* (1934); NICHOLAS SPYKMAN, *America's Strategy in World Politics* (1942, reprinted 1970); CARL J. FRIEDRICH, *Foreign Policy in the Making* (1938); BROOKS EMENY, *The Strategy of Raw Materials* (1935); ABRAM KARDINER, *The Psychological Frontiers of Society* (1945); QUINCY WRIGHT, *A Study of War,* 2nd ed., 2 vol. (1965); and E.H. CARR, *The Twenty Years' Crisis, 1919–1939,* 2nd ed. (1946, reprinted 1964). The theory of political realism is expressed by HANS J. MORGANTHAU in *Politics Among Nations* (1948). The idealist attempt to answer the challenge of political realism may be traced in THOMAS I. COOK and MALCOLM MOOS, *Power Through Purpose: The Realism of Idealism as a Basis for Foreign Policy* (1954); and JOHN H. HERZ, *Political Realism and Political Idealism* (1951). Four books on the psychological and cultural aspects of the behavioral study of international relations providing an excellent introduction are J. DAVIS SINGER, *Human Behavior and International Politics* (1965); OTTO KLINEBERG, *The Human Dimension in International Relations* (1964); JOSEPH H. DE RIVERA, *The Psychological Dimension of Foreign Policy* (1968); and HERBERT C. KELMAN, *International Behavior* (1965). The most famous book of its time on a psychocultural interpretation of national behaviour was RUTH BENEDICT, *The Chrysanthemum and the Sword* (1946, reprinted

1967). RICHARD C. SNYDER, H.W. BRUCK, and BURTON SAPIN, *Decision-Making as an Approach to the Study of International Politics* (1954), is still basic reading on the decision-making approach, but see also the data in GLENN D. PAIGE, *The Korean Decision* (1968). The most convenient compilation of varied examples of the theory and research of the behavioral decade is JAMES N. ROSENAU, *International Politics and Foreign Policy,* rev. ed. (1969). For conflict theory and international applications of game theory, see KENNETH E. BOULDING, *Conflict and Defense: A General Theory* (1962); THOMAS C. SCHELLING, *The Strategy of Conflict* (1960); and ANATOL RAPOPORT, *Fights, Games and Debates* (1960). EDWARD MCWHINNEY, *Conflict and Compromise: International Law and World Order in a Revolutionary Age* (1981), studies the effectiveness of law in resolving disputes among nations.

An introductionto general system theory in the social sciences is WALTER BUCKLEY, *Sociology and Modern Systems Theory* (1967). MORTON A. KAPLAN, *System and Process in International Politics* (1957); and CHARLES A. MCCLELLAND, *Theory and the International System* (1966), take different approaches to the applications of general systems ideas in the study of international relations. Important material on computer applications is included in DAVIS B. BOBROW and JUDAH L. SCHWARTZ, *Computers and the Policy-Making Community; Applications to International Relations* (1968).

Comparative law: A good historical survey is H.C. GUTTERIDGE, *Comparative Law,* 2nd ed. (1949). J.H. WIGMORE, *A Panorama of the World's Legal Systems,* 3 vol. (1928; 1-vol. ed., 1936), gives a general account of 16 legal systems. The ASSOCIATION OF AMERICAN LAW SCHOOLS, *A General Survey of Events, Ideas, Persons and Movements in Continental Legal History* (1912), is a pioneer book, in which the legal traditions of various European countries are discussed by specialists from each country. R. DAVID and J.E.C. BRIERLEY, *Les Grands systèmes de droit contemporains* (1964; Eng. trans., *Major Legal Systems in the World To-day,* 1968), a more up-to-date book originally devised for students, it describes the problems and value of comparative law and provides information on civil, Socialist, common, and religious and traditional law, ending with a valuable bibliography. *The International Encyclopaedia of Comparative Law,* proposed 16 vol. (1971–), will, when completed, constitute a major source of information.

Social Structure and Change

Social structure and social change are general concepts used by social scientists, particularly in the fields of sociology and social and cultural anthropology. They are often conceived of as polarized twin concepts, social structure referring to permanence, social change to the opposite. The relationship between the two concepts is, however, more complicated. "Structure," for instance, does not necessarily indicate lack of change. Those features of a society, or any other social group, that are regarded as parts of its structure are always generated by dynamic processes. For example, the kinship structure of a given society (the typical composition of household units and the rules governing marriage and line of descent) is maintained by continuous changes in families, as marriages are concluded; children are born, grow up, and become adults; and people die. Second, although many social processes show a cyclical pattern—the formation, dissolution, and reformation of families being one example—social life never repeats itself completely. The kinship relations in one generation are never an exact replica of those in the previous one. The same processes that serve to maintain the social structure may also lead to social change and modification of the structure over a long period.

The concepts of social structure and social change pertain not only to basic characteristics of human social life but also to certain ideals and preferences. The structure, or order, of the society, generally regarded as harmonious and conducive to the general well-being, has also been seen as conflict-ridden and repressive. Similarly, social change has been conceived of both as progress and as decay, as emancipation on the one hand and as deviance from good tradition on the other. Such widely varying evaluations have influenced different theories concerning the nature of social structure and social change, and they continue to be reflected, to some extent, in present-day social thought.

This article is divided into the following sections:

SOCIAL STRUCTURE

The term structure has been used with reference to human societies since the 19th century. Before that time, it had been already applied to other fields, particularly construction and biology. Its biological connotations are evident in the work of several social theorists of the 19th and early 20th centuries, such as Herbert Spencer in England. He and others conceived of society as an organism, the parts of which are interdependent and thereby form a structure that is similar to the anatomy of a living body.

Structure compared to anatomy

The metaphor of construction is clear in the work of Karl Marx, where he speaks of "the economic structure [*Struktur*] of society, the real basis on which is erected a legal and political superstructure [*Überbau*] and to which definite forms of social consciousness correspond." This phrase expresses the Marxian view that the basic structure of society is economic, or material, and determines, at least to a large extent, the rest of social life, which is defined as spiritual or ideological.

Although social scientists since Spencer and Marx have disagreed on the concept of social structure, their definitions have certain elements in common. In the most general way, social structure may be defined as those features of a social entity (a society or group within a society) that have a certain permanence over time, are interrelated, and determine or condition to a large extent both the functioning of the entity as a whole and the activities of its individual members.

As may be inferred from this definition, several ideas are implicit in the notion of social structure. The concept expresses the idea that human beings form social relations that are not arbitrary and coincidental, but exhibit some regularity and persistence. The concept also refers to the observation that social life is not amorphous but is differentiated into groups, positions, and institutions that are interdependent, or functionally interrelated. These differentiated and interrelated characteristics of human groupings, although constituted by the social activities of individuals, are not a direct corollary of the wishes and intentions of these individuals; instead, individual choices are shaped and circumscribed by the social environment. The notion of social structure implies, in other words, that human beings are not completely free and autonomous in choosing their activities, but rather they are constrained

Ideas implicit in structure

by the social world they live in and the social relations they form with one another.

The social structure is sometimes simply defined as patterned social relations—those regular and repetitive aspects of the interactions between the members of a given social entity. Even on this descriptive level, the concept is highly abstract: it selects only certain elements from ongoing social activities. The larger the social entity considered, the more abstract the concept tends to be. What is considered as the social structure of a small group is generally much nearer to the daily activities of its individual members than that which is regarded as the social structure of a larger society. In the latter case the problem of selection is acute: what to include or not include as components of the social structure. The solution to the problem varies with the different theoretical views according to which characteristics of the society are regarded as particularly important.

Aspects of structure

Apart from these different theoretical views, some preliminary remarks on general aspects of the social structure of any society may be made. Most generally, social life is structured along the dimensions of time and space. Specific social activities take place at specific times, and time is divided into periods that are connected with the rhythms of social life—the routines of the day, the month, and the year. Specific social activities are also organized at specific places; particular places, for instance, are designated for such activities as working, worshiping, eating, or sleeping. Territorial boundaries delineate these places. These boundaries are defined by rules of property, which in any society structure the use and possession of scarce goods. In any society, moreover, there is a more or less regular division of labour. Yet another universal structural characteristic of human societies is the regulation of violence. The use of violence is everywhere a potentially disruptive force; at the same time, it is a means of coercion and coordination of activities. Human beings have formed political units, such as nations, within which the use of violence is strictly regulated and which, at the same time, are organized for the use of violence against outside groups.

In any society, furthermore, there are arrangements within the structure for sexual reproduction and the care and education of the young. These arrangements partly take the form of kinship and marriage relations. Finally, systems of symbolic communication, particularly language, everywhere structure the interactions between the members of a society.

Within the broad framework of these and other general features of human society, there is an enormous variety of social forms between and even within societies. Several theories have been developed to account for both the similarities and the varieties. In these theories certain aspects of social life are regarded as basic and, therefore, central components of the social structure.

Murdock's taxonomic scheme

Some social scientists use the concept of social structure as a device for creating an order for the various aspects of social life. Thus, the U.S. anthropologist George P. Murdock, in his *Social Structure* (1949), a comparative study of kinship systems, used the concept as a taxonomic scheme for classifying, comparing, and correlating aspects of kinship systems of different societies. In other studies, the concept is of greater theoretical importance; it is regarded as an explanatory concept, a key to the understanding of human social life. Some of the more prominent of these theories are reviewed here.

Structural functionalism. A.R. Radcliffe-Brown, a British social anthropologist, gave the concept of social structure a central place in his approach and connected it to the concept of function. In his view, the components of the social structure have indispensable functions for each other—the continued existence of the one component is dependent on that of the others—and for the society as a whole, which is seen as an integrated, organic entity. Radcliffe-Brown defined the social structure empirically as patterned, or "normal," social relations (those aspects of social activities that conform to accepted social rules or norms). These rules bind society's members to socially useful activities.

Structural functionalism was elaborated further by Talcott Parsons, a U.S. sociologist, who, like Radcliffe-Brown, was strongly influenced by the French social scientist Émile Durkheim. While Radcliffe-Brown focused on so-called primitive societies, Parsons attempted to formulate a theory that was valid for large and complex societies as well. For Parsons, the social structure is essentially normative; it consists of "institutionalized patterns of normative culture." Social behaviour is structured insofar as it conforms to norms, ranging from general ideas of right and wrong (values) to specific rules of behaviour in specific situations. These rules vary according to the positions of the individual actors: they define different roles, such as various occupational roles, or the roles of husband–father and wife–mother. Norms also vary according to the type of activities or sphere of life: they form clusters called social institutions, such as the institution of property or the institution of marriage. Norms, roles, and institutions are components of the social structure on different levels of complexity.

Relation of structure and norms

Theories of class and power. Parsons' work has been criticized for several reasons. One has been the comparatively meagre attention he paid to inequalities of power, wealth, and other social rewards. Other social theorists, including functionalists like the U.S. sociologist Robert K. Merton, have given these distributional properties a more central place in their concepts of social structure. For Merton and others, the social structure consists not only of normative patterns but also of the inequalities of power, status, and material privileges, which give the members of a society widely different opportunities and alternatives.

Social structure by class

In complex societies these inequalities define different strata, or classes, which form the stratification system, or class structure, of the society. Both aspects of the social structure, the normative and the distributive aspect, are strongly interconnected, as may be inferred from the observation that members of different classes often have different and even conflicting norms and values.

This leads to a consideration contrary to structural functionalism: certain norms in a society may be established, not because of any general consensus about their moral value, but because they are forced upon the population by those who have both the interest and the power to do so. To take one example, the "norms" of apartheid in South Africa reflect the interests and values of only one section of the population, which has the power to enforce them upon the majority. In theories of class and power this argument has been generalized: norms, values, and ideas are explained as the result of the power inequalities between groups with conflicting interests.

The Marxian view of structure

The most influential theory of this type has been Marxism, or historical materialism. The Marxian view is succinctly summarized in Marx's phrase that "the ideas of the ruling class are, in every age, the ruling ideas." These ideas are regarded as reflections of class interests and are connected to the power structure, which is identified with the class structure. This Marxian model, which was claimed to be particularly valid for capitalist societies, has met with several criticisms. One basic problem is its distinction between economic structure and spiritual superstructure, which are identified with social being and consciousness, respectively. This suggests that economic activities and relations are in themselves somehow not conscious, as if they were conceivable without knowing and thinking human beings.

Nevertheless, the Marxian model has become influential even among non-Marxist social scientists. The distinction between material structure and nonmaterial superstructure continues to be reflected in sociological textbooks as the distinction between social structure and culture. Social structure here refers to the ways people are interrelated or interdependent; culture refers to the ideas, knowledge, norms, customs, and capacities that they have learned and share as members of a society.

Structuralism. The concept of structure in the study called structuralism, as in structural functionalism and the class and power theories, is theoretical and explanatory. Unlike those other studies, however, it is not descriptive. The concept here refers to the underlying, unconscious regularities of human expressions, which are not observ-

Lévi-Strauss and underlying structure

able but explain what is observed. Claude Lévi-Strauss, a French anthropologist, derived this concept from structural linguistics as developed by the Swiss linguist Ferdinand de Saussure. Any language is structured in the sense that its elements are interrelated in nonarbitrary, regular, rule-bound ways; a competent speaker of the language largely follows these rules without being aware of doing so. The task of the theorist is to detect this underlying structure, including the rules of transformation that connect the structure to the various observed expressions.

According to Lévi-Strauss, this same method can be applied to social and cultural life in general. He constructed theories concerning the underlying structure of kinship systems, myths, and customs of cooking and eating. The structural method, in short, purports to detect the common structure of widely different social and cultural forms. The structure does not determine the concrete expressions; the variety of expressions it generates is potentially unlimited. The structures that generate the varieties of social and cultural forms ultimately reflect, according to Lévi-Strauss, basic characteristics of the human mind.

Structuralism became an intellectual fashion in the 1960s in France, where such different writers as Roland Barthes, Michel Foucault, and Louis Althusser were also regarded as representatives of the new theoretical current. Structuralism in this wide sense, however, is not one coherent theoretical perspective. The Marxist structuralism of Althusser, for example, is far removed from Lévi-Strauss's anthropological structuralism. The structural method, when applied by different scholars, appears to lead to different results.

The criticisms launched against structural functionalism, class theories, and structuralism indicate that the concept of social structure is problematic. Yet the notion of social structure is not so easy to dispense with, because it expresses ideas of continuity, regularity, and interrelatedness in social life. Other terms are often used that have similar, but not identical, meanings, such as social network, social figuration, or social system. The British sociologist Anthony Giddens has suggested the term "structuration" in order to express the view that social life is, to a certain extent, both dynamic and ordered.

SOCIAL CHANGE

Social change in the broadest sense is any change in social relations. In this sense, social change is an ever-present phenomenon in any society. In order to give the concept a more restricted meaning, it has been defined as change of the social structure. A distinction is made then between processes within the social structure, which serve, at least partially, to maintain the structure (social dynamics), and processes that modify the structure (social change). Because the concept of social structure does not have one generally accepted and unambiguous meaning, however, this distinction does not clearly determine which social processes belong to the field of social change.

The specific meaning of social change depends first of all on the social entity considered. Changes in a small group may be important on the level of that group itself, but negligible on the level of the larger society. Similarly, the observation of social change depends on the time span taken; most short-term changes are negligible if a social development is studied in the long run. Even if one abstracts from small-scale and short-term changes, social change is a general characteristic of human societies: customs and norms change, inventions are made and applied, environmental changes lead to new adaptations, conflicts result in redistributions of power.

Biological roots of change

This universal human potential for social change has a biological basis. It is rooted in the flexibility and adaptability of the human species—the near absence of biologically fixed action patterns on the one hand and the enormous capacity for learning, symbolizing, and creating on the other hand. The human biological constitution makes changes possible that are not biologically (genetically) determined. Social change, in other words, is only possible by virtue of biological characteristics of the human species, but the nature of the actual changes cannot be reduced to these species traits.

Historical background. Several ideas of social change have been developed in various cultures and historical periods. Three of them may be distinguished as the most basic: (1) the idea of decline or degeneration, or, in religious terms, the fall from an original state of grace; (2) the idea of cyclical change, a pattern of subsequent and recurring phases of growth and decline; and (3) the idea of continuous progress. These three ideas were already prominent in Greek and Roman antiquity and have characterized Western social thought from that time. The concept of progress, however, became the most influential idea, especially since the 18th-century Enlightenment. Social thinkers like Anne-Robert-Jacques Turgot and the Marquis de Condorcet in France and Adam Smith and John Millar in Scotland advanced theories on the progress of human knowledge and technology.

Social evolution as progress

Progress was the key idea in 19th-century theories of social evolution, and evolutionism was the common core shared by the most influential social theories of the century. Evolutionism implied that mankind as a whole progresses along one line of development; that this development is predetermined and inevitable, since it corresponds to definite laws; that some societies are more advanced in this development than other ones; and that Western society is the most advanced and therefore indicates the future of the rest of mankind. Auguste Comte, a French philosopher and sociologist, advanced a "law of three stages," according to which mankind progresses from a theological stage, which is dominated by religion, through a metaphysical stage, in which abstract speculative thinking is most prominent, and onward toward a positivist stage, in which scientific theories based on empirical research come to dominate.

The most encompassing theory of social evolution was developed by Herbert Spencer, who, unlike Comte, linked social evolution to biological evolution. According to Spencer, biological organisms and human societies follow the same universal, natural evolutionary law: "a change from a state of relatively indefinite, incoherent, homogeneity to a state of relatively definite, coherent, heterogeneity." In other words, as societies grow in size, they become more complex; their parts differentiate, specialize into different functions, and become, consequently, more interdependent.

Morgan's evolutionary rankings

Evolutionary thought also dominated the new field of social and cultural anthropology in the second half of the 19th century. Anthropologists such as Sir Edward Burnett Tylor and Lewis Henry Morgan classified contemporary societies on an evolutionary scale. Morgan ranked them from "savage" through "barbarian" to "civilized." Tylor postulated an evolution of religious ideas from animism through polytheism to monotheism. Morgan classified societies on the basis of the level of technology, or sources of subsistence, which he connected with the kinship system. He assumed that monogamy was preceded by polygamy, and patrilineal descent by matrilineal descent.

Marx and Friedrich Engels too were highly influenced by evolutionary ideas. The Marxian distinctions between primitive communism, the Asiatic mode of production, ancient slavery, feudalism, capitalism, and future socialism may be interpreted as a list of stages in one evolutionary development, although the Asiatic mode did not fit well in this scheme. Marx and Engels were impressed by Morgan's anthropological theory of evolution, which became evident in Engels' book *Der Ursprung der Familie, des Privateigentums und des Staats* (1884; *The Origin of the Family, Private Property and the State*).

The originality of the Marxian theory of social development lay in its combination of dialectics and gradualism. In Marx's view social development was a dialectical process: the transition from one stage to another took place through a revolutionary transformation, which was preceded by increasing deterioration of society and intensifying class struggles. Underlying this discontinuous development was the more gradual development of the forces of production (technology and organization of labour).

Marx was influenced by the countercurrent of Romanticism, which was opposed to the idea of progress. This influence was evident in his notion of "alienation," which meant that in the course of social development people had increasingly lost control over the social forces that they had produced by their own activities. Romantic counterprogressivism was, however, much stronger in the work of other social theorists of the century, such as Ferdinand Tönnies, a German sociologist. He distinguished between the community (*Gemeinschaft*), in which people were bound together by common traditions and ties of affection and solidarity, and the society (*Gesellschaft*), in which social relations had become contractual, rational, and nonemotional.

Gemeinschaft and *Gesellschaft*

Durkheim and Max Weber, sociologists who began their careers at the end of the 19th century, showed ambivalence toward the ideas of progress. Durkheim regarded the increasing division of labour as a basic process, which was at the roots of modern individualism, but could also lead to "anomie," or lack of moral norms. Weber rejected evolutionism by arguing that the development of Western society was quite different from that of other civilizations and therefore historically unique. It was characterized, according to Weber, by a peculiar type of rationalization, which had brought modern capitalism, modern science, and rational law, but also, on the negative side, a "disenchantment of the world" and increasing bureaucratization.

The work of Durkheim, Weber, and other social theorists around the turn of the century marked a transition from evolutionism toward more static theories. Evolutionary theories were criticized on empirical grounds—they could be refuted by a growing mass of research findings—and because of their determinism and Western-centred optimism. Theories of cyclical change that denied long-term progress gained popularity in the first half of this century; these included the theory of the Italian economist and sociologist Vilfredo Pareto on the "circulation of elites" and those of Oswald Spengler and Arnold Toynbee on the life cycle of civilizations. Although the interest in long-term social change never disappeared, it faded to the background, especially when, from the 1920s until the 1950s, functionalism, emphasizing an interdependent social system, became the dominant paradigm both in anthropology and in sociology. "Social evolution" was substituted for the more general and neutral concept of "social change."

Decline of evolutionism

From the 1950s and increasingly through the 1960s and 1970s there was a revival of interest in long-term social change. Neo-evolutionist theories were proclaimed by several anthropologists, including Ralph Linton, Leslie A. White, Julian H. Steward, Marshall D. Sahlins, and Elman Rogers Service. These authors hold to the idea of social evolution as a long-term development of mankind, which is patterned and cumulative in some respects. Neo-evolutionism differs from 19th-century evolutionism in that it does not assume that all societies go through the same stages of development; much attention is paid to variations between societies as well as to relations of influence among them. The latter concept has come to be known by the term acculturation. Moreover, social evolution is not regarded as predetermined or inevitable but is rather conceived in terms of probabilities. Finally, evolutionary development is not equated with progress.

The revival of interest in long-term social change has been partly induced by the problems of the so-called underdeveloped countries. In order to explain the gaps between rich and poor countries, Western sociologists and economists in the 1950s and 1960s elaborated modernization theories. These theories implied a covertly Western-centred evolutionism insofar as they assumed that poor countries had stagnated on a relatively low level of development and could and should develop, or modernize, in the direction of a Western-type society. Modernization theories have been criticized for their lack of attention to international power relations, in which the richer countries dominate the poorer ones. These relations have been brought into the centre of attention by more recent theories of international dependency or, in Immanuel Wallerstein's terms, the "world capitalist system."

Modernization theories

Since about 1965 there has been some convergence between sociology and anthropology on the one hand and history on the other. Historians have become interested in theories of long-term social change, while many sociologists and anthropologists increasingly turn toward history for the empirical testing and refinements of their theoretical viewpoints.

Patterns of social change. The common assumption of theories of social change, old and new, is that the course of such change is not arbitrary but, to a certain degree, regular or patterned. The three traditional ideas of social change—those of decline, cyclical change, and progress—have influenced modern theories. However, insofar as these theories are nonnormative, or scientifically determined, they do not distinguish explicitly between decline and progress. Such values cannot be derived from empirical observations alone but depend on normative evaluations, or value judgments. In nonnormative terms, then, two basic patterns of social change emerge: the cyclical and the one-directional. Often the time span of the change determines which pattern is observed.

Cyclical change. A regular alternation of stages characterizes cyclical change. Much of ordinary social life is organized in cyclical changes: those of the day, the week, and the year. These short-term cyclical changes may be regarded as conditions necessary to structural stability. Other changes that have a more or less cyclical pattern are less regular. For example, business cycles, recurrent phenomena of capitalist and industrial societies, are patterned to some extent yet hard to predict in concrete cases. A well-known theory of the business cycle is that of the Soviet economist Nikolay D. Kondratyev, who tried to show the recurrence of long waves of economic boom and recession on an international scale. He charted the waves from the end of the 18th century, with each complete wave comprising a period of about 50 years. Subsequent research has shown, however, that the patterns in different countries have been far from identical.

Kondratyev's waves

Long-term cyclical changes are rendered by theories on the birth, growth, flourishing, decline, and death of civilizations. Toynbee conceived world history in this way in the first volumes of *A Study of History* (1934–61), as did Spengler in his *Untergang des Abendlandes* (1918–22; *Decline of the West*). These theories have been criticized for their conception of civilizations as natural entities with sharp boundaries because this tends to neglect the interrelations between civilizations.

One-directional change. A continuation in terms of more or less characterizes one-directional change. Such change is usually cumulative; it implies growth or increase, such as that of population density, the size of organizations, or the level of production. However, the direction of the change may also be one of decrease, or a combination of growth and decrease. An example of this last process is what the American cultural anthropologist Clifford Geertz has called "involution," found in some agrarian societies: population growth coupled with decreasing per capita wealth. Or the change may be a shift from one to the other pole of a continuum—from religious to scientific ways of thinking, for example. Such a change may be defined as either growth (of scientific knowledge) or decline (of religion).

The concept of involution

The simplest type of one-directional change is linear: the extent of social change is constant over time. Another type of regular social change is exponential growth, in which the growth percentage is constant over time and the change accelerates correspondingly. Population growth and production growth often approximate this pattern during some periods of time.

A pattern of long-term growth may also conform to a three-stage S-curve: at the beginning of the period under consideration the change is almost imperceptibly slow, then accelerates, then slackens, until it approaches a supposed upper limit. The model of the demographic transition in industrializing countries exhibits this pattern. In the first stage, premodern or preindustrial, both the birthrate and the mortality rate are high, and, consequently, the population grows very slowly; then mortality decreases, and the population grows much faster; in the third stage both the birthrate and the mortality rate have become low, and the population growth approaches zero. The same model has been suggested, more hypothetically, for the rate of technological and scientific change.

Combined patterns of change. Cyclical and one-directional changes may be combined in one way or another. Very often short-term changes are cyclical while long-term development is in one direction. Figures on the production rates of industrializing countries conform, more or less, to this pattern, short-term business cycles occurring within long-term economic growth.

All of these pattern models cannot be applied simply and easily to social reality. They are at best approximations of parts of social reality. Comparing the model with the reality is not always possible because of a lack of reliable data. Moreover, and more importantly, many social processes do not lend themselves to precise quantitative measurement. Processes like bureaucratization or secularization, for example, can be defined as changes in a certain direction, but it is hard to measure the extent to which the change in a given period has taken place. It is doubtful that models like those of linear or exponential growth can be used in such cases.

Determination of long-term change

It remains to be seen whether or not long-term social change in a certain direction may be ascertained. Many investigations have sought answers to this question for Western society since the Middle Ages. The transformation of medieval society into the Western nations of the 20th century may be conceived in terms of several interconnected, long-term, one-directional changes; some of the more important of these include commercialization, increasing division of labour, growth of production, formation of national states, bureaucratization, growth of technology and science, secularization, urbanization, spread of literacy, increasing social and geographical mobility, and growth of organizations. Many of these changes have also occurred in non-Western societies. Most changes have not originated in the West, but some important changes did originate there—particularly such complex transformations as the rise of capitalism and the Industrial Revolution. These subsequently had a strong impact on non-Western societies. Groups of people outside western Europe have been incorporated in a global division of labour, in which the Western nation-states dominated both politically and economically.

General trends of social evolution

The extent to which these changes are part of a global, long-term social development is the central question of social evolution, which is conceived as a very long-term one-directional change for mankind as a whole. Although knowledge concerning this question is far from complete, some very broad and general trends may be hypothesized on firm ground. First, technological innovations and growing empirical knowledge led to an increasing control of natural forces for the satisfaction of human needs. Parts of this development were the use and control of fire, the cultivation of plants and the domestication of animals (dating from about 8000 BC), the use of metals, and the process of industrialization. This technological development, combined with long-term capital accumulation, led to rising production levels and, therefore, made possible population growth and increasing population density. Energy production and consumption grew, if not per capita then at least per square mile.

Interconnected with technological development and growth of production were the process of division of labour and social differentiation. On the one hand, it was only by division of labour and corresponding specialization of knowledge and abilities that the technical control of natural forces could increase beyond certain limits. On the other hand, the growth of production as a result of technological innovations contributed to further social differentiation; more people, in other words, could specialize in activities that were not immediately necessary for survival. Growing size and density of populations and social differentiation led to increased interdependence between growing numbers of people over longer distances. In hunting and gathering societies people were strongly interdependent within their small bands, depending on very little outside their groups. In modern times, most of the world's people are enmeshed in worldwide networks of interdependence.

These processes were not inevitable in the sense that they corresponded to any "law" of social change. They had the tendency, however, to spread whenever they occurred. For example, once the set of transformations known as the agrarian revolution had taken place anywhere in the world, their extension over the rest of the world was predictable. Societies that adopted these innovations grew in size and became more powerful. As a consequence, other societies had only three options: to be conquered and incorporated by a more powerful agrarian society; to adopt the innovations; or to be driven away to marginal places of the globe. Something similar might be said of the Industrial Revolution and other power-enhancing innovations, such as bureaucratization and the introduction of more destructive weapons. This last example illustrates that these processes should not be equated with progress in general.

Causal connections between social processes

Explanations of social change. One way of explaining social change is to show causal connections between two or more processes. This may take the form of a kind of determinism or reductionism, which explains all social change by reducing it to one supposed autonomous and all-determining causal process. A more cautious assumption is that one process has relative causal priority, without implying that this process is completely autonomous and all-determining. Following are some of the processes conceived as having caused social change.

Natural environment. Changes in the natural environment may vary from climatic ones to those caused by the spread of diseases. For example, both the worsening of climatic conditions and the epidemics of the Black Death have been submitted as factors that explain the crisis of feudalism in 14th-century Europe. Changes in the natural environment may be either independent of human social activities or the result of these activities. Deforestation and erosion, air pollution, and the exhaustion of natural resources belong to the last category, and they in turn may have far-reaching social consequences.

Demographic processes. Population growth and increasing population density represent, in particular, demographic forms of social change. Population growth may lead to geographical expansion of a society, military conflicts, and the intermingling of cultures. Increasing population density may also stimulate technological innovations, which may increase division of labour and social differentiation, commercialization, and urbanization. This has been observed as affecting western Europe from the 11th to the 13th century and England in the 18th century, where population growth was a factor in the Industrial Revolution. On the other hand, population growth may contribute to economic stagnation and increasing poverty, as may be witnessed in several Third World countries today.

Technological innovations. According to several theories of social evolution, technological innovations are regarded as the most important determinants of societal change. The social significance of such technological breakthroughs as the invention of the smelting of iron, the introduction of the plow in agriculture, the invention of the steam engine, and the development of the computer is indeed evident. Of course, it is possible to dispute the relative importance of such innovations when compared to other determinants of social change.

Economic processes. Technological changes are often considered in conjunction with economic processes, including the formation and extension of markets, modifications of property relations (such as the change from feudal lord–peasant relations to contractual proprietor–tenant relations), and changes in the organization of labour (such as the change from independent craftsmen to factories). Historical materialism, as developed by Marx and Engels, is the most influential theory that gives priority to economic processes, but it is not the only one. Materialist theories have been developed even in opposition to Marxism, one being the "logic of industrialization" thesis by the U.S. scholar Clark Kerr, which states that industrialization everywhere has similar consequences, whether the property relations are called capitalist or communist.

Ideas. Other theories have stressed the significance of ideas in the causation of social change. Comte's law of three stages is such a theory. Weber regarded religious ideas as important in contributing to economic development or stagnation; according to his controversial thesis, the individualistic ethic of Christianity, and in particular

Protestantism, partially explains the rise of the capitalist spirit, which brought economic dynamism in the West.

Social movement. A change of collective ideas is not merely an intellectual process; it is often connected to the formation of a new social movement. This in itself might be regarded as a potential cause of social change. Weber called attention to this factor in conjunction with his concept of "charismatic leadership." The charismatic leader, by virtue of the extraordinary personal qualities attributed to him, is able to create a group of followers who are willing to break established rules.

Political processes. Changes in the regulation of violence, in the nature of the state organization, and in international relations may also determine social change. For example, the German sociologist Norbert Elias has analyzed the formation of states in western Europe as a relatively autonomous process that led to an increasing control of violence and, consequently, to rising standards of self-control. According to recent theories of political revolution, the functioning of the state apparatus itself and the nature of interstate relations are of decisive importance in the outbreak of a revolution: it is only when the state is not able to fulfill its basic functions of maintaining law and order and territorial integrity that revolutionary groups have any chance of success.

Criticism of determinism

Each of these processes is a possible determinant of other ones; none of them is the only determinant. One reason why deterministic, or reductionist, theories run into difficulties is that the process they use to explain the process as a whole is actually not autonomous but has to be itself explained. Moreover, social processes are often intertwined to such a degree that it would be misleading to consider them separately. For example, there are no sharp and fixed borderlines between economic and political processes, nor between economic and technological processes. Technological change may in itself be regarded as a specific type of cultural or conceptual change. The causal connections between distinguishable social processes are a matter of degree and vary over time.

Mechanisms of social change. The scope of any causal explanation of social change in which initial conditions or basic processes are specified is limited. A more general and theoretical way of explaining is to construct a model of recurring mechanisms of social change. Such mechanisms, incorporated in different theoretical models, include the following.

Mechanisms of one-directional change: accumulation, selection, and differentiation. Some evolutionary theories stress the essentially cumulative nature of human knowledge. Because human beings are innovative, they add to existing knowledge, replacing less adequate ideas and practices with more adequate ones. As they learn from mistakes, they select new ideas and practices in a trial-and-error process (sometimes compared to the process of natural selection). The expansion of collective knowledge and capabilities beyond a certain limit is only possible by specialization and differentiation. Growth of technical knowledge stimulates capital accumulation, which leads to rising production levels. Population growth may also be incorporated in this model of cumulative evolution: it is by the accumulation of collective technical knowledge and means of production that human beings can multiply their numbers; this growth then leads to new problems that stimulate further innovations.

Mechanisms of curvilinear and cyclical change: saturation and exhaustion. Models of one-directional change assume that change in a certain direction induces further change in the same direction; models of curvilinear or cyclical change, on the other hand, assume that change in a certain direction creates the conditions for change in another (perhaps even the opposite) direction. More specifically, it is often assumed that growth has its limits and that in approaching these limits the change curve will inevitably be bent. Ecological conditions like the availability of natural resources, in particular, set limits to population growth and economic growth.

Shorter term cyclical changes are explained by comparable mechanisms. Some theories of the business cycle, for example, assume that the economy is saturated periodically with capital goods: investments become less necessary and less profitable, the rate of investments diminishes, and a negative spiral resulting in a recession sets in. After a period of time, however, essential capital goods will have to be replaced: investments are pushed up again and a phase of economic expansion begins.

Group conflict as a cause of change

Conflict, competition, and cooperation. Group conflict has often been viewed as a basic mechanism of social change, especially of those radical and sudden social transformations identified as revolutions. Marxists in particular tend to depict social life in capitalist society as a struggle between a ruling class, which wishes to maintain the system, and a dominated class striving for radical change; social change then is the result of that struggle. These ideas are basic to what Dahrendorf has called a conflict model of society.

The notion of conflict becomes more relevant for the explanation of social change if it is broadened to include competition between rival groups as well. Nations, firms, universities, sports associations, and artistic schools are groups between which such rivalry occurs. Competition stimulates the introduction and diffusion of innovations, especially when they are potentially power-enhancing. Thus, the leaders of non-Western states feel the necessity of adopting Western science and technology, even though their ideology may be anti-Western, because it is only by these means that they can maintain or enhance national autonomy and power.

Additionally, competition may lead to the growing size and complexity of the entities involved. The classic example of this process, analyzed by Marx, is the tendency in capitalism for monopolies to form as small firms are driven out of competition by larger ones. Marx's analysis has been applied to another area by Norbert Elias, who explained the formation of national states in western Europe as the result of competitive struggles between feudal lords.

Competition is also put forward in individualistic theories, which conceive social change as the result of the actions of individuals pursuing their self-interest. With the help of game theory and other mathematical devices it has been shown that individuals acting on the basis of self-interest will cooperate, given certain conditions, in widening social networks.

Cultural lag

Tension and adaptation. In structural functionalism, social change is regarded as the adaptive response to some tension within the social system. When some part of an integrated social system changes, a tension between this and other parts of the system is created, which will be resolved by the adaptive change of the other parts. An example is what the U.S. sociologist William Fielding Ogburn has called cultural lag, which refers in particular to a gap that develops between fast-changing technology and other slower paced sociocultural traits.

Young urban professionals

Diffusion of innovations. Some social changes are to be regarded as the result of the diffusion of innovations, such as technological inventions, new scientific knowledge, new beliefs, or a new fashion in the sphere of leisure. Diffusion is not automatic but selective; an innovation is only adopted by people if they are motivated to do so and if it is compatible with important aspects of their culture. One reason for the adoption of innovations by larger groups is the example of higher status groups, which are reference groups for other people. Successful innovations, which affect the majority of the people of a society, tend to follow a pattern of diffusion from higher to lower status groups. More specifically, most early adopters of innovations in modern Western societies, according to several studies, are young, urban, and highly educated, with a high occupational status. Often they are motivated by the wish to distinguish themselves from the mass of the population. After diffusion has taken place, however, the innovation is no longer a symbol of distinction, which motivates the same group to look for something new again. This mechanism may explain the succession of trends in several fields.

Planning and institutionalization of change. Social change may be, to a certain extent, the result of goal-directed, large-scale social planning. The possibilities of planning by government bureaucracies and other large organizations have increased in modern societies. Most social planning is short-term, however; the goals of planning are often not attained, and, even if the planning is successful in terms of the stated goals, it often has unforeseen consequences. The wider the scope and the longer the time span of planning, the more difficult it is to attain the goals and to avoid unforeseen and undesired consequences. This has become especially clear in Communist societies, where the most serious efforts have been taken to put the ideal of integral and long-term planning into practice. Large-scale and long-term social developments in any society are still largely unplanned.

Planning implies institutionalization of change, but institutionalization does not imply planning. Many unplanned social changes in modern societies are institutionalized; they originate in organizations permanently oriented to innovation, such as universities and the research departments of governments and private firms, but their social repercussions are not controlled. It is in the fields of science and technology especially that change is institutionalized, producing social change that is partly intended and partly unintended.

These mechanisms of social change are not mutually exclusive. On the contrary, some of them are clearly interconnected. For example, innovation by specialized organizations is stimulated by competition. Several mechanisms may be combined in one explanatory model of social change.

CONCLUSION

The interconnection of structure and change

Social structure and social change are central theoretical concepts of the social sciences that refer to basic and complementary characteristics of social life in general—permanence, continuity, and repetitiveness on the one hand, dynamics and changeability on the other. Both concepts are interconnected: the social structure cannot be conceptualized adequately without some notion of actual or potential change, and social change as a more or less regular process is inconceivable without the notion of continuity. To the degree that change processes are regular and interconnected, social change itself is structured. Any separation of the two concepts, as though they refer to divergent fields, is therefore misleading. This is not to deny that the relative stress on either structural continuity or dynamic change varies in social scientific theories and empirical studies. Since about 1965 there has been a shift from "structure" to "change" in social theory. Change on different levels—social dynamics in everyday life, short-term transformations and long-term developments in society at large—has become the focus of attention.

BIBLIOGRAPHY. A general reader on social structure is PETER M. BLAU (ed.), *Approaches to the Study of Social Structure* (1975). The most important theoretical works in structural functionalism are A.R. RADCLIFFE-BROWN, *Structure and Function in Primitive Society* (1952, reissued 1965, reprinted 1968); and TALCOTT PARSONS, *The Social System* (1951, reprinted 1964). For coverage of the debate on structural functionalism, see N.J. DEMERATH and RICHARD A. PETERSON (eds.), *System, Change, and Conflict* (1967, reprinted 1968). A more empirical type of functionalism is represented by ROBERT K. MERTON, *Social Theory and Social Structure: Toward the Codification of Theory and Research,* new ed. (1968), in which due consideration is given the distributive aspects of the social structure. These are stressed even more by PETER M. BLAU, *Inequality and Heterogeneity: A Primitive Theory of Social Structure* (1977). RALF DAHRENDORF, *Class and Class Conflict in Industrial Society* (1959; originally published in German, 1957), advances a power-and-conflict model of society. Other, more sophisticated power models are contained in PETER M. BLAU, *Exchange and Power in Social Life* (1964); STEVEN LUKES, *Power: A Radical View* (1974); and NORBERT ELIAS, *What Is Sociology?* (1978; originally published in German, 3rd ed., 1978). An introduction to structuralism is DAVID ROBEY (ed.), *Structuralism* (1973). CLAUDE LÉVI-STRAUSS, *Structural Anthropology,* 2 vol. (1963–76; originally published in French, 1958–73), contains several articles on the structural method and its applications. Examples of different empirical applications of the concept of social structure are GEORGE PETER MURDOCK, *Social Structure* (1949, reissued 1965); PETER M. BLAU and OTIS DUDLEY DUNCAN, *The American Occupational Structure* (1967, reprinted 1978); and PETER V. MARSDEN and NAN LIN (eds.), *Social Structure and Network Analysis* (1982). A synthesis of different views is offered by ANTHONY GIDDENS, *Central Problems in Social Theory: Action, Structure and Contradiction in Social Analysis* (1979, reprinted 1983).

On the history of ideas concerning social change, see ROBERT A. NISBET, *Social Change and History: Aspects of the Western Theory of Development* (1969). An introduction to 18th- and 19th-century evolutionism is LOUIS SCHNEIDER, *Classical Theories of Social Change* (1967). Original texts in social evolutionism are HERBERT SPENCER, *The Principles of Sociology,* 3 vol. in 4 (1876–96, reprinted in 3 vol., 1975), and *Herbert Spencer: Structure, Function, and Evolution,* ed. by STANISLAV ANDRESKI (1971, reissued 1972); LEWIS HENRY MORGAN, *Ancient Society* (1877, reissued 1985); and EDWARD B. TYLOR, *Primitive Culture,* 2 vol. (1871, reissued 1970). Good selections of Marxian texts are KARL MARX, *Selected Writings in Sociology and Social Philosophy,* ed. by T.B. BOTTOMORE and MAXIMILIAN RUBEL (1956, reprinted 1964); and KARL MARX and FREDERICK ENGELS, *Selected Works,* 2 vol. (1935, reissued in 1 vol., 1968). The most influential study in Marxist evolutionism is FREDERICK ENGELS, *The Origin of the Family, Private Property and the State* (1902, reissued 1978; originally published in German, 1884). A criticism of Spencer's evolutionism is contained in ÉMILE DURKHEIM, *Émile Durkheim on the Division of Labor in Society* (1933, reissued 1984 as *The Division of Labor in Society;* originally published in French, 1893); while MAX WEBER, *The Protestant Ethic and the Spirit of Capitalism* (1930, reprinted 1985; originally published in German, 1920, in vol. 1 of his *Gesammelte Aufsätze*), contains a criticism of historical materialism.

Anthropological neo-evolutionism is represented by: LESLIE A. WHITE, *The Evolution of Culture: The Development of Civilization to the Fall of Rome* (1959); JULIAN H. STEWARD, *Theory of Culture Change: The Methodology of Multilinear Evolution* (1955, reprinted 1973); MARSHALL D. SAHLINS and ELMAN R. SERVICE (eds.), *Evolution and Culture* (1960, reprinted 1982); W.F. WERTHEIM, *Evolutie en revolutie: De golfslag der emancipatie* (1971), from which an abridged English trans., *Evolution and Revolution: The Rising Waves of Emancipation* (1974), was made; and ELMAN R. SERVICE, *Cultural Evolutionism: Theory in Practice* (1971). A sociological textbook with an evolutionary approach is GERHARD LENSKI and JEAN LENSKI, *Human Societies: An Introduction to Macrosociology,* 4th ed. (1982). S.N. EISENSTADT, *Tradition, Change, and Modernity* (1973, reprinted 1983), represents a sophisticated version of the modernization theory. Good examples of historical sociology are NORBERT ELIAS, *The Civilizing Process,* 2 vol. (1978; originally published in German, 1939); BARRINGTON MOORE, JR., *Social Origins of Dictatorship and Democracy: Lord and Peasant in the Making of the Modern World* (1966, reissued 1984); and IMMANUEL WALLERSTEIN, *The Modern World-System,* vol. 1, *Capitalist Agriculture and the Origins of the European World-Economy in the Sixteenth Century* (1974). Akin to these books are comprehensive historical studies on long-term developments, such as WILLIAM H. MCNEILL, *The Rise of the West: A History of the Human Community* (1963, reissued 1965); and FERNAND BRAUDEL, *Capitalism and Material Life, 1400–1800* (1974; originally published in French, 1967). An overview of this field is given by THEDA SKOCPOL (ed.), *Vision and Method in Historical Sociology* (1984).

General theoretical books on social change are: WILBERT E. MOORE, *Social Change,* 2nd ed. (1974), and *Order and Change: Essays in Comparative Sociology* (1967), two treatises in the functionalist tradition; EVA ETZIONI-HALEVY and AMITAI ETZIONI (eds.), *Social Change: Sources, Patterns, and Consequences,* 2nd ed. (1973), a reader representing various approaches; WILLIAM FIELDING OGBURN, *Social Change with Respect to Culture and Original Nature,* new ed. (1950, reprinted 1965); AMITAI ETZIONI, *The Active Society: A Theory of Societal and Political Processes* (1968, reprinted 1971), which explores the possibilities of planned change; ROBERT L. HAMBLIN, R. BROOKE JACOBSEN, and JERRY L.L. MILLER, *A Mathematical Theory of Social Change* (1973); HENRY TEUNE and ZDRAVKO MLINAR, *The Developmental Logic of Social Systems* (1978); and KENNETH E. BOULDING, *Ecodynamics: A New Theory of Societal Evolution* (1978, reprinted 1981).

Controversial theories on the cyclical development of civilizations have been advanced by OSWALD SPENGLER, *The Decline of the West,* 2 vol. (1922, reissued 1981–83; originally published in German, 1918–22); and ARNOLD J. TOYNBEE, *A Study of History,* 12 vol. (1934–61, reprinted 1948–61). A theory of the circulation of elites can be found in VILFREDO PARETO, *The Mind and Society: Treatise on General Sociology,* 4 vol. (1935, reprinted 1983; originally published in Italian, 2nd ed., 3 vol., 1923), and *Sociological Writings,* ed. by S.E. FINER (1966, reprinted 1976). An empirical test of theories of economic growth and the business cycle is given by ANGUS MADDISON, *Phases of Capitalist Development* (1982). The concept of involution is explained by CLIFFORD GEERTZ, *Agricultural Involution: The Process of Ecological Change in Indonesia* (1963, reprinted 1968).

The significance of demographic processes is analyzed by CARLO M. CIPOLLA, *The Economic History of World Population,* 7th ed. (1978), and an analysis of one stage of development is presented in MARK NATHAN COHEN, *The Food Crisis in Prehistory: Overpopulation and the Origins of Agriculture* (1977, reprinted 1979). A classic account of the influence of technological change is V. GORDON CHILDE, *Man Makes Himself,* rev. ed. (1951, reissued 1983). CLARK KERR *et al., Industrialism and Industrial Man: The Problems of Labor and Management in Economic Growth,* 2nd ed. (1964, reissued 1973), represents a non-Marxist materialist view. Theories of political revolution are developed by CRANE BRINTON, *The Anatomy of Revolution,* rev. and expanded ed. (1965); and THEDA SKOCPOL, *States and Social Revolutions: A Comparative Analysis of France, Russia, and China* (1979). EVERETT M. ROGERS, *Diffusion of Innovations,* 3rd ed. (1983), deals with the social aspects of technological innovations. The individualistic approach to social change processes is exemplified by DOUGLASS C. NORTH, *Structure and Change in Economic History* (1981); MANCUR OLSON, *The Rise and Decline of Nations: Economic Growth, Stagflation, and Social Rigidities* (1982, reprinted 1984); and ROBERT AXELROD, *The Evolution of Cooperation* (1984).

An influential criticism of deterministic theories of social development is KARL R. POPPER, *The Poverty of Historicism,* 2nd ed. (1960). Examples of pessimistic social forecasting with much attention to ecological conditions are DONELLA H. MEADOWS, *et al., The Limits to Growth,* 2nd ed. (1974, reprinted 1982); and MIHAJLO MESAROVIC and EDUARD PESTEL, *Mankind at the Turning Point* (1974, reissued 1976). Much more optimistic examples are HERMAN KAHN and ANTHONY J. WIENER, *The Year 2000* (1967); DANIEL BELL, *The Coming of Post-Industrial Society: A Venture in Social Forecasting* (1973, reprinted 1976); and CLARK KERR, *The Future of Industrial Societies: Convergence or Continuing Diversity?* (1983). For a history of ideas about future social developments, see KRISHAN KUMAR, *Prophecy and Progress: The Sociology of Industrial and Post-Industrial Society* (1978).

(N.Wi.)

Social Welfare

The basic concerns of social welfare—poverty, disability and disease, the dependent young and elderly—are as old as society itself. The laws of survival once severely limited the means by which these concerns could be addressed; to share another's burden meant to weaken one's own standing in the fierce struggle of daily existence. As societies developed, however, with their patterns of dependence between members, there arose more systematic responses to the factors that rendered individuals, and thus society at large, vulnerable.

Religion and philosophy have tended to provide frameworks for the conduct of social welfare. The edicts of the Buddhist emperor Aśoka in India, the sociopolitical doctrines of ancient Greece and Rome, and the simple rules of the early Christian communities are a few examples of systems that addressed social needs. The Elizabethan Poor Laws in England, which sought relief of paupers through care services and workhouses administered at the parish level, provided precedents for many modern legislative responses to poverty. In Victorian times a more stringent legal view of poverty as a moral failing was met with the rise of humanitarianism and a proliferation of social reformers. The social charities and philanthropic societies founded by these pioneers formed the basis for many of today's welfare services.

Because perceived needs and the ability to address them determine each society's range of welfare services, there exists no universal vocabulary of social welfare. In some countries a distinction is drawn between "social services," denoting programs, such as health care and education, that serve the general population, and "welfare services," denoting aid directed to vulnerable groups, such as the poor, the disabled, or the delinquent. According to another classification, remedial services address the basic needs of individuals in acute or chronic distress; preventive services seek to reduce the pressures and obstacles that cause such distress; and supportive services attempt, through educational, health, employment, and other programs, to maintain and improve the functioning of individuals in society. Social welfare services originated as emergency measures to be applied when all else failed; they are now generally regarded as a necessary function in any society, a means not only of rescuing the endangered but also of fostering a society's ongoing, corporate well-being.

This article treats first the personal social services—those provided on an individual basis to persons in need; collectively these services constitute the professional field of social work. A discussion of government-sponsored social security programs, such as social assistance and social insurance, follows.

The article is divided into the following sections:

Social work: the personal social services

The majority of personal social services are rendered on an individual basis to people who are unable, whether temporarily or permanently, to cope with the problems of everyday living. Recipients include families faced with loss of income, desertion, or illness; children and youths whose physical or moral welfare is at risk; the sick; the disabled; the frail elderly; and the unemployed. When possible, services are also directed toward preventing threats to personal or family independence.

The social services generally place a high value on keeping families together in their local communities, organizing informal support from friends or neighbours when kinship ties are weak. Where necessary, the services provide substitute forms of home life or residential care, and they play a key role in the care and control of juvenile delinquents and other socially deviant groups, such as drug and alcohol abusers.

MODERN EVOLUTION

In the advanced industrial societies the personal social services have always constituted a "mixed economy of welfare," involving the statutory, voluntary, and private sectors of welfare provision. Although their role is crucial, they account for only a small proportion of total welfare expenditures. The most substantial increases in expenditures have occurred in social security systems, which provide assistance to specific categories of claimants on the basis of both universal and selective criteria. The development of modern social security systems from the 1880s reflects not only a gradual but fundamental change in the aims and scope of social policy but also a dramatic shift in expert and popular opinion with regard to the relative significance of the social and personal causes of need (see below *Social security: government welfare programs*).

Poor relief

In the belief that personal shortcomings were the chief cause of poverty and of people's inability to cope with it, the major 19th-century systems of poor relief in western Europe and North America tended to withhold relief from all but the truly destitute, to whom it was given as a last resort. This policy was intended as a general deterrent to idleness. The poor-law relieving officer was the precursor of both the public assistance officials and the social workers of today in his command of statutory financial aid. The voluntary charitable agencies of the time differed on the relative merits of deterrent poor-law services on the one hand, implying resistance to the growth of statutory welfare, and on the provision of alternative assistance to the needy, coupled with the extension of statutory services, on the other hand. From the 1870s the Charity Organization Society and similar bodies in the United States, Britain, and elsewhere held strongly to the former option, and their influence was widespread until the outbreak of World War II.

Settlement movement

The settlement movement in Britain and the United States drew voluntary workers into direct contact with the serious material disadvantages suffered by the poor. The pioneer of this movement was the vicar Samuel A. Barnett, who in 1884 with his wife and a number of university students "settled" in a deprived area of London, calling their neighbourhood house Toynbee Hall. Two visitors to this settlement soon introduced the movement into the United States—Stanton Coit, who founded Neighborhood Guild (later University Settlement) on the Lower East Side of New York City in 1886, and Jane Addams, who with Ellen Gates Starr founded Hull House on the Near West Side of Chicago in 1889. From these prototypes the movement spread to other U.S. cities and abroad through Europe and Asia.

The origins of modern social casework can be traced to the appointment of the first medical almoners in Britain in the 1880s, a practice quickly adopted in North American and most western European countries. The almoners originally performed three main functions: ascertaining the financial eligibility and resources of patients faced with the rising costs of medical care, providing counseling services to support patients and their families during periods of ill health and bereavement, and procuring adequate practical aids and other forms of home care for discharged patients. Elsewhere secular and religious charitable associations providing financial help, educational welfare, and housing for the poor began to employ social workers.

By the turn of the century there were various schemes for organizing charitable work on "scientific" principles according to nationally agreed standards of procedure and services. In Britain, the United States, Germany, and, later, Japan, leading charities worked in conjunction with poor-law and public assistance authorities, an approach endorsed in 1909 in the majority report of the British Royal Commission on the Poor Law. The first schools of social work, usually run by the voluntary charitable agencies, appeared in the 1890s and early 1900s in London, New York City, and Amsterdam, and by the 1920s there were similar ventures in other parts of western Europe and North America and in South America. The training programs combined casework methods and other practical forms of intervention and support, with particular emphasis on working in cooperation with individuals and families to restore a level of independence.

Early social work training

From the 1900s onward the surveys conducted by Charles Booth in London and Seebohm Rowntree in York and by other researchers began to transform conventional views of the role of the state in social welfare and the relief of poverty, and the social causes of poverty came under scrutiny. At the same time, the scope of social work was growing, with the spread of settlement houses, to include group work and community action.

In most countries social welfare services, or personal social services, rather than being separately organized and administered, are often attached to other major social services, such as social security, health care, education, and housing. This is explained by the course of their historical development. The means open to policy-making and administration in the personal social services are often incompatible. For example, the demands of the general integration and coordination of care programs can conflict with the provision of services that take due account of the needs of specific client groups. Also to be reconciled are the provision of individual services and the provision for family and neighbourhood needs.

Statutory and voluntary social services have evolved in response to needs that could not be fully met by individuals either alone or in association with others. Among the factors determining the present nature of such services are, first, that the growth in the scale and complexity of industrial societies has added to the obligations of central and local governments. Second, the increasing wealth and productivity of industrial societies has heightened public expectations regarding standards of living and standards of justice, at the same time augmenting the material capacity to meet those expectations. Third, the processes of social and economic change have grown to such proportions that individuals are increasingly ill-equipped to anticipate and cope with the adverse effects of such change. Fourth, it is difficult and sometimes impossible to recognize and provide for the idiosyncratic needs arising from the interaction of social and personal life.

Any family can experience crises that it is powerless to control. The hardships of ill health and unemployment can be compounded by loss of income; divorce and separation can impede the welfare and development of young children; and long-term responsibility for dependent relatives can impair the physical and emotional well-being of those who provide the care.

A very small number of families experience such intractable problems that they require almost continuous help from personal social services. Some of these families present problems of deviant behaviour, including family violence and child abuse, irregular attendance or nonenrollment in school, alcohol and drug abuse, and crime and delinquency. Not all poor families, however, make heavy demands on social welfare services; indeed considerable hardship could be alleviated through more efficient use of existing services.

Over time, social workers have acquired a special responsibility for people whose particular needs fall outside the aegis of other professions and agencies. Apart from the requirements of individuals and families with serious long-term social and emotional problems, personal social services meet a wide spectrum of needs arising from the more routine contingencies of living. Inevitably personal social services are primarily concerned with reacting to a crisis as it occurs, but today much effort is being invested in preventive work and in the enhancement of welfare in the wider community. In this respect comparison can be made with the traditional aim of social security—the reduction of poverty—and the more ambitious objective of income maintenance (see below *Social security: government welfare programs*).

The organization of personal social services in different societies is extremely variable. Ethnicity and urban deprivation have added new dimensions to need that cut across the traditional client categories of families, children, youth, the sick and handicapped, the unemployed, the aged, and the delinquent. Nevertheless, there are continuities and consistencies in the pattern of needs that characterize these major client groups.

MAJOR AREAS OF CONCERN

Family welfare. Social philosophers and caseworkers generally regard family life as the ideal context for the promotion of social welfare. Family welfare programs seek to preserve and strengthen the family unit through both economic assistance, where available, and personal assistance with a variety of services. Personal assistance services include marriage counseling in most developed countries and in urban centres of developing countries; maternal, prenatal, and infant care programs; family planning services; family-life education, which promotes both the enrichment of family relationships and the improvement of home economics; "home-help" or "homemaker" services providing household assistance to families burdened with chronic illness, handicaps, or other dependencies; and care of the aged through such programs as in-home meal services, transportation, regular visitation, and reduced-cost medicines.

Family services

Child welfare. A paramount concern in all family welfare programs is the welfare of children. Whenever possible, children's services are rendered within the setting of home life. Income assistance to parents may help ensure the basic security of the family structure. Maternal, prenatal, and child health-care programs are important in all societies but especially so in those affected by widespread disease and malnutrition; infant and maternal mortality rates are in fact the most basic indexes of child welfare. The increasing number of working mothers worldwide has given rise to day-care services ranging from simple custodial supervision to educational and health-care programs. In some countries, industries are required to provide such facilities for their employees, in recognition of the changing economic pressures on family life.

Day-care services

While the family unit is imbued with great value by most child-welfare programs, these programs must also address the special needs of unwed mothers and their children, broken families, and children whose families, although intact, are sources of abuse and neglect rather than love and nurture. Attitudes vary greatly among the world's societies toward pregnancy out of wedlock. Historically, social and even physical persecution have been common in some communities, but most modern societies recognize a responsibility toward the welfare of unmarried mothers and their children. In industrial countries, and in some developing countries through private charity, services typically include medical care and delivery and counseling regarding the decision to keep the baby or to give it up for adoption. In many countries institutional homes provide for the care both of unwed expectant mothers and of mothers and babies after delivery, in a setting sheltered from the often rigid strictures of family and community. Procedures of adoption vary considerably worldwide, but arrangements are frequently carried out by social service agencies in cooperation with legal authorities.

Whereas orphans once made up the majority of children living in institutional homes, the number of children who lose both parents through death has been greatly reduced by medical advances. Institutional and foster care are now provided predominantly to children whose home lives have been disrupted, permanently or temporarily, by illegitimacy, marital discord, financial hardship, parental irresponsibility, neglect, or abuse. While foster care might be considered preferable because it offers the intimate atmosphere of family living, some children, such as those severely affected by parental abuse or emotional disturbance, may adjust more comfortably to the more impersonal environment of an institution. Although it cannot be determined conclusively whether the increasing incidence of reported child abuse is attributable to falling standards of parental care or to improvements in detection and reporting, much effort has been invested in supervision, social education, and cooperation between personal social services and health care, education, police, and housing authorities.

Institutional and foster care

Youth welfare. The underlying aim of most social welfare services for young people, apart from those services that address immediate basic needs, is to prepare them for the assumption of responsible roles in the adult world. The majority of programs provide adult-supervised leisure-time group activities, which may range from cultural and social events to athletics to hiking and camping. Participation in such programs is high in most European countries. The Soviet youth organizations, called Pioneers and Komsomol, are the largest in the world. Some programs, such as Boy Scouts, Girl Scouts or Girl Guides, Young Men's Christian Associations, and Young Women's Christian Associations, have spread nearly worldwide, stimulating the formation of similar groups tailored to local needs. In addition to group activity, youth welfare programs also provide counseling and guidance services on a more individual basis to help meet the personal, social, educational, and vocational needs of young people.

While the above services are intended to provide constructive outlets for the energies of young people, there remain many destructive influences in society. Social services have directed increasing attention to the problem of delinquency in an effort to provide alternatives to the traditional juvenile court/institutional methods of control. In some urban areas so-called street workers approach the problem at its source. Recognition of the importance of peer groups in youth behaviour has led to the use of group therapy in many correctional institutions and in communities as a preventive service or as an adjunct to parole.

Delinquency

Welfare of the elderly. The elderly now constitute the largest single client group using personal social services worldwide. In all advanced industrial societies the proportion of infirm elderly is on the increase, and, although they constitute only a small minority of the retired population, their claim on social services is disproportionately heavy. Because social care for the elderly is often labour-intensive, most countries give full support to the promotion of family care and the expansion and rationalization of informal care on a voluntary or quasi-voluntary basis. Services include transportation, friendly visiting, home delivery of hot meals, nurse visitation, and reduced-cost medical supplies. Senior centres sponsor group activities such as crafts, entertainment, outings, and meals on a regular basis. Nursing homes, variously funded, provide medical and custodial care for those who are unable to live independently. Paradoxically, the majority of retired people lead independent lives, seldom utilizing personal social services. Indeed, fit elderly people are increasingly in demand as a source of voluntary service.

Group welfare. The settlement movement arose in response to the collective needs of deprived urban communities. Settlement houses today, and similar community centres and other organizations, seek to promote the common welfare of local groups that may differ in language, national origin, race, or religion. Whereas, in the United States, attempts were formerly made to Americanize such groups by supplanting foreign traits of language and custom with American ones, the emphasis of educational and training programs has changed; language and other assimilating skills are taught, but the preservation of cultural diversity is also promoted. In addition to educational and cultural programs, settlements may offer legal advocacy, recreational activities, and health clinics.

Throughout the 20th century the resettlement of massive numbers of refugees forced from their homes has placed great demand on social welfare services. In Europe and North America various church denominations have taken an active role in relief and other welfare work for such groups as well as for migrant and transient elements within the general population.

Refugees and migrants

Welfare of the sick and disabled. Serious illness and disability account for many of the problems addressed by social services. In addition to the need for adequate primary care, the ill and disabled also frequently face disruption or loss of income, inability to meet family responsibilities, the long-term process of recovery or adjustment to handicaps, and ongoing care in the form of medication, therapy, and the observance of dietary or other precautions.

In some countries, medical social workers are local-authority social workers who have been attached to hospitals, local general-practice health centres, and child guidance agencies. They provide the counseling and other supportive services required by the physically ill and the disabled and their families. Especially in countries where free medical care is not available to the poor, the responsibility for means-testing gives the workers an additional, advisory role with respect to their clients' financial problems. Personal social services make arrangements for domiciliary care in the form of regular visits from home-helpers and occupational therapists; special appliances and home adaptations are supplied either by personal social services or by health services. In the case of severely disabled people personal social services run day-care centres to provide relief for family care providers and small residential homes for the most dependent disabled when they no longer require hospital care.

Welfare of the mentally ill. The social aspects and consequences of mental illness were recognized early in the history of social work. The speciality of psychiatric social work developed initially as an adjunct to hospital care in urban areas. Such services have also been provided under military auspices, particularly in wartime. In developed countries today the psychiatric social worker serves at all levels of patient care; social casework may contribute to diagnosis and the course of treatment; educational and counseling services help other family members cope with the problems of hospitalization, treatment, and aftercare; close work with housing authorities and employers can facilitate the readjustment of patients into community life by means of foster care, halfway houses, sheltered workshops, and regular employment.

Psychiatric social work

Personal social services have been a major contributor to the development of community care for the mentally ill and the mentally handicapped. In the industrialized world generally, though less so in the Soviet Union, policy calls for a reduction in the number of patients hospitalized on a long-term basis; this goal can be achieved only by returning patients to their families or accommodating them in neighbourhood hostels providing adequate support and supervision. The bulk of this responsibility has fallen on local authorities and voluntary agencies, which provide the professional staff and volunteers. Treatment programs are also increasingly designed to prevent hospital admissions and to avoid compulsory admission in all but exceptional cases.

THE WORK OF THE PERSONAL SOCIAL SERVICES

Social work training. In practice the demand for personal social services does not fall into clearly defined categories. Welfare needs often overlap, and the needs of individuals often affect their families or associates. The range of skills required for effective service provision is equally complex. Inevitably, therefore, opinions differ on the training and deployment of social workers.

In the United States, the United Kingdom, Canada, Australia, New Zealand, Japan, and India the bulk of training is provided in the higher-education system, whereas in France, West Germany, Norway, and Sweden it is conducted mainly in separate institutions. Most social workers are employed in either statutory or voluntary agencies; outside the United States very few are engaged in private practice. There is much diversity in their training and deployment, but the role of social workers has broadened, making them individually responsible for a wide range of methods and client groups. In some cases specialized social workers are deployed in teams. Opinions differ on the relative effectiveness of the alternative methods of intervention—direct casework, or counseling, on the one hand and indirect social-care planning on the other. Voluntary and private agencies tend to perform more specialized roles, centred on particular client groups and age groups requiring special methods of care and service delivery.

Administration of services. *Basic organization.* There are marked national variations in the organization and funding of personal social services. To begin with, there are differences in the relative importance of the statutory, voluntary, and private sectors. Second, even if governments are the major contributors, the proportional allocation of funds for the statutory and nonstatutory sectors varies from country to country. Third, there are variations in the relative importance of central, regional, and local governments with respect to statutory funding, policy-making, and service delivery. Fourth, there are also variations in the degree of administrative autonomy granted to the personal social services.

The social service staff

The paid staff of statutory personal social services includes social workers, community workers, social care assistants, home-helps (homemakers), workers who supply mobile meals, occupational therapists, and psychologists working in a variety of field, day-care, and residential settings. Although social workers account for a small proportion of the social service workforce, they constitute the majority of its professional staff. Their job is to provide casework, or counseling, services in cooperation with individuals and families and to engage in tasks of social-care planning, such as seeing to the delivery of direct services in kind and fostering the involvement and support of informal care providers and volunteers. In most industrial societies social workers have more or less exclusive responsibility for mandatory duties related to fostering, adoption, and other work affecting parental rights as well as for the management of substitute home care or residential care for the main client groups. Probation officers act as social workers with a special attachment to the courts, the administration of probation usually being separate from that of other statutory personal social services.

The increasing orientation toward community care calls for social policies that strengthen the association between formal personal social services and informal networks of social care without losing sight of their differences. The formal public, or statutory, sector and the voluntary and private sectors all have paid career staffs whose objectives and management are bound by explicit rules. The primary tasks of the public sector are laid down by statute; most voluntary and private organizations are registered, respectively, as charities and companies. In countries such as the United States, the United Kingdom, West Germany, The Netherlands, and Japan formal voluntary and private agencies receive direct or indirect grants from the statutory sector in return for agreed amounts of contracted work. In the developing countries many welfare agencies are internationally organized and jointly financed by charitable donations and government grants.

Informal care

Informal care is spontaneously provided in the context of families, neighbourhoods, and other loosely structured community-based associations. Without these supporting networks the personal social services would be overwhelmed by demand. Consequently they often make small grants to informal self-help groups and supplement the unpaid services provided to dependents by their relatives and friends. Professional social workers and community workers are increasingly deployed in the recruitment, training, and general assistance of informal care providers. Payment for fostering is a long-established practice in many countries, and this policy has spread to the care of other groups such as the handicapped and the infirm elderly.

Personal social services are prime movers in the humanitarian trend toward caring for dependent people in their own communities, to which the high cost of residential care adds an economic incentive. It is evident that there is no clear boundary between the formal and informal sectors of social welfare. Nevertheless, informal care cannot take the place of formal services, the two sectors being mutually supportive rather than alternative sources of social welfare. Formal social services are a matter of legal obligation; their providers and users are normally strangers to each other, whereas informal care is given and received on the basis of personal relationships. Formal services have a wide membership and are delivered on a continuous basis, without regard to personal considerations. Informal care is highly localized and, although it may reflect intense loyalty and devotion, is often less reliable than formal care in the long run because family and neighbourhood networks are vulnerable to personal crisis and social change. Such care also does not usually extend to those without living relatives or other close associates. There are, of course, changes in priority within formal social services in response to trends such as the increasing incidence of reported child abuse, especially in the United States and the United Kingdom, the growing proportions of unemployed and infirm elderly, and the heightened awareness of racial inequality and injustice.

The United States. In the United States the main social assistance and personal social service programs are county- and state-administered, with substantial federal government support. Many programs are delegated to local governments, and voluntary organizations are heavily subsidized by public bodies via contracts for provision of services. The Department of Health and Human Services is the chief federal agency, and each state has a counterpart of this agency. In addition there is a small but popular and growing private market for fee-charging social services that overlaps the voluntary sector.

Federal policies for the personal social services have changed significantly since the 1960s. The Social Security amendments of 1962 put a premium on the role of rehabilitative casework, although states could also include homemaking and foster care. Between 1967 and 1977, however, income maintenance services (Aid to Families with Dependent Children excepted) were regrouped under the Social Security Administration, and primary responsibility for personal social services was transferred to the Office of Human Development. The 1974 amendments to the Social Security Act (Title XX) considerably extended the scope of eligibility for social services, giving priority to preventive work and positive efforts to improve the quality of life rather than to the traditional focus on poverty abatement. Casework, or counseling, however, lost ground to community-oriented service programs such as day-care provision, mental health centres, and nutrition programs. Problems of child abuse and alcohol and drug dependence have steadily assumed greater importance.

There has been significant growth in employer-sponsored welfare programs in the private sector and service-purchase schemes linking public, voluntary, and private agencies, accompanied by increasing use of paid volunteers. The promotion of for-profit entrepreneurial services and decentralization of funding and policy management from federal to state agencies is intended to diversify still further the mixed economy of welfare that typifies the personal social services of the United States.

Treatment of child abuse

In both the United States and Canada special treatment programs have been developed for the prevention and treatment of child abuse, but lower priority has been given to preschool and family support programs designed to encourage better parenting and child development. The U.S. Child Abuse Coordinating Program set up in 1972 is based on an interservice approach involving municipal and quasi-public bodies, one of which provides the agency officers. American child protection law is extremely complex because of its dual federal and state components, and, although the best interests of children are generally paramount, it is thought difficult to consider them in isolation from those of the parents.

The mental health care legislation of 1970 and 1972 stepped up the funding of community mental health centres in poor areas, but it was not until the Mental Health Systems Act of 1980 that priority federal funding began to reach those with the worst economic or ethnic disadvantages among the chronically ill, the retarded, and the elderly. There is a growing problem of homelessness among the more mobile patients discharged from mental hospitals, who need higher incomes and more social support if they are to resume independent lives.

Social services for elderly American citizens constitute a typical mixed economy of welfare. Amendments to the Older Americans Act of 1965 have led to the establishment of a network of more than 600 Area Agencies on Aging, which are area-wide planning and coordinating agencies. Locally sponsored senior citizen centres provide group meals and counseling, homemaker, information, referral, transportation, educational, legal, and recreational services. There are also a strong volunteer sector and a rapidly expanding private market. Provisions for the frail elderly under Medicaid and Medicare do not include long-term social care, and the poorest groups are dependent on social insurance and social assistance for the requisite finance. Many not-for-profit and for-profit agencies have developed nursing-home and other special housing schemes that are linked to various reverse-equity mortgage options. Nearly three-quarters of all the states have tax policies designed to reduce the cost of independent living for elderly homeowners with low incomes.

The United Kingdom. In the United Kingdom, as a result of the Seebohm reforms of 1970–71, the funding and organization of personal social services are highly centralized at the local authority level. In each local authority a single social services department serves all categories of client and welfare need. In Scotland, however, the probation service is separate. Personal social services are provided from catchment area offices, although some local authorities delegate this responsibility to small "patch" teams serving neighbourhoods. Roughly half of local authority funding comes from the central government; nevertheless, within strict cash limits, the local authorities exercise wide discretionary powers over the organization and deployment of personal social services. Social work training is centrally regulated, and there is only one (general) qualification in professional social work.

Status of social work

Although income maintenance was transferred to the central government in 1948, local-authority social workers continue to provide small cash grants to families with children when shortage of money is deemed likely to cause a family breakdown. In Britain the separation of income maintenance and social work services was part of an overall policy designed to end the historically stigmatizing association between public assistance and social work in particular and the more general association between poor relief and social welfare. It was also hoped that social work and the other personal social services would shed their low status and become more acceptable in all sectors of society. This philosophy was adopted by the Seebohm Report of 1968 and reflected in the Local Government and Social Services Act (1970), but the resources for a truly universal network of services oriented toward preventing problems were not forthcoming.

British child care law developed in piecemeal fashion over a long period. Nevertheless, it places a clear obligation on the local authorities to protect children at risk and to receive them into care when their welfare is at stake because their parents are deemed unable to provide satisfactory care. Under certain circumstances local authorities can assume full parental rights until a child reaches the age of 18. Separate provisions are made for compulsory admission into care through juvenile court proceedings, when children are "in need of care and control" on various defined grounds, or through matrimonial, divorce, separation, wardship, or criminal proceedings. Care orders may also be issued under the Children and Young Persons Act of 1969, as amended by the Criminal Justice Act of 1982, when children or young persons are found guilty of an offense that, if committed by an adult, would be punishable by imprisonment. Observation and assessment centres and secure community homes with educational facilities on the premises are run by the Department of Health and Social Security.

There are strict regulations on boarding out children in care with foster parents, including thorough investigation of prospective homes, frequent inspections, and the keeping of case records. In English law, adoption is an almost complete and irrevocable transfer of a child from one family to another. Adoption orders are made in the Magistrates', County, or High courts, and adoption proceedings can be initiated only by registered, not-for-profit adoption agencies (including local authorities).

Although English law makes extensive provision for the protection of children, personal social services have a well-established tradition of working with children and families on the basis of a cooperative partnership whenever possible. This tradition includes avoidance of recourse to legal intervention or residential care unless it is in the best interests of the children concerned.

British mental health legislation

With regard to the mentally ill and mentally handicapped, the British Mental Health Act of 1959 anticipated the general trend toward voluntary treatment and voluntary hospital admission, and legislation in 1982 introduced even stricter criteria for the protection of patients' rights. Since 1983 certain procedures in the admission and discharge of mentally ill patients have been reserved to a new category of specially trained approved social workers. In cases of compulsory detention, patients have a strengthened right of appeal to the Mental Health Review Tribunals, and there are special provisions for the guardianship of certain types of discharged patients. Although there are still serious deficiencies in community care for the mentally ill or handicapped as well as the elderly and the physically handicapped, various joint government and local-authority funding schemes have helped to reduce the numbers in institutional care.

Services for the elderly and the physically handicapped account for roughly half of all British local-authority personal social service expenditure, mainly because of the steady increase in the numbers of the frail elderly and the high cost of care for the minority who live in residential homes. Extensive efforts have been made to improve the quality of domiciliary support, but relatives carry the main burden of home care. There are special housing schemes for the elderly sponsored by statutory, voluntary, and private agencies, and a growing number of local authorities employ paid volunteers to visit elderly people and help them with a range of daily tasks. Perhaps the best guarantee of independence in old age, however, is an adequate income from social security (see below *Social security: government welfare programs*).

The formal voluntary sector makes its own important contribution to the care of all the major need groups, although it is heavily dependent on direct and indirect financial support from both central and local governments. Within the voluntary sector the churches have always played a major part in the provision of both community and residential care. Nevertheless as statutory funding has lagged well behind demand, the private market, especially with respect to services for the elderly, has begun to expand.

Australia. In Australia the state governments and the local authorities, with some federal funding, have the main responsibility for personal social services. Each state has a welfare department, usually an amalgamation of the former children's and public relief departments, providing a general range of casework and community services. Some of the municipal authorities also provide welfare services in conjunction with their public health, educational, housing, and legal aid services. In addition there is a well-established tradition of volunteer work that is subsidized by statutory bodies, sometimes provided on a dollar-for-dollar matching basis. Some of the religiously based charities, such as the Brotherhood of Lawrence, the Society of St. Vincent de Paul, and the Salvation Army, are pioneers in work with severely deprived groups.

France. In France personal social services are not administratively autonomous. A variety of social workers and social care workers are employed by other major public services, such as social security, hospitals, community health care, education, housing, and the courts. There are several types of social worker, including the family social worker (*assistante sociale*) and other specialists in child protection, medical social work, and court work; the homemaker (*travailleuse familiale*); child development workers specializing in the care of handicapped children; social allowance guardians with special responsibilities for families in serious financial difficulties; and the community worker (*animateur socioculturel*), who serves neighbourhood groups. Apart from the statutory services there is an extensive network of semipublic agencies (*caisses*) based on trade unions, family associations, and religious denominations, as well as a variety of independent, not-for-profit organizations financed by state grants.

Social work specialists

The French system of child care is explicitly family-oriented. It is based on services financed by the Ministry of Health and the Ministry of Justice, in cooperation with other family income support services. The judicial services are called upon only if parents refuse to cooperate. Social workers are employed in maternal and child health centres and in municipal and family allowance agencies. Special child-protection officers work closely with pediatric nurses in cases of actual or suspected child abuse, and the procedures for removing children from the home and for providing substitute care are in principle similar to those in Britain. Child care services are unified at *département* level, and there is close liaison between the courts and specialized medical services in child protection work.

The reforms of the 1960s and 1970s improved the quality of French social services not only for children but also for the mentally and physically handicapped and the elderly. Since the late 1950s domiciliary care and sheltered housing provisions have been strengthened and diversified, objectives that were upheld in the Laroque Report of 1960 and in the provisions of the Sixth (1971–75) and Seventh (1976–80) Plans. The plans specifically referred to the growing need for more trained staff and for more sheltered housing, residential homes, and nursing homes in addition to increased community care and more generous income support within a better-coordinated framework of health and welfare programs at neighbourhood, local, and regional levels. Social care services for the mentally ill are mainly controlled by the health and employment authorities, but the social workers attached to the regional and local *caisses* play a major part in the provision and coordination of community care.

West Germany. In the Federal Republic of Germany there is a long tradition of cooperation between the statutory and voluntary sectors and between these formal agencies and the informal networks of family and neighbourhood care. These arrangements exemplify the principle of subsidiarity (the belief that informal care should, whenever possible, take precedence over state intervention) in European Roman Catholic welfare philosophy, although in West Germany all of the major religious denominations play an important part in social welfare service. The health care provisions of the income maintenance services do not extend to the longer term welfare needs of the elderly mentally ill or handicapped or those of the physically disabled. These are met largely from public aid. About half of the total expenditure on welfare services comes from the Aid for Care program, which channels much of its funding through the larger not-for-profit charitable organizations.

Roman Catholic welfare philosophy

Sweden. The modern Swedish welfare state emerged from poor-law and charitable traditions in which the churches were prominent. Since the years between the two world wars, the scope and funding of statutory agencies have steadily increased. Local authorities, assisted by central government grants, provide most personal social services and a social assistance scheme, in which investigation of needs and means is undertaken by social workers. There has been a trend toward the unification of specialist agencies into local joint welfare boards, but the municipal communes still exercise considerable local discretion in the organization of their services. Although the extensive role of the state in Swedish welfare has elicited much comment, the scale of voluntary effort is equally noteworthy, as it is in Norway and Denmark.

Israel. Israel has a complex system of welfare services distributed by central ministries, with subdivisions for all the major need groups, including services for wounded soldiers and surviving dependents, a Jewish agency with special responsibilities for immigrants, and a universal labour union (Histadruth) with extensive roles in insurance and welfare and a long tradition of mutual aid based on local collectives (kibbutzim) and cooperative villages (moshavim). This has been supplemented by a network of community centres funded by the central and local governments and by membership fees and overseas donations.

Japan. Japanese social welfare provision is uniquely

Work-based social services

reliant on employer- and work-based social services, although there is also an extensive but relatively underfunded system of statutory local-authority personal social services for the major need groups. Social workers in these municipal agencies are responsible for both discretionary income support and protective social care. In major cities they cooperate with a growing number of voluntary agencies, of which the Minsei-iin is the oldest and largest. As in the case of income support, health care, and housing, access to welfare services for most Japanese workers largely depends on the size and financial stature of the organizations employing them. Although traditional familial ties are still pervasive, they are weaker in the large cities, as a result of social and geographical mobility. At the same time the number and proportion of the dependent elderly show a marked increase. Accordingly, Japanese policy has turned toward the expansion of statutory services, and much has been done to foster neighbourhood networks of mutual aid that go beyond the traditional notions of kinship and obligation.

Socialist countries. It is as difficult to make generalizations about social welfare in socialist countries as it is in the case of the democratic societies referred to above. Nevertheless, in the foremost socialist societies the state provides the formal social services, and the workplace and the trade unions play a large part in service management and delivery. In these planned economies, where work is both a civic right and a formal obligation, social assistance for the unemployed is minimal. In the absence of firm data on this area of provision it must be presumed that families shoulder the main financial responsibility for many of the exceptional needs covered by discretionary provision in the West.

There are no professional social workers in either the Soviet Union or China; social service workers perform similar functions, especially with regard to child protection and delinquency. The Soviet Union has a long tradition of nurtured interdependence between the formal social services and a complex network of mutual aid, lay counseling, and supportive services. The latter are distributed by street, block, and house committees in the towns and cities, by agricultural collectives in the countryside, and by the parallel agencies of the trade unions and the Communist Party.

Self-reliance and mutual aid

The Chinese system of social welfare is also strongly based on the industrial or agricultural workplace. Many essential social services, such as health care, are funded from the profits of collective work and administered by neighbourhood committees. Throughout the People's Republic the guiding welfare principles are self-reliance and mutual aid. Although, in exceptional cases, families receive grants-in-aid to help with care for dependent relatives, Article 13 of the 1950 Marriage Law states that children and parents are jointly responsible for mutual support in hardship and old age. At the same time extensive and sustained support is given to schemes of mutual support that extend to neighbourhoods and workplaces, and priority is given to the needs of dependent persons without families of their own.

Decentralization of services

The trend in Yugoslavia has been toward the decentralization of personal social services and the promotion of neighbourhood voluntary work. State-sponsored organizations such as the Alliance of Friends of the Young and the Pensioners' Associations act in conjunction with a growing network of professionally staffed social work centres financed by the 600 communities that are the basic units of local government. Similar developments can be seen in the other socialist countries of eastern Europe, where, as in the Soviet Union and China, there is a strong commitment to the expansion of informal provision for family dependents and neighbours.

Developing countries. In former colonies, such as Ghana, Sri Lanka, Jamaica, India, the Philippines, and Francophone Africa, the basic welfare services grew out of modified versions of the European poor laws, charitable and missionary activities, and the introduction of Western juvenile justice procedures. The oldest school of social work in Latin America was founded in Santiago, Chile, in 1925, and the Ratan Tata Foundation established the first Indian school in Bombay in 1936. New training institutions have since proliferated throughout the so-called Third World, many of them sponsored by the United States Agency for International Development.

Disaster relief

In developing countries, where formal social services are generally under-resourced, traditional networks of informal care are the main source of assistance in adversity and old age. High rates of migration and unplanned urban growth, however, have weakened these networks in impoverished rural areas and overwhelmed the limited public services in new cities and towns. Indigenous overcrowding and poor housing, unemployment and low wages, and inadequate sanitation and endemic disease are not responsive to Western methods of personal social service intervention. Priority, often within severe economic restraints, must go to major programs of preventive health care, family planning, basic education, income support, and slum clearance. Nevertheless, community development work is also important in these processes of social development. In the poorest rural areas, where the majority of people live at or well below subsistence level, disaster relief is heavily supplemented by international aid agencies such as the United Nations and its associated agencies, including the World Health Organization and the International Labour Organization (ILO), charities such as Oxfam and the Save the Children Fund, and the governments of richer nations. In the longer term the enhancement of living standards depends on horticultural improvements, reforestation, water conservation, and those irrigation schemes that can be managed within small communities.

CONCLUSION

It is clear that the processes of economic and social change create new prospects and new hazards for every generation. This requires constant adjustment on the part of the social services. Political considerations and levels of resources largely determine how social services are organized and how responsibility is apportioned between the statutory, voluntary, and private sectors. Even in prosperous societies the scale and diversity of needs is such that the formal social services are obliged to utilize and support informal systems of social care and mutual aid. The idea of the welfare state as a universal provider for largely passive populations has never had any reality in fact, nor much serious support in political theory. There is widespread evidence of a general trend toward the development of closer links between the formal and informal systems of social care, although this might lead to further variation in social welfare services as societies become more sensitive to their indigenous cultural diversity and develop their own responses to change. (R.A.P.)

Social security: government welfare programs

In international usage the term social security has come to mean all collective measures established by legislation to maintain individual or family income or to provide income when some or all sources of income are disrupted or terminated or when exceptionally heavy expenditures have to be incurred (*e.g.,* in bringing up children or paying for health care). Thus social security may provide cash benefits to persons faced with sickness and disability, unemployment, crop failure, loss of the marital partner, maternity, responsibility for the care of young children, or retirement from work. Benefits may be provided in cash or kind for medical need, rehabilitation, domestic help during illness at home, legal aid, or funeral expenses. Social security may be provided by court order (*e.g.,* to compensate accident victims), by employers (sometimes using insurance companies), by central or local government departments, or by semipublic or autonomous agencies.

The ILO uses three criteria to define a social security system. First, the objective of the system must be to grant curative or preventive medical care, to maintain income in case of involuntary loss of earnings or of an important part of earnings, or to grant a supplementary income to persons having family responsibilities. Second, the system must have been set up by legislation that attributes specified individual rights to, or that imposes specified obligations on, a public, semipublic, or autonomous body. And third, the system should be administered by a public, semipublic, or autonomous body.

In its statistics the ILO includes provisions according to which the liability for the compensation of employment injuries is imposed directly on the employer, although such schemes do not strictly meet the third criterion above. For this reason employer liability is included here.

An alternative but wider term for social security in the countries that are members of the European Economic Community is social protection, which includes voluntary schemes not set up under legislation. In some countries the term social security is used in a narrower sense. For example, in the United Kingdom only statutory benefits in cash are regarded as social security. The term social services is used to cover social security; health, education, and housing services; and provisions for social work and social welfare. In the United States the term social security is restricted to the federal social insurance system (OASDI) as distinct from state benefits and "welfare," which in Europe would be called social assistance. In some countries (*e.g.,* Denmark and the United Kingdom) the reduction of poverty historically has been a central aim of social security policy, and the concept of maintaining income has been grafted on at a later stage. In other countries, such as France, measures to deal with poverty have been seen as quite separate from the income maintenance aims of social security.

A report published in 1984, prepared by 10 international experts appointed by the director of the ILO, set out the ultimate aims of social security.

> Its fundamental purpose is to give individuals and families the confidence that their level of living and quality of life will not, insofar as is possible, be greatly eroded by any social or economic eventuality. This involves not just meeting needs as they arise but also preventing risks from arising in the first place, and helping individuals and families to make the best possible adjustment when faced with disabilities and disadvantages which have not been or could not be prevented. . . . It is the guarantee of security that matters most of all, rather than the particular mechanisms such as contributory or tax financing, the insurance or service model of delivery, or the ownership of facilities (public/private, profit/non-profit) by which that guarantee is given. . . . The means should not be confused with the ends.

Approximately 140 countries have some type of social security scheme. Nearly all of these countries have schemes covering work-related injury and old-age and survivors' pensions. Well over half have provisions for sickness, and nearly half have provisions for family allowances. The least commonly provided schemes are for unemployment, though at least 40 countries have them.

THE RATIONALE FOR SOCIAL SECURITY

Industrial societies

Because general social security schemes based on compulsory insurance did not develop until the last 20 years of the 19th century, it has often been argued that social security in its modern form has been a response to industrialization, which caused large numbers of people to become dependent for their security solely on earnings from employment. Indeed many families became dependent on one male earner and thus on his capacity to find work, to undertake it, and to remain in it. Moreover, industrialization led to the migration of people toward centres of work, thus separating them from the support given by the wider family. In addition, the development of compulsory education prolonged the period during which children were dependent on their parents; later the system of enforced retirement created dependency at the other end of life. This situation is contrasted with the idealized image of the extended rural family with access to land, on which both husband and wife worked, children started work early, and old people continued to work until they became too frail or disabled to do so. On the basis of this oversimplification, some theorists have proposed that social security developed out of a need peculiar to industrial societies and that there is less need or no need for such programs in the rural areas of developing countries today.

It is true that support from the extended family, often enforced by local custom and religious beliefs, contributes to the survival of peasant societies. But by no means all the rural populations of developing countries have access to land, and many people work for wages in agricultural estates and mines. Moreover, peasant farmers are subject to formidable risks of crop failure, quite apart from the risks associated with the shorter average life span that characterizes developing countries. Although there is a need for social security in rural societies, the importance of specific risks may vary from region to region. Moreover, the irregular incomes in cash and kind emanating from agriculture do not lend themselves to the payment of regular social insurance contributions. Thus, what may be lacking is the economic and administrative base for providing such security. Furthermore, provision for sickness and old age is not generally seen as the highest priority by peasant farmers overwhelmed by problems of weather and debt.

Agricultural societies

While industrialization has undoubtedly added to the need for social security by breaking up the extended family and leading to urban poverty, it is by no means the sole reason why the system evolved. Two of the first three countries to make provision for old-age pensions were primarily agricultural societies—Denmark in 1891 and New Zealand in 1898. The Danish scheme was clearly an attempt to alleviate rural rather than urban poverty. And it is notable that the first province in Canada to develop compulsory health insurance (1962) was Saskatchewan, which was overwhelmingly agricultural. Thus, statutory social security may evolve for a variety of reasons. Moreover, it depends to a considerable degree on the economic level attained by the groups that might be covered and the administrative capacity of the country to operate such a scheme. It is certainly the case that, as countries become wealthier, there is greater willingness to defer consumption by paying insurance contributions or taxes.

HISTORICAL EVOLUTION

In many societies charity has been the traditional way in which provision was made for the poor. Charitable giving has been encouraged by many different religions, and in many parts of the world religious agencies have long collected charitable donations and distributed help to those in need.

Obligations on communities to pay taxes to provide for the poor can be traced back for hundreds of years in a number of different societies. For example, part of the function of the Christian tithe or the Islāmic zakat was to provide for the poor. Town poor laws were passed in Germany from 1520 onward, and a law of 1530 clearly placed on towns and communities the obligation of sustaining the poor. In 1794 the Prussian states assumed the responsibility of providing food and lodgings for those citizens unable to support and fend for themselves. From the 16th century it became recognized in England that there were people who could not find work, and legislation was passed to provide work for the poor and houses of correction for rogues and idlers. From 1598 a clear obligation was placed on parishes to levy local taxes and appoint overseers of the poor to give relief to those who could not work and to provide work for those who could. This was the essence of the Elizabethan Poor Laws, an early provision of social assistance.

Poor Laws

The Elizabethan Poor Laws were poorly enforced in the 17th century but widely used and liberalized by the end of the 18th century. A new Poor Law enacted in 1834, and reflecting a harsh moral view of poverty, required the poor persons to be admitted to the workhouse so as to receive relief only in kind, with occasional exceptions, but this again was by no means uniformly enforced, though it added greatly to the unpopularity of the Poor Laws. Some U.S. states copied the Elizabethan Poor Laws but exempted recent immigrants. The English Poor Laws were also introduced in Jamaica in 1682 for destitute European immigrants and much later in Mauritius (1902) and Trinidad (1931). In Latin America the Spanish colonists, instead of establishing a public relief agency, gave grants to charities to provide "hospitals" for the poor (*beneficencias*), and the Portuguese promoted lay brotherhoods such as the Misericórdia.

The first general social insurance scheme was introduced in Germany in 1883. The scheme drew upon three types of precedent. The first was the ancient system of guild collection boxes—funds to which each member of a particular trade was required to contribute at regular intervals; such funds were originally used for hospital and funeral expenses and for food and lodging for aged and disabled members. By the middle of the 14th century these arrangements were covered by statutes and regulations. Relief funds were later established by associations of miners. The second precedent was a Prussian ordinance of 1810 that placed on masters a duty to ensure that their servants were given medical attention in case of illness. From 1849 communities could make bylaws requiring both employers and employees to contribute to relief funds, and a law of 1854 introduced compulsory health and accident insurance for miners. The third precedent was the employer's legal liability to pay damages for accidents caused by negligence. As a result of this liability, which was widened in 1871, many employers took out private insurance. The system did not work well because the burden of proof lay with the worker, who normally had to incur high legal costs and delay before he could hope to obtain lump-sum compensation.

Chancellor Otto von Bismarck's 1883 sickness insurance law provided to employees in defined types of industry both medical care and cash benefits during a period of sickness, to be paid for out of contributions from both employees and employers. This was followed by a law of 1884 making accident insurance compulsory. The schemes were operated by numerous funds controlled by the insured and their employers. Finally a law establishing a pension for all workers in trade, industry, and agriculture from the age of 70 was passed in 1889. This was directly administered by the Imperial Insurance Office. Austria followed part of the German example in 1888, Italy in 1893, and both Sweden and The Netherlands in 1901.

Friendly societies

Bismarck's political aim in introducing social insurance had been to address the legitimate grievances of workers so as to check the growth of socialism and avert revolution. A proportion of previous earnings were to be paid in cases of sickness, injury, widowhood, and old age. Employers and employees were to work together in implementing the scheme. In Austria part of the driving force was the Christian Socialists' aim of improving the worker's position. Although Britain had been the first country to industrialize, the developments in Germany and Austria originally attracted little British interest because of an aversion to state intervention, an apparently lesser likelihood of revolution, and the slower development of British socialism. In Britain self-help through friendly societies and savings banks was seen as the solution. The friendly societies were run by skilled workers with no employer participation and provided flat-rate cash benefits for sickness as well as treatment by the society's doctor, who was normally paid a flat rate per member insured—a so-called capitation payment. By 1870 membership had grown to 1,250,000 and by the early 20th century to 7,000,000. Apart from the regulation of friendly societies, the only social security legislation passed in the United Kingdom during the 19th century was to widen the liability of employers to compensate workers for personal injury arising out of work. By a law of 1897, compensation could be obtained whether or not the employer had been negligent.

Further action arose in the United Kingdom out of social concern about poverty, which was systematically investigated both in London and in York. In 1899 the government carried out an inquiry into the incomes of 12,000 elderly people. The influential precedents for action were those of New Zealand and Denmark, which had made provision for old age without establishing social insurance schemes, in contrast with Germany, where the scheme was based on insurance. In 1908 in Britain, pensions at age 70 were introduced in a noncontributory, income-tested basis, partly because such a scheme could bring immediate relief to the aged poor, as opposed to a contributory scheme, which could only pay pensions to those who had paid contributions. The social insurance approach was, however, applied to sickness and also to unemployment in certain occupations three years later. This compulsory scheme, including the first state scheme of unemployment insurance, again reflected Britain's concern to address the main causes of poverty. Benefits and contributions for sickness and unemployment insurance were flat-rate, building on the precedents established by the friendly societies and ensuring the maximum impact on the living standards of low earners. From 1925 the social insurance approach began to be extended to provide for widowhood and old age.

Unemployment insurance

Unemployment insurance was subsequently introduced in Austria and Belgium (1920), Switzerland (1924), Germany (1927), and Sweden (1940). In the case of health insurance, Denmark, Norway, and Sweden promoted voluntary health insurance before making such schemes compulsory, much later than in Britain or Germany. In France voluntary insurance had long been less developed, and mutual insurance societies had long been regarded by government with suspicion, and therefore suppressed. When they ultimately were allowed to expand, around the end of the 19th century, the bulk of their membership was middle class. During the second half of the 19th century larger employers established their own pension and welfare institutions. An employers' liability law was passed in 1898 for accidents at work irrespective of negligence, and in 1910 modest contributory pensions were introduced for industrial and agricultural workers. This law met with limited success, owing to opposition on the part of workers, noncompliance among employers, the loss of rights on change of job or bankruptcy of the employer, and the erosion of the value of pensions during inflation. Health insurance, though provided for in a law of 1920, did not come into effect until 1930, owing to the opposition of the medical profession.

A major innovation came in Belgium (1930) and France (1932) with the introduction of family allowances, although New Zealand had introduced a limited means-tested scheme in 1927. These derived from the ideas of social Christianity regarding "the just wage" and had originally been introduced by Christian employers on a private basis; special funds were later set up to equalize financial burdens among employers. Family allowances became relatively generous in France, partly because of concern to increase the birthrate after the heavy loss of men in World War I. (There is, however, no clear evidence that family allowances have any impact on birthrates.) France later introduced family allowances in many of its colonies during the 1950s.

During the interwar period social insurance schemes were introduced in more and more countries in Europe and Latin America. The most common model was that established in Germany—autonomous funds paying earnings-related benefits. The first group to benefit in Latin America was civil servants, followed by those working in railways and public utilities. There were separate schemes for hospital personnel in Argentina (1921), shipbuilders in Uruguay (1922), merchant seamen in Chile (1925), and dockworkers in Peru (1934). Thus the foundations were laid for the complex social security schemes in Latin-American countries that later reformers tried to amalgamate. The first comprehensive scheme for industrial workers was established in Chile in 1924. In African colonies many schemes of social security were originally introduced only for expatriate Europeans.

U.S. Social Security Act of 1935

The Great Depression of the 1930s finally overcame opposition in the United States to federal intervention in social security. Earlier government activity had consisted of piecemeal initiatives at the local or state level. The Social Security Act of 1935 not only provided federal grants for state public assistance to the aged, blind, disabled, and dependent children but also established a federal old-age insurance scheme and federal financial backing for state unemployment insurance plans that met federal guidelines. Provision for survivors was added four years later and for disability later still. A quite different approach was taken in New Zealand, which introduced in 1938 the first universal non-means-tested pension from age 65, available only on a test of residence and financed in part from a special social security tax on income.

A major influence on world developments was the British government's report by Sir William (later Lord) Beveridge in 1942, which argued for the maintenance of full employment as a responsibility of government, family allowances for all children after the first, comprehensive health care for the whole population, and a unified national scheme of social insurance run by the state with the safety net of a unified national scheme of social assistance. The aim was to eliminate want or poverty. By 1948 the scheme had been introduced in the United Kingdom with some compromises and modifications. A drive, inspired by Pierre Laroque, to unify social insurance in France after World War II was less successful.

During the period of rapid world economic growth from 1945 to 1973 there was a further major expansion of social insurance to more countries, covering higher percentages of population and wider risks. The expansion was particularly notable in Latin America and in certain French colonies in Africa, where comprehensive social insurance schemes were introduced following the original schemes for family allowances. In the British colonies a different approach was taken: provident funds (see below) were widely developed for particular categories of workers. Discrimination on racial grounds was widely prohibited but still persisted in South Africa.

Innovations after World War II

The major innovations in social insurance after World War II were the protection of pensions by linking them to the inflation rate; the development of dynamic pension formulas that indexed past pension contributions to the level of earnings at the time of retirement; the introduction of flexible retirement providing for part pension and part-time earnings in the last few years before full retirement; the movement toward equal rights for men and women; attempts to provide for all disabled people on the basis of the degree rather than the cause of disability (*i.e.,* whether or not work-related); the growing recognition of extra needs arising from disability and of the needs of persons caring for the disabled; special provisions for one-parent families; the development of parental allowances in addition to family allowances; the integration of child tax allowances with family allowances; and the extension of the same health-care rights to all citizens.

METHODS OF PROVISION

Legal liability. Many countries that once held employers themselves legally responsible for compensating victims of work accidents and for paying for their medical care have now adopted state schemes of compulsory insurance. From the point of view of the worker the problems with the former system include the delays and costs of going to court and the possibility that the employer may be uninsured, unable to pay, or bankrupt by the time the case is heard. Moreover, a lump sum awarded by a court cannot be invested so as to provide a secure inflation-protected income for life. And when the employer is privately insured, the insurance company is in a position to offer the worker a small lump sum soon after the accident, knowing that the worker may well accept it rather than incur the delay, costs, and uncertainty of a court case to obtain the full value of the claim. From the national point of view such a system is wasteful because of the legal costs and the high administrative costs incurred by the insurer and passed along to the insured by way of higher premiums. The argument in favour of this approach is that insurers quote premiums for individual employers according to their experience of risk, which provides financial incentives for industrial safety. But insofar as such incentives are effective, premiums for a national program of accident insurance can also be risk-rated.

Private versus statutory compensation

In some countries, when a statutory insurance scheme of occupational injury has been introduced, the right of the employee to sue the employer for negligence is removed. In other countries the employee is free to supplement industrial injury benefits by making a claim for negligence.

The legal liability approach is still used in many developing countries for the general provision of medical care. Thus large employers or employers of labour in mines or specific agricultural estates (*e.g.,* sugar, tea, and rubber) are required to provide clinics and hospitals for their employees and dependents. This is one way of ensuring that health services are provided to people working far from the main urban health services. It is, however, difficult to ensure that employers comply with the spirit of the law. Moreover, employees may suspect that the doctors and nurses working in such services owe their primary loyalty to the employer and thus tend to economize on the treatment or are reluctant to certify time off for sickness. A further problem is that it is uneconomic to provide government services in these areas for the remainder of the population who are not employed by the major local employer and is difficult to integrate employers' services with government services.

In several countries employers are required to provide defined levels of cash benefits during short periods of sickness (*e.g.,* six to eight weeks). This avoids the administrative complexity of a social insurance benefit paid by a national scheme or a sick fund supplemented by an employer's scheme. Provision may be made to protect the workers' rights if the employer goes out of business.

While social insurance is preferred to the employer liability approach by social security experts because it can give better protection, employer liability is still widely used in developing countries not only for employment injury but also for sickness and maternity benefits and employer severance payments.

Lump-sum benefit

Provident schemes. Many developing countries require certain employers to contribute to a provident scheme providing a lump-sum payment in the event of death or disability or on retirement. Such a scheme differs from a social insurance scheme in that each worker usually has his own personal account from which he or she can draw if certain contingencies arise; there is no pooling of risks among members as there is in a social insurance scheme. Such schemes, which avoid the administrative complexity of paying a regular cash benefit, may be a step toward a full-fledged social insurance scheme. There are three disadvantages of such schemes from the point of view of the beneficiary. First, provision is inadequate for risks occurring early in working life. Second, the funds are generally invested in government stock with a rate of interest fixed in money terms that may be below market rates; the real value of the accumulated savings may thus be substantially eroded by inflation by the time of retirement. Third, a lump sum once received cannot normally be securely invested to provide an income protected against inflation. Moreover, it may be frittered away or unwisely invested. From the point of view of governments, however, such schemes are attractive in that they generate forced savings that can be used to finance national development plans.

Social insurance. The use of compulsory insurance as a mechanism to provide medical benefits and cash benefits in the case of sickness, disability, widowhood, and old age became acceptable to legislative bodies fearful of accepting extended state intervention that would require higher taxes to finance pensions or other benefits. In societies where self-help by voluntary insurance had been widely supported, the further step of compulsory insurance was seen as a means of making workers "good" by legislation. Because the schemes were financed by contributions levied on both employers and employees with, in some cases, modest state subsidies, unacceptable levels of national taxation were avoided; indeed, as such schemes reduced the need for social assistance or poor relief, the burdens on local taxation were reduced.

Reduction of tax burden

Compulsory insurance contributions are essentially a tax on earned income. Employers try—and probably succeed in most circumstances—to shift the burden of their share of the contribution either to consumers in higher prices or more probably, in the long run, to their employees by paying them less in cash. Thus employers' contributions are in most cases not paid at the expense of profits. However, the fact that the worker is told that the employer has to pay a proportion of the total contribution helps to make such schemes acceptable to employees, quite apart from the clearly defined benefits that flow from paying their share. Compared with the complexities of an income tax, a social insurance tax is a simple one to collect. But if the level of contributions is high, it creates incentives for workers to become self-employed in what has come to be called the "black," or "underground," economy and for employers to avoid contribution liability by employing contract labour rather than full-time staff.

In terms of meeting social needs or reducing poverty the social insurance method of provision has a number of disadvantages. Over the years many countries have tried to find means of countering these. First, the analogy with private insurance, which made such schemes politically salable, carries with it the social disadvantage that benefits should be paid to those who have contributed. Thus such schemes cannot provide benefits to persons who have never worked, for example, persons who have become disabled before reaching the age to enter employment, those incurring risks very soon after entering employment, and women (or men) who do not enter the labour force because of family responsibilities. Second, the expectation that benefits should be related to the amount paid in discriminates against individuals, usually women, who because of family responsibilities have fewer years in paid employment. Moreover, workers with dependent spouses and children have greater needs than single persons, though the assumption of marital responsibilities—or the converse assumption of marital dependency—is not strictly speaking an insurable risk. Third, where contributions are related to earnings, the benefit will be low for low earners, thus failing to protect them from poverty. The alternative approach, which some countries have adopted, of flat-rate contributions and flat-rate benefits can impose heavy burdens on low earners with family responsibilities. Fourth, it is difficult to bring the self-employed and those working for small employers (*e.g.,* agriculture or domestic work) into such a scheme.

Over the years many countries that started with a purist insurance approach have modified their schemes to try to overcome many of these disadvantages. For example, extra benefits have been provided to persons with dependents. Contributions have been credited to persons outside the labour force for reasons of family responsibility, sickness, or disability. Minimum benefits have been introduced above those strictly warranted by low earnings-related contributions, or the benefit formula has been weighted in favour of lower earners. And some countries have made contributions earnings-related or integrated them with income tax while still paying flat-rate benefits.

Demogrants

Benefits to all residents. Because of the disadvantages of the social-insurance approach, some countries have made certain benefits available to all residents and financed them out of taxation. When the benefit is paid on the basis of age it is sometimes called a demogrant. The most common benefit selected for this approach is the family allowance. The underlying philosophy is that provision for children should not depend on whether the parent is or has been in paid employment. Some countries have adopted this approach for pensions or at least for a minimum pension. In some cases this evolved from an earlier provision of an income-tested pension. In other cases this was the only way forward for governments in which the power to levy social insurance contributions did not rest at the federal level. Some countries have more recently applied this approach to provision for the disabled in the form of a minimum benefit based only on the extent of disability. It is increasingly applied to medical benefits on the grounds that all citizens have a right to health care.

Means and income tests

Social assistance. The development of social insurance and demogrants has not removed the need for social assistance to fill gaps in provision in advanced societies. Social assistance is based on need and thus requires declarations of income, family size, and other circumstances. Thus it is provided on the basis of a means test that takes into account not only income but also capital; persons with a specific level of savings may be ineligible. Alternatively it may be only income-tested, the income from capital being assessed in the same way as other income. Often those who have been given the task of operating the scheme (*e.g.,* social workers) have been allowed considerable discretion in deciding whether to give assistance and how much to give in certain types of cases. Not all basic rules are known to claimants. The tendency in industrialized countries has been to try to transform assistance into a right with published scales and regulations and opportunities for appeal. With codification has often come standardization and the unfortunate removal of some of the flexibility available under discretionary systems.

In some countries social assistance plays a residual role, providing a less favourable level of support than is normally available from social insurance benefits. In other countries (*e.g.,* the United Kingdom) social assistance plays a considerable role in supplementing social insurance benefits for those without other sources of income such as sick pay or employers' pension schemes as well as providing for those without rights to benefits (*e.g.,* one-parent families other than widows) or those whose benefits have run out because they are paid only for a specific number of months (*e.g.,* unemployment benefits).

Criticisms of social insurance

There are disadvantages of the social assistance approach. First, it penalizes saving and earning because income from any source is normally deducted from the assistance that would be payable, and persons with a certain level of savings may be ineligible until they have used them up. Second, it tends to stigmatize the recipient; and third, partly for this reason and partly because of the difficulty of knowing detailed rules of entitlement, there are considerable numbers of people who would be eligible but do not make claims. Partly because of this problem of stigma, social assistance programs are called by a variety of different names in the hope that they will be more acceptable to applicants. For example, the term used is supplementary benefit in the United Kingdom and GAIN (guaranteed income) in British Columbia. Eligibility rules differ considerably from country to country and are usually determined locally rather than centrally. Moreover, schemes are generally financed wholly from taxes—often local taxes. In the United Kingdom, where rules are determined centrally, persons in full-time work are not eligible. In the United States only households headed by a single parent are eligible for the Aid to Families with Dependent Children program, which creates incentives for desertion or fictitious desertion. There are, however, further programs for the blind, the disabled, and the aged.

The United States uses what is essentially the social assistance approach for meeting the medical care needs of low-income persons under the Medicaid program. Ireland operates a scheme by which persons with low income can apply for a medical card that gives them more extensive rights to free health care than are available to other income groups. Those with low incomes in South Korea can also apply for cards giving rights to free or nearly free health care.

A number of countries in Europe have developed separate income-tested provisions to help persons with low incomes meet the cost of rent or property taxes. Such housing allowances are available to persons whether in work or not and take account of family composition as well as rent payable.

Negative income tax. Partly because of the stigma attached to social assistance, the difficulty the potential beneficiaries have in understanding eligibility, and their reluctance to apply, it is often proposed that the information provided to the state from income tax returns should be used by the state to determine the need for cash payments to persons with low incomes. The ability to do this depends on persons' being required to make income tax declarations by a certain date however low their incomes, which is not the practice in every country. Canada has a program to supplement on the basis of this information the incomes of persons drawing pensions. This approach is much less appropriate for younger people whose financial circumstances change considerably from year to year and month to month due to sickness, unemployment, job changes, marriage breakdown, remarriage, and so on. People need money when poverty strikes, not after the end of the income tax year.

CASH BENEFIT PROGRAMS

Provisions for cash benefits change from time to time in all countries. Thus no description can be fully up-to-date. The information presented here is chiefly based on the returns made by 140 countries to the Social Security Administration of the United States and published in 1985 as *Social Security Programs Throughout the World.*

Pensions. Three basic types of state pension schemes predominate. The first is a flat-rate pension with no income test. This may be available on a test of residence only or with the stipulation that the person has been employed for some specific period and has paid requisite contributions. This approach is found mainly in Scandinavia and the Commonwealth countries. The second is an income-tested pension. The third, and most common, type is a pension related in some way to earnings during working life. A further complication is that most countries with a flat-rate pension later developed a second tier of pension rights based on earnings during working life. In other words, the first and third principles are combined.

New Zealand pays a flat rate pension; financed from general taxation, to all who meet residence requirements at age 60. The rate for qualified married couples is twice the rate for single people. The rate of pension is quite a high percentage of average earnings. The Netherlands also provides all residents with a substantial pension but at age 65; it is financed from contributions and reduced if contributions due have not been paid in any year. The supplement for a wife of any age is less than half the rate paid to the husband. In Ireland the pension is less generous and only available to employed persons with minimum contributions paid. Australia combines the first and second approaches with a flat-rate pension from age 70 and an income-tested pension from age 60 for women or from age 65 for men.

Two-tiered schemes

Several countries in Scandinavia abandoned an early means-tested pension in favour of a flat-rate pension after World War II because of the unpopularity, complexity, and discouragement to savings of the means test. Later the level of the pension was regarded as inadequate for all except the low-paid, and an earnings-related tier was established on top. Thus flat-rate pensions are provided on tests of residence in Denmark, Finland, Norway, and Sweden. In three of these schemes a married couple receives substantially less than two single persons. In each case the schemes are supplemented by earnings-related pensions. Canada followed a pattern of development similar to those of the Scandinavian countries. The United Kingdom also gradually moved over to a two-tiered pension, but rights to both tiers depend on contributions paid with credits for absence from work for approved reasons; employers' schemes can be used to provide a specified minimum upper tier of pension.

The Scandinavian and Canadian two-tiered approaches have a number of advantages. First, non-means-tested basic pensions can be provided to persons without a contribution record—including the disabled, those who have not worked because of family responsibilities, and divorced or separated wives. There is a similar advantage in New Zealand's scheme. But, in addition, those who have had higher earnings and thus paid higher contributions receive higher pensions with the value of these guaranteed in terms of purchasing power by the government. This reduces the scope for employers' pension schemes in which the purchasing power of the pension finally paid depends on how far the yield of investments has managed to keep pace with inflation.

Capitalization

Contributory pension schemes, when they were first established, were run on much the same basis as private pension schemes. The level of contributions was calculated by an actuary, and a capital fund was built out of which the pensions could be paid. Even if there were no further contributions, the money was intended to be available to pay out pensions to contributors from the accumulated value of their contributions. This arrangement is known as capitalization or fully funded financing. The first scheme in Germany, enacted in 1889 and based on capitalization, covered most employed persons with earnings up to a specified level. The earnings-related contributions were equal for employees and employers, and there was a subsidy from the state to provide the low-paid with somewhat higher pensions than their contributions warranted. A breach with the principles of private insurance was made to allow workers close to retirement when the scheme went into effect to receive higher pensions than their contributions had earned them. This system of "blanketing in" older workers has frequently been used in other countries when new pension schemes have been established.

It was the experience of rapid inflation after World War II that led to a fundamental change in the financial basis of pensions. Instead of the contribution level's being sufficient to build up a large capital fund, it was calculated according to the expected cost of pensions due to be paid over the next few years. This pay-as-you-go method of financing statutory pension schemes, which became the normal arrangement, contrasts sharply with private pension schemes. The latter still have to accumulate capital funds because, unlike state schemes, they have no power to compel future generations to join them. Thus state pension schemes are essentially a "compact between generations." Those at work are compelled to pay to the pensioners of today in expectation, written into the law, that their pensions will be paid by the next generation of workers.

A second major development in pensions began in the late 1950s in response to rapid economic growth. It became recognized that if pensions were paid out on the basis of the money value of contributions paid in over a working life during which real earnings had been growing rapidly, pensions would amount to a low proportion of earnings at the time of retirement and a still lower proportion of what those at work would be earning 10 or 20 years later. Thus complex formulas were introduced to adjust pensions to the general level of earnings at the time of retirement. West Germany set the pattern in 1957 and was followed by several other European countries—for example, Austria, Switzerland, and the United Kingdom. An alternative approach (*e.g.,* in Italy and some eastern European countries) is to base the pension on the last few years of earnings. As this can be unfavourable to workers whose earnings decline in the later years of working life, some countries (*e.g.,* France) base pensions on the best few years of earnings. The Soviet Union offers an option of the last earning year or the best five consecutive years out of the last 10.

Minimum pension

The practice of giving low-paid workers higher pensions than were earned by their contributions and those of their employers, which was built into the original German scheme but later abandoned, has been copied in a number of later schemes (*e.g.,* those of the United States and the Soviet Union). An alternative or further way of helping low-paid workers is to provide a minimum pension, as in West Germany or the United States (though in 1981 the U.S. provision was removed for people not yet retired). This particularly helps women, whose average annual income, despite legal inroads against discrimination, remains well below that of men, and whose pension contributions are now likely to be interrupted by leave from work for family responsibilities. A much more common provision is an income-tested social pension as, for example, in Belgium or France.

Another development mainly of the period after World War II has been the automatic adjustment of pensions according to an index of prices or in some cases to the average level of earnings, or whichever is more favourable. Some countries have postponed adjustments or modified their formulas, particularly when prices were increasing faster than earnings.

Pension age

The age at which full pension can normally be drawn varies considerably between countries. In Europe the normal age for men can be as high as 67 and as low as 60 and for women as high as 66 and as low as 55. Some developing countries have still lower pension ages. To some extent pension age tends to reflect the expectation of life in the particular country. The pension age for women, however, is often lower than for men; one reason often cited for this is that husbands tend to be older than their wives, and so the disparity in pension ages permits simultaneous retirement. The arrangement, however, is disadvantageous for women who are retired compulsorily at the lower age after having had less time to accumulate a record of contributions. There is, therefore, a trend to equalize pension ages between the sexes. To do this by lowering the male pension age is expensive; it is for this reason that the European Communities has not made this binding on member states in its directive on equal rights to social security.

Some countries have long had provisions allowing the pension to be drawn a few years earlier than the stipulated age of retirement with an actuarially calculated reduction in the pension paid. Such provisions are suited to the more generous earnings-related schemes in which a reduced pension would not normally cause poverty. Ill health is a common reason for early retirement, though many choose this option in order to enjoy retirement while still in good health. There commonly are also provisions by which people who wish to postpone their retirement and continue to contribute can draw a larger pension. In some cases these arrangements have been introduced in the hope of encouraging later retirement, thus modifying the deterioration of the ratio between the employed population and the retired population, which necessitates higher levels of contribution by those still working as the proportion of the pensioned population increases.

Despite the logic of raising the normal pension age in line with an improved expectation of life, changes in schemes of industrial countries in the 1960s tended to lower the age. This trend has continued as the level of unemployment has increased, despite the financial burden this places on the schemes, particularly in the long run. The political objectives of reducing the number of persons recorded as unemployed and creating jobs for younger people have taken priority. Thus a wide variety of complex provisions have been written into pension schemes defining the circumstances in which full pensions can be drawn a few years earlier than otherwise stipulated. This may be allowed to those with many years of insurance (*e.g.,* 35), to those who have been unemployed for a substantial period (*e.g.,* a year), to those who are disabled, to those with arduous or unhealthy occupations, and to those whose jobs are being released for younger persons. In some countries the pension is income-tested below the normal age. Contrary to this trend for earlier pensions, the United States has raised the future pension age in two steps from 65 to 67 in response to the long-run financial prospects for the pension scheme.

Partial pension

A development pioneered by Norway in 1972, and since followed by more and more countries, was to allow persons aged 67 to 69 to reduce their working hours and receive at the same time a partial pension. This enabled older people to make a gradual transition between work and retirement. The change was made when the pension age was lowered to 67. Sweden followed in 1976 with a provision for those aged 60 to 64. Partial pensions have also been introduced in Spain and, on a much more restricted basis, in the United Kingdom.

In most schemes in industrialized societies there is a limit on what the pensioner can earn without leading to a reduction in pension. Some schemes specifically require the pensioner to leave his or her job on receipt of the pension. These provisions add to the wider pressures leading to the steady fall in the proportion of persons in full-time work above the normal pension age. But the main reason for this trend is the increasing generosity of pensions, both public and private.

Early pension schemes made extra provision for a dependent wife, and more did so between World Wars I and II. This can mean that women's contributions are "wasted" in the sense that the pensions they earn are less than they have a right to as a dependent wife. The greater frequency of divorce and cohabitation has meant that more women are wholly dependent on the pensions they earn in their own right. Moreover, some pension schemes make no provision for a dependent wife (*e.g.,* in West Germany, Austria, and Italy). The issue of women's rights to pensions is particularly important in the context of poverty, as women on average live longer than men.

A few countries allow housewives to contribute to pension schemes on a voluntary basis, but few women do so in practice. Others have adopted provisions for the dividing of pension credits between spouses. In the United Kingdom a man or woman can be credited with a full year's pension rights for each year up to a maximum of 20 during the whole of which he or she is caring for a dependent child or disabled relative. These rights are based on the individual's previous record of contributions.

In the early schemes widows over pension age were entitled to a proportion of the pension of their husbands. More and more schemes have been amended to make similar provisions for widows and widowers. Usually survivors can choose between their own personal rights and a proportion of the rights of their deceased spouse, but in Sweden widows can receive both earnings-related benefits on top of one flat-rate pension. This right is available, up to a maximum, to a widower as well as to a widow in the United Kingdom.

Disability and sickness benefits. In most countries provision for occupational injury is the oldest form of social security. The original German law of 1884 provided for workers to receive half pay for four weeks followed by two-thirds pay during temporary disability. In cases of permanent disability two-thirds of earnings from the year preceding the accident were paid out, with a proportion of this pension paid in cases of partial incapacity. Extra provision could be made for persons needing constant attention. The scheme was wholly financed by the employer, who paid insurance contributions, assessed on the degree of risk involved in the employee's occupation, to statutorily established associations. The associations then paid out any benefits.

The British law of 1897 made employers liable for compensation but did not require employers to insure against the risk. Compensation was half the basic pay for up to six months at which point the claim could be settled by a lump sum. These two very different precedents influenced developments in other countries. Continental European countries tended to follow the German model and the Commonwealth and the United States that of the United Kingdom. An act modeled on the British law of 1897 was passed in India in 1923, though the coverage was small. Moreover, the Belgians, Dutch, and French as well as the British preferred to introduce in their colonies laws imposing liability on employers rather than funded insurance schemes. By the end of World War II most colonies had such laws. These laws were often later augmented or replaced by insurance schemes. Some Scandinavian countries require the employer to insure but allow him to choose his own insurer.

Under an act of 1946 the United Kingdom introduced compulsory insurance through a state scheme with the same rate of premium for all employers. Benefits for incapacity were at a flat rate followed by a disablement pension based on degree of disability to which were added other allowances depending on the situation of the pensioner, including the loss of earnings and need for attendance.

Insurance is now compulsory in most industrialized countries, but the use of private insurance continues in a few countries (*e.g.,* Denmark and Finland) and the majority of U.S. states, while some countries give the employer the right to choose between a public or private insurer. Work-related injuries and an increasing number of occupational diseases lead in nearly all countries to higher benefits and more generous provision than are paid for sickness or injury not arising from work. For example, some countries in western and eastern Europe provide 100 percent of previous earnings as a temporary disability benefit. These benefits normally continue until recovery or the award of a long-term benefit. In most countries loss of earning capacity is a major consideration in the assessment of long-term benefits, and partial disability is more generously treated than in other social insurance programs. The long-term benefits in some countries can also amount to 100 percent of earnings. But the procedure of seeking lump-sum settlements from the courts still remains in some countries and some states of the United States, with all the associated costs, delays, and uncertainties and the difficulty of turning a lump sum into a secure income.

There are three special features of most occupational injury schemes that reflect their historical origins in the employer's liability. First, schemes are normally financed solely by employers' contributions. Second, the right to benefits operates from the very first day of employment. Third, a cash benefit is seen as compensation rather than income maintenance. For this reason dependents' benefits are not normally provided, but there is provision for surviving dependents. In addition, a compensatory benefit may sometimes be paid in addition to earnings or pensions. These features are found only in provisions for sickness or disability that are of occupational origin.

Both employers and employees normally contribute when the scheme is based on social insurance. Some minimum period or amount of contribution is generally required before there is entitlement to benefit. The amount of the benefit may depend on how long contributions have been paid, as for pensions, which is disadvantageous for those disabled early in working life. The main benefit is intended for income maintenance and thus cannot be drawn at the same time as other benefits or pensions with the same purpose. Finally, there is more likely to be provision for a dependent spouse.

Increasing uniformity of disability schemes

There has been a tendency in the period since World War II to bring occupational injury schemes into a closer relation to other social security schemes. Switzerland has always covered work-related and other accidents in the same scheme, established in 1911; New Zealand later adopted the same practice. The separate provisions for occupational injury and other disability raise difficult problems in specifying the distinction. Occupational injury normally has to "arise out of and in the course of employment." Some schemes allow travel to and from work to be considered within the "course of employment," while others do not. There are considerable difficulties in identifying whether certain disabilities (*e.g.,* deafness or arthritis) arise from work, and there are instances in which an injury is only partially attributable to the work situation. Part of the justification for combining the provisions for occupational injury and other disability is to eliminate such ambiguities. In addition there is the social argument that it is wrong to pay different benefits to different people, all of whom have the same degree of disability no matter how or when the respective conditions were caused. The Netherlands is the only country that has responded to this argument. From 1976, unified provision for disability has been made irrespective of cause. Costs of such a program can be substantial if all disability coverage is raised to a level approaching that of the previous, often considerably higher, occupational injury coverage.

In the case of sickness that is not associated with any occupational factors, most industrial countries pay a short-term benefit followed by a long-term pension after periods varying from about six months or less to a year or more. Some countries, such as Austria, Belgium, West Germany, and the United Kingdom, place responsibility for paying a benefit on the employer for the early weeks of sickness (though he may be reimbursed), after which the social security fund assumes payment. In some countries benefits may not be payable for an instance of illness lasting less than, for example, three days. In longer periods payment for the first three "waiting" days may be included in the benefit. Doctors' certificates may not be required for short spells of sickness. Benefits may be as high as 100 percent of earnings (*e.g.,* Austria and Belgium) in the early weeks of sickness or subject to a maximum, as in Norway, or for the full 52 weeks, as in Luxembourg. Or the rate may be 90 percent, subject to a maximum (Sweden and Denmark). Other countries normally pay only 50 or 60 percent (*e.g.,* France, Canada, and Greece). The benefit is flat-rate with extra for dependents in Ireland and the United Kingdom (after the eight weeks paid by the employer). The benefit is also paid on this basis in Australia and New Zealand, but it is means-tested. The United States is the exception among highly industrialized societies in that in most states there is no provision for short-term sickness apart from a special scheme for railway employees and social assistance, or welfare. In practice, provision is left for bargaining between employers' and employees' representatives.

Long-term invalidity pensions

Long-term invalidity pensions were included in the original 1889 German pension law (which was the first piece of legislation of this kind) for those who had lost two-thirds of their earning capacity. Many countries followed this model as part of (or as a later development of) their pension laws. In European countries invalidity pensions became payable after full short-term sickness benefit rights had been received. After World War II provisions were made in some countries for those who had considerable partial invalidity. Some countries require persons to have been insured for five or more years in order to be eligible for an invalidity pension, though generally there are means-tested pensions in industrialized countries for those who do not meet these requirements. In Australia and New Zealand those who meet residence requirements are eligible for income-tested pensions.

In countries with earnings-related pension schemes the invalidity pension is often calculated in the same way as the old-age pension. This means that the level depends on the number of years of contribution, though some countries have special concessions to enhance the pensions of those drawing them early in working life. Invalidity pensions may be supplemented by allowances for dependents and for constant attendance and other special needs.

Some countries make special provision for housewives who lack the contribution records that would qualify them for an invalidity pension. One such country is the United Kingdom, though the benefit is low and flat-rate. In Denmark a housewife can receive a substantial income-tested pension in her own right. Another group for which some countries have begun to make special provision is those who have been disabled from birth or before entering the labour market. These groups are provided for in the unified scheme of The Netherlands.

Most countries, however, are far from the position in The Netherlands, where all disabled persons are treated on a similar basis irrespective of the cause of disability. Those whose disability arises out of the work situation are generally most favourably treated; some countries provide full compensation for loss of earnings plus special allowances when required. Those who have paid contributions are generally treated better than those who have not, and often benefits depend on how long contributions have been paid.

Unemployment benefits. While sickness and disability are actuarial risks in that the incidence does not vary greatly from year to year, this is not the case with unemployment. It is partly for this reason that the duration for which unemployment benefits can be paid is limited in most countries or that benefits are reduced after a designated period. A further reason is to induce the unemployed to seek and accept work after benefits end or when they fall, although such work may be less well paid than the individual's earlier work and may provide an income lower than the unemployment benefit that has ceased.

Limits of coverage

The payment of contributions plays a critical role in policing eligibility for unemployment benefits; as a result the benefit is not payable to all persons who are involuntarily unemployed. The school dropout who has never had a job or only held one for a short period is normally ineligible for unemployment benefits. Women seeking to return to work after child-rearing are also ineligible, even though contributions were paid before leaving work. A prospective recipient must normally have held a job from which he has been released immediately before the benefit is claimed, and the individual must establish that he is available for work by registering at an employment office. Normally anyone who has voluntarily left a job or been discharged for misconduct is denied benefits or penalized.

In some countries the level of unemployment benefits is deliberately set at the same rate as the benefit for short-term sickness (*e.g.,* Canada, Denmark, and The Netherlands) so as to create no incentive for the beneficiary to try to establish eligibility for the higher benefit. In other countries the benefit for unemployment is at a lower level than the benefit for short-term sickness (*e.g.,* West Germany, Greece, and Hungary). Some countries that pay an earnings-related benefit for sickness pay a flat rate for unemployment (*e.g.,* Bulgaria and Italy). In Australia and New Zealand unemployment benefits, like sickness benefits, are subject to a test of income. The duration of the benefit varies from 13 weeks in Bulgaria to six months in

Hungary, Italy, and The Netherlands and a year in France, West Germany, Luxembourg, and the United Kingdom; in Belgium benefits can be continued indefinitely. In many, but not all, countries the unemployed can claim social assistance after their unemployment benefits cease. In several countries in northern Europe unemployment benefit schemes are operated by trade unions, though with substantial government subsidy.

Family, maternity, and parental allowances. While only a few countries had family allowances before World War II and several of the schemes covered employed persons only, with financing by the employer, there was a rapid extension of schemes in the 1940s and 1950s. The extension was in large part attributable to the influence of the Beveridge Report in the United Kingdom. Following the British example most of the new schemes in Europe, Canada, and Australasia included all resident children. A second influence was France, which introduced flat-rate family allowances for all children of employed persons in its African colonies—a system also introduced in some Latin-American countries (*e.g.,* Bolivia, Brazil, and Chile). The majority of schemes cover only employed persons, but a minority, particularly to be found in industrialized countries, pay allowances to all residents. The United States is exceptional among the latter countries in making no provision at all except in aid to dependent children paid on a means-tested basis.

Variations in dependent children allowances

Some systems of family allowances are intended to reduce poverty in large families or, particularly in eastern Europe, to increase the birthrate; the rate paid per child increases with the number of dependent children, reaching a maximum rate with the fifth or sixth child and subsequent children in, for example, Australia, Belgium, France, East Germany, Ireland, and Norway, or the eighth child, as in The Netherlands. In the Soviet Union family allowances start with the fourth child and reach the maximum rate at the 11th. Some systems seem to suggest a desired maximum family size insofar as the rate falls for subsequent children once there are three (*e.g.,* Bulgaria and Czechoslovakia) or two (*e.g.,* Greece and Hungary), or allowances may be payable for a maximum of six children (*e.g.,* Morocco). Finland recognizes that a mother is less likely to go to work if a child is under three years of age and thus pays a supplement. On the other hand, Austria pays higher rates for older children because they are more costly to maintain. Entitlement to family allowances ceases when a child reaches a particular age—often the age when compulsory education ceases, though allowances may be continued when a child continues in full-time education or is disabled. Allowances are payable only up to age five in the Soviet Union.

During the 1970s a number of countries decided to abolish income tax allowances for children and make a corresponding increase in the level of their family allowances. It was recognized that the largest beneficiaries from the tax allowances were high-income families with high marginal tax rates, and it was decided that this indirect benefit for children should be fairly shared among all families so as to increase the efficacy of family allowances in reducing poverty. Changes of this kind were made in Australia, Canada, Denmark, West Germany, Israel, New Zealand, and the United Kingdom. Denmark has gone one stage further and removed family allowances from the higher income groups by means of an income test. The United Kingdom has an additional income-tested allowance called the family income supplement which gives further help to low-income families.

It is the general practice for schemes that provide sickness benefits also to provide a maternity allowance starting before the birth of a child and extending for a number of weeks afterward. In some cases the rate of benefit is the same as for a sickness benefit, but in many cases the rate is higher—66 to 100 percent of previous earnings. Sweden has pioneered a parental allowance that can be drawn by the father as well as the mother to encourage fathers to take their turn in staying at home to look after the young child. In some cases a lump sum is also paid on the birth of a child to help pay for nursery goods and clothing.

Parental allowance for fathers

During the 1970s there was a concerted effort in eastern Europe to try to increase the birthrate by increasing the period for which a maternity benefit was paid and by giving credits in the social insurance scheme to mothers who stayed at home to look after a young child. Similar credits are provided in the United Kingdom for persons who stay at home to care for a child or a disabled relative, but the motive in this case is to increase the personal pension rights of those, particularly women, who have accepted family responsibilities.

Benefits for survivors and single parents below pension age. Provision is normally made for a widow below pension age left with a dependent child. Where pensions are earnings-related, the pension for a widow typically amounts to one-half to three-quarters of her husband's pension rights. In some countries the benefit is income-tested or time-limited (*e.g.,* three years in France). Other schemes vary considerably in the extent to which provision is made for widows. Some countries pay benefits providing widows are of a certain age when their husbands die. The age may vary between 40 (The Netherlands) and 55 (France). Some countries only pay the benefit providing the marriage has lasted for a specified period (six months in Greece; two years in France). Other countries pay the benefit to any widow who is disabled or to widows of any age for a short period or indefinitely. Widows' benefits normally cease on remarriage. A widower may be able to claim rights similar to those of a widow if he was dependent on his wife. Some countries extend widows' rights to divorced women. Increasingly, long-term provision for widows without dependent children is being questioned in societies where the trend has been for more and more married women to engage in paid work.

Provision for single parents, other than widows, is normally left to social assistance where such a scheme exists. Some countries have a special income-tested benefit. In Australia this is at the same level as an old-age pension for a person aged at least 65 but less than 70. In New Zealand it is less than half this rate for a single parent with one child. The problem with either of these arrangements is that a less skilled woman is unlikely to be able to improve her position by taking paid work because earnings lead to a reduction of the benefit or assistance. Denmark pays an extra family allowance higher than the normal rate per child for a single parent. Norway pays an extra allowance as if for one more child. The United Kingdom pays an extra allowance at just over half the level of child benefit.

Variations in provision between countries. All of the industrialized countries have social insurance schemes, and nearly all of them cover the main contingencies discussed above. The United States is exceptional in not providing family allowances, in not providing short-term sickness benefits in the vast majority of states, and in having no general scheme of national health insurance other than for the aged and the poor. The extent of provision in developing countries varies between those that still make provision by employers' liability and those that make provision by social insurance.

BENEFITS IN KIND

Systems of organizing health services or health insurance systems and of paying providers are changed occasionally but less frequently than the detailed provisions for cash benefits.

Introduction in Germany

The first national compulsory health insurance scheme, introduced in Germany under Bismarck's law in 1883, built upon precedents going back many years in the separate German states. Health insurance had developed mainly on an occupational basis and was a requirement for that occupation. The feudal obligation of the employer to his workers was given legislative substance in a society developing national markets, in which the employer without an obligation to pay to a sick fund might undercut the employer who had such an obligation. But the main reason for the scheme, as mentioned earlier, was to try to contain socialist tendencies.

The administration of compulsory health insurance was left in the hands of numerous local sick funds operating under legislative regulations. They became jointly controlled by employers and employees and made their own contracts with particular doctors and hospitals for the provision of services. All lower earning workers were eventually required to be members of a fund. Doctors were paid in a variety of different ways, including salary and capitation. In the course of time there were major protests from doctors excluded from contracts with the funds, and the profession demanded the right for any doctor to undertake health insurance work. The substitution of payment per case and later fee-for-service payment, which the German medical profession fought for and eventually won, was a means of establishing open competition between all doctors wishing to take part in the scheme.

Health insurance was enacted in Austria in 1888 and Hungary in 1891 on a similar basis. A bill to introduce such a scheme in Switzerland was, however, decisively rejected by a plebiscite in 1900. The British Radical politician David Lloyd George visited Germany in 1908 to see the scheme firsthand and subsequently introduced compulsory health insurance for persons with earnings below an upper limit in Britain by a law of 1911. However, the scheme provided only for the services of the general practitioner and the drugs he prescribed; hospital benefits were excluded except for some provision for tuberculosis, partly so as not to disturb the charitable hospitals that provided free care to those in need. Moreover, as a result of pressure from the medical profession, the benefit in kind was administered by statutory committees for each area, which enabled every general practitioner to participate who wished to do so, rather than by the large number of friendly societies that had previously provided medical benefits under voluntary insurance and had made their own contracts with particular doctors. Payment was on a capitation basis, as in the previous friendly society schemes.

The introduction of compulsory health insurance was considered in Sweden in 1884 and Denmark in 1885, but both countries decided instead to encourage voluntary insurance by government subsidy. Whereas Norway introduced compulsory health insurance in 1911, Denmark did not follow until 1933, and Sweden not until 1955. In these countries public hospitals were well developed and heavily subsidized. A compulsory health insurance law was passed in France in 1920 but, as mentioned earlier, did not come into effect until 1930 owing to disagreement about the local control of the scheme and a dispute with the doctors about the method of payment. Fee-for-service payment was finally substituted for the capitation system originally proposed. Moreover, as the doctors refused to accept the intrusion of any third party between them and their patients, the scheme operated on a reimbursement basis; the patient paid the fee and claimed a refund for the major part of it from the relevant insurance fund. This reimbursement system was adopted later in Sweden, Finland, and Australia (under subsidized voluntary insurance).

Reimbursement system

When health insurance was established in Russia in 1912, insurance doctors were paid salaries and practiced from government-owned premises. This was the pattern adopted in Chile in 1924. Payment of doctors on a part-time salaried basis for work performed on premises owned by the sick fund became the general pattern in Latin-American countries and in Spain, Portugal, and Greece. In most of Europe and Australasia, however, existing hospitals began accepting insured patients when hospital care became covered by insurance; special hospitals for insured persons were built in Spain, some parts of Italy, and a number of countries in Latin America.

The next major step in the evolution of medical benefits was for countries to make them available to the entire resident population, financed wholly by taxation or financed in part by social insurance contributions. This step was taken first by Hungary in 1920 and then by the Soviet Union in 1937. New Zealand implemented similar coverage in a series of steps—free inpatient treatment for the whole population in 1939 and outpatient treatment, free pharmaceuticals, and part payment of general practitioners' bills in 1941, with further steps later on. The United Kingdom established its National Health Service in 1946. Norway made services available to all residents in 1956, Sweden in 1962, Denmark in 1973, Portugal in 1979, and Italy in 1980. By the 1980s, more than 20 countries had adopted this system. This does not necessarily mean that all services are free at the time of use. Nor does it necessarily follow that all services are government-owned. Of the eastern European countries, some (Bulgaria, Czechoslovakia, Hungary, and Romania, as well as the Soviet Union) have adopted this approach; others (such as East Germany and Poland) have not. About half of all countries retain an element of financing by social security contributions after adopting this approach.

Canada was relatively late in establishing compulsory health insurance. The first province to do so was Saskatchewan in 1962. By 1971 all provinces had done so, spurred on originally by a 50 percent grant from federal funds; the provincial schemes became available to all residents. The not-for-profit general hospitals were given budgets by the provinces to provide this care. Australia was also late in changing from subsidized voluntary insurance to compulsory health insurance. The United States and Switzerland are left as the only highly industrialized countries without general compulsory health insurance or a health service available to all residents. There have been many attempts, against strong opposition from the American Medical Association, to introduce compulsory insurance in the United States. However, a limited scheme of compulsory health insurance for the aged (Medicare) was finally introduced in 1966 along with a system of means-tested medical care operated by each state for the indigent and medically indigent (Medicaid).

Developments in the United States

Some countries in Europe have succeeded in securing high coverage of the population under compulsory health insurance without switching to a service available to all residents. Schemes cover the employed, the self-employed, and all social security beneficiaries and their spouses and dependent children: this can amount to 99 percent of the population. Other European countries (West Germany and The Netherlands), nearly all of which have some system of private insurance, exclude the higher income groups from statutory health insurance. Alternatively, some benefits (*e.g.,* hospital care) are available to the whole population, while higher income groups must make their own arrangements for certain other benefits (Ireland).

Apart from Cuba, which has a national health service, only three countries in Latin America (Argentina, Brazil, and Costa Rica) have managed to cover 80 percent or more of the population by health insurance. Moreover, coverage may not necessarily mean that services are equally available. Coverage extends to about half the population in Mexico, Panama, and Uruguay, and more than a quarter in Bolivia and Venezuela. In the remaining countries coverage is 10 percent or less. By no means do all of these countries extend the same rights to the spouse and children of the insured person. Several provide only maternity care and pediatric care for dependents. Coverage is more easily provided for the employees of larger establishments, which tend to be concentrated in urban areas. Even in urban areas those excluded tend to be the self-employed, domestic servants, and itinerant workers. The obstacles to expanding rural coverage include the much lower levels of earnings, the geographic dispersion, the less formal employment conditions, and more extensive self-employment and seasonal employment. Most important of all, some schemes have become too costly to extend on the same basis with tax subsidy to cover the whole population. Thus the remaining population must depend on poorly financed and staffed services provided by ministries of health. Health insurance is, therefore, increasingly criticized for exacerbating inequality in health care by outbidding government health services for trained manpower and for creating a heavy emphasis on sophisticated and expensive curative services in urban areas while the main health need is for preventive services to cut the incidence of infectious diseases in both urban and rural areas.

Obstacles to rural coverage

Japan has managed to avoid the worst of these effects and to achieve high coverage. India, conscious of the damage that health insurance could do to government services, has developed health insurance slowly as resources have become available for doing so in particular states. South Korea has introduced health insurance for the urban employed population and also has provided rights to those with low incomes in urban areas; the problem of covering the remaining half of the population in rural areas remains to be solved.

Many developing countries, particularly those that were previously British colonies, have made health services available to the whole population, providing free or nearly free services. This is the pattern, for example, in the West Indies, Kenya, Zimbabwe, India, Sri Lanka, Malaysia, and many Arab states in the Middle East. In most cases services were originally developed for the expatriate colonialists and extended in the course of time to local residents. The services tend for this reason to be heavily concentrated in urban areas, with little or no coverage of the rural population. With their limited resources, these countries are striving, as part of the World Health Organization's program Health for All, to extend rural coverage with primary health care to all areas by the year 2000.

Methods of provision

Among the various national health schemes, benefits are provided in three ways. First is the direct service approach in which the government or insurance fund owns the facilities (hospitals and clinics), pays for supplies, and remunerates the staff on a full- or part-time basis. This is the approach used in the United Kingdom for hospitals and community services and in Scandinavia, where local authorities provide hospitals and clinics, though there may also be a parallel system of doctors working from their own offices. It is also generally used in eastern Europe, in Greece, Spain, and Portugal, in most countries in Latin America, and in most other developing countries. The hospital system in Canada is exceptional; the scheme determines budgets for general hospitals that remain in the hands of not-for-profit agencies.

The second method is the indirect contract with providers. The providers may be private entities (hospitals or practitioners) or public hospitals, but the health insurance scheme makes a contract with the provider and pays each provider for services used according to rates established in a negotiated contract. This is the system used for all services in such countries as Belgium, West Germany, Luxembourg, and The Netherlands.

The third method is reimbursement, in which the patient pays the bill and submits the receipted bill for reimbursement. The provider may be public or private. This approach is widely used in France, some northern European countries for the parallel system using practitioners in the private sector, and to some extent in Australia and Sweden. The patient may be left to pay part of the bill, as, for example, in France. A fee schedule may be established for rates of reimbursement, but unless strong measures are taken to prevent it, some practitioners may charge more than the established fee.

In practice many countries use a combination of these systems. Thus, for example, the National Health Service in the United Kingdom, with its direct service provision of hospitals and community services, uses indirect contracts for general practitioners, community pharmacists, opticians, and most dentists. Moreover, where private hospitals are used they are paid under contract, as is also the case in Greece, Italy, and Portugal. In a number of countries in Latin America health insurers use the direct service approach in urban areas but service dispersed populations in rural areas by using indirect contracts.

Health insurance schemes vary in the method by which providers are paid, and this can have a substantial impact on costs. Where doctors and dentists are paid on a fee-for-service basis this provides incentives for the provision of further services—even in France where the patient has to pay a proportion of the cost. In the Common Market countries about twice as many prescriptions are issued to patients when the doctor is paid on a fee-for-service basis as when he is paid on a capitation basis. More surgery is performed where doctors receive fees rather than salaries. Moreover, the patient normally has direct access to specialists and can visit several different doctors in the course of one illness; this also adds to costs. When hospitals are paid on the basis of an itemized bill, more items are often provided. Where hospitals are paid per day of care, there are incentives for the hospital to keep patients for longer than necessary. For this reason, some countries in Europe (Belgium, France, and The Netherlands) have required hospitals paid on this basis to adhere to a predetermined budget. Where hospitals are given a budget from the local or central government, costs are kept under control. Financial incentives for the provision of further services are avoided where doctors are paid on a salary or capitation basis (The Netherlands and the United Kingdom). But this can lead to delays in receiving treatment either as an inpatient or as an outpatient. A provision permitting access to specialists, normally only on the basis of referral by a general practitioner, can be enforced where the patient normally has access to only one practitioner; this helps to limit costs. The system of paying doctors part-time salaries, leaving the doctor free to undertake practice, as in Greece, Portugal, Spain, and most countries in Latin America, can lead to what patients see as poor quality in services—a lack of courtesy and limitation of time devoted to the consultation. For this reason many countries are beginning to offer full-time salaries without rights for the doctor to undertake private practice.

The right to free medical treatment was included in the original German scheme for industrial injury, and provision for rehabilitation was added in 1925. In the course of time more and more emphasis came to be placed on efforts to restore working capacity, and specialized institutions were created for this purpose. Many countries have copied the German example and developed highly specialized institutions owned by sick funds or under the control of the agency responsible for national health insurance for both physical and vocational rehabilitation.

ADMINISTRATION AND FINANCE

Administration of social security. Countries vary considerably in the extent to which social security is centralized and unified. A high degree of centralization obtains in the Commonwealth countries and Scandinavia (except for health care and social assistance, which are decentralized to lower levels of government). A centralized scheme may be run by a ministry or by a semiautonomous agency. In other countries schemes are more often run by separate occupational funds or by funds providing for different risks, as tends to be the pattern in continental Europe and Latin America. The control may rest with boards composed equally of employers and employees. Or it may be tripartite, with the government participating as the third party. In the United States social security as defined here is divided between federal and state responsibility. There have been attempts in some countries to secure greater unification, but such efforts have often run into strong resistance from particular occupational groups with better benefits or lower contributions attributable to lower risks.

Complexity of regulations

Social security regulations have become extremely complex and difficult to understand. Where there are separate funds, each may have a national office, with no branch offices to which the public has access. Disputes often arise over which fund is responsible for paying benefits to particular claimants. It is, therefore, not necessarily the case that all claimants obtain what they are entitled to receive, and substantial delays can occur while entitlements are sorted out. Problems of this kind are not, however, unique to the public sector. Some private insurance companies are resistant to paying out claims. Unified social security systems with local offices are more accessible to the public, but the offices are not always adequately staffed to give the public prompt and efficient service.

Social assistance regulations are inevitably even more complex to operate than other parts of the social security system. Moreover, they frequently contain a considerable element of discretion. Where schemes are administered by social workers there can be what beneficiaries see as potential coercion; failure to follow the social worker's advice may be thought to lead to the reduction or removal of benefits. Some have argued that all social assistance regulations should be published so that claimants can know their rights and thus be in a position to appeal against decisions to refuse benefits or extra allowances. Adoption of this approach has led in some cases to regulations that are too complex for the staff to operate efficiently, or in others to regulations that have been streamlined at the expense of former provisions for discretion. Particularly contentious is the question of cohabitation. If an unemployed married woman living with her wage-earning husband is not entitled to social assistance, it would seem at first sight only fair that an unemployed woman cohabiting with an employed man should be treated in the same way. But cohabitation may not be accompanied by maintenance and is anyway extremely hard to define. The borderline between a lodger and a cohabitant is by no means clear cut in all cases nor readily established by any outside agency. Attempts to do so can involve considerable invasion of personal privacy.

The issue of cohabitation

Financing of social security. In most countries the major part of the cost of social security is paid for by proportional contributions of earnings from employers and employees. The contributions may be divided equally between employers and employees, except for the whole cost of the occupational injuries scheme, which falls to the employer. Alternatively the employer may pay about twice the amount falling to the employee. There is usually a "ceiling," or level of earnings, beyond which the contribution becomes flat-rate at the level of contribution due on this maximum of earnings, though this is not the case in either Sweden or Switzerland. The maximum varies from around 50 percent above average earnings (*e.g.,* France, Ireland, and Italy) to twice average earnings (*e.g.,* West Germany, the United Kingdom, and the United States) or higher (Norway). The reason for this may be to prevent insurance contributions from overlapping with high marginal rates of income tax or to leave the replacement of high earnings to the private sector. Some countries also exempt very low earners from contributions or make the employer pay them instead of the employee.

Usually some portion of costs is left to be met from taxation. At the very least the government will stand by to meet any deficit between benefits and contribution income. During the 1970s there was a trend in most countries in western Europe for costs to be shifted away from employers and onto taxes (*e.g.,* Denmark, Ireland, Italy, The Netherlands, Portugal, and the United Kingdom) or to employees (Austria, France, and West Germany). One reason for the trend toward tax financing was the growth of unemployment financed by social assistance payments.

The role of taxes

Countries where no costs at all fall on taxes include the small schemes in Burundi and Ethiopia and the wider schemes in Malaysia, the Philippines, and Singapore. At the other extreme, countries where contributions play a very small role and by far the bulk of costs is covered by taxation are Australia, Czechoslovakia, Denmark, New Zealand, and the Soviet Union. In the United Kingdom, where the national health service is primarily financed from taxes and social assistance plays a major role, roughly half of the costs are borne by taxes and half by contributions. Several eastern European countries have no employee contributions; their schemes are mainly financed by employers.

Contributory versus tax-financed schemes

The relative merits of financing by contributions or taxes have long been debated. In favour of contributions it is argued that making beneficiaries pay prevents irresponsible increases in benefits and, where there are separate funds, encourages participation by both employees and employers. The payment of contributions also helps to ensure that commitments are honoured. Contributions are administratively easy to collect since the employee has an interest in securing compliance by the employer. The benefits to the employee of paying are clearly identified, while the cost falling on employers may create some incentive to prevent certain occupational risks from arising. Finally, only by earmarking contributions can earnings-related benefits be justified.

The critics of contributions argue that where they are flat-rate or where earnings-related contributions are only payable up to a low ceiling of income they are regressive and constitute a heavy burden on the poor; progressive taxes on income would be preferable, as they vary according to ability to pay and are also levied on investment income. It is also argued that tax-financing enables governments to judge priorities among all fields of public expenditure, and, where it leads to administration by government, this secures closer coordination between social security and other services. In addition, high contributions lead to the growth of the black, or underground, economy. This is a major problem in France and Italy with their high employers' contributions and leads to a widespread lack of social insurance coverage.

An argument that became more strongly pressed when levels of unemployment rose in the 1970s was that high employers' contributions made products uncompetitive in world markets, particularly in the case of labour-intensive industries, compared with products from Third World countries where social security is less developed. This was said to sharpen the recession and aggravate unemployment in highly industrialized countries. While it is true that employers might gain a short-term advantage if contributions were lowered, it is much less certain that this gain would be sustained in the long run. What was gained in lower contributions might sooner or later have to be conceded in higher wages and salaries or in other wage costs. If the argument were valid, such countries as Australia, Denmark, or New Zealand, which make little use of employers' contributions, would be seen to be cornering a heavy share of world trade. The fact that this has not happened reinforces the argument that it is total labour costs, of which social security contributions are only a part, that affect competitiveness.

It has been claimed that high employers' contributions particularly damage labour-intensive firms and encourage the replacement of labour with capital. In examining this assertion it is relevant first to remember that firms making capital goods also have to pay the same high employers' contributions and that capital-intensive firms pay them indirectly on raw materials, facilities and equipment, and energy. Second, high employers' contributions may well cause cash wages to be lower than would otherwise be the case so that total labour costs are not, in fact, increased by employers' contributions. Third, insofar as high employers' contributions encourage all firms to use more capital-intensive methods of production, this applies to labour-intensive firms as well. This encouragement of investment may lead to production at lower cost and thus a more competitive position in world markets in the longer run.

While there is a lack of convincing evidence that employers' contributions are bad for employment, a low ceiling on contributions may itself damage employment. It may discourage offers of part-time work and lead employers to prefer offering overtime to taking on additional workers. This was the view of international experts appointed by the International Labour Office, who recommended in their report of 1984 that contribution ceilings be abolished.

The substitution of taxes for contributions may not relieve poorer workers if the extra taxes come from goods such as tobacco that are consumed more heavily by those with low incomes than those with high incomes in industrialized countries. There is no guarantee that governments would raise the extra revenue from progressive taxes; they may, for example, lower the threshold at which income tax is paid.

The argument in favour of contributions

The strongest case for contributions is that they justify earnings-related benefits. The strongest case for taxes is that they are used in many countries to make benefits available to all residents—whether the benefits be health care, family allowances, or minimum flat-rate pensions. Solutions to the problem of persons not currently covered or inadequately covered by social insurance programs normally require a greater element of tax financing. This has been the trend in many countries.

The rising cost of social security. The cost of social security rose substantially in the period after World War II both in real terms and as a proportion of rising gross domestic product. While social security spending amounted to less than 10 percent of the gross national product in nearly all countries in 1950, it had risen to 20 to 30 percent or more in many European countries by 1980. Among the reasons were the extension of the coverage of social security, the widening of the risks covered, the indexing of benefits, and the greater generosity of benefits, which moved up to or near 100 percent replacement of earnings for certain contingencies in some countries. But also of major importance was the maturing of pension schemes. Many of them were recast in the 1940s and 1950s; it was not until the 1980s that people had had the opportunity to contribute on the new basis for all or most of their working lives and thus draw pensions approaching or reaching the maximum for which these schemes provided. Three further factors were the increasing proportion of aged persons in the population, the decline in pension ages, and the lower proportion of working population.

The costs of health care also rose sharply after World War II. Several reasons contributed to this trend. First, the higher proportion of elderly in the population influenced health care costs as well as the costs of cash benefits. Persons over pension age require two to three times more health care than persons of working age, and the difference is still greater for those over 75, the fastest growing age group. A second factor was the decline in working hours, which meant that more persons (*e.g.*, nurses) were needed in order to staff 24-hour services. A third factor was the continuous development of medical technology, such as new equipment and labour-intensive procedures. Instead of replacing labour, as in industry, innovations in health care normally required more labour for their operation. A further reason was the removal of supply restraints with the provision of more doctors and dentists, a major growth of medical auxiliaries, and the construction of new hospitals, which were more expensive to run. A fifth reason was the financial incentives to supply more services, which underlay many of the systems of paying providers under health insurance.

Consequences of new technology

The final and critical factor that destabilized the finances of social security schemes was the rapid growth of unemployment beginning in the 1970s. In those countries that included unemployment benefits in their social insurance schemes, this phenomenon created both unpredicted higher costs for benefit payments and a loss of revenue from those who were unemployed. The burdens on social assistance programs were also substantial in some countries, coming at a time when unemployed persons were no longer in a position to contribute to tax revenue.

The rapid growth of social security expenditure attracted little attention during the period of rapid economic growth up to 1973. It began to cause concern after the steep rise in oil prices checked economic growth in oil-importing countries. The revenue that financed social security ceased to be buoyant at the same time as new major demands were made on the system. From the late 1970s there was talk of a crisis in social security financing.

By 1980 social security expenditure amounted to 32 percent of the gross national product in Sweden, between 25 and 30 percent in Belgium, Denmark, France, and The Netherlands, and between 20 and 25 percent in Austria, West Germany, Ireland, Luxembourg, and Norway. These figures were much higher than for Australia (12 percent), Canada (15 percent), Japan (11 percent), New Zealand (14 percent), the United States (13 percent), or the United Kingdom (18 percent). The cost was much lower in developing countries. High costs are associated with high levels of social security benefits and also with costly systems of providing health care. Some countries, such as Sweden, have allowed health care costs to continue to rise because of the capacity of this service sector of the economy to provide further jobs and thus avoid high rates of unemployment.

Attempts to contain costs

The aim in many industrialized market countries came to be the containment of the costs of social security. This requires that program costs not grow faster than the yield of contributions. Various devices were introduced to help secure this result. Systems of indexing benefits and pensions to prices or earnings were revised downward, or adjustments were made less frequently. Pensioners were made to pay contributions toward health-care benefits. In France tax income was brought in to supplement the yield of contributions. In the United Kingdom the earnings-related additions to short-term benefits were abolished.

A series of measures was introduced to limit the cost of health care. Charges and copayments were increased or new charges were introduced. Payment for drugs was introduced in West Germany (1977), Italy (1975), and Portugal (1982). Portugal and Luxembourg joined France and Belgium in charging for consultations with doctors. Charges for hospital care were introduced or extended in Belgium, West Germany, Portugal, and France. By 1984 there was no country in western Europe that provided free care to all its insured population.

Payment systems under health insurance were revised to reduce incentives for overservicing. The aim in West Germany was to pay the doctor more for the consultation and less for medical procedures. Payments for diagnostic tests were sharply reduced in Belgium. As part of the introduction of a national health service in Italy, payment to all general practitioners was changed from fee-for-service to capitation, and the bulk of specialists began to receive full-time or part-time salaries. Budgets for each hospital were introduced in Belgium, France, and The Netherlands, in part to discourage unnecessary retention of patients paying per day of care. Countries in which hospitals were already paid on a budget basis reduced the budgets. In the United States hospitals began to be paid under Medicare and Medicaid according to a schedule of costs for various groups of diagnoses.

Countries maintained strong controls over new hospital construction or expansions, and incentives were created in a number of countries to transfer beds from general use to the care of the long-term sick. Several countries took measures to develop alternatives to hospital care, such as outpatient surgery, outpatient hospitals, nursing homes, residential homes, and home care by domiciliary teams. The United Kingdom closed some 400 hospitals over a period of 10 years. Restrictions on the installation of major new medical equipment went into effect in Belgium and France. By 1955, 10 of the 12 countries of the European Economic Community had instituted quotas for medical schools. In Denmark, France, Ireland, Portugal, and Spain the number of medical students was cut substantially.

Most countries in western Europe introduced restrictions as to what medications a doctor could prescribe under the health service or health insurance system. Most of these countries exercised tight control over pharmaceutical prices and pharmacists' margins. New measures were introduced in the effort to control overprescribing.

Variations in social security spending

Social security spending tends to vary between countries in direct proportion to their respective standards of living; in other words, the more affluent a country is, the more it is likely to spend on social security. Spending also tends to vary according to the proportion of elderly people in the population. Third, it varies according to the year in which the first legislation was adopted: countries with older social security programs tend to spend more. There are, of course, exceptions to this pattern. For example, the United States and Japan are low spenders both for their standard of living and for their proportion of elderly, and New Zealand is a low spender for a country that introduced pensions as early as the end of the 19th century.

This type of analysis has been criticized, however, for ignoring private arrangements, particularly employers' provisions established as part of collective bargaining. Thus, for example, the large role of fringe benefits in Japan helps to explain the relative lack of development of statutory social security. Similarly, the large role of occupational pensions and health insurance negotiated between employers and employees helps to explain the underdevelopment of statutory social security in the United States. Hence it is argued that private and public social security must both be taken into account in any comparison of national programs. In federal countries such as Australia, Canada, Switzerland, and the United States there were constitutional obstacles to adopting social security that led to the private sector's playing a larger role.

Political orientation also plays a role in explaining the extent to which social security has been developed in the public sector. After some initial opposition, political parties drawing substantial support from the working classes and the trade unions have promoted the expansion of social security. This includes European Catholic Workers' movements. Extensions of social security may be introduced by coalition governments with a conservative majority as the price needed to keep the coalition together. The high spending in Scandinavia can be explained by the strong influence of social democratic parties in the period following World War II. Trade unions have had less influence in this direction in Australia and New Zealand. The absence of a working-class party in the United States is part of the explanation of the relative underdevelopment of its social security program.

Implications

Some of the trends leading to increased costs are bound to continue. While the number of aged persons in most highly industrialized societies is likely to stabilize during the later years of the 20th century and the early years of the 21st century, the proportion within it of those over 75 will continue to increase substantially. This has major implications for further increases in the cost of health care. Moreover, pension schemes are still maturing, and there are pressures for further improvements of benefits, particularly to provide sex equality, lower pension ages, and better assistance for persons, particularly women, inadequately provided for previously. On top of all this, costly developments in medical technology continue. If the trend to shorter working hours continues this will also have a further major impact on the cost of health services.

Looking further ahead, the proportion of aged in the population is expected to start to increase substantially in the second and third decades of the 21st century as the increase in births after World War II becomes reflected in an increase in pensioners. It is this prospect that has led the United States to plan for increases in pension ages and the United Kingdom to decide to scale down its second tier earnings-related pension scheme.

The level of contributions and taxes needed to sustain present plans for social security cannot be predicted. While the continuing trend toward a higher number of aged in the population can be safely predicted, the birthrate is much harder to forecast. Of vital importance is the level of unemployment because of its impact on both sides of the balance sheet; reduced unemployment would add to contributions and tax income as well as lower the cost of benefits. Nevertheless, the prospect of a substantial increase in pensioners in the 21st century has led to fears in some quarters that the "compact between generations" may not perpetually be honoured. Hence it is argued that the pay-as-you-go method of pension contribution should be replaced by the capitalization method used in early pension schemes and in the private sector. Alternatively it is argued that the privatization of social security pensions would lead to higher savings and investment out of which future pensions could be paid. The disadvantages of either of these approaches are that there would need to be an immediate increase in contributions to provide the planned level of pensions. This could lead to pressure for higher cash earnings. Moreover, the level of pensions would no longer be indexed but would depend on the yield of investments.

CRITICISMS

It has been argued that the high cost of social security is in part responsible for the low levels of economic growth in industrialized societies since 1973. The argument takes three forms. First, it is said that high levels of unemployment benefits reduce the incentives to take paid work. Second, resistance to the payment of taxes and contributions leads to wage demands, inflation, and government deficits. Third, it is argued that because people have rights to social security benefits they are less likely to save; this lowers investment and thus economic growth. For all these reasons social security is said to have contributed to or even to have been responsible for not only low growth but also for high levels of unemployment.

In response to these criticisms it has been pointed out that empirical investigations lend little support to the contention that people prefer benefits to work, though the availability of benefits may make them less willing to take low-paying jobs. Second, it is argued that tax resistance would apply whether pensions were provided in the private or in the public sector. Indeed, if pensions were provided in the private sector they would have to be capitalized, which would require higher contributions and therefore lower cash earnings, leading to still greater pressures for higher pay. Third, the evidence that social security reduces savings is by no means conclusive; indeed, in many countries there has been a boom in the variety of different forms of saving following the establishment of pay-as-you-go systems of financing social security. Moreover, investment is limited by the availability of profitable investment opportunities rather than by any shortage of savings. And if low savings does limit investment, governments can generate a budget surplus out of which investment can be financed.

Effects on savings

Some critics argue that social insurance benefits should be replaced by a negative income tax. As countries get richer, it is argued, an increasing proportion of the population is in a position to take out private insurance against the risks for which social security provides. If social security were concentrated exclusively on the lower income groups, provision could be more generous and the burden of public provision could be reduced. The administrative and other problems of using annual tax returns as the basis of making cash payments to individuals whose circumstances are constantly changing as they go in and out of employment, marriage, and cohabitation are considerable. But in the context of saving, it was because income-tested pensions were thought to be damaging to thrift that many social insurance programs were established in the first place. Low earners are unlikely to save if the yield of their savings leads to a dollar-for-dollar reduction in pension. Moreover, many countries in Europe already have income-related housing allowance schemes that serve much the same function even though they are separate from income taxes. Where this is the case, there is no room for a further negative income tax or other income-tested scheme without imposing extremely high tax rates on increased earnings. Most important of all, it is by no means clear that the economically securer members of the population would be willing to accept anything like the existing level of contributions and taxes if they stood to gain nothing from social security. As a result, provision for the poor might be no better or, more probably, it might even be worse than it is as part of a scheme to which all contribute and on which all are in a position to make claims. Historically, services for the poor have always tended to be poor services.

Empirical studies have shown some small association between higher levels of social security spending and lower rates of economic growth. But it is not clear that one necessarily causes the other. Many other factors are at work. Countries that had a high proportion of the population in agriculture were in a favourable position to achieve high growth in the postwar period as their agricultural populations declined. Moreover, countries that have had relatively low rates of economic growth, such as the United Kingdom and the United States, are relatively low spenders on social security, while countries that have had high rates of economic growth, such as Belgium, Denmark, and The Netherlands, are high social security spenders.

Low target efficiency

Critics of social security are not confined to those concerned about its effects on the economy or about personal freedom regarding the extent to which and methods by which individuals provide for their security. There are also those concerned about the "target inefficiency" of social security, or its limited redistribution to the poor. This attack is generally directed at earnings-related benefits. Proposals have been made to use the yield of social security contributions, supplemented by taxes, to provide everyone with a minimum income on which they could live at a modest level supplemented by earnings if they wished to take paid work. Social dividend schemes of this kind are seen not only as a way of redistributing income but also of reducing unemployment. A major problem with such schemes is the high level of contributions and taxes needed to finance the minimum income if it is to go to those with jobs as well as to those without them and be sufficient to live on, if only at a minimum level.

It is true, however, that high spending on social security has failed to solve the problem of relative poverty in industrialized societies. Yet abolishing poverty was never the original intention, or at least it was not in many countries.

Social security was seen as a system of maintaining income by redistribution from the well to the sick, from the young to the old, and from those with jobs to those without them. This involves substantial redistribution but not necessarily redistribution from rich to poor. For instance, while there is more illness and unemployment among low earners, higher earners tend to live longer and thus draw pensions for a longer period.

A study financed by the European Economic Community showed the extent to which poverty remained in the Common Market countries around the year 1975. Poverty was defined as half the average level of living for each country. The study showed that the greatest success in combating poverty was achieved in The Netherlands and, second, in the United Kingdom, though Belgium and West Germany came close to the United Kingdom. Both of the first two countries have primarily flat-rate benefits. Poverty, however, was at its greatest in Ireland and Italy—both countries with substantial agricultural populations—though Ireland also relies on flat-rate benefits.

A variety of reasons explain why poverty persists in industrialized countries despite their elaborate provisions for social security; the precise reasons and their relative importance differ from one country to another. One reason may be that the arbitrarily selected poverty line is just above the level of living provided by social assistance. A second may be the failure of all those entitled to benefits to claim them. A third may be that certain categories of people in some countries are not entitled to claim social assistance (*e.g.*, the long-term unemployed). A fourth reason may be that earnings-related benefits do not secure a sufficient income for low earners to rise above the poverty line or that their record of contributions is insufficient to achieve this result. But considerable poverty may also persist among families headed by a full-time worker. This is more likely to occur in one-parent families when the earner is a female with limited skills and low earnings. But it may also occur in two-parent families with one earner and several children, where family allowances fall below the cost of maintaining a child at the minimum level or the cost of rent is considerable.

In the case of developing countries social security is criticized for reinforcing the dichotomies between urban and rural populations in general and between employed and unemployed persons in the urban sector. Social insurance contributions, which are in effect taxes specifically tied to providing benefits to the members of the schemes, cannot be used by governments for the benefit of the community as a whole. This limits the capacity of governments to raise tax revenues for broader purposes. Moreover, different health benefits as well as cash benefits may be provided for different occupational groups, thus perpetuating and accentuating inequalities. Those who defend social security argue in reply that requiring part of earnings to be put into an insurance fund is robbing no one outside the scheme, since only by providing the benefits could the particular taxes be justified and compliance with paying them be secured. Criticisms regarding inequality should be directed at the pattern of original earnings, not at social security, which mobilizes part of them for good purposes. (B.A.-S.)

BIBLIOGRAPHY

Social welfare: Key texts from the extensive British literature include the *Report of the Committee on Local Authority and Allied Personal Social Services* (1968), known as the Seebohm Report; ERIC SAINSBURY, *The Personal Social Services* (1977); *Social Service Teams: The Practitioner's View* (1978); and EILEEN YOUNGHUSBAND, *Social Work in Britain, 1950–1975: A Follow-Up Study*, 2 vol. (1978). The recent historical development of these services is analyzed in JOAN COOPER, *The Creation of the British Personal Social Services, 1962–1974* (1983); and *Social Workers: Their Role & Tasks* (1982), known as the Barclay Report, which brings together different views of the role of the personal social services. *The Future of Voluntary Organisations* (1978), known as the Wolfenden Report, gives a clear account of voluntarism in Britain; and HUGH W. MELLOR, *The Role of Voluntary Organisations* (1985), provides more up-to-date analysis. MARTIN BULMER (ed.), *Neighbours: The Work of Philip Abrams* (1986), studies the role of informal care and reviews the debate on the relationship between the formal and the informal sectors. See also RUDOLF KLEIN and MICHAEL O'HIGGINS (eds.), *The Future of Welfare* (1985).

There are a number of useful comparative studies, including BARBARA N. RODGERS, ABRAHAM DORON, and MICHAEL JONES, *The Study of Social Policy: A Comparative Approach* (1979), on the United Kingdom, France, Israel, and Australia; ALFRED J. KAHN and SHEILA B. KAMERMAN, *Social Services in International Perspective: The Emergence of the Sixth System* (1976, reissued 1980), which covers Canada, the United Kingdom, France, West Germany, Poland, Yugoslavia, Israel, and the United States; SHEILA B. KAMERMAN and ALFRED J. KAHN (eds.), *Family Policy: Government and Families in Fourteen Countries* (1978); JOAN HIGGINS, *States of Welfare: A Comparative Analysis of Social Policy* (1981); NEIL GILBERT, *Capitalism and the Welfare State* (1983, reprinted 1985); J.A. YODER (ed.), *Support Networks in a Caring Community: Research and Policy, Fact and Fiction* (1985); and ELSE ØYEN (ed.), *Comparing Welfare States and Their Futures* (1986). See also CATHERINE JONES, *Patterns of Social Policy: An Introduction to Comparative Analysis* (1985).

Comparative studies on socialist policies include VIC GEORGE and NICK MANNING, *Socialism, Social Welfare, and the Soviet Union* (1980); JOHN DIXON, *The Chinese Welfare System, 1949–1979* (1981); and BOB DEACON, *Social Policy and Socialism: The Struggle for Socialist Relations of Welfare* (1983).

Key issues on personal social services in developing countries are discussed in JAMES MIDGLEY, *Professional Imperialism: Social Work in the Third World* (1981); and MARGARET HARDIMAN and JAMES MIDGLEY, *The Social Dimensions of Development: Social Policy and Planning in the Third World* (1982).

Several of the following studies of social security, notably those of Wilensky *et al.*, Köhler and Zacher, Jones, Easton, and Midgley, include material on the personal social services.

Social security: Nearly all countries make periodic reports summarizing their social security provisions; these are published every few years by the UNITED STATES. SOCIAL SECURITY ADMINISTRATION. OFFICE OF RESEARCH, STATISTICS, AND INTERNATIONAL POLICY, with the title *Social Security Programs Throughout the World.* A second basic international source is *The Cost of Social Security,* published irregularly by the INTERNATIONAL LABOUR OFFICE, which contains comparative tables of the costs, benefits, and financing of social security schemes. For the Common Market countries provisions are periodically summarized in *Comparative Tables of the Social Security Systems in the Member States of the European Communities: General Systems,* published by the COMMISSION OF THE EUROPEAN COMMUNITIES.

A summary of the findings of comparative research is found in HAROLD L. WILENSKY *et al., Comparative Social Policy: Theories, Methods, Findings* (1985). For economic aspects see L.D. MCCLEMENTS, *The Economics of Social Security* (1978). The International Labour Office report by 10 experts referred to in the text is *Into the Twenty-First Century: The Development of Social Security* (1984).

The historical evolution of the schemes in Austria, France, Germany, Great Britain, and Switzerland is described against a wide economic, social, and political background in PETER A. KÖHLER and HANS F. ZACHER (eds.), *The Evolution of Social Insurance 1881–1981* (1982). For a penetrating comparison between Britain and Sweden see HUGH HECLO, *Modern Social Politics in Britain and Sweden: From Relief to Income Maintenance* (1974). For the United States see BRUNO STEIN, *Social Security and Pensions in Transition: Understanding the American Retirement System* (1980, reprinted 1983). Other historical studies of advanced societies include M.A. JONES, *The Australian Welfare State: Growth, Crisis and Change,* new ed. (1983); DENNIS GUEST, *The Emergence of Social Security in Canada,* 2nd ed. rev. (1985); and BRIAN EASTON, *Social Policy and the Welfare State in New Zealand* (1980). For the evolution and current role of social security in developing countries, see JAMES MIDGLEY, *Social Security, Inequality, and the Third World* (1984).

Descriptions of health insurance and health services in various western European countries are given in BRIAN ABEL-SMITH and ALAN MAYNARD, *The Organization, Financing, and Cost of Health Care in The European Community* (1978); and BRIAN ABEL-SMITH, *Cost Containment in Health Care: The Experiences of 12 European Countries, 1977–83* (1984). For other countries, see MICHAEL KASER, *Health Care in the Soviet Union and Eastern Europe* (1976); LEE SODERSTROM, *The Canadian Health System* (1978); SIDNEY SAX, *A Strife of Interests: Politics and Policies in Australian Health Services* (1984); and *Medical Care Under Social Security in Developing Countries* (1982), papers from a meeting of the International Social Security Association.

Modern Socio-Economic Doctrines and Reform Movements

Since the 17th century, and more markedly since the 19th, political life and thought have been affected by systems of belief often characterized as ideological, by which is meant that they derive programs of practical action in the political sphere (understood to include broadly socio-economic concerns) from more or less systematically argued views of the proper structure and ends of human society. The history and general nature of ideological thought is considered in some detail in the *Macropædia* article IDEOLOGY. This article describes the major categories of modern ideology. Individual ideologies associated with particular theorists or historical settings are discussed separately elsewhere in the encyclopaedia; *e.g.,* for a full treatment of Marxism, see the *Macropædia* article MARXISM; for information on Nazism, see in the *Micropædia* under NATIONAL SOCIALISM and NAZI PARTY.

This article is divided into the following sections:

Socialism

Socialism refers to both a set of doctrines and the political movements that aspire to put these doctrines into practice. Although doctrinal aspects loomed largest in the early history of socialism, in its later history the movements have predominated over doctrine, so much so that there is no precise canon on which the various adherents of contemporary socialist movements agree. The most that can be said is that socialism is, in the words of Anthony Crosland, a British socialist, "a set of values, or aspirations, which socialists wish to see embodied in the organization of society."

Problems of definition

Although it is possible to trace adumbrations of modern socialist ideas as far back as Plato's *Republic,* Thomas More's *Utopia,* and the profuse Utopian literature of the 18th-century Enlightenment, realistically, modern socialism had its roots in the reflections of various writers who opposed the social and economic relations and dislocations that the Industrial Revolution brought in its wake. They directed their critical shafts against what they conceived to be the injustice, the inequalities, the suffering brought about by the capitalist mode of production and the free and uncontrolled market on which it rested. To the acquisitive individualism of their age they opposed a vision of a new community of producers bound to each other through fraternal solidarity. They conceived of a future in which the masses would wrest control of the means of production and the levers of government from the capitalists.

Although the great majority of men calling themselves socialists in the 19th and 20th centuries have shared this vision, they have disagreed about its more specific ideas. Some of them have argued that only the complete nationalization of the means of production would suffice to implement their aims. Others have proposed selective nationalization of key industries, with controlled private ownership of the remainder. Some socialists insist that only strong centralized state direction and a command economy will suffice. Others advocate a "market socialism" in which the market economy would be directed and guided by socialist planners.

Socialists have also disagreed as to the best way of running the good society. Some envisage direction by the government. Others advocate as much dispersion and decentralization as possible through the delegation of decision-making authority to public boards, quasi-public trusts, municipalities, or self-governing communities of producers. Some advocate workers' control; others would rely on governmental planning boards. Although all socialists want to bring about a more equal distribution of national income, some hope for an absolute equality of income, whereas others aim only at ensuring an adequate income for all, while allowing different occupations to be paid at different rates.

"To each according to his need" has been a frequent battle cry of socialists, but many of them would in fact settle for a society in which each would be paid in accordance with his contribution to the commonwealth, provided that society would first assure all citizens minimum levels of housing, clothing, and nourishment as well as free access to essential services such as education, health, transportation, and recreation.

Socialists also proclaim the need for more equal political rights for all citizens, and for a levelling of status differences. They disagree, however, on whether difference of status ought to be eradicated entirely, or whether, in practice, some inequality in decision-making powers might not be permitted to persist in a socialist commonwealth.

The uses and abuses of the word socialism are legion. As early as 1845, Friedrich Engels complained that the socialism of many Germans was "vague, undefined, and undefinable." Since Engels' day the term socialism has been the property of anyone who wished to use it. The same Bismarck who as German chancellor in the late

1870s outlawed any organization that advocated socialism in Germany declared a few years later that "the state must introduce even more socialism in our Reich." Modern sophisticated conservatives, as well as Fascists and various totalitarian dictators, have often claimed that they were engaged in building socialism.

ORIGINS OF THE SOCIALIST IDEA

The utopians of the early 19th century

The term socialism, in its modern sense, made its first appearance around 1830. In France it was applied to the writings of Fourier and the Saint-Simonians and in Britain to those of Robert Owen.

Saint-Simon and Fourier. Comte Henri de Saint-Simon (1760–1825) was an erratic genius with a fertile and yet disorganized mind. His socialist writings revolved around the idea that his age suffered from an unhealthy and unbridled individualism resulting from a breakdown of order and hierarchy. But he held that the age also contained the seeds of its own salvation, which were to be found in the rising level of science and technology and in the industrialists and technicians who had already begun to build a new industrial order. The joining of scientific and technological knowledge to industrialism would inaugurate the rule of experts. The new society could not be equalitarian, Saint-Simon argued, because men were not equally endowed by nature. Yet it would make the maximum use of potential abilities by assuring that everyone would have equal opportunity to rise to a social position commensurate with his talents. By eradicating the sources of public disorder, it would make possible the virtual elimination of the state as a coercive institution. The future society would be run like a gigantic workshop, in which rule over men would be replaced by the administration of things.

Saint-Simon's followers bent the founder's doctrine in a more definitely socialist direction. They came to see private property as incompatible with the new industrial system. The hereditary transmission of power and property, they argued, was inimical to the rational ordering of society. The rather bizarre attempt of Saint-Simon's followers to create a Saint-Simonian church should not obscure the fact that they were among the first to proclaim that bourgeois-capitalist property was no longer sacrosanct.

François-Marie-Charles Fourier (1772–1837), a lonely and neglected thinker who was more than a little mad, was led to his anticapitalist vision by a loathing for a world of competition and wasteful commerce in which he spent most of his life as a salesman. Possessed by an inordinately wide-ranging imagination, he argued that the regenerated world to come would be characterized not only by social but also by natural and even cosmological transformations. The ocean would be changed into lemonade, and wild animals would turn into anti-lions and anti-tigers serving mankind.

Fourierist communities

With meticulous and obsessive care, Fourier set forth plans for his model communities, the *phalanstères,* the germ cells of the good society of the future. In these communities men would no longer be forced to perform uncongenial tasks but would work in tune with their temperaments and inclinations. They would cultivate cabbages in the morning and sing in the opera in the evening. Fourier's was an antinomian vision in which human spontaneity made outside regulation unnecessary. Whereas Saint-Simon called for the rule of experts, Fourier was convinced that love and passion would bind men together in a harmonious and noncoercive order.

Owenism. The Welshman Robert Owen (1771–1858) held more sober views. Early in his career he became known as a model employer in his textile works in Scotland, and as an educational and factory reformer. Despairing of his fellow capitalists he later turned to the emergent trade union movement. Acutely conscious of the evils of industrialism by which he had acquired his wealth, he thought that the new productive forces could be turned to the benefit of mankind if competition were eliminated and the effects of bad education were counteracted by rational enlightenment. He advocated cooperative control of industry and the creation of Villages of Unity and Cooperation in which the settlers, in addition to raising crops, would improve their physiques as well as their minds. Owenite communities established in New Harmony, Indiana, and elsewhere in America all failed. His attempts to join the cooperative and the trade union movements in a "great trades union" also proved a failure. Yet he left a lasting imprint on the British socialist tradition; his indictment of the competitive order, his stress on cooperation and education, his optimistic message that men could increase their stature if only the stultifying effects of an unhealthy environment were removed have continued to inform the socialist movement.

Other early socialists. The 1840s saw the rise of a number of other socialist doctrines, particularly in France. Louis-Auguste Blanqui evolved a radical socialist—or, as he called it, communist—doctrine based on a democratic populism and on the belief that capitalism as an inherently unstable order would soon be replaced by cooperative associations. Impatient with theorizing, given to a strong belief in voluntarism and the virtues of revolutionary action, he is remembered for his many attempts at organizing insurrections rather than for his theoretical contributions.

Étienne Cabet, in his influential utopian work *Voyage en Icarie* (1840), carried on the tradition of Thomas More as well as of Fourier. Louis Blanc is best known for *L'Organisation du travail* (1839), in which he advocated the establishment of national workshops with capital advanced by the government. These workshops would remain free from government control, with workers electing their management. The national workshops he organized in Paris after the revolution of 1848 were soon dissolved by a resurgent middle class. His plans for the "organization of labour" and his pleas for the recognition of the "right to work" were nevertheless a foreshadowing of the modern welfare state.

Pierre-Joseph Proudhon (1809–65) is best viewed as one of the founders of the anarchist tradition. But his attacks against private property and the institutions on which it rests, as well as his championing of a system of human relationships in which reciprocity, equity, and justice would replace what he saw to be rapacity, exploitation, and greed, powerfully stimulated the socialist imagination. His anti-statist and federalist vision of producers' communities provided a counterweight to the centralizing and statist impulses in the socialist tradition.

In England, the first half of the 19th century saw the emergence of a number of writers attacking the inequities of capitalism and basing their indictment of wage labour on radical interpretations of the thinking of an eminent economist, David Ricardo. Somewhat later, a Christian socialist movement led by Frederick Denison Maurice and Charles Kingsley attempted to combine radical economic views with political conservatism. The radical Chartist Movement of the 1830s and 1840s is better viewed as a political movement of the working class than as a specifically socialist formation, though anticapitalist ideas played a strong part in it.

MARX AND THE RISE OF SOCIAL DEMOCRACY

The idea of class struggle

In the perspective of intellectual history, all of these pre-Marxist socialist thinkers produced ideas of considerable intrinsic worth. But from the viewpoint of the subsequent development of socialism their ideas seem to be tributaries feeding the mighty stream of the Marxist movement that came to dominate the socialist tradition in the last third of the 19th century.

The Communist Manifesto. Karl Marx (1818–83) had a synthesizing mind. He fused German idealistic philosophy with British political economy and French socialism. Marx's earlier writings are discussed elsewhere (see MARXISM). In this section the focus is on his mature thought as first developed in *The Communist Manifesto* (1848), which he wrote in conjunction with Friedrich Engels, his lifelong intellectual companion.

To Marx, society is a moving balance of antithetical forces; strife is the father of all things, and social conflict is the core of the historical process. Men struggle against nature to wrest a livelihood from her. In the process they enter into relations with one another, and these relations differ according to the stage they have reached in their productive activities. As a division of labour emerges in human society, it leads to the formation of antagonistic classes that are the prime actors in the historical drama. In contrast to his predecessors, Marx did not see history as simply a struggle between the rich and the poor, or the powerful and the powerless; he taught that such struggles differ qualitatively depending on what particular historical classes emerge at a given stage in history. A class is defined by Marx as a grouping of men who share a common position in the productive process and develop a common outlook and a realization of their mutual interest.

Marx, like Hegel and Montesquieu, considered societies as structured wholes; all aspects of a society—its legal code, its system of education, its religion, its art—are related with one another and with the mode of economic production. But he differed from other thinkers in emphasizing that the mode of production was, in the last analysis, the decisive factor in the movement of history. The relations of production, he held, constitute the foundation upon which is erected the whole cultural superstructure of society.

Marx distinguished this doctrine, which he called scientific socialism, from that of his predecessors whom he labelled utopian socialists. He asserted that his teachings were based on a scientific examination of the movement of history and the workings of contemporary capitalism rather than simply on idealistic striving for human betterment. He claimed to have provided a guide to past history as well as a scientific prediction of the future. History was shaped by class struggles; the struggle of contemporary proletarians against their capitalist taskmasters would eventuate in a socialist society in which associated producers would mold their collective destinies cooperatively, free from economic and social constraints. The class struggle would thus come to an end.

The growth of organized parties

The First International. *The Communist Manifesto,* which had been written as a program for the Communist League, a group of continental workmen, failed to have an impact on the European revolutions of 1848. For a number of years thereafter Marx and Engels lived in complete isolation from the labour movements developing in England and on the Continent. Socialism in those years was only the creed of isolated sects, often of exiles. In 1864, however, after a gathering in London of continental and English workers' representatives and associated intellectuals, there emerged the International Working Men's Association, commonly known as the First International. Although it encompassed various tendencies ranging from simple trade unionism to anarchism, Marx dominated it from its inception and made it an instrument for the diffusion of his message. Its headquarters were in London, but it never exerted much influence in England, where the labour movement remained impervious to Marxist revolutionary ideology. On the Continent, particularly in Germany, Marxism spread rapidly and soon became the major doctrine of the emerging labour movement.

German Social Democracy. In Germany, Ferdinand Lassalle (1825–64), the architect of the German labour movement, agreed with Marx on the need for autonomous organization of the working class but differed from him in wanting the government to provide the necessary capital for the establishment of producers' cooperatives that would emancipate labour from capitalist domination. To Marx, any appeal to the bourgeois state was out of the question, and he proceeded to organize followers in Germany against Lassalle. In 1869 they created the Social Democratic Party. The division between the followers of Lassalle and those of Marx persisted until 1875, when the two parties united on the basis of a compromise program (which Marx sharply criticized for its Lassallean vestiges).

The German Social Democratic movement grew rapidly, despite Chancellor Otto von Bismarck's attempts to suppress it through anti-socialist legislation and to undercut its appeal by social reforms. In 1877 the Socialists obtained half a million votes and a dozen members in the Reichstag. In 1881 the party claimed 312,000 members, and, by 1890, 1,427,000. After the repeal of the anti-socialist laws the party adopted the so-called Erfurt Program of 1891, eliminating all demands for Lassallean state-aided enterprises and pledging itself to the orthodox Marxian goal of "the abolition of class rule and of classes themselves."

Revisionism. It soon became apparent that Marx's own thought had gone through a process of evolution so that different disciples could quote chapter and verse in support of fairly divergent political views. In particular, whereas Marx in the late 1840s and early 1850s had asserted that only a violent revolutionary overthrow of bourgeois rule and the emergence of the "dictatorship of the proletariat" would lead to the emancipation of the working class, by the late 1860s his views had considerably mellowed. Writing in England after the second Reform Bill (1867), which had given the vote to the upper strata of the workers, Marx suggested the possibility of a peaceful British evolution toward socialism. He also thought that such a peaceful road might be possible in the United States and in a number of other countries.

Although the leaders of German Social Democracy liked to speak in revolutionary Marxist rhetoric, they had in daily life become increasingly absorbed in parliamentary activities. Under the intellectual guidance of their theoretician Karl Kautsky (1854–1938) they developed a brand of economic determinism according to which the inevitable development of economic forces would necessarily lead to the emergence of socialism. The official Social Democratic platform remained ideologically intransigent, while the party's activities became increasingly pragmatic.

Eduard Bernstein (1850–1932), once a close companion of Engels, challenging prevailing orthodoxy in his famous *Die Voraussetzungen des Sozialismus und die Aufgaben der Sozialdemokratie* (1899; Eng. trans., *Evolutionary Socialism,* 1909), appealed to the party to drop its revolutionary baggage and recognize theoretically what it had already accepted in practice: namely, that Germany would not have to go through revolutionary convulsions in order to reach socialist goals. Ignoring the differences between political conditions in Germany and England, Bernstein urged the party to travel along the English road in hope of gradually transforming capitalism through socialist reforms brought about by parliamentary pressure.

Defeat of revisionism

The struggle between Kautsky's orthodoxy and Bernstein's revisionism shook the German party. Bernsteinian doctrine was officially defeated in 1903, but revisionism in fact permeated the party, especially its parliamentary and trade union leaders. At the outbreak of World War I practically all the leaders supported the government and the war, thus ending the party's revolutionary pretensions.

Other Social Democratic parties on the Continent. In France, the Marxists had to contend with rival socialist traditions that had profound roots in French working-class history. The followers of Blanqui and Proudhon played leading roles in the Paris Commune of 1871. In the years that followed, French socialism was torn by conflicting tendencies. The Parti Ouvrier founded by Jules Guesde in 1875–76 represented Marxist orthodoxy, but there were other socialist parties that reflected the influence of Blanqui, Blanc, and Proudhon, as well as the 18th-century revolutionary heritage. Even after the various parties amalgamated in 1905, the movement continued to be torn by dissension between its revolutionary and reformist wings. Nonetheless, it continued to grow. At its first congress the unified party claimed 35,000 members, and in the elections of 1906 it won 54 seats in Parliament. By 1914 it had more than 100 members in the Chamber of Deputies. As in Germany, however, revolutionary rhetoric usually went hand in hand with pragmatic action, and the party became in fact a skillful participant in the parliamentary games of the Third Republic. After Jean Jaurès, the great Socialist orator and a principled leader of the peace elements, was assassinated on the eve of World War I, most of the Socialists supported the French war effort.

In the last part of the 19th century, Social Democratic parties generally beholden to Marxist doctrine sprang up in most of the countries of continental Europe. A Danish Social Democratic Party was founded in the 1870s, the Swedish Socialist movement in 1889. The Norwegian Labour Party (first called the Social Democratic Party) was formed in 1887 but became a major political force only in the early 20th century. In central Europe, Social Democratic parties fairly rapidly assumed a major place on the political horizon. An Austrian Social Democratic

Party was founded in 1888. By 1908 it had gained about one-third of the vote cast in the parliamentary elections, to become the strongest Socialist party outside Germany. The Belgian Labour Party, formed in 1885 as an amalgamation of trade union, cooperative, and other groups, rapidly organized thousands of mutual aid societies, built a very strong trade union movement, and led a number of general strikes on behalf of more liberal suffrage laws. The Dutch Socialist-Democratic Workers Party, founded in 1894, became a significant force only in the years immediately preceding World War I. It held 20 percent of the seats in the lower house of Parliament in 1912.

All of the continental parties were torn by internal tensions. Proposals to enter liberal coalition governments often were defeated by only narrow margins; Marxist orthodoxy prevailed only after sharp struggles. In The Netherlands, for example, a proposal to enter a coalition government was rejected by the close vote of 375 to 320 at the party congress of 1913.

Anarchist tendencies. In the less industrialized parts of Europe, particularly in Italy and Spain, Marxism had to contend with anarchist tendencies mainly rooted in the precapitalist and peasant strata. European anarchism as a political force was created by Mikhail Bakunin, the highly influential Russian libertarian thinker. His Anarchist Federation had belonged to the First International, but quarrels with Marx led to the expulsion of Bakunin and his followers in 1872.

The Anarchist Federation

Bakuninist and other anarchist strains of thought remained powerful in Spain, despite the founding of the Social Labour Party in 1879. The Spanish socialist movement suffered from the competition of the anarchists throughout its subsequent history, and only after World War I did it become a political force to be reckoned with.

In Italy anarchist tendencies also impeded the growth of a socialist movement. The Italian representatives to the First International followed Bakunin's lead. Not until 1892 was a distinctly Socialist party formed under the leadership of Filippo Turati. In 1913, after the electoral franchise was broadened, the official Socialist Party secured 51 seats in Parliament, and two other Socialist parties that had split from its ranks gained 31 seats. Although it continued to suffer from internal dissension and from anarchist tendencies in the more backward areas of the country, by World War I the Italian Socialist Party had become one of the strongest Marxist organizations in Europe.

The Second International. The First International had brought into being a variety of Socialist movements throughout Europe. When these began to grow roots in their respective political systems, it became apparent that the international movement could no longer be controlled by a single directing centre. After the dissolution of the First International in 1876, Marx and Engels remained father figures whose counsel the movement eagerly sought; but they could no longer direct it. The history of socialism now became largely the history of separate national movements that, for all their ceremonial acknowledgment of Marxist orthodoxy, increasingly tended toward a revisionist and nonrevolutionary line. By the early years of the 20th century socialism had become a powerful parliamentary force in most European countries. Except in Russia, where autocracy still held sway, the Socialists were reformers seeking a transformation of the existing system rather than its violent overthrow. Only left-wing minorities within the various parties still stood for revolutionary orthodoxy.

The Second International, founded in 1889, reflected the changed character of the movement. It was a kind of international parliament of socialist movements rather than the unified and doctrinally pure organization that the First International had attempted to be. It was dominated by the German party. With traditional Marxist rhetoric, the German delegates stood adamant against proposals to sanction socialist participation in bourgeois governments, and thus appeared to favour a "left" course. But socialist participation in government was not a realistic option in Kaiser William's Germany, and so the German delegates could be intransigent at no cost to themselves. When the issue was put to a vote at the Amsterdam congress in 1904, the Germans sided with those who opposed participation, against Jaurès and those who condoned it. But Jaurès had the better of it when he pointed out that "behind the inflexibility of theoretical formulas which your excellent comrade Kautsky will supply you with till the end of his days, you concealed . . . your inability to act." As with the issue of government participation, so with the issue of war. The Second International, under its German leadership, issued many moving and stirring manifestoes against war, but when war broke out it disclosed its paralysis. Most of its national components sided with their own governments and abandoned the idea of international working-class solidarity. Almost all of them recognized what they may secretly have believed for a long time: the workers, after all, had a fatherland.

OTHER SOCIALIST TENDENCIES BEFORE WORLD WAR I

The non-Marxists

British Fabianism. Although Marxism triumphed in the continental Socialist movement, it did not do so in Great Britain. Henry Hyndman, a radical journalist, founded the Social Democratic Federation on strictly Marxist principles in the 1880s, but it ever remained marginal to the British socialist movement. The Socialist League, founded by the poet William Morris, propounded libertarian-syndicalist ideas and likewise failed to make headway. Fabian socialism, on the other hand, based on non-Marxist ideas, was to have an enduring influence in Britain.

The Fabian Society was organized in the 1880s by a number of young radical intellectuals among whom Sidney and Beatrice Webb, Graham Wallas, Sidney Olivier, and George Bernard Shaw were the most outstanding. It developed an evolutionary and moderate form of socialism. Convinced of "the inevitability of gradualness," the Fabians never endeavoured to become a mass organization but preferred to be a ginger group of intellectuals working to transform society through practical and unobtrusive advice to the men of power. The extremely influential *Fabian Essays* (begun in 1889) contained detailed blueprints for social legislation and reform that influenced policymakers whether they were socialists or not. Through "permeation," which Shaw defined as "wire-pulling the government in order to get socialist measures passed," the Fabians attempted to convince key politicians, civil servants, trade union officials, and local decision makers of the need for planned and constructive reform legislation. Basing their doctrine at least as much on non-Marxist economics as on the continental socialist tradition, they worked for a new order "without breach of continuity or abrupt change of the entire social tissue."

Syndicalism. The syndicalist movement grew out of French trade unionism when it was reconstituted after the bloodletting of the Paris Commune (1871). Convinced of the futility of parliamentary and political activity, the syndicalists stressed that only direct action by workers organized in their unions would bring about the desired socialist transformation. Under the leadership of Fernand Pelloutier the Fédération des Bourses du Travail (founded in 1892), which was later amalgamated with the Confédération Générale du Travail (1902), was built on the idea that the emancipation of labour would come through a "general strike" that would paralyze the country and deliver power into the hands of organized workers. The unions would become the directing and administering nuclear cells of production.

The general strike tactic

The syndicalists attracted a number of intellectuals to their ranks, who attempted to provide a philosophical basis for syndicalism and its rejection of the political road to socialism. The most important of their writings, Georges Sorel's *Réflexions sur la violence* (1908; Eng. trans., *Reflections on Violence,* 1916), has continued to exercise considerable influence on the thinking of revolutionary militants, even though Sorel himself soon shifted his allegiance to the extreme right.

Guild socialism. The guild socialist tradition developed in Britain in the years before World War I. Sharing the general socialist hostility to the wage system and production for profit, guild socialists took from the syndicalists their distrust of the state and their emphasis on producers' control. They looked back to the Middle Ages when independent producers, organized in guilds, controlled the conditions of their employment and took pride in creative work. Aiming at self-government in industry, guild socialists urged that industrial organizations, churches, trade unions, cooperative societies, and municipalities be granted autonomy. They argued that every group in society should carry out its particular functions without control from above, and that individuals should have a say in the direction of all those functional units in which they happened to be interested. Cooperation between functional units would replace direction by the state, which would be restricted to providing needed national services such as police protection. The state would be a functional unit among many others, rather than an all-encompassing sovereign.

Although guild socialism owes its origin to several thinkers, it grew into a mature doctrine only when in 1913 it recruited G.D.H. Cole, a brilliant Oxford don, two of whose early books, *The World of Labour* (1913) and *Self-Government in Industry* (1917), contain the best exposition of guild socialist doctrine. The movement never attained wide popular appeal but has continued to be a source of ideas in the British labour movement, if only as a counterpoint to the bureaucratic and centralizing tendencies of Fabianism.

Socialism in the United States. Socialism never became as influential in the United States as it did in Europe. When the Socialist Party was formed in 1901 it claimed a membership of 10,000 that grew to 150,000 in 1912, in which year the party polled a presidential vote of 897,000, or 6 percent of the national total. Although its strongest roots were among recent immigrants from Europe, it also drew its inspiration from the utopian colonies of the 19th century, from the slavery abolitionists, trade unionists, and agrarian reformers, and from isolated socialist groups of the 1880s and 1890s.

The Socialist Labor Party, a predecessor of the Socialist Party, was formed in 1877 but acquired a distinct outlook only when the journalist and polemicist Daniel De Leon joined it in 1890. De Leon attempted to marry a doctrinaire brand of Marxism to a "labourism" nourished in part on French syndicalist doctrine. He and his followers wished to raise the membership of the unions above "paltry routine business" and prepare them for a successful contest with the power of capital, both at the ballot box and in industrial combat.

The U.S. Socialist Party

The Socialist Labor Party remained a sect. But the Socialist Party developed into a mass movement under the leadership of Eugene Debs, a former union official who had been converted to socialism by reading the works of various socialist writers while in jail. The Socialist Party of Debs was neither centralized nor politically homogeneous. In its ranks it harboured reformists and revolutionaries, orthodox Marxists, Christian ministers, municipal reformers, populists who hated the railroads and the trusts, and Jewish garment workers dreaming of fraternity in the sweatshops. It produced no major theoretical works, but it managed in its undoctrinaire way to be an effective voice for the idea of socialism in America. It declined after World War I, its last well-known leader being Norman Thomas.

THE RISE OF RUSSIAN SOCIALISM

The populist tradition. The dominant radical tendency in 19th-century Russia was populism, a doctrine first developed by the author and editor Aleksandr Herzen, who saw in the peasant communes the embryo of a future socialist society and argued that Russian socialism might skip the stage of capitalism and build a cooperative commonwealth based on ancient peasant tradition. Herzen idealized the peasantry. His disciples inspired many students and intellectuals to "go to the people" in order to stir them into revolutionary action.

In the 1860s and 1870s, the more radical populists lost their faith in a peasant revolt and turned instead to terrorism. Small groups of student revolutionaries sought to bring down tsarism through terroristic action; their efforts culminated in the assassination of Alexander II in 1881. Sergey Nechayev's *Revolutionary Catechism,* in the writing of which Bakunin had a hand, stressed that the sole aim of the revolutionary is to destroy "every established object root and branch, [to] annihilate all state traditions, orders and classes in Russia." It is one of the ironies of history that Bakunin helped create in Russia an elitist and terrorist movement composed almost exclusively of alienated intellectuals, while in western Europe he appealed to skilled craftsmen and peasants and appeared to be the heir of Proudhon.

Within the broad stream of populism, terrorism was opposed by an evolutionary socialism that put its faith in peaceful propaganda and the education of the masses. While the elitists pursued their campaign of terror, the gradualists stuck to propaganda among the people.

Marxism in prerevolutionary Russia. The father of Russian Marxism was Georgy Plekhanov, who began his socialist career as a populist and was converted to Marxism when he settled in Geneva in 1880; in 1883 he founded the first Russian Marxist organization, the Osvobozhdenie Truda (Liberation of Labour Group). Plekhanov thought Russian socialism ought to be based primarily on the growing factory proletariat. Rejecting Herzen's idea that Russia was exceptional, he held that the revolution would be European in character and that Russia's place in it would be determined by its own labour movement. In a variety of books and pamphlets in the 1880s and 1890s, Plekhanov attacked the populists and argued that Marx had shown the objective historical necessity of socialism. The laws of social evolution could not be flouted. A bourgeois revolution in Russia was inevitable in the course of industrial development. The organized working class would know how to take advantage of the bourgeois revolution and push it forward.

The Leninists

Against this German brand of Marxism, Vladimir Ilich Ulyanov (1870–1924), later to be known by his party name of Lenin, argued for a more militant approach to revolution. In *What Is To Be Done?* (1902) he formulated his characteristic doctrine. Socialism would be achieved only when professional revolutionaries succeeded in mobilizing and energizing the masses of workers and peasants. Left to themselves, the workers would get no farther than a trade union consciousness. A militant, disciplined, uncompromising organization of revolutionaries was needed to propel the masses into action.

Lenin's followers parted company with the other Russian Marxists at the second congress of the (illegal) Russian Social Democratic Workers Party held in London in 1903. The anti-Leninist position was formulated by the leader of the more orthodox Marxists, L. Martov, when he declared, "In our eyes, the labour party is not limited to an organization of professional revolutionaries. It consists of them, plus the entire combination of the active, leading elements of the proletariat . . . ."

Mensheviks and Bolsheviks

The two factions within the Russian Social Democratic movement at first cooperated and even held joint meetings; the final split came only in 1912. Individual leaders switched from one faction to another (Plekhanov, who originally sided with Lenin, joined his opponents in 1904). Others, such as Leon Trotsky, attempted for a time to stay free from factional alignments. These disputes were fought out in the West, where most of the leaders of both sides lived as émigrés. Within Russia itself, however, Lenin's opponents (the Mensheviks) mainly attracted the better educated and skilled workers, as well as the Jewish intelligentsia, while his Bolsheviks tended to be most successful among the more backward strata of the working class.

After the February Revolution of 1917 toppled the tsarist regime and installed a liberal and vaguely socialistic leadership, the Bolsheviks managed to extend their organization among the urban masses. When Lenin returned from exile in April 1917, he startled his followers by calling for an entirely new strategy. Previously they had believed that their immediate task was to work within the limits of a democratic republic while preparing for future revolutionary opportunities. Lenin argued instead that they must seek power at once. The desire of the masses for an immediate end to the war, the land hunger of the peasantry, the feebleness of the new regime, he urged, made possible what had not been possible in the abortive revolution of 1905: a socialist revolution led by Bolshevik cadres. Moreover, Lenin argued, a Russian revolution would not be isolated for it would soon be followed by a German revolution.

The soviets (workers' and peasants' councils), which had sprung up spontaneously when the tsarist power collapsed, were the main organizational bases from which the Bolsheviks mounted their assault on the established order. Lenin's slogan "All power to the soviets" found a ready response in the major urban centres. In September 1917 the Bolsheviks won elections for the Moscow and St. Petersburg soviets. These now became centres of "dual power" challenging the official government. It was the St. Petersburg soviet that in October 1917 gave Trotsky the military instrument with which he was able to topple the provisional government and install a revolutionary regime headed by Lenin.

Lenin and the Third International. The Bolshevik seizure of power had been undertaken in the belief that the revolution would soon spread to the rest of Europe. Lenin's perspective had always been internationalist. When most of the socialist leaders of the Second International rallied to their national governments in 1914, Lenin denounced them as traitors to the cause and sought to lay the groundwork for a new organization of revolutionary Socialists. After their seizure of power, the Bolsheviks resolved to create a Third International. By the time the delegates had assembled in Moscow in 1919, a revolutionary uprising in Berlin had been crushed and its leaders murdered. The great majority of the German working class was evidently willing to give the Social Democratic leadership of the new German republic a chance. But to the Russian leaders' world revolution still seemed near. Soon after the first congress of the Third International a short-lived soviet republic was proclaimed in Hungary and another in the German state of Bavaria. Communist parties began to be organized in all the major countries of Europe.

When the so-called Communist International (Comintern) met for its second world congress in July 1920, it was no longer a small gathering of individuals or representatives of small sects but a union of delegations from a dozen major Communist parties. The outcome of this meeting was to give the Russian leaders control of the new International, now broken away sharply from the Socialist movement. It adopted 21 conditions for membership in the Comintern, demanding that its adherents reject not only those Socialist leaders who had been "social patriots" in the war but also those who had taken a middle position. It aimed at creating a disciplined and militantly revolutionary world organization patterned after the Russian model, which would accept willingly the direction and unquestioned authority of the Russian leadership.

By 1923 the hoped-for revolutionary tide in Europe had not developed. New uprisings in parts of Germany failed completely in 1923. The Red Army's attempted invasion of Poland had been thrown back. Many Socialists who had for a time joined the Comintern, including the leadership of the Norwegian Labour Party, left-wing Communists in Germany, and Syndicalists in France and Spain, now turned away, rejecting its policy of centralized dictation.

Europe achieved a measure of economic and social stabilization. By the time of Lenin's death in 1924, Moscow was beginning to use the parties over which it still held command as instrumentalities of Russian foreign policy. Although some Comintern leaders like Trotsky still believed that world revolution was on the agenda, their faith was no longer shared by the majority of the Russian leadership.

SOCIALISM BETWEEN THE WARS

Socialists and Communists

The split with the Communists. Communists throughout the world denounced the leaders of the reconstructed Socialist parties as "social traitors" who "objectively" fostered the maintenance of capitalism. They accused them of having repudiated Marxism and betrayed international socialism by collaborating during the war with the bourgeoisie in the defense of their national states. The Socialist leaders retorted by pointing to the dictatorial features of the Soviet state and accusing the Communists of having betrayed the democratic socialist tradition.

The European Socialist movement was irremediably split. In Germany, the Social Democrats united again and succeeded in enrolling the bulk of the working class under their banner; the Communists were reduced to a minority position in the German labour movement. In France, where the Communists at first succeeded in attracting the majority of the Socialist Party, their opponents soon regained ascendancy and the Communists became a minority on the French left. Italian socialism split into Communists and left-wing and right-wing Socialists and thus greatly facilitated Mussolini's march to power. In Great Britain the Communists hardly made a dent in the Labour Party and never became more than a radical sect. European socialism as a whole, as well as socialist movements on other continents, was sharply split between adherents of the Second International and the Communists organized in the Third.

The Comintern followed an erratic course, sometimes veering toward a revolutionary line and sometimes making attempts to collaborate with the more militant strata of the socialists. After the onset of the economic depression in 1929 the Comintern took a sharp leftist turn, expecting the "final crisis" of capitalism to bring proletarian revolution everywhere. It denounced Social Democratic leaders as "social Fascists" and enemies of the working class. In the Prussian Landtag the Communists actually voted with the Nazis to bring down a Social Democratic government, on the theory that the Nazi movement was a passing phenomenon.

At the same time the Socialists gave up in practice, though not always in theory, their commitment to revolutionary doctrine. They became in effect pressure groups trying to extract maximum advantages for the working classes from their respective national regimes. In Germany, in Britain, and in the Scandinavian countries they participated at times in the government. Elsewhere, as in France, they tended to support congenial left-bourgeois regimes. But they lacked, on the whole, a concrete plan of social and economic action, and consequently were ineffective when the world depression unsettled the economies and political regimes of western and central Europe.

Response to the world economic crisis. Nowhere, except in Sweden and Belgium, did the socialists press for comprehensive socialist planning during the depression. Where they were in power they followed orthodox policies of budgetary management and public finance. When they were out of power they contented themselves with a defense of the immediate interests of the workers by demanding more unemployment insurance and opposing reductions in wages.

As the crisis deepened, the Communists gained influence, particularly among the unemployed and those unskilled workers hit most severely by the depression. They did not make deep inroads among other workers.

The rise of Fascism. Hitler's rise in Germany led to the destruction of both the Communists and the Socialists in that country. The Communists had hoped that a Nazi victory would be only temporary, and that afterward they would be called upon to lead the masses of Germany to victory. Their battle cry was, "After the Nazis—We." The Socialists played politics as usual, expecting that the depression would run its "natural" course and that a gradual decline of the Nazi fever would follow. A disunited labour movement proved unable to stay the Nazi march to power. This disaster led both Communists and Socialists to reconsider their previous policies and to revise their strategy and tactics.

Austrian Socialists, threatened with destruction by the reactionary regime of Chancellor Engelbert Dollfuss, resolved to offer armed resistance in February 1934. The Austrian party had long been regarded as a model for both its theoretical contributions and its concrete accomplishments. It enjoyed the nearly total support of the workers; 500,000 of Vienna's 2,000,000 inhabitants were dues-paying members. But the party was almost completely metropolitan and urban. Consequently the bloody battles of February 1934 remained localized in Vienna. The uprising was suppressed after four days, and the party had to go underground.

Socialists in office

Experience in government. *Germany.* The end of World War I had seen a somewhat reluctant Social Democratic Party installed in the seat of German government. Friedrich Ebert, the head of the party, became the first president of the new republic. But the Socialists were split internally. The "majority Socialists," the right wing of the party, wished to proceed in a cautious and pragmatic manner. The "independent Socialists," led by Kautsky and his former antagonist Bernstein, pressed for fundamental structural reforms. The extreme left, led by Rosa Luxemburg and Karl Liebknecht, wished to organize a revolutionary party and founded the Communist Party of Germany. When younger extremists, overruling Luxemburg and Liebknecht, organized a left-wing Putsch early in 1919, they were isolated and easily defeated by the government of the majority Socialists and its allies among right-wing officers. Luxemburg and Liebknecht were assassinated, and the remaining leaders took the group into the Comintern. Another left-wing and Communist putsch in Bavaria a few months later was also unsuccessful. In the early 1920s, the independents reunited with the majority Socialists.

In the first election to the new National Assembly in 1919 the majority Socialists obtained a plurality of the votes cast (39.3 percent), and the independent Socialists won another 8 percent. The Socialist government proclaimed the need for socialization of monopolistic industries and other radical measures. But after the elections of June 1920, a non-Socialist cabinet took office. In subsequent years the cabinets were largely non-Socialist in character, though Socialists participated in some of them. The middle classes were again in the saddle, and when President Ebert died in 1925 the conservative nationalist Hindenburg succeeded him. Throughout the turmoil of the first years of the Weimar Republic, the Social Democrats remained a bulwark of republican legality against both the extreme right and the extreme left. In the *Länder* (states), Prussia in particular, they held positions of governmental power and managed to institute a number of reformist welfare measures. But they failed to gain a controlling voice in national politics.

In the May 1928 elections the Social Democrats emerged as the strongest party in the Reichstag. Although they lacked a majority, their leader Hermann Mueller became chancellor, and their financial expert was named minister of finance. This largely Socialist government, however, proved unable to deal with the economic depression that soon afflicted Germany along with the rest of the world. The government followed an orthodox deflationary policy, pressed for the reduction of unemployment benefits in order to save taxes, and attempted to reduce budget deficits. Unable to stem the tide of depression, it resigned in 1930. This was the last government of the Weimar Republic in which Social Democrats participated. Soon afterward, the Nazis started on their way to power.

Britain. In the general election of 1923 the Labour Party, which had adopted a Socialist program only five years earlier, won a plurality; with the support of the Liberals it formed the first Labour government under Ramsay MacDonald in January 1924. Its tenure proved short. After implementing a few modest reform measures, it was ousted by an electorate which, partly because of manufactured fears of a "Bolshevist menace," turned sharply to the right in the elections of October 1924.

In June 1929 the Labour Party had its second chance. It won 288 out of 615 seats in the House of Commons and, with the support of the Liberals, formed the second Labour government, again under Ramsay MacDonald. But Labour, like the German Social Democrats, proved unable to deal with the depression, particularly with mounting unemployment. It was pledged to far-reaching social reforms that it was not prepared to carry out. The flight of capital from London assumed catastrophic proportions; business circles demanded a balanced budget and lower unemployment benefits. When MacDonald proposed to accede to some of these demands, the trade unions sharply opposed him. He then split the Labour government and formed a national coalition with the Conservatives and the Liberals. For the remainder of the 1930s the Labour Party was out of power.

Italian crises of 1919–22

Italy. In the Italian elections of 1919, the Socialists won 2,000,000 votes out of a total of 5,500,000. Italy seemed on the verge of revolution; large-scale strikes, mass demonstrations, factory occupations, and spontaneous expropriations of landed estates spread throughout the country. In August 1920 a revolutionary situation developed in the industrial north after a breakdown in wage negotiations; 500,000 workers occupied the factories, kept production going, and prepared for armed resistance. The far left called for an extension of the strike, but a divided Socialist leadership hesitated. The discouraged workers retreated. Mussolini's Blackshirts began breaking up working-class meetings. In 1921 the right-wing Socialists proposed that the party form a coalition government with the Liberals, but the left vetoed the idea. Mussolini's terror squads made further inroads in the large industrial centres. A general strike called by the trade unions proved a dismal failure. Soon afterward Mussolini made his March on Rome (October 1922) and was installed as premier. By 1926 parliamentary government had completely ended in Italy. The Socialists were driven underground.

France. None of the French governments from the end of World War I until the middle 1930s included Socialists. Although the Socialist Party was in fact deeply committed to gradualism, it still clung to its prewar policy of not participating in "bourgeois" governments. Only in the mid-1930s, when militant right-wing groups threatened the Third Republic, did the Socialists change their policy. In June 1936 a government took office representing a Popular Front, ranging from the Communists on the left to Radical Socialists in the centre and headed by the Socialist leader Léon Blum. The Communists had at last abandoned their doctrine of "social Fascism" and were now willing to enter coalitions with other parties of the centre and left.

The victory of the Popular Front in June 1936 was accompanied by sit-down strikes in the factories; these helped push the government, headed by Léon Blum, in a radical direction. Collective bargaining rights, never recognized before by French employers, were now protected by law; social security and general working conditions were significantly improved; the 40-hour week was made mandatory. The Blum government attempted to institute a French version of the U.S. New Deal. But after the initial enthusiasm had waned, French employers took courage and pressed the government to return to traditional fiscal and budgetary policies. When in June 1937 his middle-of-the-road partners in the coalition refused his demands for emergency fiscal powers, Blum resigned. The Socialists participated in the next government headed by a Radical Socialist, and Léon Blum later formed another Popular Front government that held office for about a month in 1938. When France went to war against Germany in 1939 the Communist Party, which opposed the war, was banned. After France's collapse in 1940, the Socialist Party was dissolved by the Vichy government.

Sweden. Only in Sweden were Socialists successful in their governmental policies. A Swedish Labour government was formed for the first time in 1932. Unlike the other European Socialist parties, the Swedes broke with orthodox budgetary and financial policies and stressed large-scale intervention by the government in the planning of economic affairs. Extensive public works, financed by borrowing from idle capital resources, helped to reduce unemployment and stimulated the economy; public investment was used methodically to offset the effects of reduced private spending. Unemployment, which had reached 164,000 in 1933, was eliminated by 1938 through a policy of steady economic expansion. The Swedish innovations helped lead the way to the economic policies practiced by almost all Western countries after World War II.

SOCIALISM AFTER WORLD WAR II

New concepts of socialism

The worldwide spread of "socialist" parties. Orthodox Marxists had always assumed that socialism would emerge first in the industrial countries of the world. But a new kind of "socialism" spread rapidly in agrarian societies and backward countries after World War II. In many of these countries Marxism became, despite the intention of its founders, the ideology of industrialization. In the struggle against colonialism the liberation movements, especially the intellectuals and semi-intellectuals who led them, adopted what they conceived to be socialist ideas. It seemed to them that meaningful national independence could be attained only through state direction of the economy. Rapid economic growth, they believed, could be fostered only by restricting consumption and channelling national resources into the building up of productive facilities. In one degree or another the new countries took the Soviet Union as their model for rapid industrialization. All manner of regimes, from totalitarian one-party states to military dictatorships, proclaimed that they were socialist. Only in India and a very few other countries did the ruling party retain the traditional Western socialist vision of social justice, equality, and democracy.

In the meantime, ironically, the Socialists of western Europe were giving up their Marxist views and turning toward the welfare state. During World War II almost all of the Socialist parties had joined governments of national unity. Afterward they sought to become popular parties following the parliamentary road to power and ready to participate in coalition governments with Liberal or Christian Democratic partners. Surrendering the idea that only full state ownership would bring the good society, they aimed at a mixed economy in which public control and a certain amount of planning would bring social benefits for all. This was, in essence, the idea of "the inevitability of gradualism" that the English Fabians and the German revisionists had preached around the turn of the century.

The transformation of western European socialism. *West Germany.* The changed orientation of the postwar German Social Democratic Party was expressed in its Frankfurt declaration of 1951, which made no mention of the class struggle and other traditional Marxist doctrine, stating instead that the party "aims to put economic power in the hands of the people as a whole and to create a community in which free men work together as equals." It advocated public control of the economy but rejected comprehensive state ownership. It accepted planning, but stressed that democratic socialist planning had nothing in common with the Communist and totalitarian kind.

From socialism to welfare

A few years later, in its program of principles adopted in Bad Godesberg in 1959, the party shed the last remnants of Marxism. The name of Marx and the words "class" and "class struggle" are not to be found in that program, which even advocates private property in the means of production. It rejects overall central planning and endorses the idea of a competitive free market. The party stands for "as much competition as possible—as much planning as necessary." A "mixed economy" is seen as the ideal. The party no longer claims to possess a universally valid doctrine, but stands for a pluralistic society in which no party seeks to impose its particular philosophy on society as a whole. Thus to all intents and purposes the Social Democratic Party of Germany, which in 1969 formed a government under the leadership of Willy Brandt, has become a reformist party striving for an extension of the welfare state.

British Labour. The British Labour Party was never committed to Marxism and hence found it easier to adjust to the political realities of the postwar world. In 1945 it won a majority in Parliament for the first time. The government of Prime Minister Clement Attlee, during its six years of power, laid the foundations of the British welfare state. A number of basic industries such as coal, railways, road transport, and steel were nationalized. A comprehensive system of nationalized medical care was established. Social services were extended. Full employment was maintained. Although Labour was voted out of office in 1951, its main achievements remained. The steel industry again reverted to private control, but the Conservatives made no effort to undo the other features of the welfare state.

Hugh Gaitskell, who succeeded Attlee in the leadership of the party, wanted to revamp its program by eliminating earlier pledges that the party seek large-scale nationalization of industry. He was not successful, but in practice the party became married to a reformist course aiming at the extension of the welfare state and of pragmatic planning. When the party returned to power in 1965, its leader, Harold Wilson, prime minister until the elections of 1970, pursued a cautiously reformist policy. Harassed by economic difficulties and forced to pay more attention to the balance of payments than to internal reforms, the Labour government made few policy decisions of a distinctively socialist character.

Trends in French and Italian socialism. The French Socialist Party, reconstituted after World War II, participated in leading positions in the first few postwar French governments. It supported nationalization of parts of French industry, especially public utilities, mining, and much of banking and insurance, as well as wide-ranging measures of public control over the economy and structural reforms in the field of social security. But the party had lost much of its prewar support among the workers to the Communists. The Socialists increasingly became a party of civil servants, middle-class professionals, and other white-collar employees. While they made no attempt to recast their program as the German Social Democrats did, their actual orientation was equally moderate. When they did at length achieve power under the leadership of François Mitterrand in 1981 they undertook to nationalize a number of industrial and financial concerns, but the exigencies of worldwide recession and pressures on the franc kept them to a notably moderate course.

Socialist government in France

The Italian Socialist movement split into a number of parties. The largest organization, the Italian Socialist Party under Pietro Nenni, attempted to revive the pre-Mussolini left-wing socialist tradition. It contended that the interests of the working class could best be served by cooperation with the Communists. Of all the Socialist parties of Europe it stood closest to the prewar Marxist tradition of class conflict and "orthodox" Marxism. After the Hungarian revolution of 1956, however, the party increasingly drew away from collaboration with the Communists, finally entering a centre-left coalition government with the Christian Democrats in 1963. Since then it has in practice become indistinguishable from other western European Socialist parties.

The second largest Socialist party of Italy during the post-World War II period has been the Democratic Socialist Party formed under the leadership of Giuseppe Saragat. It was committed to moderate social reforms, and participated in almost every Italian coalition government after 1947. In 1966 the two major Socialist parties merged, but they separated again in the late 1960s.

The welfare state. All the western European Socialist parties have become committed to the welfare state, though they vary in the extent to which they have formally abandoned their Marxist orientation. Some of their theoreticians still cling to the hope that socialism will eventually go beyond the welfare state toward a society in which class distinctions will have been erased and wealth will be more equitably distributed. But while this may be their dream, it no longer informs their political actions.

African socialism. Socialist ideas were carried to North Africa mainly by French-educated African intellectuals; in addition, many French settlers, especially schoolteachers and civil servants, were Socialists or Communists. The various national liberation movements, especially in Tunisia and Algeria, linked the struggle against colonial domination with socialist ideas. When Algeria became independent its first leader, Ahmed Ben Bella, surrounded himself with French advisers from various Marxist groups.

Collectivization of agriculture and self-management in industry stood high on the agenda of the Algerian national government. When these programs failed, Ben Bella was replaced by Col. Houari Boumedienne, who was pledged to continue "Algerian socialism" but settled in fact for an economy based on state-directed enterprises and private landholdings. The country was, in fact, run by a military dictatorship.

Algerian socialism

In Tunisia a one-party regime was installed after the liberation of 1956; under its leader, Habib Bourguiba, it proceeded to nationalize the major enterprises. The ruling party, the Destour Socialist Party, permitted no rival political organization; it was committed to modernization through planned development of the economy.

Elsewhere in Africa a variety of "African socialisms" sprang up in the 1950s and 1960s. Pres. Léopold Sédar Senghor of Senegal advocated a socialist "humanism" based only partly on Marx. Pres. Sékou Touré of Guinea sought to combine Marxist-Leninist ideas with the communal values of precolonial Africa—to "Africanize" Marxism. Pres. Kwame Nkrumah of Ghana proclaimed "consciencism" as the basis for his regime and stated that "only totalitarian measures can preserve liberty"; he was overthrown in 1966.

In Kenya, Tanzania, and other African countries, the ruling elites proclaimed their adherence to one or another version of "African socialism" while in fact being committed above all to rapid industrialization and modernization. Many African socialist writers stressed the need to build their socialism upon African traditions such as communal land ownership, the egalitarian practices of some tribal societies, and the network of reciprocities and obligations that once existed in tribal societies.

Throughout Africa the commitment to socialism was hardly more than lip-service to an ideal. The pressing need was to move from a subsistence to a market economy, to industrialize, and to organize health services, education, housing, and public administration. Autonomous institutions in which men might strive for concerted political and social goals independent of government control scarcely existed in Africa. Hence the prospect for democratic, as distinct from imposed, socialism was remote.

Arab socialism. The "socialist" movements of the Middle East have been led by European-educated intellectuals belonging to a new middle class of civil servants, army officers, and schoolteachers. Trying to appeal to the Arab people as a whole, and without distinction as to class, they have stood for modernization and for the brotherhood of all Arabs.

The major socialist movement has been the Arab Socialist Party, usually called the Baʿth Party. Founded in Syria, it has rejected tribal or regional loyalties. Baʿth factions have held power in Iraq and Syria but have not promoted specifically socialist measures or made concrete reforms.

When Gamal Abdel Nasser came to power in Egypt in 1952, his group of young army officers of lower middle class origin had little if any interest in socialism. Nasser was led to socialist ideas in his struggle against the domination of foreign business. By the middle of the 1960s Egypt had nationalized all large industrial and financial enterprises, whether domestic or foreign; it had expropriated large-scale landowners; and it had placed all important sectors of the economy under the control of state planners. But the structure of power remained that of a military dictatorship.

Failure of socialism to take root in Asia

Asian socialism. Representatives of a dozen Asian Socialist parties met in Rangoon in January 1953 for the first Asian Socialist Conference. Some of the delegates had international reputations. The governments of several Asian countries—India, Burma, Ceylon, Indonesia, and Singapore—called themselves Socialist. Yet the Socialist parties soon thereafter lost even the semblance of power and influence. In India, where several Socialist organizations competed, the ruling Congress Party was in fact a national party striving to unite within its ranks many divergent political and social tendencies. The Burmese Socialist Party was for many years part of a coalition that ruled the country, but it was outlawed in 1962 when Gen. Ne Win seized power. The Indonesian Socialist Party was abolished by President Sukarno in 1960. Except in Singapore, the postwar Socialist parties in Southeast Asia played no major role in the 1960s.

As the influence of the European-style Socialist parties waned, a variety of authoritarian regimes arose speaking in socialist accents. Indonesia's President Sukarno proclaimed Resopim (Revolution, Indonesian Socialism, and National Guidance) his official ideology. The Burmese military dictatorship proclaimed Burma a socialist state. North Vietnam (and later all of Vietnam) was ruled by a Communist party; in the rest of Indochina, revolutionary movements inspired by Communist ideology battled traditionalist forces supported by the United States. In China, the Communist government of the People's Republic has been in power since 1949.

The Socialist parties of Southeast Asia, after playing a brief role in the struggle for independence, failed to take root in national politics. They were led by European-educated intellectuals, who attempted to emulate European models and were committed to the idea of a democratic road to socialism. But the countries of Southeast Asia were not prepared to follow them; they turned instead to authoritarian regimes that pursued industrial development. Only in Singapore and India were attempts made to combine democracy and socialist planning. In most of Asia, as in Africa, "socialism" has become the ideology of new elites seeking modernization and rapid industrialization.

Japan. Only in Japan, by far the most developed of Asian countries, have traditional socialist organizations become firmly established. The first Socialist Party of Japan, formed in 1901, was soon dissolved and forced to go underground. During and after World War I socialist organizations again sprang up. In 1936 the Social Mass Party elected 18 members to the Parliament and received more than half a million votes. After World War II socialist organizations that had been suppressed since 1940 appeared again. In 1946 the Socialist Party won over 90 seats to become the third strongest party. A year later it gained the largest number of seats in Parliament, and its leader Katayama Tetsu became prime minister in a coalition government. In October 1948, however, the conservatives took office. The Socialists were deeply split between gradualists and revolutionaries. The left wing tended to be sharply anti-American and leaned toward the Soviet Union; the right wing favoured a gradual relaxation of close military and political ties with the United States. The two wings broke apart in the 1950s to form the (left) Socialist Party of Japan and the (right) Democratic Socialist Party. Together they controlled about one-third of the seats in Parliament, but they seemed condemned to a permanent minority status. Japanese socialism still awaits a transformation similar to that undergone by western European Socialism in the postwar era.

Success in Australia, New Zealand, Canada

Other areas and countries. *Australia.* Socialism has deep roots in the British Commonwealth countries of Australia, New Zealand, and Canada. The Australian Labor Party was formed in 1901, when the Australian Commonwealth came into existence. Only three years later its leader, J.C. Watson, became the world's first Labor prime minister. In 1908, and again from May 1910 to June 1913, Labor headed the government. In subsequent years the Labor Party has been frequently in office.

New Zealand. A loose Liberal-Labour alliance dominated New Zealand politics between 1893 and 1906, but the New Zealand Labour Party, as a social-democratic party committed to the socialization of the means of production, did not emerge until 1913. It grew steadily, coming to power in 1935 for the first of several periods of varying duration.

The Australian and New Zealand labour movements have been committed to a gradualist and reformist course since their inception. They are strongly tied to the unions, and though in principle pledged to a Socialist program they are in fact mainly concerned with using governmental control as a means of dealing with immediate problems and expanding social services. The various social security acts that they introduced helped to make Australia and New Zealand modern welfare states, and relatively equalitarian societies, even before World War II.

Canada. Canadian socialism had a slower beginning than its Australian and New Zealand counterparts. Prior to World War I the Canadian Socialist movement was split between two parties, neither of which managed to win seats in the federal Parliament. During the 1920s various Socialist and Labour parties flourished in different parts of Canada, but only rarely did they send a representative to the federal Parliament. Only with the organization of the Co-operative Commonwealth Federation (CCF) in 1932 did the Socialist movement begin to achieve national importance. Basing its campaigns on the need for "social and economic planning on a bold and comprehensive scale," it gained support in most provincial elections and in June 1944 was able to form a government in the province of Saskatchewan, where it remained in power for 20 years. In 1961 progressive union leaders of the labour congress met with the CCF leadership and formed the

New Democratic Party. Whereas the CCF had been largely agrarian in character, the new party had a following in the industrialized parts of the country. Advocating a planned economy, it stood for increased social security, government employment guarantees, large-scale construction of low-rent housing, and the like. Its policies were similar to those of postwar western European socialism.

Latin America. The historical roots of Latin American socialism are fairly old. Several branches of the First International were established in Argentina in the early 1870s. In Chile and Argentina, and to a lesser extent in other Latin American countries, socialists at times played leading roles, but they were hampered by a variety of splits and by the fact that their following consisted mainly of immigrant industrial workers. They failed to make an impact in rural areas. In Chile, however, they participated in various coalition and popular front governments in the 1920s, 1930s, and 1940s. In the elections of 1958, Chilean socialists supported the Popular Action Front (FRAP) candidate, Salvador Allende. He was narrowly defeated, and defeated again in 1964. In 1970, however, he won by a narrow plurality in a three-way presidential election and became head of a government supported by a popular front ranging from Communists to democratic reformers. His government, pledged to the nationalization of foreign-owned industry and to the planned reconstruction of the country, met with increasing economic turmoil and opposition from the middle class; Allende's expulsion by military coup in 1973 left the future of socialism in Chile uncertain. (L.A.C.)

Chilean socialism

Communism

The word communism, a term of ancient origin, originally meant a system of society in which property was owned by the community and all citizens shared in the enjoyment of the common wealth, more or less according to their need. Many small communist communities have existed at one time or another, most of them on a religious basis, generally under the inspiration of a literal interpretation of Scripture. The "utopian" socialists of the 19th century also founded communities, though they replaced the religious emphasis with a rational and philanthropic idealism. Best known among them were Robert Owen, who founded New Harmony in Indiana (1825), and Charles Fourier, whose disciples organized other settlements in the United States such as Brook Farm (1841–47). In 1848 the word communism acquired a new meaning when it was used as identical with socialism by Karl Marx and Friedrich Engels in their famous *Communist Manifesto.* They, and later their followers, used the term to mean a late stage of socialism in which goods would become so abundant that they would be distributed on the basis of need rather than of endeavour. The Bolshevik wing of the Russian Social-Democratic Workers' Party, which took power in Russia in 1917, adopted the name All-Russian Communist Party in 1918, and some of its allied parties in other countries also adopted the term Communist. Consequently the Soviet state and other states governed by Soviet-type parties are commonly referred to as "Communist" and their official doctrines are called "Communism," although in none of these countries has a communist society yet been established. The word communism is also applied to the doctrines of Communist parties operating within states where they are not in power. (For the ideological basis of Communism, see MARXISM.)

THE ORIGINS OF SOVIET COMMUNISM

Communism as it had evolved by 1917 was an amalgam of 19th-century European Marxism, indigenous Russian revolutionary tradition, and the organizational and revolutionary ideas of the Bolshevik leader Lenin. Marxism held that history was propelled by class struggles. Social classes were determined by their relationship to the means of production; feudal society, with its lords and vassals, had been succeeded in western Europe by bourgeois society with its capitalists and workers. But bourgeois society, according to Marxism, contained within itself the seeds of its own destruction: the number of capitalists would diminish, while the ranks of the impoverished proletariat would grow until finally there would be a breakdown and a Socialist revolution in which the overwhelming majority, the proletariat, would dispossess the small minority of capitalist exploiters.

Plekhanov's Marxism

Marxism had been known and studied in Russia for at least 30 years before Lenin took it up at the end of the 19th century. The first intellectual leader of the Russian Marxists was G.V. Plekhanov. Implicit in the teachings of Plekhanov was an acceptance of the fact that Russia had a long way to go before it would reach the stage at which a proletarian revolution could occur, and a preliminary stage would inevitably be a bourgeois democratic regime that would replace the autocratic system of Tsarism.

Plekhanov, like most of the early Russian Marxist leaders, had been reared in the traditional Russian revolutionary movement broadly known as Populism, a basic tenet of which was that the social revolution must be the work of the people themselves, and the task of the revolutionaries was only to prepare them for it. But there were more impatient elements within the movement, and it was under their influence that a group called "People's Will" broke off from the Populist organization "Land and Freedom" in 1879. Both groups were characterized by strict discipline and highly conspiratorial organization; "People's Will," however, refused to share the Populist aversion to political action, and in 1881 some of its members succeeded in assassinating Tsar Alexander II.

Lenin and Russian Populism. During the period of reaction and repression that followed, revolutionary activity virtually came to an end. By the time Lenin emerged into revolutionary life in Kazan at the age of 17, small revolutionary circles were beginning to form again. Lenin was a revolutionary in the Russian tradition for some time before he was converted to Marxism (through the study of the works of Marx) before he was yet 19. From the doctrines of the Populists, notably P.N. Tkachev, he drew the idea of a strictly disciplined, conspiratorial organization of full-time revolutionaries who would work among important sections of the population to win support for the seizure of power when the moment was ripe; this revolutionary organization would take over the state and use it to introduce Socialism. Lenin added two Marxist elements that were totally absent in Populist theory: the notion of the class struggle and the acceptance of the need for Russia to pass through a stage of capitalism.

Lenin's concept of the revolutionary party

Lenin's most distinctive contributions to Communist theory as formulated in *What Is To Be Done?* (1902) and the articles that preceded it were first, that the workers have no revolutionary consciousness and that their spontaneous actions will lead only to "trade union" demands and not to revolution; second, the corollary that revolutionary consciousness must be brought to them from outside by their intellectual leaders; and third, the conviction that the party must consist of full-time, disciplined, centrally directed professionals, capable of acting as one man.

Lenin's tactics led in 1903 to a split in the Russian Social-Democratic Workers' Party. With his left-wing faction, called the Bolsheviks, he strove to build a disciplined party and to outwit and discredit his Social-Democratic opponents. After the collapse of tsarism in February 1917, he pursued a policy of radical opposition to the Socialists and Liberals who had come to power in the provisional government and he eventually succeeded in seizing power in October 1917. Thereafter he eliminated both the opposition of other parties and his critics among the Bolsheviks, so that by the 10th party congress in March 1921 the Bolsheviks (or Communists) had become a monolithic, disciplined party controlling all aspects of Russian life. It was this machine that Stalin inherited when he became general secretary of the party in 1922.

THE THIRD INTERNATIONAL

The victory of the Bolsheviks in Russia gave a new impetus to the more extreme left wings of the Socialist parties in Europe. Lenin's relations with the European Socialist parties had been hostile even before World War I. During the war he had endeavoured to assert his influence over the dissident left wings of the Socialist parties of the belligerent powers, and at two conferences in Switzerland, in 1915 and in 1916, he had rallied these dissident groups to a policy of radical opposition to the war efforts of their governments and to an effort to turn the war into a civil war. He had already decided by 1914 that, after the war, a Third International must be formed to take the place of the Second International of Socialist parties, which had failed to oppose the war despite its strong antiwar tradition. By 1919, when the new Soviet regime in Russia was fighting for its survival, the intervention on the anti-Soviet side by Britain, France, and the U.S. was a powerful and practical argument to be used by Soviet Russia in its appeals for revolution in capitalist countries. It early became clear the Third International would reflect the influence of Soviet Russia and that it was likely to become subordinate to Soviet aims and needs.

Communism's emergence as an international movement

Lenin's 21 conditions. The Third International, or Comintern, had its first congress in 1919. This gathering of a very few parties in Moscow was more symbolic than real; the main structure of the new International was not hammered out until the second congress in July 1920, also in Moscow. Hopes of world revolution ran high; the prestige of the new Soviet state was in the ascendant, and the resolutions adopted at this congress reflected in the fullest possible way Lenin's idea of what a Communist party should be. It was to be the "main instrument for the liberation of the working class," highly centralized and disciplined according to the formula of "democratic centralism" on which the Bolshevik Party had been founded. Twenty-one conditions were laid down by the congress as prerequisites for parties affiliating with the Comintern. These conditions were designed to ensure a complete break with the older Social Democratic parties from which the Communist parties were splitting off. The new parties were required to adopt the name Communist in their title, to urge open and persistent warfare against reformist Social Democracy and the Second International, to maintain a centralized and disciplined party press, to conduct periodic purges of their ranks, and to carry on continuous and systematic propaganda in the army and among the workers and peasants. Each constituent party was to support in every possible way the struggle of "every Soviet republic" against counterrevolution. Decisions of the Comintern and of its executive committee were to be binding on all members, and the breach of any of these conditions was to be ground for expelling individual members from their parties—a provision that in future years was to be interpreted very broadly.

The New Economic Policy. The prestige of Soviet Russia, the rigid discipline imposed by the 21 conditions, and certain other factors ensured the predominance of Russian control and Russian interests over the Comintern. Though the predominance increased during Stalin's time, it was clearly evident while Lenin was still alive. At the third world congress in June and July 1921, the Comintern was confronted by Lenin with his New Economic Policy—a program encouraging small private enterprise, which several months earlier he had put into effect inside Russia. Lenin wanted a temporary halt to the revolutionary upsurge in Europe to give him time to develop stable trade relations with capitalist countries, to whom the Soviet state was preparing to grant trading and industrial concessions. Comintern members were required to support this policy, and the expulsion of the German Communist leader Paul Levi after the failure of a Communist uprising in Germany in March 1921 showed how determined the leaders of the Comintern were to put down inconvenient left-wing "adventures." It was with the requirements of the New Economic Policy in mind that the Comintern executive committee in December 1921 launched the turnaround policy of the United Front and of trade union unity. This policy of rapprochement with Socialists and liberals was likewise designed to gain support for Lenin's policy of consolidation at home by appealing to a broader spectrum of opinion in the capitalist countries.

STALINISM

From Lenin to Stalin

Socialism in one country. Lenin's successor, Joseph Stalin, always claimed to be his faithful follower, and this was to some extent true. Stalin's doctrine that Socialism could be constructed in one country, the Soviet Union, without waiting for revolution to occur in the main capitalist countries (a position he had developed as an integral part of his struggle against Trotsky) was not far removed from the line pursued by Lenin in 1921 when he introduced the New Economic Policy. Both Lenin and Stalin accepted the primary importance of the survival and strengthening of the Soviet state as the main bastion of the future world revolution; both accepted the need for a period of coexistence and trade with the capitalist countries as a means of strengthening socialism in Soviet Russia. Nor did Stalin's later policy of industrialization and collectivization, in theory at least, represent a departure from Lenin's doctrine. Industrialization was central to Lenin's plans, though he did not live to put them into practice. Stalin's view, however, that the construction of socialism led inevitably to an intensification of the class struggle, which in turn required a policy of internal repression and terror, is nowhere to be found in Lenin's writings. On the contrary, Lenin repeatedly emphasized in 1922 and 1923 the necessity of bringing about a reconciliation of the classes and especially of the peasants and workers.

Stalin's internal policy was to have wide repercussions in the Comintern and on Communism generally. From 1924 until 1928 his first concern was to defeat his main rival, Trotsky, and this seems to have been one of the main factors determining his policy at this time. As against the more internationalist and doctrinaire Trotsky, Stalin pursued "socialism in one country" and continued to implement Lenin's New Economic Policy with its limited freedom for business enterprise and peasant individualism. In this he could still claim to be following Lenin's wishes. But Stalin also worked with great skill to ensure his control over the party. By 1927 when Trotsky was expelled from the party, Stalin already controlled both the network of party officials (the *apparat*) and the delegates to congresses and conferences. Debate had been replaced by ritualized unanimity; dissent was permitted only when it served the purposes of the leadership.

When Trotsky was exiled from the country in 1929, he became the focal point for opposition to Stalin among dissident Communists all over the world, although he was to be more a symbol than an active political force. Having defeated Trotsky and his allies, Stalin next switched policies, abandoning the New Economic Policy in favour of rapid industrialization along with the collectivization of agriculture. The collectivization policy ultimately produced a famine, costing the lives of millions of peasants. The reversal of the New Economic Policy and of Lenin's policy necessarily involved eliminating from the political scene Stalin's former allies, headed by Nikolay Bukharin, who wanted to go slower with industrialization and to cultivate support among the peasants. The protracted conflict, first with Trotsky and his ally G.Y. Zinovyev and then with Bukharin, was reflected in the Comintern and in the world Communist movement, which became increasingly subordinated to Stalin's policy concerns inside the Soviet Union.

Stalin and the Comintern. The regimentation of the Comintern and of the parties represented in it began at the fifth world congress in June 1924, immediately after Lenin's death. The elimination of Trotsky and his supporters within the Soviet party was followed by widespread expulsions of the "left" from the other world parties. The control of the Soviet-dominated Comintern apparatus was increasingly asserted over the tightly disciplined governing bodies of the foreign parties, which in turn ruled over their members with the instrument of the purge. Ideologically, this procedure was carried out at first under the screen of the United Front, which called for cooperation with Social Democrats and other moderate leftists. At the sixth world congress in 1928, however, a further switch in policy was dictated by Stalin's internal conflict: the United Front tactic was abandoned, and the Social Democrats now became enemies along with Fascists. The sixth congress also declared the main duty of the international working-class movement to be the support of the U.S.S.R. by every means. The united front tactic was revived in 1935 at the seventh (and last) world congress of the Comintern under the name of the Popular Front, calling for united action by Communists and Socialists together against Fascism.

The Nazi–Soviet pact

Comintern policy changed again in August 1939 when the Soviet Union and Germany concluded a 10-year treaty of nonaggression. This had the effect of freeing Hitler to fight a war against Britain and France. Anti-Fascism was now jettisoned, and the Communist parties were required, up to the moment when Germany invaded the Soviet Union on June 22, 1941, to denounce the allied war against Hitler and to recognize Nazism as "the lesser evil" in comparison with Western imperialism. The Soviet alliance with Germany is usually seen as proof that Stalin was primarily concerned with what he considered to be the interests of the Soviet Union. A secret protocol annexed to the treaty assigned the Baltic states (Latvia, Lithuania, and Estonia), about half of Poland, and Bessarabia to the Soviet sphere of influence. The evidence suggests that Stalin considered the deal with Hitler to be based on mutual interests; the German invasion in 1941 took him by surprise. After the defeat of Hitler, Soviet territorial demands were again advanced.

Stalin's method of rule. The Communist parties of the world were also called on to adopt official Soviet justifications for Stalin's internal purges, which involved the extermination of a large proportion of the Soviet party membership, including most of the leading cadres. The subservience of some Communist parties to official assertions made by the Soviet authorities sometimes earned them the reputation of being little more than agents of the Soviet Union inside their own countries, though this did not necessarily diminish their influence or importance in several countries of Europe or in the United States. They found much support among sympathizers with Marxism, who were prepared to overlook Soviet realities in the service of their ideals or of what they considered to be the historical destiny of mankind—in which they saw Stalinism as merely a transitory stage. The Communists and their parties and their contacts provided a valuable recruiting ground for intelligence agents of all kinds prepared to act against their own countries in the interests of Soviet Russia. The effects of Stalin's internal policy on the Communist parties outside the Soviet Union are of vital importance in understanding the attitude adopted by these parties after 1956, when much of Stalin's policy was officially repudiated.

Stalin's method of rule came, by imitation, to be the standard in all other parties. It hinged primarily upon the dominance of his own personality. He ruled over the country in large measure not through the party, as Lenin had, but through personal agents (like Lavrenty Beria, Andrey Vyshinsky, or Georgy Malenkov) and also through the security police (NKVD). The party as an institution declined under Stalin, and between 1934 and 1952 there was only one party congress, in 1939. The general secretaries of the Communist parties abroad imitated Stalin, and strict hierarchical subordination became the way of party life.

GROWTH OF COMMUNISM DURING AND AFTER WORLD WAR II

The wartime prestige of the U.S.S.R.

The undeclared assault by Hitler on the Soviet Union provoked a wave of sympathy for that country among both the open and secret enemies of Hitler in Europe. The Soviet pact with Hitler, and even the manifest blemishes of Stalin's regime, were forgotten: sympathy with the newly emerged force of resistance to the Nazi scourge far outweighed past memories. Many, it is true, expected the immediate defeat of the Soviet Union. As time went on, however, and the Soviet struggle continued with enormous sacrifice of life and with courage and skill that none could help but applaud, admiration for Soviet military achievements grew even among those who had been most critical and apprehensive of the Soviet political role before the war. The Communists of other countries shared in the prestige won by Soviet military prowess. This was particularly the case in occupied France and Italy where the underground Communist parties played a vital role in the resistance movements. In Yugoslavia, too, the Communist partisan movement led by Tito (Josip Broz) outstripped the nationalist guerrillas in effectiveness and won the material support of Britain.

Russian nationalism. The policy pursued by Stalin accentuated the nationalist side of the war and attempted in every way to play down the Communist element. At home, tsarist history and the rituals of the Eastern Orthodox Church were invoked in efforts to raise patriotic sentiments to the highest possible pitch. Abroad, Communist aims and ideals were replaced by anti-Nazi, liberal-democratic slogans. The dissolution of the Comintern in 1943 was in line with this policy. It had long ceased to be necessary as an instrument of Soviet control over the foreign Communist parties, which was carried on through other channels; but the publicizing of its dissolution added force to the growing persuasion abroad that the Soviet Union had left its revolutionary past behind it and was now a great power with traditional nationalist and security aims. Stalin himself emphasized that the dissolution of the Comintern would "put an end to the lies spread by Hitler that the Soviet Union wished to Bolshevize other countries" and that Communist parties "followed foreign directives." Still another factor promoting the influence of Communism during World War II was the enhanced prestige of Stalin himself and the extent to which his personality influenced the allied leaders Winston Churchill and Franklin D. Roosevelt.

Stalin and eastern Europe. His growing military and political prestige in turn influenced Stalin's policy towards his allies and determined the future course of Communism after victory was won in 1945. Two main lines of Soviet policy can be discerned in the wartime conferences at Tehrān, Yalta, and elsewhere: first, a determination by the Soviet Union that friendly political regimes should be established in the countries on Russia's borders, and second, that the Soviet Union's hard-won status as a great power should be fully recognized in the postwar settlements. These demands were not in themselves unreasonable, considering the enormous price that the Soviet people had paid for victory. In pursuing the creation of a solid Soviet-dominated bloc of Communist states in east-central Europe, Stalin was able to take advantage of the presence of a victorious Soviet army in Poland, Bulgaria, Romania, Hungary, and East Germany. The cases of Yugoslavia and Albania were different, but the regimes that emerged in all these countries were broadly similar forms of Communist party domination based on the Soviet model, even though the ways in which the Communists achieved power varied.

The expansion of Soviet influence

Broadly speaking, three phases could be distinguished. In the first phase there was a genuine coalition of Communist and Socialist parties. This lasted until the spring of 1945 in Romania and Bulgaria, until the spring of 1947 in Hungary, and until February 1948 in Czechoslovakia. Yugoslavia, Albania, Poland, and East Germany never knew this phase: the former two started as "monolithic," while the latter two began their postwar history in the second phase, an alleged coalition in which the Socialist parties were nominally independent and had some share in power but in which their leaders and policies were largely determined by the Communists. In the third phase, the "monolithic" phase, the nominally independent Socialist parties were required to fuse with the Communists, political opposition was largely suppressed, and Socialist leaders went into exile or were dealt with by staged treason trials. In Poland, Bulgaria, and Romania the third phase began in the autumn of 1947; in Hungary, in the spring of 1948. In East Germany the third phase was complete by 1949.

In his policy toward the countries which were destined to form the Soviet bloc, Stalin was aided in part by the inability or unwillingness of the Western allied powers to take steps during the first or second phases described above to prevent the beginning of the third phase and in part by the skillful infiltration of local Communists into key positions. The peasant and Socialist parties, which had substantial support in their countries, were attacked in various ways and demolished as independent political bodies.

Yugoslavia was an exception. There the Communists under the leadership of Tito enjoyed a considerable measure of mass support because of their wartime role as partisan fighters. The People's Democracy they instituted in Yugoslavia was for some years little different in character from that of other Communist-party-dominated states of eastern Europe. An attempt to set up a People's Democracy in Greece failed after three years of civil war, in which the Greek Communists were supported by Yugoslav aid.

The failure in western Europe

In the countries of Europe outside the Soviet bloc, Communist parties proved unable to exploit the prestige that they had acquired during the war. Both in France and in Italy they enjoyed considerable support: in the parliamentary election of 1945 in France the Communists received 26 percent of the vote, and in the general elections to the Constituent Assembly in Italy in June 1946 they received 19 percent. Both parties, however, failed to achieve real national power in the postwar period; their role was confined to fomenting strikes and disorder in the interests of Soviet policy. The detailed story of the Italian and French Communist parties during the period 1945 to 1949 is complex, but, broadly speaking, their attempts at insurrection foundered against the facts of the power of the army and the police and a lack of revolutionary zeal among their worker supporters. On the other hand, their attempts to win power by parliamentary means were frustrated by the distrust that the Socialists felt for them as colleagues in Parliament or in government and by their own evident lack of interest in a viable parliamentary system.

Communism's growth in Asia. Powerful Communist parties emerged after the war in various parts of Asia, in many cases largely as a result of the resistance of the Western powers to growing nationalist movements. Communist-led insurrections, allegedly coordinated by Moscow, broke out in the summer of 1948 in Burma, Malaya, and Indonesia. In Indochina, after the surrender of Japan, the Communists under Ho Chi Minh seized power in the three northern provinces of the country. French colonial policy helped drive the nationalists into the arms of Ho Chi Minh, and by the end of 1946 a guerrilla war had broken out in the country that was to last for nearly three decades before the Communist victory of 1975. In Japan democratic legislation imposed by the United States after its victory permitted the Communists to operate legally. In the succeeding few years they made little progress toward governmental power but won considerable gains in the trade unions and an important measure of influence among university students. In India the Communist Party supported the British war effort after June 1941 and gained ground as a result; it switched to violent insurrection after Indian independence but abandoned this policy in 1950.

Chinese Communism

The most significant factor in the postwar history of Communism in Asia may have been the victory in 1949 of the Chinese Communist Party under the leadership of Mao Tsetung. China, rather than the Soviet Union, seemed destined to play the leading role in Asian Communism. The victory of the Chinese Communists over Chiang Kai-shek and the Kuomintang, like that of Tito's forces in Yugoslavia, owed little if anything to Soviet aid—save that the Russians had handed over to the Chinese Communists the military stores captured from the Japanese during the very short period when the U.S.S.R. was at war with Japan in 1945. Although the Chinese Communist Party had developed under the aegis of the Comintern and acknowledged the doctrinal authority of Lenin and Stalin, its experience had been very different. Its victory had been preceded by long guerrilla warfare. Mao's rise to power had, moreover, been achieved by ignoring Soviet advice as much as by following it. Stalin showed quite clearly from the outset that he intended to keep China in a position of subordination not unlike that which he had successfully marked out for most of eastern Europe—a status the Chinese Communist leaders were not likely to accept. Culturally, economically, and geographically, China was in a strong position to become the model for Communist revolution in Asia and to wrest the leadership of Asian Communism from the Soviet Union. These and other factors were to produce signs of a possible breach between China and the U.S.S.R. within less than 10 years of the proclamation of the Chinese People's Republic on October 1, 1949.

THE WORLD MOVEMENT UP TO STALIN'S DEATH

The Cold War

The wartime alliance had given rise to some hopes that Soviet-Western amity would continue. Stalin's relentless pursuit of security through the domination of neighbouring countries shattered this hope. At home Stalin returned to his prewar tactics: widespread arrests and deportations occurred in the newly incorporated or reincorporated territories of the Soviet Union; the restriction of cultural life was intensified; the straitjacket was reimposed on the party, on the peasants, and on the industrial workers. There is some evidence to suggest that at the time of his death in March 1953 Stalin was planning a new purge on the scale of the 1936–38 purges.

The struggle with the West. Soviet expansion into eastern Europe led to counteractions by the Western powers that Moscow interpreted as part of a master plan to encircle and subjugate the Soviet Union. These included the Truman Doctrine of containment of Soviet expansion proclaimed in March 1947; the offer in June of that year by United States Secretary of State George Marshall to underwrite the economic recovery of Europe; and the North Atlantic Treaty of April 1949, which established a permanent defense force for western Europe, including in its orbit West Germany. Another factor that affected Soviet policy was the monopoly of the atomic bomb enjoyed by the United States from 1945 until 1949. The Soviet Union rejected the Baruch Plan put forward by the U.S. for the international control of atomic weapons and made every effort to produce its own, succeeding in September 1949. The "Cold War" was on.

The defection of Yugoslavia. In September of 1947 a new international organization, the Communist Information Bureau (Cominform), was established. Unlike the old Third International (Comintern), the Cominform was limited in membership to the Communist parties of the Soviet-dominated countries of east-central Europe and to the French and Italian Communist parties. The aim of the Cominform was to consolidate and expand Communist rule in Europe. Plans for the establishment of Communist rule in Czechoslovakia were discussed, and the French and Italian parties were reproved for their failure to win power in their own countries.

The Cominform did not prove a success. Certainly one of its purposes was to hold Yugoslavia more securely within the Communist fold, and for this reason Belgrade was chosen as the seat of the new organization. But within a few months a quarrel broke out between the Soviet and Yugoslav parties, and when the Cominform held its second meeting in June 1948, it was for the purpose of denouncing the Yugoslav Communist Party and expelling it from the organization. The quarrel with Yugoslavia resulted largely from Tito's refusal to submit to domination by the Soviet Union; there was also some suspicion on the Soviet side, possibly well founded, that the Yugoslav party leader hoped to build up a bloc of Communist states in southeastern Europe that would not be totally dependent on the Soviet Union.

The effect of the Soviet-Yugoslav quarrel, which has never completely healed, was momentous. First, it shattered the doctrine that the Communist movement must be monolithic, since a Communist party had challenged Moscow and survived. Second, Yugoslavia, having broken with the U.S.S.R., was in a position to assume a role of considerable influence in the world, especially toward states formed in formerly colonial territories. The Yugoslavs could speak as Communists who, while opposed to the policy of the imperialist powers, were no mere agents of Soviet policy. This position carried a particularly strong appeal in India, but the impact of the Soviet quarrel with Tito was much wider.

A third effect of the Yugoslav defection was a tightening of the Soviet hold over the remaining members of the Communist bloc. In Soviet-dominated lands "Titoism" became synonymous with treason, much as "Trotskyism" had been in the '30s. Purges and public trials ensued throughout eastern Europe. In some cases, like that of Władysław Gomułka in Poland (who was left alive), or Koci Xoxe in Albania, the charge of sympathy with Yugoslavia may have been true; in others, like those of

László Rajk in Hungary or Traicho Kostov in Bulgaria, the offense may have been only an attempt to resist Soviet domination; in the trial of Rudolf Slánský in Czechoslovakia in 1952, a strong anti-Semitic element played a part. Countries of the Communist bloc were seething with anti-Soviet and nationalist feeling by the time Stalin died. Though Stalin's postwar policy was successful in extending the boundaries of Soviet military and political control well into eastern and central Europe, Communism did not win out in France or in Italy, where its chances had appeared strongest. The policy of expansionism and of intransigence founded on suspicion of the United States led to a kind of consolidation of the West against the Soviet Union. In the Far East the Korean War was probably not a success from the Communist point of view. Korea had been divided after the defeat of Japan: in the northern part a Communist government came to power in elections held in November 1946, and in the south a non-Communist government was established. Each claimed to be the legal government of the whole country. Invasion of the south by the north in June 1950 was condemned by the Security Council of the United Nations as aggression, and the Security Council approved military assistance to South Korea under a unified American command. (The absence of the Soviet representative from the Security Council prevented the U.S.S.R. from vetoing this resolution.) The long war, in which China intervened on the side of North Korea, brought heavy burdens and few, if any, advantages, and the conflict between the major powers that it involved led them in the fears of many to the verge of world war. In June 1951 the Soviet Union proposed discussions for an armistice, to which the Western powers agreed. The negotiations were protracted and did not result in an armistice until after Stalin's death in 1953.

THE BREAKUP OF THE WORLD COMMUNIST MONOLITH

Stalin's heirs

The Khrushchev era. Stalin died on March 5, 1953. For a short time, until the beginning of 1955, power was nominally divided between Georgy Malenkov, the chairman of the Council of Ministers, and Nikita Khrushchev, the first secretary of the Communist Party. Almost from the beginning, Khrushchev was the dominant of the two; his victory over his rival was only a matter of time. Malenkov, it would seem, decided quite early that the Soviet Union could not maintain its hold over the Eastern bloc without substantial economic relaxation. The difficulties that always beset the reform of an oppressive regime were soon illustrated in East Germany. Within a week of the announcement by East German leaders that "aberrations" of the past would be rectified and some of the hardships of life alleviated, there was an uprising in the streets of East Berlin; it spread to other parts of East Germany and was quelled only by the use of Soviet armed forces. The blame for this was laid on Lavrenty Beria (the Soviet security chief, shortly to be deposed and executed) and by implication on Malenkov. The new relaxed policy continued, however, in most of the Soviet-bloc countries. Economic reforms were initiated in Hungary, Czechoslovakia, and Poland, but the system of political rule remained unchanged.

Khrushchev, who by the beginning of 1955 had ousted Malenkov, had a comprehensive vision of how the Eastern bloc should be run. He was determined to find a way out of the straitjacket in which Stalin had confined Soviet life; the outcome was to have momentous consequences for Soviet dependencies abroad, which Khrushchev probably did not at the time foresee. His policy toward the Communist satellite countries may be summarized as one of cooperative integration instead of exploitation, with some degree of economic and political autonomy (under Communist Party leadership). A political and military convention between the European Communist states and the U.S.S.R. (the Warsaw Pact) was signed in May 1955. Khrushchev also sought to redesign the Council for Mutual Economic Assistance, the Communist counterpart of western Europe's Common Market, which Stalin had set up in January 1949: he tried (though with indifferent success) to transform the Council for Mutual Economic Assistance into a device for promoting the division of labour, economic specialization, and technical and financial cooperation among the countries of the bloc.

The crises of 1956. In order to demonstrate that Stalin's policy was a thing of the past, Khrushchev made substantial efforts to effect a reconciliation with Tito and the Yugoslav Communists (against the opposition of some of his colleagues, including Vyacheslav Molotov). An agreement with Yugoslavia in June 1956 recognized that "the conditions of Socialist development are different in different countries" and stated that no Socialist country should impose its views on another. This was a momentous change in policy, since it meant that a country could be described as "Socialist" without being obliged to follow all the practices adopted by the Soviet Union or every Soviet turn in foreign relations.

Khrushchev's criticism of Stalin

The reconciliation with Yugoslavia was only one of several important events that made the year 1956 a watershed in the history of Communism. In February, at the 20th congress of the Communist Party, Khrushchev delivered a speech in secret session in which he attacked the period of Stalin's rule in most forthright terms. The speech was not published within the Soviet Union, but its text was widely circulated among Communists both within and outside the Soviet Union and was published by the U.S. State Department. Its effect was enormous. Although the disclosures were neither complete nor entirely new, the fact that Khrushchev had uttered them caused a ferment in the Communist movement that was to prove irreversible. It inaugurated a period of freedom of debate and criticism that had been unknown for a quarter of a century; despite efforts both by Khrushchev and by his successors to keep criticism of the "cult of personality" (the accepted euphemism for Stalin's misdeeds) within bounds, the ferment could not be contained.

The Hungarian Revolution. In the European Communist countries, Khrushchev's disclosures opened the floodgates of pent-up criticism and resentment against the local Stalin-type leaders. In Hungary, Mátyás Rákosi was ousted as party leader in July 1956 and replaced by Ernő Gerő. But Gerő was unable to contain the rising tide of unrest and discontent, which broke out into active fighting late in October, and appealed for Soviet help. The first phase of the Hungarian Revolution ended in victory for the rebels: Imre Nagy became premier and agreed, in response to popular demands, to establish a multiparty system; on November 1 he declared Hungarian neutrality and appealed to the United Nations. On November 4 the Soviet Union, profiting from the lack of response to Nagy from the Western powers, and from the British and French involvement in action against Egypt, invaded Hungary in force and stopped the revolution. In Poland, where the ferment was also reaching dangerous intensity, the Soviet Union accepted a new party leadership headed by the more moderate Władysław Gomułka. There are believed to have been two reasons for this difference in Soviet policy. One was that in Poland the Communist Party remained in control of the situation. The other was that the invasion and subjugation of Poland would have required a military force several times that required in Hungary.

Polycentrism. Inside the Communist states, the suppression of the Hungarian Revolution had a restraining effect. There was, nevertheless, no return to the Stalinist type of domination and exploitation; a slow evolution followed toward a degree of internal autonomy, even in Hungary. The events of 1956 also had profound effects upon Communists outside the Soviet bloc. There were many resignations after the Hungarian Revolution, and those who remained in the fold began to question both Soviet leadership and the nature of a system that had made the ascendancy of Stalin possible. The most trenchant questioning came from the leader of the Italian Communist Party, Palmiro Togliatti, who concluded that the Soviet pattern could no longer be the model for all other countries and called in June 1956 for decentralization of the Communist movement, a view that became known as "polycentrism." "The whole system becomes polycentric, and . . . we cannot speak of a single guide but rather of a progress which is achieved by following paths which are often different." Although the Italian Communist Party, or segments of it, were still prepared to support the Soviet Union at times of crisis, at other times it took positions different from those of the Soviet Union.

Opening of the rift with China

The Sino-Soviet dispute. A gathering of Communist parties in Moscow in November 1957, in which China played a leading role, attempted to reassert a common doctrine while recognizing the need for differences in national practice. At Chinese insistence it also retained the Stalinist emphasis on the leadership of the Soviet Union. For a short time relations between the Soviet Union and China were harmonious: after 1955 Khrushchev had put an end to the humiliating terms that Stalin had imposed on China and inaugurated a policy of substantial economic aid.

The differences between China and the Soviet Union, which were to erupt into an open campaign of mutual abuse by 1962, were discernible to most observers by 1959, when the Soviet Union failed to give immediate political backing to Chinese military action against India and when China, at the same time, showed suspicion of Soviet talks with the United States in pursuit of Khrushchev's policy of "peaceful coexistence." In 1960 the differences widened, though they were still unpublicized. The Soviet Union withdrew its technical advisers from China as a preliminary to what was to prove an almost complete severing of economic relations. A facade of agreement was maintained, and at a conference of Communist parties held in Moscow in 1960 a series of resolutions was put forth to show that unity prevailed as ever in the ranks of the world Communist movement. News of serious disagreements, however, soon leaked out, for the increasing number of dissident groups within the several parties had by now rendered the maintenance of secrecy impossible. In the following year, 1961, the Soviet Union began a public polemic against the Chinese viewpoint. This was disguised as an attack on Albania, since 1959 a client of China and increasingly critical of Khrushchev's foreign policy. By 1962 the quarrel had become open and very bitter. It was conducted as a dispute over doctrine, but the practical issue underlying it was a basic rivalry for leadership of the world revolutionary movement.

The Sino-Soviet dispute had three major effects on this movement. It shattered the pretension that Marxism-Leninism offered a single world view, since at least two radically different ways of interpreting Marxism-Leninism were presented to Communists throughout the world, each backed by a Communist party in power with the prestige of a victorious revolution behind it. Second, it seriously impaired, if it did not destroy, the Soviet claim to be the leader of the world revolutionary movement. Since 1960 nearly all Communist parties have split into pro-Soviet and pro-Chinese portions, though outside Asia the Soviet portion has usually retained predominance. In the important parts of Asia, with the possible exception of India, where the party is divided into several warring factions, China has become the predominant influence upon Communist parties. Third, the mere fact of the dispute tended to create greater flexibility for individual parties within the Communist movement as a whole, even in the case of parties that nominally accepted Soviet leadership. The Romanians, for example, were able to follow a nationalistic course by which they successfully resisted Soviet attempts to integrate the Romanian economy into the bloc pattern. The Romanians also took an independent line in their trade relations with other countries, in refusing to participate in the 1968 invasion of Czechoslovakia, and in their policy toward Israel.

After the fall of Khrushchev in October 1964, his successors made efforts to reunite the world movement. They were only moderately successful. Seventy-five parties met in Moscow in June 1969, but of 14 parties in power five did not attend, and Cuba sent only an observer; Asia and Africa, the main areas of Chinese influence, were very poorly represented. Little unity emerged from the conference; in particular, the efforts of the Soviet Union to secure condemnation of China were unsuccessful. The resolution finally adopted was couched in such general terms as scarcely to conceal that the cracks had been merely pasted over. In the course of the 1970s, the hold of the Soviet Communist party over Communist parties outside the bloc seemed for a time to become weaker, with several parties (notably of France, Spain, and Italy) asserting independence from Moscow and the right to criticize Soviet policy. This movement, nicknamed "Eurocommunism," had lost much of its force by the end of the decade, however.

PROBLEMS OF INTERNAL REFORM

The attempt to modify Stalinism

A continuing problem in the history of Communist countries after the death of Stalin was the reform of their overcentralized political and economic structures. The only country that may be said to have achieved success was Yugoslavia, which had since 1948 asserted and maintained its independence from Soviet interference. After initially collectivizing much of its agriculture, Yugoslavia allowed the collective farms to dissolve. It also established Workers' Councils in the factories and publicized them in its foreign propaganda despite Soviet disapproval. The Yugoslav party program of 1958 contained three points in particular that were diametrically opposed to Soviet theory: that Socialism can be achieved without a revolution, that the Communist Party need not have a monopoly of leadership, and that danger of war arises from the existence of two power blocs in the world and not (as the Soviet Union contended) from the aggressive intentions of the United States. In January 1974, a new constitution was adopted that, apart from making changes in the representational system, provided for a collective presidency consisting of one member from each republic and autonomous province. Tito was elected president for life; after his death in 1980 this office rotated among the several members of the collective presidency.

Suppression of reform in Czechoslovakia. The most dramatic failure of an attempt at reform was in Czechoslovakia. The resignation of the old Stalinist party leader Antonín Novotný and his replacement by Alexander Dubček in January 1968 inaugurated a process of liberalization. The reformers hoped to humanize Communist rule by introducing basic civil freedoms, an independent judiciary, and other democratic institutions. The support of leading economists for this program was particularly significant since it indicated that they realized that the already accepted policy of economic decentralization (which included giving a measure of initiative to individual enterprises) would fail unless accompanied by political changes.

Invasion of Czechoslovakia

While the Czechoslovak Communists had repeatedly declared their intention to remain within the existing system, Moscow, possibly fearing that the developments they had set under way would ultimately endanger the stability of eastern Europe, endeavoured to induce the Czechoslovak party leaders to abandon their course. The Soviet effort failed, possibly because there were no Czechoslovak Communist leaders prepared, with Soviet help, to oust Dubček. Finally a group of Warsaw Pact forces—predominantly Soviet, but with token contributions from the other Warsaw Pact members except Romania—invaded Czechoslovakia on the night of August 20–21, 1968, effectively killing the momentum of the reform movement in Czechoslovakia. A Soviet-controlled security service was installed, and the Dubček leadership was gradually forced out of top posts and eventually expelled from the party. Although the repression was thorough, there was no mass terror.

The Soviet invasion of Czechoslovakia came as a greater shock to many Communists than the invasion of Hungary because it was directed against Communist leaders who strongly asserted their loyalty to Moscow. The motives that prompted Soviet action were probably two: one was the fear that the Soviet defense area created by Stalin after World War II might be endangered if the Dubček regime were allowed to continue; the other was the fear that the entrenched and conservative Communist parties in other European Communist countries, and in the Soviet Union itself, might not be equal to the challenge posed by a reformed Communism in Czechoslovakia.

Khrushchev's reforms. This concern that the power of the Communist party might be diminished may also have acted as a brake on internal reform. The reforms carried out by Khrushchev between 1953 and 1964 had been extensive. The arbitrary powers of the security police were brought under control; there were widespread reviews and rehabilitations (often posthumously) of the sentences of those sent to labour camps under Stalin; and reforms (in 1958) removed the worst anomalies of Soviet criminal law and procedure. The stringent controls over the lives of workers and farmers were relaxed. Discussion and debate were tolerated among writers and intellectuals to a degree that would have been inconceivable under Stalin. The whole system of agricultural management was considerably relaxed, and a system of incentives for the collective farmers was introduced. The limit of reform, as Khrushchev saw it, was the point at which any threat appeared to the party's control over all aspects of life. Under his successor, Leonid Brezhnev, the brake on reform was applied more heavily. Criticism of Stalin decreased. Freedom of opinion was considerably restricted by the introduction of penal provisions against "slandering" the Soviet system: for the first time since Stalin's death there were trials of writers, and the courts ceased to show any inclination to assert their independence as they had under Khrushchev. The numbers of political prisoners steadily increased, although the Brezhnev regime could not be compared to Stalin's. A movement toward economic reform had started under Khrushchev, aiming at some decentralization of economic control through greater freedom for enterprises to plan their own operations and through more influence for market forces. This was continued and officially encouraged after 1964 by Prime Minister Aleksey Kosygin, but it made little headway and was abandoned. The period of the 1970s was one of economic stagnation and conservatism at home, coupled with expansion of military power abroad.

Brezhnev's policy toward reform

COMMUNIST DOCTRINE AFTER STALIN

The errors of "revisionism" and "dogmatism." The most far-reaching innovation in Communist doctrine during the period 1953–70 was the Chinese interpretation of Marxism-Leninism known as Maoism. In the Soviet sphere several profound changes in doctrine took place after the death of Stalin. One change was the rise of ideological dispute for the first time since the early 1920s. The Yugoslav ideas were denounced as "revisionism," a term that harked back to the turn of the century when it had been used to characterize the views of Eduard Bernstein, who had argued that Socialism could be achieved without a revolution. After 1957 the terms "revisionism" and "dogmatism" became an integral part of Communist discourse. They were applied in a variety of meanings. By the Chinese, "revisionism" was used to mean, in effect, Khrushchevism—*i.e.,* the policies Khrushchev had introduced in both domestic and international relations, and which the Chinese opposed. On the Soviet side, "revisionism" became a catch-phrase to designate any political reform that appeared to endanger the dominance of the Communist Party: as defined at the Moscow conference of 1957 (with Chinese approval then) it was applied to all reform movements within the Communist system that denied "the historical necessity of the proletarian revolution," or the "Leninist principles for the construction of the party." The term "dogmatism," in Soviet usage, means a doctrinal conservatism that ignores changing realities, a clinging to received ideas in a way "calculated to alienate the party from the masses." The proper course, in the Soviet view, lies between revisionism and dogmatism: between excessive liberalism (as in Czechoslovakia in 1968), which may threaten the party's power, and excessive conservatism, which can lead to popular revolt (as in Hungary in 1956).

Program of the 22nd congress

Different roads to Socialism. The most important new elements in Soviet doctrine were set out in the party program adopted by the 22nd congress in October 1961; they were also, to some extent, embodied in the declarations of the Moscow conferences of 1957 and 1960. First, there was the concession that there are different roads to Socialism. This may have been no more than a practical recognition of the fact that since the breach with Yugoslavia and the death of Stalin it had no longer been possible for the Soviet Union to impose its own pattern on all Communist states. The invasion of Hungary in 1956, of Czechoslovakia in 1968, and of Afghanistan in 1979 were not, according to Moscow, inconsistent with this doctrine, since in each case the Soviet Union acted out of a duty to assist a fraternal Socialist state in putting down a counterrevolution. In the case of Czechoslovakia, which had not asked for such assistance, a new tenet was added by Brezhnev in November 1968. He contended that when "internal and external" forces hostile to Socialism attempted to restore capitalism in a Socialist country, it became a matter of concern to the whole Socialist community. This tenet was used to justify the action of the Warsaw Pact forces in August 1968 and of the Soviet forces in December 1979.

Peaceful coexistence. The second change in Soviet doctrine was the view that war between the capitalist and Socialist powers was no longer inevitable, as had always been asserted by both Lenin and Stalin. This was a practical recognition of the fact that a war waged with nuclear weapons would be more likely to lead to mutual annihilation than to victory. Khrushchev emphasized the possibility of "peaceful coexistence" between different social systems and the achievement of Socialism by peaceful means. In the 1970s "peaceful coexistence" became known as "détente." This doctrine raised hopes of real peace between Communist and non-Communist states, but the Soviet leaders made it clear that détente would not affect either political warfare against the West or military support for wars of liberation. The massive invasion of Afghanistan by the Soviet Uniȯn in December 1979 left détente seriously impaired.

The third doctrinal change after 1953 was also dictated by practical reality. The Comintern had rigidly applied concepts drawn from Western history to revolutions in Africa and Asia: industrialization, the emergence of a proletariat, and a Socialist revolution carried out under the leadership of a Communist party. This Marxist analysis proved to be totally unrealistic in the case of underdeveloped countries in which the predominant force was nationalism. This was increasingly recognized, after 1956, in Soviet doctrine that declared the proper revolutionary aim in the developing countries to be "national democracy." In Khrushchev's words this meant accepting a "noncapitalist path of development," which would be in the interests "not only of one class but of the broad strata of the people."

Priorities for the future. In the late 20th century the Soviet leadership faced two main problems: a slowing down in the rate of economic growth, to which the party had tied its promises of an improved standard of living, and a ferment of criticism among an intellectual minority, which included an influential component of leading scientists. Two alternatives seemed the most likely in the foreseeable future: either a return to more repressive measures, reminiscent of Stalin, or a reform of the Soviet system in the direction the Yugoslavs had taken. By the beginning of the 1980s, the prospects of reform in the direction of relaxation seemed remote, though the emergence of new leadership following the deaths of Leonid Brezhnev in 1982 and his successor Yury Andropov in 1984 left the question of the future open.

The Polish challenge

In other Communist countries within the Soviet sphere the fate of Czechoslovakia in 1968 seemed likely for some time to act as a deterrent against overbold attempts at reform. However, a return to the kind of domination achieved by Stalin seemed improbable, and the Soviet Union seemed likely to tolerate some degree of autonomy and variety among its fellow members of the Warsaw Pact. The emergence in Poland of Solidarity, a mass trade union movement independent of the Communist Party, briefly challenged the party's power in 1980, but, under Soviet pressure, the government responded in December 1981 with a decree of martial law under which Solidarity and other signs of dissidence were suppressed.

The future of Communism as a world movement necessarily depended upon relations between the Soviet Union and China. Their rivalry and their differences in doctrine seemed too deep for reconciliation. The economic backwardness of China, which would require decades to overcome, was likely to ensure a continuing gap in outlook between the two powers. In the competition for influence over potential revolutionary forces in Asia, Africa, and Latin America the advantages seemed to lie with China, which was closer to them in social and economic structure. On the other hand, the Soviet Union seemed likely to retain its lead over Communist parties in the industrially developed countries; even if it could no longer hope to use them as Stalin had, it could look to them as useful instruments in its continuing struggle against the non-Communist powers in general and the United States in particular. While the threat of Eurocommunism had receded, there seemed little prospect in the early 1980s of a return to the monolithic world Communist movement that Stalin had created.

(L.B.S.)

Anarchism

Anarchism is a term describing a cluster of doctrines and attitudes whose principal uniting feature is the belief that government is both harmful and unnecessary. Derived from a Greek root signifying "without a rule," the terms anarchism, anarchist, and anarchy are used to express both approval and disapproval. In early contexts all these terms were used pejoratively: during the English Civil War of the 17th century the opponents of the radical Levellers referred to them as "Switzerising anarchists," and during the French Revolution the Girondin leader Jacques-Pierre Brissot accused his most extreme rivals, the Enragés, of being the advocates of "anarchy."

> Laws that are not carried into effect, authorities without force and despised, crime unpunished, property attacked, the safety of the individual violated, the morality of the people corrupted, no constitution, no government, no justice, these are the features of anarchy.

These words uttered by the leader of the French Revolutionary moderates in 1793 could serve as a model for the denunciations delivered by all opponents of the anarchists. The latter, for their part, would admit many of Brissot's points. They deny man-made laws, regard property as a means of tyranny, and believe that crime is merely the product of a society based on property and authority. But they would argue that their denial of constitutions and governments leads not to "no justice" but to the real justice inherent in the free development of man's sociality, his natural inclination, when unfettered by laws, to live according to the principles and practice of mutual aid.

ANARCHIST THINKERS

The first man who willingly called himself an Anarchist was the French political writer and pioneer Socialist Pierre-Joseph Proudhon. In 1840, writing his controversial study of the economic bases of society, *Qu'est ce que la propriété?* (*What Is Property?*), Proudhon set out to shock his readers into attention by declaring: "I am an anarchist!" He went on to explain that in his view the real laws of society have nothing to do with authority but stem from the nature of society itself; he foresaw the eventual dissolution of authority and the emergence of a natural social order.

> As man seeks justice in equality, so society seeks order in anarchy. Anarchy—the absence of a sovereign—such is the form of government to which we are every day approximating.

The essential elements of the philosophy to which Proudhon in 1840 gave the name of Anarchism had already been developed by various earlier thinkers. There is a tradition of the rejection of political authority going back to classical antiquity, to the Stoics and the Cynics, and recurring throughout Christian history in dissenting sects such as the medieval Catharists and certain factions of Anabaptists during the Reformation. With such groups—often mistakenly claimed as ancestors by modern anarchist writers—the rejection of political government is merely one aspect of a retreat from the material world into a realm of spiritual grace; it becomes part of the search for individual salvation and as such is hardly compatible with the sociopolitical doctrine of Anarchism that in all its forms consists of (1) a fundamental criticism of the existing power-based order of society, (2) a vision of an alternative libertarian society based on cooperation as opposed to coercion, and (3) a method of proceeding from one order to the other.

The Diggers

English anarchist thought. The first sketch of an anarchist commonwealth in this sense was developed in the years immediately following the English Civil War by Gerrard Winstanley, a dissenting Christian who identified God with reason; he founded the minute Digger movement. In his pamphlet of 1649, *Truth Lifting Up Its Head Above Scandals,* Winstanley laid down what later became basic principles among the anarchists: that power corrupts; that property is incompatible with freedom; that authority and property are between them the begetters of crime; and that only in a society without rulers, where work and its products are shared, can men be free and happy, acting not according to laws imposed from above but according to their consciences. Winstanley was not only the pioneer of anarchist theory but also the forerunner of anarchist activism. He held that only by their own deeds can the people bring an end to social injustice, and in 1649, calling upon the people "to manure and work upon the common lands," he led a band of his followers in occupying a hillside in southern England, where they set about cultivation, established free communism among themselves, and offered passive resistance to the hostile landlords.

The Digger experiment was destroyed by local opposition, and Winstanley himself vanished into such obscurity that the place and date of his death are unknown. But the principles he defended lingered on in the traditions of English Protestant sects and reached their ultimate flowering in the masterpiece of a former dissenting minister, William Godwin, who in 1793 published his *Political Justice*—of which Sir Alexander Gray has said that in it "Godwin sums up, as no one else does, the sum and substance of anarchism, and thus embodies a whole tradition" (*The Socialist Tradition,* 1946, p. 134). This is essentially true, since Godwin not only presents the classic anarchist argument that authority is against nature and that social evils exist because men are not free to act according to reason but also sketches out a decentralized society in which the small autonomous community (the parish) is the essential unit. In his community, democratic political procedures are dispensed with as far as possible, because even the rule of the majority is a form of tyranny, and such procedures as voting dilute the responsibility of the individual; Godwin also condemns "accumulated property" as a source of power over others and envisages a loose economic system in which men will give and take according to their needs. Godwin was a prophet of technological progress; he believed that industrial development would eventually reduce the necessary working time to half an hour a day, provided men lived simply, and that this would facilitate the transition to a society without authority.

Godwin's classic argument

Godwin enjoyed great celebrity in the 1790s and influenced such varied writers as Percy Bysshe Shelley (whose *Queen Mab* and *Prometheus Unbound* are virtually anarchist poems), William Wordsworth, William Hazlitt, and Robert Owen, but he was almost forgotten by the time of his death in 1836. Though his ideas were to have, through Owen, a subterranean influence on the British labour movement, it is only recently that professed Anarchists have recognized his affinities with them. His *Political Justice* had virtually no effect on the quasi-political movement on the continent of Europe during the mid-19th century.

French anarchist thought. It was Pierre-Joseph Proudhon who laid the theoretical foundations of this movement. A brewer's son of peasant stock from the Franche-Comté, he started life (like many later anarchists) as a printer, but by the revolutionary year of 1848 he had already become a polemicist and a radical journalist with two books to his credit, *Qu'est ce que la propriété?* and *Système des contradictions économiques* (*System of Economic Contradictions*). These established him among the leading theoreticians of Socialism, a term that in the early 19th century embraced a wide spectrum of attitudes. In Paris during the 1840s, Proudhon associated with Karl Marx and the Russian Mikhail Bakunin, and, out of the experiences of the Revolution of 1848 (when he served in the Constituent Assembly and voted against the constitution "because it is a constitution"), he developed the libertarian theories that he discussed in later works such as *Du principe fédératif* (*The Federal Principle*) and *De la capacité politique des classes ouvrières* (*The Political Capability of the Working Classes*).

The work of Proudhon

Proudhon was a complex and voluminous writer who remained obstinately independent, refusing to consider himself the founder of either a system or a party. Yet he was justly regarded by Bakunin, Peter Kropotkin, and other leaders of organized Anarchism as their true ancestor, for he had adumbrated their philosophy.

Mutualism, federalism, and direct action were the essential doctrines Proudhon taught. By mutualism he meant the organization of society on an egalitarian basis. He declared that "property is theft," but this did not mean that he advocated communism. He attacked the use of property as a means of exploiting the labour of others, but he regarded "possession"—the right of a worker or group of workers to control the land or tools necessary for production—as an essential bulwark of liberty. He therefore envisaged a society formed of independent peasants and artisans, with factories and utilities run by associations of workers, all united by a system of mutual credit founded on people's banks. In place of the centralized state—the enemy of all Anarchists—Proudhon suggested a federal system of autonomous local communities and industrial associations, bound by contract and mutual interest rather than by laws, with arbitration replacing courts of justice, workers' management replacing bureaucracy, and integrated education replacing academic education. Out of such a network would emerge a natural social unity compared with which the existing order would appear as "nothing but chaos, serving as a basis for endless tyranny."

Proudhon remained all his life an independent polemicist, but in his final, posthumously published work, *De la capacité politique des classes ouvrières,* with its insistence that the liberation of the workers must be the task of the workers themselves organized in industrial associations, he laid the intellectual foundations of a movement that would reject democratic and parliamentary politics in favour of various forms of direct action. Unlike their master, Proudhon's working-class followers of the 1860s did not accept the title Anarchist (though in 1850 an independent revolutionary, Anselme Bellegarrigue, had founded a short-lived magazine entitled *L'Anarchie*); they preferred to call themselves Mutualists, after a working-class secret society bearing the same name to which Proudhon had belonged in Lyons during the 1830s. In 1864, shortly before Proudhon's death, a group of them joined with British trade unionists and European Socialists exiled in London to found the International Workingmen's Association (the First International). The Mutualists became the first opposition within the International to Karl Marx and his followers, who advocated political action and the seizure of the state in order to create a proletarian dictatorship. Marx's most formidable opponents, however, were not the Mutualists but the followers of Mikhail Bakunin, a Russian nobleman turned revolutionary who entered the International in 1868 after a long career as a political conspirator.

The work of Bakunin

Russian anarchist thought. Bakunin had begun as a supporter of nationalist revolutionary movements in various Slav countries. In the 1840s he had come under the influence of Proudhon, and by the 1860s, when he entered the International, he had not only founded his own proto-Anarchist organization, the Social Democratic Alliance, with a considerable following in Italy, Spain, Switzerland, and the Rhône Valley, but had modified the Proudhonian teachings into the doctrine that became known as collectivism. Bakunin accepted Proudhon's federalism and his insistence on the need for working-class direct action, but he argued that the modified property rights Proudhon allowed were impractical and instead suggested that the means of production should be owned collectively, though he still held that each worker should be remunerated only according to the amount of work he actually performed. The second important difference between Bakunin and Proudhon lay in their concepts of revolutionary method. Proudhon believed it was possible to create within existing society the mutualist associations that could replace it; he therefore opposed violent revolutionary action. Bakunin, declaring that "the passion for destruction is also a creative urge," refused to accept the piecemeal approach; a violent revolution, sweeping away all existing institutions, was in his view the necessary prelude to the construction of a free and peaceful society.

Though the individualism and nonviolence implicit in Proudhon's vision have survived in the peripheral currents of the anarchist tradition, it was Bakunin's stress on collectivism and violent revolutionary action that dominated the mainstream from the days of the First International down to the destruction of anarchism as a mass movement at the end of the Spanish Civil War in 1939.

The First International was itself destroyed by the conflict between Marx and Bakunin, a conflict rooted as much in the contradictory personalities of the two leaders as in their rival doctrines—revolution by a disciplined party versus revolution by the spontaneous insurgence of the working class. When the international finally broke apart at the Hague congress in 1872, Bakunin's followers were left in control of the working-class movements in the Latin countries—Spain, Italy, southern France, and French-speaking Switzerland—and these were to remain the principal bases of Anarchism in Europe. In 1873 the Bakuninists set up their own International, which lasted as an active body until 1877; during this period its members finally accepted the title of Anarchist rather than collectivist.

The work of Kropotkin

Bakunin died in 1876. His ideas had been developed in action rather than in writing, for he was the hero of many barricades, prisons, and meetings. His successor as the ideological leader, Peter Kropotkin (who renounced the title of prince when he became a revolutionary in 1876), is more celebrated for his writing than for his actions, though in his early years he led an eventful career as a revolutionary militant, which he described in a fine autobiography, *Memoirs of a Revolutionist* (1899). Under the influence of the French geographer Elisée Reclus (a former disciple of the Utopian Socialist Charles Fourier), Kropotkin developed the variant of anarchist theory known as anarchist communism. Kropotkin and his followers went beyond Bakunin's collectivism, since they argued not only that the means of production should be owned cooperatively but also that there should be complete communism in terms of distribution; this revived the scheme Sir Thomas More had sketched out in his 16th-century *Utopia* of common storehouses from which everyone should be allowed to take whatever he wished on the basis of "From each according to his means, to each according to his needs." In *La Conquête du pain* (*The Conquest of Bread,* 1892) Kropotkin sketched the vision of a revolutionary society organized as a federation of free communist groups. He reinforced the vision by writing *Mutual Aid: A Factor in Evolution* (1902), in which he endeavoured to prove by means of biological and sociological evidence that cooperation is more natural and usual among both animals and men than competition. In his *Fields, Factories and Workshops* (1899) he put forward ideas on the decentralization of industry appropriate to a nongovernmental society.

ANARCHISM AS A MOVEMENT

Anarchism and terrorism

Kropotkin's writings completed the theoretical vision of the Anarchist future, and little new has been added since his time. But this work was of less immediate importance than the emergence among the Italian anarchists of the theory of "propaganda of the deed." In 1876 Errico Malatesta expressed the belief of the Italian Anarchists that "the *insurrectionary deed,* destined to affirm socialist principles by acts, is the most efficacious means of propaganda." The first acts were rural insurrections, intended to arouse the illiterate masses of the Italian countryside. After the insurrections failed, Anarchist activism tended to take the form of individual deeds of protest by terrorists, who would attempt to kill ruling figures in the hope of demonstrating the vulnerability of the structure of authority and inspiring the masses by their self-sacrifice. In this way, between 1890 and 1901, a series of symbolic murders was enacted; the victims included King Umberto I of Italy, the empress Elizabeth of Austria, President Carnot of France, President McKinley of the United States, and Antonio Cánovas del Castillo, the prime minister of Spain. This brief but dramatic series of terrorist acts established the image of the Anarchist as a mindless destroyer; after 1901, however, the Anarchists continued to practice widespread terrorism only in such countries as Spain and Russia, where the general political atmosphere was conducive to violence.

During the 1890s, especially in France, Anarchism was adopted as a philosophy by avant-garde painters and writers. Gustave Courbet had already been a disciple of Proudhon; among those who in the 1890s accepted an Anarchist philosophy were Camille Pissarro, Georges Seurat, Paul Signac, Paul Adam, Octave Mirbeau, Laurent Tailhade, and, at least as a strong sympathizer, Stéphane Mallarmé. At the same time in England, Oscar Wilde declared himself an Anarchist and, under Kropotkin's inspiration, wrote his libertarian essay, "The Soul of Man Under Socialism" (1891).

The artists were attracted by the individualist spirit of Anarchism. By the mid-1890s, however, the more militant Anarchists in France began to realize that an excess of individualism had tended to detach them from the workers they sought to liberate. Anarchists, indeed, have always found it difficult to reconcile the claims of general human solidarity with the demands—equally insistent—of the individual who desires freedom. Some Anarchist thinkers, such as the German Max Stirner, who published *Der Einzige und sein Eigentum* (*The Ego and His Own*) in 1845, have refused to recognize any limitation on the individual's right to do as he will or any obligation to act socially; and even those who accepted Kropotkin's socially oriented doctrines of Anarchist communism have in practice been reluctant to create forms of organization that threatened their freedom of action or seemed likely to harden into institutions.

In consequence, although a number of international Anarchist congresses were held (the most celebrated being those of London in 1881 and of Amsterdam in 1907), no effective worldwide organization was created, even though by the end of the century the Anarchist movement had spread to all continents and was united by informal links of correspondence and friendship between the leading figures. National federations were weak even in countries where there were many Anarchists, such as France and Italy, and the typical unit of organization was the small group dedicated to propaganda by deed or word. Such groups engaged in a wide variety of activities; in the 1890s many of them concentrated on setting up experimental schools and communities that attempted to live out Anarchist principles.

Revolutionary Syndicalism. In France, where individualist trends had been most pronounced and public reaction to terrorist acts had imperilled the very existence of the movement, an effort was made to acquire a mass following. The Anarchists infiltrated the trade unions. They were particularly active in the *bourses du travail* ("labour exchanges"), local groupings of unions, originally set up to find work for their members, that appealed to the Anarchist ideal of decentralization. In 1892 a national confederation of *bourses du travail* was formed, and by 1895 the Anarchists, led by Fernand Pelloutier, Émile Pouget, and Paul Delesalle, had gained effective control and were developing the theory and practice of working-class activism that became known as Anarcho-Syndicalism, or Revolutionary Syndicalism.

Anarchism and the workers

The Anarcho-Syndicalists argued that the traditional function of trade unions—to struggle for better wages and working conditions—was not enough. The unions should become militant organizations dedicated to the destruction of capitalism and the state. They should aim to take over factories and utilities, which would then be operated by the workers. In this way the union or syndicate would have a double function—as an organ of struggle under the present dispensation and as an organ of administration after the revolution. To sustain militancy, an atmosphere of incessant conflict should be induced, and the culmination of this strategy should be the general strike. Many of the Syndicalists believed that such a massive act of noncooperation would bring about what they called "the revolution of folded arms," resulting in the collapse of the state and the capitalist system. But, although partial general strikes, with limited objectives, were undertaken in France and elsewhere with varying success, the millennial general strike aimed at overthrowing the social order in a single blow was never attempted. The Anarcho-Syndicalists acquired great prestige among the workers of France and, later, of Spain and Italy, because of their generally tough-minded attitude at a time when working conditions were bad and employers tended to respond brutally to union activity. After the great French trade-union organization, the Confédération Générale du Travail (CGT), was founded in 1902, their militancy enabled the Anarchists to retain control of the organization until 1908 and to wield considerable influence on its activities until after World War I.

Like Anarchism, Revolutionary Syndicalism proved attractive to certain intellectuals, notably Georges Sorel, whose *Réflexions sur la violence* (1908; Eng. trans., *Reflections on Violence,* 1914 and 1950) was the most important literary work to emerge from the movement. He argued the importance of the general strike as a social myth. The more purist Anarchist theoreticians were disturbed by the monolithic character of Syndicalist organizations, which they feared might create powerful interest structures in a revolutionary society. At the International Anarchist Congress at Amsterdam in 1907, a crucial debate on this issue took place between the young Revolutionary Syndicalist Pierre Monatte and the veteran Anarchist Errico Malatesta. It defined a division of outlook that still lingers in what remains of the historic Anarchist movement, which has always included individualist attitudes too extreme to admit any kind of large-scale organization.

Revolutionary Syndicalism did transform Anarchism, for a time at least, from a tiny minority current into a movement with considerable mass support, even though most members of Syndicalist unions were sympathizers and fellow travellers rather than committed Anarchists. In 1922 the Syndicalists set up their own International with its headquarters in Berlin, taking the historic name of the International Workingmen's Association; it still survives, with headquarters in Stockholm. When it was established the organizations that formed it could still boast considerable followings. The Unione Sindicale Italiana had 500,000 members; the Federación Obrera Regional Argentina, 200,000 members; the Portuguese Confederação General de Trabalho, 150,000 members; and the German Freie Arbeiter Union, 120,000 members. There were smaller organizations in Chile, Uruguay, Denmark, Norway, Holland, Mexico, and Sweden. In Britain the influence of Syndicalism was shown most clearly in the Guild Socialist movement that flourished briefly in the early years of the present century. In the United States, Revolutionary Syndicalist ideas were manifested in the Industrial Workers of the World (IWW), which in the years immediately before and after World War I played a vital part in organizing American miners, loggers, and unskilled workers; but only a small minority of the IWW militants were ever avowed Anarchists.

Syndicalist organizations

Anarchism in Spain. The reconciliation of Anarchism and Syndicalism was most complete and most successful in Spain; for a long period the Anarchist movement in that country remained the most numerous and the most powerful in the world. The first known Spanish Anarchist, Ramón de la Sagra, a disciple of Proudhon, founded the world's first Anarchist journal, *El Porvenir,* in La Coruña in 1845; it was quickly suppressed. Mutualist ideas were later publicized by Pi y Margall, a federalist leader and the translator of many Proudhon books; during the Spanish revolution of 1873, Pi y Margall attempted to establish a decentralist, or "cantonalist," political system on Proudhonian lines. In the end, however, the influence of Bakunin was stronger. In 1868 his Italian disciple, Giuseppe Fanelli, visited Barcelona and Madrid, where he established branches of the International. By 1870 they had 40,000 members, and in 1873 the movement numbered about 60,000, organized mainly in working men's associations. In 1874 the Anarchist movement in Spain was forced underground, a phenomenon recurring often in subsequent decades. It flourished, nevertheless, and Anarchism became the favoured type of radicalism among two very different groups, the factory workers of Barcelona and other Catalan towns and the impoverished peasants who toiled on the absentee-owned estates of Andalusia.

As in France and Italy, the movement in Spain during the 1880s and 1890s was inclined toward insurrection (in Andalusia) and terrorism (in Catalonia). It retained its strength in working-class organizations because the courageous and even ruthless Anarchist militants were often the only leaders who would stand up against the army and the employers, who hired squads of gunmen to engage in guerrilla warfare with the Anarchists in the streets of Barcelona. The workers of Barcelona were finally inspired by the success of the French CGT to set up a Syndicalist organization, Solidaridad Obrera (Workers' Solidarity). Established in 1907, Solidaridad Obrera quickly spread throughout Catalonia, and in 1909, when the Spanish army tried to conscript Catalan reservists to fight against the Riffs in Morocco, it called a general strike. "La Semana Tragica," "the Tragic Week" of largely spontaneous violence that followed (with hundreds dead and 50 churches and monasteries destroyed), ended in violent repression. Tortures of Anarchists in the fortress of Montjuich and the execution of the internationally celebrated advocate of free education Francisco Ferrer led to worldwide protests and the resignation of the conservative government in Madrid. These events also resulted in a congress of Spanish trade unionists at Seville in 1910, which founded the Confederación Nacional del Trabajo (CNT).

Moderates and activists

The CNT, which included the majority of organized Spanish workers, was dominated throughout its existence by the Anarchist militants; these in 1927 founded their own activist organization, the Federación Anarquista Iberica (FAI). While there was recurrent conflict within the CNT between moderates and FAI activists, the atmosphere of violence and urgency in which radical activities were carried on in Spain ensured that the more extreme leaders, such as Garcia Oliver and Buenaventura Durutti, tended to wield the decisive influence. The CNT was a model of Anarchist decentralism and antibureaucratism: its basic organizations were not national unions but *sindicatos únicos,* which brought together the workers of all trades and crafts in a certain locality; the national committee was elected each year from a different locality to ensure that no individual served more than one term; and all delegates were subject to immediate recall by the members. This enormous organization, which claimed 700,000 members in 1919, 1,600,000 in 1936, and more than 2,000,000 during the civil war, employed only one paid secretary. Its day-to-day work was carried on in their spare time by workers chosen by their fellows. This meant that the Spanish Anarchist movement was not dominated by the *déclassé* intellectuals and self-taught printers and shoemakers who were so influential in other countries. One consequence was that the Spanish movement contributed nothing original to the ideological literature of Anarchism; like Bakunin, whom they favoured most among the classic libertarian thinkers, the Spanish Anarchists developed their attitudes in action rather than in writing.

Anarchists in the Spanish Civil War

The CNT and the FAI, which remained clandestine organizations under the dictatorship of Primo de Rivera, emerged into the open with the abdication of King Alfonso XIII in 1931. Their antipolitical philosophy led them to reject the republic as much as the monarchy it had replaced, and between 1931 and the military rebellion led by Francisco Franco in 1936 there were several unsuccessful Anarchist risings. In 1936 the Anarchists, who over the decades had become expert urban guerrillas, were mainly responsible for the defeat of the rebel generals in both Barcelona and Valencia, as well as in country areas of Catalonia and Aragon; and for many early months of the Civil War they were in virtual control of eastern Spain, where they regarded the crisis as an opportunity to carry through the social revolution of which they had long dreamed. Factories and railways in Catalonia were taken over by workers' committees, and in hundreds of villages in Catalonia, Levante, and Andalusia the peasants seized the land and established libertarian communes like those described by Kropotkin in *La Conquête du pain.* The internal use of money was abolished, the land was tilled in common, and village products were sold or exchanged on behalf of the community in general, with each family receiving an equitable share of food and other necessities. An idealistic Spartan fervour characterized these communities, which often consisted of illiterate labourers; intoxicants, tobacco, and sometimes even coffee were renounced; and millenarian enthusiasm took the place of religion, as it has often done in Spain. The reports of critical observers suggest that at least some of these communes were efficiently run and more productive agriculturally than the villages had been previously.

The Spanish Anarchists failed during the Civil War largely because, expert though they were in spontaneous street fighting, they did not have the discipline necessary to carry on sustained warfare; the columns they sent to various fronts were unsuccessful in comparison with the Communist-led International Brigades. In December 1936 four leading Anarchists took posts in the Cabinet of Francisco Largo Caballero, radically compromising their antigovernmental principles. They were unable to halt the trend toward left-wing totalitarianism encouraged by their enemies the Communists, who were numerically far fewer but politically more influential. In May 1937 bitter fighting broke out in Barcelona between Communists and Anarchists. The CNT held its own on this occasion, but its influence quickly waned. The collectivized factories were taken over by the central government, and many agricultural communes were destroyed by Franco's advance into Andalusia and by the hostile action of General Lister's Communist army in Aragon. In January 1939 the Spanish Anarchists were so demoralized by the compromises of the Civil War that they were unable to mount a resistance when Franco's forces marched into Barcelona; the CNT and FAI became phantom organizations in exile.

The competition of Communism

Decline of the Anarchist movement. By this time the movement outside Spain had been either destroyed or greatly diminished as a result of two developments: the Russian Revolution and the rise of right-wing totalitarian regimes. Though the most famous Anarchist leaders, Bakunin and Kropotkin, had been Russian, the Anarchist movement had never been strong in Russia, partly because the more numerous Socialist Revolutionary Party (the Narodniki) had adopted Bakuninist ideas while remaining essentially a constitutional party. After the 1917 revolution the small anarchist groups that emerged in Petrograd (now Leningrad) and Moscow were powerless against the Bolsheviks, and Kropotkin, who returned from exile, found himself without influence. Only in the south did N.I. Makhno, a peasant Anarchist, raise an insurrectionary army that by brilliant guerrilla tactics held a large part of the Ukraine from both the Red and the White armies; but the social experiments developed under Makhno's protection were rudimentary, and when he was driven into exile in 1921 the Anarchist movement became extinct in Russia.

In other countries, the prestige of the Russian revolution enabled the new Communist parties to win much of the support formerly given to the Anarchists, particularly in France, where the CGT passed permanently into Communist control. The large Italian Anarchist movement was destroyed by Benito Mussolini's Fascist government in the 1920s, and the small German Anarchist movement was smashed by the Nazis in the 1930s. In Japan, Anarchism had emerged during the Russo-Japanese war of 1904–05, when the Socialist leader Shusui Kotoku became converted by reading Kropotkin in prison; Kotoku and other Anarchists were executed in 1911 for their involvement in a plot against the Emperor, but, after World War I, new Anarchist organizations appeared, including a Black Federation and a Syndicalist federation. After the Japanese invasion of Manchuria in 1931, the imperial government began to suppress all left-wing groups, and the Anarchist movement was finally destroyed in 1935 after a secret society, the Anarchist Communist Party, had been accused of plotting armed insurrection.

Anarchism in the Americas suffered similar reverses. In the United States, a native and mainly nonviolent tradition developed during the 19th century in the writings of Henry David Thoreau, Josiah Warren, Lysander Spooner, and Benjamin Tucker (editor of *Liberty,* an anarchist journal published in Boston and later in New York City, 1881–1908). Activist Anarchism in the U.S. was mainly sustained by immigrants from Europe, including Johann Most (editor of *Die Freiheit*), Alexander Berkman (who attempted to assassinate steel magnate Henry Clay Frick in 1892), and Emma Goldman, whose *Living My Life* gives a picture of radical activity in the United States at the turn of the century. Anarchism appeared as a dramatic element in American life in 1886, when seven policemen were killed in the Haymarket bombing in Chicago and four Anarchist leaders were executed—unjustly, as later investigations revealed. In 1901 a Polish Anarchist, Leon Czolgosz, assassinated President McKinley. In 1903 the U.S. congress passed a law to bar foreign Anarchists from the country and to deport alien Anarchists found within it. In the repressive mood that followed World War I the Anarchists, like the IWW, were suppressed; Alexander Berkman, Emma Goldman, and many others were imprisoned and deported.

In Latin America strong Anarchist elements were involved in the Mexican Revolution. The Syndicalist teachings of Ricardo Flores Magon influenced the peasant revolutionism of Emiliano Zapata. After the deaths of Zapata in 1919 and Flores Magon in 1922, the revolutionary image in Mexico, as elsewhere, was taken over by the Communists. In Argentina and Uruguay considerable Anarcho-Syndicalist movements existed early in the 20th century, but they too were greatly reduced by the end of the 1930s through intermittent repression and the competition of Communism.

CONTEMPORARY CURRENTS

Wider influence of anarchist ideas

In the 1970s the theories of Anarchism aroused more interest and sympathy than at any time since the Russian revolution. The same cannot be said of the Anarchist movement itself. After World War II, Anarchist groups and federations re-emerged in almost all countries where they had formerly flourished—the notable exceptions being Spain and the Soviet Union—but these organizations wielded little influence compared to that of the broader movement inspired by libertarian ideas.

Such a development is not inappropriate, since Anarchists have never stressed the need for organizational continuity, and the cluster of social and moral ideas that are identifiable as Anarchism has always spread beyond any clearly definable movement. The Russian writer Count Leo Tolstoy refused to call himself an Anarchist because those who used the title at that time in Russia were terrorists; nevertheless, he had developed out of his rational Christianity a form of pacifist radicalism that rejected the state and all forms of government, called for the simplification of life in the name of moral regeneration, and sought to replace property by free communism. An impressive example of the breadth of Anarchist influence is Mahatma Gandhi, who based his strategy of nonviolent civil disobedience in South Africa and India on the teachings of nonviolent Anarchists such as Tolstoy and Thoreau and who remembered his reading of Kropotkin when he devised for India the plan of a decentralized society based on autonomous village communes. Gandhi's village India has not come into being, but the movement known as Sardovaya, led by Vinoba Bhave and Jaya Prakash Narayan, has been working toward it through *gramdan*—community ownership of land. By 1969 a fifth of the villages of India had declared for *gramdan,* and, while this remained largely a matter of unrealized gestures, it represented perhaps the most extensive commitment to basic Anarchist ideas in the contemporary world.

Anarchism's appeal to intellectuals

In the West the appeal of Anarchism has been strongest, at least since 1917, among the intellectuals. Kropotkin's arguments for decentralization have wielded their strongest influence among writers on social planning such as Patrick Geddes, Lewis Mumford, and Paul Goodman—himself a declared Anarchist. Anarchist treatises from Godwin onward have contributed to the progressive movement in education, and the most influential of the many books written by the libertarian critic Sir Herbert Read was his *Education Through Art* (1943). But in the 1960s and 1970s Anarchism became popular among rebellious students and the left in general because of the values it opposed to those of the increasingly technological cultures of western Europe, North America, and Japan.

Here the mediating thinker was undoubtedly Aldous Huxley, who anticipated many elements of the "counter culture" of the 1960s and 1970s. In *Brave New World* (1932) Huxley had presented a warning vision of the kind of mindless, materialistic existence a society dominated by technology might produce. In his "Foreword" to the 1946 edition, he stated his belief that only by radical decentralization and simplification and by a politics that was "Kropotkinesque and co-operative" could the dangers implicit in modern society be avoided. In his later writings he explicitly accepted the validity of the Anarchist critique of existing society.

The emergence of Anarchist ideas in a wider frame of reference began in the American civil rights movements in the 1950s, with their recognition of the need to resist injustice through other than legal channels in the name of a morality different from that recognized by constituted authority. By the end of the 1950s the new radicalism in the United States, Europe, and Japan had begun to take a course separating it from the narrower issues of the civil rights movement; it shifted toward a general criticism of the elitist structure and materialist goals of modern industrial societies—Communist as well as capitalist. Within this movement there was a limited revival of traditional Anarchism—exemplified in the sudden popularity of the American writer Paul Goodman and the emergence in Britain of a sophisticated monthly, *Anarchy,* that applied Anarchist ideas to the whole spectrum of modern life.

Anarchism and contemporary rebellion

In all of this, however, Anarchism was only one strand in what can be described as a climate of rebellion rather than an ideology. Anarchist ideas were mingled with strains of Leninism, early Marxism, unorthodox psychology, and often with elements of mysticism, neo-Buddhism, and Tolstoyan Christianity. None of the leaders of the student rebellions in the United States and Germany or the militants of Zengakuren in Japan could be called in any literal and complete sense an Anarchist, although they had read Bakunin as well as Marx and "Che" Guevara. In Paris, the leaders of the Anarchist Federation admitted that they had no influence at all on the strikes and street fighting in 1968 that seemed to threaten the very existence of the French state.

To all these movements, which rejected the old parties of the left as strongly as they did the existing political structure, the appeal of Anarchism was strong and understandable. The Anarchist outlook, in its insistence on spontaneity, on theoretical flexibility, on simplicity of life, on love and anger as complementary and necessary components in both social and individual action, appeals to those who reject the impersonality of institutions and the calculations of political parties. The Anarchist rejection of the state, the insistence on decentralism and local autonomy, found strong echoes among those who talked of participatory democracy. The recurrence of the theme of workers' control of industry in so many manifestos of the 1960s, notably during the Paris insurrection of 1968, showed the enduring relevance of Anarcho-Syndicalist ideas.

The Anarchist insistence on direct action had an almost universal appeal to the radicals of the 1960s and 1970s, who advocated extraparliamentary action and confrontation. Some student groups in France, the United States, and Japan accepted Bakunin's pan-destructionism, holding that existing society was so corrupt that it had to be swept completely away. They were fond of quoting a sentence of Bakunin:

> There will be a qualitative transformation, a new living, life-giving revelation, a new heaven and a new earth, a young and mighty world in which all our present dissonances will be resolved into a harmonious whole.

This kind of secular apocalypticism, which envisaged total violence as the paradoxical way to total reconciliation, linked many of the radicals with the Anarchists who took to terrorism in the 1880s and 1890s. Now, as then, violence proceeded from theory to action, as the upsurge of terrorist bombings and urban-guerrilla activity demonstrated at the end of the 1960s.

Community reform

Anarchism as an ideal. But there were others who believed with Tolstoy and Gandhi that a moral change must come first and who sought revolution by evolution. Paul Goodman, with his proposals for urban reform as a step toward a freer society, was one of them. Some turned to the creation of models of a different kind of society in the form of utopian communities. This has been a recurrent feature of radical movements, appearing in the United States during the mid-19th century, in Britain as a form of constructive pacifist protest during World War II, and in the United States in the 1970s as a way of manifesting one's rejection of normal life-styles.

Experience suggests that utopian experiments and radical actions are not likely to achieve that wholly nongovernment society of which libertarians have dreamed. The true value of their vision was stated by the Anarchist poet Herbert Read in his last book, *The Cult of Sincerity* (1968):

> My understanding of the history of culture has convinced me that the ideal society is a point on a receding horizon. We move steadily towards it but can never reach it. Nevertheless we must engage with passion in the immediate strife . . .

It is precisely as an ideal, as a touchstone to judge the existing world, that the Anarchist vision is useful. It corresponds to a recurrent and necessary strain in human thought—the revulsion against regimentation, against large organizations, against complexity and luxury. The insights of the Anarchist are likely to find their maximum usefulness in urban and rural planning, in the development of community relations based on full participation, in integrated education, and perhaps most of all in encouraging what Read calls a "process of individuation, accomplished by general education and personal discipline." Anarchism is a moral and social doctrine before it is a political one; it stands as a permanent reminder of the perils of national and corporate giantism and of the virtues of local interests and loyalties. It teaches the vigilance by which man may be able to avoid such bleak utopias as those of Aldous Huxley and George Orwell. (G.W.)

Fascism

Fascism comprises a political attitude and a mass movement that tended to dominate political life in central, southern, and eastern-central Europe between 1919 and 1944. Common to all fascist movements was an emphasis on the nation (race or state) as the centre and regulator of all history and life, and on the indisputable authority of the leader behind whom the people were expected to form an unbreakable unity. The word fascism itself was first used in 1919 by Benito Mussolini in Italy; in the following years the influence of fascism made itself felt in countries as far away as Japan, Argentina, Brazil, and the Union of South Africa, its specific aspects varying according to the country's political traditions, its social structure, and the personality of the leader. The Italian word *fascio* (derived from the Latin *fasces,* a bundle of rods with an ax in it) symbolized both aspects: the power of many united and obeying one will and the authority of the state, which was the supreme source of law and order and all national life.

THE PHILOSOPHICAL BASES OF FASCISM

The Spartan model

Fascism rejected the main philosophical trends of the 18th and 19th centuries, the "spirit" of the American and French revolutions with their emphasis on individual liberty and on the equality of men and races. The message of the Enlightenment had served to enhance the dignity of the individual and had emphasized openness in a secularized society. In contrast, fascism extolled the supreme sovereignty of the nation as an absolute. It demanded the revival of the spirit of the ancient *polis* (city-state), above all of Sparta with its discipline and total devotion to duty, and of the complete coordination of all intellectual and political thought and activities against modern individualism and scientific skepticism. The Italian slogan "to believe, to obey, to combat" was fascism's antithesis to "liberty, equality, fraternity," and to the prophetic and Christian messages of peace. The combination of an unquestioning faith and of a virile combativeness was to transform the nation into a permanently mobilized armed force to conquer, maintain, and expand power.

In its beginnings fascism was not a doctrine and had no clearly elaborated program. It was a technique for gaining and retaining power by violence, and with astonishing flexibility it subordinated all questions of program to this one aim. From the beginning it was dominated by a definite attitude of mind that exalted the fighting spirit, military discipline, ruthlessness, and action and rejected all ethical motives as weakening the resoluteness of will. Stressing the irrational and instincts and activism, fascism insisted that the strong will always prevail over the weak, the more resolute over the irresolute. Ultimately everything depended upon the decisions of the leader, decisions to be blindly obeyed and immediately executed. Fascism returned to an authoritarian order, based upon the subordination of the individual and the inequality of caste and rank.

The reliance on power. Power is, of course, an element present in all political life. The first major writer to abandon the moral and normative approach to politics in favour of pure power was the Florentine man of letters Niccolò Machiavelli (1469–1527). A man of the Renaissance, he looked to the people of pre-Christian antiquity as the original possessors of *virtú,* the civic virtue necessary to the modern ruler; he believed that Christianity was, unfortunately, "true," but that its stress on meekness and humility would damage political man, weakening and at the same time fanaticizing him. Machiavelli's methodology involved the empirical observation of human nature and behaviour, which he believed to be changeless. His deep feelings about the degradation and corruption of Italy at his time led him to put his hope into the daring and the violence of a great man who would exercise power ruthlessly but with prudence. Power, Machiavelli apparently believed, legitimized the state, if rationally applied, as *raison d'état,* by a man able to manipulate the people and use the army for his own purposes. In his quest for a "new prince" and a new principle of policy he knew that he was opening "a road as yet untrodden by man." The road led to the absolute sovereign state.

The emphasis on sovereign-state power. In the bitter and protracted religious conflict of 16th-century France, the French jurist Jean Bodin (1530–96) stressed the importance of the sovereign, but by no means unlimited, power of the state in effective government. During the constitutional crisis of 17th-century England the philosopher Thomas Hobbes (1588–1679) saw sovereign power as more absolute, unlimited by the subjects who have authorized it and responsible only to God. For Machiavelli the state was a work of art, created by the skill of the prince whom Machiavelli wished to teach the rules of conduct; for Bodin and Hobbes the state was a rational contrivance to lift central authority above religious and civil disputes. The peace treaty of Westphalia in 1648, in an attempt to end over a century of religious warfare, gave the secular sovereign, generally a hereditary absolutist monarch, the right to determine the religious beliefs of his subjects. The maintenance of law and order became the highest guiding principle, but even at this stage the state had not yet become the object of awe or emotional veneration.

The state in German Romanticism

The state became such only after the French Revolution, and above all in the emotional teaching of German Romantic philosophers, such as Johann Gottlieb Fichte (1762–1814) and Georg Wilhelm Friedrich Hegel (1770–1831). For these men the national collectivity assumed, morally and politically, an absolute rank. Fichte's utopian "closed state" was authoritarian, anti-individualistic, and economically self-sufficient.

But Fichte did not endow the state with the sacral aura that Hegel gave it. For a century German historiography was to accept the Hegelian concept of the absolute-power state that acts in its own self-interest without consideration for humanitarian principle or for the rights of individuals or of other states. Hegel's followers, like those of Fichte, overlooked the complexity and ambiguity of his philosophy and concentrated on his exaltation of the state as an end in itself, as the "actuality of the ethical idea," as "absolutely rational," and as the source of all "concrete freedom." Only as a subject of the state (specifically, for Hegel, the Prussian monarchy) does the individual gain objective reality and an ethical life. The state's unconditional sovereignty reveals its nature above all in war.

The integrally autarkic state: the Dreyfus Affair. In the first part of the 19th century Hegel was, then, the philosopher of a militaristic monarchy opposed to the growing strength of 19th-century middle-class liberalism. At the end of the century another antiliberal, anti-individualistic, and authoritarian movement made its influence felt, this time in the middle-class democracy of the French Republic. Its leader was Charles Maurras (1868–1952), who repudiated the disunity and verbosity of parliamentarianism. He admired the Roman Catholic Church (but not Christianity, which in his opinion glorified universalism, social unrest, and pacifism), but for the virtues of hierarchic discipline and traditionalist order. The supreme norm of political life was to Maurras the absolute primacy of France and this meant action in France's interest instead of hesitation, parliamentary discussion, and consideration of world opinion.

Maurras and Barrès: the state can do no wrong

In 1894 a military tribunal convicted Capt. Alfred Dreyfus, the only Jewish officer in the French general staff, of pro-German espionage. Dreyfus insisted on his innocence, and his case became the centre of a bitter dispute involving questions of the precedence of national interest over objective justice. If Dreyfus were innocent, then the French army command on which France depended was dishonoured and stood accused of intrigue and worse. Antiliberal forces saw in the dispute an opportunity to overthrow the parliamentary republic, in which many high army officers and the church saw something fundamentally un-French, the work of Freemasons and Protestants, Anglo-Saxons and Jews. Whereas Maurras, in his struggle against democracy, pleaded for a return to the ancient monarchy, his compatriot, Maurice Barrès (1862–1923), saw the remedy in a leader who, being in close touch with the masses, would be the embodiment and the effective will of their thought and feeling. Against the rational cosmopolitanism of the "uprooted" intellectuals (a term that he made the title of his most famous novel in 1897), Barrès extolled the close community of a nation with its deep roots in past generations and in the ancestral soil (the "blood" and "soil"—*Blut* and *Boden* of Hitler). To Barrès the individual was merely a link in the chain of generations, inevitably determined by the blood of common forefathers.

Vitalism and elitism. The beginning of the 20th century felt the influence of Friedrich Nietzsche's (1844–1900) contradictory and often misunderstood work. Not a forerunner of fascism, Nietzsche despised German nationalism, anti-Semitism, and the authority of the state. He was, in fact, an extreme individualist, in revolt against all uncritical obedience by believers or followers and against the traditional values of church and fatherland. But he also despised the common man and democracy; he believed in great personalities and their exclusive rights. He found his time lacking in greatness and heroism, and he glorified the courage of warriors, though he meant first of all warriors of the mind, strong enough to overcome their own pettiness and their acceptance of faith or belief that came to them from second or third hand.

Spengler and Sorel: the struggle of peoples

Oswald Spengler (1880–1936) shared Nietzsche's feeling of the decadence of Western civilization, brought about by Christianity and democracy, and his faith in the need for an aristocratic elite. Writing during World War I, Spengler insisted that all history is struggle among nations and that each nation's future will be decided by its power relationships to other peoples. Each people must be "in condition" for inevitable struggle and must trust its leaders; what is significant is not the victory of truth but the triumph of the will-to-power.

The French radical antiliberal Socialist Georges Sorel in his revolutionary syndicalism emphasized the dynamism and new vitality of a heroic proletariat against an effete bourgeoisie. In his *Reflections on Violence* (1908) Sorel claimed that the working-class movement needed irrational myths to carry out its role in history. This idea influenced many Socialists in Latin countries, especially in north-central Italy, at the time Benito Mussolini was growing up. Violence, Sorel declared, was "sublime" when it was exercised by a movement with a historical mission. In Sorel, radical socialist theory of the left fused with a radical conservatism of the right in common rejection of bourgeois "mediocrity."

Among Italian pre-1914 social philosophers, other more conservative forerunners preached an elitist doctrine of vitality and the competitive power struggle. They turned from Count Cavour's liberal faith in parliamentarianism, which had established the unified Italian kingdom of 1861, to a quest for new elites and new rationales. Among them was Gaetano Mosca (1858–1941). Mosca's *Elimenti di scienza politica* (1896; Eng. trans. *The Ruling Class,* 1939) owed much to the Austrian professor of public law Ludwig Gumplowicz (1838–1909), whose fundamental work *Der Rassenkampf* ("Racial Struggle") in 1883 established the "group" as the fundamental unit of sociology, which he interpreted as the science of the interaction of groups. Material need was to Mosca the prime motive of human conduct; conquest and the satisfaction of the conqueror's need by the labour of the conquered, the fundamental essence of history.

Mosca and Vilfredo Pareto (1848–1923) argued that there had always been a ruling class of a few men who held power over the majority; that society is, thus, hierarchically organized, though the elites may change and, in fact, the change of elites is as much the essence of history as are wars between ethnic groups. The new elites carry with them their own values, expressed in social myths that can neither be proved nor disproved and that serve as a call and inspiration to action. The collective psychology of Scipio Sighele (1868–1913) and Gustave Le Bon (1841–1931) hypothesized that crowds obey collective subconscious emotions rather than the rational individuality of their single members, and, therefore, that crowds are highly susceptible to manipulation by leadership that can arouse in them heroism or savagery of which the individual alone would be incapable. Endlessly reiterated statements rather than rational thought influence public morality.

THE CONDITIONS FOR THE EMERGENCE OF FASCISM: POLITICAL PREREQUISITES

The troubled state of Europe in the years before 1914 was greatly intensified by the pressures that World War I put on societies that were not yet socially and politically modernized. This was true in varying degrees of Germany, Italy, and Japan, all of whom had entered the war in the expectation of great gains in territory and status, and of acquiring full equality with the older societies of the West. The deep moral depression and confusion which the defeat of 1918 produced in Germany was due to the apparently inexplicable difference between expectations and final failure.

National frustration

The discrepancy between Germany's advanced industry and her semifeudal-state structure, with its traditional authoritarian basis, had weakened her war effort. The failure on the battlefield led to a deeply emotional nationalism which ascribed the shortcomings not to Germany's backward political structure but to enemy plots and domestic "enemies." Thus the authoritarian militarist elite was not discredited by the defeat of 1918; on the contrary, the fear of Bolshevism brought support for the defense of the traditional structure.

Though Italy was to be among the victors in World War I, the relative backwardness of its political, social, and economic structure in 1914 put an immense strain on all aspects of Italian society and life. The failure of expected gains from the war to materialize led to a weakening of the country's insecure liberal foundations. Those who, like Benito Mussolini, had agitated for Italy's entrance into the war in 1915 tried to direct the discontent and fear of the population against the victorious democracies who, unlike Italy, had emerged strengthened from the war. Social unrest frightened the propertied classes, the major landowners, and the church. Instead of carrying through long overdue reforms, they sought for a strong man who could sway part of the masses, war veterans, and lower middle class and turn them against the threat of Bolshevism. Fascism was thus regarded as a bulwark against the modernization of Italy. Though this was an underestimation of the syndicalist and radical aspects of Mussolini's original position, he was able to achieve, more than Hitler did later, an accommodation with the old ruling class, the monarchy, the army, and the church.

Fascist movements, wherever they have arisen, have frequently been inspired by national feelings of disappointment and by the assumed need to close ranks in order to reach often fantastic goals (*e.g.,* the revival of Roman glory). Japan's fascist movement was linked to its attempt in World War I to establish a protectorate over China, which was frustrated, largely, as Japan felt, by the United States. Similarly, the strength of the fascists in Hungary owed much to the bitter national resentment at the loss of its non-Magyar subjects to new or enlarged nation-states created at the end of the war. These new states were not politically strong, and, as in Spain or Latin America, traditional right-wing conservatism, backed by the church and the pre-1914 oligarchy, found itself in conflict with the dynamism of fascism and its contempt for traditional ideas. Later, both were to enter into uneasy alliances in their fear of Bolshevism.

SOCIAL AND ECONOMIC CONDITIONS THAT ENCOURAGE THE DEVELOPMENT OF FASCISM

Politically and socially the modern, industrial middle-class societies that developed in Britain, Scandinavia, Switzerland, the Low Countries, and France in the 19th century showed a great power of resistance to fascism, which was, on the whole, confined to fringe movements. Even in Germany, with her bitter resentments accumulated from her failure in World War I, which Hitler masterfully manipulated and fused with older resentments, fascism would probably not have come to power had it not been for the inflation crisis of 1923 and the widespread unemployment of the early 1930s. Finally, the rise of fascism in Germany owed much to the weakness of civilian democracy in that country. Germany had originated as a nation-state in 1871, thanks almost entirely to the military-authoritarian tradition of Prussia and the victories achieved by its army without the aid of any other power. The new *Reich* was proclaimed at the gates of Paris, the capital of the defeated enemy, and the German middle classes and German scholarship all willingly accepted the traditional values of the efficient ruling class, though by 1900 these values were insufficient to support an expanding modern industrial society.

Nationalism and economic crisis

Neither a capable semimilitary bureaucracy nor a scientific technology existed in Italy, Spain, Portugal, Greece, or Romania, where low urban and rural productivity during the early 20th century constantly widened the gap between these countries and the modern West and provided a basis for the growth of fascism.

In Italy, the farthest advanced of these countries, it was estimated in 1900 that half the population could neither write nor read. Though the north of Italy made great progress in the first 15 years of the present century, the fact is that even in 1914 the per capita income of the country, measured in standard gold units, was only 105 compared with 237 for Britain and 182 for France. Southern Italy's peasant population lived, according to one account, "in conditions of utmost destitution, illiteracy was the rule. Afflicted with gross dietary deficiency, accustomed to deprivation, and mulled by ceaseless toil, whole regions were innocent of the most elementary education and were consequently not equipped to participate in the challenge" offered by modern civilization. Archaic traditions and authoritarian religion preserved in Italy and Spain, in Romania, Greece, and Hungary a social system that was outside the modern world.

Fascism was an effort to employ anti-individualism and authoritarianism in modernizing economically backward societies. Arturo Labriola (1873–1959), an early syndicalist, spoke of Italy as a colony of "plutocratic Europe." The leader of an aggressive Italian nationalism, Enrico Corradini (1865–1931), influenced by Nietzsche and Maurras, saw the future as a conflict not between workers and capitalists but between proletarian and plutocratic nations. It was in that sense that fascism may have influenced the new African nations as they tried to organize themselves in the 1950s and 1960s. Despite its reactionary view of man, fascism regarded itself as representing youth against senility, the wave of the future against the effete heritage of the 19th century, biological vitality against the craving for peace and comfort.

THE ITALIAN EXPERIENCE

It has been shown that fascist movements arose where traditions and social structures favoured them. Unlike democracy, fascism demands a charismatic leader, a "new prince" as Machiavelli called him, who can gather all the prefascist emotional and social strains into one persuasive philosophy and will appeal to the masses. In Italy Benito Mussolini (1883–1945) was such a leader. From 1902 to 1914 Mussolini wrote many articles in the spirit of a radical Marxist. In this Marxist period of his life he became in 1912 editor of Italy's leading socialist daily, *Avanti!,* in Milan, a position of great influence for such a young man. He was then an extremist in his Marxist views, stressing revolutionary idealism and militant antimilitarism but deprecating dogmatism.

Dynamics of Italian Fascism

Whereas Marx's conception of history was based on 19th-century humanism and rationalism, Mussolini's was influenced by an early 20th-century emphasis on vitality and biological vital force, on a synthesis of Nietzsche and Sorel with Marx. This inclination to a heroic and active life-force made him, together with Gabriele D'Annunzio (1862–1938), the poet and glorifier of action, the chief propagandist of Italy's entrance into the war on the side of the Allies. It was over this issue that he broke with the Socialist Party, resigned from his editorship, and founded his own paper, *Il Popolo d'Italia.*

Mussolini's philosophy. Mussolini's philosophy, which developed slowly as his struggle for power and for a powerful state progressed, was officially presented in his article on the *Dottrina del fascismo* ("Doctrine of Fascism") in the *Enciclopedia Italiana* (1932). It reveals the pragmatic beginnings of the movement with complete frankness: "Our program is simple. We wish to govern Italy. They ask us for programs, but there are already too many. It is not programs that are wanting for the salvation of Italy but men and will power." By 1932 he had found a traditional philosophical garb for his vitalistic doctrine in the neo-Hegelian idealism of Giovanni Gentile (1875–1944), which saw the state as the source of all ethics and all individual life.

For Mussolini, all theoretical considerations were subservient to the "inexorable dynamics" of the factual situation. It is, he insisted, the role of the leader to master this dynamic process: he knows that the "iron logic of nature" will make the strong prevail over the weak. In contrast to Marxism, which asserts a rational logic of history that it claims will bring about the final triumph of the weak in an act of universal salvation, there is no fulfillment of history in Fascism. Instead, all history is incessant struggle, and the struggle itself is welcomed for its own ethical value. For

> war alone brings up to their highest tension all human energies and puts the stamp of nobility upon the peoples who have the courage to meet it. Fascism carries this antipacifist struggle into the lives of individuals. It is education for combat. . . . War is to the man what maternity is to the woman. I do not believe in perpetual peace; not only do I not believe in it but I find it depressing and a negation of all the fundamental virtues of man.

Triumph and decline of Italian Fascism. From 1922, when he first seized control of the Italian government in Rome, until 1927, Mussolini progressively consolidated his dictatorship, and the Fascist state took form. State and party became monolithic instruments in the hands of Mussolini, the *capo di governo* (head of the government) of the state, the *duce* (leader) of the party. The *legge fascistissime* (most Fascist laws), drafted by the leading Fascist jurist Alfredo Rocco, turned Parliament into a party congress, practically fused legislative and executive power, and made the Grand Council of Fascism an instrument of the duce, who alone could summon it and determine its agenda.

With this success Mussolini began to look farther into the future. Until 1930 he had emphasized the long overdue modernization of a backward country by a strong and efficient government and a new dedicated elite that could communicate a sense of vitality, virility, and energy to the whole people. But on October 25, 1932, Mussolini assured a Milan audience of the world leadership of fascist Italy. "Today, with a fully tranquil conscience, I say to you, that the twentieth century will be a century of fascism, the century of Italian power, the century during which Italy will become for the third time the leader of mankind." In 1934 Mussolini claimed that Fascism, an Italian movement in 1922, had "since 1929 become not merely an Italian phenomenon but a world phenomenon." To achieve his ends, Mussolini demanded the transformation of Italy into a *nazione militarista* and *guerriera.* In this goal he succeeded even less than in that of Italy's modernization.

The ambition of Italian Fascism

In his earlier stages Mussolini regarded Fascism as a development within Western civilization and looked with distrust generally upon Germany and specifically upon Hitler's National Socialism, which he recognized as "one hundred percent racism: Against everything and everyone: Yesterday against Christian civilization, today against Latin civilization, tomorrow, who knows, against the civilization of the whole world." But his imperialism and his overestimation of the power of Fascism drove him into the arms of National-Socialist Germany.

The conquest of Ethiopia (1935) opposed Italy to the West and the League of Nations. In the following year, dazzled by German success, Mussolini began to speak of a Rome-Berlin Axis and celebrated it during his visit in Berlin in 1936 and Hitler's return visit in May 1938. Hitler's sincere admiration for him as "the leading statesman in the world, to whom none may even remotely compare himself" increased Mussolini's self-delusion. The intervention for Fascism in Spain's Civil War and the Munich accord with England in September 1938 seemed a crowning success in Mussolini's policy; in reality they masked, with Italy's acceptance of German anti-Semitic laws, the fall of Italy to the position of Germany's satellite. As such, but also out of desire for glory and booty, Italy in June 1940 entered the war started by Germany in September 1939. The war revealed Italy's backwardness and inefficiency, until three years of warfare brought the fall of Mussolini and his party.

THE GERMAN EXPERIENCE

Hitler found a much better prepared soil in the antidemocratic traditions of the German *Reich* than Mussolini did in the tradition of the Italian Risorgimento, the 19th-century movement for Italian unity. Like Maurras and unlike Mussolini, Hitler had never been a Socialist or a man of the left. He was entirely unknown even in 1919 when as an agitator for the *Reichswehr* (army) he attacked the Western and German democrats, moderate Socialism, and Russian Bolshevism. He was, unlike Mussolini, the man of the one idea, which in him assumed demonic or maniac dimensions, but he was in tune with older currents of German thought and emotionalism.

Hitler's racial myths

Hitler's "Mein Kampf" and German anti-Semitism. Hitler grew up as a subject of the multi-ethnic Catholic Habsburg monarchy. He shared with the Austrian Georg von Schönerer (1842–1921) a virulent hatred for the Habsburgs, the "inferior" Slavs, for Catholicism as un-German, and above all for Jews and Judaism as non-Aryan. Hitler's propaganda methods were influenced by another Austrian, Karl Lueger (1844–1910) who, though a supporter of the dynasty and church, became a popular mayor of Vienna by opposing capitalistic liberalism and Marxian Socialism and appealing to the emotions of a lower middle class that felt threatened by both. In the restless years after 1918 Hitler took up this appeal. His anti-Semitism went far beyond Lueger's, becoming an obsession with him; the Jewish problem was no longer political, religious, or economic but the all-explaining theme of history. Hitler regarded the Nordic Aryans as the only creative race on earth, the only source of human greatness and progress. He believed that its end would mean the end of all civilization. Since he saw the German *Reich* as the highest expression of Aryanism, he proclaimed that it was necessary, not only for Germany but for the salvation of mankind, to secure the victorious survival of Germany by maintaining the purity of German "blood" against contamination by inferior races.

The total rejection of all miscegenation was one of the two fundamental pillars in Hitler's two-volume *Mein Kampf,* which he wrote in 1924 and 1926, and which became the bible of the new faith. The other was the absolute necessity of conquering a vast land base in eastern Europe, which was to become German by the ejection and enslavement of the "inferior" though white Slavic peoples. Germans would settle the immense and fertile plains and thus create a geopolitically unassailable *Reich.* The existing (and any future) Slav leadership class was to be exterminated to secure German domination. To these two fundamental ideas Hitler remained faithful from the very beginning of his agitation until his death. They had no parallel in Mussolini's writings, which glorified war and its spirit but presented no plan of a great aggressive war or any racial fanaticism. When Hitler dictated his last will shortly before his suicide, he repeated once more his fundamental interpretation of history: "Above all, I demand of the nation's leaders and followers scrupulous adherence to the race laws and to ruthless resistance against the world poisoners of all peoples, international Jewry," which he identified with the despised liberalism of Western capitalism and the socialism of Russian Marxism. His last words in 1945 expressed the same ideas that had guided him in 1919.

Hitler's program

Hitler's persuasion of the Germans. From the beginning, Hitler served the fascist movement by his understanding of the potential of the spoken word and the psychology of the masses. His appeal to the Germans as the most exalted race in the world counteracted the disillusionment and inferiority complex of a people believing itself surrounded by a hostile world. Hitler wrote in *Mein Kampf* that all propaganda must hold its intellectual level at the capacity of the least intelligent of those at whom it is directed and that its truth is less important than its success. "The slighter its scientific ballast, and the more exclusively it considers mass emotions, the more complete will be its success." In 1937, moreover, at the ninth party congress in Nürnberg, Hitler declared that "Germany has experienced the greatest revolution in the national and racial hygiene which was undertaken for the first time on an organized basis in the country. The consequences of this German race policy will be more decisive for the future of our people than the effects of any other laws. For they are creating the new man."

Many Germans believed in the reality and the superiority of this new man. Thus the racial interpretation of history and the fascist contempt for democracy lured Germany into war against Communism and democracy at the same time. By 1942 Germany had challenged the whole world and seemed at that point to have a good chance of emerging victorious from this total ideological war. Three years later it collapsed.

OTHER FASCIST MOVEMENTS IN EUROPE

The defeat of German fascism sealed the future of many other fascist movements that had come to power or grown in importance in many European countries partly with Germany's help or protection. In some of them, radical revolutionary fascism, eager for the modernization of the country, found itself in conflict with the authoritarian, semifeudal structure with which it often made common cause against Western liberalism, represented by a generally weak domestic middle class, and against an often exaggerated threat of Bolshevism from the outside. Yet reactionary authoritarianism and fascism fused in different ways in different countries, and with Italy's and Germany's defeat, the merely authoritarian reactionary regimes survived more easily than did the outright fascist ones.

The Spanish Falange

In most European countries there were a number of competing small fascist parties with no strong leader. Some of these came to power by National Socialist military success. In other cases (Britain, Switzerland, Sweden, or Denmark) the liberal parliamentary forces proved to be strong enough to keep the fascist movements within narrow bounds, and in others reactionary elements were able to use fascist movements as their support. The only one of these movements that could claim world attention on the international scene was the originally very radical Falange Española under the leadership of José Antonio Primo de Rivera (1903–36). The Spanish republican regime was established in April 1931, and Rivera was elected a deputy of the right in 1933. But in the next year he broke with it and united the Falange with the Juntas de Ofensiva Nacional Sindicalistas (Committees of Nationalist Syndicalist Offensive), "a movement steeped in true Spanish frenzy, launched by the young and dedicated to combatting . . . the irresponsible hypocrisy of the bourgeoisie" (Eugen Weber, *Varieties of Fascism,* D. Van Nostrand Co., Inc., Princeton, New Jersey, 1964, p. 117). The Falange was ultranationalist and eager for a thorough reform of Spain's antiquated social order. But in the election of 1936, won by the popular front of leftist moderate and radical parties, the Falange was unable to elect even a single deputy.

When civil war broke out in Spain in 1936, the republican government outlawed the Falange, which sided with General Francisco Franco; and in 1937 Franco united it with the military formations of the deeply reactionary Catholic Carlists, the Requetés, and made it an instrument of his personal leadership. But whereas in Italy and Germany fascism had absorbed the state, in Spain the victorious conservative oligarchy absorbed fascism.

In a similar way the authoritarian and traditionalist oligarchy in Antônio de Oliveira Salazar's Portugal kept fascist movements within very narrow limits, while using some of Mussolini's conservative slogans, as did the clerical semi-fascism in Austria under the two chancellors Engelbert Dollfuss (assassinated by the National Socialists in 1934) and Kurt von Schuschnigg and the Slovakian independence movement under Father Josef Tiso.

Fascism in the Balkans

Radical fascist movements developed in some Balkan countries—most prominently in Croatia, Hungary, and Romania. They shared with the conservatives the bitter hostility to Marxism and the Soviet Union, but they were obsessed by an extremist spirit of terroristic violence in a strange union with religious fanaticism. As a result of German victory the Croatian Ustaše, a party under the leadership of Ante Pavelić (1889–1959), turned Croatia into a state on the model of the most extremist National Socialist Party formation, the SS, or Schutzstaffel, into which only the most dedicated and racially pure Germans were admitted. The Ustaše persecuted and killed hundreds of thousands of Orthodox Serbs and Jews. Catholic monks and other priests are alleged to have taken an active part in this struggle for the "purity" of the Croatian land and faith, and the Ustaše envisaged the revival of the Great Croatian kingdom as it had existed under Peter Krešimir (1058–74) and Zvonimir (1076–89). The dream was destroyed first by Fascist Italy's occupation of Croatian Dalmatia and of Slovenia and finally by the collapse of Italy and Germany.

Fascism ruled in Croatia only four years; an even more violent fascism disturbed the political life of Romania for almost 25 years. Independent of the rise of Italian or German fascism, the fascism of Corneliu Zelea Codreanu was rooted in older traditions of the Romanian Orthodox Church and the Romanian peasantry. As a student at the University of Iași, Codreanu organized fellow students, sons of poor priests and peasants, into a National Christian Anti-Semitic League, which indulged in murder and a strange fanatical morality. In 1927 the movement was reorganized as a Legion of the Archangel Michael, characterized not by a flag but by an icon and by its members' dedication to a frugal ascetic life. The Iron Guard, as the Legion called its armed branch, represented an attempt at a fundamental reform of Romanian life. But the attempt to build a new life was made on the basis of wild blood sacrifices, one of whose victims in 1938 was Codreanu himself. In 1940, after the abdication of the King, a civil war within a coalition of the conservative Army under Gen. Ion Antonescu and the Legion under Horia Sima, Codreanu's successor, ended with the Army crushing the Legion in January 1941. Antonescu's Romania actively participated in Germany's war against Russia, but the Romanian fascist movement remained, after orgies of death, crushed, and its surviving leaders found refuge in National Socialist Germany.

In a similar way the fate of fascism and of reactionary circles was intertwined in Hungary. The Hungarian government under the regency of Miklós Horthy (1868–1957), the last commanding admiral of the Austro-Hungarian Navy, dreamed of the restoration of the former nine-centuries-old Great Hungarian realm. The suppression of the short-lived communist regime in Budapest in 1919 combined with the fascist hatred of Bolshevism to produce what was, for that time, an unprecedented "white" terror. But Horthy himself was a moderate conservative, and even when Hungarian extreme nationalism led him to form a profascist government under Gyula Gömbös in October 1932, Horthy followed a moderate course. Gömbös died suddenly in October 1936. In September 1940 the Hungarian National Socialist Party merged with the Arrow Cross Party and found its leader in Ferenc Szálasi, who had been a capable general staff officer in the army but had developed a fanatical racial faith in Hungarism that in some ways recalled Hitler and Codreanu. After Hungary's entry into the war, the Germans in 1944 occupied Hungary and interned Horthy. Szálasi was finally the head of a state, which he planned as the "Corporatist Order of the Working Nation." But the war was soon lost after a bloody winter of massacres of Jews and political opponents. Szálasi was executed; Horthy found refuge in Portugal.

Fascism elsewhere in Europe

Fascism outside Italy and Germany suffered from the lack of charismatic leaders who could embody a nationalist myth and yet be adroit political tacticians. In Nordic Germanic Europe, which, according to racial doctrine, should have shown a strong penchant for National Socialism, except for Norway few sympathized with German fascism—much fewer than among the eastern and southern Europeans. In Norway the great writer Knut Hamsun (1859–1952) and Vidkun Abraham Quisling (1887–1945), former minister of war in the farmers' party administration and son of a rural clergyman, took a pro-Nazi stand based on their opposition to Western "plutocracy" and their fascination with peasant rootedness, the opposition of the "natural" countryside to the "corruption" of urban civilization. Quisling founded, in 1933, the Nasjonal Samling, with the cross of St. Olaf as a symbol and the restoration of the greatness of Viking Norway as a goal. Under the German occupation Quisling became prime minister, but his following remained insignificant in his native land.

Stronger than in northern Europe was the fascist movement in Belgium. This was partly due to the fact that the Belgian nation was divided into a dominant French-speaking minority and a Flemish-speaking majority that struggled for complete equality. In 1931 Flemish extremists formed the Verbond van Dietsche Nationalsolidaristen, the Union of Dutch National Solidarists, who dreamed first of a Great Netherlands, later of a Great Burgundy, both times avoiding a close cooperation with German National Socialism. A more important fascist group originated in French-speaking Belgium and found in Lêon Degrelle an energetic demagogue and leader who strove for an agreement with the Flemish and showed understanding for modern social developments. Degrelle had grown up as a Catholic and in his young years had been influenced by Charles Maurras. He called his organization Rex and virulently attacked the parliamentary system. After a rapid growth his party lost its influence and Degrelle himself was defeated in a by-election in 1937 by a typical representative of the Belgian upper middle class with the approval of the Catholic primate. Degrelle's Flemish adherents joined the radical wing of the Flemish nationalists, the Vlaamsche National Verbond, and Degrelle formed a Walloon legion for the German SS and fought in the war against Russia. The confused character of the Rexists was symbolized by its red flag with a crown and a cross on it. In Belgium, as in Switzerland and The Netherlands, the parliamentary system of the conservative middle class was too strong to allow the success of a fascist party, and any threat of communism was too remote and improbable. In these countries terroristic violence so characteristic of the regimes of Mussolini, Hitler, Codreanu, or Szálasi remained unknown.

Of a very different nature was the short-lived fascist movement in England, where Sir Oswald Mosley, a member of the aristocracy, formerly a member of the Conservative Party, and later a member of the Labour government, founded in 1932 under the impact of the economic crisis the British Union of Fascists. The Union's plan was to replace the "old gang" of politicians by a new young elite, in tune with the new time. The paramilitary form of his party meetings and its "defence force" ran so deeply counter to Britain's centuries-old civilian tradition that in spite of Mosley's undeniable rhetorical and intellectual gifts the English masses resisted him, and the strong British Conservative government of the period offered little foundation for arousing fear of a domestic "Bolshevik" threat. The Conservative government was intelligent enough to forbid, after some street fighting in 1936, all paramilitary uniforms. By 1938 Mosley, perhaps the most intelligent and rational of all fascist leaders, ceased to be a figure of public importance.

The picture offered by France in the critical years was more complex. But there, too, fascist movements were diffuse and short-lived. One of the followers of Charles Maurras, George Valois, disappointed with Maurras's lack of active interest in social reforms, founded in 1925 the Faisceau, composed largely of war veterans; but only the crisis of the 1930s produced a number of groups, all nationalist, anticapitalist, and anti-Marxist. The largest of them, the Croix de Feu (Fiery Cross) of Col. François de La Rocque, rejected dictatorship and most of the fascist rhetoric. Characteristic for French fascism were the "proletarian" anti-Communists, led by former Socialists and Communists like Marcel Déat, the founder of the Rassemblement National Populaire, and Jacques Doriot, the former Communist mayor of Saint-Denis, a Parisian "red" suburb, who founded the Parti Populaire Français. More than in other countries, these French fascist groups were joined by some intellectuals who were disenchanted with the apathy of French life and yearned for revolution and action. The most prominent of them, Pierre Drieu La Rochelle (1893–1945), summed up the nihilism that is fundamental to all fascism when he wrote in 1934: "Liberty is exhausted. Man must seek new strength in his black basic nature. I say it, an intellectual, the eternal libertarian." (From *Socialisme Fasciste,* Gallimard, Paris, 1934, p. 102.)

FASCIST MOVEMENTS OUTSIDE EUROPE

Reaction and fascism in Japan

Like nationalism, socialism, and Communism, fascism was a European movement. But in the 1930s, when economic crisis seemed to reveal weaknesses of the liberal tradition, in general, fascism spread to Asia and Latin America, adapting itself to the social conditions of the countries there. Only in two cases did it become significant and assume an official role. The first instance was Japan, where fascism resembled German National Socialism in its reassertion of ancient models of life. On February 26, 1936, the army took control of Japan and supported a national or tribal mysticism that bore a close resemblance to that of Germany. Young "patriotic" officers tried to assassinate a number of leading Japanese statesmen, aristocrats, and high officers who seemed to them to represent the influence of foreign "dangerous thought," of the West, of liberalism, and of individualism, which threatened the traditional military spirit and absolute dedication to the cult of the emperor. In a number of cases the young officers were able to kill their victims. "The massacre was immensely popular in the army. The army acted as though the revolt was the work of the whole body and had succeeded. In its new orders the army said that it could not tolerate liberalism, that internationalism and individualism must be banished, and nationalism and the Japanese principle be promoted." (A. Morgan Young, *Imperial Japan 1926–1938,* William Morrow and Co., Inc., New York, 1941, p. 34.)

Different from other fascist countries, Japan saw the embodiment of its national ideal not in a popular leader but in the emperor. The national destiny was to be fulfilled by observing the duty to the throne and thus attaining the highest pinnacle of morality. The imperial will was to fix standards of justice and injustice, of right and wrong. Philosophy was regarded as good only when it was in conformity with the imperial will. Except for Germany, Japan was then the only nation that thought itself strong enough to extend its national ideal over the five continents. In the late 1930s Japanese professors and writers, as did their German colleagues, demanded the rejection of rational and universal ethics and the return to the ancient tribal gods in order to make the nation the most perfect instrument for its mission of conquest. The war in China was "not presented as one of conquest and exploitation but rather as a holy crusade to rid the land of unjust rulers [Chiang Kai-shek, red communists] and inaugurate there a regime of peace, righteousness and prosperity." (Harley F. MacNair, *The Real Conflict Between China and Japan,* The University of Chicago Press, Chicago, 1938, p. 193.) Later Japan spoke of a coprosperity sphere of a new Japan-led Asia.

Perón's fascistic populism

Less ambitious were the aspirations of fascism in Argentina, where the movement resembled that of Italy rather than of Germany. The initiative in Argentina came, however, not from former socialists and syndicalists but from officers, the Grupo de Oficiales Unidos (Group of United Officers), who seized power in 1943. The initials of the group's name stood for *gobierno* (authoritarian government), *orden* (order), and *unidad* (national unity). The officers believed that as a result of its relative wealth and its ethnically pure Caucasian population, Argentina was to assume the leadership in the struggle against "Yankee imperialism" and in the modernization of the continent. Among the officers, Juan Perón assumed a leading role and turned the movement into one of national socialism. With the help of his wife, Eva María (1919–52), he sought the support of the poorer masses, the *descamisados,* or shirtless ones. His attack on the traditional ruling oligarchy brought him wide popular support, so that he was twice elected president of Argentina, in 1946 and 1951. Perón organized the workers into a Confederación General del Trabajo, which was devoted to him, and claimed to have replaced "plutodemocracy." He created a mass party standing for "justicialism," a middle way between Communism and capitalism. But his own inconsistent policies and the accusation of widespread graft provoked a revolt of the armed forces in September 1955, as a result of which Perón left the country and settled in Spain.

By the latter years of the 20th century fascism seemed to have lost the attractions it had exercised in the 1920s and 1930s. After the fall of fascism in Germany and Japan both nations experienced a wave of great prosperity, which weakened, especially in the young generation, the formerly strong appeal of a militant nationalism. The conquest of a "living space," which Germany, Japan and Italy before World War II thought indispensable for the growth of their national economy, not only revealed itself as unachievable even to a broad anticommunist coalition, such as the three leading fascist powers established in 1937, but as a superfluous fancy, for the loss of empire brought misery neither to Britain nor Germany, The Netherlands or Italy, France or Japan. An unexpected industrial and agrarian productivity raised the living standards of the masses in the democracies, which could now concentrate upon necessary domestic reforms and abandon the lure of military glory. By the late 20th century fascism seemed a trend characteristic of the recent and yet faraway past. Except for small marginal movements, most elements were seeking to secure what fascism had denied, the cooperation of peoples of various civilizations and ideologies and the condemnation of war.

(H.K.)

Nationalism

Nationalism may be defined as a state of mind in which the individual feels that everyone owes his supreme secular loyalty to the nation-state. Nationalism is a modern movement. Throughout history men have been attached to their native soil, to the traditions of their parents, and to established territorial authorities; but it was not until the end of the 18th century that nationalism began to be a generally recognized sentiment molding public and private life and one of the great, if not the greatest, single determining factors of modern history. Because of its dynamic vitality and its all-pervading character, nationalism is often thought to be very old; sometimes it is mistakenly regarded as a permanent factor in political behaviour. Actually, the American and French revolutions may be regarded as its first powerful manifestations. After penetrating the new countries of Latin America it spread in the early 19th century to central Europe and from there, toward the middle of the century, to eastern and southeastern Europe. At the beginning of the 20th century nationalism flowered in the ancient lands of Asia and Africa. Thus the 19th century has been called the age of nationalism in Europe, while the 20th century has witnessed the rise and struggle of powerful national movements throughout Asia and Africa.

Identification of state and people

Nationalism, translated into world politics, implies the identification of the state or nation with the people—or at least the desirability of determining the extent of the state according to ethnographic principles. In the age of nationalism, but only in the age of nationalism, the principle was generally recognized that each nationality should form a state—its state—and that the state should include all members of that nationality. Formerly states, or territories under one administration, were not delineated by nationality. Men did not give their loyalty to the nation-state but to other, different forms of political organization: the city-state, the feudal fief and its lord, the dynastic state, the religious group, or the sect. The nation-state was nonexistent during the greater part of history, and for a very long time it was not even regarded as an ideal. In the first 15 centuries of the Christian Era, the ideal was the universal world-state, not loyalty to any separate political entity. The Roman Empire had set the great example, which survived not only in the Holy Roman Empire of the Middle Ages but also in the concept of the *res publica christiana* ("Christian republic" or community) and in its later secularized form of a united world civilization.

As political allegiance, before the age of nationalism, was not determined by nationality, so civilization was not thought of as nationally determined. During the Middle Ages civilization was looked upon as determined religiously; for all the different nationalities of Christendom as well as for those of Islām there was but one civilization—Christian or Muslim—and but one language of culture—Latin (or Greek) or Arabic (or Persian). Later, in the periods of the Renaissance and of Classicism, it was the ancient Greek and Roman civilizations that became a universal norm, valid for all peoples and all times. Still later, French civilization was accepted throughout Europe as the valid civilization for educated people of all nationalities. It was only at the end of the 18th century that, for the first time, civilization was considered to be determined by nationality. It was then that the principle was put forward that a man could be educated only in his own mother tongue, not in languages of other civilizations and other times, whether they were classical languages or the literary creations of other peoples who had reached a high degree of civilization.

Cultural nationalism

From the end of the 18th century on, the nationalization of education and public life went hand in hand with the nationalization of states and political loyalties. Poets and scholars began to emphasize cultural nationalism first. They reformed the mother tongue, elevated it to the rank of a literary language, and delved deep into the national past. Thus they prepared the foundations for the political claims for national statehood soon to be raised by the people in whom they had kindled the spirit.

Before the 18th century there had been evidences of national feeling among certain groups at certain periods, especially in times of stress and conflict. The rise of national feeling to major political importance was encouraged by a number of complex developments: the creation of large, centralized states ruled by absolute monarchs who destroyed the old feudal allegiances; the secularization of life and of education, which fostered the vernacular languages and weakened the ties of church and sect; the growth of commerce, which demanded larger territorial units to allow scope for the dynamic spirit of the rising middle classes and their capitalistic enterprise. This large, unified territorial state, with its political and economic centralization, became imbued in the 18th century with a new spirit—an emotional fervour similar to that of religious movements in earlier periods. Under the influence of the new theories of the sovereignty of the people and the rights of man, the people replaced the king as the centre of the nation. No longer was the king the nation or the state; the state had become the people's state, a national state, a fatherland. State became identified with nation, as civilization became identified with national civilization.

That development ran counter to the conceptions that had dominated political thought for the preceding 2,000 years. Hitherto man had commonly stressed the general and the universal and had regarded unity as the desirable goal. Nationalism stressed the particular and parochial, the differences, and the national individualities. Those tendencies became more pronounced as nationalism developed. Its less attractive characteristics were not at first apparent. In the 17th and 18th centuries the common standards of Western civilization, the regard for the universally human, the faith in reason (one and the same everywhere) as well as in common sense, the survival of Christian and Stoic traditions—all of these were still too strong to allow nationalism to develop fully and to disrupt society. Thus nationalism in its beginning was thought to be compatible with cosmopolitan convictions and with a general love of mankind, especially in western Europe and North America.

EUROPEAN NATIONALISM

The first full manifestation of modern nationalism occurred in 17th-century England, in the Puritan revolution. England had become the leading nation in scientific spirit, in commercial enterprise, in political thought and activity. Swelled by an immense confidence in the new age, the English people felt upon their shoulders the mission of history, a sense that they were at a great turning point from which a new true reformation and a new liberty would start. In the English revolution an optimistic humanism merged with Calvinist ethics; the influence of the Old Testament gave form to the new nationalism by identifying the English people with ancient Israel.

English Puritanism and nationalism

The new message, carried by the new people not only for England but for all mankind, was expressed in the writings of John Milton, in whose famous vision the idea of liberty was seen spreading from Britain, "celebrated for endless ages as a soil most genial to the growth of liberty" to all the corners of the earth.

> Surrounded by congregated multitudes, I now imagine that . . . I behold the nations of the earth recovering that liberty which they so long had lost; and that the people of this island are . . . disseminating the blessings of civilization and freedom among cities, kingdoms and nations.

English nationalism then was thus much nearer to its religious matrix than later nationalisms that rose after secularization had made greater progress. The nationalism of the 18th century shared with it, however, its enthusiasm for liberty, its humanitarian character, its emphasis upon the individual and his rights and upon the human community as above all national divisions. The rise of English nationalism coincided with the rise of the English trading middle classes. It found its final expression in John Locke's political philosophy, and it was in that form that it influenced American and French nationalism in the following century.

American nationalism was a typical product of the 18th century. British settlers in North America were influenced partly by the traditions of the Puritan revolution and the ideas of Locke and partly by the new rational interpretation given to English liberty by contemporary French philosophers. American settlers became a nation engaged in a fight for liberty and individual rights. They based that fight on current political thought, especially as expressed by Thomas Jefferson and Thomas Paine. It was a liberal and humanitarian nationalism that regarded America as in the vanguard of mankind on its march to greater liberty, equality, and happiness for all. The ideas of the 18th century found their first political realization in the Declaration of Independence and in the birth of the American nation. Their deep influence was felt in the French Revolution.

Jean-Jacques Rousseau had prepared the soil for the growth of French nationalism by his stress on popular sovereignty and the general cooperation of all in forming the national will, and also by his regard for the common people as the true depository of civilization.

The nationalism of the French Revolution was more than that: it was the triumphant expression of a rational faith in common humanity and liberal progress. The famous slogan "liberty, equality, fraternity" and the Declaration of the Rights of Man and of the Citizen were thought valid not only for the French people but for all peoples. Individual liberty, human equality, fraternity of all peoples: these were the common cornerstones of all liberal and democratic nationalism. Under their inspiration new rituals were developed that partly took the place of the old religious feast days, rites, and ceremonies: festivals and flags, music and poetry, national holidays and patriotic sermons. In the most varied forms, nationalism permeated all manifestations of life. As in America, the rise of French nationalism produced a new phenomenon in the art of warfare: the nation in arms. In America and in France, citizen armies, untrained but filled with a new fervour, proved superior to highly trained professional armies that fought without the incentive of nationalism. The revolutionary French nationalism stressed free individual decision in the formation of nations. Nations were constituted by an act of self-determination of their members. The plebiscite became the instrument whereby the will of the nation was expressed. In America as well as in revolutionary France, nationalism meant the adherence to a universal progressive idea, looking toward a common future of freedom and equality, not toward a past characterized by authoritarianism and inequality.

Napoleon's armies spread the spirit of nationalism throughout Europe and even into the Near East, while at the same time, across the Atlantic, it aroused the Latin Americans. But Napoleon's yoke of conquest turned the nationalism of the Europeans against France. In Germany the struggle was led by writers and intellectuals, who rejected all the principles upon which the American and the French revolutions had been based as well as the liberal and humanitarian aspects of nationalism.

German nationalism began to stress instinct against reason; the power of historical tradition against rational attempts at progress and a more just order; the historical differences between nations rather than their common aspirations. The French Revolution, liberalism, and equality were regarded as a brief aberration, against which the eternal foundations of societal order would prevail.

The 1848 revolutionary wave

That German interpretation was shown to be false by the developments of the 19th century. Liberal nationalism reasserted itself and affected more and more people: the rising middle class and the new proletariat. The revolutionary wave of 1848, the year of "the spring of the peoples," seemed to realize the hopes of nationalists such as Giuseppe Mazzini, who had devoted his life to the unification of the Italian nation by democratic means and to the brotherhood of all free nations. Though his immediate hopes were disappointed, the 12 years from 1859 to 1871 brought the unification of Italy and Romania, both with the help of Napoleon III, and of Germany; at the same time the 1860s saw great progress in liberalism, even in Russia and Spain. The victorious trend of liberal nationalism, however, was reversed in Germany by Bismarck. He unified Germany on a conservative and authoritarian basis and defeated German liberalism. The German annexation of Alsace-Lorraine against the will of the inhabitants was contrary to the idea of nationalism as based upon the free will of man. The people of Alsace-Lorraine were held to be German by objective factors, by race, independent of their will or of their allegiance to any nationality of their choice.

In the second half of the 19th century, nationalism disintegrated the supranational states of the Habsburgs and the Ottoman sultans, both of which were based upon prenational loyalties. In Russia, the penetration of nationalism produced two opposing schools of thought. Some nationalists proposed a westernized Russia, associated with the progressive, liberal forces of the rest of Europe. Others stressed the distinctive character of Russia and Russianism, its independent and different destiny based upon its autocratic and orthodox past. These Slavophiles, similar to and influenced by German romantic thinkers, saw Russia as a future saviour of a West undermined by liberalism and the heritage of the American and French revolutions.

One of the consequences of World War I was the triumph of nationalism in central and eastern Europe. From the ruins of the Habsburg and Romanov empires emerged the new nation-states of Austria, Hungary, Czechoslovakia, Poland, Yugoslavia and Romania. Those states in turn, however, were to be strained and ravaged by their own internal nationality conflicts and by nationalistic disputes over territory with their neighbours.

Russian nationalism was in part suppressed after Lenin's victory in 1917, when the Bolsheviks took over the old empire of the tsars. But the Bolsheviks also claimed the leadership of the world Communist movement, which was to become an instrument of the national policies of the Russians. During World War II Stalin appealed to nationalism and patriotism in rallying the Russians against foreign invaders. After the war he found nationalism one of the strongest obstacles to the expansion of Soviet power in eastern Europe. National communism, as it was called, became a divisive force in the Soviet bloc. In 1948 Tito, the Communist leader of Yugoslavia, was denounced by Moscow as a nationalist and a renegade; nationalism was a strong factor in the rebellious movements in Poland and Hungary in the fall of 1956; and subsequently its influence was also felt in Romania and Czechoslovakia and again in Poland in 1980.

ASIAN AND AFRICAN NATIONALISM

Nationalism began to appear in Asia and Africa after World War I. It produced such leaders as Kemal Atatürk in Turkey, Sa'd Pasha Zaghūl in Egypt, Ibn Sa'ūd in the Arabian peninsula, Mahatma Gandhi in India, and Sun Yat-sen in China. Atatürk succeeded in replacing the medieval structure of the Islāmic monarchy with a revitalized and modernized secular republic in 1923. Demands for Arab unity were frustrated in Africa and Asia by British imperialism and in Africa by French imperialism. Yet Britain may have shown a gift for accommodation with the new forces by helping to create an independent Egypt (1922; completely, 1936) and Iraq (1932) and displayed a similar spirit in India, where the Indian National Congress, founded in 1885 to promote a liberal nationalism inspired by the British model, became more radical after 1918. Japan, influenced by Germany, used modern industrial techniques in the service of a more authoritarian nationalism.

The new nations

The progress of nationalism in Asia and Africa is reflected in the histories of the League of Nations after World War I and of the United Nations after World War II. The Treaty of Versailles, which provided for the constitution of the League of Nations, also reduced the empires of the defeated Central Powers, mainly Germany and Turkey. The league distributed Germany's African colonies as mandates to Great Britain, France, Belgium, and South Africa, and its Pacific possessions to Japan, Australia, and New Zealand under various classifications according to their expectations of achieving independence. Among the League's original members, there were only five Asian countries (China, India, Japan, Thailand, and Iran) and two African countries (Liberia and South Africa), and it added only three Asian countries (Afghanistan, Iraq, and Turkey) and two African countries (Egypt and Ethiopia) before it was dissolved in 1946. Of the mandated territories under the League's control, only Iraq, Lebanon, and Syria achieved independence during its lifetime.

Of the original 51 members of the United Nations in 1945, eight were Asian (China, India, Iraq, Iran, Lebanon, Saudi Arabia, Syria, and Turkey) and four were African (the same as in the League). By 1980, 35 years after its founding, the United Nations had added more than 100 member nations, most of them Asian and African. Whereas Asian and African nations had never totalled even one-third of the membership in the League, they came to represent more than one-half of the membership of the United Nations. Of these new Asian and African nations, several had been created, entirely or in part, from mandated territories.

After World War II, India, Pakistan, Ceylon (Sri Lanka), Burma, and Malaya (Malaysia) in Asia, and Ghana in Africa achieved independence peacefully from the British Commonwealth, as did the Philippines from the United States. Other territories had to fight hard for their independence in bitter colonial wars, as in French Indochina (Vietnam, Laos, Cambodia) and French North Africa (Tunisia, Algeria). Communism recruited supporters from within the ranks of the new nationalist movements in Asia and Africa, first by helping them in their struggles against Western capitalist powers, and later, after independence was achieved, by competing with Western capitalism in extending financial and technical aid. Chinese nationalism under Chiang Kai-shek during World War II was diminished with the takeover of the Chinese Communists. But Chinese Communism soon began to drift away from supranational Communism, as the European Communist countries had earlier. By the late 1960s Russian and Chinese mutual recriminations revealed a Chinese nationalism in which Mao Tse-tung had risen to share the place of honour with Lenin. As Chinese Communism turned further and further inward, its influence on new Asian and African nations waned.

Political and religious differences

Ambitions among new Asian and African nations clashed. The complex politics of the United Nations illustrated the problems of the new nationalism. The struggle with Dutch colonialism that brought the establishment of Indonesia continued with the UN mediation of the dispute over West Irian (Irian Jaya). In the Suez crisis of 1956, UN forces intervened between those of Egypt and Israel. Continuing troubles in the Middle East, beginning with the establishment of Israel and including inter-Arab state disputes brought on by the establishment of the United Arab Republic, concerned the UN. Other crises involving the UN included: the India-Pakistan dispute over Jammu and Kashmir; the Korean partition and subsequent war; the four-year intervention in the Congo; the struggle of Greece and Turkey over newly independent Cyprus; and Indonesian and Philippine objection to the inclusion of Sarawak and Sabah (North Borneo) in newly formed Malaysia.

Many new nations, all sharing the same pride in independence, faced difficulties. As a result of inadequate preparation for self-rule, the first five years of independence in the Congo passed with no semblance of a stable government. The problem of widely different peoples and languages was exemplified in Nigeria, where an uncounted population included an uncounted number of tribes (at least 150, with three major divisions) that used an uncounted number of languages (more than 100 language and dialect clusters). The question of whether the predominantly Muslim state of Jammu and Kashmir should go with Muslim Pakistan or Hindu India lasted for more than 20 years after the India Independence Act became effective in 1949. Desperate economic competition caused trouble, as in Israel where the much-needed waters of the Jordan River kept it in constant dispute with its water-hungry Arab neighbours.

In Europe the spirit of nationalism appeared to wane after World War II with the establishment of international economic, military, and political organizations such as NATO, the European Coal and Steel Community, Euratom, and the Common Market. But the policies pursued by France under Pres. Charles de Gaulle and the problem of a divided Germany showed that the appeal of the nation-state was still very much alive. (H.K./Ed.)

Liberalism

Liberalism does not lend itself to easy definition. A major difficulty is that, with some exceptions, liberals have shunned dogma, preferring generally a pragmatic to a doctrinaire approach to social problems. Another, which has been a prolific source of misunderstanding, has been liberals' own frequently opposing views concerning the scope of government. The confusion thus engendered is sometimes compounded by a tendency to identify liberalism exclusively with its 18th- and 19th-century variant, or with the program of this or that liberal party, in a formulation that has on occasion led many to announce the "decline" or "end" of liberalism and to compose obituaries that have been quite misleading. Through the centuries liberalism has changed drastically in content, but it has maintained a constant form. Those who note the first and neglect the second understandably find the term confusing and its application inconsistent.

HISTORICAL BACKGROUND

Liberalism is the culmination of a development that goes back to the Hebrew prophets, the teachings of the pre-Socratic philosophers, and the Sermon on the Mount, from all of which there emerged a sense of the importance of human individuality, a liberation of the individual from complete subservience to the group, and a relaxation of the tight hold of custom, law, and authority.

Throughout much of his history, man as an individual has been submerged in his group. His emancipation as an individual can be understood as a unique achievement of Western culture, perhaps its very hallmark. If this be so, then the emergence of liberalism was, in an important sense, inseparable from Western man's quest for freedom; for liberalism, in the broadest sense, seeks to protect the individual from arbitrary external restraints that prevent the full realization of his potentialities.

Mercantilism and the rise of the middle class

Medieval society did not provide a soil in which the first seeds of liberalism might easily germinate. The Middle Ages produced a society of status in which the rights and responsibilities of the individual were determined by his place in a stratified, hierarchically ordered system. Such a closed, authoritarian order, however grandiose in outline and noble in aspiration, was bound to place great stress upon acquiescence and conformity. As new needs and interests, generated by the slow commercialization and urbanization of Europe, gained strength, the medieval system was modified to accommodate the ambitions of national rulers and the requirements of an expanding industry and commerce. The ensuing policies and arrangements came to be known as mercantilism, a policy of state intervention that, in theory at least, might be extended to regulation of the most minute details of economic life (*cf.* Eli Heckscher, *Mercantilism,* 1935). However, as such intervention came more and more to serve established interests and to inhibit enterprise, it was challenged by the members of the newly emerging middle class. The challenge took the form of revolt, first against the Universal Church, and later against mercantilist states, presided over by absolute monarchs. The former manifested itself in the Protestant Reformation and the quest of Calvinists and Calvinist sects for freedom of conscience; the latter in the great revolutions that rocked England and France in the 17th and 18th centuries, notably the Glorious Revolution of 1688, the French Revolution a century later, and the successful revolt of England's American colonies. Classical liberalism as an articulated creed is a product of those great collisions.

The fortunes of liberalism differ with the historical conditions in each country—with the strength of the crown, the élan of the aristocracy, the pace of industrialization, and the circumstances of national unification. Thus, by contrast with England, the character of liberalism in France reflected the decadence of its nobility and the absolutism of the Bourbons. The failure of liberalism in Germany in the 19th century was attributable in great part to the dominant role of a militarized and Lutheran Prussia and the reactionary influence of Austria. The advent of liberalism in Italy was delayed by the armies of Austria and of Louis-Napoleon and the opposition of the Vatican. Whatever the variations, the liberal impact on authoritarianism reverberated throughout Europe and its dominions, voiced by a Kossuth in Hungary, a Mazzini in Italy, a Thorbecke in The Netherlands, a Bolívar in South America. For a moment even Russia, in 1905 and again between March and November in 1917, heard the echo and, had there been a sufficiently numerous middle class to listen, the course of modern history would no doubt have been changed.

ECONOMIC AND POLITICAL FOUNDATIONS

The authors of the liberal creed differ widely, even in the countries in which liberalism was cradled. But their agreements sufficiently exceed their differences to permit their being included in the same tradition—a tradition whose main manifestations are both economic and political. The fact that the classical liberals, perhaps more perceptively than their successors, regarded these as only abstractly separable is indicated in the very title of their science—political economy.

"Private vices, public benefits"

The economics of the "free" market. On the economic side 18th- and 19th-century liberalism based itself on the sovereignty of the market and the "natural harmony of interests." On this view, if individuals are left free to pursue their self-interest in an exchange economy based upon a division of labour, the welfare of the group as a whole will necessarily be enhanced. Classical liberal economists describe a self-adjusting market mechanism free from all teleological influences. While moral goals are invoked and ethical criteria presupposed in passing ultimate judgment on the system, they play no part in determining the sequence of events within it. The one propelling force is the selfishness of the individual, which becomes harnessed to the public good because in an exchange economy he must serve others in order to serve himself. It is only in a *free* market, however, that this happy consequence can ensue; any other arrangement must lead to regimentation, exploitation, and economic stagnation. The most celebrated formulation of this doctrine is to be found in Adam Smith's *Wealth of Nations:*

> He generally, indeed, neither intends to promote the public interest, nor knows how much he is promoting it.... by directing... industry in such a manner as its produce may be of the greatest value, he intends only his own gain, and he is in this, as in many other cases, led by an invisible hand to promote an end which was no part of his intention. Nor is it always the worse for the society that it was no part of it. By pursuing his own interest he frequently promotes that of the society more effectually than when he really intends to promote it. I have never known much good done by those who affected to trade for the public good. It is an affectation, indeed, not very common among merchants, and very few words need be employed in dissuading them from it.

The same thought had been expressed more tersely by Bernard de Mandeville (*c.* 1670–1733) in the phrase, "private vices publick benefits." A poet (Pope) said it best:

Thus God and Nature link'd the gen'ral frame,
And bade Self-love and Social be the same.

Every economic system must be concerned with at least two basic problems: first, arrangement must somehow be made for determining *what* shall be produced—*i.e.,* how "scarce means" shall be allocated—and, second, there must be some way of apportioning what is produced. In a controlled economy this is accomplished by a planning agency acting at the behest of the government. In the economy envisaged by the classical economists of the 18th and 19th centuries, and those conservative economists who today may be called neoclassicists, this is accomplished in the free market through the price mechanism. In such a market the theoretically free choices of individual buyers and sellers determine how the resources of society (labour, goods, capital) shall be employed. These choices manifest themselves in bids and offers that in their totality determine the price at which a commodity will sell. Theoretically, when the demand for a commodity is great, prices will rise, making it profitable for producers to increase the supply; as supply approximates demand, prices will tend to fall until producers divert productive resources to other uses. In this way the closest possible coincidence is said to be achieved between what is wanted and what is produced. Moreover, in the distribution of the wealth thereby produced, the system is asserted to assure a reward in proportion to merit. The assumption is that in a freely competitive economy in which no one is barred by status from engaging in economic activity, the income received from such activity is a fair measure of its value to society.

Man—the rational economic animal

Presupposed in the foregoing is a conception of man as an economic animal rationally engaged in minimizing costs and maximizing gains (wages, profit, interest). Egoistic and hedonistic assumptions about human nature, which were taken for granted, led easily to an emphasis on man as a forward-looking and end-seeking creature. "When matters of such importance as pain and pleasure are at stake... who is there that does not calculate," Bentham asked. In Pope's descriptive couplet, although

Self-love, the spring of motion, acts the soul;
Reason's comparing balance rules the whole.

If, as the Enlightenment liberals assumed, "reason's comparing balance" rarely fails man in any of his activities (Bentham went so far as to construct an entire theory of penology based on the assumption that even would-be lawbreakers carefully balance the pleasure to be derived from their contemplated crime against the pain of punishment), it could be affirmed *a fortiori* that they would also meticulously balance utilities against costs at the marketplace. Since rational men best know their own interest, it must follow that interference by agencies of government could only diminish that "greatest happiness of the greatest number" that the followers of Bentham claimed to desire.

Assumed also by the classical creed is a conception of the consumer as sovereign, decreeing by his purchases how the resources of society shall be allocated. No one has celebrated this coronation of the consumer more eloquently than Ludwig von Mises in his *Omnipotent Government:*

> Within the market society the working of the price mechanism makes the consumers supreme. They determine through the prices they pay and through the amount of their purchases both the quantity and quality of production. They determine directly the prices of consumers' goods, and thereby indirectly the price of all material factors of production and the wages of all hands employed.
>
> ... In that endless rotating mechanism [*i.e.,* a market society] the entrepreneurs and capitalists are the servants of the consumers. The consumers are the masters, to whose whims the entrepreneurs and capitalists must adjust their investments and methods of production. The market chooses the entrepreneurs and the capitalists and removes them as soon as they prove failures. The market is a democracy in which every penny gives a right to vote and where voting is repeated every day.

The justification of private property

Implied by the logic of this economic creed is a functional justification of private property, often buttressed, to be sure, by a doctrine of natural right to shield manifestly functionless claims to property. John Locke's *Two Treatises of Government* (1690) pointed the way by defining property as "whatsoever... [man] hath mixed his labour with...." Adam Smith found that "The property which every man has in his own labour... is the original foundation of all property...." And Bentham noted that "It is this right that has overcome the natural aversion to labour...." Since acquisitiveness and indolence were regarded as inborn and ineradicable human traits, security of property had to be preserved if incentive was not to be destroyed and the production of goods discouraged. Both French revolutionaries and English gentry could be rallied to such a defense of property; and the American Constitution as well as the French Declaration of the Rights of Man and of the Citizen, both of them liberal testaments, charge government with basic responsibility for its protection.

The role of government. On the political side the guiding principle of historical liberalism has been an undeviating insistence on limiting the power of government. Inspired by the need to remove the state from destructive interference with the economic life of the community, the principle degenerated, under the influence of men like Herbert Spencer, into a doctrinaire form of antistatism. Spencer would even forbid government, either local or national, to assume responsibility for the paving, lighting, and sanitation of cities. Even the less doctrinaire Bentham's sole advice to the state was to "Be quiet," and Edmund Burke—who in this context must be reckoned a liberal—declared that "It is in the power of the state to prevent much evil; it can do very little positive good...." Thomas Paine, eloquent pamphleteer for the American Revolution (of which Burke approved), wrote in his "Common Sense" that "Government, even in its best state, is but a necessary evil...," and generations of Americans almost ritualistically repeated Thomas Jefferson's advice that that government is best that governs least.

The prevailing view was perhaps best spelled out in Adam Smith's enumeration of government functions. Smith assigned the "sovereign" three tasks: to protect the group from outside violence; to protect individual members of society from the injustices or oppressions of their fellow citizens; and, finally, to erect and maintain "those public institutions and those public works, which, though they may be in the highest degree advantageous to a great society, are however of such a nature, that the profit could never repay the expense to any individual, or small number of individuals...." An agenda more faithful to Adam Smith's intent would provide a central place for the enforcement of contracts, without which voluntary individual arrangements could hardly replace government fiat in the conduct of economic affairs.

In general, liberals believed that government must not do for the individual what he is able to do for himself. Legislation like Britain's Ten Hours Act (1847), which limited the labour of women and children to 58 hours a week, was denounced by the English jurist A.V. Dicey as late as 1905 as socialistic. Criticizing the Adulteration of Food or Drink Act and the Sale of Food and Drugs Act of 1899, he contended that such laws safeguard individuals from mistakes "which often may be avoided by a man's own care and sagacity" and therefore "rest upon the idea... that the State is a better judge than a man himself of his own interest..." (*Law and Public Opinion in England,* 2nd ed.; 1914; pp. 237–238; 263–264). Such views were even more prevalent in the United States.

Separation of powers. The institutional devices by means of which liberals sought to limit government to the exercise of its proper functions were numerous: federalism (though not in France and Britain), bicameralism, the separation of powers. The last of these, that is, the distribution of power among such functionally differentiated agencies of government as the legislature, the executive, and the judiciary, and the system of checks and balances by which it was accomplished, was given its classic embodiment in the U.S. Constitution and its political justification in that brilliant apology for the Constitution *The Federalist* (1787–88), by Hamilton, Madison, and Jay. Montesquieu had already formulated such a doctrine in his famous *De l'esprit des loix* (1748; Eng. trans., *The Spirit of Laws,* 1750), receiving the idea from Locke, who had not developed it fully.

The Federalist

Such a separation of powers could have been achieved, of course, through a "mixed constitution," that is, by having a monarch, a hereditary chamber, and an elected assembly share in power with some appropriate differentiation of function. The Greek historian Polybius hailed such a mixed government as the glory of the Roman constitution, and Blackstone (misled perhaps by Montesquieu) in his famous *Commentaries on the Laws of England* (1765–69) extolled its embodiment in the constitution of England, as Burke was to do later with greater eloquence. But it was precisely despotic kings and functionless aristocrats (more functionless in France than in England) who thwarted the interests and ambitions of the middle class, which turned, therefore, to the principle of majoritarianism.

Liberal conflicts of interest. The greatest check on government is, of course, the threat of dismissal by its constituents. But in determining the crucial question of who the constituents are to be, classical liberalism fell victim to an ambivalence, torn between the great emancipating tendencies generated by the revolutions with which it was associated and middle-class fears that democracy would undermine private property. Most 18th- and 19th-century liberal spokesmen feared popular sovereignty, and for a long time suffrage was limited to property owners. In Britain even the important Reform Act of 1867 did not completely abolish property qualifications. France, for her part, bore revolutionaries but suckled reactionaries: although the Revolution of 1789 proclaimed the ideal of universal manhood suffrage and the Revolution of 1830 reaffirmed it, there were no more than some 200,000 qualified voters in a population of about 30,000,000 during the reign of Louis-Philippe, "citizen king" installed by the ascendant bourgeoisie in 1830. And, in the United States, Jefferson's brave language in the Declaration of Independence notwithstanding, it was not until 1860 that universal white male suffrage prevailed.

Although by the time of the Revolution he had changed his opinion, Benjamin Franklin spoke for the Whig liberalism of the Founding Fathers when he observed that "as to those who have not landed property the allowing them to vote is an impropriety." John Adams in his famous *Defense of the Constitutions of Government of the United States of America* (1787) was more explicit, finding that, if the majority were to control all branches of government, "Debts would be abolished first; taxes laid heavy on the rich, and not at all on others; and at last a downright equal division of everything be demanded and voted." Thomas Babington Macaulay spoke for English Whigs when he found universal suffrage "incompatible, not with this or that form of government, but with all forms of government." French statesmen like François Guizot (1787–1874) and Adolphe Thiers (1797–1877) expressed similar sentiments, and on the rest of the continent universal suffrage was for the most part a remote ideal until the turn of this century.

The fear of majority tyranny

Objections to democracy were not limited to misgivings about the fate of private property. Many liberals genuinely feared the potentialities for tyranny latent in democracy. If the will of the majority is to be supreme, everyone will be at its mercy. Benjamin Constant (1767–1830), noted French diplomat, expressed a general concern when he observed that from the point of view of the individual it makes no difference whether he is tyrannized by a single despot or by the totality of individuals composing his society; he is oppressed just the same. Indeed the latter could well be worse: tyrannicide might rescue him from an individual oppressor and, in any event, others would commiserate with him; whereas if oppressed by a large majority, he would have no comparable recourse or comfort.

Despite such misgivings, the voices of Thomas Paine and Jefferson, of Rousseau and de Tocqueville, and of the English philosophical radicals led by Bentham and James and John Stuart Mill finally prevailed among the liberal philosophers. But the democratic principle that they espoused had first to be reconciled with the liberal requirement that power be limited. The problem was to accomplish this in a manner consistent with the democratic ideal, that is, without doing violence to the majoritarian principle and in conformity with Bentham's dictum that each person is to count as one and no one as more than one. How, since hereditary elites were discredited, could the power of a majority be checked without giving greater voice to property owners or some other kind of "natural" elite?

The liberal formula. The essence of the liberal solution is twofold. It lies partly in making the decision of any given majority subject to the concurrence of other majorities distributed over a period of time. The majority that elects a president of the United States, for example, is different from the majority that two years before elected one-third of the Senate and two years later elects another third. Likewise two-thirds of the senators are elected by a majority other than the majority by which members of the House of Representatives are elected. These groups, in turn, are checked by the Constitution, which was approved and later amended by majorities no longer alive. While an act of Britain's Parliament is forthwith a part of the British constitution, Parliament before acting on a highly controversial issue of great concern to the country will seek a mandate from the people, that is to say, a majority other than the majority that elected it. Thus, the "people" to be consulted in a liberal democracy, if they are not quite that partnership envisaged by Burke "... between those who are living, those who are dead, and those who are to be born," are not either, except in a revolutionary crisis, a "momentary aggregation" whose sovereign will may be ascertained by a plebiscite. Burke's characterization of democracy as "the vulgar practice of the hour" may well apply to those spontaneous assemblies of the people to which Rousseau would assign plenary power; it can be denied that it applies to the mainstream version of liberal democracy that is essentially *constitutional* democracy, that is to say, democracy in which the power of a current majority is checked by the verdicts of majorities that preceded it.

The second part of the solution is related more directly to the initial inspiration of liberalism, its basic commitment to the autonomy and integrity of the individual, which the limitation of power is, after all, intended to preserve. In the liberal understanding, the individual is not only a citizen who shares a social compact with his fellows; he is a person and, as such, he possesses rights that the state may not invade. Even as a citizen, he must, if majoritarianism is to be meaningful, possess such rights. Majorities do not form in a vacuum. Unless a majority verdict is some miraculous coincidence or spontaneous merger of individual judgments—which it is not—it can come about only if individuals are free to some extent to formulate and express and exchange their views. This involves, beyond the right to speak and write freely, the freedom to associate and organize and, above all, freedom from fear of reprisal. But the individual has rights apart from his role as citizen. These are rights that secure his personal safety and hence his protection from arbitrary arrest and punishment. And beyond these are those rights that preserve large areas of *privacy*. In a liberal democracy there are affairs that do not concern the state, even if the state's interest in them reflects the will of an overwhelming majority. Such affairs may range from the worship of God, to works of art, to how parents raise their children. And for the liberals of the 18th and 19th centuries they included, above all, most of those activities in which individuals engage in production and trade.

Classical liberals differed in their interpretation of individual rights—whether to understand them as "natural" (Locke) and therefore "inalienable" and "indefeasible," to justify them as functional (Bentham) or traditional (Burke). But eloquent and persuasive declarations affirming such rights were embodied in the English Bill of Rights of 1689, the American Declaration of Independence and Constitution, the French Declaration of the Rights of Man and of the Citizen of 1789, and the basic documents of nations throughout the world that later used these as their models. Freedom thereby became more than the right to make a fractional contribution in an intermittent mandate to government; it designated the right of men to live their own lives.

The problems of the dispossessed

Rhetoric and reality rarely coincide. Liberals were not usually troubled over the small numbers by whom, in fact, such freedom was enjoyed, and the masses were still too inarticulate to remind them. In the dawn of the Industrial Revolution, the blessings of liberty must have seemed remote to millions of brutally exploited factory workers huddled together in the slums of their dreary cities. Liberals have been accused of concentrating exclusively on the property right to the neglect of such abuses, and, in general, few liberals paused to ponder how the freedom they cherished would be used, and it did not occur to them, as it has to a later generation of libertarians, that such freedom brings with it a heavy burden of choice and decision. Finally, in their concern for the individual, liberals depicted him too simply as an isolated monad, and society as a collection of such monads, failing to reckon with the myriad social relationships through which individuals achieve identity.

ACHIEVEMENT AND FAILURE

In historical perspective it can be seen that the complex of forces, of which classical liberalism was the rationalization, wrought great changes. The feudal system was destroyed. Capitalism replaced the static society of the Middle Ages. A functionless aristocracy was deprived of its privileges. Tyrants were challenged and curbed. The middle class was left free to employ its energies in expanding the means of production and vastly increasing the wealth of society. Representative government came into its own. As they set about limiting the sovereign power, liberals converted the ideal of constitutional government into a reality, and they developed a doctrine of individual rights, including the right to worship freely, the right of a free press, of free speech, and of free assembly, which lies at the heart of modern democracy. J.S. Mill's essay *On Liberty* (1859) is justly celebrated as one of the great testimonials to civil liberties.

However, vast economic changes, first in Great Britain and later in the United States, led increasingly at the turn of this century to disenchantment with the principal economic basis for liberalism—the ideal of a market economy. (This ideal had never evoked comparable loyalties on the continent of Europe.) The advent on a large scale of absentee ownership made it increasingly difficult to invoke a functional justification for many forms of private property. Multitudes whose real bargaining power fell far short of what it was in theory—especially those seeking work—did not actually enjoy the "free choices" postulated by the economists. Economic man's "pecuniary sagacity" (Veblen) fell far short of the idealizations of textbook writers; and modern psychology suggests that he is at least as much a creature of impulse, habit, and custom as he is a rational calculator with his eye on the main chance. The often impenetrable complexity of goods offered on the market in an economy where transactions are no longer simple affairs of horse-trading, not to mention the mendacity of much advertising, seemed to make the consumer more a subject than a sovereign. Reality failed to approximate the state of free competition envisaged by the classical economists. Orthodox liberal economists have accordingly referred with increasing frequency to "frictions" and "exceptions" and have employed qualifications ("in the long run"; "other things being equal") to save their generalizations. The result has been an abstract science that a new generation of liberals and multitudes of socialists came to regard as having only limited relevance to the real world.

Concentration of wealth and irrational economies

Worst of all, according to its critics, the profit system concentrated vast wealth in relatively few hands, with several decisively adverse consequences. First, great masses of people failed to benefit from the wealth flowing from mines and mills and lived under impoverished conditions that became increasingly anomalous in an affluent society. Second, since those who alone could consume the output of a vastly expanded productive system lacked the purchasing power, the system, after other markets were glutted, endemically failed to realize its productive potentialities and recurrently came to a near halt in periods of stagnation that have come to be called "depressions." Finally, those who owned the means of production, or their managers, were endowed with vast power that could be used to overwhelm the individual as surely as the power of a 17th-century despot, thanks to the device of incorporation on a scale far beyond the simple requirements of efficiency and economy in production. In short, the near atrophy of government achieved in the 19th century had left a vacuum that private interests readily filled. Businesses were effectively organized and some of them used their power to influence and control government, to manipulate an inchoate electorate, to limit competition, and to obstruct substantive social reform. Some of the same forces that had once released the productive energies of Western society now restrained them; some of the very energies that had demolished the power of despots now nourished a new despotism. Such, at any rate, was the verdict of 20th-century liberals and such were the conditions that led them to oppose private collectivism by supporting a positive role for government and encouraging the formation of power centres outside business and government.

CONTEMPORARY LIBERALISM

The contemporary variant of liberalism is even more amorphous than the classical. There are no "fathers" such as John Locke or Adam Smith. In Germany and the Scandinavian countries, where socialists, even though they trace their ancestry to Marx, are overwhelmingly revisionist, it is difficult to distinguish between their program and programs elsewhere designated as liberal. British mainstream socialism never embraced Marx, and the Labour Party has at times been difficult to distinguish from the Liberal Party, which largely accounts for the decline of the latter. U.S. liberal social legislation since the crash of 1929 has been notably formless. But even so, the outlines of contemporary liberalism are fairly discernible.

Critique of the market. Cognizant of the real achievements of the profit system, liberals do not seek its abolition, only its modification and control. They find no fixed line laid up in heaven eternally dividing the private and the public sectors of the economy; the determination, they contend, must be by reference to what works. The spectre of regimentation in completely planned economies and the dangers of bureaucracy even in mixed economies deter them from jettisoning the market and substituting an omnicompetent state. On the other hand—and this is a basic difference between classical (or neoclassical) and contemporary liberalism—most liberals now believe that the dispensations of the market, as it has in fact operated, must be supplemented and corrected in substantive ways. They hold that the rewards dispensed by the market are too crude a measure of the contribution many or most people make to society, and that the needs of those who lack opportunity or are physically handicapped are ignored. They contend that enormous social costs incurred in production are not reflected in market prices, and that resources are used wastefully. Not least, liberals charge that the market biasses the allocation of human and physical resources in the direction of satisfying superficial wants (for oversized motor cars in annual models, changing fashions in attire, and unnecessary gadgets), while basic needs (for schools, housing, rapid public transit, sewage treatment plants) go unmet. Finally, although liberals believe that prices, wages, and profits should continue to be subject to negotiation among the interested parties and responsive to conventional market pressures, they insist that price–wage–profit decisions *affecting the economy as a whole* must be reconciled with public policy.

The liberal program. To achieve a juster distribution of rewards, liberals have relied on two major strategies. First, they have promoted the organization of workers and consumers to improve their power to bargain with employer-producers. Such a redistribution of power has had political as well as economic consequences, making possible a party system in which at least one party is responsive to the interests of wage earners and consumers. Second, enlisting the political support of the economically deprived, liberals have evolved the so-called welfare state, with its panoply of social services "from the cradle to the grave."

Foundations of the welfare state

Social legislation, beginning with free public education and workmen's accident insurance, now includes support for all who are physically and mentally handicapped, programs of old-age, unemployment, and health insurance, minimum-wage laws, and—for the most part still in the blueprint stage—guaranteed annual incomes. Such legislation is most comprehensive in the Scandinavian countries and, among countries with mature economies, possibly least comprehensive in the United States, where social legislation at the federal level was virtually ignored until passage of the Social Security Act of 1935.

Liberals have been less successful in correcting what they regard as an irrational schedule of priorities by using the taxing powers of government to obtain greater allocations for the public sector of the economy. They have been least successful, at any rate in the United States, in persuading the business community and labour unions to accept government participation in pricing and wage decisions.

Initially, the quest for these objectives was viewed as requiring a redistribution of wealth to be achieved by steeply graduated income and death (inheritance) taxes—a program likely, if it were to become confiscatory, to evoke the unlimited resistance of high-income groups. Increasingly, as modern technology promised mature economies miracles of abundance, attention shifted to the institutional failures that kept such economies from fully realizing their productive potentialities, especially during periods of mass unemployment and depression. The culmination of this effort was the White Paper on Employment Policy produced by Britain's wartime coalition government and, in the United States, the Employment Act of 1946, which goes well beyond the British, declaring it to be "the continuing policy and responsibility of the Federal Government to use all practicable means . . . to promote maximum employment, production, and purchasing power." Thereafter the old rhetoric about "sharing the wealth" gave way to concentration on growth rates as liberals, inspired by J.M. Keynes' *General Theory of Employment, Interest and Money,* urged the use of fiscal policy—*i.e.,* use of the government's power to borrow, tax, and spend—not merely to counter contractions of the business cycle but to encourage expansion of the economy. Here, clearly, was a program less disruptive of class harmony and the basic consensus essential to a democracy than the old Robin Hood method of "taking from the rich and giving to the poor."

Industrialism reconsidered

In the 1960s the emphasis of liberals again shifted as it became more and more evident that expanding production is not an unmixed blessing. The litany is now a familiar one. The same industry that produces our wealth pollutes our rivers, lakes, and atmosphere. Its gleaming artifacts become mountains of junk and it menaces the ecological balance of nature. It concentrates millions in drab cities that, in the United States at least, are being evacuated by those who can afford to escape to the suburbs. The result is a daily movement of traffic, choking the highways, poisoning the air, jangling the nerves. The inventory could be extended indefinitely. Much of the "wealth" produced by industry hardly justifies such consequences.

Some criticism goes deeper. It is urged that, quite apart from its disastrous impact on the environment, modern technology deracinates man, depriving him of his sense of identity, chaining him to a treadmill, trapping him in a depersonalized, regimented, over-organized society. The voice of the romanticist, denouncing preoccupation with production as a bourgeois aberration or an archaic Protestant ethic and urging a return to the relaxed, simple life, is once again heard. That voice is often found persuasive, it so happens, by a new generation of youthful intellectuals and vagabonds.

Most liberals contend that environmental disruption is not a necessary consequence of expanding industry but of a failure to subordinate the quest for quick profits to the requirements of intelligent planning. The "fallacy of romantic regression," as the American psychologist Kenneth Keniston has called it, is also rejected. Nevertheless, there is increased respect for Freud's reminder in *Das Unbehagen in der Kultur* (Eng. trans., *Civilization and Its Discontents,* 1930) that "power over nature is not the *only* precondition of human happiness," and more and more concern is expressed for the "quality" of life. However, Freud went on to observe that, if happiness requires more than power over nature, this "is no ground for inferring that technical progress is worthless from the standpoint of happiness." Mainstream liberals have agreed.

THE FUTURE OF LIBERALISM

The traditional coalition on which liberals in the United States have relied is in disrepair. Ethnic minorities have become confused and divided by the separatist creed of their more militant leaders; turmoil has left the academic community traumatized; and labour unions lack a good deal of their old dynamism. Even the once engagé artist has been lost to aestheticism and esotericism. The increasing polarization between right and left finds the liberals attacked on both flanks, but the appearance of beleaguerment may well be deceptive. Much of the liberal program has in fact become public policy. When, in the 1930s, Pres. Franklin D. Roosevelt established the National Resources Planning Board, it was called un-American by conservatives, its budget was slashed, and it was finally abolished. Today, although most conservatives might resist liberal proposals to establish a council on national *goals,* they would no doubt support a national agency to plan the use of natural resources. Despite appearances, Western society could be on the eve of less, rather than more, polarization.

All of this suggests a new source of strength for liberalism epitomized in what has been called the "end of ideology." Whether the movement of Western capitalist nations toward mixed economies and the Soviet Union's flirtation with the profit motive is indicative of such a trend need not be explored here. But, clearly, both socialists and conservatives in western Europe (and the British Commonwealth) are much less prone to apply pre-established dogma to new problems. And, except for the far right and left, there is a growing tendency in the United States to reject doctrinaire approaches to social problems. Ideology may not be dead, but it appears to be in decline. If the result is a pragmatic, experimental temper in which old principles are adjusted to new needs and dissent is not identified with disloyalty, this is very much in the liberal mood.

Changing policies, enduring values

The expansion of government power and responsibility sought by liberals today is clearly opposed to the contraction of government power and responsibility sought by liberals yesterday. The content of liberalism varies with varying conditions: liberals may one day challenge and another day cherish the church; in one age they may seek less government intervention in economic affairs, in another age more; they have been hospitable to the interests and ambitions of the business community, under changed circumstances they may be hostile; for decades they have preached the virtues of labour unions, they may one day consider their vices. But in every case the inspiration is the same: a hostility to concentrations of power that threaten the freedom of the individual and prevent him from realizing his potentialities; a willingness to reexamine and reconstruct social institutions in the light of new needs. This willingness, tempered by aversion to sudden, cataclysmic change, is what sets the liberal off from the radical, who often ignores its hazards. Also the very eagerness constantly to entertain and encourage useful change distinguishes the liberal from the conservative. If the content of liberalism varies, the above listed characteristics constitute its distinctive and enduring form.

The 18th-century French philosopher Condorcet could write that "human perfectibility is in reality indefinite" and that "the progress of this perfectibility, henceforth independent of any power that might wish to stop it, has no other limit than the duration of the globe upon which nature has placed us." Another French philosopher of the Enlightenment, Helvétius, wrote that "to be happy and to be powerful is only a matter of perfecting the science of education." In his *Autobiography,* John Stuart Mill, reminiscing about the elder Mill, writes:

> So complete was my father's reliance on the influence of reason over the minds of mankind, whenever it is allowed to reach them, that he felt as if all would be gained if the whole population were taught to read, if all sorts of opinions were allowed to be addressed to them by word and in writing, and if by means of the suffrage they could nominate a legislature to give effect to the opinions they adopted. He thought that when the legislature no longer represented a class interest, it would aim at the general interest, honestly and with adequate wisdom . . .

Commenting on the faith of the mid-19th century, Henry Adams noted: "Education was divine, and man needed only a correct knowledge of facts to reach perfection . . ."

Sobered by the tragic events of this century and informed by new psychological insights into man's biasses and perversities, a chastened and far more sophisticated liberalism no longer shares the naive confidence of most classical liberals in man's rationality and perfectibility and in the inevitability of progress. Most of today's liberals are more likely to heed those who warn that human nature is ineradicably flawed than heed those who hope that man may be persuaded to apply the scientific method to the solution of social problems and thereby find contentment. There is a strong suspicion that if man had no serious social problems he would invent them. Nevertheless, the strong commitment of liberals to social reform suggests a persistent optimism and a belief that man can control his fate and build a better world. To this extent the Heavenly City of the Philosophers still beckons them. (H.K.G.)

Conservatism

Continuity and stability

The term conservatism, although it has had different implications in varying historical and geographical contexts, is best reserved to denote a preference for institutions and practices that have evolved historically and that are thus manifestations of continuity and stability. Political thought, from its beginnings, contains many strains that can be retrospectively labelled conservative, but it was not until the late 18th century that conservatism began to develop as a political attitude and movement reacting against the French Revolution of 1789. The noun seems to have been first used after 1815 by French Bourbon restorationists such as François-René, vicomte de Chateaubriand. It was used to describe the British Tory Party in 1830 by John Wilson Croker, the editor of *The Quarterly Review;* and John Calhoun, a formulator of conservative minority rights against majority dictatorship in the United States, also used the term in the 1830s. The generally acknowledged originator of modern, articulated conservatism (although he never employed the term) was the British parliamentarian and political writer Edmund Burke in his essay *Reflections on the Revolution in France* (1790). Pro-parliamentarian opponents of the French Revolution, such as Burke, believed that the violent, untraditional, and uprooting methods of the Revolution outweighed and corrupted its liberating ideals. More authoritarian opponents, such as the polemicist and diplomat Joseph de Maistre, also rejected the ideals themselves. The general revulsion against the course of events in France provided conservatives with an opportunity for restoring the pre-Revolutionary traditions, and a sudden flowering of more than one brand of conservative philosophy followed.

CONSERVATIVE ATTITUDES

Because Burke's case against radicalism and revolution has also influenced liberals, there is often no sharp distinction between liberals and conservatives in action. In philosophy, however, conservatism has maintained certain sharply nonliberal assumptions about human nature.

Whether intentionally or unconsciously, whether literally or metaphorically, for example, conservatives tend to assume in politics the Christian doctrine of man's innate original sin, and herein lies a key distinction between conservatives and liberals. Men are not born naturally free or good (conservatives assume) but are naturally prone to anarchy, evil, and mutual destruction. What the 18th-century French philosopher Jean-Jacques Rousseau denounced as the "chains" that hinder man's "natural goodness," are for Burkeans the props that make man good. These "chains" (society's traditional restrictions on the ego) fit man into a rooted, durable framework, without which ethical behaviour and responsible use of liberty are impossible.

Conservatism as a state of mind

The conservative temperament may be, but need not be, identical with conservative politics or right-wing economics; it may sometimes accompany left-wing politics or economics. Regardless of a conservative's politics or economics, however, it can be said that two characteristics of the conservative temperament are: a distrust of human nature, of rootlessness, of untested innovations; and a corresponding trust in unbroken historical continuity and in traditional frameworks within which human affairs may be conducted. Such a framework may be religious or cultural or may be given no abstract or institutional expression at all. In relation to the latter aspect, many authorities on conservatism—a minority in France and a majority in England—consider conservatism an inarticulate state of mind and not at all an ideology. Liberalism argues; conservatism simply *is.* When conservatism becomes ideologized, logical, and self-conscious, then it resembles the liberal rationalism that it opposes. According to this British approach, logical deductive reasoning is too doctrinaire, too 18th century. Whereas the liberal and rationalist mind consciously articulates abstract blueprints, the conservative mind unconsciously incarnates concrete traditions. And, because conservatism embodies rather than argues, its best insights are almost never developed into sustained theoretical works equal to those of liberalism and radicalism.

Conservatism is often associated with some traditional and established form of religion. After 1789, the appeal of religion redoubled for those craving security in an age of chaos. The Roman Catholic Church, because its roots are in the monarchic Middle Ages, has appealed to more conservatives than any other religion. Himself a Church of England Protestant, Burke praised Catholicism as "the most effectual barrier" against radicalism. But conservatism has had no dearth of Protestant and strongly anticlerical adherents also.

Conservatives typically view society as a single organism and condemn as "rationalist blueprints" the attempts of progressives to plan society in advance from pure reason instead of letting it evolve naturally and unconsciously, flowering from the deep roots of tradition. They dismiss a liberal society as "atomistic," meaning composed of disrupted elements held together merely mechanically. A society, they argue, has to be rendered whole by religion, idealism, shared historical experiences, commitment to its long-standing political institutions, and by the emotions of reverence, cooperation, and loyalty; a society, they believe, can, to the contrary, be rendered atomistic by materialism, class war, excessive laissez-faire economics, greedy profiteering, overanalytical intellectuality, subversion of shared institutions, insistence on rights above duties, and by the emotions of skepticism and cynicism. Except for the German Romantic school, conservatives do not carry their conceptions of the organic wholeness of society to the extreme at which the individual becomes nothing, society everything, for they recognize that, at that extreme, one no longer has conservatism but totalitarian statism.

VARIETIES OF CONSERVATISM

The Burkean foundations. Burke did more than any other thinker to turn the intellectual tide from a rationalist contempt for the past to a traditionalist reverence for it. An Irishman, he loved England, including its established Anglican Church and its nobility, with an outsider's passion. In 1765 he became private secretary to Charles Watson-Wentworth, 2nd marquess of Rockingham, the head of the less liberal wing of the Whig Party. Against the untraditional tyranny of George III, Burke defended the American Revolution of 1776, which he viewed as being in defense of traditional liberties, but attacked the radical French Revolution of 1789 as tyranny by mobs and deracinated theorizers. At a time (1790) when the French Revolution still seemed a bloodless utopia, he predicted its later phase of terror and dictatorship, not by any lucky blind guess but by an analysis of its devaluation of tradition and inherited values.

Burke's conception of the social contract

Indeed, the core of Burke's thought and of conservatism is fear of rootlessness. Rousseau's *Social Contract* of 1762 had favoured a contract merely among the living, to arrange government for their mutual benefit. Burke, instead, argued:

> Society is indeed a contract... [but] as the ends of such a partnership cannot be obtained in many generations, it becomes a partnership not only between those who are living, but between those who are dead, and those who are to be born.... Changing the state as often as there are floating fancies,... no one generation could link with the other. Men would be little better than the flies of a summer.

Burke's veneration of the past may be contrasted with the rationalist hostility of Karl Marx, the most influential social critic of modern times: "The legacy of the dead generations weighs like a nightmare upon the brains of the living." But for Burke the contract is with "the future" as well as with the past, and he thus urges improvement, as long as it is evolutionary: "A disposition to preserve and an ability to improve, taken together, would be my standard of a statesman."

Burke was defending not conservatism in the abstract but, rather, one concrete instance of it, the unwritten British constitution. His arguments, however, were not always consistent. Sometimes he justified that constitution by "natural rights"; more often by "prescriptive right." Natural rights meant a universal code external to any given constitution; prescriptive right, a local code authoritative (prescriptive) by virtue of its age and its links with the past, which are prima facie evidence of its value. Sometimes he argued that natural rights preceded the constitution and gave it "latent wisdom." But, when arguing against French rationalists, who would justify their own revolutionary constitution by natural rights, he argued instead, and more typically:

> Our constitution is a prescriptive constitution... [whose] sole authority is that it has existed time out of mind... without any reference whatever to any other more general or prior right.

Burke shocked his century by his brutal frankness in defending "illusions" and "prejudices" as socially necessary. In doing so, however, he was, in fact, being not so much a cynic as one of the few old-fashioned Christians among 18th-century intellectuals. He was an old-fashioned Christian in the sense of believing man innately depraved, innately steeped in original sin, and incapable of bettering himself by his feeble reason. So defined, man could be tamed only by following an ethically trained elite and by education in "prejudices," such as family, religion, and aristocracy. He called landed aristocrats "the great oaks" and "proper chieftains," provided they tempered their rule by a spirit of timely reform from above and remained within the constitutional framework. He defended the Church of England for its political as well as its religious function, "To keep moral, civil, and political bonds, together binding human understanding."

Coleridge and Wordsworth. After Burke, the English poets Samuel Taylor Coleridge and William Wordsworth were significant figures in the formulation and expression of conservative sentiment. They began, however, as utopian liberals supporting the French Revolution. Wordsworth spoke for a whole generation of European intellectuals with his famous salute to the new dawn in France: "Bliss was it in that dawn to be alive, but to be young was very heaven." Disillusionment followed, and Coleridge and Wordsworth reacted against liberalism and rationalism and turned to traditional monarchy and the Church of England.

In 1798 Wordsworth and Coleridge jointly published their book of poems, *Lyrical Ballads,* marking the revolt of the human heart against abstract 18th-century rationalists and thereby helping to create a new philosophical climate. Conservatism was permanently influenced by Coleridge's prose works: *Lay Sermons,* 1816–17; *Biographia Literaria,* 1817; *Philosophical Lectures,* 1818–19; *Aids to Reflection in the Formation of a Manly Character, on the Several Grounds of Prudence, Morality, and Religion,* 1825; and his various *Letters* and *Specimens of Table Talk.* His public lectures exercised an indirect influence by molding the minds of university students who later became national leaders.

Coleridge's views on social classes

According to Coleridge, society divided its functions among different "class orders." Each class had its valuable function, but this did not necessarily include the right to vote and rule. That right was best left to an ethically trained aristocracy, functioning within the strict lawful limits of Parliament. All classes, Coleridge argued, must cooperate harmoniously within the organic unity of the constitution. His greatest influence on practical politics was through his disciple Benjamin Disraeli, later to be Conservative prime minister, and his disciple's disciple, Sir Winston Churchill. Coleridge considered businessmen often subversive, not conservative; they allegedly gnawed at the foundations of Christian monarchy by substituting a newfangled, un-Christian religion known as economic profit. Thus Coleridge, defining "shopkeepers" as "the least patriotic and the least conservative" class, fought against the Whig Reform Bill of 1832, which made "hucksters" the dominant voting group.

Maistre and Latin conservatism. It would convey an unbalanced picture of conservatism to present only the moderate and British brand founded by Burke and to omit the more extreme and Latin brand founded by Maistre (died 1821). Whereas Burkean conservatism is evolutionary, the conservatism of Maistre is counterrevolutionary. Both favour tradition against the innovations of 1789, but their traditions differ: the former fights against 1789 for the sake of traditional liberties, the latter for the sake of traditional authority. The former is not authoritarian but constitutionalist—and often parliamentary—whereas the latter, in its stress on the authority of some traditional elite, is often justifiably called not conservative but reactionary. To call it totalitarian, however, would be to go much too far, for its authority does not try to be "total," in the sense of taking over the total personality, the total culture, but is restricted to politics—and sometimes also religion. The distinction between the authoritarian and the totalitarian separates even the most reactionary conservative from the totalitarian Nazis and Communists.

After the breakdown of the French Revolution, Maistre became the most influential philosophical spokesman for the *ancien régime.* Against the slogan "liberty, equality, fraternity," he seemed almost personally to embody the slogan "throne and altar." His program consisted of a restoration of hereditary monarchy, but a more religious and less frivolous monarchy than before. He was an international refugee after the French, during the Revolution, invaded his native Savoy—then a French-speaking province of the Italian-speaking monarchy of Piedmont-Sardinia. He became for 14 years Sardinian ambassador to Russia, where his restorationist faith was strengthened by the example of the absolute monarchy still functioning there.

Maistre on the role of monarchy

Both restorationist and evolutionary conservatives defended monarchy as a social cement needed to hold society together, to keep it "organic," not "atomistic." But, while the Maistre school (key source of conservative thought in Spain and Italy as well as France) defends monarchy as absolute, the evolutionary British school defends it merely as being "pragmatic"; that is, useful. Maistre and many continental monarchists carried their belief in the monarchy to the extreme of demanding "love" even for an "unjust" ruler, earthly or heavenly:

> We find ourselves in a realm whose sovereign has proclaimed his laws. . . . Some . . . appear hard and even unjust . . . What should be done? Leave the realm, perhaps? Impossible: the realm is everywhere. . . . Since we start with the supposition that the master exists and that we must serve him absolutely, is it not better to serve him, whatever his nature, with love than without it?

This chain of authoritarian reasoning reached its climax in a logical if inhuman paradox: "The more terrible God appears to us . . . the more our prayers must become ardent. . . ." Cruel as these arguments sound, the motive of the personally mild Maistre was humane: revolts against cruel authority would inflict even crueler sufferings on mankind. He drew from the French Revolution the lesson that submission to traditional authority, though admittedly a bitter pill, was Europe's cure for a still more bitter chaos.

Maistre's politics were a theological drama in which "order" (his key concept) was angelic, "chaos" diabolic, and "revolution" original sin. Seduced by the glittering *Social Contract* of Rousseau, giddy and inexperienced nations might lust after democracy or a plebeian Bonapartist dictatorship. But they would come to a perfectly dreadful end, which would serve them right for provoking the wages of sin: "Because she [Europe] is guilty, she suffers" (1810). From suffering, Maistre argued, Europe would learn that the purest order is a fatherly Christian monarchy. Even kings must avoid rocking the boat of order with liberal "innovations": Europe must "suspect" the word "reform." In *Du Pape* (1817; "Concerning the Pope"), he analyzed "order" further: its hierarchical pyramid logically required one supreme apex. That apex must be no earthly monarch, of which there were so many, but the union of earthly and spiritual power in the papacy.

The vast extent of the instability following the French Revolution surprised even its supporters, and the problem of how to restabilize society emerged as one of some practical importance. According to Maistre's *Soirées de Saint-Pétersbourg* (left unfinished 1821; "Evening Conversations in St. Petersburg"), the solution was more faith and more police. That combination he summed up in his own frank formula: "the pope and the executioner." The pope was the positive bulwark of order: he gave faith. The executioner was the negative bulwark: he suppressed disorder. Himself an intellectual, Maistre indicted intellectuals as "rebellious" and "insolent" fomenters of disorder.

Maistre, this very secular exalter of clericalism, resembled not the Church Fathers but the very rationalists he attacked. He arrived at his glorification of unreason and of divine authority not by mystic intuition—not even by unthinking acceptance of traditional authority—but by using his own mind independently, rationally, and with steps of deductive logic. Though Maistre would never have admitted it, he might be characterized as the last abstract rationalist of the whole Voltairean Age of Reason. Even more than the rationalist Voltaire and as much as the rationalist Jacobins, Maistre believed in pure and absolute ideas, although his idea was absolute authority rather than absolute reason. In Maistre the destructive deductive logic of the 18th century was carried so far that it destroyed even itself—pure reason committing suicide for the sake of pure order.

This division into Burke and Maistre wings does not mean both were equal in importance or influence. No work of Maistre or any other anti-Jacobin has approached the influence of Burke's classic essay. Burke, above all, was the first to formulate the rebuttal to the French Revolution; his arguments were borrowed, sometimes word for word, by all later conservatives, including the restorationists. Maistre's rigid hierarchical conservatism is in the latter part of the 20th century dying out, whereas Burke's more flexible brand is stronger than ever, permeating all parties of the West, emphatically including democratic Socialists with their increasing stress, in Great Britain and Germany, on what a Fabian Socialist has called, in good Burkean language, "the inevitability of gradualness."

Later French conservatism

French conservatism after Maistre presents a diversified range of views, from the thought of Charles Maurras, the far-right editor of *L'Action Française* who seemed more fascist than conservative and became a Nazi collaborator, to the anti-authoritarian Alexis de Tocqueville, author of *Democracy in America* (1835–40) and the most Burkean French critic of the Revolution and of plebiscitarian mass democracy. To some extent, however, Tocqueville, an evolutionary parliamentarian, can also be regarded as a liberal thinker. In between Maurras and Tocqueville come the great anti-Jacobin Hippolyte-Adolphe Taine; the philosophical novelist Maurice Barrès, more a nationalist than anything else but conservative in his stress on organic roots; and Louis-François Veuillot, the editor after 1843 of the newspaper *L'Univers Réligieux* and a clerical restorationist who ably readapted Maistre to the industrial modern world. An influential right-wing extremist, less clerical and more statist than Maistre and Veuillot, was Louis-Jacques-Maurice de Bonald, the apologist for Napoleon's empire and then for the Bourbon Restoration.

Metternich and the Concert of Europe. The problems posed by the widespread social unrest of the Revolutionary and Napoleonic periods and their aftermath, and the insecurity of governments in the face of demands for constitutions and liberal reforms, provoked a reaction of more immediate and far-reaching consequence than the writings of conservative theorists. During the period 1815–48, Prince Metternich, a major influence in Austria and in Europe generally, devoted his energies to erecting an anti-revolutionary chain of international alliances throughout Europe in order to protect the multinational empire that he administered.

Metternich viewed the liberal revolutions of the 1820s and 1830s in Italy, Spain, and Germany as being unhistorical and unrealistic. Liberals were trying to transplant from England free institutions, which had no historic roots on the Continent. He retorted with Burkean arguments about the need for old roots and orderly organic development. Hence, his sarcastic comments on the liberal revolutions in Naples and elsewhere:

> A people who can neither read nor write, whose last word is the dagger—fine material for constitutional principles! . . . The English constitution is the work of centuries. . . . There is no universal recipe for constitutions.

Though his repressive Carlsbad Decrees of 1819 infringed inexcusably on basic liberties, his attitude was not always so negative. Just before his fall in 1848, he was at last winning acceptance from the archdukes of his sincere, thoughtful, and practical plan (postponed too long by the reactionary emperor Francis I) to convoke delegates from all the provincial estates to a representative body in Vienna.

Metternich was a dominating figure at the Congress of Vienna, the international peace conference of 1815 after the Napoleonic Wars. The Vienna peace was based on certain conservative principles shared by the Austrian delegate

Conservative objectives following the Napoleonic Wars

Metternich, the British delegate Robert Castlereagh, the French delegate Talleyrand, and the formerly liberal Russian tsar Alexander I. These principles were conservatism, in reaction against Revolutionary France; traditionalism, in reaction against 25 years of rapid change; legitimism (the principle of hereditary monarchy as the only lawful rule); and restoration (the principle of restoring the kings ousted after 1789).

The European great powers also aimed at the enforcement of peace by subsequent conferences between kings, and those subsequent conferences gave rise to a period of international cooperation known as the Concert of Europe. As liberal democrats correctly pointed out, the weakness of that first successful attempt at a "United Nations" was its narrowly aristocratic base. But it did achieve the positive function—and important precedent—of peacefully arbitrating several disputes. The debit of the conservative Concert of Europe was its bigoted suppression of democratic social progress.

Goethe's spiritual conservatism. Johann Wolfgang von Goethe was Germany's greatest dramatist, poet, and personality. In his youthful "storm and stress" period of the 1770s, Goethe went through a phase of revolt and of nationalism. In his old age, however, he became Germany's greatest cultural influence for classical balance and for antinationalist cosmopolitanism, influencing many outside Germany, including, in England, Coleridge. In 1815 Goethe and Metternich both took pride in being "good Europeans," not German nationalists. After a friendly personal conversation with Metternich, Goethe wrote that Metternich "inspires with the assurance that reason, reconciliation, and human understanding will lead us out of present chaos." Later, in 1830, Goethe urged a mature synthesis between a conservative framework and liberal goals:

> The genuine liberal tries to achieve as much good as he can with the available means to which he is limited; but he would not use fire and sword to annihilate the often inevitable wrongs. Making progress at a judicious pace, he strives to remove society's deficiencies gradually without at the same time destroying an equal amount of good by violent measures. In this ever-imperfect world he contents himself with what is good until time and circumstances favor his attaining something better.

His rhymed credo "Nature and Art" (1802) expressed his conservative and classic stress on voluntary submission to law: "Only in self-restriction does the master reveal himself. And only law can give us liberty." His political drama *Die natürliche Tochter* (1803; *The Natural Daughter*) reflected his hostility to the French Revolution, radicalism, and mass movements. Much quoted by classicists, such as the United States' Irving Babbitt, was Goethe's definition: "The classical I call the healthy and the romantic the diseased." Yet his *Faust* drama (*Part I* published 1808, *Part II* 1832) retained the liberal-minded stress of his younger days on constant change, "constant striving," as salvation. His most unique achievement consisted of his being, so to speak, self-invented. By sheer strength of character, he remolded his naturally revolutionary and romantic temperament into what the world accepted as a conservative and classicist temperament.

Savigny and Ranke

Perhaps Germany's most mature conservative thought came from her great historians. Friedrich Karl von Savigny (died 1861) and Leopold von Ranke (died 1886) were outstanding as pupils of Burke in their reverence for history as organic growth. Savigny stressed that custom, operating over centuries, creates its own framework. On custom, Savigny founded an entire science of historical jurisprudence, denying the abstract, liberal "rights of man." Similarly, Ranke saw every society in terms of its own unique evolution. He opposed the universal generalizations of the 18th-century Enlightenment; every people, he wrote, "is related directly to God" in its own concrete way.

Tsarist and Dostoyevskyan conservatism. Whereas Western conservatism arose from reactions to the French Revolution, Russian tsarist conservatism had different and older origins. The practice of the absolute Tatar khans and the theory of Byzantine caesarism combined to produce an un-Western elephantiasis of autocracy. Nevertheless, two antiliberal traditionalists of Russia made such an impact on the West—the first by politics, the second by art—that their mention is indispensable: Konstantin Pobedonostsev and Fyodor Dostoyevsky. The former was the tutor and chief ideologist of two tsars (Alexander III and, until the Revolution of 1905, Nicholas II). His book *Reflections of a Russian Statesman* (1898) denounced free press, trial by jury, parliamentary government, secular education, skepticism toward the divine mission of tsars, and, above all, intellectuals.

Dostoyevsky's disillusionment with his youthful radicalism resembled Coleridge's in its psychological as well as literary consequences. Both turned to an organic, religious, and monarchic society, to which they paid more homage via literature than via politics. Dostoyevsky attacked Socialism, liberalism, materialism, and atheism. He preached Greek Orthodox tsarism, Slavic traditionalism, and the redemption of mankind by "Holy Russia." His novel *The Possessed* (1871–72) pictured the idealistic ends of Socialists as corrupted by their terroristic means, and he boasted somewhat fawningly to Alexander III about the book's effectiveness against radicals. His novel *The Brothers Karamazov* (1880) contrasted a dry Western rationalism with a more deeply moving Russian mysticism. To the end he retained from his young Socialist days his characteristic compassion for what he called "the insulted and injured"; only now he expressed this in the more spiritual creed of Christian love. What influences many modern readers so compellingly is not his political but his cultural conservatism, exalting vision beyond external material progress.

American conservatism. The American Revolution owed many of its ideals to Burke's interpretation of the British heritage of 1688, the heritage of mature self-government. Burke favoured the Revolution as defending the traditional rights of freeborn Englishmen against newfangled royal usurpations. In that sense, one might describe it not as the Revolution but as the "Conservation" of 1776.

In *The Rights of the British Colonies Asserted and Proved* (1764) the American spokesman James Otis typically argued that the demand for no taxation without representation was an old British tradition. America, he said, was conserving "the British Constitution, the most free one on earth." "We claim nothing," added George Mason of Virginia, "but the liberty and privileges of Englishmen." Almost all other revolutions, colonial or otherwise, have been radical in the sense of demanding new or increased liberties and a new order. In contrast, the American demand of July 6, 1775 (*Declaration of the Causes & Necessity of Taking Up Arms*), was for conserving old liberties and the old order: "in defence of the freedom that is our birth right and which we ever enjoyed until the late violation of it." Such words promulgated no democracy, no abstract "Rights of Man"; rather, they promulgated what Burke called "prescriptive right. . . . considering our liberties in the light of an inheritance." Despite important exceptions, which should not be minimized, it was not until the election of the more truly "revolutionary" Andrew Jackson (1828) that the democratic doctrines of the pamphleteer Thomas Paine gained solid roots in the United States, dividing the nation between conservative and progressive traditions. Paine was the man whom the Burkean John Adams (president 1797–1801) came to loathe most—for eternally sloganizing about apriorist utopias. A leading historian, Daniel Boorstin, has observed in *The Genius of American Politics* (1953):

> The ablest defender of the Revolution—in fact, the greatest political theorist of the American Revolution—was also the great theorist of British conservatism, Edmund Burke. . . . Ours was one of the few conservative colonial rebellions of modern times.

Conservative doctrines of Hamilton and Madison

The spirit of the United States was partly molded by two masterpieces of Burkean conservatism, both published in 1787–88: *The Federalist,* by Alexander Hamilton, James Madison, and John Jay, and *Defence of the Constitutions of Government of the United States of America,* by John Adams. The achievements attributed by historians to the *Federalist* papers exceed those of any other series of newspaper articles in history, for they helped forge national unity during a separatist crisis. In the context of Shays's Rebellion of 1786 against the judiciary, they saved government by law from government by mob and established minority rights against majority dictatorship. They based American liberty on the Burkean principle of historical roots, prescriptive right, and judicial precedent instead of on vague grand rhetoric about democratic utopias and the masses. Similar in thought and richer in historical background was the *Defence* by Adams, one of the most penetrating analyses of self-government ever written.

The U.S. Constitution was drawn up in Philadelphia by the U.S. Constitutional Convention of 1787. The objectives of many liberal democrats were: easy amendment; facilities for mass pressure and rapid change; unchecked popular sovereignty; universal manhood suffrage; a single parliamentary body; and the basing of liberty on a long list of universal a priori abstractions, such as Burke later criticized in the French Declaration of the Rights of Man and of the Citizen. But in the Constitution of 1787 the Federalists foiled each of these objectives. They made amendments slow and difficult, greatly reduced the number of voters by property restrictions, created a congress of two parliamentary bodies, and based liberty primarily, though not entirely, on the concrete, inherited precedents of British tradition. Except for the House of Representatives (a sop to democrats), the main cogs of government—president, Senate, justices—were not to be chosen directly by the people but, respectively, by the electoral college, state legislatures, and appointment, and not until 1913 did an amendment eliminate this intentionally undemocratic election of senators. The judicial branch (Supreme Court) continues to be a nonelective, nonremovable elite not responsible to democratic majorities. Yet it can veto as unconstitutional measures passed by a democratic majority of the two elective, removable branches of Congress.

The American Founding Fathers adopted a conservative constitution in reaction against current mob excesses and against the democratic–utopian rhetoric of the earlier Declaration of Independence (drawn up by Thomas Jefferson) with its grand abstractions about "life, liberty, and the pursuit of happiness." Yet the Constitution was the Burkean, not the reactionary brand of conservatism. Thus it defeated not only the liberal objectives but also the more extreme conservative ones, including a hereditary, titled aristocracy and Hamilton's notion of a president for life with absolute veto power.

John Calhoun

The United States' only consistently conservative party was the Federalist Party of John Adams and Alexander Hamilton. Hamilton was perhaps too much the reckless commercial adventurer to be classified under conservative or any other principles, but Adams remains the closest New World equivalent to Burke. After the death of the Federalist Party in the early 1800s, two mutually hostile kinds of political conservatism emerged: that of the urban New England Brahmins and that of the Southern semifeudal landowners. The latter received their most persuasive defense in the famous *A Disquisition on Government and Discourse on the Constitution and Government of the United States* of Calhoun, the closest New World equivalent to Maistre. This more extreme, very regional Calhoun conservatism is still influential in much of the American south, typically cutting across Democrat or Republican party lines, and is still alien to New England conservatism.

Modern U.S. political parties, being pragmatic alliances of geographic patronage groups rather than matters of doctrine, cannot realistically be classified under "isms." It is nearer to reality to look for conservatism, instead, in the indirect diffusion—cutting across all party lines—of the above described restraining principles of the Constitution.

CONSERVATISM IN THE 20TH CENTURY

The 19th and, particularly, the 20th century (that is, the period since the 18th-century Enlightenment) have in many ways been antithetical to conservatism, both as a political philosophy and as a program of particular parties identified with conservative interests. As described above, the consciously articulated conservatism of Burke was formulated in reaction to the French Revolution; similarly, the anti-liberal, anti-revolutionary policy that was a major factor in European international relations during the Metternich period (1809–48) was a reaction to the political discontent aroused by demands for liberal reforms and constitutions. The Enlightenment, in fact, had resulted in the propagation of certain attitudes and ideas that were to have far-reaching political consequences during the succeeding centuries, the most significant of which were a belief in the possibility of improvement in the human condition—a belief, that is, in the idea of progress—and a concomitant disposition to tamper with or discard existing institutions or practices in pursuit of progress, a disposition that has been characterized as "rationalist." Such rationalist politics embrace a broad segment of the political spectrum, including much of liberal reformism, socialism of the welfare-state or mixed-economy variety characteristic of western Europe, and Marxist socialism. The changes that have been wrought under the banner of rationalist politics have thus been immense and point to what has been described as a dilemma of modern conservatism—the extent to which, in face of constant rationalist innovation, conservatives may be forced to adopt a merely defensive role, so that the political initiative lies always in the other camp.

The responses of conservatives to this predicament have naturally varied considerably in differing political contexts; an account of some of these responses is given below. An analysis of the role of conservatism in contemporary politics, however, cannot be confined merely to an account of the programs of political parties identified with the conservative cause, for conservatism makes its influence felt in a variety of ways less direct than through expression in party platforms. Conservatism in the 20th century has in fact been a pervasive force in the political life of those parliamentary democracies in which rationalist politics have seemed to hold sway, as well, of course, as in less liberal political climates.

Non-political manifestations of conservatism

Conservative influences operate indirectly (*i.e.,* other than via the programs of political parties) largely by virtue of the fact that, while man is undeniably a persistent innovator, there is also much in the human temperament that is naturally or instinctively conservative: among such conservative traits are the tendency to fear and avoid sudden change and the tendency to act according to habit. While these are traits of the individual, they may find collective expression in, for example, resistance to imposed political change and in a whole cluster of value preferences that contribute to the formation and stability of a particular culture. The tendency for value preferences to find expression in cultural forms and political institutions (the so-called pragmatism of the British, for example, in their unwritten constitution) constitutes a profound conservative influence in political life over and above any explicit articulation of particular conservative interests that may be undertaken by a political party, for it gives rise to practices and institutions that are products of a long process of social and political evolution and are closely related to other culture-related factors, such as religion and property relationships. The existence of such cultural restraints on political innovation constitutes in all societies a fundamental conservative bias, the implications of which have been aphoristically expressed by an English commentator, F.J.C. Hearnshaw: "It is commonly sufficient for practical purposes if conservatives, without saying anything, just sit and think, or even if they merely sit." Mere inertia, however, has rarely sufficed to protect conservative values in an age dominated by rationalist dogma and by social change related to continuous technological developments. The conservative reaction, however, is best analyzed in specific political contexts. Historians, it may be noted, cannot safely agree on there being more than four great political parties of the 20th century deserving of the name: the Conservative Party of England, the Christian Democrats of Italy and of Germany, and the Liberal Democrats of Japan.

In England, Disraeli's successor, Lord Salisbury, was prime minister in 1885, from 1886 to 1892, and from 1895 to 1902; Arthur Balfour succeeding him from 1902 to 1905. This longest era of Conservative rule was characterized by imperialism, high tariffs, and the gradual erosion of the party's working-class vote, which Disraeli had so far-sightedly nurtured by extending the franchise to the workers in 1867. The party had thereby broadened its original class basis (landed aristocracy and established church) to outflank from below and above the new commercial class and its Liberal Party. It may be said that conservatism in Great Britain since Disraeli's time has veered between a passive and largely resigned acceptance of changes introduced by its Liberal and, later, Labour opponents and a more positive conservatism, the aim of which has been to foster a social environment in which the individual is encouraged to advance his own interests without undue hindrance from, or reliance on, the state—a policy descended from the liberal individualism of the 19th century, associated particularly with the Liberal Party. This positive conservatism of liberal individualism tinged with a strong sense of social conscience was given its earliest formulation by Disraeli, who combined a desire to mitigate harsh conditions suffered by the working class under conditions of unrestrained capitalism with a belief in the value of existing institutions such as the monarchy, the church, and the class system. Disraeli's foreign policy, which emphasized the need for Britain to act constructively as a "moderating and mediatorial" power and to maintain its interest in its empire, also reflected the view that conservatism must be a force shaping events rather than merely reacting to them. These three elements—the improvement of material conditions both by encouragement of individual initiative and timely reform of abuses, emphasis on the value of traditional institutions, and belief in the need for an active foreign policy—have been recurring themes of British conservatism in the 20th century. Later conservative thinkers have elaborated on the value of divergency of personality and attitudes, the role of property as an expression of individuality, and the central role of the family in providing a stable environment in which the individual may develop.

British conservatism after Disraeli

In its less positive periods (as, for example, during the interwar period), conservatism in Britain has been identified with the defense of class privileges and of the status quo, an unconstructive opposition to socialism, and, during the 1930s, a deal-making commercialist approach to the rising Nazi menace. Faced, however, with the introduction of a mixed economy and the vast extension of state welfare services by the Labour Party after 1945, the Conservatives, when returned to power in 1951, reversed very few of their socialist predecessors' innovations, emphasizing instead their claim to be more able to administer the welfare state efficiently and to some extent outbidding their opponents, especially in areas of social policy related to their fundamental beliefs—the encouragement of a heavy program of house building being an example. The Conservative resurgence that resulted in the election of Margaret Thatcher as prime minister in 1979 inspired a more activist, if not doctrinaire, spirit, particularly in the fields of economic and fiscal policy (including, for example, the "privatization" of a number of industries nationalized under Labour governments).

Western Europe. It is of significance that the British Conservative Party has been the more ardent of the two major British parties in championing British membership of the European Economic Community (EEC), reflecting an internationalism voiced by Sir Winston Churchill when, in 1940, he appealed for a Franco-British union and, in 1946, for a European union. Originally conceived as a means by which the economies of the European countries might be integrated—so that war between them would be impossible—the nascent community assumed significance during and after the Cold War as a means of strengthening western Europe against the threat of external Communist aggression and internal subversion. Together with the military North Atlantic Treaty Organization alliance, it thus assumed a role as a bulwark of parliamentary democracy and capitalism.

In the arena of party politics, conservatism in western Europe is generally represented by two or more parties, ranging from the liberal centre to the moderate and extreme right. Three types of party may be discerned: agrarian parties (particularly in Scandinavia), Christian democratic parties, and conservative parties linked strongly with big business interests and sometimes with a markedly nationalistic outlook. Such categories are very general and are not mutually exclusive.

The Christian democratic tradition

Among parties of the right, the Christian democratic tradition has the longest continuity, the predecessors of contemporary parties having emerged during the first half of the 19th century to represent supporters of the church and the monarchy against liberal elements. Especially after World War I, business interests became a third important element. The clerical interest is strongest in the Democrazia Cristiana (DC; Christian Democrat Party) of Italy, which has dominated government since 1945. Through this party, Catholicism has set limits on policy concerning such church-related matters as divorce and contraception; in regard to other social questions, however, the party has never presented a coherent policy, largely because it comprises little more than an alliance of disparate and often conflicting interest groups.

In West Germany, a country divided between Catholics and Protestants, the church plays a far less significant role in the main conservative party, the Christlich-Demokratische Union (CDU; the Christian Democratic Union). After 1950, following debate within the party over economic and social questions, advocacy of a free-enterprise economy coupled with a strong commitment to maintain and improve social insurance and other welfare provisions became established policy. The conservative temper of the political climate in Germany since the beginning of economic recovery may be judged from the fact that since the early 1950s the main opposition party, the Sozialdemokratische Partei Deutschlands (SPD; the Social Democrats), has progressively eliminated the socialist content of its program, a congress at Bad Godesberg (1959) in fact going so far as to champion the profit motive.

France provides an exception to the general pattern of the representation of moderate conservative opinion by a Christian democratic party; the closest equivalent has been the Catholic, right-wing, Mouvement Républicain Populaire, which by the late 1960s had become little more than a political club. Instead, a large proportion of conservatives in France has supported Gaullist groups such as the Union pour la Défense de la République. Gaullist conservatism has been markedly nationalistic, involving assumptions concerning French leadership of a united Europe and emphasizing tradition, order, and the regeneration of France. Gaullists espouse divergent views on domestic social issues, however, as do non-Gaullist groups such as the Centre National des Indepéndants et Paysans. The number of conservative groups, their lack of stability, and their tendency to be identified with local issues defy simple categorization. Conservatism in France, however, as in Italy and Germany, has been the dominant political force since World War II.

Conservatism in Europe is thus revealed as a dominating political influence in the major states, finding expression in parties of very different character. These parties represent traditional bourgeois values and oppose unnecessary state involvement in economic affairs and any radical attempts at income redistribution. They are also characterized by an absence of ideology and often of even a well-articulated political philosophy, but this tends to be of little consequence in terms of their influence since they give political expression to the conservatism of temperament mentioned above as an important underlying bias in political conflict, as well as to persistent culture-related values that are of great importance in terms of continuity and stability.

Japan. The relationship between conservatism as an underlying bias related to psychological factors and cultural values and conservatism as an articulated political credo is illustrated by the history of party politics in Japan since its opening to Western influence in the middle of the 19th century. The political and social changes that took place following the Meiji Restoration (1868) were of major proportions, involving the abolition of feudal institutions and the introduction of such Western political ideas as constitutional government. But despite institutional innovations and the dislocations resulting from rapid industrialization, traditional loyalties and attitudes proved to be more important factors in shaping political developments.

Majority conservatism in Japan

Except for the period of intervention by the militarists during the 1930s and 1940s, Japan has been ruled by conservatives since the beginning of party politics in the 1880s. The conservative parties (the two most important of which merged to form the Liberal-Democratic Party in 1955) have been dominated by personalities rather than by ideology and dogma; and personal loyalties to leaders of groups within the party (factions) rather than commitment to policy have determined the allegiance of conservative members of the Diet. As one American scholar, Nathaniel B. Thayer, has described it, the factions

> have adopted the social values, customs, and relationships of an older Japan.... The old concepts of loyalty, hierarchy, and duty hold sway in them. And the Dietman (or any other Japanese) feels very comfortable when he steps into this world.

The Liberal-Democratic Party is intimately linked with big business interests, and its policies are guided primarily by the objective of fostering a stable environment for the development of Japan's free-enterprise economy; to this end, the party functions as a broker of conflicting business interests. Policy toward other Asian countries, national defense, and internal security are other conservative preoccupations.

The United States. It may be argued that the United States has no nationwide conservative or liberal parties but instead only two fluctuating, all-inclusive coalitions. Both the Democrat and Republican coalitions include interest groups occasionally labelled conservative—the racists among southern Democrats, for example, and such Republican offshoots as the local New York Conservative Party. On a journalistic level the word conservative has been used loosely for a segment of the Republican party associated with Sen. Barry Goldwater and with Ronald Reagan, a former California governor elected president in 1980.

Modern American conservatism has been highly influential in the literary and religious realm in such masterpieces of conservative outlook as Irving Babbitt's *Democracy and Leadership* (1924) or the aristocratic traditionalism of the Nobel Prize-winning novelist William Faulkner. Indeed, such figures as the novelist Herman Melville and the theologian Reinhold Niebuhr, usually independent of each other and eschewing conservative labels, have performed the nation's spiritual arithmetic, calculating the spiritual price of material progress and of a robotizing technology. Unconsciously conservative in this sense, even when under radical slogans, is the impulse among young people in the 1970s and after to conserve ecology and environment against what Melville called "the impieties of progress." These unconscious young conservers sublimate the old class-based elitism into a new value-based elitism, open to all, thereby rescuing quality (the cultural as well as physical ecology) from the parvenu plutocrats of quantity (mass culture and robot technology).

The impact of the horrors allowed at Auschwitz has purged—in effect conservatized—many modern liberals out of their most unconservative axiom: the Rousseauist doctrine of the "natural goodness" of man and the masses. For many, the real battle for the future now seems to be an alliance of such chastened liberals with conservatives in jointly defending their shared constitutional and ethical framework against extremist destroyers from a mirror-image right and left.

Conservative reticence

It is arguable that conservatism, whether its influence operates through political parties or through psychological, cultural, and institutional factors, is a far more persuasive influence in democratic societies than the rate of social and economic change and the welter of rationalist dogma would suggest. That it is often lacking in articulation and that, as critics of conservatism point out, there is a comparative lack of persuasive presentations of the conservative cause compared with the abundant literature of rationalist politics is in part a consequence of its underlying strength and in part a result of a certain coyness among the best conservative thinkers deriving from the fear that a conservatism that needs to present itself in the same terms as the doctrines it opposes is no longer conservatism or is a conservatism in retreat. In the latter part of the 20th century, however, many would say that it may be argued that the predilection of governments to extend their role in social life is so strong as to necessitate a more articulate, even aggressive, conservatism. One particularly important task of conservatives will be to emphasize that the social sciences, particularly anthropology and psychology, so long enlisted in the cause of social engineering and liberal utopianism, also reveal much about the role of tradition, custom, and evolution in the survival of societies. (Pe.V.)

BIBLIOGRAPHY

Socialism: DANIEL BELL, "Socialism," in *International Encyclopedia of the Social Sciences,* 14:506–534 (1968), one of the best short surveys of socialism from its origins to the present day; G.D.H. COLE, *A History of Socialist Thought,* 5 vol. (1953–60), the most complete and detailed general study; H.W. LAIDLER, *History of Socialism,* rev. and enl. ed. (1968), and CARL LANDAUER, *European Socialism,* 2 vol. (1959), two histories written from a social democratic perspective; IRVING HOWE (ed.), *Essential Works of Socialism* (1970), a collection of readings in many varieties of Marxist thought; C.A.R. CROSLAND, *The Future of Socialism* (1957), an assessment of the prospects for socialism by a leading member of the British Labour Party; MICHAEL HARRINGTON, "Why We Need Socialism in America," *Dissent,* 17:240–303 (1970), a defense of the relevance of socialism in the United States by a leading American socialist; JAMES JOLL, *The Second International 1889–1914* (1966), a standard but very readable history of 19th-century social democracy; GEORGE LICHTHEIM, *Marxism* (1961), a sophisticated and searching work dealing with the transformation of Marxism from the time of its founders to that of Lenin and Stalin; *A Short History of Socialism* (1970) and *The Origins of Socialism* (1969), idiosyncratic but stimulating reading; A.F. STURMTHAL, *The Tragedy of European Labor* (1943), a study of the failures of social democratic policies during the depression of the 1930s, by a sympathetic observer; ANTHONY GIDDENS, *A Contemporary Critique of Historical Materialism,* 2 vol. (1982–).

Communism: SHLOMO AVINERI, *The Social and Political Thought of Karl Marx* (1968); ISAIAH BERLIN, *Karl Marx,* 2nd ed. (1948); R.N. CAREW-HUNT, *The Theory and Practice of Communism,* 5th rev. ed. (1957, reprinted 1963); J.L.H. KEEP, *The Rise of Social Democracy in Russia* (1963), an outstanding history of the subject up to 1906; LEONARD SCHAPIRO, *The Origin of the Communist Autocracy: Political Opposition in the Soviet State: First Phase, 1917–1922* (1955); ADAM ULAM, *The Bolsheviks* (1965); FRANCO VENTURI, *Il populismo russo* (1952; Eng. trans., *The Roots of Revolution: A History of the Populist and Socialist Movements in Nineteenth Century Russia,* 1960); BERTRAM D. WOLFE, *Three Who Made a Revolution* (1948), a readable, stimulating history of Bolshevism in its formative years.

Works on Stalinism include ROBERT CONQUEST, *The Great Terror: Stalin's Purge of the Thirties* (1968); IAN GREY, *The First Fifty Years: Soviet Russia 1917–1967* (1967); LEONARD SCHAPIRO, *The Communist Party of the Soviet Union,* 2nd rev. ed. (1970), a detailed history of the Communist Party in theory and in practice up to 1968.

The world movement up to Stalin's death is treated in HAMILTON FISH ARMSTRONG, *Tito and Goliath* (1951), an excellent study of the conflict between Yugoslavia and the Soviet Union; ZBIGNIEW K. BRZEZINSKI, *The Soviet Bloc: Unity and Conflict,* rev. ed. (1961); C. BRANDT, BENJAMIN SCHWARTZ, and J.K. FAIRBANK, *A Documentary History of Chinese Communism* (1952); VLADIMIR DEDIJER, *Tito Speaks* (1953); JANE DEGRAS (ed.), *Communist International Documents, 1919–1943,* 3 vol. (1956–65), a collection of documents with commentary; HERBERT FEIS, *Churchill, Roosevelt, Stalin* (1957), a well-documented study of wartime diplomacy; GUNTHER NOLLAU, *Die Internationale: Wurzeln und Erscheihungsformen des proletarischen Internationalismus* (1959; Eng. trans., *International Communism and World Revolution,* 1961); E. REALE, *Avec Jacques Duclos: Au Banc des Accusés* (1958); DAVID REES, *Korea: The Limited War* (1964); HUGH SETON-WATSON, *The Pattern of Communist Revolution,* rev. ed. (1961), a study of the rise of Communism in eastern Europe.

Developments after Stalin are surveyed in ADAM BROMKE (ed.), *The Communist States at the Crossroads, Between Moscow and Peking* (1965); ALEXANDER DALLIN (ed.), *Diversity in International Communism: A Documentary Record, 1961–63* (1963); HELENE CARRERE D'ENCAUSSE and STUART R. SCHRAM, *Le Marxisme et l'Asie, 1853–1964* (1965; Eng. trans., *Marxism and Asia: An Introduction with Readings,* 1969); EDWARD CRANKSHAW, *The New Cold War: Moscow v. Peking* (1963); GHITA IONESCU, *The Break-up of the Soviet Empire in Eastern Europe* (1965); WALTER LAQUEUR and LEOPOLD LABEDZ (eds.),

Polycentrism (1962), a valuable collection of essays on dissent in the Communist parties; WOLFGANG LEONHARD, *Kreml ohne Stalin* (1959; Eng. trans., *The Kremlin Since Stalin,* 1962); THE RUSSIAN INSTITUTE, COLUMBIA UNIVERSITY, *The Anti-Stalin Campaign and International Communism* (1956), an annotated text of Khrushchev's secret speech in 1956, with some other documents; HUGH SETON-WATSON, *The Imperialist Revolutionaries* (1978); H. GORDON SKILLING, *The Governments of Communist East Europe* (1966); MICHEL TATU, *Le Pouvoir en U.R.S.S.* (1967; Eng. trans., *Power in the Kremlin,* 1969); DONALD S. ZAGORIA, *The Sino-Soviet Conflict, 1956–61* (1962); MILORAD M. DRACHKOVITCH (ed.), *Fifty Years of Communism in Russia* (1968), a symposium by a number of experts on changes in communist doctrine; LEONARD SCHAPIRO (ed.), *The USSR and the Future* (1962), essays by specialists on various aspects of the party program of 1961; GUSTAV WETTER, *Dialektischer und historischer Materialismus* (1962; Eng. trans., *Soviet Ideology Today,* 1966).

Anarchism: The principal anarchist classics are mentioned in the text. In recent years many have been reprinted, notably WILLIAM GODWIN, *Enquiry Concerning Political Justice and Its Influence on Morals and Happiness,* 3 vol. (1793, reprinted 1946); PETER KROPOTKIN, *Memoirs of a Revolutionist,* 2 vol. (1899, reprinted 1968), and *Mutual Aid* (1890–96, reprinted 1939); and PIERRE JOSEPH PROUDHON, *Qu'est-ce que la propriété?* (1840; Eng. trans., *What Is Property?,* 2 vol., 1898–1902, reprinted 1966). G.P. MAXIMOFF (ed.), *The Political Philosophy of Bakunin: Scientific Anarchism* (1953), is a good anthology of Bakunin's writings; and VERNON RICHARDS (ed.), *Errico Malatesta: His Life and Ideas* (1965), contains a collection of writings by Malatesta, many of which were previously unavailable in English. TOLSTOY's principal writings in the anarchist vein, *The Kingdom of God Is Within You, The Slavery of Our Time,* and *What I Believe,* are available in standard editions. HERBERT EDWARD READ's anarchist writings are mainly collected in *Anarchy and Order* (1954, reprinted 1971) and *The Cult of Sincerity* (1968); his *Education Through Art* (1963) should also be consulted. The best general accounts of anarchist thought and history are GEORGE WOODCOCK, *Anarchism* (1962); JAMES JOLL, *The Anarchists* (1965); DANIEL GUERIN, *L'Anarchisme, de la doctrine à l'action* (1965; Eng. trans., *Anarchism: From Theory to Practice,* 1970); and APRIL CARTER, *The Political Theory of Anarchism* (1971). A useful collection of essays on contemporary trends is DAVID E. APTER and JAMES JOLL, *Anarchism Today* (1970); two recent anthologies that contain writings drawn from the whole libertarian tradition are LEONARD I. KRIMERMAN and LEWIS PERRY (eds.), *Patterns of Anarchy* (1966); and IRVING L. HOROWITZ (ed.), *The Anarchists* (1964). P. ELTZBACHER, *Der Anarchismus* (1900; Eng. trans., 1908), is a classic account of leading anarchist thinkers. ALAN RITTER, *Anarchism: A Theoretical Analysis* (1981), is a lucid, sympathetic study of the writings of major anarchistic theorists.

On anarchism in Russia: PAUL AVRICH, *The Russian Anarchists* (1967); FRANCO VENTURI, *Il populismo russo* (1952; Eng. trans., *Roots of Revolution: A History of the Populist and Socialist Movements in Nineteenth Century Russia,* 1960); and DAVID FOOTMAN, *Civil War in Russia* (1961). On anarchism in Spain: GERALD BRENAN, *The Spanish Labyrinth: An Account of the Social and Political Background of the Civil War,* 2nd ed. (1950, paperback 1960); BURNETT BOLLOTEN, *The Grand Camouflage: The Communist Conspiracy in the Spanish Civil War* (1961); and HUGH THOMAS, *The Spanish Civil War* (1961). On anarchism in Italy: RICHARD HOSTETTER, *The Italian Socialist Movement,* vol. 1 of a projected 3-volume work (1958). On anarchism in the United States: JAMES J. MARTIN, *Men Against the State: The Expositors of Individualist Anarchism in America, 1827–1908* (1953); and RUDOLF ROCKER, *Pioneers of American Freedom* (1949). On anarchism in France: EUGENIA W. HERBERT, *The Artist and Social Reform: France and Belgium, 1885–1898* (1961).

Fascism: H. ROGGER and E.J. WEBER (eds.), *The European Right: A Historical Profile* (1965); S.J. WOOLF (ed.), *European Fascism* (1969); H. KOHN, *Political Ideologies of the Twentieth Century,* 3rd rev. ed. (1966), a discussion of fascism and other ideologies in their historical setting; E. NOLTE, *Der Faschismus in seiner Epoche* (1963; Eng. trans., *Three Faces of Fascism,* 1965), the best theoretical analysis of fascism, and *Die Krise des liberalen Systems und die faschistischen Bewegungen* (1968), a continuation of his earlier work, with an extensive bibliog.; G.A. BORGESE, *Goliath, Der marsch des fascismus* (1938), on the historical and intellectual roots of Italian Fascism; D.L. GERMINO, *The Italian Fascist Party in Power: A Study in Totalitarian Rule* (1959); E. WISKEMANN, *Fascism in Italy: Its Development and Influence* (1969); R. DE FELICE, *Mussolini,* vol. 1, *Il rivoluzionario, 1883–1920* (1965); A.J. GREGOR, *The Ideology of Fascism* (1969), an analysis based upon the philosophy of Giovanni Gentile, with an extensive bibliog.; F.W. DEAKIN, *The Brutal Friendship: Mussolini, Hitler and the Fall of Italian Fascism* (1962); M. BAUMONT *et al.* (eds.), *The Third Reich* (1955), an authoritative symposium by European and American scholars; W. EBENSTEIN, *The Nazi State* (1943); H. RAUSCHNING, *Die revolution des nihilismus* (1938; Eng. trans., *The Revolution of Nihilism: Warning to the West,* 1940); H. MOHNE, *Der Orden unter dem Totenkopf,* 2 vol. (1969), a detailed study of the most militant Nazi organization, the SS; A. BULLOCK, *Hitler: A Study in Tyranny* (1952); R. HILBERG, *The Destruction of the European Jews* (1961); G. BRENAN, *The Spanish Labyrinth: An Account of the Social and Political Background of the Civil War* (1943); S.G. PAYNE, *Falange: A History of Spanish Fascism* (1961); H. THOMAS, *The Spanish Civil War* (1961); C.A. MACARTNEY, *A History of Hungary, 1929–1945,* 2 vol. (1956–57); J. PLUMYENE and R. LASIERRA, *Les Fascismes Français, 1923–1963* (1963); E.J. WEBER, *Varieties of Fascism: Doctrines of Revolution in the 20th Century* (1964); H.F. MACNAIR, *The Real Conflict between China and Japan: An Analysis of Opposing Ideologies* (1938); A. DEL BOCA and M. GIOVANA, *I "figli del sole": mezzo seculo di nazifascismo nel mondo* (1965; Eng. trans., *Fascism Today: A World Survey,* 1969), a well-documented comprehensive survey of the resurgence of fascism after 1945; *Who Were the Fascists: Social Roots of European Fascism,* ed. by STEIN LARSON *et al.* (1981), fifty essays on fascism in over twenty countries.

Nationalism: The origins and development of nationalism as a political idea are discussed in detail in HANS KOHN, *The Idea of Nationalism* (1944, reprinted 1967). Another discussion of the development of nationalism, including various interpretations in modern times, is analyzed in LOUIS L. SNYDER, *Varieties of Nationalism* (1976). A sociological treatment of the subject is ANTHONY D. SMITH, *Theories of Nationalism* (1971). HUGH SETON-WATSON, *Nations and States* (1977), is a detailed, worldwide study. A new approach to the problem of nationalism was introduced by KARL W. DEUTSCH, *Nationalism and Social Communication* (1953), and *Tides Among Nations* (1979), an overview of the development of his thinking. On nationalism in the Third World, see RUPERT EMERSON, *From Empire to Nation: The Rise to Self-Assertion of Asian and African Peoples* (1960); and SELIG S. HARRISON, *The Widening Gulf* (1978). There are two valuable bibliographies: KOPPEL S. PINSON, *A Bibliographical Introduction to Nationalism* (1935); and KARL W. DEUTSCH, *Interdisciplinary Bibliography on Nationalism* (1956).

Liberalism: General works include R.D. CUMMING, *Human Nature and History: A Study of the Development of Liberal Political Thought* (1969); H.K. GIRVETZ, *Evolution of Liberalism,* rev. ed. (1963), a comparison of classical and contemporary liberalism that examines the psychological assumptions underlying the political and economic views of the classical liberals; L. HARTZ, *The Liberal Tradition in America: An Interpretation of American Political Thought Since the Revolution* (1955); K. MARTIN, *The Rise of French Political Thought,* 2nd ed. K.R. MINOGUE, *The Liberal Mind* (1963), on the contention that liberalism now reflects a moral and political consensus; W.A. ORTON, *The Liberal Tradition: A Study of the Social and Spiritual Conditions of Freedom* (1945); F.M. WATKINS, *The Political Tradition of the West: A Study in the Development of Modern Liberalism* (1948).

Classical liberalism is treated in A.V. DICEY, *Lectures on the Relation Between Law and Public Opinion in England During the Nineteenth Century* (1905); E. HALEVY, *La formation du radicalisme philosophique,* 3 vol. (1901–04; Eng. trans., *The Growth of Philosophical Radicalism,* 1928); L.T. HOBHOUSE, *Liberalism* (1911); H.J. LASKI, *The Rise of Liberalism: The Philosophy of a Business Civilization* (1936); GUIDO DE RUGGIERO, *Storia del liberalismo europeo* (1925; Eng. trans., *The History of European Liberalism,* 1927); LESLIE STEPHEN, *The English Utilitarians* (1900).

Works on contemporary liberalism include A.A. BERLE and G.C. MEANS, *The Modern Corporation and Private Property* (1933), the classic account of how the private corporation has generated "managerial" power; W.H. BEVERIDGE, *Full Employment in a Free Society* (1945), by the chief English architect of the "welfare" state; G.D.H. COLE, *Economic Planning* (1935); C.A.R. CROSLAND, *The Future of Socialism* (1957), by a leading theoretician of the British Labour Party who believes that the Keynesian revolution has made many traditional socialist attitudes obsolete; JOHN DEWEY, *Human Nature and Conduct: An Introduction to Social Psychology* (1922), the best criticism of the psychological preconceptions of the classical liberals, *Liberalism and Social Action* (1935); JOHN KENNETH GALBRAITH, *American Capitalism: The Concept of Countervailing Power,* 2nd ed. rev. (1956), *The Affluent Society* (1958), one of the first works to contend that liberal emphasis should shift from greater productivity to the question of priorities, *The New Industrial State* (1967); A.H. HANSEN, *Economic Policy and Full Employment* (1947), by a leading American exponent of Keynesianism, *Fiscal Policy and Business Cycles* (1941); S.E. HARRIS, *Economic Planning* (1949), an examination of economic planning in ten

European countries as well as in the U.S., Argentina, Japan, and India; JOHN KEYNES, *The End of Laissez-faire* (1926), *The General Theory of Employment, Interest and Money* (1935–6), the most influential economic tract of the first half of this century; W.A. LEWIS, *The Principles of Economic Planning* (1951), on the difference between direct and indirect planning, and its important implications; JAMES E. MEADE, *Planning and the Price Mechanism* (1949), a liberal socialist approach to the problems of planning and use of the price mechanism in postwar Britain; GUNNAR MYRDAL, *Beyond the Welfare State* (1960), on the social impact of economic planning in highly industrialized states and the economic relations between them and less developed economies, *Challenge to Affluence* (1963); E.V. ROSTOW, *Planning for Freedom* (1959), an analysis of the impact of the Keynesian "revolution" on government intervention in the economic sphere. See also ANDREW LEVINE, *Liberal Democracy: A Critique of its Theory* (1981).

Conservatism: Among "Burkean-conservative" works sharing an anti-extremist centre with moderate liberals are DANIEL J. BOORSTIN, *The Genius of American Politics* (1953); THOMAS I. COOK and MALCOLM MOOS, *Power Through Purpose* (1954); ERIC HOFFER, *The True Believer* (1951); ROSS J.S. HOFFMAN and PAUL LEVACK (eds.), *Burke's Politics* (1949); HENRY A. KISSINGER, *A World Restored* (1957); WALTER LIPPMANN, *The Cold War* (1947); REINHOLD NIEBUHR, *The Irony of American History* (1952), *Christian Realism and Political Problems* (1953), and *The Self and the Dramas of History* (1955); ROBERT A. NISBET, *Community and Power* (1962); CLINTON L. ROSSITER, *Conservatism in America,* 2nd ed. rev. (1962); GEORGE SANTAYANA, *Dominations and Powers* (1951); LEO STRAUSS, *Natural Right and History* (1953) and *What Is Political Philosophy? and Other Studies* (1959); FRANK TANNENBAUM, *A Philosophy of Labor* (1951); PETER VIERECK, *Conservatism Revisited* (1949; paperback rev. ed., 1965), *The Unadjusted Man* (1956), and *Shame and Glory of the Intellectuals* (1953; paperback rev. ed., 1965); ERIC VOEGELIN, *The New Science of Politics* (1952); and *Order and History,* 3 vol. (1956–58); FRANCIS G. WILSON, *The Case for Conservatism* (1951). For British Conservatives, see LEOPOLD AMERY, *The Forward View* (1935); ARTHUR BRYANT, *The Spirit of Conservatism* (1929); LORD HUGH CECIL, *Conservatism* (1912); HENRY FAIRLIE, *The Life of Politics* (1968); QUINTIN HOGG, *The Conservative Case,* rev. ed. (1959); F.J.C. HEARNSHAW, *Conservatism in England* (1933); MICHAEL J. OAKESHOTT, *Rationalism in Politics, and Other Essays* (1962); and PEREGRINE WORSTHORNE, *The Socialist Myth* (1971). BURTON Y. PINES, *Back to Basics* (1982), an account of the conservative resurgence of the 1970s in the U.S.

More extreme views, whether right-wing nationalist in politics or militantly business-oriented in economics (mainly by contributors to the contemporary New York periodical *National Review*), may be found in WILLIAM F. BUCKLEY, JR., *God and Man at Yale: The Superstitions of Academic Freedom* (1951) and *Up from Liberalism,* rev. ed. (1968); JAMES BURNHAM, *Congress and the American Tradition* (1959) and *Suicide of the West* (1964); MILTON FRIEDMAN, *Capitalism and Freedom* (1962); BARRY GOLDWATER, *Conscience of a Conservative* (1963); JEFFREY P. HART, *The American Dissent* (1966); NELLIE D. KENDALL (ed.), *Willmoore Kendall contra mundum* (1971); RUSSELL KIRK, *The Conservative Mind, from Burke to Santayana* (1953), *Prospects for Conservatives* (1956), and *Enemies of the Permanent Things* (1969); ERIK VON KUEHNELT-LEDDIHN, *Liberty or Equality* (1952); FRANK S. MEYER, *In Defense of Freedom* (1962) and *The Conservative Mainstream* (1969); THOMAS S. MOLNAR, *The Counter-Revolution* (1969); ENOCH POWELL, *Freedom and Reality* (1969); RONALD REAGAN, *The Creative Society* (1968).

Useful anthologies include PETER VIERECK (ed.), *Conservatism: From John Adams to Churchill* (paperback rev. ed. 1956); and PETER WITONSKI (ed.), *The Wisdom of Conservatism* (1971).

Socrates

Socrates of Athens, who flourished in the last half of the 5th century BC, was the first of the great trio of ancient Greeks—Socrates, Plato, and Aristotle—who laid the philosophical foundations of Western culture. As Cicero said, Socrates "brought down philosophy from heaven to earth"—*i.e.,* from the nature speculation of the Ionian and Italian cosmologists to analyses of the character and conduct of human life, which he assessed in terms of an original theory of the soul. Living during the chaos of the Peloponnesian War, with its erosion of moral values, Socrates felt called to shore up the ethical dimensions of life by the admonition to "know thyself" and by the effort to explore the connotations of moral and humanistic terms.

LIFE

Socrates was born in or about 470 BC, 10 years after the Battle of Salamis. His father, Sophroniscus, was a friend of the family of Aristides the Just, founder of the Delian League, from which the empire arose. The tale that his father was a sculptor rests on Plato's reference to the mythical sculptor Daedalus as the ancestor, or work-lineage, of Socrates. Although the philosopher's mother, Phaenarete, acted as a "midwife," this fact implies nothing about her social status.

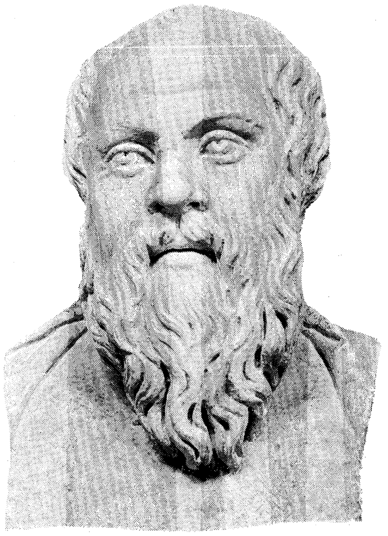
Early life and connections

The memoir writer Ion of Chios mentioned meeting Socrates at Samos in the company of the philosopher Archelaus, a pupil of Anaxagoras (Athens' first philosopher), presumably during the military operations of 441–439. The connection between the two men is also asserted by the musicologist Aristoxenus, whereas the tradition of commentaries based on Theophrastus, Aristotle's successor, calls Socrates the "disciple" of Archelaus.

Plato and Aeschines the Socratic, both writers of Socratic dialogues, agree with the military historian Xenophon in depicting him as intimate with the leading figures of the Periclean circle (Aspasia, Alcibiades, Axiochus, Callias), dominant in Athens at the time. Xenophon concurs with Plato in saying that he was well versed in both geometry and astronomy, and this representation of Socrates agrees with the narrative of Plato's *Phaedo* as well as the burlesque *The Clouds,* which was written by the playwright Aristophanes.

Socrates must already have been a conspicuous figure at Athens when Aristophanes and Ameipsias both made him the subject of their comedies in 423, and, because they made a special point of his neediness, he had probably suffered recent losses. (The marked poverty of his old age is said in Plato's *Apology* to have been caused by his preoccupation with his mission to mankind.)

Socrates was married, apparently late in life, to Xan-



Socrates, herm with a restored nose probably copied from the Greek original by Lysippus, *c.* 350 BC. In the Museo Archeologico Nazionale, Naples.

By courtesy of the Soprintendenza alle Antichita della Campania, Naples thippe, by whom he left three sons, one an infant. Xenophon speaks of her high temper; there is no evidence, however, that she was a "shrew"; the sons, according to Aristotle, proved insignificant.

Socrates' record for endurance was distinguished. He served as a hoplite, perhaps at Samos (440), and at several stations during the Peloponnesian War. (At Potidaea he saved the life of Alcibiades.) In politics he took no part, knowing, as he told his judges, that office would mean compromise with his principles. Once at least, in 406–405, he was a member of the Boule, or legislative council, of 500; and at the trial of the victors of Arginusae, he resisted, at first with the support of his colleagues, afterward alone, the unconstitutional condemnation of the generals by a collective verdict. He showed the same courage in 404, when the oligarchy of the Thirty Tyrants in Athens, wishing to implicate honourable men in their proceedings, instructed him and four others to arrest Leon, one of their victims. Socrates disobeyed, and he says in Plato's *Apology* that this might have cost him his life but for the counterrevolution of the next year. (For the background to these events see GRECO-ROMAN CIVILIZATION.)

Indictment, trial, and death

In 399 Socrates was indicted for "impiety." The author of the proceedings was the influential Anytus, one of the two chiefs of the democrats restored by the counterrevolution of 403; but the nominal prosecutor was the obscure and insignificant Meletus. There were two counts in the accusation, "corruption of the young" and "neglect of the gods whom the city worships and the practice of religious novelties." Socrates, who treated the charge with contempt and made a "defense" that amounts to avowal and justification, was convicted, probably by 280 votes against 220. The prosecutors had asked for the penalty of death; it now rested with the accused to make a counterproposition. Though a smaller, but substantial, penalty would have been accepted, Socrates took the high line that he really merited the treatment of an eminent benefactor: maintenance at the public table. He consented only for form's sake to suggest the small fine of one mina, raised at the entreaty of his friends to 30.

The claim to be a public benefactor incensed the court, and death was voted by an increased majority, a result with which Socrates declared himself well content. As a rule at Athens, the condemned man "drank the hemlock" within 24 hours, but, in the case of Socrates, the fact that no execution could take place during the absence of the sacred ship sent yearly to Delos caused an unexpected delay of a month, during which Socrates remained in prison, receiving his friends daily and conversing with them in his usual manner. An escape was planned by his friend Crito, but Socrates refused to hear of it, on the grounds that the verdict, though contrary to fact, was that of a legitimate court and must therefore be obeyed. The story of his last day, with his drinking of the hemlock, has been perfectly told in the *Phaedo* of Plato, who, though not himself an eyewitness, was in close touch with many of those who were present.

Main sources of information. Socrates wrote nothing; therefore, information about his personality and doctrine has to be sought chiefly in the dialogues of Plato and in the *Memorabilia* of Xenophon. As both men were nearly 45 years younger than Socrates, they could speak from firsthand knowledge about only the last 10 to 12 years of his life.

Xenophon, whose relations with Socrates seem not to have been close, has even been suspected of drawing from Plato. His admitted deficiencies in imagination and capacity for thinking do not make him the more faithful exponent of a philosophical genius. Moreover, Xenophon's apologetic purpose calls for some discounting. His most valuable statements are those that appear to be most at variance with his main thesis, viz., that the prosecutors of Socrates were mistaken even from their own point of view.

Plato's depiction of Socrates

Plato's more vivid picture has been suspected on the grounds that he used Socrates as a "mouthpiece" for speculations of his own: the theory of "Ideas" or doctrine of "Forms" is thus held to have been originated by Plato. There are serious reasons for denying this assumption, though they have not yet convinced many scholars; in any case, to employ it, without investigation, to discredit Plato's testimony begs the question.

In some important respects, Plato's testimony is confirmed by the extant writings of Aeschines Socraticus. *The Clouds* of Aristophanes yields valuable information about Socrates in his middle 40s, though allowance must be made for the work's character as a burlesque. It should be compared carefully with the autobiographical statements put into the mouth of Socrates in the *Phaedo,* which, though not "contemporary evidence," are clearly meant to express Plato's bona fide belief about his master's intellectual history. Whichever way the evidence is interpreted, however, a Platonic view of Socrates is available in the *Dialogues* that is valuable in its own right; hence the following discussion will draw heavily upon the *Dialogues* as the primary source for the portrait of Socrates.

Personal characteristics. Though Socrates was a good fighting man, his outward appearance was grotesque. Stout and not tall, with prominent eyes, snub nose, broad nostrils, and wide mouth, he seemed a very Silenus. But, as his friends knew, he was "all glorious within," "the most upright man of that day" (Plato, *The Seventh Letter* [324*e*]). His self-control and powers of endurance were exemplary; "he had so schooled himself to moderation that his scanty means satisfied all his wants."

But Socrates was no self-tormenting ascetic: he "knew both how to want and how to abound" and could be the soul of the merriment at a gay party. He had no sympathy with the slatternliness of his friend Antisthenes nor with the godly dirtiness often affected by the followers of Pythagoras (the philosopher of number). There was nothing of the complacent self-righteousness of the Pharisee nor of the angry bitterness of the satirist in his attitude toward the follies or even the crimes of his fellowmen. It was his deep and lifelong conviction that the improvement not only of himself but also of his countrymen was a task laid upon him "by God," not to be executed, however, with a scowling face and an upbraiding voice. Like St. Francis Xavier, he understood that to win men's souls one must be "good company." Conscious of his own infirmities, he felt a profound sympathy for the intemperate.

Socrates was a true patriot who felt that he could best prove his devotion to Athens by setting his face resolutely against the attractions of specious and popular, but deadly false theories of public and private morality. When the city brought him to trial and threatened him with death, his sense of civic duty forbade him to escape into exile either before or after the trial. It was his very patriotism that made him an unsparing critic of the Athenian "democracy" and so led to his being condemned to death.

The Socratic irony

Nothing was more marked in his character than an unusually keen appreciation of the comic in human nature and conduct that protected him at once against sentimentality and against cynicism. This is what his opponents in Plato call his "irony" and treat as an irritating affectation. "Intellectually the acutest man of his age, he represents himself in all companies as the dullest person present. Morally the purest, he affects to be the slave of passion" (W.H. Thompson). No doubt, in part, this irony was "calculated"; it "disarmed ridicule by anticipating it." But its true source is the spontaneous sense of fun that makes its possessor the enemy of all pretentiousness, moral or intellectual. And it is certain that, though the purity of Socrates is beyond question, he really had an ardent and amorous temperament.

Religious beliefs. Socrates was clearly a man of deep piety with the temperament of a mystic. He regarded mythology, with its foolish or immoral tales about gods, as a mere invention of the poets. But he found it easy to combine his own strong belief in God as ruler of the world with the view that, in practice, one could worship God in the way prescribed by "the usage of the city." God's existence is shown, he held, not only by the providential order of nature and the universality of the belief in him but also by warnings and revelations given in dreams, signs, and oracles. The soul of man partakes of the Divine; and, as Plato argued in the *Phaedo,* Socrates believed in the soul's immortality. Aristophanes makes Socrates combine the parts of "infidel" physicist and hierophant of a mysterious private faith and, in *The Birds,* presents him as presiding at a fraudulent séance. He was regular, says Xenophon, in prayer and sacrifice, though he held that, because only the gods know what is good for a man, his prayer should simply be "give me what is good." It is clear from Plato that Socrates was quite familiar with Pythagorean and Orphic religious ideas—with the doctrine of the divine origin and destiny of the soul, for example—though he regarded the ordinary Orphic mystery monger with healthy contempt.

The evidence that Socrates had a markedly "mystical" temperament is abundant. Plato tells of his curious "rapts," in one of which he stood spellbound for 24 hours in the trenches. The accounts of the philosopher's "divine sign" tell the same story. This, according to Plato, was a "voice" often heard by Socrates from childhood. It forbade him to do things but never gave positive encouragement. According to Plato, it merely gave prognostications of good or bad luck, and the occasions of its occurrence were often "very trivial." Thus, it was neither an intuitive conscience nor a symptom of mental disorder but an interior psychic audition.

The test of the Delphic oracle

Mode of life. Socrates seemed to spend all his time in the streets, the marketplace, and, more particularly, the *gymnasia.* He cared little for the country. Though he frequented by choice the society of young men of promise, he also talked freely to politicians, poets, and artisans about their various callings, their notions of right and wrong, the familiar matters of interest to them. The object of all this dialogue was to test the famous oracle of Apollo at Delphi, which had pronounced him the wisest of men. This pronouncement was made before Socrates had become conscious of his mission to his fellowmen: even at that early date, it is implied, he had the highest of reputations in circles interested in wisdom. (This early date is attested by the fact that the Eleatics from Megara and the young pupils of the Pythagoreans from Thebes and Phlious who were attached to Socrates must have formed their connection with him before the Peloponnesian War.)

Socrates set himself to convict "the god" of falsehood. But finding that those who thought themselves wise were unable to give any coherent account of their wisdom, Socrates had to admit that he was wiser than others, just because he alone was aware of his own ignorance. This account is plainly tinged with the usual "irony." Socrates took the Delphic oracle seriously enough to probe into its real import. He believed himself charged with a mission from God to make his fellowmen aware of their ignorance and of the supreme importance of knowledge of what is for the soul's good. This is proved by his declaration that he was more than ready to face instant death rather than to neglect his commission.

The poverty in which this mission had involved him and the austerity of the rule of life that it entailed were notorious. Summer and winter, Socrates' coat was the same; he had neither shoes nor shirt. "A slave who was made to live so," the Sophist Antiphon said, "would run away." This self-imposed life of hardships was the price of his spiritual independence.

His message, however, was variously received. Some of those whose false pretensions were exposed by his trenchant criticizing regarded him with ill will; many thought him an officious busybody. Among the younger men, many merely thought it good sport to see their elders silenced. Others, such as Alcibiades and Critias, deliberately attached themselves to him for a time "for private ends," believing that to learn the secret of so acute a reasoner would be the best preparation for success in the law courts, the council, and the assembly. Others sincerely hoped by associating with him to become good men and true, capable of doing their duty by house and household, by relations and friends, by city and fellow citizens. Finally, there was an inner circle that entered more deeply into Socrates' principles and transmitted them to the next generation. But these were not "disciples" united by a common doctrine. The bond of union was a common reverence for a great man's intellect and character. It was, in the main, this group—many from states that had been enemies of Athens in the recent war—that collected around Socrates on the day of his death.

His association with political enemies

The accusation and its causes. The explanation of the attack made on Socrates is simple. He had been on terms of close friendship with the two men whose memories were most obnoxious to the democrats: Critias, the fiercest spirit among the extremists of the "terror" of 404; and Alcibiades, whose self-will had done so much to bring about the downfall of the Athenian empire. The charge of "educating Alcibiades" was made prominent in the pamphlet written a few years after the trial by the Sophist Polycrates, in justification of the verdict. More than half a century later, the orator Aeschines reminds his audience that Socrates had been put to death because he was believed to have educated Critias. In point of fact, it was absurd to make Socrates responsible for the ambitions of Alcibiades, and, as he reminded his judges, he had disobeyed an illegal order from Critias and his colleagues at the risk of his life. But it is natural that he should have had to suffer for the crimes of both men, the more so because he had been an unsparing critic of democracy and of the famous democratic leaders and, furthermore, had not, like the advanced democrats, withdrawn from Athens during the "terror."

Socrates was, in fact, suspected of using his great abilities and gifts to pervert his younger associates from loyalty to the principles of democracy, and the convinced democrats who had recovered the city in 403 were unwilling, as J. Burnet has said, "to leave their work at the mercy of reaction." The motives of Anytus, an upright, unintelligent democrat, are thus quite explicable: from his point of view, Socrates would be at the best a moderate oligarch, and democrats who remembered the career of the statesman Theramenes, who had tried to mix oligarchy and democracy, could not be expected to make a fine distinction between the moderate oligarch and the traitor.

The real grounds for the attack could not be disclosed in the indictment because of the amnesty that had terminated the struggle, of which Anytus himself had been a main promoter. Hence, the charge took the form of a vague accusation of "corruption of the young." Probably for the same reasons, Anytus was ashamed to appear as the principal in the matter and put forward the obscure Meletus, who might venture on "indiscretions" more openly. If this was the same Meletus who prosecuted Andocides on the same charge of "impiety," he must have been a half-witted fanatic—and this may explain why the charge of irreligion was added. Xenophon suggests that the allusion was to the "divine sign," but this cannot be correct. Meletus said nothing about the "sign" at the prosecution, and Socrates is speaking with his "usual irony" when he pretends to guess that the mention of "religious novelties" in the indictment referred to the "sign." In the *Apology,* Socrates says that the prosecution is, no doubt, relying on memories of Aristophanes' *The Clouds,* where he had been made to talk "atheism" as part of the burlesque on men of science.

Meaning of the charge against him and his conviction

But there must have been more behind the charge. It seems likely that the prosecution of Andocides revived the old scandal of the "profanation of the mysteries" that had thrown Athens into a ferment on the eve, in 415, of the Sicilian expedition. The two chief victims, Alcibiades and his uncle Axiochus, had both been among the intimates of Socrates, and there is reason to think that others of his friends were affected. If this is what lay behind the charge, it can be understood why its real meaning seems never to have been explained: for in view of the terms of the amnesty, the matters in question were not within the competence of the court.

Socrates himself treats the whole matter with contempt. His defense consists in narrating the facts of his past life, which had proved that he was equally ready to defy the populace and the Thirty in the cause of right and law, and in insisting on the reality of his mission from God and his determination to discharge it, even at the cost of life. The prosecutors had no desire for blood. They counted on a voluntary withdrawal of the accused from the jurisdiction before trial; the death penalty was proposed to make such a withdrawal certain. Socrates himself forced the issue by refusing at any stage to do anything involving the least shade of compromise. The prosecution had raised the question whether he was a traitor or, as he held himself to be, an envoy from God; Socrates was determined that the judges should give a direct verdict on the issue without evasion. This is not only what makes him a martyr but also what forbids us to call Anytus a murderer.

DOCTRINE AND METHOD

Socrates was a man of the Periclean age, which witnessed one of the periodic "bankruptcies of science." Cosmological speculation, which had been boldly pursued from the beginning of the 6th century, seemed to have led to a chaos of conflicting systems of thought. The Rationalist Parmenides of Elea had apparently cut away the ground from science by showing that the real world must be quite unlike anything that the senses reveal and that, consequently, the interpretation of the world by familiar analogies is inherently fallacious; and his pupil Zeno of Elea seemed to have shown that even the postulates of mathematics are mutually contradictory. Thus, the ablest men, such as the Sophists Protagoras and Gorgias, had turned away from the pursuit of science and concerned themselves not with truth but with making a success of human life.

Socrates' early interest in "natural science"

Socrates, as a young man, was enthusiastically interested in "natural science" and familiarized himself with the various current systems—with the Milesian cosmology with its flat Earth and the Italian with its spherical Earth and with the mathematical puzzles raised by Zeno about "the unit" (*i.e.,* the problem of continuity). There was a complete lack of critical method. For a moment, Socrates hoped to find salvation in the doctrine of Anaxagoras that "Mind" is the source of all cosmic order because this seemed to mean that "everything is ordered as it is best that it should be," that the universe is a rational teleological system. But on reading the book of Anaxagoras, he found that the philosopher made no effective use of his principle; the details of his scheme were as arbitrary as those of any other.

The Socratic "hypothesis." After this disappointment, Socrates resolved from then on to consider primarily not "facts" but *logoi,* the "statements" or "propositions" that one makes about "facts." His method would be to start with whatever seemed the most satisfactory "hypothesis," or postulate, about a given subject and then consider the consequences that follow from it. So far as these consequences proved to be true and consistent, the "hypothesis" might be regarded as provisionally confirmed. But one should not confuse inquiry into the consequences of the "hypothesis" with proof of its truth. The question of truth could be settled only by deducing the initial "hypothesis" as a consequence from some more ultimate, accepted "hypothesis."

The doctrine of Forms. According to Plato, Socrates next proceeded to take it as his own fundamental "hypothesis" that every term (such as "good," "beautiful," "man") that has an unequivocal denotation directly names a self-same object of a kind inaccessible to sense perception and apprehensible only by thought. Such an object Socrates calls an *Idea* or *Eidos; i.e.,* a Form. The sensible things on which a man predicates beauty, goodness, humanity, have only a secondary and derivative reality; they *become* this or that for a time, in virtue of their "participation" in the Form.

Whether the Forms are Socratic

Scholars in the 19th century usually assumed that this doctrine of Forms was consciously devised by Plato after the death of Socrates. The chief argument for this view is based upon the observation of Aristotle that Socrates rightly "did not separate" the universal from the particular as, it is apparently implied, Plato did. He might equally have meant, however, that the doctrine of the *Phaedo* does not itself involve the kind of "separation" to which he objects in the Platonic theory. On the other side, the doctrine is expressly said in the *Phaedo* to be a familiar one, which Socrates "was always" repeating; and, if untrue, it is hard to see what could be the point of such a mystification and harder to understand how Plato could have expected it to be successful, especially as most of the personages of the *Phaedo* were certainly still alive. If true, however, one must be prepared to admit the possibility that he is also reproducing the thought of Socrates in the *Symposium* and *Republic,* in which he speaks of a supreme Form, that of Beauty, or Good, the vision of which is the far-off goal of all intellectual contemplation. Unfortunately, no complete separation of the Socratic and the Platonic is possible.

Logical methods. On the logical side, both Plato and Xenophon bear out the remark of Aristotle that Socrates may fairly be credited with two things: "inductive arguments" and "universal definitions." The "universal definition" is an attempt to formulate precisely the meaning of a universally significant predicate—*i.e.,* to apprehend what the *Phaedo* calls a Form. And it is from the practice of Socrates, who aimed at the clarification of thought about the meaning of moral predicates as the first indispensable step toward the improvement of practice, that the theory of logical division and definition, as worked out by Plato and Aristotle, has arisen.

The "inductive arguments" mean the characteristic attempts to arrive at such formulations by the consideration of simple and striking concrete illustrations, the perpetual arguments about "shoemakers and carpenters and fullers," which the fashionable speakers in Plato profess to think vulgar. Induction, on this view of it, is not regarded as a method of proof; its function is that of suggestion: it puts the meaning of a proposed "definition" forcibly and clearly before the mind. The justification of the definition, then, has to be sought in a consideration of the satisfactoriness of the "consequences" that would follow from its adoption. Socrates himself sought for his "definitions" principally in the sphere in which he was most interested: as Aristotle says, he concerned himself with the "ethical," character and conduct, both private and public, not with "nature" at large.

Ethics and politics. With Socrates the central problem of philosophy shifted from cosmology to the formulation of a rule of life, to the "practical use of reason." As the *Apology* relates, the specific message from God that Socrates brought to his fellowmen was that of the "care" or "tending" of one's "soul," to "make one's soul as good as possible"—"making it like God," in fact—and not to ruin one's life, as most men do, by putting care for the body or for "possessions" before care for the "soul"; for the "soul" or *psychē* is that which is most truly a man's self.

His original view of the soul

Socrates' view of the soul stands in sharp contrast with the Homeric and Ionian view of the *psychē* as "the breath of life," which is given up when the man "himself," his body, has perished, and also with the view prevalent in circles influenced by Orphic-type religions, according to which the soul is a sort of stranger loosely inhabiting the body, which "sleeps while the body is active, but wakes when the body sleeps"; instead, the soul came in the 4th century to be viewed as the normal walking personality, the seat of character and intelligence, "that," as Socrates says in Plato, "in virtue of which we are called wise or foolish, good or bad." And as this usage of the word first appears in writers who are known to have been influenced by Socrates (Isocrates, Plato, and Xenophon), it may fairly be ascribed to his influence. Thus the soul *is* the man.

A man's happiness or well-being, in Socrates' view, depends directly on the goodness or badness of his soul. No one ever wishes for anything but true good—*i.e.,* true happiness. But men miss their happiness because they do not *know* what it is. For real good they mistake things that are not really good (*e.g.,* unlimited wealth or power). In this sense, "all wrong-doing is involuntary." Men need to *know* true good and not confuse it with anything else, so as to keep from *using* strength, health, wealth, or opportunity wrongly. If a man has this knowledge, he will always act on it, since to do otherwise would be to prefer known misery to known happiness. If a man really knew, for instance, that to commit a crime is worse than to suffer loss or pain or death, no fear of these things would lead him to commit the crime. To the professional Sophist, "goodness" is a neutral "accomplishment" that can always be put to either of two uses, a good one or a bad one. To Socrates, in contrast, knowledge of good is the one knowledge of which it is impossible to make an ill use; the possession of it is a guarantee that it will always be used properly. Thus, Socrates becomes—as against the relativism of Protagoras—the founder of the doctrine of an absolute morality based on the conception of a felicity that is the good not of Athenians or Spartans or even of Greeks but of man as man, as part of universal humanity.

His political philosophy

Politics, from this point of view, is the statesman's task of "tending" the souls of all his fellow citizens and making them "as good as possible." The knowledge of good is also the foundation of all statesmanship. The radical vice of ancient democracy, according to Socrates, is that of putting society in the hands of men without true insight and with no adequate expert knowledge. His main criticism, however, is that, though in some departments democracy takes the advice only of a qualified expert, on questions of morality and justice it treats any one citizen's opinion as of equal value with another's.

Even a Themistocles or a Pericles plainly had no knowledge of true statesmanship: they gave the populace the things that tickled its taste, such as a navy and a commerce; but they were no "physicians of the body politic," for they did not promote "righteousness and temperance," the spiritual health of the community. Socrates maintained that he alone deserved the name of statesman, because he understood, as the men of action did not, that knowledge of the absolutely good is the necessary and sufficient condition of national well-being and felicity. Indeed, Plato's *Republic* may fairly be viewed as a picture of life in a society governed by this Socratic conviction. How far any of the special regulations of the *Republic* embody actual convictions of Socrates is more than can be said, though it is significant that the *Aspasia* of Aeschines represents Socrates as maintaining one of Plato's "paradoxes," the capacity of women for war and for politics.

Socrates exerted a temporary influence on a group of men who have come to be known as "the minor Socratics," among whom the most important were Antisthenes of Athens and Eucleides of Megara, with whom the Cynics and the Megarian school were connected. It was mainly through his influence on Plato, however, who took up the thought of Socrates and continued it in his own life's work, that Socrates' efforts bore their full fruit for subsequent ages (see PLATONISM and PHILOSOPHICAL SCHOOLS AND DOCTRINES: *Platonism*). (A.E.Ta.)

BIBLIOGRAPHY

General studies: A thorough and balanced introduction to Socrates is W.K.C. GUTHRIE, *A History of Greek Philosophy,* vol. 3, *The Fifth-Century Enlightenment,* pp. 323–507 (1969). Socrates' cultural and philosophical context is concisely described in FRANCIS M. CORNFORD, *Before and After Socrates* (1932, reprinted 1979); and in W.K.C. GUTHRIE, *The Greek Philosophers: From Thales to Aristotle,* ch. 4 (1950, reissued 1975), on the reaction toward humanism. Older classical accounts by JOHN BURNET, *Early Greek Philosophy,* 4th ed. (1930, reissued 1963); A.E. TAYLOR, *Socrates* (1932, reissued 1979); and CONSTANTIN RITTER, *Sokrates* (1931, in German), ascribe to Socrates himself much of Plato's formal theory of Ideas while also giving sympathetic portraits of his personality and thought.

The historical Socrates: Many studies centre on the historical value of the principal informants about Socrates: Plato and Xenophon, Aristotle and Aristophanes. The main source materials and problems are presented by RICHARD L. LEVIN and JOHN BREMER, *The Question of Socrates* (1961); a brief informative survey of positions comes from C.J. DE VOGEL, *Philosophia,* part 1, *Studies in Greek Philosophy,* ch. 5 (1970). Reliable accounts of the Socrates–Plato relationship are given by GUY C. FIELD, *Plato and His Contemporaries,* 3rd ed. (1967); and of Socrates' last days by COLEMAN PHILLIPSON, *The Trial of Socrates* (1928). Historical facts are skeptically regarded and the functions of myth and political polemic on the part of the sources are stressed by OLOF A. GIGON, *Sokrates: Sein Bild in Dichtung und Geschichte,* 2nd ed. (1979); A.H. CHROUST, *Socrates, Man and Myth: The Two Socratic Apologies of Xenophon* (1957), with special criticism of Xenophon and Antisthenes; and the two reporting dissertations by V. DE MAGALHÃES-VILHENA: *Le Problème de Socrate* (1952), and *Socrate et la légende platonicienne* (1952). There are some scholarly defenses and methodological interpretations of the historicity of the major Socratic sources: AUGUSTE DIÈS, *Autour de Platon,* 2 vol. (1927, reprinted 1975); T. DEMAN, *Le Témoignage d'Aristote sur Socrate* (1942); KENNETH J. DOVER's introduction and commentary to his edition of Aristophanes, *Clouds* (1968); and HUGH TREDENNICK's introduction to his translation of Xenophon, *Memoirs of Socrates and the Symposium (The Dinner Party)* (1970).

Socrates in history: The personality, ideals, and examples of Socrates are a perennial inspiration for subsequent thinkers and traditions. His influence is visually manifested in the many illustrations and texts of MICHELINE SAUVAGE, *Socrates and the Human Conscience,* (1960; originally published in French, 1956); as well as in the collection of testimonies gathered by HERBERT SPIEGELBERG in *The Socratic Enigma* (1964). His educational impact is measured by WILLIAM K. RICHMOND, *Socrates and the Western World* (1954), while his deep impress upon Christian religious awareness and Existential thinking is affirmed in ROMANO GUARDINI, *The Death of Socrates* (1948, reissued 1965; originally published in German, 1943). Samples of Socrates' relationships with modern philosophy are: SØREN KIERKEGAARD, *The Concept of Irony, with Constant Reference to Socrates* (1965, reissued 1968; originally published in Danish, 1841), reformulating his view of irony in terms of Romanticism and Hegel; LEONARD NELSON, *Socratic Method and Critical Philosophy* (1949, reprinted 1965), giving a Neo-Kantian interpretation of his maieutic method; and LASZLO VERSÉNYI, *Socratic Humanism* (1963, reprinted 1979), showing Socrates' implications for modern reflective and Existential humanisms; and WERNER J. DANNHAUSER, *Nietzsche's View of Socrates* (1974).

Philosophy: GREGORY VLASTOS (ed.), *The Philosophy of Socrates* (1971, reissued 1980), a collection of scholarly essays; JAMES BECKMAN, *The Religious Dimension of Socrates' Thought* (1979), and GERASIMOS F. SANTAS, *Socrates: Philosophy in Plato's Early Dialogues* (1979), detailed analyses of the *Apology* and *Crito.* See also RICHARD D. MCKIRAHAN, *Plato and Socrates: A Comprehensive Bibliography, 1958–1973* (1978).

Soil Organisms

The soil, often considered to be lifeless and inert, contains vast numbers of living organisms, which range in size from microscopic single cells to small mammals. One square metre of rich soil may contain more than 1,000,000,000 organisms.

This article deals with the importance of soil organisms, their general features, and the roles of microorganisms and animals in soil. It is divided into the following sections:

IMPORTANCE OF SOIL ORGANISMS

As decomposers. Soil organisms are important because they improve soil fertility by breaking down plant and animal tissues; during this process, the nutrients that are released and the minerals that are fixed are incorporated into the soil. Soil flora and fauna break down dead plant material into a finely divided organic complex called humus; the exact composition of humus is unknown, but it probably contains a small proportion of water-soluble organic substances, many phenolic compounds, some organic phosphates, and a polyuronoid substance containing complex sugars. It consists of about 60 percent carbon; the ratio of carbon to nitrogen is about 10 to 1 (*i.e.,* the nitrogen content is about 6 percent). Soil animals incorporate the humus into soil, where it is gradually broken down by microorganisms that release its constituents for plant nutrition.

Humus

As pests. Some soil organisms are pests of crops or animals. Growth of a single crop favours the proliferation of specific soil animals that feed on roots; these organisms then become pests and may kill the plants or cause decreased crop yields. Among the soil animals that feed on, or in, roots are nematodes, slugs and snails, symphylids, beetle larvae, fly larvae, caterpillars, and root aphids. Millipedes and springtails may occasionally attack growing roots, although normally they feed on decaying matter. Some soil organisms cause rots such as those in potato wart disease and potato blight (see DISEASE: *Diseases of plants*). Some soil microorganisms release substances that inhibit the growth of higher plants, and some soil animals are intermediate hosts for organisms that cause animal diseases, particularly those caused by nematode or helminth parasites.

Effects of pesticides

Pesticides and other soil pollutants affect the populations of many soil organisms. Some soil invertebrates are susceptible to pesticides. The active predatory species often are killed first, allowing the numbers of their prey to increase; for example, populations of springtails increase when their mite predators are killed by DDT. Other agricultural practices decrease the populations of soil organisms. Although the ecological balance of the soil is changed by pesticides, the total numbers or weight of soil organisms is not always decreased. Persistent pesticides affect the fauna over long periods of time. Herbicides, which may kill the soil microflora, often affect the soil fauna indirectly by killing some of their plant foods.

GENERAL FEATURES OF SOIL ORGANISMS

Types of soil organisms. *Protists.* Many of the microorganisms in the soil participate in breaking down organic matter, in soil formation and fertility, and in returning mineral elements to the soil. The smallest and most numerous soil microorganisms are bacteria. These spherical, rod-shaped, or spiral cells usually reproduce by simple division and survive unfavourable periods as resistant spores; they are more numerous in alkaline than in acid soils. The actinomycetes resemble both bacteria and fungi; actinomycete spores, although similar to those of bacteria, germinate into very fine colourless mycelia (or threads) that resemble those of fungi. Such fungi as molds, mildews, or mushrooms are usually larger and more variable in form than either bacteria or actinomycetes; they prefer acid soils. They also have resting spores, which germinate into actively growing, straight or branched, white or colourless mycelia that produce fruiting bodies on which spores develop. There are also algae, which are found as motile single cells or nonmotile filaments and contain pigments (*e.g.,* chlorophyll); they are most abundant near the soil surface (see Figure 1).

Microfauna. The soil microfauna, which are usually defined as animals less than 100 microns long (1 micron = 0.001 millimetre or about 0.00004 inch), include single-celled protozoans, some smaller nematodes, small flatworms, rotifers, and tardigrades (eight-legged arthropods); the microfauna feed on microorganisms. The abundant soil protozoans range from the shapeless amoeba to forms with whiplike flagella or tiny hairlike cilia; all protozoans have a nucleus, multiply by cell division, and form resting cysts. Much of the microfauna is confined to water films in litter and soil.

Mesofauna (Meiofauna). Other soil animals, somewhat larger than microfauna, have been placed in a heterogeneous group called the mesofauna. Many of them are nematodes, which are bisexual, survive unfavourable conditions as eggs in resistant cysts, and feed on microorganisms, other soil animals, decaying organic matter, or living plants. The mites (Acarina), which are the most numerous arthropods in soil, have eight legs when adult and feed on plant or animal material; some are important in breaking down organic matter. Springtails (Collembola), which are wingless insects commonly found in soil, feed on decaying organic matter and micro-organisms; collembolans that live near the soil surface have a springing organ, which enables them to leap. Small, wingless, insect-like organisms called proturans lack antennae and eyes and probably feed on fungi; members of another arthropod group, the pauropods, have nine pairs of legs when mature and feed on decaying plant material.

Macrofauna. The most common soil animals in the group known as the macrofauna are potworms (Enchytraeidae), small, white, segmented worms that feed on fungi, bacteria, and decaying plant material. The myriapods include the small white symphylids, which have 12 pairs of legs and feed on plant roots or decaying material; the centipedes (Chilopoda), which are many-legged, long, slender arthropods that prey on other soil animals; and the millipedes (Diplopoda), which have many legs arranged in pairs and feed principally on decaying plant material. Among the other macrofauna are slugs and snails, which eat mostly plant tissues and organic debris. Among the soil-inhabiting insects are fly larvae, and beetles and their larvae; some of these are predatory but most feed on decaying matter.

Megafauna. The megafauna are the largest soil organisms and include the larger earthworms, which pass both soil and organic matter through their guts, and several vertebrates (*e.g.,* moles, mice, hares, rabbits, badgers, gophers, snakes, lizards), whose food habits vary. The earthworm is important in maintaining soil fertility.

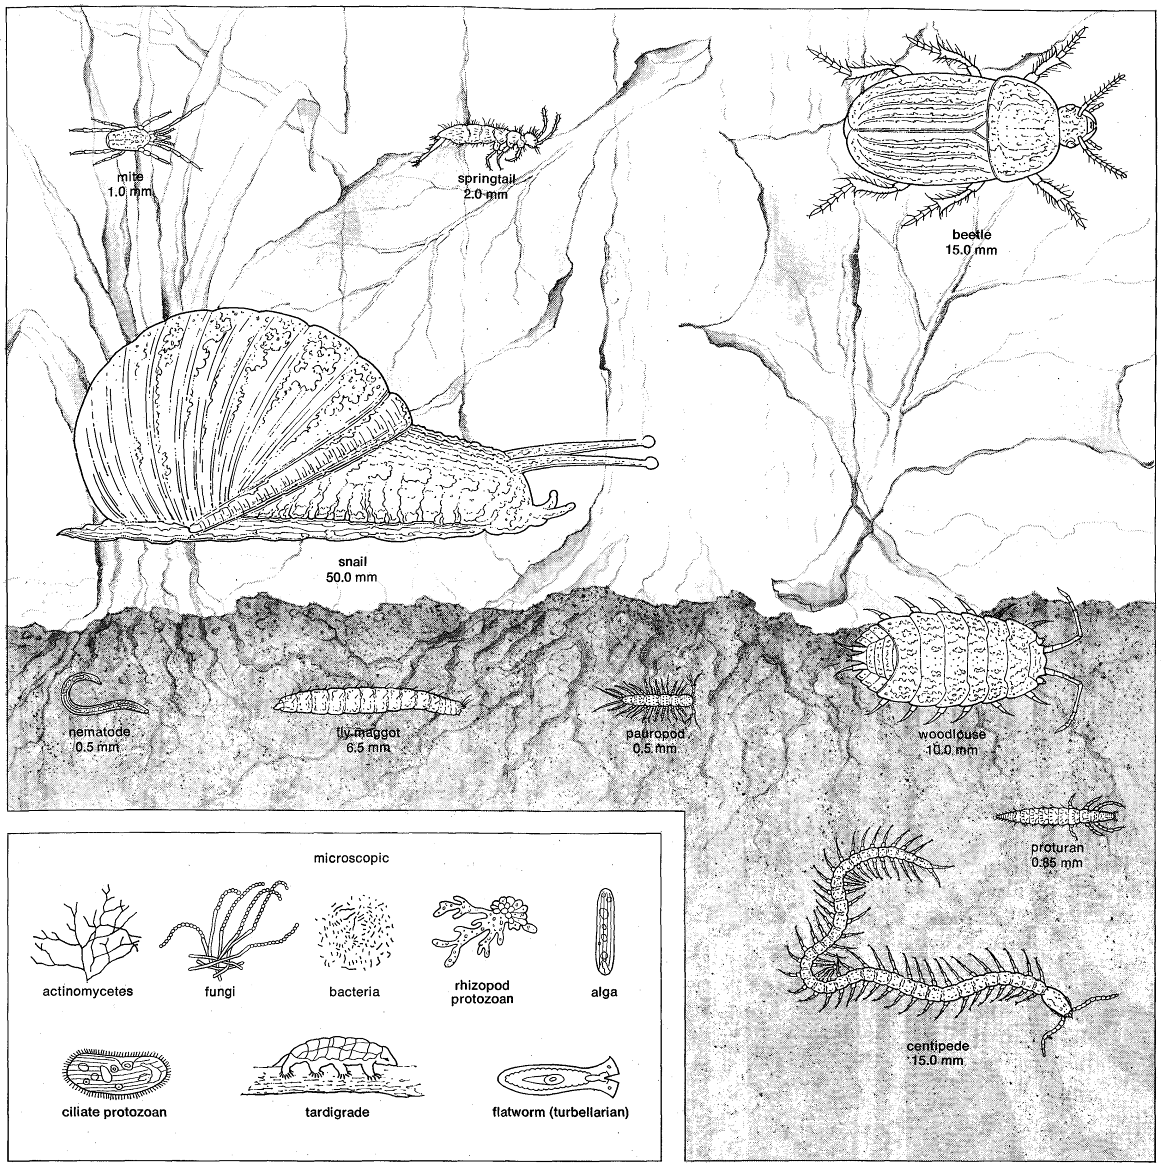


Figure 1: Types of soil organisms.

Vertical distribution of soil organisms. The vertical distribution of soil organisms is not uniform; most of them are concentrated in the litter layer and the top two inches of soil in woodlands. It has been calculated that as much as 90 percent of the soil fauna may be in this upper stratum. Many soil invertebrates move up and down through the soil either daily, seasonally, or in response to changes in temperature or moisture in the upper soil. Some invertebrates penetrate deep into the subsoil, usually moving through cracks and fissures. The vertical distribution of microorganisms follows that of organic matter; as a result, much of the soil microflora is concentrated close to the soil surface.

Movement through soil

THE ROLE OF MICROORGANISMS IN SOIL

The most important functions of soil microorganisms are to break down plant and animal organic matter and to help convert it into a form usable by plants. Heterotrophic soil microorganisms, which derive their carbon and energy from organic materials, are concerned mainly with the breakdown of organic matter, the carbon cycle, and nitrogen fixation. Autotrophic microorganisms, which obtain carbon from carbon dioxide and energy from the oxidation of simple organic compounds, form nitrites and nitrates and oxidize sulfur and iron compounds. Most microorganisms produce carbon dioxide, which dissolves in water to form a weak acid (carbonic acid); this carbonic acid dissolves relatively insoluble soil minerals, which thereby makes these minerals available to plants as nutrients.

Since most functions of soil microorganisms are beneficial, soils with large populations are usually naturally fertile. Microorganisms are more numerous and more active in woodland soils than they are in pasture soils; these in turn have a greater microbial activity than fallow or cultivated soils.

The carbon cycle. One of the most important functions of soil microorganisms is to recycle the carbon that is bound as complex substances in decaying plant and animal matter. Green plants convert carbon dioxide and water into organic plant substances. Animals eat these plants and convert their constituents into animal tissues. When plants and animals die, microorganisms begin the decay process and complete the carbon cycle by liberating carbon dioxide to the atmosphere. They also liberate minerals (for example, nitrogen and sulfur) and such complex molecules as proteins, polysaccharides, and nucleic acids into the soil.

The nitrogen cycle. Nitrogen, because it is an important component of proteins, is an indispensable element for the growth of microorganisms, plants, and animals. The availability of nitrogen in soil, in a form that is useful to plants, quite often influences natural vegetation and crop yields.

One essential role of soil microorganisms in the nitrogen cycle is to break down complex nitrogenous compounds (*e.g.*, proteins, polypeptides, nucleic acids) in soil and humus to simple inorganic compounds (ammonium ions, nitrite, and nitrate) that can be used by plants. Proteins can be decomposed by certain bacteria and fungi. Bacteria usually are most active in alkaline soils, whereas fungi are more active in acid ones. Microorganisms may release nitrogen in the form of ammonium ions (ammonification); these ions may be oxidized to nitrates by other microorganisms in a process that is known as nitrification.

Some microorganisms (*e.g., Nitrosomonas* species) reduce nitrates to nitrites; others (*e.g., Nitrobacter* species) convert nitrites to ammonium ions; still others convert nitrites or ammonium ions back to gaseous nitrogen (denitrification). Soils may be depleted of their nitrogen in this way if no organisms are present to convert the nitrogen back into compounds useful to plants.

Nitrogen fixation

Another essential role of soil microorganisms in the nitrogen cycle is to return (or fix) nitrogen from the atmosphere; this can occur either by the activity of free-living microorganisms or as a result of a symbiotic association between plants and microorganisms.

Free-living microorganisms capable of utilizing atmospheric nitrogen include bacteria (*e.g., Azotobacter, Clostridium*) and blue-green algae (*e.g., Anabaena*). Since many of these bacteria also can use ammonium ions and other nitrogenous compounds as nitrogen sources, they fix nitrogen only when alternative sources are not available. Their transformations are not as important as the symbiotic associations between plants and bacteria described below.

The genus *Rhizobium* causes the formation of root nodules on suitable leguminous plants as well as some trees and shrubs. The roots of the plants secrete substances that stimulate growth and multiplication of *Rhizobium* in the soil around the roots. During nodule formation, atmospheric nitrogen is fixed by these bacteria.

The sulfur cycle. Sulfur is an essential component of plant and animal tissues. Although abundant in nature, as much as three-fourths of soil sulfur may be bound in a form that is unavailable to plants. The most important forms of sulfur for plant nutrition are sulfate salts, although some sulfur in the atmosphere may be taken into plants through the leaves as sulfur dioxide gas. Soil microorganisms release sulfur from organic compounds and form inorganic compounds; hydrogen sulfide, for example, is released into the atmosphere. Some autotrophic microorganisms oxidize inorganic forms of sulfur into elemental sulfur, then to sulfurous acid, and, finally, to sulfuric acid.

Sulfates formed by the combination of sulfuric acid and calcium, magnesium, sodium, and potassium provide food for plants. Sulfates may be reduced to sulfites by specific bacteria in transformations that are similar to those that occur in the nitrogen cycle. In well-aerated soil, sulfates are formed readily; in oxygen-depleted soils, however, as are often common in swamps, hydrogen sulfide is produced.

(For additional information about biogeochemical cycles, see BIOSPHERE.)

Adverse effects of soil microorganisms. Although most soil microorganisms are beneficial, some are harmful. There are pathogens that cause root rots of higher plants; in greenhouses, for example, "soil sickness" may result from large populations of pathogenic organisms.

Microorganisms sometimes compete with higher plants for available nutrients, particularly nitrogen and phosphorus. The addition of carbon-rich organic matter to soil often causes significant increases in the numbers of microorganisms, which utilize the nitrates available in the soil, thus depriving higher plants of nitrogen.

Toxins

Another harmful effect of soil microorganisms is their production, particularly under oxygen-poor conditions, of substances that inhibit or prevent the growth of higher plants and other microorganisms. These toxic substances (*e.g.,* methane, hydrogen sulfide, phosphine, skatole, indole, various organic acids) are found most commonly in woodland soils and in lesser amounts in pastures and plowed and cultivated soils.

Their concentrations are highest in summer and autumn and lowest in the spring. Soil can be detoxified by washing or flooding, by adding lime, by using fertilizers, and by cultivating frequently.

THE ROLE OF ANIMALS IN SOIL

Animals are usually not important in maintaining the fertility of agricultural soils. In woodlands, however, soil animals are essential; they maintain the cyclic breakdown of organic material, return organic matter to the soil, and improve soil structure. Soil animals feed on decaying organic matter, living plants, animal excreta, or other animals. The number of animals in a given area of soil is dependent on the availability of food, temperature, moisture, and the degree of aeration and drainage; several hundred million animals (with a fresh weight of as much as 900 kilograms [one ton]) are probably a valid estimate for the number of animals in an acre of soil (see Figure 2).

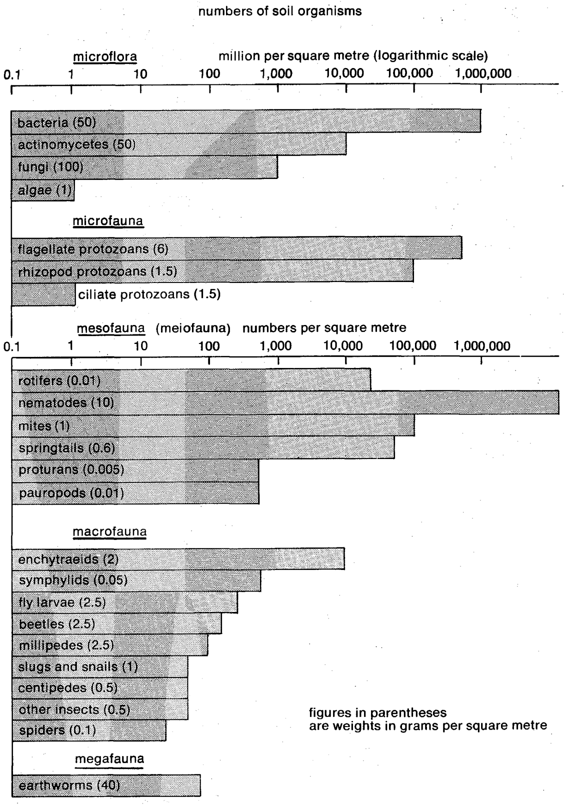

Figure 2: Characteristics of populations of soil organisms.

Formation of humus. Although they contain microorganisms when they fall, leaves usually are unpalatable to soil animals until they have weathered for several weeks in a litter layer. During this period, after water-soluble materials (*e.g.,* polyphenols) are leached out of the leaves, they are invaded by fungi and other microflora (called primary microorganisms) and become damp and soft in texture. These changes render the leaf tissues palatable to various soil animals.

A period of intense invertebrate activity occurs; the invertebrates that attack litter at this early stage have been called primary soil animals (see Figure 3). They include millipedes, wood lice, fly larvae, springtails, oribatid mites, enchytraeid worms, and earthworms. Earthworms are important; the burrowing species, such as the "night crawler" (*Lumbricus terrestris*), break up large quantities of leaves before pulling them down into their burrows as food. During this fragmentation of the litter, the invertebrates initiate the conversion of leaf material into a medium suitable for the growth of microflora; for example, invertebrates increase the surface area of leaf tissues by feeding on them. The organic constituents of leaf tissues do not undergo much change, however, as they pass through the invertebrate intestines.

Some chemical changes occur during fragmentation of the litter by soil animals. A few complex molecules are broken down into simpler molecules; for example, certain invertebrates, with the help of symbiotic organisms in their guts, can break down complex substances such as cellulose, keratin, and chitin. The leaf litter and the feces of the

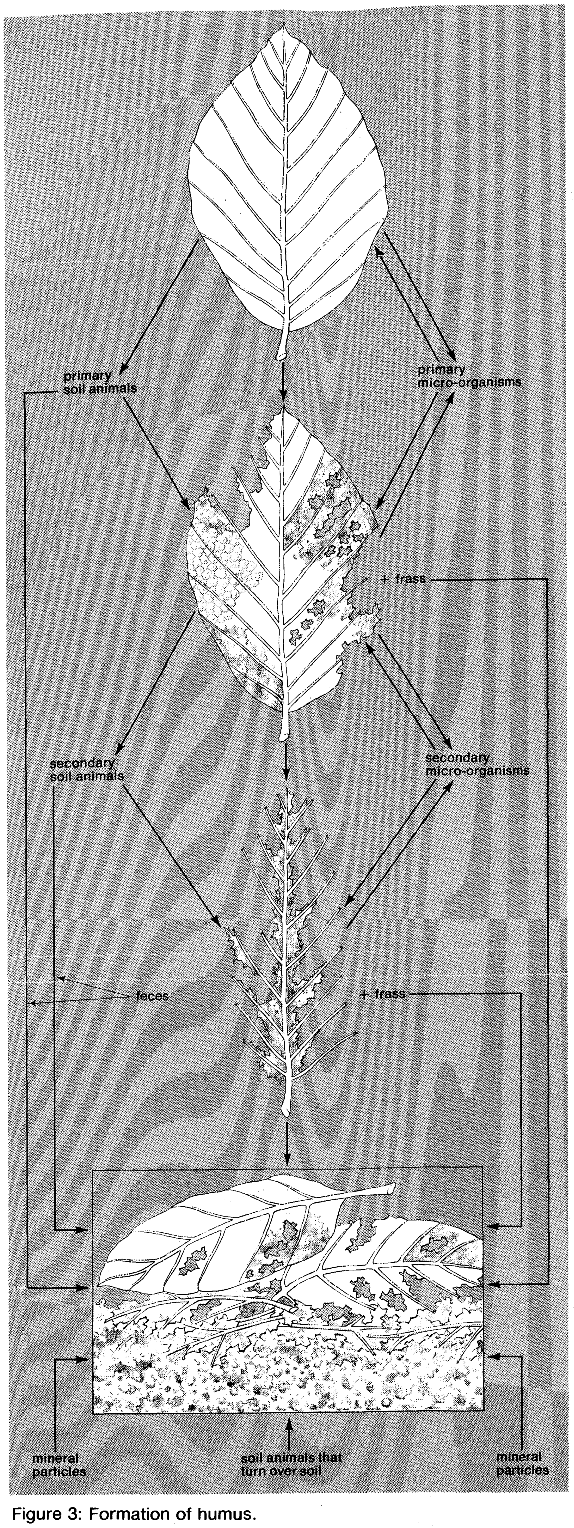

Figure 3: Formation of humus.

animals are now suitable substrates for the growth of other microorganisms, and a second wave of microbial activity occurs. These microorganisms act on the organic matter to make it palatable to other soil animals (the secondary decomposers), which flourish only on predigested material.

The secondary animals, which feed on this and also on microorganisms, include springtails, oribatid mites, and enchytraeid worms. Some secondary animals may also be primary decomposers, but different species usually are involved. The arthropods produce distinctive feces in the form of fine pellets, and enchytraeid worms produce amorphous black feces. During this stage algae, protozoans, nematodes, and rotifers invade the fine water films that form on the surfaces of leaf fragments and animal feces. (Many activities of the soil fauna and flora are dependent on moisture; if the litter layer dries, many soil organisms encyst or enter a resting stage.)

Complementary roles of organisms

The roles of the soil fauna and microflora in decomposing organic matter are complementary and interrelated. If soil animals are numerous, bacteria also are abundant. Consumption, digestion, and excretion of leaf litter by soil animals alternates with increases in the population of microorganisms; as a result the proportion of humic substances in the litter increases and mixes thoroughly with other materials.

The soil fauna ultimately destroy the mesophyllic tissues of the leaves, leaving only veins and toughened leaf margins. The rate at which destruction of the mesophyll continues is dependent on the moisture and temperature of the litter layer; destruction is rapid when the litter is moist and temperatures are high.

The organic matter of leaves, therefore, is continuously eaten and excreted by soil animals, acted upon by microorganisms, and mixed with other soil materials. As this process proceeds, the cellulose, protein, and sugar content of the humus diminishes; the ratio of carbon to nitrogen decreases as starches and sugars in the litter are broken down to carbon dioxide and water. Mineral elements such as sodium, potassium, and magnesium are leached away gradually; eventually the humic substances that remain may represent as little as one-fourth of the organic matter in the original leaf tissues. The remainder of the content of the humus at this stage is lignin (a substance related to cellulose) and protein; fats, waxes, and other residual materials also are present.

Humus increases the porosity and the water-holding capacity of soil and also acts as a reservoir for essential plant nutrients; these substances, released gradually, are made available to plants by the action of soil microorganisms.

Soil fertility and structure. After the formation of humus, soil animals play an important role in soil fertility and structure. The incorporation of humus from litter into soil is a gradual process dependent on the activities of soil animals. In soil that contains small animals and a few microorganisms, most of the leaves and wood fragments are not decomposed and lie on the soil surface; below the surface is a distinct humus layer, and soil horizons are defined; such a soil is said to be in a mor, or raw humus, condition.

When the soil flora and fauna are abundant, however, decomposition of plant material is rapid, and the humus is mixed into the soil so that layers or horizons are hard to define; such a soil is classified as a mull humus form.

Turnover of soil

The earthworms are important soil animals in temperate soils; they create the mull condition by turning over the soil—*i.e.,* taking organic matter deep into the soil and bringing subsoil to the surface as "casts" (*i.e.,* excrement). Estimates as to the amount of soil turned over in this way by earthworms vary from 7,000 to 54,000 kilograms per hectare (three to 24 tons per acre) per year, with an average of 10,000 kilograms (11 tons). This is equivalent to completely turning over all the soil on the earth to a depth of 2.5 centimetres (one inch) every 10 years.

Soil also is turned over by earthworm species that do not burrow or cast soil to the surface. Moles, which feed mainly on earthworms, also turn over large quantities of soil as they tunnel. In tropical soils, termites, as they construct mounds or gallery systems, are more important than earthworms in turning over soil. Many other animals distribute soil by tunnelling; in particular millipedes, wood lice, ants, and mollusks can turn over large amounts. An important aspect of soil turnover by animals is that it distributes microorganisms to suitable substrates.

Soil animals also aerate and drain the soil as they dig their tunnels or burrows. Earthworms, termites, ants, wood lice, millipedes, centipedes, and mites break open soil that has been compacted and improve its aeration as they move through it.

Soil without animals lacks "aggregates." Mineral soil particles (particularly clay and lime) and organic matter are cemented together as they pass through the intestines of soil animals; when these substances are excreted they are in the form of water-soluble aggregates; millipedes, wood lice, and earthworms are particularly valuable in forming such aggregates.

Soil animals contribute to the turnover of soil nitrogen; their feces contain nitrogen in forms such as ammonia, urea, uric acid, and other compounds that are readily converted to substances that plants can utilize. It has been calculated that the amount of nitrogen excreted by an average earthworm population is about equal to the amount removed by an average crop of hay—*i.e.,* about 56 kilograms of nitrogen per hectare (50 pounds per acre); however, soil microorganisms contribute much greater quantities of nitrogen. Organic matter bound in the tissues of soil animals is perhaps as much as 2,250 kilograms per hectare (one ton per acre), expressed as fresh weight. This is a reservoir of nutrients that is released gradually to the soil as the animals die.

Soils

Soil may be defined as the fine earth covering land surfaces that has the important function of serving as a substratum of plant, animal, and human life. Soil acts as a reservoir of nutrients and water, and absorbs and oxidizes the injurious waste substances that plant growth accumulates iu the rhizosphere (*i.e.,* the root zone). These functions of soil are possible because it contains clay minerals and organic substances (clay and humus form the finer part of soil) that absorb both ions (electrically charged atoms) and water.

This article treats soil formation and the influential factors that are involved, soil profiles, soil properties and their dependence on geographic factors, soil classification, and the geographical distribution of soil. Soil-plant relations are treated in the article ECOSYSTEMS. For coverage of the processes of rock weathering and the products that are involved, see GEOMORPHIC PROCESSES and MINERALS AND ROCKS: *Clay minerals.* The interaction of soils and climate is discussed in CLIMATE AND WEATHER. See also HYDROSPHERE for the role of soils in the world's water system.

This article is divided into the following sections:

GENERAL CONSIDERATIONS

Soil usually consists of a sequence of chemically and biologically differentiated layers, called horizons, that have been formed by the action of natural forces on the unconsolidated residue (regolith) of rocks and minerals on the Earth's surface. The regolith itself is the result of weathering of the original massive rocks at the surface and may be considered to be incipient soil. In the process of weathering, fracturing occurs along planes of weakness in the rocks and their mineral components react chemically with water, oxygen, and organic, carbonic, nitric, and sulfuric acids that are derived from the atmosphere and living organisms. Through the continuation of these chemical, physical, and biological actions and reactions, the regolith material is transformed into soil that exhibits one to four master horizons called, from the surface downward, A, B, and C horizons (the soil profile), and the underlying consolidated rock, R.

Regolith and the four horizons

Surface and subsurface horizons are distinguished by the differences in conditions at various depths. Some materials accumulate in the soil and some substances decompose or are dissociated to release compounds that may be dispersed, dissolved, or transported from one horizon to another; they may even be carried away from the immediate locality. Solutions are present in the soil layers, and these vary in composition and concentrations, and thus in the chemical changes they effect. These several conditions determine the abundance and variety of living organisms, from microscopic ones to vertebrates, which in turn influence the further development and the properties of the soil. In the soil profile that results, the horizons differ from each other in characteristics such as colour, chemical composition, particle sizes and distribution, and structure (*i.e.,* arrangement of the particles in groups, aggregates, or independent units).

The A horizon extends from the ground surface to the unmodified regolith or consolidated rock. It is the horizon in which weathering is most intense, with partial removal of the resulting products and a zone of accumulation of organic material. In a typical high-productive soil, the A horizon is rich in humus (more than 1 percent carbon) to a depth of 15 centimetres (6 inches) or more; it contains the greater part of immediately available plant nutrients. Soils of low productive capacity tend to have A horizons that are poor in humus and plant nutrients. The B horizon lies immediately beneath the A horizon and may reach a depth of 65 to 90 centimetres (26 to 35 inches). It is a zone of more moderate weathering in which there is an accumulation of many of the products removed from the A horizon. Sometimes the B horizon is very clayey and impermeable, constituting a serious impediment to plant growth. In a productive soil water, air, and root penetration is easy to a depth of 75 centimetres (30 inches) or more and the water-holding capacity of the entire layer is 15 centimetres (6 inches) of available water, or more. The C horizon contains the parent materials, from which the A and B horizons are formed. The R layer is not part of the soil proper; it is an underlying layer that has properties much different from those of the C horizon immediately above it and that influences the soil by its position. Because of soil development factors that will be discussed in following sections of this article, some master horizons can be missing in certain soil profiles. For example, erosion may remove the A horizon; shortness of time or absence of key factors may preclude development of a B horizon; a shallow, weathered layer may be transformed completely into A and B horizons, so that no parent materials are left to constitute a C horizon; or conversely a deep regolith can screen the A layer to the point that the latter does not influence the properties of the overlying soil horizon.

There are many functions provided by soil that are important to man. Agriculture and animal husbandry produce more than 90 percent of man's food; together with forestry these soil-connected activities produce many other materials needed by man, such as wood, cellulose, textile fibres, and leather. The utilization of soil by agriculture, animal husbandry, and forestry is often termed "soil exploitation." Soil is necessary for dwellings, highways, airports, and recreation areas, and it also provides road fill and material for water retention structures and many other essential functions.

PROCESSES OF SOIL FORMATION

The weathering process

Clay formation. The most fundamental soil forming process is weathering. During the weathering process the crystals of feldspars and other silicate minerals are broken up, releasing chemical compounds such as bases, silica, and oxides of iron and aluminum (specifically the sesquioxides: Fe_2O_3 and Al_2O_3). Leaching (*i.e.*, washing or draining away by percolation of water through the soil) removes most of the bases and some of the silica, and the remaining silica combines with alumina and forms crystalline clays.

The kind of crystalline clay produced depends on leaching intensity. Rapid leaching leaves little silica to combine with alumina and results in what are known as 1:1 clays consisting of a tetrahedral (silica) and octahedral (alumina) layer; slow leaching leads to the formation of 2:1 clays, consisting of one octahedral (alumina) layer sandwiched between two tetrahedral (silica) layers. In neither case is the result solely one of the two types, but 1:1 clay is predominant after rapid leaching, and 2:1 clay more abundant when leaching is slow (see Figure 1).

leaching rate

Figure 1: Influence of weathering and leaching rates on clay mineralogy and cation-exchange capacity; rates increase in the direction shown by the arrows (see text).

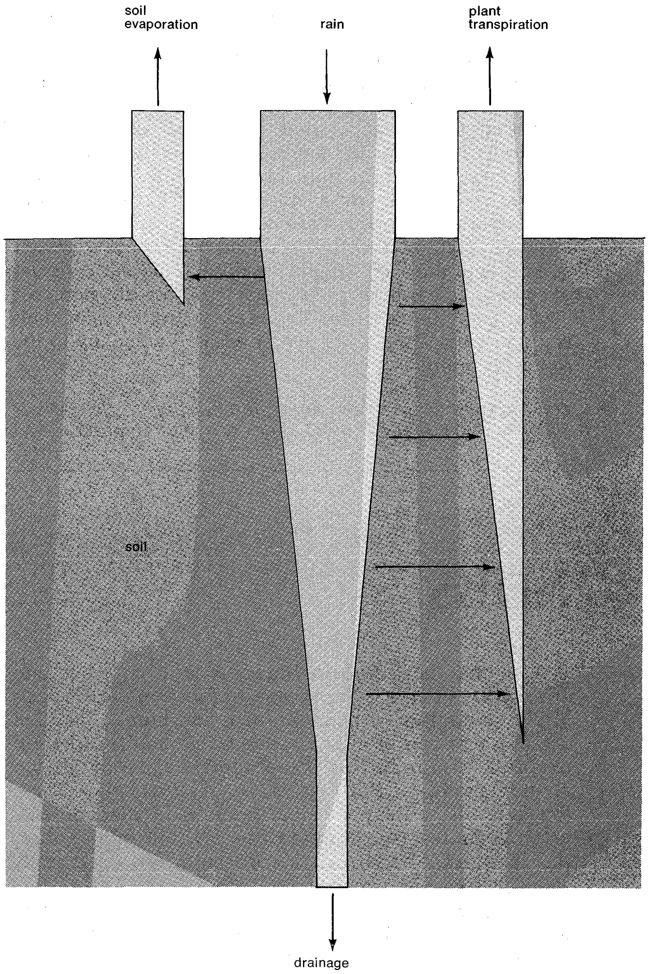

Figure 2: *Water movement in the soil.*
In general, water moves in the soil in only one direction—it descends. While descending it is absorbed by plant roots, and the substances it contains precipitate; in this way various substances are transported from the higher layers (horizons) to the lower ones. Under moderate rainfall, the quantity of water that is lost by drainage is little, if any, and only very soluble substances are eliminated.

Ions are atoms or groups of atoms that have become electrically charged through the loss or gain of electrons; ions of positive charge are cations and those of negative charge, anions. The phenomenon known as cation exchange is the result of the differences in the force with which clay holds different cations. The surfaces of clay minerals contain many negative charges, which are balanced electrically by the adsorption (*i.e.*, taking up on the surface, as opposed to taking up and distributing throughout the body of an absorbent) of cations. The tightness with which the soil holds cations varies; it is greatest for hydrogen cations and decreases for other cations in the following order: calcium, magnesium, potassium, sodium. Because of the differences in attractive forces, adsorbed cations may be removed and replaced by other cations. Because clay formation is very slow, for long time periods the silica and alumina constitute an amorphous (structureless) clay that has a cation-exchange capacity several times greater than that of crystalline clays. Alumina-rich 1:1 clays have low cation-exchange capacity. Silica-rich 2:1 clays have higher cation-exchange capacity, but lower than that of amorphous clays. Thus young soils and lower horizons that have undergone little weathering have high cation-exchange capacities per unit of clay, as do volcanic soils, because their weathering has been so rapid that clay formation has not had time to take place. Such capacity is lower in old soils in dry or cold climates, and it is lowest in tropical soils.

The most significant aspect of weathering is its relationship to clay crystallization or leaching, rather than its rapidity. Minerals differ greatly in their weatherability, and they have been classified in this respect. Clay crystallization seems to be accelerated by a basic medium, especially magnesium. Leaching is an irreversible process (see Figure 2), and thus the effect of a humid season cannot be undone by a dry season. What is important is leaching rainfall, Ln., which is the difference between rainfall and potential evapotranspiration (*i.e.*, return to the air by direct evaporation or by transpiration of vegetation, or both) during the humid season. Leaching rainfall is low in temperate countries, even when they are humid (as in London and Moscow), and high in tropical countries, even when they have a long dry season (as in Kano, Nigeria). The prevalence of 1:1 clays in tropical countries is more directly the result of leaching rainfall (see Table 1) than of the great age of the rocks.

The character of clay

Rocks subjected to weathering, young soils, and soils formed from easily weatherable materials (*e.g.*, volcanic ashes, lava, or basalt) are rich in amorphous clays of high cation-exchange capacity. Such amorphous clays are mixed with 1:1 clays or 2:1 clays, depending on leaching intensity. Old soils and soils formed from materials that weather with difficulty are poor in amorphous clays and rich in 1:1 clays or 2:1 clays according to whether leaching is rapid or slow. Soil usually contains a great variety of clays that differ in their relative proportions.

In addition to the absorbing capacity for water and ions, which is the most important soil property, clay mineralogy affects such physical properties of soil as its structure and permeability to air and water. A soil rich in amorphous clays has a low apparent density and is very permeable to air and water; decay of organic matter is slow and humus content is unusually high. Soils rich in 1:1 clays usually have a stable structure and swell very little when moistened; on the other hand, a soil rich in 2:1 clays, more especially montmorillonite, has a weak structure, low permeability, and swells easily when moistened.

Tropical soils are usually dominated by 1:1 clays, whereas those of temperate countries contain chiefly 2:1 clays. But pedology, the study of soils, began in temperate countries and is consequently based on what is observed in soils with 2:1 clays; it was some time before the fundamental difference between tropical and temperate soils was realized and understood. For analogous reasons, and because amorphous clays were lost when preparing clay samples for analysis, understanding of volcanic soils has been much delayed. It is only recently that they have been recognized as a special group. Even now the volcanic soils of dry climates are little known.

Mica is a platy silicate mineral that is directly altered (*i.e.*, changed in mineralogical composition) to clays. The first clays formed have high cation-exchange capacity; later 2:1 or 1:1 clays dominate, so that the foregoing outline of the weathering process is applicable to soils formed from materials rich in mica.

Experiments show that weathering is more rapid in a medium containing organic acids. Hence, when soil is covered by raw humus, as in podsolic regions, amorphous clays are formed as a result of the rapid weathering.

By eluviation (the transposition of soil material from one horizon to another) an illuvial horizon is formed by the deposition of materials leached out of an overlaying layer. The illuvial horizon of podsols, called the spodic horizon, is rich in amorphous clays and resembles ando (volcanic ash) soil in many respects.

Clay mineralogy is usually studied by X-rays and techniques of differential thermal analysis, which provide information on structural changes during heating. Soils may be classified on the basis of the relationship between cation-exchange capacity and clay content. Gradations between ando soils and those rich in the clay mineral kaolinite have cation-exchange capacity similar to those of soils dominated by 2:1 clays, but when conditions favour the formation of 2:1 clays, or the soil is young, volcanic soils exhibit very high cation-exchange capacities.

Humification. Second only to clay in importance as a soil constituent is organic matter, which contributes significantly to soil absorbing capacity. Roots die continuously, vegetation and crop residues fall on the soil surface and decay, and the organic leaching products enter the soil. Part of these residues is mixed with soil by organisms living in the soil or by tillage operations; some algae produce organic matter that also is added to soil.

Types of humus

All these residues are transformed by microorganisms into a mixture of organic substances called humus. Two kinds of humus may be distinguished: (1) mild humus is dark in colour, well saturated with bases, especially calcium, rich in humic acids (of high molecular weight), and serves to stabilize clay; (2) raw humus is more red in colour, less basic, rich in fulvic acids (of low molecular weight), and favours dispersion of clay. Soil also contains organic matter that has not yet been humified and in certain cases peat, which is more or less carbonized material that still retains its original structure.

Vegetation determines the kind of humus a soil contains. Grasses produce mild humus rich in humic acids, and conifers produce raw humus rich in fulvic acids. But the base content of soils is also important in determining humus type; for example, calcium-rich soils produce milder humus than do hydrogen-saturated soils. Waterlogging also has an effect, favouring production of raw humus. Root growth is more abundant near the soil surface, and aerial residues accumulate on the surface; thus, organic-matter content decreases with depth.

The effects of leaching. Except for the amount that is immediately evaporated from the surface, rainwater moves through the soil in only the downward direction, and while descending it is absorbed by plant roots. Excess water may be eliminated by drainage, so that even in dry climates the upper layers of soil are somewhat leached. Leaching decreases with depth (see Figure 2). Descending water dissolves various substances, which are precipitated when the water is absorbed by roots. Descending water transports substances from the higher layers to the lower ones, and when some of the water is lost by drainage, the substances it carries are lost as well. More soluble substances are more easily leached away from a layer and are accumulated at greater depth. All chlorides and sodium, potassium, and magnesium sulfates are more soluble than gypsum, which is in turn more soluble than calcium and magnesium bicarbonates.

When there is no drainage, all substances remain in the profile, stratified according to their solubility (see Figure 3)—chlorides and sulfates at the lowest part of the rhizo sphere (root zone of plants), gypsum above them, and calcium carbonate at a higher level. With more leaching the profile deepens, salts are leached away, gypsum accumulates in the lowest part of the rhizosphere, and lime above it. Still further leaching removes first the gypsum, while the lime accumulates in the lower part of the rhizosphere; then it removes the lime, and the soil becomes

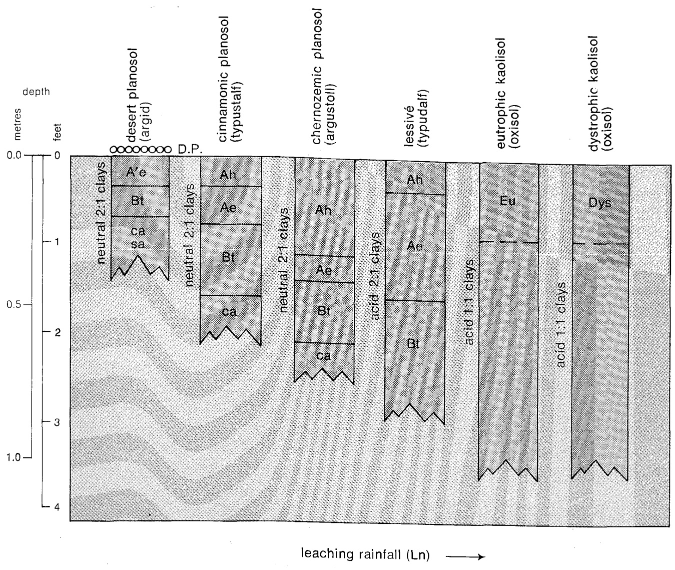

Figure 3: *Influence of leaching rainfall (Ln) on soil formation.* Leaching rainfall increases from left to right, as shown by the arrow. D.P., desert pavement; A'e, surface horizon poor in humus and eluvial; Bt, textural B; ca, lime accumulation; sa, salts accumulation; Ah, surface horizon rich in humus; Ae, eluvial surface horizon; Eu, eutrophic upper soil; Dys, dystrophic upper soil (see text).

acidified. Because silica is less soluble than lime, 1:1 clays are usually formed in an acid medium, and are usually acid. But an acid soil may later be basified, and 1:1 clays are sometimes inherited from parent material, as in the case of allochthonous soils (*i.e.,* those transported from other environments).

Base saturation acidity

Dispersion mechanisms of soil constituents. *Biological transport of elements.* Plants absorb various elements from the profile and deposit them, with their residues, on the soil surface, a process that counteracts leaching. In soils rich in bases leaching is more important. This accounts for the fact that base saturation and pH (the standard measure of acidity, related to the concentration of hydrogen ions; a pH value of 7.0 is neutral, whereas that from 1.0 to 7.0 is acid and that from 7.0 to 14.0 is alkaline) usually increase with depth. In acid soils, leaching is difficult because cations are firmly retained by soil colloids, and biological transport to the surface prevails; base saturation decreases with depth. In the kaolisols of the humid tropics, the upper 25 centimetres (10 inches) of soil often contain more bases than the rest of the profile to a depth of 150 centimetres (59 inches). The process is selective, however; *e.g.,* sodium and magnesium are less absorbed by plants than are potassium and calcium.

Addition of constituents by running water and wind. Floodwaters always contain salt, and soil, when flooded, may become saline (*i.e.,* high in chlorides and sulfates of sodium, potassium, calcium, and magnesium) unless some of the water is lost by drainage. Floods sometimes deposit fine earth or coarse materials on the soil surface. Sea winds often bring salts, and some soils, such as those of New Zealand and the Falkland Islands (Islas Malvinas), have probably been salinized in this way. In other cases winds bring dust or volcanic ash, additions that may counteract leaching and modify the soil profile.

Subirrigation. In some soils there is a water table one to two metres below the rhizosphere. During the dry season water rises by capillary action from this water table to the rhizosphere, where it is absorbed by plant roots, and the substances it contains accumulate. In this way a horizon of salts, gypsum, lime, silica, or iron accumulation is formed, depending upon the substances that are contained in subirrigation water. When the accumulation takes place in a layer poor in clay, the lime, silica, or iron are deposited on the surface of sand or gravel and may cement them, forming a hardpan (cemented layer impenetrable by roots). Many calcareous horizons, duripans, fragipans, and iron pans have this origin, but they also may be cemented by substances that descend in the profile. When the water table is shallow, the hardpan may reach the soil surface.

Solonization. Sodium clay is easily dispersible, and in sodium soils it is transported from the surface to some depth. Sodium soils swell when moistened, however, which impedes clay movement, so that clay illuviation takes place near the surface rather than at depth. This process is called solonization, or solonetization, and results in sodium-saturated soils (solonetz) that have a richer clay horizon at depth than at the surface.

Transport of chemicals in soils

Leaching activated by vegetation, however, produces organic acids and transports calcium from the lower layers to the surface. Sodium then is replaced by calcium or hydrogen in the eluvial layer and the upper part of the illuvial one. Clay illuviation thus takes place at a greater depth, and soil becomes planosol or solod (calcium- or hydrogen-saturated soils with considerable difference in clay content between the eluviated surface and the clay illuvial horizon).

Planosols can also be formed directly from a slightly sodium-saturated soil; low sodium saturation is sufficient to facilitate clay dispersion and permits clay movement to greater depth. Solonetz are often formed from sodium-saline soils, and planosols from easily weatherable materials, such as volcanic ash, under conditions that impede leaching (*e.g.,* dry climate or poor drainage or both).

Iron and clay illuviation. Fulvic acids react with iron and may cause its eluviation and that of clay. For that reason, soils formed under forest vegetation, which produces humus rich in fulvic acids, are often leached; there is a difference in clay content between the surface horizon and the B horizon in which the clay is illuviated. Moreover, such soils are relatively rich in free iron, and a difference in free iron content is often observed between the surface horizon, which is poorer, and a lower enriched horizon. Because dispersed iron is easily precipitated by bases or concentration of soil solution, soils developed under conditions that favour the formation of fulvic acid-rich humus are usually rich in iron that is finely precipitated with organic matter, which gives them a brown colour (brunisolic soils).

Podsolization. Weathering in a strongly acid medium produces an eluviation of the sesquioxides (Fe_2O_3 and Al_2O_3) released by weathering. Because weathering is very rapid amorphous clays of high cation-exchange capacity are formed. The soil formed has an upper horizon rich in unweathered minerals (sand), and an illuvial one rich in amorphous clays ("spodic" horizon). Such soils are called podsols. Although vegetation and other conditions may favour the accumulation of raw humus, its acidity is neutralized when soil contains lime or when weathering releases bases in sufficient quantity. Podsolic weathering is therefore observed in sandy materials rich in quartz and other minerals of low weatherability. The organic matter that produces eluviation of clay or sesquioxides decays and cannot accumulate in the illuvial horizon; but when this horizon is waterlogged or when its temperature is very low, an accumulation of organic matter takes place and a humus illuvial horizon is formed. Such soils are called humus podsols.

Rubification. When soil is thoroughly dried from time to time, precipitates of iron and organic matter cannot accumulate and the organic matter disappears by decay, causing irreversibly dehydrated iron sesquioxides to form. This process is known as rubification, and the resulting soils, called cinnamonic, are rich in fine crystallites of dehydrated iron sesquioxides.

Formation of cemented pans

Ferrugination. Iron sesquioxides adhere firmly to sand grains and gravel, give them a red colour, and may cement them to form an iron pan. This process is most common in soils that have been formed from materials that release much iron upon weathering and leave much sand, whereas humic horizons are seldom ferruginized, probably because organic acids and reductive processes remove the iron coating from sand grains. Fulvic acids favour iron eluviation and the formation of ferruginized horizons at some depth; thus, fragipans and other iron-cemented pans are common in podsols and brunisolic soils. The ferruginous horizons of tropical soils are formed similarly, fulvic acids contributing to their formation, but reductive processes can also be responsible for iron eluviation. Periodic soil drying may consolidate iron coatings, especially in climates in which a humid and a dry season alternate. It seems that iron coatings protect sand and gravel grains from weathering, and they are the cause of many "stone lines" parallel to soil surface.

Segregation of iron. In soil that is rich in iron and poor in 2:1 clays that retain it, iron tends to segregate, forming irregular concretions and nodules. After repeated moistenings and dryings, the nodules become as hard as stone and may form a pan cemented with iron and gravel (laterite). Waterlogging seems to further iron segregation, and alternative moistenings and dryings harden the nodules or pan. This process resembles ferrugination, the difference being in degree of segregation.

Gleization. Under waterlogging conditions, iron becomes ferrous and has a valence of 2+. (Valence is an expression of the combining power of an element, which is determined by the number of electrons in its outer or valence shell of electrons; valence is represented by a number that corresponds to the number of electrons an atom of the element can accept [if the number is positive] or donate [if the number is negative]). Ferrous soil has gray-blue colours, is called gley, and the process is called gleization. When waterlogging is less severe and transitory, ferrous iron is oxidized (*i.e.,* loses an electron, with a resulting change in valence to 3+, which is that of ferric iron, F^{3+}), and ruggy mottles (spots) are produced in the soil. Because ferrous iron is more mobile than ferric iron, gleization favours iron eluviation, resulting in a leached upper horizon; iron accumulates at a lower depth or is leached away. Or the iron may ascend by capillarity from the water table to the lower part of the rhizosphere.

Development of soil characteristics. *Soil profile and horizons.* Humification, leaching, clay eluviation, and other soil-forming processes all create differences between soil horizons. Soil profiles vary considerably in horizon types and their thicknesses.

Soil properties. Both water-holding capacity and cation exchange depend on clay content, clay mineralogy, humus content, kind of humus, and nature of absorbed ions. Mineral constituents larger than clay also have some water-holding capacity, and in some cases silt exhibits considerable ion exchange capacity. This may be attributed to its formation by aggregates of amorphous clays or by amorphous clay that adheres to silt particles.

Nature of soil texture and structure

Soil texture (*i.e.,* the relative proportion of mineral constituents classified according to their size) determines to a considerable extent soil porosity and, consequently, permeability to air and water, which are essential for root life and many processes that take place in soil. A high content of coarse constituents usually increases porosity. But clay and humus bind single soil grains together in increasingly larger aggregates.

Soil has a "structure" on which its porosity-permeability depends greatly. Soil structure is built up by alternate moistening and drying, and plant roots contribute greatly by opening pores between soil aggregates; it is undone by waterlogging. The stability of aggregates increases with humus content, especially humus that originates from grass vegetation (forest humus is less effective).

Calcium and hydrogen soils have structural stability, whereas sodium soils lose stability easily. Soils rich in amorphous clays are very porous and permeable, and their apparent density is exceptionally low. Soils rich in 1:1 clays are also permeable. High content of 2:1 clays, however, is usually associated with low permeability because the soil swells when moistened and the pores close. The clay type is very important; montmorillonite is the worst in this respect. Water movement in 2:1 clayey soils is chiefly through cracks produced when soil dries, and water movement in pores between small aggregates is very slow. Soils rich in coarse constituents are usually permeable. Soils with a high fine-sand content, however, have low permeability, poor aggregation, and small pores between single grains of fine sand; moreover, they are not extensible, and they resist root penetration.

Texture variations in horizons

Because soil horizons vary in texture, humus content, and absorbed ions, soil properties vary from horizon to horizon. This fact should be taken into consideration in evaluating the soil as a whole. Distinction must be made between intrinsic qualities—such as texture, clay mineralogy, the nature of absorbed cations, and their variation along the profile—and the secondary qualities that are consequences of the first and are more or less transitory—such as structure and permeability. Humus content and soluble salts are intermediary; they can be modified by management, added, or leached away.

From an agricultural point of view, the most important soil qualities are cation-exchange and water-holding capacities, the nature of absorbed cations, richness in assimilable plant nutrients and certain other substances (*e.g.,* lime, free aluminum), permeability, structure, humus content, and waterlogging. For engineering uses, texture, clay mineralogy, humus content, swelling capacity, capacity to corrode metals, structure (which can be modified), permeability, and waterlogging (chiefly extrinsic), are important.

Horizon nomenclature. Usually the upper horizon, which is generally richer in humus and may be eluvial, is called A; it may be "humic" (Ah), eluvial (Ae), or "bleached" (A_2). The horizon in which clay has been illuviated is called Bt; that of amorphous clays produced by podsolization ("spodic" horizon) Bir (from iron, which was considered the most important illuviated substance); and that of humus illuviation Bh. Weathered material that has not been sufficiently enriched in humus to be humic and has not had important illuviation of clay or humus is called C. Underlying consolidated rock is called an R horizon.

A horizon of lime accumulation is usually called ca, but the term can be extended to all horizons that give effervescence with an acid. An accumulation of gypsum is indicated as cs; a horizon unusually rich in easily soluble salts by sa; cn designates an accumulation of ferruginous concretions and nodules; mf a ferruginous hardpan; mc a calcic hardpan; x a fragipan (fragil hardpan cemented with iron); G denotes strong gleying; g moderate gleying.

According to clay mineralogy a horizon may be allophanic, illitic, kaolinitic, or superkaolinitic, the diagnosis being chiefly based on the relation between cation-exchange capability (CEC) and clay content. According to base saturation, a horizon may be acid, neutral, natric, magnesic, or calcic. Fifteen percent sodium saturation is sufficient to make a horizon "natric." The terms acid and neutral are replaced by dystrophic and eutrophic (poor or rich in nutrients) in the case of kaolinitic and organic soils in which the relation of absorbed cations to clay content is a better diagnostic indicator than base saturation. Many of these terms are poorly defined in the literature, and definitions vary from author to author.

Mineral composition and rock weathering

Rates of soil formation. Rates of soil formation vary enormously according to the process involved, and for the same process according to conditions. Weathering varies according to the weatherability of the material, and minerals may be classified in this respect. Weathering of a consolidated rock is usually slow at the beginning, accelerates as the rock breaks up and more surface area is exposed to attack, and then becomes increasingly slower as weatherable minerals disappear. It is accelerated by plant roots and by the accumulation of raw humus, and also by a rapid removal of the bases by leaching.

Weathering is more rapid than is usually thought. In experimental leaching of coarse gravel of basalt with pure water at 20° C (68° F), 0.45 percent of the silica was eliminated in 11 months. Leaching with water containing acetic acid (pH 2.5, which is a common acidity value in the vicinity of roots and decaying organic matter) accelerated the process by a factor of 21. Volcanic ashes weather sufficiently to support vigorous vegetation in a few decades.

Tombstones and other man-made structures weather more slowly because they are not in contact with plant roots or decaying organic matter, and, moreover, the surface of attack is very small.

Humification is a very rapid process. Experiments and agricultural practice all over the world have shown that soil organic matter can be doubled or reduced to half in

5–50 years. Podsolization is also rapid, and it has been reported that soils planted with conifers have been podsolized in a century. Salinization and desalination are also rapid because of the higher solubility of salts less soluble than gypsum. Decalcification and acidification with water containing carbon dioxide are intrinsically slower but may be accelerated when produced by water containing organic acids, which is usually the case.

There is less information concerning clay eluviation, but experiments show that this is a relatively rapid process because water often moves through soil cracks, carrying much clay per unit of water. The formation of argillic (clay illuvial) horizons has been estimated to require between 550 and 5,250 years. In many cases the age of soil that has been formed in previously glaciated areas, newly formed terraces, or from recent volcanic material, is known; but it is not always possible to ascertain whether clay eluviation required all this time. In any case, existing evidence and the fact that soils correspond well to present climatic conditions indicate that soil formation processes are relatively rapid.

BASIC FACTORS INVOLVED IN SOIL FORMATION

Climate. The amount and kind of clay that is formed, soil depth, base saturation, and the formation and depth of saline, gypsic, or calcic horizons all depend on leaching intensity. Consequently, the significant factor is leaching rainfall (see Figure 3). The soils of temperate climates are rich in 2:1 clays, whereas those of tropical countries are rich in 1:1 clays. But in both cases when the soil is young, or has been formed from volcanic ashes, it contains considerable amorphous clays, which increase its cation-exchange capacity.

Effects of Ln on weathering depth

Temperature is another influence in soil formation. Because the solubility of silica increases with temperature, high temperatures favour the formation of 1:1 clays, which is another reason for the abundance of such clays in tropical soils. Water penetration and root penetration depend on leaching rainfall, so that the depth of weathering and of soil increase with Ln. Soils of tropical countries are usually very deep; those of cold or dry climates, or of both, shallower. Temperature is also important. At high latitudes and altitudes the lower layers of soil are very cold, even in summer; consequently, weathering and soil depth are limited, which is important in the case of autochthonous soils (*i.e.,* formed in the original location) developed from consolidated rocks. Permafrost limits both soil depth and drainage. In very dry climates no water is lost by drainage. In dry climates substances formed by weathering accumulate in the profile, stratified according to their solubility, and as leaching increases the lower horizons disappear, and the profile becomes deeper. Finally, there are insufficient bases in the soil to neutralize the organic acids produced by decay of roots and organic matter. Solution in the soil then tends toward acidity, the soil is leached with acid water, and hydrogen ions replace other ions. The result of this cycle is an increasingly more acid soil. Acidification, however, also depends greatly on vegetation type, temperature, and waterlogging. In addition to the above direct influences, climate greatly affects vegetation, which is one of the most important factors in soil formation.

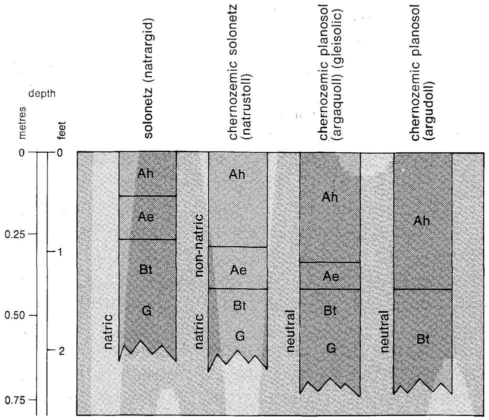

Figure 4: *Influence of drainage on soil formation.* Ah, rich in humus surface horizon (layer); Ae, eluvial surface horizon; Bt, textural B (clay illuviation); G, gley.

Drainage and topography. Leaching is impossible without drainage; thus, impeded drainage has to some extent the same effect as drought. Impeded drainage may result in the formation of soils with 2:1 clays, well saturated with bases, saline, gypsic, or calcareous horizons. It also causes gleization and may result in the formation of a water table, which has various influences, especially salinization and formation of various pans—petrocalcic horizons, duripan, ironstone, fragipan, laterite, etc. (see Figure 4). Topography greatly influences erosion, drainage, flooding, and subirrigation, which have a profound influence on soil formation, as has been discussed. Soils on slopes are usually shallow and stony (lithosols), and those in the valleys are alluvial.

Variation in humus

Vegetation and living organisms. Vegetation largely determines the kind of humus that is formed. Some trees, especially conifers, usually produce raw humus that may cause podsolization. Other trees produce weakly acid humus capable only of producing iron mobilization and clay illuviation. Such soils are brown (brunisolic) and more or less leached. Grasses produce mild humus rich in acids that stabilize clay. The distribution of humus along the profile also depends on the type of vegetation. Grasses have numerous roots that decay rapidly and enrich soil in humus to considerable depth. Tree roots contribute little to soil humus; thus, the humic horizon of forest soils is usually shallow (see Figure 5).

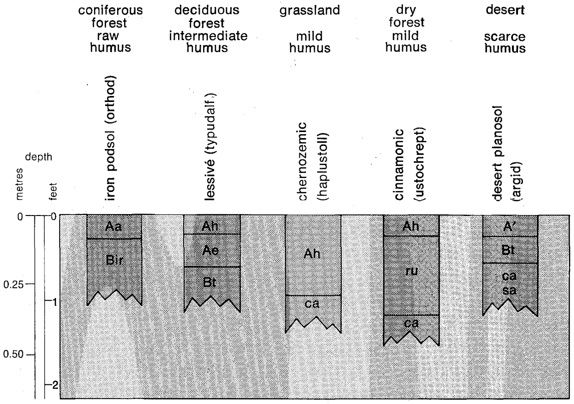

Figure 5: *Influence of vegetation and humus on soil formation.* Aa, albic (ashy) surface horizon (layer); Bir, iron podsolic B (spodic horizon); Ah, humus rich surface horizon; Ae, eluvial surface horizon; Bt, textural B (clay illuvial); ca, lime accumulation; ru, rubified, A′, poor in humus surface horizon; sa, salts accumulation.

Vegetation protects soil from the Sun's rays and retards organic matter decay; it absorbs calcium, potassium, and phosphorus from the lower soil layers and counteracts their leaching; and it protects soil against erosion. Erosion, even hydraulic, is severe in deserts because there is no vegetation to protect the soil. Living creatures within the soil such as earthworms and termites mix the various soil horizons and counteract their differentiation; they also mix soil plant residues on the soil surface and contribute to organic matter decay and humus formation. A certain mixing also occurs when old trees are uprooted by wind.

Parent material. Soil is parent material that has been altered by various processes, and its ultimate nature depends upon its original composition. In soils formed from unconsolidated sedimentary rocks, much of the clay is inherited from parent material. Materials rich in lime are difficult to decalcify, acidify, or podsolize. Materials rich in iron usually give red soils.

Time. Although in geological terms soil formation is rapid, in human terms it requires many decades or centuries. Soil age has a great influence on soil properties. The age of a soil usually is measured from the time the rock was first exposed to the surface or from the time the alluvial material was deposited. The time factor is not always clear because erosion and deposition are continual processes. Moreover, clay is often much older than the deposition, having been formed in one place and transported to another.

Young soils commonly have an undifferentiated profile. Saline, gypsic, and calcic horizons are formed more rapidly than those of clay accumulation, whereas a humic horizon may be formed in a few decades. Young soils are richer in amorphous clays and, under conditions that favour acidification, are less acid than old ones; pH increases with depth in young soils, and it decreases with depth in old ones.

The polygenesis of soils

Interaction of factors and processes. Any effect that each factor has on soil formation depends on the other factors; for example, the effect of climate depends on drainage, parent material, time, etc., and the other factors are similarly interdependent. Different soils are formed under the same climatic conditions according to drainage, parent material, time, vegetation, and other relevant influences; in like manner, different soils may be formed from the same parent material. Because soil is the result of various processes and each factor acts on several of them, it is better to relate soils to processes, and through processes to factors. The environment under which a soil is formed may vary during its formation: drainage may improve or deteriorate; exposure to such factors as erosion, flooding, or subirrigation may be ended or initiated; or there could be a change in vegetation. Thus soil does not always reflect the conditions under which it is encountered.

Climatic changes are very slow, and to affect soil formation appreciably they must be radical. A change in drainage will impede leaching, just as will a very drastic reduction of leaching rainfall; waterlogging may cause the formation of raw humus that produces podsolization in a warm climate, that otherwise favours organic matter decay and excludes podsolization, when drainage is normal. Little leaching rainfall is needed to leach a coarse soil; a great deal of rainfall is needed to leach a clayey soil. Acidification is faster and more extensive when parent material is poor in bases. For all these reasons, caution should be used when attributing the properties of a soil to climatic changes or, still more, when explaining climatic changes on the basis of pedologic evidence.

There are cases, however, in which such evidence is convincing. In Australia and Africa, for example, soils that are rich in 1:1 clays are found in the desert; they have most certainly been formed under a considerably more rainy climate. Because allitic weathering (that producing chiefly 1:1 clays) is deep, subsequent erosion and deposition merely transport such soils from one place to another. In some cases 1:1 clays have been transported great distances from where they were formed: for example, in the delta of the Paraná, near Buenos Aires, there are soils with clays that came from the centre of Brazil, and many soils of northern India have 2:1 clays that have been formed in the Himalayas.

The frequent variation in conditions during soil formation, resulting in polygenetic soils, usually is more closely related to topography than to climate; also, the clay found in a soil may have been formed in past time or at a distant site.

SOIL GROUP CLASSIFICATION AND NOMENCLATURE

Observation of natural categories. The question of soil classification is a controversial one, but there is no doubt that classification should be based on categories that exist in nature, rather than on arbitrary creations of a classification system.

Rationale of group selection

In a natural classification, groups are recognized and subsequently arranged in a system; the system may change, but the groups will pass almost unchanged from one system to another. Pedologists have approached soil classification in such a manner. Observing that some soils have an ashy surface horizon, resting on another darker in colour and richer in fine earth, pedologists called them podsols (ashy soils). Other soils with a deep, dark horizon rich in organic matter and well saturated with calcium were termed chernozems (black soils). Soils of rather undifferentiated profile and of red colour were named krasnozems (red soils). In this way, groups of soils have been recognized and arranged in classification systems; although opinions differ as to how these groups should be arranged within a classification system, essentially the same groups exist for all pedologists.

Fundamental classes of soil

The soil continuum. Because soils form a continuum, it has been difficult to follow the example of other scientists in categorizing on the basis of clear distinctions between groups. The same processes are involved in the formation of various soils, with the result that a soil may have the essential features of ando soils (amorphous clays) and those of chernozemic soils (deep humic horizon, dark and well saturated with bases) and thus be both ando and chernozemic. Soils may reflect many such heterogeneous conditions—for example, chernozemic (mollic) and gleisolic, gleisolic and podsol, and the like. Accordingly, soil classification must be manifold, recognizing that the same soil may belong to various groups. When this necessity is understood, the problem of soil classification is simplified, and the major categories shown in Table 2 may be recognized (see Figure 6).

Table 2: Major Soil Types

Ando	rich in amorphous clays
Brunisolic	2:1 clays; braunified or acid horizons
Chernozemic	2:1 clays; deep neutral dark humic horizons
Cinnamonic	2:1 clays; reddish colour; rich in dehydrated iron oxides
Dark clays	2:1 clays; rich in expanding clays; well saturated with bases
Gleisolic	gray-blue colours or mottles due to waterlogging
Kaolinitic	tropical; rich in 1:1 clays; may have undifferentiated profile, or horizons rich in iron concretions or laterite
Lessivé	clay illuviation produced by organic matter
Organic	extremely rich in organic matter; may have peaty and/or organic horizon
Podsols	eluviation of alumina and iron, usually producing ashy sandy surface horizon and illuvial horizon rich in amorphous clays
Planosols	clay eluviation produced by sodium; illuvial horizon not natric
Rankers	2:1 clays; humic horizon resting on rock or permafrost
Raw	2:1 clays; undifferentiated soil profile
Rendzinas	high lime content
Solonchaks	rich in salts such as chlorides, sulfate, etc.; related to gypsisols, rich in gypsum
Solonetz	clay illuviation produced by sodium; natric illuvial horizon

Supplementary descriptions. Various other terms, denoting special features, also may be precisely and simply defined and included in soil nomenclature. For example: clay, loam, sand (referring to soil texture); lithosol (stony, gravelly); regosol (sandy); aeolian (formed by wind, dune); hammada (stony desert); and rock outcrop. Acid (H s.), natric (Na s.), magnesic (Mg s.), Ca soil, eutrophic, and dystrophic all refer to absorbed cations. Takyr and lunettes are special kinds of saline soils. Roof clays and sulfate saline clays (cat clays) are special kinds of clays. Gray-brown podsolic, noncalcic brown, graywooded, red-yellow podsolic, and lateritic podsolic are different kinds of lessivé soils; the first three have 2:1 clays, the later two are kaolinitic. Sod and humic are used for soils unusually rich in humus for their groups. Prairie, chestnut (kastanozems), and reddish chernozemic are different kinds of chernozemic soils. Podsolized, leached, or degraded chernozems are types of brunisolic or leached soils or both. Claypan planosols are planosolic clays. Serozems are rendzinas lacking humic horizon. Rubrozems are kaolisols with a deep humic horizon. Red desert are mini-planosols (thin horizons). Mini-planosols, mini-solonetz, and mini-podsols are planosols, solonetz, or podsols with thin horizons. Arctic browns are brunisolic permafrost rankers. Terra rossa is a cinnamonic soil from hard limestone. Terra roxa is an ando-kaolisol intergrade soil. Terre de barre is a eutrophic latosolic kaolisol. Low humic gley is an

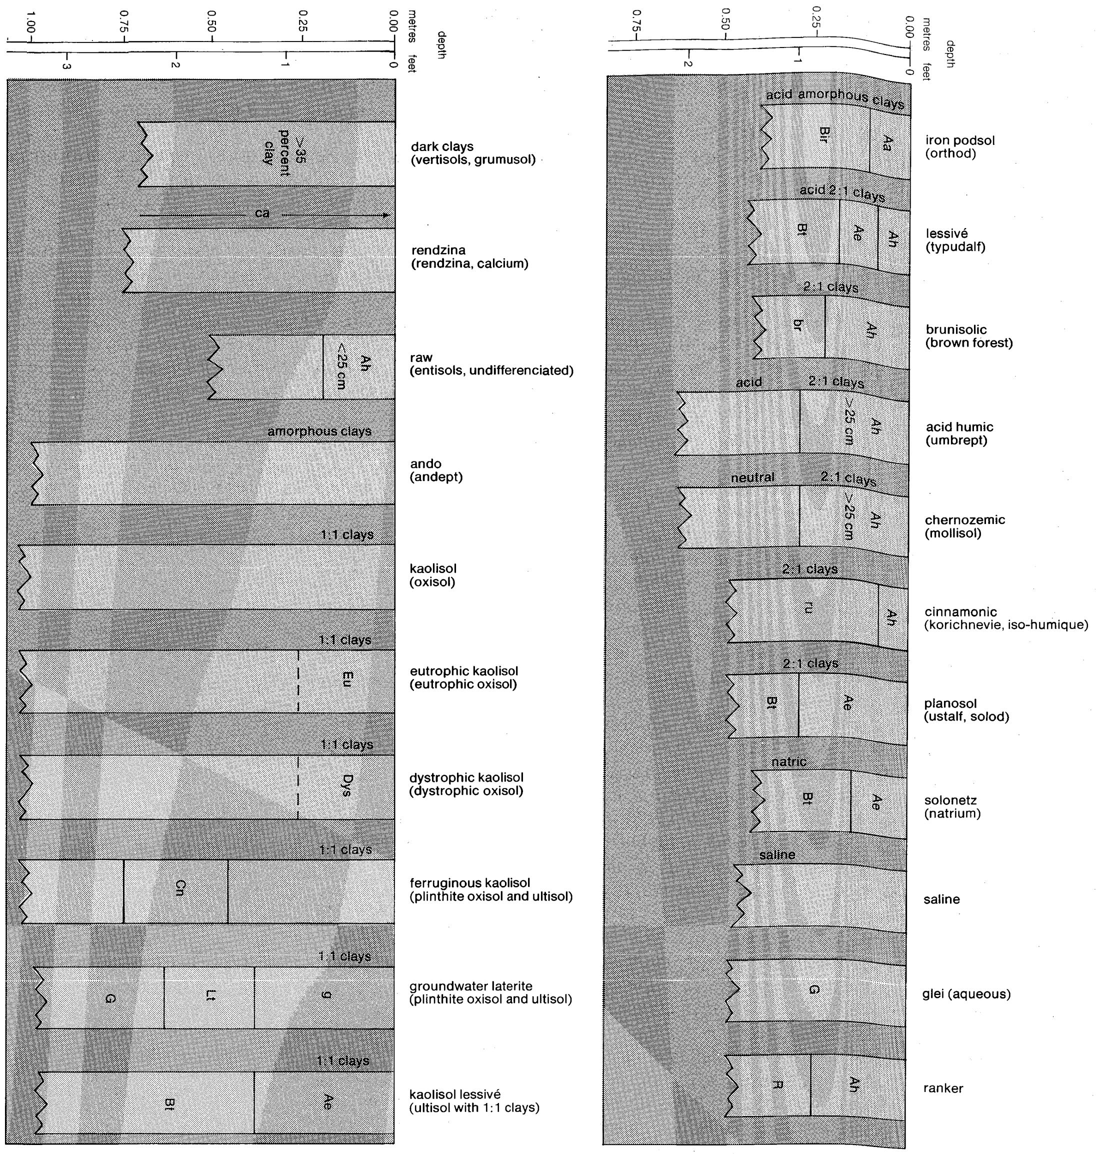

Figure 6: *Fundamental characteristics of some soil groups.*
Specifications referring to reaction (acid, neutral) and to type of clay refer to the whole profile. Aa, albic (ashy) surface; Bir, iron podsolic B (spodic); Ah, humus rich surface h.; Ae, eluvial surface h.; Bt, textural (clay illuvial) B; br, braunified; ru, rubified; G, gley; R, rockbed; Eu, eutrophic (rather well provided with bases) soil; Cn, ferruginous concretions and nodules; Lt, laterite; Dys, dystrophic (poor in bases) upper soil.

acid gleisolic soil. Humic gley is a gleisolic chermozemic soil. Desert crust is an accumulation of products of weathering in virtual absence of leaching. Alluvial, desert, forest, forest-steppe, grassland, groundwater, lowland, mangrove, meadow, mountain, paddy, paramo, prairie, tropical, and tundra are environmental, nontaxonomic terms often used in soil nomenclature.

Precise definition of soil properties

Seventh Approximation System. A system based on measurable soil properties rather than on theories of soil formation, the 7th American Approximation System, was introduced in 1960 and has expanded continuously by supplements. It is the first approach to precise definition of soil groups and pedologic terms, and, moreover, it has implicitly adopted manifold classification: adjectives (mollic, spodic, andic, etc.) are used to show relationships with other groups; names are formed by aggregation of formative elements that denote special characteristics, and consequently groups. Many of the groups named in the preceding section correspond in 7th Approximation to several taxa the nomenclature of which includes the corresponding formative element. For example, andepts and andic correspond to ando; histosols to organic; spodosols to podsols; vertisols to dark clays. The formative element aqu denotes gleisolic; natrarg, solonetz; rend, rendzina; sal, saline.

Indication of soil properties. Some formative elements show soil properties: acr denotes extreme weathering; allic, free aluminum; anthr, man-made soil; arenic, sandy; calci, calcic; chrom, high chroma (red colours); dys or dystr, dystrophic; eu or eutr, eutrophic; gibbs, presence of gibbsite; hydr, saturated with water; lithic, stony; pale, old (soil); pell, dusky colour; psam, sandy; rhod, red; sal, saline; sider, rich in free iron; sombri, dark colour; thapto, a buried soil is included in the profile; vermi, wormholes, worm casts, or filled animal burrows; vitr, ando rich in unweathered volcanic glass.

Identification of horizons. Other formative elements denote presence of certain horizons: abruptic, abrupt textural change; alb, albic horizon; cumulic, thickened humic horizon; dur, duripan; ferr, B horizon rich in free iron, or iron concretions or nodules; frag, fragipan; glossic or gloss, horizon A_2 is tongued; hapl, typical profile; hum, unusually deep humic horizon, or humus podsolic B horizon; ochr, light-coloured A horizon; pachic, thick A; petrocalcic, petrocalcic horizon; plac, thin pan; plinth, laterite; ruptic, broken (discontinuous) horizon; stratic, stratified horizon; superic, laterite in the surface; umbr, deep nonchernozemic humic horizon. Other formative elements of the nomenclature indicate the manner in which the material has been deposited: fluv; alluvial; limnic, lacustrine.

Climatic elements of the system. Although soil temperature and moisture are not intrinsic soil properties, they are used as diagnostic features in the 7th Approximation; *i.e.,* soils are classified according to the climate in which they are encountered. Such formative elements include: bor, boreal; cryo, very cold; pergelic, permafrost; torri, torrid (usually dry); trop, small annual range of temperature; ud, usually humid; ust, dry but not long dry seasons; xer, long dry seasons.

The 7th Approximation System demonstrates that soil description, classification, and nomenclature may be achieved with few symbols that, in combination, can represent the enormous variety of soils existing in nature.

GEOGRAPHIC DISTRIBUTION OF SOILS

Because soil formation depends so much on climate, topography, vegetation, and parent material, soils vary in association with other geographic features, and soil regions may be distinguished in the same manner as climatic and vegetation regions. Such soil regions lend themselves to being further subdivided or combined into higher groups. Each region contains a variety of soils, many of which are also encountered in other regions, but the distribution of soils follows a definite pattern.

The function of soil maps

The concept of soil region is important from both a theoretical and a practical point of view. Theoretically, soil distribution is often the key to answering many questions about soils. From a practical viewpoint, it is difficult and costly to prepare detailed maps of soil locations, which can vary in short distances—sometimes within a few metres.

Polar regions. *Tundra.* Vegetation is scarce in tundra regions (see Figure 7) and consists of herbs and grasses that do not produce very acid humus. Rainfall in the tundra is low and leaching rainfall (Ln) is still lower: 40 millimetres (one inch equals 25 millimetres) in Baker Lake, Northwest Territories; 20 in Eureka, Alaska; 60 in Resolute, Northwest Territories, Canada; 30 in Barrow, Alaska; 40 in Anadyr, 70 in Bulun, 50 in Nizhnekolymsk, and 40 in Russkoye Ustye, Siberia. The bases that are leached from the surface accumulate in the lower part of the profile and circulate in it through plants and by capillarity (the soil surface is often humid and soils are shallow); moreover, drainage is often impeded by permafrost. Acidity is not sufficient to produce podsolization, but it reacts with iron to produce complexes that result in brunisolic soils. The soils formed, arctic brown, are relatively shallow; the pH increase with depth is more rapid than usual; and there is a tendency toward the formation of a humus-rich horizon on the surface of permafrost. In the drier parts of tundra, the lower horizons are often calcareous.

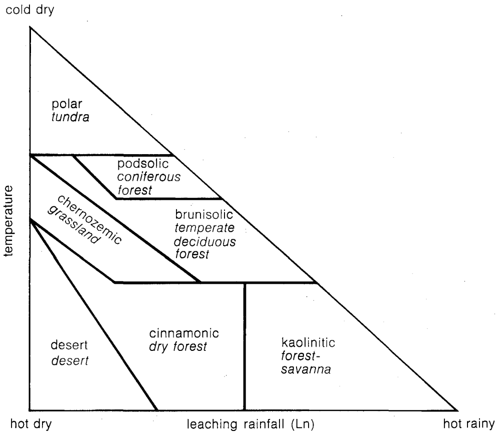

Figure 7: Distribution of soil regions with associated vegetation according to temperature and leaching rainfall (see text).

Waterlogging is frequent in tundra because of the presence of permafrost, resulting in the accumulation of organic matter, a prevalence of reducing conditions and peat formation. Gleisolic and organic (half bog) soils are frequent. The general pattern of distribution is arctic brown in well-drained sites to gleisolic and half-bog mini-podzols in depressions. Alternate freezing and thawing results in a patterned surface (polygonal).

Subglacial desert. In the subglacial desert vegetation is almost absent, weathering is very slow, and the soils formed are very shallow (lithosols, etc.). The limits of tundra and subglacial desert soil regions correspond rather well with the homonymous climatic regions.

Podsolic regions. With a short summer and conditions not too frosty for forest, so that an evergreen coniferous forest prevails, a raw, highly acid humus is produced and podsolization takes place. The soils formed in well-drained sites are iron podsols.

Drained and waterlogged conditions

In waterlogged sites organic matter accumulates, reducing conditions prevail, and gleisolic soils, sometimes organic, are formed. When there is no drainage, bases cannot be eliminated from the profile and soil is less acid, a condition common in the drier podsolic regions. When there is a slow drainage, however, soil is acidified and becomes humus podsol, somewhat gleisolic and peaty. Such soils usually have heath or sphagnum vegetation.

Humus podsols are more common in Atlantic regions because of their higher rainfall, than in continental regions. Hardpans are more common in Atlantic regions. Some regions of Central Siberia have permafrost that interferes with drainage; moreover leaching rainfall is low, with the result that iron leaching is incomplete and the eluvial horizon is yellow rather than ashy. The yellow podsols may be considered as intergrades to arctic brown.

Brunisolic regions. With a longer summer, deciduous forest prevails, which produces milder, less acid humus that forms brunisolic soil, more or less leached. Where leaching rainfall is low and parent materials are calcareous or basalt, soils are neutral (braun erde); in the opposite rainy condition, soil is acid (brun acide).

The most important brunisolic regions are in western Europe, the eastern United States, the state of Washington, and the adjacent Canadian coast. In western Europe, there are many small regions with calcareous materials, basalt, or loess, and low leaching rainfall. Braun erde abound; some of them are chernozemic or have a calcareous horizon at some depth or both. In the transition zone to the chernozemic region of North America, chernozemic braun erde (brown earth) and chernozemic lessivé (prairie) are common, and in the Appalachian Mountains, brun acide.

Chernozemic regions. A grassland vegetation with chernozemic soils occurs when spring is not dry, winter is relatively cold, and leaching rainfall is low. Calcareous, gypsic, or salic horizons are frequent. Solonchaks, solonetz, and planosols—more or less gleisolic and chernozemic—are common in poorly drained depressions.

The three chernozemic regions

The most important chernozemic regions of the world are the Danube Basin and the southern Soviet Union in Eurasia, the Great Plains of the United States and the prairies of Canada, and the Pampas region of Argentina. But there are some differences among them. The parent materials of Russian chernozems are more calcareous and the leaching rainfall is lower (for the same humidity index). Consequently, soils are richer in lime; effervescence with hydrogen chloride begins immediately below the humic horizon or within it; clay eluviation and planosolic chernozems are not common; and the humic horizon is, in general, deeper and richer in organic matter. In the North American Great Plains, parent materials are less calcareous, lime is encountered at greater depth or not at all, clay eluviation is more frequent, planosolic chernozems more common, and the humic horizon is in general shallower and poorer in organic matter. In Argentina, parent materials are chiefly volcanic; cation-exchange capacity is unusually high (andic chernozemic); much sodium is released by weathering; clay eluviation is frequent; and planosolic chernozems, solonetz, and solonchaks are common.

The general pattern of soil distribution in chernozemic regions is chernozemic soils in well-drained areas, with planosols, solonetz, and solonchaks, more or less chernozemic and gleisolic, in areas of deficient drainage.

Cinnamonic regions. In climates with dry seasons where soil is dried thoroughly to considerable depth, fine crystallites or irreversibly dehydrated iron sesquioxides are formed, giving reddish colours and cinnamonic soils. In cinnamonic soils organic matter decays rapidly and does not accumulate on soil surface. Humus originates chiefly in roots and it is well distributed along the profile. Many cinnamonic regions have a Mediterranean climate. Those with a monsoon climate are usually transitional to brunisolic, chernozemic, desertic, or kaolinitic regions. Except for Australia, a Mediterranean climate is associated with mountainous topography and high frequency of limestones and volcanic materials; moreover, leaching rainfall varies considerably from zero to very high figures. Brown cinnamonic (bruns mediterraneans) and red cinnamonic (rouges mediterraneans) are common in areas with high leaching rainfall or ferruginous materials or both. They are sometimes acid and rich in 1:1 clays, being intergrades to kaolisols (krasnozems).

Desert regions. Vegetation is very scarce in the desert, and soil erosion is very severe from wind and occasional rains; weathering is slow and shallow, and leaching is almost absent. Soils are very poor in organic matter and do not have a humic horizon.

Occurrence of mini-horizons

Because sodium elimination is difficult, autochthonous soils are usually planosols and solonetz with very thin horizons (mini-planosols and mini-solonetz); a calcareous horizon usually underlies the B horizon. Soil is often covered by coarse material (desert pavement), which partly results from wind erosion and protects the soil. In such absolute deserts as the Chilean desert, however, products of weathering remain in the place of their formation and a loosely cemented desert crust is formed. Materials eroded from higher land accumulate in depressions, forming dunes and alluvial soils. Where waters accumulate, planosolic, solonetzic, and saline soils abound, and "salares" also are frequent. There are many good alluvial soils, however (rendzinas, chernozemic, etc.), and some of them are gleisolic.

The general pattern of soil distribution may be summarized as follows: high plateaus and plains areas exhibit autochthonous soils, mini-planosols, mini-solonetz, and solonchaks with salares (salt accumulations); slopes exhibit lithosols; and depressions exhibit dunes and alluvial soils, with many solonetz, solonchaks, serozems, and gleisolic soils with salares.

A distinction may be made between American (North and South), Asian, and African deserts. American deserts received much volcanic ash from active volcanoes, and mini-solonetz, mini-planosols, and duripans are plentiful. In Asia, calcareous materials abound, and raw (undifferentiated) soils that produce effervescence with hydrogen chloride are common. In Africa and Australia, palaeosols formed from kaolinitic materials are frequent.

Kaolinitic regions. The high leaching rainfall of tropical countries, even though there may be a long dry season, results in formation of 1:1 clays. Soils are usually acid in the lower horizons, whereas the upper horizon may be eutrophic. The difference between eutrophic and dystrophic soils, which is important from an agricultural point of view, seems well associated with the presence or absence of a dry season. A dry season, even a short one, activates decay of organic matter, favours fires, and interferes with the production of acid humus, which is the principal factor of acidification, several times more effective than water mixed with carbon dioxide.

Water-logging and iron concretions

In soils rich in 1:1 clays, waterlogging produces segregation of iron in the form of concretions or nodules. For that reason laterite is common in waterlogged areas, and, because it is impermeable, aggravates waterlogging and may reach the surface. In granite, gneiss, and similar materials, very common in Africa, the iron released by weathering may adhere to sand or gravel surfaces and cover them with a red coating. When soil is thoroughly dried periodically, such coatings become irreversibly dehydrated, protect the particle or gravel from further weathering, and a ferruginous horizon is formed. Such protection is insufficient in the upper horizon, where organic acids abound, and also in the lower horizons, which are waterlogged continuously; as a result, the ferruginous horizon is encountered at some depth. Some of the iron may come from the waterlogged horizons.

It is of interest that concretions of gravel and laterite contain unweathered material imprisoned in iron sesquioxides. Such material is virtually absent in the overlying and underlying horizons, indicating that both ferruginous horizons and laterite are formed at an early stage of weathering. This also indicates that stone lines of geologic origin may contribute to the formation of ferruginous horizons. It is, however, difficult to believe that there was a stone line parallel to soil surface each time a ferruginous horizon was formed. Ferruginous horizons and laterite are seldom found in soils formed from easily weatherable materials such as basalt, fine sand, and in continuously humid climates.

Young soils from volcanic ash are naturally ando in type. With time amorphous clays crystallize, cation-exchange capacity decreases, and soil becomes first terra roxa (intergrade ando-kaolinitic) and then kaolinitic. Terra roxa, however, is often made up of young soils formed from basalt and abounds in basaltic slopes, where erosion does not permit soil to become old (Misiones, Argentina; coffee region, Brazil).

Mountainous regions. Erosion is the main characteristic of mountainous regions. The soils are usually young, consisting of lithosols and rankers in slopes and alluvial soils in the valleys and surrounding the mountain plains.

Three kinds of mountainous regions may be distinguished: humid-temperate, dry, and humid-tropical. In humid-temperate climates organic matter accumulates and there is an abundance of brunisolic soils (braun erde, brun acide). There are also lessivé and podsols, but many podsols do not have an ashy horizon. The spodic horizon, rich in amorphous clays, is overlain by a gray-brown horizon (brown podsols); and limestones often form lithosolic rendzinas. Acid humus and peaty soils, more or less gleisolic, are common in depressions.

In dry but not desertic mountains, grassland vegetation, sometimes scattered with woody plants, is common. Lithosols and other raw soils and rendzinas, basically cinnamonic and chernozemic, are widespread, with saline, solonetzic, planosolic, and organic, relatively gleisolic soils in depressions.

In humid-tropical mountains the growing season is longer and the growth index much higher; soils are deeper and richer in organic matter (some giant podsols have been found); otherwise they resemble those of humid-temperate climate of the same summer type. At lower altitudes kaolinitic weathering begins and forms kaolinitic soils; erosion, however, results in soils remaining younger than in the lowlands, eutrophic soils and terra roxa are more frequent, and soils are also richer in organic matter. These characteristics partly account for the higher density of population in mountainous regions.

Intermediate and modified regions. Passage from one type of soil region to another is gradual, and intermediate regions can be recognized. Moreover, preponderance of allochthonous alluvial soils, waterlogging, or presence of a particular material justify separation of some regions from the main type.

Nature of transition belts

In the transition belt from podsolic to brunisolic regions, the prevailing soils are podsols and lessivé (gray-brown podsolic), and the distribution is chiefly determined by parent material. In the transition between podsolic and chernozemic regions, Soviet authors recognize a forest-steppe zone with gray-wooded soils (lessivé with somewhat ashy horizon, better saturated with bases, and sometimes calcareous at some depth). Near this forest-steppe region are many sod-podsols (podsols with rather well developed humic horizon), attributed to cropping. An analogous transitional region in Canada occurs between the podsolic and chernozemic region.

The prairie soils in the United States are characteristic of the transition between chernozemic and brunisolic regions and may be considered as chernozemic lessivé or chernozemic braun erde. They are also found in the Danube Basin and other parts of Europe, and combine characteristics of both the chernozemic and brunisolic, or lessivé groups. The region of red-yellow podsolic soils of the southeastern United States may be considered as a transitional kaolinitic-brunisolic region with soils usually lessivé and very acid, usually low in cation-exchange capacity in comparison to their clay content. In other parts of the world, the transition between brunisolic and kaolinitic coincides with mountainous topography or special parent materials. The transition between brunisolic and cinnamonic regions in Europe is marked by cinnamonic-brunisolic intergrades (brun mediterraneans, southern braun erde, etc.); that between chernozemic and cinnamonic regions in the United States by reddish chernozems. The transition between cinnamonic and desertic regions in the United States is marked by reddish brown soils. Comparable soils are encountered in many parts of Asia, Africa, and Australia. Planosolic, solonetzic, and saline soils are common in these transitional regions.

In the transition between cinnamonic and kaolinitic regions, materials rich in easily weatherable minerals give soils with 2:1 clays, whereas 1:1 clays predominate in the opposite case, a condition that prevails in many parts of the Mediterranean Basin with high leaching rainfall and mild winters (*e.g.,* Portugal). In Africa and Australia, however, many kaolisols of such a transitional region are palaeokaolisols.

Humid, and dry volcanic soils

Volcanic regions. Volcanic ashes have such great influence on soil formation that volcanic regions constitute a special group. Ando soils are frequent in volcanic regions. A distinction may be made between humid volcanic regions with acid ando, often deficient in phosphorus, and dry volcanic regions with soils well provided with bases, often chernozemic. Planosolic, solonetzic, and saline soils, and duripans or calcareous horizons, are frequent in dry volcanic regions and still more so in desertic ones, where planosols and solonetz become mini-planosols and mini-solonetz. Ando soils are usually fertile, and as a result settlements grow around volcanoes in spite of dangers. The most important volcanic soil regions of the world are: the Cordillera (western mountain ranges) of North America; the entire Pacific coast of North and South America; the Great Basin of North America located within the Cordillera to the west of the Rocky Mountains; the Andes mountain ranges of South America, the plains to the north and west, and many lands to the east; all of Patagonia, the Pampas region of Argentina, and to a certain extent the Chaco; many parts of the Mediterranean Basin, especially in Italy; Indonesia, the Philippines, Japan, and Kamchatka; and some parts of Ethiopia, Kenya, Uganda, Rwanda, Burundi, and Cameroon.

Alluvial and waterlogged regions. Some regions have alluvial soils of materials that came from regions of different climate. The most conspicuous examples are the alluvial region of northern Italy, one of the better agricultural regions of the world, and those of northern India and Indochina, which nourish a dense population or export much food. In Australia, and to a certain extent in Africa, are regions in which the soils have been formed from kaolinitic materials developed under different conditions; these regions may be called palaeokaolinitic.

In some regions waterlogging is so common that the soils may be called gleisolic. Some of them are podsolic, for example the southwestern coast of Hudson Bay in Canada, most of Finland, and most of northern Soviet Union. Others are chernozemic, as the "Pampa Deprimida" of Buenos Aires, Argentina. Still others are found in the transition region between chernozemic and kaolinitic soils of southern Brazil, Uruguay, and Corrientes, Argentina. Soils vary as a consequence: gleisolic humus podsols and peat in the first case; gleisolic chernozemic planosols and solonetz in the second; chernozemic lessivé (prairie), chernozemic gleisolic (humic gley), dark clays (vertisols), planosols, acid gleisolic (low humic gley), kaolinitic podsolic (red-yellow podsolic), with krasnozems and terra roxa on basaltic hills in the third.

Some tropical regions have relatively young soils, many of which have been formed from calcareous materials. This is the case in the Yucatán Peninsula of Mexico, in the West Indies, and on the coral islands of Oceania. Their soils are predominantly brunisolic-kaolinitic.
